It is well known that an $n\times n$ unitary matrix depends on n^2 parameters,[30,31] that are usually taken as $n(n-1)/2$ angles and $n(n+1)/2$ phases, each set taking values within $[0,\pi/2]$, and, respectively, $[0,2\pi)$. Equation (2) tells us that, given a definite unitary matrix, all the unitary matrices obtained by multiplying it at left and/or at right by diagonal phase matrices, $D=\mathrm{diag}(e^{i\phi_1},\ldots,e^{i\phi_n})$, with arbitrary real ϕ_i, $i=1,\ldots,n$, generate a single double stochastic matrix. That means that we can simplify a little bit the form of a unitary matrix since the values of $2n-1$ phases are at our disposal, and a common choice for them is 0 and/or π. In high energy physics this property is known as phase invariance.[32–36] Thus we can take the entries from the first row and the first column as non-negative quantities, such that the number of independent parameters entering a unitary matrix gets $n^2-(2n-1)=(n-1)^2$, and it is equal to the number of independent parameters entering a double stochastic matrix. Hence we could say that the embedding (2) suggests that the "natural" coordinates to parametrize a unitary matrix could be the moduli of its entries. Unfortunately that can be done only for 3×3 matrices, but even in this case there are supplementary relations that have to be fulfilled by the moduli in order to get from them a unitary matrix.

Besides these transformations there are other transformations: multiplication at left and/or right by permutation matrices. Permutation matrices are matrices whose elements on each row and each column are zero, but that equal unity. They interchange rows, and, respectively, columns between themselves. Both diagonal phase matrices and permutation matrices are subgroups of unitary matrices. If D denotes a diagonal phase matrix and P a permutation matrix then

$$DD^\dagger = PP^\dagger = I_n.$$

Other equivalent unitary matrices can be obtained by taking the complex conjugate matrix, and/or the transpose of the original one. If we denote the transpose operator by T, and by C the complex conjugation, both these transforms form a subgroup because

$$T^2 = C^2 = \mathrm{Identity}.$$

Thus the product group

$$K = D\times P\times T\times C$$

is the gauge invariance subgroup of unitary matrices, and, in the following, we work only with the coset defined by

$$X \cong U(n)/K, \tag{5}$$

where $U(n)$ denotes the n-dimensional unitary group. The C invariance has an important consequence: the range of all independent phases entering $U(n)$ is $[0,\pi]$. The multiplicity of solutions appearing in the recovery problem of a unitary matrix from a double stochastic one will be given modulo the above-noted simplest transformations of unitary matrices.

III. PARAMETRIZATION OF UNITARY MATRICES

For devising a recovery algorithm of unitary matrices from double stochastic ones, or from experimental data, we need an explicit parametrization of them. That will lead us easily to the necessary and sufficient conditions a double stochastic matrix has to satisfy for also being unistochastic, even if a complete explicit solution is found only for $n=3$. These conditions will lead to separation criteria between the double stochastic and unistochastic matrices.

There are essentially two types of parametrizations: first the classical result by Murnagham,[30] which states that the matrices from the unitary group $U(n)$ are products of a diagonal phase matrix containing n phases, and $n(n-1)/2$ matrices whose main building block has the form

$$U=\begin{pmatrix} \cos\theta & -\sin\theta e^{-i\varphi} \\ \sin\theta e^{i\varphi} & \cos\theta \end{pmatrix}, \tag{6}$$

i.e., a parametrization in terms of $n(n-1)/2$ angles θ_i, and $n(n+1)/2$ phases φ_i. The usual parametrization of the CKM matrix[37] used in high energy physics is of this type. A second parametrization, also through factorization, is that given in Ref. 38. The idea behind such a parametrization comes from the following sequence:

$$U(n)\cong\frac{U(n)}{U(n-1)}\times\frac{U(n-1)}{U(n-2)}\times\cdots\times\frac{U(2)}{U(1)}\times U(1)\cong S^{2n-1}\times S^{2n-3}\times\cdots\times S^3\times S^1. \tag{7}$$

This sequence shows that each factor can be parametrized by an arbitrary point on the corresponding complex sphere, i.e., by a single complex $(n-k)$-dimensional unit vector. Such a parametrization could be appealing for high energy physicists since it shows that the information brought by each generation of quarks, or leptons is contained in a single complex unit vector. The first parametrization of CKM matrix, Ref. 19, is of this form. The explicit realization of this parametrization, which is the main result in Ref. 38, is given by

Theorem 1: *Any element $U_n\in U(n)$ can be factored into an ordered product of n matrices of the following form*

$$U_n=B_n^0\cdots B_{n-1}^1\ldots B_1^{n-1}, \tag{8}$$

where

$$B_{n-k}^k=\begin{pmatrix} I_k & 0 \\ 0 & B_{n-k} \end{pmatrix}$$

and $B_{n-k}\in U(n-k)$ are special unitary matrices, each one generated by a single complex $(n-k)$-dimensional unit vector, $b_{n-k}\in S^{2(n-k)-1}$. For example, $B_1=e^{i\varphi}$, where φ is an arbitrary phase.

If $y_m\in S^{2m-1}$, $m=1,\ldots,n$, is parametrized by

$$y_m=(e^{i\varphi_1}\cos\theta_1,e^{i\varphi_2}\sin\theta_1\cos\theta_2,\ldots,e^{i\varphi_m}\sin\theta_1\cdots\sin\theta_{m-1})^t,$$

where t means transpose, then the m columns of B_m are given by

$$v_1=y_m=\begin{pmatrix} e^{i\varphi_1}\cos\theta_1 \\ e^{i\varphi_2}\sin\theta_1\cos\theta_2 \\ \vdots \\ e^{i\varphi_m}\sin\theta_1\cdots\sin\theta_{m-1} \end{pmatrix}$$

and

$$v_{k+1}=\frac{\mathrm{d}}{\mathrm{d}\theta_k}v_1(\theta_1=\cdots=\theta_{k-1}=\pi/2),\quad k=1,\ldots,m-1,$$

where in the above-mentioned formula one calculates first the derivative and afterwards the restriction to $\pi/2$.

In what follows we need an explicit parametrization of B_{n-k}, $k=0,\ldots,n-1$, and by taking into account that we work with representatives from the X coset, Eq. (5), we choose the corresponding n generating vectors as follows:

$$y_n = (\cos a_1, \sin a_1 \cos a_2, \ldots, \sin a_1 \ldots \sin a_{n-1})^t,$$

$$y_{n-1} = (-\cos b_1, e^{i\beta_1} \sin b_1 \cos b_2, \ldots, e^{i\beta_{n-2}} \sin b_1 \ldots \sin b_{n-2})^t,$$

$$\vdots \tag{9}$$

$$y_2 = (-\cos z_1, e^{i\psi_1} \sin z_1)^t,$$

$$y_1 = -1.$$

With this choice the first row of U_n has the form

$$U_{11} = \cos a_1, \quad U_{12} = \cos b_1 \sin a_1, \cdots U_{1n} = \sin a_1 \ldots \sin z_1 \tag{10}$$

and the first column is given by y_n. In the following we will assume that U_n, Eq. (8), has its first column given by y_n, and its first row given by (10), and this is our standard form in the rest of the paper for a unitary matrix. A similar parametrization was obtained recently, see Ref. 39; for the case $n=3$ see also Refs. 40 and 41.

IV. PHENOMENOLOGICAL MODELS

By "phenomenological model" we will understand in the following a relationship between the entries of a double stochastic matrix and the entries of a unitary matrix, the main goal being the finding of the necessary and sufficient conditions that separate the two sets. Depending on the context the "experimental data" will denote either the entries of a double stochastic matrix, or the numbers, affected by errors, measured in an experiment. Usually the experimental data on the 3×3 CKM matrix entries from the quark sector are given in terms of moduli of the unitary matrix that define the theoretical model, $|U_{ij}|$, or angular looking objects $U_{\alpha j}U_{\beta k}U^*_{\alpha k}U^*_{\beta j}$, which are equivalent to the angles of the triangles generated by the orthogonality relations. For the beginning we assume that the data have no errors, which is the current mathematical setting, i.e., the moduli are the entries of a double stochastic matrix, and we want to solve problems (i)–(iii) from Sec. I. For doing that we have at our disposal an explicit parametrization of unitary matrices, (8) and (9), and the unitarity property

$$UU^\dagger = U^\dagger U = I_n.$$

This concise form is equivalent to $2n$ relations

$$\sum_{i=1}^{i=n} |U_{ji}|^2 - 1 = 0, \quad j = 1, \ldots, n,$$

$$\sum_{i=1}^{i=n} |U_{ij}|^2 - 1 = 0, \quad j = 1, \ldots, n \tag{11}$$

showing that the numbers $m_{ij}=|U_{ij}|^2$ define a double stochastic matrix, which implies that only $2n-1$ relations from the set (11) are independent, and by $n(n-1)$ orthogonality relations

$$\sum_{i=1}^{i=n} U_{ji}U_{ki}^{*}=0, \quad j<k, \quad i=1,\ldots,n,$$
$$\sum_{i=1}^{i=n} U_{ij}U_{ik}^{*}=0, \quad j<k, \quad i=1,\ldots,n, \tag{12}$$

which can be visualized as polygons in the complex plane. The last relations are the supplementary relations the numbers U_{ij} have to satisfy in order that the corresponding matrix should be unitary. The number of relations (11) and (12) is greater than n^2, but we have written all of them since they could be useful in over-constraining the experimental data, which usually are affected by errors.

The relations (11) and, respectively, (12) can be used to define two different phenomenological models. The first model is given by the relations (11) together with

$$m_{ij}=|U_{ij}|^2, \quad i,j=1,\ldots,n-1, \tag{13}$$

where m_{ij} are the entries of a double stochastic matrix, and U_{ij} are the entries of a unitary matrix parametrized as in Theorem 1. The last relation is equivalent to the following:

$$m_{11}=\cos^2 a_1, \quad m_{12}=\sin^2 a_1\cos^2 b_1,\ldots,m_{1n}=\sin^2 a_1\cdots\sin^2 z_1,$$
$$m_{21}=\cos^2 a_2\sin^2 a_1,\ldots,m_{nn-1}=\sin^2 a_1\cdots\sin^2 a_{n-1}, \tag{14}$$

$$m_{22}=\cos^2 a_1\cos^2 a_2\cos^2 b_1+\cos^2 b_2\sin^2 a_2\sin^2 b_1$$
$$+2\cos a_1\cos a_2\cos b_1\cos b_2\sin a_2\sin b_1\cos\beta_1, \tag{15}$$

$$m_{32}=\cos^2 a_1\cos^2 a_3\cos^2 b_1\sin^2 a_2+\cos^2 a_2\cos^2 a_3\cos^2 b_2\sin^2 b_1+\sin^2 a_3\sin^2 b_1\sin^2 b_2$$
$$-2\cos a_1\cos a_2\cos^2 a_3\cos b_1\cos b_2\sin a_2\sin b_1\cos\beta_1$$
$$+2\cos a_1\cos a_3\cos b_1\sin a_2\sin a_3\sin b_1\sin b_2\cos\beta_2$$
$$-2\cos a_2\cos a_3\cos b_2\sin a_3\sin^2 b_1\sin b_2\cos(\beta_1-\beta_2),\ \text{etc}\,., \tag{16}$$

where we have written only the simplest equations. It is easily seen from the above-noted equations that, since m_{1i} and m_{i1}, $i=1,\ldots,n-1$, are entries of a double stochastic matrix, there is a unique solution for $\cos a_i\in(0,1)$, $i=1,\ldots,n-1$, of the form

$$\cos^2 a_1=m_{11}, \quad \cos^2 a_k=\frac{m_{k1}}{1-\sum_{i=1}^{k-1} m_{i1}}, \quad k=2,\ldots,n-1 \tag{17}$$

and similarly for $\cos b_1$, $\cos c_1,\ldots,\cos z_1$. Hence the number of angles that have to be found is $(n-1)(n-2)/2-(2n-3)=(n-2)(n-3)/2$. In that way the number of equations of the form (15) and (16) we have to solve is only $(n-2)^2$. We substitute the forms for $\cos a_i$, $\sin a_i$, and similar ones, from the first column and the first row, in Eqs. (15) and (16), such that we get $(n-2)^2$ equations that depend on $(n-1)^2$ moduli m_{ij}, $i,j=1,\ldots,n-1$. We now do a relabeling of the angles, $b_i\to b_{i-1}$, $i=2,\ldots,n-2$, $c_2\to b_{n-1},\ldots$, etc., and similarly for the phases. With this notation the necessary and sufficient conditions for a double stochastic matrix to be also unistochastic are given by the relations

$$0\leqslant\cos b_i\leqslant 1, \quad i=1,\ldots,\frac{(n-2)(n-3)}{2}, \tag{18}$$

$$-1 \leqslant \cos \beta_i \leqslant 1, \quad i = 1, \ldots, \frac{(n-1)(n-2)}{2}, \tag{19}$$

where $\cos b_i$ and $\cos \beta_i$ are the solutions in terms of m_{ij} of the $(n-2)^2$ equations of the form (15) and (16). The above-noted relations are at the same time the separation criteria between the double stochastic and unistochastic matrices, and their fulfillment is equivalent to the existence of at least one unitary matrix compatible with the m_{ij}. To check them we have to solve analytically or numerically the $(n-2)^2$ equations (15) and (16). Numerically this can be done when m_{ij} are the elements of a double stochastic matrix, but for the real case of experimental data with errors we need an analytic solution to be used in a χ^2-test, and until now this was found only for the case $n=3$. In conclusion for 3×3 data coming from an exact double stochastic matrix we have only one constraint, namely, $-1 \leqslant \cos \beta_1 \leqslant 1$. If the data come from an experiment we have to check also the compatibility of the entries from the first row and first column with the relations (17), i.e., to see if the conditions $0 \leqslant \cos^2 a_i \leqslant 1$ are satisfied.

Taking into account the relation (13), $m_{ij}=|U_{ij}|^2$, which shows how the unitary matrices are embedded into the double stochastic ones, the parametrization of unitary matrices by their moduli seems to be very appealing in this case, although it is not a natural one in the general case. A natural parametrization would be one whose parameters are free, i.e., there are no supplementary constraints upon them, as Eqs. (18) and (19), to enforce unitarity.

The problem we addressed in Ref. 11 was to what extent the knowledge of the moduli, $m_{ij} = |U_{ij}|$, of an $n\times n$ unitary matrix U determines U. If we identify the parameters to the moduli, they will be lying within the simple domain

$$D = (0,1) \times \cdots \times (0,1) \equiv (0,1)^{(n-1)^2},$$

where the above-presented notation means that the number of factors entering the topological product is $(n-1)^2$. We excluded only the extremities of each interval, i.e., the points 0 and 1 that is a zero measure set within $U(n)$ and has no relevance to the problem of recovery of a unitary matrix from a double stochastic one.

Nothing remains but to check if the new parametrization is one-to-one. A solution to the last problem is the following: start with a one-to-one parametrization of $U(n)$, such as that given in the preceding section, and then change the coordinates taking as new coordinates the moduli of the $(n-2)^2$ entries; these ones are obtained by deleting the first and the last row, respectively, the first and the last column. The moduli of the first row and the first column are in one-to-one correspondence with the parameters entering the unitary matrix, see, e.g., Eq. (17), and the moduli entering the last row and the last column are uniquely determined by the double stochasticity property. Afterwords use the implicit function theorem to find the points where the new parametrization fails to be one-to-one. The corresponding variety upon which the application is not a bijective one is given by setting to zero the Jacobian of the transformation, i.e.,

$$J = \frac{\partial(m_{22}, \ldots, m_{2n-1}, \ldots, m_{n-1n-1})}{\partial(b_1, \ldots, b_{(n-2)(n-3)/2}, \beta_1, \ldots, \beta_{(n-1)(n-2)/2})} = 0. \tag{20}$$

One gets that, generically, for $n \geqslant 4$ the unitary group $U(n)$ cannot be fully parametrized by the moduli of its entries,[6–17] i.e., for a given set of moduli there exists a continuum of solutions, the simplest example being the case of complex Hadamard matrices.[13–17] The maximum dimension of the above-mentioned variety is $(n-2)^2-1=(n-3)(n-1)$. For $n=3$, $J\neq 0$, and only in this case the parametrization of a unitary matrix through the moduli could be one-to-one. If the moduli are outside of the above-mentioned variety an upper bound for the multiplicity is $2^{[n(n-3)]/2}$, bound that is saturated for $n=3$, when there is essentially only one complex matrix, if we take into account the gauge invariance of unitary matrices.

In the case of exact double stochastic matrices, as we showed before, only $(n-2)^2$ moduli

enter the game since the angles entering the first column and the first row are uniquely determined. To have a flavor of the problem we consider more in detail the case $n=4$, when there are four equations, two of them being Eqs. (15) and (16), and the last two are

$$\begin{aligned} m_{23} = {} & \cos^2 b_1 \cos^2 b_2 \cos^2 c_1 \sin^2 a_2 + \cos^2 a_1 \cos^2 a_2 \cos^2 c_1 \sin^2 b_1 + \sin^2 a_2 \sin^2 b_2 \sin^2 c_1 \\ & - 2 \cos a_1 \cos a_2 \cos b_1 \cos b_2 \cos^2 c_1 \sin a_2 \sin b_1 \cos \beta_1 \\ & + 2 \cos b_1 \cos b_2 \cos c_1 \sin^2 a_2 \sin b_2 \sin c_1 \cos \gamma_1 \\ & - 2 \cos a_1 \cos a_2 \cos c_1 \sin a_2 \sin b_1 \sin b_2 \sin c_1 \cos(\beta_1 + \gamma_1), \end{aligned} \tag{21}$$

$$\begin{aligned} m_{33} = {} & \cos^2 a_2 \cos^2 a_3 \cos^2 b_1 \cos^2 b_2 \cos^2 c_1 + \cos^2 a_1 \cos^2 a_3 \cos^2 c_1 \sin^2 a_2 \sin^2 b_1 \\ & + \cos^2 b_1 \cos^2 c_1 \sin^2 a_3 \sin^2 b_2 + \cos^2 b_2 \sin^2 a_3 \sin^2 c_1 + \cos^2 a_2 \cos^2 a_3 \sin^2 b_2 \sin^2 c_1 \\ & + 2 \cos a_1 \cos a_2 \cos^2 a_3 \cos b_1 \cos b_2 \cos^2 c_1 \sin a_2 \sin b_1 \cos \beta_1 \\ & - 2 \cos a_2 \cos a_3 \cos^2 b_1 \cos b_2 \cos^2 c_1 \sin a_3 \sin b_2 \cos(\beta_1 - \beta_2) \\ & - 2 \cos a_1 \cos a_3 \cos b_1 \cos^2 c_1 \sin a_2 \sin a_3 \sin b_1 \sin b_2 \cos \beta_2 \\ & + 2 \cos a_2 \cos a_3 \cos b_1 \cos^2 b_2 \cos c_1 \sin a_3 \sin c_1 \cos(\beta_1 - \beta_2 - \gamma_1) \\ & + 2 \cos a_1 \cos a_3 \cos b_2 \cos c_1 \sin a_2 \sin a_3 \sin b_1 \sin c_1 \cos(\beta_2 + \gamma_1) \\ & + 2 \cos^2 a_2 \cos^2 a_3 \cos b_1 \cos b_2 \cos c_1 \sin b_2 \sin c_1 \cos \gamma_1 \\ & - 2 \cos b_1 \cos b_2 \cos c_1 \sin^2 a_3 \sin b_2 \sin c_1 \cos \gamma_1 \\ & + 2 \cos a_1 \cos a_2 \cos^2 a_3 \cos c_1 \sin a_2 \sin b_1 \sin b_2 \sin c_1 \cos(\beta_1 + \gamma_1) \\ & - 2 \cos a_2 \cos a_3 \cos b_1 \cos c_1 \sin a_3 \sin^2 b_2 \sin c_1 \cos(\beta_1 - \beta_2 + \gamma_1) \\ & + 2 \cos a_2 \cos a_3 \cos b_2 \sin a_3 \sin b_2 \sin^2 c_1 \cos(\beta_1 - \beta_2). \end{aligned} \tag{22}$$

From Eq. (14) we get

$$\cos a_1 = \sqrt{m_{11}}, \quad \sin a_1 = \sqrt{1 - m_{11}},$$

$$\cos a_2 = \sqrt{\frac{m_{21}}{1 - m_{11}}}, \quad \sin a_2 = \sqrt{\frac{1 - m_{11} - m_{21}}{1 - m_{11}}},$$

$$\cos a_3 = \sqrt{\frac{m_{31}}{1 - m_{11} - m_{21}}}, \quad \sin a_3 = \sqrt{\frac{1 - m_{11} - m_{21} - m_{31}}{1 - m_{11} - m_{21}}}, \tag{23}$$

$$\cos b_1 = \sqrt{\frac{m_{12}}{1 - m_{11}}}, \quad \sin b_1 = \sqrt{\frac{1 - m_{11} - m_{12}}{1 - m_{11}}},$$

$$\cos c_1 = \sqrt{\frac{m_{13}}{1 - m_{11} - m_{12}}}, \quad \sin c_1 = \sqrt{\frac{1 - m_{11} - m_{12} - m_{13}}{1 - m_{11} - m_{12}}}.$$

By substituting relations (23) into Eqs. (15) and (16) and (21) and (22) we obtain four equations that depend on nine moduli m_{ij}, $i,j=1,2,3$, and on the nonrelabeled parameters b_2, β_1, β_2, γ_1,

$$f_{22}-m_{22}=0,\quad f_{23}-m_{23}=0,$$
$$f_{32}-m_{32}=0,\quad f_{33}-m_{33}=0. \tag{24}$$

In general the rank of the Jacobian matrix

$$J=\frac{\partial(f_{22},f_{23},f_{32},f_{33})}{\partial(b_2,\beta_1,\beta_2,\gamma_1)} \tag{25}$$

will be less than $(n-2)^2$ since we know that there are particular solutions that depend on an arbitrary phase. If we look at the Jacobian (25) as a function on the Birkoff's polytope, i.e., depending on $(n-1)^2=9$ independent moduli m_{ij}, it could be possible to find a domain where rank $(J)=4$, i.e., in this case we have only one solution. Then the compatibility relations between the double stochastic matrix entries $(m_{ij})_{i,j=1}^{3}$, and the unitarity property, or in other words, the separation criteria between the two sets, are four, and they have the form

$$0\leqslant \cos b_2\leqslant 1,\quad -1\leqslant \cos\beta_1\leqslant 1,\quad -1\leqslant \cos\beta_2\leqslant 1,\quad -1\leqslant \cos\gamma_1\leqslant 1. \tag{26}$$

The above-presented relations are the necessary and sufficient conditions the moduli of a 4×4 double stochastic matrix have to satisfy in order for there to be a unitary matrix whose moduli coincide with m_{ij}, and their intersection gives the maximal domain within the m_{ij} simplex that is compatible to the existence of unitary matrices.

In the case when for a given numerical matrix, rank $(J)<4$, there is no one-to-one correspondence between the entries m_{ij} of a double stochastic matrix and the independents parameters entering a unitary matrix, i.e., there is at least one solution that depends on an arbitrary parameter, phase, or, angle.

The checking of criteria (26) requires explicit analytic solutions for

$$\cos b_2,\quad \cos\beta_1,\quad \cos\beta_2,\quad \cos\gamma_1$$

in terms of m_{ij}, and when these ones are not numbers, solving Eq. (24), is not a simple problem even with the symbolic calculation software packages nowadays available. The only results in this direction are those obtained in Ref. 9 however they have to be used with caution since the authors assumed that no matter how the numbers entering a double stochastic matrix are, Eq. (24) has a physical solution.

By taking into account the above-noted considerations the following result holds.

Theorem 2: *Suppose we have a generalized spherical coordinate system on the unitary group* $U(n)$, *and let* $U\in U(n)$ *be a given matrix parametrized as in Theorem 1*, *through* $n(n-l)/2$ *angles*, *each one taking values in* $[0,\pi/2]$, *and* $(n-1)(n-2)/2$ *phases taking values in* $[0,\pi]$, *and let* $M=(m_{ij})$ *be an* $n\times n$ *double stochastic matrix*, *whose entries are supposed to come from a unistochastic matrix U by the embedding*

$$m_{ij}=|U_{ij}|^2,\quad i,j=1,\ldots,n-1. \tag{27}$$

From Eq. (14) *we get a unique solution for the angles entering the first column and the first row of U as follows:*

$$\cos^2 a_1=m_{11},\quad \cos^2 a_2=\frac{m_{21}}{1-m_{11}},\ldots,\cos^2 a_{n-1}=\frac{m_{n-11}}{1-m_{11}-\sum_{i=2}^{n-1}m_{i1}},$$
$$\cos^2 b_1=\frac{m_{12}}{1-m_{11}},\ldots,\cos^2 z_1=\frac{m_{1n-1}}{1-m_{11}-\sum_{i=2}^{n-1}m_{1i}}. \tag{28}$$

We substitute them in Eq. (27) *obtaining a set of* $(n-2)^2$ *equations that*, *after relabeling of the angles and phases*, *is of the form*

$$f_{ij}(b_1,\ldots,b_{\frac{(n-2)(n-3)}{2}},\beta_1,\ldots,\beta_{\frac{(n-1)(n-2)}{2}})=m_{ij},\quad i,j=2,\ldots,n-1. \tag{29}$$

The solutions of the above equations are compatible with the existence of a unitary matrix, if and only if, all the angles and phases satisfy the unitarity constraints (18) and (19). *For* $n\geqslant 4$ *the solutions of Eq.* (29) *could depend on arbitrary angles and/or phases on the variety obtained by setting to zero the determinant of Jacobian matrix of the transformation* (29)

$$J=\frac{\partial(f_{22},\ldots,f_{2n-1},f_{n-12}\ldots,f_{n-1n-1})}{\partial(b_1,\ldots,b_{[(n-2)(n-3)]/2},\beta_1,\ldots,\beta_{[(n-1)(n-2)]/2})}. \tag{30}$$

If p *is the rank of the Jacobian matrix* (30) *the solution of* (29) *depends upon* $(n-2)^2-p$ *arbitrary parameters, angles and/or phases. Outside this variety the number of discrete solutions* N_s *satisfies* $1\leqslant N_s\leqslant 2^{[n(n-3)]/2}$.

Proof: Since we use a spherical coordinate system, (29) are trigonometric equations in our parametrization, as the example of case $n=4$ shows, and consequently the multiplicity of the solutions may arise from the two possible phase solutions for all values of sine or cosine functions that satisfy Eq. (29) and the constraints (18) and (19). The number of independent phases is $(n-1)(n-2)/2$ and, since we do not make any distinction between U and its complex conjugate U^*, condition that halves the number of solutions, the above bound for N_s follows.

For $n=3$ the Jacobian does not vanish and one gets $1\leqslant N_s\leqslant 1$, and this bound implies the existence of a complex unitary matrix, if and only if, when the values m_{ij}, coming from a double stochastic matrix satisfy the relation $-1\leqslant\cos\beta_1\leqslant 1$. □

An example of a unitary matrix that cannot be recovered from its moduli is the following. If P and $Q_i, i=1,\ldots,m$, are $m\times m$ and, respectively, $n\times n$ unitary matrices whose first rows and first columns are positive numbers and depend on p and, respectively, q_i arbitrary phases, then the following $m\times n$ array

$$M=\begin{pmatrix} p_{11}Q_1 & \cdot & \cdot & p_{1m}Q_m \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ p_{1m}Q_1 & \cdot & \cdot & p_{mm}Q_m \end{pmatrix} \tag{31}$$

defines a unitary matrix that could depend on

$$p+q_1+(m-1)\sum_{i=2}^{n}q_i \tag{32}$$

arbitrary phases.

Indeed it is easily seen that we can multiply at left all the matrices $Q_2,\ldots,Q_m$ by diagonal phase matrices $D_j=\mathrm{diag}(1,e^{\imath\varphi_{1,j}},\ldots,,e^{\imath\varphi_{n-1,j}}), j=2,\ldots,m$, by preserving the entries from the first row and column of M positive numbers, obtaining a set of unitary matrices that are all applied in the same double stochastic matrix. Thus their recovery from the moduli cannot be done because all the arbitrary phases φ_{ij} disappear when one computes their moduli, and as a consequence they do not appear in equations such as (15) and (16).

A second phenomenological model can be defined by starting from the orthogonality relations (12), but since in this case the polygons angles enter the game its formulation for arbitrary n is more difficult. Thus in the following we will discuss the case $n=3$ for both the models, which has applications in high energy physics.

A. Unitarity condition method

In the $n=3$ case the unitary (CKM) matrix is parametrized by *four* independent parameters given by the so-called mixing angles, θ_{12}, θ_{13}, θ_{23}, and the *CP*-violating phase δ. Hence in the following we will change the notation from Sec. III to another notation that is more familiar to

experimenters and phenomenologists. That means that in Eq. (9) defining the generating vectors we make the substitution: $(a_1 \to \theta_{12}, a_2 \to \theta_{23}, b_1 \to \theta_{13}, \beta_1 \to \delta)$; after that we make the notation

$$\cos\,\theta_{ij} = c_{ij}, \quad \sin\,\theta_{ij} = s_{ij}, \quad ij = 12,13,23$$

and by using Theorem 1 we get the following form

$$U = \begin{pmatrix} c_{12} & c_{13}s_{12} & s_{12}s_{13} \\ c_{23}s_{12} & -c_{12}c_{13}c_{23} - e^{i\delta}s_{13}s_{23} & -c_{12}c_{23}s_{13} + e^{i\delta}c_{13}s_{23} \\ s_{13}s_{23} & c_{23}s_{13}e^{i\delta} - c_{12}c_{13}s_{23} & -c_{13}c_{23}e^{i\delta} - c_{12}s_{13}s_{23} \end{pmatrix}. \tag{33}$$

The theoretical model (33) is supplemented by the experimental data supplied by experimenters. In the quark sector one measures two kinds of parameters: the moduli of the unitary matrix (33), see Ref. 18, under the form of a positive entries matrix, written with the physicists notation

$$V = \begin{pmatrix} V_{ud}^2 & V_{us}^2 & V_{ub}^2 \\ V_{cd}^2 & V_{cs}^2 & V_{cb}^2 \\ V_{td}^2 & V_{ts}^2 & V_{tb}^2 \end{pmatrix}, \tag{34}$$

where u, s, b, etc., are names for quarks, and the angles of the so-called standard unitarity triangle,[20] denoted by α/ϕ_1, β/ϕ_2, γ/ϕ_3.[42] In this paper V denotes either a double stochastic matrix, or a set of numbers affected by errors, when V_{ij} are measured in experiments. More generally the experimental data are given in terms of some functions $f_k(V_{ij})$, $k=1,\ldots,N$, that depend on the V entries, or the theoretical parameters s_{ij} and δ.

Similar to the general case treated in the previous section, we define our phenomenological model as a relationship between the theoretical object (33) and the experimental data (34). It is given by the double stochasticity relations (11), which now take the form

$$\begin{aligned} &\sum_{i=d,s,b} V_{ji}^2 - 1 = 0, \quad j = u,c,t, \\ &\sum_{i=u,c,t} V_{ij}^2 - 1 = 0, \quad j = d,s,b \end{aligned} \tag{35}$$

and by the embedding relation of a unitary matrix into the double stochastic set

$$V = |U|^2,$$

which leads to the following relations:

$$\begin{aligned} &V_{ud}^2 = c_{12}^2, V_{us}^2 = s_{12}^2 c_{13}^2, V_{ub}^2 = s_{12}^2 s_{13}^2, \\ &V_{cd}^2 = s_{12}^2 c_{23}^2, V_{td}^2 = s_{12}^2 s_{23}^2, \\ &V_{cs}^2 = c_{12}^2 c_{13}^2 c_{23}^2 + s_{13}^2 s_{23}^2 + 2c_{12}c_{13}c_{23}s_{13}s_{23}\cos\,\delta, \\ &V_{cb}^2 = c_{12}^2 c_{23}^2 s_{13}^2 + c_{13}^2 s_{23}^2 - 2c_{12}c_{13}c_{23}s_{13}s_{23}\cos\,\delta, \\ &V_{ts}^2 = c_{23}^2 s_{13}^2 + c_{12}^2 c_{13}^2 s_{23}^2 - 2c_{12}c_{13}c_{23}s_{13}s_{23}\cos\,\delta, \\ &V_{tb}^2 = c_{13}^2 s_{23}^2 + c_{12}^2 c_{13}^2 s_{23}^2 + 2c_{12}c_{13}c_{23}s_{13}s_{23}\cos\,\delta. \end{aligned} \tag{36}$$

The above-noted phenomenological model was introduced in Ref. 43. The relations (36) depend only on $\cos\,\delta$, which has the consequence that we can restrict δ to the interval $[0,\pi]$, this property

being equivalent to the CKM matrix invariance under the complex conjugation, as was shown in Sec. II.

Especially for physicists we want to make a few remarks. First we stress that in any phenomenological analysis one works with *two* distinct objects: the first is the theoretical one, that in our case coincides with the matrix U, Eq. (33), which is *assumed and built as a unitary matrix*; the second object is provided by the *experimental data*, $V=(V_{ij}^2)$, Eq. (34). The aim of any phenomenological analysis is twofold: (a) *checking the consistency of data with the theoretical model*, and (b) *determination of parameters entering the theoretical model from the experimental data, if these ones are consistent with it*. That is the reason for making a clear distinction between the theoretical quantities and the experimental ones, by using different symbols for denoting them. The second remark concerns the double stochasticity relations, Eq. (35), which are considered by (many) high energy physicists as testing the *unitarity*, statement which is wrong, since it is well known that for $n\geqslant 3$ there exist double stochastic matrices which are not unistochastic.[2] Checking the consistency, of the data with the theoretical model means checking the consistency of relations (36), i.e., we have to see if the solutions of Eq. (36) lead to physical values for the mixing parameters θ_{ij} and δ; and only in this case Eq. (35) *together* with Eq. (36) prove the unitarity property of the data.

Let us assume for a moment that relations (35) are exactly satisfied. Then it is an easy matter to find from the first five relations (36) three independent ones which give a unique solution for the c_{ij}, $ij=12,13,23$. In other words, if the experimental numbers satisfy the relations

$$V_{ud}^2+V_{us}^2+V_{ub}^2=1,$$

$$V_{ud}^2+V_{cd}^2+V_{td}^2=1,$$

we always get a solution for c_{ij} that is unique and depends on the three chosen independent parameters. Substituting this solution in the last equations one gets four equations for $\cos\delta$, which lead to a unique solution for it. But nobody guarantees us that the solution will satisfy the physical constraint

$$-1\leqslant\cos\delta\leqslant 1. \tag{37}$$

The last relation gives the necessary and sufficient condition the data have to satisfy in order that the 3×3 matrix (34) comes from a unitary matrix, i.e., it is the consistency condition between the data and the theoretical model.

To better understand the above-noted considerations and see the power of the found criterion (37) and how it works, we will give a few numerical examples, and for that we will use moduli entering the first two rows. We make the following notation:

$$V_{ud}=a,\quad V_{us}=b,\quad V_{ub}=c,\quad V_{cd}=d,\quad V_{cs}=e,\quad \text{and}\quad V_{cb}=f.$$

First we choose as independent moduli a, b, d, and e and with them form the square root of a double stochastic matrix

$$S_1=\begin{pmatrix} a & b & \sqrt{1-a^2-b^2} \\ d & e & \sqrt{1-d^2-e^2} \\ \sqrt{1-a^2-d^2} & \sqrt{1-b^2-e^2} & \sqrt{-1+a^2+b^2+d^2+e^2} \end{pmatrix}, \tag{38}$$

i.e., S_1^2 is an exact doubly stochastic matrix, where the square is taken entry-wise, by using the Hadamard product from linear algebra. From the relations (36) we get the solution

$$c_{12}=V_{ud}=a,\quad c_{13}=\frac{V_{us}}{\sqrt{1-V_{ud}^2}}=\frac{b}{\sqrt{1-a^2}},\quad c_{23}=\frac{V_{cd}}{\sqrt{1-V_{ud}^2}}=\frac{d}{\sqrt{1-a^2}}. \tag{39}$$

$$\cos\,\delta_1 = \frac{-(1-a^2)^2(1-e^2)+(1-a^2)(b^2+d^2)-b^2d^2(1+a^2)}{2abd\sqrt{1-a^2-b^2}\sqrt{1-a^2-d^2}}. \tag{40}$$

In the second case we take b, c, d, and, f as independent moduli, and get

$$S_2 = \begin{pmatrix} \sqrt{1-b^2-c^2} & b & c \\ d & \sqrt{1-d^2-f^2} & f \\ \sqrt{b^2+c^2-d^2} & \sqrt{d^2+f^2-b^2} & \sqrt{1-c^2-f^2} \end{pmatrix}, \tag{41}$$

$$c_{12} = \sqrt{1-b^2-c^2}, \quad c_{13} = \frac{b}{\sqrt{b^2+c^2}}, \quad c_{23} = \frac{d}{\sqrt{b^2+c^2}}, \tag{42}$$

$$\cos\,\delta_2 = \frac{b^2(b^2+c^2)-d^2(b^2-c^2+c^2(b^2+c^2))-f^2(b^2+c^2)^2}{2bcd\sqrt{1-b^2-c^2}\sqrt{b^2+c^2-d^2}}. \tag{43}$$

If the data are the entries of the following double stochastic matrix

$$V = \begin{pmatrix} \frac{1}{3} & \frac{1}{2} & \frac{1}{6} \\ \frac{1}{4} & \frac{2}{5} & \frac{7}{20} \\ \frac{5}{12} & \frac{1}{10} & \frac{29}{60} \end{pmatrix} \tag{44}$$

we get from Eqs. (39) and (40) and (42) and (43),

$$c_{12} = \frac{1}{\sqrt{3}}, \quad c_{13} = \frac{\sqrt{3}}{2}, \quad c_{23} = \frac{\sqrt{6}}{4}, \quad \cos\,\delta_1 = \cos\,\delta_2 = \frac{4\sqrt{15}}{25} \tag{45}$$

and the results show that the data are compatible to the existence of a unitary matrix. We remark that no matter how the independent moduli are chosen, c_{ij} and $\cos\,\delta$ take the same value, and this is a consequence of the fact that the properties of a double stochastic matrix do not change by multiplying it at left and/or right by permutation matrices. From a mathematical point of view the story ends here, because we can easily reconstruct the unitary matrix whose moduli are given in (44), by using the results (45) in the unitary matrix (33). We get

$$U = \begin{pmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{6}} \\ \frac{1}{2} & -\frac{9}{20}\sqrt{\frac{3}{2}} - \frac{1}{20}\sqrt{\frac{77}{2}}i & \frac{7}{20\sqrt{2}} + \frac{1}{20}\sqrt{\frac{231}{2}}i \\ \frac{1}{2}\sqrt{\frac{5}{3}} & -\frac{13}{20\sqrt{10}} + \frac{1}{20}\sqrt{\frac{231}{10}}i & -\frac{61}{20\sqrt{30}} - \frac{3}{20}\sqrt{\frac{77}{10}}i \end{pmatrix}. \tag{46}$$

Hence the reconstruction algorithm of unitary matrices from the double stochastic ones is the following: *Start with a double stochastic matrix such as* (44) *and solve the system of equations* (36). *If the numerical value for* $\cos\,\delta$ *satisfies the inequalities* (37), *then with the values for* c_{ij} *and* $\cos\,\delta$ *go to* (33) *and find the corresponding unitary matrix.*

When the matrices S_1 and S_2, Eqs. (38) and (41), do not lead to the same double stochastic matrix, as for experimental data recommended in Ref. 18, the situation changes. For example, by using the numbers: $a=0.9738\pm0.0005$, $b=0.22\pm0.0026$, $c=0.00367\pm0.00047$, $d=0.224\pm0.012$, $e=0.996\pm0.013$, $f=0.0423\pm0.0015$, to define two doubly stochastic matrices S_1^2 and S_2^2 one gets

$$\cos\delta_1^+ = -0.03i, \quad \cos\delta_1^c = 1.59, \quad \cos\delta_1^- = 1.08, \tag{47}$$

$$\cos\delta_2^+ = 8.95i, \quad \cos\delta_2^c = 5.985i, \quad \cos\delta_2^- = 7.699, \tag{48}$$

where the indexes $+$, c, $-$ denote the $\cos\delta$ values obtained from central values $+1\sigma$, the central values, and, respectively, central values -1σ. The above results show that our criterion (37) is very sensitive to small variations of the parameters of the order of errors, and, on the other hand, one sees that the fulfillment of unitarity for experimental data is not an easy problem. We remark that $\cos\delta_1 \neq \cos\delta_2$, although by construction both the matrices S_1^2 and S_2^2 are double stochastic. But these ones are different because numerically, e.g., $e \neq \sqrt{1-d^2-f^2}$. Hence in the case of experimental data we have to take care and try to find how the necessary and sufficient conditions for the existence of a unitary matrix could be implemented. In this case also the relations (35) are not exactly fulfilled. Consequently the numbers c_{ij} obtained from relations (39) and (42) could be different, depending on the independent parameters we use for their determination. On the other hand the last four relations (36) provide us formulas for $\cos\delta$ and these formulas have to give the same number when comparing theory with experiment, by supposing the data come from a unitary matrix. Their explicit form depends on the independent four parameters we choose to parametrize the data. In fact there are 58 independent groups of four independent moduli that lead to 165 different expressions for $\cos\delta$. Depending on the explicit choice of the four independent parameters we get one, two, three, or four different expressions for $\cos\delta$.

Looking at Eqs. (39) and (40) and (42) and (43) we see that the expressions defining the mixing angles and phase δ are quite different. Thus if the data are compatible to the existence of a unitary matrix these angles c_{ij} and phases $\delta^{(i)}$ have to be equal, and these are the most general necessary conditions for unitarity; they can be written as

$$0 \leqslant c_{ij}^{(m)} \leqslant 1, \quad c_{ij}^{(m)} = c_{ij}^{(n)}, \quad m,n = 1, \ldots, 58, \quad \cos\delta^{(i)} = \cos\delta^{(j)}, \quad i,j = 1, \ldots, 165.$$

The above-presented relations are also satisfied by the double stochastic matrices, and the condition that separates the unitary matrices from the double stochastic ones is given by relation (37), i.e., $-1 \leqslant \cos\delta^{(i)} \leqslant 1$.

The formulas such as (40) and (43), together with the condition $-1 \leqslant \cos\delta \leqslant 1$, give the description of the physical region in terms of the four independent moduli we have chosen. Indeed the physical region is given by

$$1 - \cos^2\delta_1 = \sin^2\delta_1 \geqslant 0$$

so we get

$$-(1-a^2-b^2-d^2+b^2d^2-2abde-e^2+a^2e^2)(1-a^2-b^2-d^2+b^2d^2+2abde-e^2+a^2e^2)$$
$$\times(a^2+b^2)^2/(4a^2b^2(-1+a^2+b^2)(-1+d^2+e^2)(-1+a^2+b^2+d^2+e^2)) \geqslant 0, \tag{49}$$

where on the last row we separated a positive factor. Thus the physical region is given by

$$-(1-a^2-b^2-d^2+b^2d^2-2abde-e^2+a^2e^2)(1-a^2-b^2-d^2+b^2d^2+2abde-e^2+a^2e^2) \geqslant 0. \tag{50}$$

If we denote by

$$l_1 = ab, \quad l_2 = de, \quad l_3 = \sqrt{1-a^2-d^2}\sqrt{1-b^2-e^2}$$

the lengths of the unitarity triangle generated by the first and the second columns of the S_1 matrix, from Heron's formula

$$A=\sqrt{p(p-l_1)(p-l_2)(p-l_3)},\quad \text{where } p=(l_1+l_2+l_3)/2$$

is the semiperimeter, we get the area, A, of the unitarity triangle, which according to Ref. 33 is the same for all the six unitarity triangles. We write it as

$$\begin{aligned}16A^2=&-(1-a^2-b^2-d^2+b^2d^2-2abde-e^2+a^2e^2)\\&\times(1-a^2-b^2-d^2+b^2d^2-2abde-e^2+a^2e^2)\geqslant 0\end{aligned}\tag{51}$$

and see that formulas (50) and (51) are the same up to a multiplicative factor, i.e., they are perfectly equivalent. This area is the geometric invariant of the 3×3 CKM matrix describing the CP-violation.[33] We remark that the positivity of A^2 is the key ingredient used to characterize the set of orthostochastic matrices and its boundary, within the double stochastic set, see Proposition 2.2 in Ref. 4.

B. Unitarity triangle method

The second phenomenological model is defined by the orthogonality relations of rows, and, respectively, columns of a unitary matrix, and by the double stochastic relations (35). Although there are six such relations, see Eq. (12), usually one considers only the orthogonality of the first and the third columns of U, a relation that is written as

$$U_{ud}U_{ub}^*+U_{cd}U_{cb}^*+U_{td}U_{tb}^*=0.\tag{52}$$

The above-presented equation can be visualized as a triangle in the complex plane. Usually (52) is scaled by dividing it through the middle term such that the length of one side is 1. Taking into account that our parametrization, Eq. (33), of a unitary matrix has the entries of the first column and the first row positive quantities, we divide by the first term, $U_{ud}U_{ub}^*$, which is positive. In fact, what matters are the angles of the triangle, and our choice has the advantage that the triangle generated by Eq. (52) has two angles which numerically coincide, modulo π, with the phases of U_{23} and U_{33}; together with the phases of U_{22} and U_{32} they can be used for the determination of the unitary matrix U, since all these angles are measurable quantities in experiments, see, e.g., Ref. 20, or 44.

The other sides have the lengths

$$\begin{aligned}R_{db,c}^{(1)}&=\left|\frac{U_{cd}U_{cb}^*}{U_{ud}U_{ub^*}}\right|=\frac{d\sqrt{1-d^2-e^2}}{a\sqrt{1-a^2-b^2}},\\R_{db,t}^{(1)}&=\left|\frac{U_{td}U_{tb}^*}{U_{ud}U_{ub}^*}\right|=\frac{\sqrt{1-a^2-d^2}\sqrt{a^2+b^2+d^2+e^2-1}}{a\sqrt{1-a^2-b^2}},\end{aligned}\tag{53}$$

where we have written on the right-hand side the R-values in our choice of the four independent parameters by using the matrix (38). The physical condition takes the form

$$|R_{db,c}^{(1)}-R_{db,t}^{(1)}|\leqslant 1\leqslant R_{db,c}^{(1)}+R_{db,t}^{(1)},\tag{54}$$

which says that with the lengths 1, $R_{db,c}$ and $R_{db,t}$ one can construct a triangle. The above noted condition is equivalent to the positivity of the squared area A^2 given by relation (51), see Ref. 4. If we use the matrix (41) we find

$$\begin{aligned}R_{db,c}^{(2)}&=\left|\frac{U_{cd}U_{cb}^*}{U_{ud}U_{ub}^*}\right|=\frac{df}{c\sqrt{1-b^2-c^2}},\\R_{db,t}^{(2)}&=\left|\frac{U_{td}U_{tb}^*}{U_{ud}U_{ub}^*}\right|=\frac{\sqrt{1-c^2-f^2}\sqrt{b^2+c^2-d^2}}{c\sqrt{1-b^2-c^2}}.\end{aligned}\tag{55}$$

We remark that in Eqs. (53)–(55) the left side is the same, and only the right side differs, because the four independent moduli we use are different. Since there are 58 different groups of independent moduli there will be 58 different expressions $R^{(i)}_{db,j}$, $j=c,t$, and $i=1,\ldots,58$.

If now we use the orthogonality between the first and the second columns, i.e.,

$$U_{ud}U^*_{us}+U_{cd}U^*_{cs}+U_{td}U^*_{ts}=0 \tag{56}$$

one gets similarly

$$\begin{aligned} R^{(1)}_{ds,c}&=\left|\frac{U_{cd}U^*_{cs}}{U_{ud}U^*_{us}}\right|=\frac{de}{ab},\\ R^{(1)}_{ds,t}&=\left|\frac{U_{td}U^*_{ts}}{U_{ud}U^*_{us}}\right|=\frac{\sqrt{1-a^2-d^2}\sqrt{1-b^2-e^2}}{ab}, \end{aligned} \tag{57}$$

and, respectively,

$$\begin{aligned} R^{(2)}_{ds,c}&=\left|\frac{U_{cd}U^*_{cs}}{U_{ud}U^*_{us}}\right|=\frac{d\sqrt{1-d^2-f^2}}{b\sqrt{1-b^2-c^2}},\\ R^{(2)}_{ds,t}&=\left|\frac{U_{td}U^*_{ts}}{U_{ud}U^*_{us}}\right|=\frac{\sqrt{b^2+c^2-d^2}\sqrt{d^2+f^2-b^2}}{b\sqrt{1-b^2-c^2}}. \end{aligned} \tag{58}$$

If as in the preceding case we compute the expressions on the right-hand side using the data (44) we find

$$R^{(1)}_{db,c}=R^{(2)}_{db,c}=\frac{3}{2}\sqrt{\frac{7}{10}},\quad R^{(1)}_{db,t}=R^{(2)}_{db,t}=\frac{1}{2}\sqrt{\frac{29}{2}} \tag{59}$$

and, respectively,

$$R^{(1)}_{ds,c}=R^{(2)}_{ds,c}=\sqrt{\frac{3}{5}},\quad R^{(1)}_{ds,t}=R^{(2)}_{ds,t}=\frac{1}{2}, \tag{60}$$

which both satisfy the inequalities of the form (54).

With the central values from Ref. 18 one gets

$$\begin{aligned} &R^{(1)}_{db,c}=0.8i,\quad R^{(1)}_{db,t}=0.71,\quad R^{(1)}_{ds,c}=1.04,\quad R^{(1)}_{ds,t}=0.037i,\\ &R^{(2)}_{db,c}=2.58,\quad R^{(2)}_{db,t}=11.72i,\quad R^{(2)}_{ds,c}=1.016,\quad R^{(2)}_{ds,t}=0.012i, \end{aligned} \tag{61}$$

a result that sends the same signal of incompatibility as in Sec. IV, see Eq. (48).

From the above-presented equations we can obtain the angles of the triangles generated by relations (52) and, respectively, (56). For each triangle we denote by φ_3 the angle of the triangle associated to the vertex $(0,0)$, the other two, φ_1 and φ_2, being associated, respectively, to the vertexes (ρ,η) and $(1,0)$, where (ρ,η) are the coordinates of the triangle apex. For the second triangle we make the substitution $\varphi_i\to\psi_i$, $i=1,2,3$, and find

$$\cos\varphi_1=4\sqrt{\frac{7}{145}}\approx 0.8,\quad \cos\varphi_2=\frac{61}{10\sqrt{58}}\approx 0.88,\quad \cos\varphi_3=-\frac{1}{2}\sqrt{\frac{7}{10}}\approx -0.42 \tag{62}$$

and, respectively,

$$\cos\psi_1 = -\frac{1}{4}\sqrt{\frac{3}{5}} \approx -0.19, \quad \cos\psi_2 = \frac{13}{20} \approx 0.65, \quad \cos\psi_3 = \frac{9}{8}\sqrt{\frac{3}{5}} \approx 0.87. \tag{63}$$

Similar to the preceding case the necessary and sufficient conditions for unitarity are the constraints: all $R^{(j)} \geqslant 0$, and

$$R^{(i)}_{db,c} = R^{(j)}_{db,c}, \quad R^{(i)}_{db,t} = R^{(j)}_{db,t}, \quad i,j = 1, \ldots, 58, \tag{64}$$

$$R^{(i)}_{ds,c} = R^{(j)}_{ds,c}, \quad R^{(i)}_{ds,t} = R^{(j)}_{ds,t}, \quad i,j = 1, \ldots, 58, \tag{65}$$

$$|R^{(i)}_{db,c} - R^{(j)}_{db,c}| \leqslant 1 \leqslant R^{(i)}_{db,c} + R^{(j)}_{db,c}, \quad j = 1, \ldots, 58, \tag{66}$$

$$|R^{(i)}_{ds,t} - R^{(j)}_{ds,t}| \leqslant 1 \leqslant R^{(i)}_{ds,t} + R^{(j)}_{ds,t}, \quad j = 1, \ldots, 58, \tag{67}$$

where in the last equations we have written only the conditions implied by two orthogonality relations, although for applications we must calculate the constraints for all six orthogonality relations.

The first remark is that this approach, in the variant used by physicists, does not make use of the double stochasticity relations, Eq. (35), the physicists implicitly assuming that these relations are satisfied by the numbers obtained from experiments. With the above notation, (ρ, η), for the apex of the triangle, Eq. (53) is written under the form, see, e.g., Refs. 20–29

$$\begin{aligned} R^{(1)}_{db,c} &= \left| \frac{U_{cd}U^*_{cb}}{U_{ud}U_{ub}} \right| = \sqrt{\rho^2 + \eta^2}, \\ R^{(1)}_{db,t} &= \left| \frac{U_{td}U^*_{tb}}{U_{ud}U_{ub}} \right| = \sqrt{(1-\rho)^2 + \eta^2}. \end{aligned} \tag{68}$$

The second remark is that in contradistinction to what physicists believe, ρ and η have no special relationship with a parametrization of the CKM matrix, in particular that provided by Wolfenstein.[45] Indeed on the right-hand side, Eq. (68), are the lengths of two sides of the above-defined triangle, those $\neq 1$. Physical meaning have only the angles of that triangle which can be measured.[20,44] The third remark is that in this approach there is no relationship between the CP-violating phase δ and the angles of the unitarity triangles. Because the phase is interesting from a physical point of view, the phenomenologists make the identification

$$\delta = \varphi_3 \quad \text{or} \quad \delta \approx \varphi_3 \tag{69}$$

see, e.g., Refs. 21–29. Looking at the numerical values obtained for $\cos\delta = (4/25)\sqrt{15}$, relation (45), and for the angles of the unitarity triangles, (62) and (63), computed by using an exact unitary matrix, we obtained a numerical proof that the claim (69) is wrong. A simpler contra example is the following: take all $V^2_{ij} = 1/3$. Then all six triangles are equilateral and by consequence we have $\phi_1 = \phi_2 = \phi_3 = 60°$, and from the first phenomenological model we get $\delta = 90°$.

Although this model in the form (68) is currently used in many phenomenological analyses, see, e.g., Refs. 25 and 26, it cannot directly provide numbers for the parameters c_{ij} and δ such that there is no (reliable) recovery algorithm for unitary matrices from double stochastic matrices. The positive thing is that, if properly used, this phenomenological model allows the determination of all the angles of all six unitarity triangles, which are measurable quantities. Hence the real problem is to find a recovery algorithm for unitary matrices starting with measured values for all these angles. This problem was first raised by Aleksan *et al.*[44] and in the next section we will solve it.

V. EQUIVALENCE OF THE TWO APPROACHES

Relations (48) and (61), as well as (45) and (62), have shown that the unitarity sends the same signal of (in)consistency between the data and the theoretical model, although each one in a specific way. This is natural since both models are based on the unitarity property of matrices modeling the CP-violation. In the following we will prove that from a theoretical point of view the above-presented phenomenological models are only *partially* equivalent in the following sense: if we start with four independent angles we can reconstruct more than a unitary matrix, the multiplicity being equal to five, *and the solutions given by the two models are the same if and only if four moduli take the same values*. This opens the possibility to define new phenomenological models, in terms of moduli and phases, by taking into account all the experimental data. In particular we provide an expression for the phase δ in the second phenomenological model.

The starting point is the relation (53) that we write in a complex form. For that we define the four independent angles that enter the CKM matrix (33), namely $U_{ij}=|U_{ij}|e^{\iota\omega_{ij}}$, $i,j=2,3$. With this notation we write the complex form of (53) as

$$R_{db,c}(\cos\omega_{23}+i\sin\omega_{23})=\frac{U_{cd}^{*}U_{cb}}{U_{ud}^{*}U_{ub}}, \tag{70}$$

$$R_{db,t}(\cos\omega_{33}+i\sin\omega_{33})=-\frac{U_{td}^{*}U_{tb}}{U_{ud}^{*}U_{ub}} \tag{71}$$

by using the fact that in our parametrization the elements of the first row and first column are positive. In the above second relation we put a minus sign since U_{33}, as well as U_{22}, has an overall phase equal to π. In fact the angles of the triangle are defined up to an integer multiple of π. From (70) we get

$$\sin\omega_{23}=\frac{c_{13}c_{23}s_{23}\sin\delta}{c_{12}s_{13}R_{db,c}}, \tag{72}$$

$$\cos\omega_{23}=-\frac{c_{23}(c_{12}c_{23}s_{13}-c_{13}s_{23}\cos\delta)}{c_{12}s_{13}R_{db,c}}. \tag{73}$$

The above-noted relations are equivalent to

$$\tan\omega_{23}=\frac{c_{13}s_{23}\sin\delta}{-c_{12}c_{23}s_{13}+c_{13}s_{23}\cos\delta}. \tag{74}$$

The last formula depends only on theoretical parameters entering (33), and does not depend on the lengths of the unitarity triangle. If in (74) we substitute values for c_{ij} and $\cos\delta$ taken for example from the phenomenological model, Eqs. (39) and (40), we get a formula for $\tan\omega_{23}$ in terms of moduli that are measurable quantities.

Conversely, from relations (72) and (73) we get a formula for $\cos\delta$. Indeed, from the identity $\sin^2\omega_{23}+\cos^2\omega_{23}=1$ we find

$$\cos\delta=\frac{c_{12}^2c_{23}^4s_{13}^2+c_{13}^2c_{23}^2s_{23}^2-c_{12}^2s_{13}^2R_{db,c}^2}{2c_{12}c_{13}c_{23}^3s_{13}s_{23}}. \tag{75}$$

If in it we substitute the formulas (39) and $R_{db,c}$ from Eq. (53) we find Eq. (40) for $\cos\delta$. If instead of (53) we use the corresponding form for $R_{db,c}$, which comes from the relation (55), one gets Eq. (43), and so on.

In the same way from relation (71) one gets

$$\tan \omega_{33} = \frac{c_{13}c_{23} \sin \delta}{c_{12}s_{13}s_{23} + c_{13}c_{23} \cos \delta} \tag{76}$$

and

$$\cos \delta = \frac{c_{12}^2 s_{13}^2 R_{db,t}^2 - c_{13}^2 c_{23}^2 s_{23}^2 - c_{12}^2 s_{13}^2 s_{23}^4}{2c_{12}c_{13}c_{23}s_{13}s_{23}^3}. \tag{77}$$

From relations (70) and (71) we find

$$\frac{R_{db,t}}{R_{db,c}}(\cos(\omega_{33} - \omega_{23}) + i \sin(\omega_{33} - \omega_{23})) = -\frac{U_{td}^* U_{tb}}{U_{cd}^* U_{cb}} \tag{78}$$

and from it we can obtain a similar formula for $\tan(\omega_{33} - \omega_{23})$.

Similarly the complex form of the second triangle, Eq. (57), is

$$R_{ds,c}(\cos \omega_{22} + i \sin \omega_{22}) = -\frac{U_{cd}^* U_{cs}}{U_{ud}^* U_{us}}, \tag{79}$$

$$R_{ds,t}(\cos \omega_{32} + i \sin \omega_{32}) = \frac{U_{td}^* U_{ts}}{U_{ud}^* U_{us}}, \tag{80}$$

wherefrom we get

$$\tan \omega_{22} = \frac{s_{13}s_{23} \sin \delta}{c_{12}c_{13}c_{23} + s_{13}s_{23} \cos \delta}, \tag{81}$$

$$\tan \omega_{32} = \frac{c_{23}s_{13} \sin \delta}{-c_{12}c_{13}s_{23} + c_{23}s_{13} \cos \delta}. \tag{82}$$

From the above-noted calculations one sees that one orthogonality relation determines only two independent angles, and from them one cannot reconstruct the unitary matrix because each angle depends on the *four* independent parameters entering the generic form (33) of a 3×3 unitary matrix.

Similar to relations (75) and (77) one can find two other independent formulas for $\cos \delta$. Since all four expressions are independent and depend on four parameters, they can be inversed to find c_{ij} and $\cos \delta$ as functions of the ratios $R_{ij,k}$, obtaining the correct formula for $\cos \delta$ in this approach. However the formulas for some c_{ij} contains more than a hundred terms, and we will not give them here.

From a mathematical point of view the angles ω_{ij}, $i, j = 2, 3$ are not very interesting, although their existence was the essential ingredient for obtaining the necessary and sufficient conditions for the existence of a unitary matrix from the entries of a double stochastic matrix, see Ref. 3. From a physical point of view they are very interesting because they are measurable quantities. Similar to the preceding cases we have to use all six orthogonality relations, although for a double stochastic matrix all the angles ω_{ij}, $i, j = 2, 3$ have the same numerical values, irrespective of the orthogonality property we use. However irrespective of what triangles we use we get the same functions $\tan \omega_{22}$, $\tan \omega_{23}$, $\tan \omega_{32}$, and $\tan \omega_{33}$. If we use the orthogonality of the second and the third columns, respectively, of the second and the third rows, we get the angles of the corresponding triangles as linear functions of ω_{22}, ω_{23}, ω_{32}, ω_{33}, modulo π, see Ref. 44. For example, the angles of the unitarity triangle generated by relation (52), or (53), are given by ω_{33}, $\pi - \omega_{23}$, and $\omega_{23} - \omega_{33}$, etc.

In the following we give the necessary and sufficient conditions for recovery of a unitary matrix when we know the angles ω_{ij}, $i, j = 2, 3$, solving the problem first raised by Aleksan *et al.*[44] In the following we make the notation

$$\tan \omega_{22} = t_{22}, \quad \tan \omega_{23} = t_{23}, \quad \tan \omega_{32} = t_{32}, \quad \tan \omega_{33} = t_{33} \tag{83}$$

and from Eqs. (74) and (76), and (81) and (82) we get

$$c_{13}^2 = \frac{t_{23}t_{33}(t_{22} - t_{32})}{t_{22}t_{23}(t_{33} - t_{32}) + t_{32}t_{33}(t_{22} - t_{23})},$$

$$c_{23}^2 = \frac{t_{32}t_{33}(t_{22} - t_{23})}{t_{22}t_{23}(t_{33} - t_{32}) + t_{32}t_{33}(t_{22} - t_{23})}, \tag{84}$$

$$c_{12}^2 = \frac{N_1}{N_2},$$

where

$$\begin{aligned} N_1 &= (t_{22} - t_{23})(t_{22} - t_{32})(t_{23} - t_{33})(t_{32} - t_{33}), \\ N_2 &= t_{23}^2 t_{32}^2 + t_{22}^2 t_{33}^2 + t_{23}^2 t_{32}^2 (t_{22}^2 + t_{33}^2) + t_{22}^2 t_{33}^2 (t_{23}^2 + t_{32}^2) \\ &\quad - 2t_{22}t_{23}t_{32}t_{33}[1 + (t_{23} + t_{32})(t_{22} + t_{33}) - t_{23}t_{32} - t_{22}t_{33}]. \end{aligned} \tag{85}$$

Substituting the values for c_{ij} from relations (84) and (85) in any equation (74), (76), (81), (82), or a combination of them, we get a formula for $\cos \delta$, that is too long to be written down here. Hence the necessary and sufficient conditions for the existence of a unitary matrix coming from the angles ω_{ij} are

$$0 \leqslant c_{12}^2 \leqslant 1, \quad 0 \leqslant c_{13}^2 \leqslant 1, \quad 0 \leqslant c_{23}^2 \leqslant 1, \quad -1 \leqslant \cos \delta \leqslant 1. \tag{86}$$

By using the numerical values

$$t_{22} = \frac{1}{9}\sqrt{\frac{77}{3}}, \quad t_{23} = \sqrt{\frac{33}{7}}, \quad t_{32} = -\frac{\sqrt{231}}{13}, \quad t_{33} = \frac{3\sqrt{231}}{61} \tag{87}$$

obtained from the matrix (46) we get by using relations (84) and (85)

$$c_{12} = \frac{1}{\sqrt{3}}, \quad c_{13} = \frac{\sqrt{3}}{2}, \quad c_{23} = \frac{\sqrt{6}}{4} \tag{88}$$

showing that Eqs. (84) and (85) uniquely define the parameters c_{ij}, in perfect accord with (45).

If in Eqs. (74) and (76), and (81) and (82) we substitute the mixing angles as given by (84) and (85) we get equations for $\cos \delta$ that lead to the solutions

$$\cos \delta = \frac{4}{5}\sqrt{\frac{3}{5}}, \quad \cos \delta = -\frac{139}{116}\sqrt{\frac{3}{5}}, \quad \cos \delta = \frac{9}{8}\sqrt{\frac{3}{5}}, \tag{89}$$

$$\cos \delta = -\frac{1}{4}\sqrt{\frac{3}{5}}, \quad \cos \delta = -\frac{41}{32}\sqrt{\frac{3}{5}}. \tag{90}$$

In fact from each equation (74)–(76) and (81) and (82) one gets two solutions for $\cos \delta$, and only one of them coincides with that found in the first phenomenological model, see (45). Hence the problem of recovering a unitary matrix when we know four independent angles ω_{ij} is not unique, and the finite multiplicity is at least five. However this result does not contradict the general result stated in Theorem 2, a theorem which gives uniqueness if and only if we use four independent moduli. To see what happens in the above-noted case, we recover the unitary matrix by using c_{ij} taken from relations (88), and the second value for $\cos \delta$,

$$\cos\delta = -\frac{139}{116}\sqrt{\frac{3}{5}}.$$

The moduli matrix has the form

$$V_1 = \begin{pmatrix} \frac{1}{3} & \frac{1}{2} & \frac{1}{6} \\ \frac{1}{4} & \frac{47}{1856} & \frac{1345}{1856} \\ \frac{5}{12} & \frac{881}{1856} & \frac{605}{5568} \end{pmatrix}. \tag{91}$$

By comparing the matrix V_1 with the original one, Eq. (44), we see that the elements of the first row and column coincide, the others are different. In order to obtain a unique solution we can use relation (77), or any other equivalent to, which make use of one of the lengths of unitarity triangle sides, which depends on the fourth independent moduli. Hence by using information coming only from triangles angles we have a finite multiplicity solution. The uniqueness is obtained if and only if the information is supplemented by an independent modulus, e.g., in the above-mentioned case $V(2,2)$, or a length of a unitarity triangle. The phenomenological implications of the above-noted results on the global fit methods for recovering a unitary matrix from moduli and angles will be treated elsewhere.

VI. RECOVERY OF UNITARY MATRICES FROM EXPERIMENTAL DATA

If the data come from an exact numerical matrix the problem to solve is quite simple: we have to test the stochasticity property, and, afterwards, the unitarity constraints, i.e., the condition, $-1 \leqslant \cos\delta \leqslant 1$, in the unitarity condition method, or the inequalities, $|R_{\alpha\beta,\gamma} - R_{\alpha\beta,\gamma}| \leqslant 1 \leqslant R_{\alpha\beta,\gamma} + R_{\alpha\beta,\gamma}$, coming from two orthogonality relations in the case of the standard unitarity triangles approach. If the data pass any one of the tests, one can easily reconstruct the unitary matrix Eq. (33) from the data (34), as the numerical examples from the previous sections have shown. If the physical conditions are violated, there is no compatibility and the discussion ends here. The real problem, from a physical point of view, is when the data come from experiment, i.e., are numbers affected by errors, and the problem is how we proceed in this situation, because neither the double stochasticity relations, nor the unitarity constraints are exactly satisfied.

There is the place where the gauge invariance subgroup K of unitary matrices enters the game, and its implications are the following. We have to find all *four* independent moduli groups and find all the possible forms for $\cos\delta$, and, respectively, the lengths of the unitarity triangles. And we have to impose that the numerical values for them should be approximately equal. The usual case with the present data is that the numerical values obtained for moduli are such that $\cos\delta^{(i)} \neq \cos\delta^{(j)}$, and/or $R^{(i)}_{\alpha\beta,\gamma} \neq R^{(j)}_{\alpha\beta,\gamma}$, $i \neq j$. Even more $\cos\delta^{(i)}$ could be outside the physical region, or the lengths of unitarity triangles are imaginary, or if they are real are not compatible with the existence of a triangle, as the numerical examples provided in the paper show. Hence, in contradistinction with the usage nowadays, see Ref. 20, we have to devise a fitting model that should implement the fulfillment of the above-noted theoretical constraints, and which should take into account the experimental data.

The method we expose here is discussed in more detail in Ref. 46. It is a least-squares method for checking the compatibility of the data with the theoretical models in both approaches, and if the data pass the physical conditions imposed by unitarity, from the fits one gets values for the parameters entering the theoretical model that by assumption gives a reliable description of the physical reality that is investigated by experiment.

It follows that in both approaches the χ^2-function must contain two separate terms, the first have to impose the fulfillment of the unitarity constraints by the free parameters entering the

physical model, and their best determination from the data, and the second one should depend on physical quantities that are measured in (different) experiments. Thus our proposal for the first terms is

$$\chi_1^2 = \sum_{i<j} (\cos \delta^{(i)} - \cos \delta^{(j)})^2 + \sum_{j=u,c,t} \left(\sum_{i=d,s,b} V_{ji}^2 - 1 \right)^2 + \sum_{j=d,s,b} \left(\sum_{i=u,c,t} V_{ij}^2 - 1 \right)^2, \quad -1 \leqslant \cos \delta^{(i)} \leqslant 1 \tag{92}$$

for the unitarity condition method, and, respectively,

$$\chi_2^2 = \sum_{\substack{\alpha\beta,\gamma \\ i<j}} (R_{\alpha\beta,\gamma}^{(i)} - R_{\alpha\beta,\gamma}^{(j)})^2 + \sum_{j=u,c,t} \left(\sum_{i=d,s,b} V_{ji}^2 - 1 \right)^2 + \sum_{j=d,s,b} \left(\sum_{i=u,c,t} V_{ij}^2 - 1 \right)^2,$$
$$R_{\alpha\beta,\gamma}^{(i)} \geqslant 0, \quad |R_{\alpha\beta,\gamma}^{(i)} - R_{\alpha\beta,\gamma}^{(i)}| \leqslant 1 \leqslant R_{\alpha\beta,\gamma}^{(i)} + R_{\alpha\beta,\gamma}^{(i)} \tag{93}$$

for the unitarity triangles method. Both the $\chi_{1,2}^2$ formulas test the double stochasticity property and the unitarity; from the point of view of numerical computation the unitarity property is the most difficult to satisfy.

Concerning the second component of χ^2-test it is of the form

$$\chi_3^2 = \sum_{i=1} \left(\frac{d_i - \tilde{d}_i}{\sigma_i} \right)^2, \tag{94}$$

where d_i are theoretical functions depending on the theoretical parameters s_{ij} and δ, or on V_{kl}, and/or the angles ϕ_i, ψ_i which are given by the phenomenological model one works with, while $\tilde{d}_i$ are the measured experimental data for d_i, and σ is the vector of errors associated to $\tilde{d}_i$. The formulas

$$\chi_u^2 = \chi_1^2 + \chi_3^2$$

and, respectively,

$$\chi_t^2 = \chi_2^2 + \chi_3^2$$

are our proposals for χ^2-tools necessary in analyzing the experimental data.

A remark is the following: as we have seen the second phenomenological model does not yet provide an explicit formula for cos δ, although our results have shown that it is possible to obtain it. In any case a global fit done by using either χ_u^2 or χ_t^2 will give values for all the moduli. Hence for the reconstruction of a unitary matrix in the second phenomenological model we have to use formulas such as (77). A true global fit will be that which will use all the experimental data by merging the above-mentioned two phenomenological models. The fulfillment of constraints (92) and (93) can be enforced by penalty functions that are equivalent to defining at least two Lagrange multipliers, etc.; but these are technical details depending on the concrete problem.

The convexity property of the double stochastic matrices allows us to devise a method for doing statistics on unitary matrices that is still an open problem in the physical literature, see, e.g., Ref. 47. Let us suppose that by doing a fit with the above-noted methods we got n moduli matrices that are consistent with n (approximate) unitary matrices, $U_1, U_2, \ldots, U_n$. The convexity property together with the embedding (2) tell us that the matrix

$$M^2 = \sum_{i=1}^{n} x_i |U_i|^2, \quad \sum_{i=1}^{n} x_i = 1, \quad 0 \leqslant x_i \leqslant 1, \ i = 1, \ldots, n$$

is double stochastic, where as usual in this paper we use the Hadamard product to define the above relation. Then the correct formulas for the mean value $\langle M \rangle$, and the error matrix σ_M are given by

$$\langle M\rangle = \sqrt{\left(\sum_{i=1}^{n} |U_i|^2\right) \Big/ n},$$
$$\sigma_M = \sqrt{\left(\sum_{i=1}^{n} |U_i|^4\right) \Big/ n - \langle M\rangle^4}. \tag{95}$$

If the entries of the mean value matrix, $\langle M\rangle$, obtained in this way are not too far from the entries coming from a unitary matrix, one can reconstruct from $\langle M\rangle$ an (approximate) unitary matrix by using the technique developed in the paper.

VII. CONCLUSIONS

Our main reason for studying the separation criteria between the double stochastic matrices and the unistochastic ones was their importance in high energy physics, where the present algorithms for reconstruction of unitary matrices from experimental data are not yet reliable in our opinion. Fortunately for the 3×3 matrices, which seem to be the physical choice in the electroweak interaction, there are explicit formulas for the independent parameters entering a unitary matrix in terms of four independent elements of a double stochastic one. That allows us to check the unitarity properties of exact double stochastic matrices, and an easy reconstruction of the unitary one from the entries of the double stochastic matrix when the compatibility conditions are fulfilled. These formulas can be used to define χ^2-functions for checking the compatibility between the experimental data and the unitarity property of the CKM matrix, and to recover a unitary matrix from error affected data. More important, starting from the convexity of the Birkhoff's polytope, we found a method for doing statistics on the (moduli of) unitary matrices.

We have also shown that, because the unitarity triangles method[20] and the unitarity condition method,[43] both being consequences of the unitarity property, are completely equivalent if and only if they are formulated in terms of four independent moduli. In the same time we have shown that the unitarity triangles method has to make effective use of the double stochasticity relations in order to obtain reliable results. Writing the unitarity triangles method in complex form we have obtained formulas for the four independent phases entering a unitary matrix, these phases being the angles of the unitarity triangles, modulo π. This opens the possibility to treat coherently all the experimental data available on moduli and angles by merging the above-mentioned phenomenological models into a true global one, the aim in view being a precise determination of the phase δ that is the key parameter in understanding the CP-violation.

(Received 29 April 2006; accepted 5 July 2006; published online 22 August 2006)

In this work we study the diamagnetic properties of a perfect quantum gas in the presence of a constant magnetic field of intensity B. We investigate the Gibbs semigroup associated with the one particle operator at finite volume, and study its Taylor series with respect to the field parameter $\omega := eB/c$ in different topologies. This allows us to prove the existence of the thermodynamic limit for the pressure and for all its derivatives with respect to ω (the so-called generalized susceptibilities). © *2006 American Institute of Physics.* [DOI: 10.1063/1.2259582]

I. INTRODUCTION

This paper is motivated by the study of the diamagnetic properties of a perfect quantum gas interacting with a constant magnetic field, $\mathbf{B} := B\mathbf{e}_3$, $B > 0$, $\mathbf{e}_3 := (0,0,1)$. The system obeys either the Bose or the Fermi statistics. Since we are only studying orbital diamagnetic effects, we consider a gas of spinless and charged particles.

We are mainly interested in the bulk response, i.e., the thermodynamic limit of the pressure and its derivatives w.r.t. cyclotron frequency $\omega := eB/c$. As in Briet *et al.* (2005) we use the term *generalized susceptibilities* to designate such quantities.

This question has been already addressed by several authors. Thus, one finds results concerning the existence of the large volume limit of pressure for both Fermi and Bose gases (Angelescu and Corciovei, 1975; Angelescu *et al.*, 1975b), the magnetization for a Bose gas (Cornean, 2000; Macris *et al.*, 1997) and the magnetic susceptibility for a Fermi gas (Angelescu *et al.*, 1975b). In (Briet *et al.*, 2005), extensions of these results to the case of generalized susceptibilities were announced.

This paper is the first in a series of two devoted to the rigorous proof of the results announced in (Briet *et al.*, 2005). Here we consider the regime in which the inverse temperature $\beta := 1/(kT)$ is positive and finite and the fugacity $z = e^{\beta\mu}$ belongs to the unit complex disk. Such conditions were also used in (Angelescu and Corciovei, 1975; Angelescu *et al.*, 1975b; Macris *et al.*, 1997). But here we also allow any positive value of the cyclotron frequency $\omega := e/cB$. In a forthcoming, paper, we will extend these results to some larger z-complex domains (in fact, to $\mathbf{D}_\epsilon$ defined below). One can also find different aspects of this problem in (Macris *et al.*, 1997; Combescure and Robert, 1990; Helffer and Sjöstrand, 1990).

The main part of this work is concerned with a new approach to the magnetic perturbation theory for a semigroup generated by a magnetic Schrödinger operator. It extends the results given

[a)]Electronic mail: briet@univtln.fr
[b)]Electronic mail: cornean@math.aau.dk
[c)]Electronic mail: louis@cpt.univ-mrs.fr

in (Angelescu *et al.*, 1975a; Cornean, 2000) and heavily relies on the use of the magnetic phase factor. This allows us to have good control on the magnetic perturbation wrt the size of the volume (Briet and Cornean, 2002; Cornean and Nenciu, 1998; Nenciu, 2002) in which the gas is confined.

Let us now describe our results. Let Λ be an open, bounded, and connected subset of $\mathbb{R}^3$ containing the origin of $\mathbb{R}^3$ and with smooth boundary $\partial\Lambda$. Set

$$\Lambda_L := \{\mathbf{x} \in \mathbb{R}^3, \mathbf{x}/L \in \Lambda\}; \quad L > 1. \tag{1.1}$$

Here we use the transverse gauge, i.e., the magnetic potential is defined as $B\mathbf{a} := (B/2)\mathbf{e}_3 \wedge \mathbf{x}$. The one particle Hamiltonian,

$$H_L(\omega) = \frac{1}{2}(-i\boldsymbol{\nabla} - \omega\mathbf{a})^2, \tag{1.2}$$

is first defined in the form sense on $H_0^1(\Lambda_L)$, and then one considers its Friedrichs extension (Reed and Simon, 2003). Thus we work with Dirichlet boundary conditions (DBC).

It is well-known that $H_L(\omega)$, $\omega \in \mathbb{R}$, generates a Gibbs semigroup,

$$\{W_L(\beta,\omega) = e^{-\beta H_L(\omega)} : \beta \geq 0\}, \tag{1.3}$$

i.e., for all $\beta > 0$, $W_L(\beta,\omega) \in B_1(L^2(\mathbb{R}^3)$, the set of trace class operators on $\mathcal{H}_L$ (Angelescu and Corciovei, 1975; Zagrebnov, 1978)

Then for $\beta > 0$, $\omega \in \mathbb{R}$, the grand canonical pressure of a quantum gas at finite volume is defined as (Huang, 1987; Angelescu and Corciovei, 1975; Angelescu *et al.*, 1975b)

$$P_L(\beta,\omega,z,\epsilon) = \frac{\epsilon}{\beta|\Lambda_L|} \cdot \mathrm{Tr}\{\ln(1 + \epsilon z W_L(\beta,\omega)\}, \tag{1.4}$$

where $\epsilon = -1 (\epsilon = 1)$ for Bose (Fermi) statistics. Since $\omega/2 = \inf \sigma(H_\infty(\omega))$, then the pressure is an analytic function wrt z on the complex domain $\mathbf{D}_\epsilon$ with

$$\mathbf{D}_{+1} := \mathbb{C} \setminus (-\infty, -e^{\beta\omega/2}], \quad \mathbf{D}_{-1} := \mathbb{C} \setminus [e^{\beta\omega/2}, \infty).$$

Let $n \geq 1$ and define the susceptibility of order n at finite volume by

$$\chi_L^{(n)}(\beta,\omega,z,\epsilon) := \frac{\partial^n P_L}{\partial \omega^n}(\beta,\omega,z,\epsilon). \tag{1.5}$$

If $n = 0$ we set $\chi_L^{(0)}(\beta,\omega,z,\epsilon) := P_L(\beta,\omega,z,\epsilon)$.

A. Results

Our first result describes the properties of the above defined quantities at finite volume, and it is given by the following theorem.

Theorem 1.1: *Let $\beta > 0$. Then the map $\mathbb{R} \ni \omega \to W_L(\beta,\omega) \in B_1(L^2(\mathbb{R}^3))$ is real analytic and admits an entire extension. For each open and bounded set $\mathcal{K}$ that obeys $\bar{\mathcal{K}} \subset \mathbf{D}_\epsilon$, $\epsilon = -1, +1$, there exists an open neighborhood $\mathcal{N}$ of the real axis such that the pressure at finite volume $P_L(\beta,\omega,z,\epsilon)$ is analytic* wrt (ω,z) *on $\mathcal{N} \times \mathcal{K}$. Let $\omega \in \mathbb{R}$, and $|z| < 1$. Then for $n \geq 0$ we have* [*see* (1.3)]:

$$\chi_L^{(n)}(\beta,\omega,z,\epsilon) = \frac{\epsilon}{\beta|\Lambda_L|} \sum_{k \geq 1} \frac{(-\epsilon z)^k}{k} \mathrm{Tr}\left\{\frac{\partial^n W_L(k\beta,\omega)}{\partial \omega^n}\right\}. \tag{1.6}$$

We now discuss the limit $L = \infty$. First, we define the candidates, $\chi_\infty^{(n)}$, for these limits. Recall that the one particle operator $H_\infty(\omega) = \frac{1}{2}(-i\boldsymbol{\nabla} - \omega\mathbf{a})^2$ on $L^2(\mathbb{R}^3)$, $\omega \in \mathbb{R}$, is positive and essentially self-adjoint on $C_0^\infty(\mathbb{R}^3)$. Denote by $W_\infty(\beta,\omega)$, $\beta \geq 0$ the semigroup generated by $H_\infty(\omega)$. Then $W_\infty(\beta,\omega)$ has an explicit integral kernel satisfying (see Sec. III):

$$G_\infty(\mathbf{x},\mathbf{x};\beta,\omega)=\frac{1}{(2\pi\beta)^{3/2}}\frac{\omega\beta/2}{\sinh(\omega\beta/2)},\quad \forall\,\mathbf{x}\in\mathbb{R}^3. \tag{1.7}$$

Note that the right hand side is independent of $\mathbf{x}$. Let $\beta>0$, $\omega\geq 0$ and $|z|<1$.

In view of (1.6), define

$$P_\infty(\beta,\omega,z,\epsilon):=\frac{\epsilon}{\beta}\sum_{k\geq 1}\frac{(-\epsilon z)^k}{k}G_\infty(\mathbf{0},\mathbf{0};k\beta,\omega), \tag{1.8}$$

which is well defined because of the estimate $\sinh(t)\geq t$ if $t\geq 0$. Then by the results of (Angelescu and Corciovei, 1975; Angelescu *et al.*, 1975b), we know that

$$\lim_{L\to\infty}P_L(\beta,\omega,z,\epsilon)=P_\infty(\beta,\omega,z,\epsilon).$$

It is quite natural to choose $\chi_\infty^{(n)}:=\partial^n P_\infty/\partial\omega^n$ provided that this last quantity exists. Note that it is not very easy to see this just from (1.8) and (1.7).

We then prove the following.

Theorem 1.2: *Let* $\beta>0$, $\omega\geq 0$ *and* $|z|<1$. *Fix* $n\geq 1$ *and define*

$$\chi_\infty^{(n)}(\beta,\omega,z,\epsilon):=\frac{\partial^n P_\infty}{\partial\omega^n}(\beta,\omega,z,\epsilon). \tag{1.9}$$

Then we have the equality:

$$\chi_\infty^{(n)}(\beta,\omega,z,\epsilon)=\frac{\epsilon}{\beta}\sum_{k\geq 0}\frac{(-\epsilon z)^k}{k}\frac{\partial^n G_\infty}{\partial\omega^n}(\mathbf{0},\mathbf{0};k\beta,\omega). \tag{1.10}$$

Moreover,

$$\lim_{L\to\infty}\chi_L^{(n)}(\beta,\omega,z,\epsilon)=\chi_\infty^{(n)}(\beta,\omega,z,\epsilon) \tag{1.11}$$

uniformly on $[\beta_0,\beta_1]\times[\omega_0,\omega_1]$, $0<\beta_0<\beta_1<\infty$, *and* $0<\omega_0<\omega_1<\infty$.

B. Relation with the de Haas-van Alphen (dHvA) effect

Our results can be easily extended to the case of more general Bloch electrons, that is, when one has a background smooth and periodic electric potential V. More precisely, let us assume that $V\in C^\infty(\mathbb{R}^3)$, $V\geq 0$, and if Γ is a periodic lattice in $\mathbb{R}^3$, then $V(\cdot)=V(\cdot+\gamma)$ for all $\gamma\in\Gamma$. Denote by Ω the elementary cell of Γ. In this case, the grand canonical pressure at the thermodynamic limit will be given by (we work with fermions; thus $\epsilon=1$)

$$P_\infty(\beta,\omega,z)=\frac{1}{\beta}\sum_{k\geq 1}\frac{(-z)^k}{k}\frac{1}{|\Omega|}\int_\Omega G_\infty(\mathbf{x},\mathbf{x};k\beta,\omega)d\mathbf{x}, \tag{1.12}$$

where $G_\infty(\mathbf{x},\mathbf{x}';k\beta,\omega)$ is the smooth integral kernel of the semigroup generated by $\frac{1}{2}(-i\nabla+\omega\mathbf{a})^2+V$. This formula only holds for $|z|<1$, but it can be analytically continued to $\mathbb{C}\backslash(-\infty,-1]$; see Angelescu and Corciovei (1975) or Helffer and Sjöstrand (1990).

Now one can start looking at the behavior of $P_\infty(\beta,\omega,z)$ as a function of ω, in particular, around the point $\omega_0=0$. Working in canonical conditions, that is when z is a function of β, ω and the fixed particle density ρ, then one is interesting in the object

$$p_\infty(\beta,\omega,\rho):=P_\infty(\beta,\omega,z(\beta,\omega,\rho)).$$

A thorough analysis of the ω behavior near 0, involving derivatives with respect to ω of the above quantity, has been already given by Helffer and Sjöstrand in 1990.

Alternatively, one can start from the finite volume quantities, and define a $z_L(\beta,\omega,\rho)$ as the unique solution of the equation $\rho_L := \beta z\, \partial_z P_L(\beta,\omega,z_L)=\rho$ and $p_L(\beta,\omega,\rho) := P_\infty(\beta,\omega,z_L(\beta,\omega,\rho))$. Is it still true that at large volumes we have, for example, that

$$\partial_\omega^n p_L(\beta,\omega,\rho) \sim \partial_\omega^n p_\infty(\beta,\omega,\rho), \quad n \geq 1\,?$$

The main achievement of our paper is that at least for small densities (which fix $|z|<1$) the answer is yes. In a companion paper we will prove that this is true for all $z \in \mathbb{C}\backslash(-\infty,-1]$.

We end the introduction by giving the plan of this paper. In Sec. II we discuss the analyticity of the Gibbs semigroup with respect to ω in the trace class sense. The trace norm estimates we obtain depend on the size of the domain, due to the linear growth of the magnetic potential. Using magnetic perturbation theory we manage to regularize the trace expansions and to extend these results to the infinite volume case in Secs. III and IV. Finally, we prove the existence of thermodynamic limits in Sec. V.

II. ANALYTICITY OF GIBBS SEMIGROUPS

A. B_1 analyticity

Let Λ_L, $L \geq 1$ be domains of $\mathbb{R}^3$ as defined in (1.1). In the following we will denote, respectively, by $\|T\|_1$, $\|T\|_2$, and $\|T\|$, the trace norm in $B_1(L^2(\Lambda_L))$, the Hilbert-Schmidt norm in $B_2(L^2(\Lambda_L))$ and the operator norm in $B(L^2(\Lambda_L))$ of T.

In this section we study, the ω expansion of $W_L(\beta,\omega)$. This question has been already considered (Hille and Phillips, 1957; Angelescu *et al.*, 1975b; Zagrebnov, 1978) in connection with the B_1 analyticity of $W_L(\beta,\omega)$. Combining their result with our analysis below, this gives the following. Define the operators

$$\hat{R}_{1,L}(\beta,\omega) := \mathbf{a}\cdot(i\boldsymbol{\nabla}_{\mathbf{x}} + \omega\mathbf{a})W_L(\beta,\omega), \tag{2.1}$$

$$\hat{R}_{2,L}(\beta,\omega) := \frac{1}{2}\mathbf{a}^2 W_L(\beta,\omega). \tag{2.2}$$

Both operators $\hat{R}_{1,L}(\beta,\omega)$ and $\hat{R}_{2,L}(\beta,\omega)$ belong to $B(\Lambda_L)$ and we have the following estimate on their norm.

Lemma 2.1: *For all* $\beta>0$, $\omega\geq 0$, *and* $L>1$, *there exists a positive constant* C *such that*

$$\|\hat{R}_{1,L}\| \leq \frac{CL}{\sqrt{\beta}} \quad \text{and} \quad \|\hat{R}_{2,L}\| \leq CL^2. \tag{2.3}$$

Proof: Let $\varphi \in L^2(\Lambda_L)$. Since $W_L(\beta,\omega)L^2(\Lambda_L) \subset \mathrm{Dom}(H_L(\omega))$ (Kato, 1966) after a standard argument [note that the absolute value of the components of $\mathbf{a}$ are bounded from above by $\mathrm{diam}(\Lambda_1)\cdot L$]:

$$\|\mathbf{a}\cdot(i\boldsymbol{\nabla}_{\mathbf{x}} + \omega\mathbf{a})W_L(\beta,\omega)\varphi\|^2 \leq CL^2\langle H_L(\omega)W_L(\beta,\omega)\varphi, W_L(\beta,\omega)\varphi\rangle \leq \frac{C\cdot L^2}{\beta}\|\varphi\|^2, \tag{2.4}$$

where the last estimate is given by the spectral theorem. The second bound of (2.3) is obvious.□

Remark 2.2: *Due to the diamagnetic inequality* [*see* (2.30)], *we have for all* $\beta>0$ *and* $\omega \in \mathbb{R}$,

$$\|W_L(\beta,\omega)\|_1 = \mathrm{Tr}(W_L(\beta,\omega)) \leq \frac{L^3}{(2\pi\beta)^{3/2}}. \tag{2.5}$$

Then both operators $\hat{R}_{1,L}, \hat{R}_{2,L}$ *are trace class*, *since we can factorize the operator* $\hat{R}_{1,L}(\beta,\omega) = \hat{R}_{1,L}(\beta/2,\omega)W_L(\beta/2,\omega)$.

For $n \geq 1$, define

$$\mathcal{D}_n(\beta) := \{0 < \tau_n < \tau_{n-1} < \ldots \tau_1 < \beta\} \subset \mathbb{R}^n. \tag{2.6}$$

Let $(i_1, \ldots, i_n) \in \{1,2\}^n$. Lemma 2.1 allows us to define the following family of bounded operators:

$$\hat{I}_{n,L}(i_1, \ldots, i_n)(\beta,\omega) := \int_{\mathcal{D}_n(\beta)} W_L(\beta - \tau_1, \omega)\hat{R}_{i_1,L}(\tau_1 - \tau_2, \omega) \times \hat{R}_{i_2,L}(\tau_2 - \tau_3, \omega) \ldots \hat{R}_{i_{n-1},L}(\tau_{n-1} - \tau_n, \omega)\hat{R}_{i_n,L}(\tau_n, \omega) d\tau, \tag{2.7}$$

where dr is the n-dimensional Lebesgue measure. These operators are in fact trace class, and we will estimate their trace norm later. Let $n \geq 1$, $(i_1, \ldots, i_n) \in \{1,2\}^n$ and χ_k^n be the characteristic function,

$$\chi_k^n(i_1, \ldots, i_k) := \begin{cases} 1, & \text{if } i_1 + \ldots + i_k = n, \\ 0, & \text{otherwise.} \end{cases} \tag{2.8}$$

Then we have the following.

Theorem 2.3: *Fix $\beta > 0$. Then the operator-valued function $\mathbb{R} \ni \omega \mapsto W_L(\beta,\omega) \in B_1$ admits an entire extension to the whole complex plane. Fix $\omega_0 \geq 0$. For all $\omega \in \mathbb{C}$ we have*

$$W_L(\beta,\omega) = \sum_{n=0}^{\infty} \frac{(\omega - \omega_0)^n}{n!} \frac{\partial^n W_L}{\partial \omega^n}(\beta,\omega_0), \tag{2.9}$$

$$\frac{1}{n!}\frac{\partial^n W_L}{\partial \omega^n}(\beta,\omega_0) = \sum_{k=1}^{n} (-1)^k \sum_{i_j \in \{1,2\}} \chi_k^n(i_1, \ldots, i_k)\hat{I}_{k,L}(i_1, \ldots, i_k)(\beta,\omega_0). \tag{2.10}$$

Moreover, there exists a positive constant C independent of $n \geq 1$, $\beta > 0$, and L such that

$$\left\| \frac{1}{n!}\frac{\partial^n W_L}{\partial \omega^n}(\beta,\omega_0) \right\|_1 \leq C^n \frac{(1+\beta)^n}{\beta^{3/2}} L^{n+3} \frac{1}{[(n-1)/4]!}. \tag{2.11}$$

For all $\omega \in \mathbb{C}$, $\{W_L(\beta,\omega), \beta > 0\}$ is a Gibbs semigroup with its generator given by the closed operator $H_L(\omega)$.

Remark 2.4: This theorem implies that the trace of the semigroup W_L is an entire function of ω, and by (2.9),

$$\mathrm{Tr}(W_L(\beta,\omega)) = \sum_{n=0}^{\infty} \frac{(\omega - \omega_0)^n}{n!} \mathrm{Tr}\left(\frac{\partial^n W_L}{\partial \omega^n}(\beta,\omega_0) \right). \tag{2.12}$$

Proof of Theorem 2.3: We will use here some results from Hille and Phillips (1957) and Angelescu *et al.* (1975b), which we briefly recall. Let $\omega_0 \geq 0$. For $\omega \in \mathbb{C}$ set $\delta\omega := \omega - \omega_0$. Then the operator

$$H_L(\omega) - H_L(\omega_0) = (\delta\omega)\mathbf{a} \cdot (i\nabla_{\mathbf{x}} + \omega_0 \mathbf{a}) + \frac{(\delta\omega)^2}{2}\mathbf{a}^2 \tag{2.13}$$

is relatively bounded to $H_L(\beta,\omega_0)$ with relative bound zero. Note that for $\beta > 0$ from (2.13) we have, in the operator sense on $\mathcal{H}_L$,

$$\hat{R}_L(\beta,\omega) := (H_L(\omega) - H_L(\omega_0))W_L(\beta,\omega_0) = \delta\omega \hat{R}_{1,L}(\beta,\omega_0) + (\delta\omega)^2 \hat{R}_{2,L}(\beta,\omega_0). \tag{2.14}$$

For every compact subset $K \subset \mathbb{C}$, and due to the estimates (2.3), this operator satisfies

$$\int_0^1 d\tau \sup_{\omega\in K}\|\hat{R}_L(\tau,\omega)\| < \infty .$$

Let $0<\beta_1\leq\beta_0<\infty$. Then the series

$$W_L(\beta,\omega,\omega_0)=\sum_{n=0}^{\infty}(-1)^n W_L^{(n)}(\beta,\omega,\omega_0), \tag{2.15}$$

where $W_L^{(0)}(\beta,\omega,\omega_0)=W_L(\beta,\omega_0)$, and for $n\geq 1$,

$$W_L^{(n)}(\beta,\omega,\omega_0)=\int_0^\beta d\tau\, W_L(\beta-\tau,\omega_0)(H_L(\omega)-H_L(\omega_0))W_L^{(n-1)}(\tau,\omega_0) \tag{2.16}$$

is uniformly B_1 convergent on $K\times[\beta_1,\beta_0]$. This result was obtained in Angelescu *et al.* (1975b). Since $W_L(\beta,\omega,\omega_0)$ is the uniform limit of a sequence of entire B_1-valued functions, it follows via the Cauchy integral formula that $W_L(\beta,\omega,\omega_0)$ is also B_1 entire in ω. Moreover, for real ω it coincides with the operator $e^{-\beta H_L(\omega)}, \beta>0$.

What we do here is to identify its nth order derivative with respect to ω. From (2.16) and (2.14), a simple induction argument yields the following finite rearranging:

$$\sum_{n=0}^{N}(-1)^n W_L^{(n)}(\beta,\omega,\omega_0)=W_L(\beta,\omega_0)+\sum_{n=1}^{N}(\delta\omega)^n\sum_{k=1}^{n}(-1)^k\sum_{i_j\in\{1,2\}}\chi_k^n(i_1,\ldots,i_k)\hat{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega_0)$$
$$+\mathcal{R}_{N+1,L}(\beta,\omega,\omega_0), \tag{2.17}$$

where

$$\mathcal{R}_{N+1,L}(\beta,\omega,\omega_0)=\sum_{n=N+1}^{2N}(\delta\omega)^n\sum_{k=1}^{N}(-1)^k\sum_{i_j\in\{1,2\}}\chi_k^n(i_1,\ldots,i_k)\hat{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega_0). \tag{2.18}$$

Now differentiation with respect to ω commutes with the limit $N\to\infty$, again due to the uniform convergence and the Cauchy integral formula. Hence (2.9) is proved, since the nth order derivative of $\Sigma_{j=0}^{N}(-1)^j W_L^{(j)}(\beta,\omega,\omega_0)$ at $\omega=\omega_0$ equals the right hand side of (2.10) if $N\geq n$.

In the second part of the proof, we use the methods of Angelescu *et al.* (1975b) in order to estimate the B_1 norm of the operators $I_{k,L}(i_1,\ldots,i_k)$ as claimed in (2.11). We first have

$$\|\hat{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega_0)\|_1\leq\int_{\mathcal{D}_k(\beta)}d\tau\|W_L(\beta-\tau_1,\omega_0)\hat{R}_{i_1,L}(\tau_1-\tau_2,\omega_0)\ldots\hat{R}_{i_k,L}(\tau_k,\omega_0)\|_1. \tag{2.19}$$

Recall that the Ginibre-Gruber inequality reads as Angelescu *et al.* (1975b),

$$\left\|\prod_{l=0}^{k}A_l T(t_l)\right\|_1\leq\left(\prod_{l=0}^{k}\|A_l\|\right)\mathrm{Tr}\,T(t_0+t_1+\cdots+t_k), \tag{2.20}$$

where $\{A_l, 0\leq l\leq k\}$ are bounded operators and $T(t), t>0$ is a Gibbs semigroup. Then taking $A_0 := W_L((\beta-\tau_1)/2,\omega_0)$, $A_l := \hat{R}_{i_l,L}((\tau_l-\tau_{l+1})/2,\omega_0)$ if $l\geq 1$ (we put $\tau_{k+1}\equiv 0$) and $T(t)=W_L(t/2,\omega_0)$. On $D_k(\beta)$, we have the estimate $\|A_0\|\leq 1\leq\sqrt{(1+\beta)/(\beta-\tau_1)}$ and by the Lemma 2.1 for $l\geq 1$,

$$\|A_l\|=\left\|\hat{R}_{i_l,L}\left(\frac{\tau_l-\tau_{l+1}}{2},\omega_0\right)\right\|\leq\mathrm{const}\cdot L^{i_l}\frac{\sqrt{1+\beta}}{\sqrt{\tau_l-\tau_{l+1}}}. \tag{2.21}$$

Let $f_k:\mathcal{D}_k(\beta)\to\mathbb{R}$ be defined as

$$f_k(\tau) := \frac{1}{\sqrt{(\beta-\tau_1)(\tau_1-\tau_2)\cdots(\tau_{k-1}-\tau_k)\tau_k}}, \tag{2.22}$$

and it satisfies

$$\int_{\mathcal{D}_k(\beta)} f_k(\tau)d\tau = \frac{\beta^{(k-1)/2}\pi^{(k+1)/2}}{\Gamma\left(\frac{k+1}{2}\right)}. \tag{2.23}$$

Let $i_1+\cdots+i_k=n$. Then from (2.5), (2.20), (2.21), and (2.23), we obtain the existence of a numerical constant C, such that for every $\beta>0$:

$$\|\hat{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega_0)\|_1 \leq \frac{L^{n+3}C^k(1+\beta)^k}{\beta^{3/2}\Gamma\left(\frac{k+1}{2}\right)}. \tag{2.24}$$

Thus, we have the estimate [see (2.10)]:

$$\frac{1}{n!}\|(\partial_\omega^n W_L)(\beta,\omega_0)\|_1 \leq C^n L^{n+3}\frac{(1+\beta)^n}{\beta^{3/2}}\sum_{k=1}^{n}\sum_{i_j\in\{1,2\}}\frac{\chi_k^n(i_1,\ldots,i_k)}{\Gamma\left(\frac{k+1}{2}\right)}. \tag{2.25}$$

But a lot of terms in the above sum are zero, since $\chi_k^n(i_1,\ldots,i_k)=0$ if $k<[(n+1)/2]$. Since Γ is increasing, we can give a rough estimate of the form

$$\sum_{k=1}^{n}\sum_{i_j\in\{1,2\}}\frac{\chi_k^n(i_1,\ldots,i_k)}{\Gamma\left(\frac{k+1}{2}\right)} \leq n2^n\frac{1}{\Gamma\left(\frac{[(n+1)/2]+1}{2}\right)} \leq n2^n\frac{1}{[(n-1)/4]!}. \tag{2.26}$$

□

B. Proof of Theorem 1.1

The analyticity properties of the pressure are now easy to prove once we have the B_1 analyticity of the Gibbs semigroup. See Angelescu *et al.* (1975a) for details.

Now let $\beta>0, \omega\geq 0$ and $|z|<1$. Since $\|zW_L(\beta,\omega)\|<1$, the logarithm in the pressure at finite volume can be expanded, and then

$$P_L(\beta,\omega,z,\epsilon) = \epsilon/(\beta|\Lambda_L|)\sum_{k\geq 1}(-\epsilon z)^k/k \operatorname{Tr} W_L(k\beta,\omega). \tag{2.27}$$

Starting from Definition (1.5), and using Theorem 2.3, we obtain

$$\chi_L^{(n)}(\beta,\omega,z,\epsilon) = \epsilon/(\beta|\Lambda_L|)\sum_{k\geq 0}(-\epsilon z)^k/k \operatorname{Tr}\left(\frac{\partial^n W_L(k\beta,\omega)}{\partial\omega^n}\right). \tag{2.28}$$

Note that (2.11) ensures that the growth in k that comes from the trace of the nth derivative of $W_L(k\beta,\omega)$ is not faster than some polynomial, but since $|z|<1$, the series in k is convergent. This finishes the proof of the theorem. □

C. Analyticity of the semigroup's integral kernel

In the rest of this paper we will only consider $\Lambda_L=(-L/2,L/2)^3, L\geq 1$. For $\omega\in\mathbb{R}$, $H_L(\omega)$ is essentially self-adjoint on

$$\left\{\phi \in C^1(\bar{\Lambda}_L) \cup C^2(\Lambda_L), \phi\big|_{\partial\Lambda_L} = 0, \Delta\phi \in L^2(\Lambda_L)\right\}.$$

Let $G_L(\mathbf{x},\mathbf{x}';\beta,\omega)$ be the integral kernel of $W_L(\beta,\omega)$ [see, e.g., Angelescu and Corciovei (1975)]. Standard elliptic estimates for the eigenfunctions of $H_L(\omega)$, together with the fact that $e^{-\beta H_L(\omega)}$ is trace class, imply that $G_L(\mathbf{x},\mathbf{x}';\beta,\omega)$ is smooth in $(\mathbf{x},\mathbf{x}') \in \Lambda_L \times \Lambda_L$. Moreover, $G_L(\mathbf{x},\mathbf{x}';\beta,\omega)=0$ if either $\mathbf{x}$ or $\mathbf{x}'$ are on the boundary.

To prove the next theorem, we need the following result from Cornean (2000), concerning the C^1 regularity up to the boundary of the integral kernel. Let $\beta>0$ and let $G_\infty(\mathbf{x},\mathbf{x}',\beta) := G_\infty(\mathbf{x},\mathbf{x}',\beta,\omega=0)$ be the heat kernel on the whole space, i.e.,

$$G_\infty(\mathbf{x},\mathbf{x}';\beta) = \frac{1}{(2\pi\beta)^{3/2}} e^{-|\mathbf{x}-\mathbf{x}'|^2/2\beta}. \tag{2.29}$$

Recall that the diamagnetic estimate reads as Angelescu and Corciovei (1975):

$$|G_L(\mathbf{x},\mathbf{x}';\beta,\omega)| \leq G_\infty(\mathbf{x},\mathbf{x}';\beta), \quad (\mathbf{x},\mathbf{x}') \in \Lambda_L \times \Lambda_L, \quad \omega \geq 0. \tag{2.30}$$

Then we have the following.

Lemma 2.5: Let $\beta>0$ and $\omega\geq 0$. Then on $\Lambda_L\times\Lambda_L$, we have

$$|(i\nabla_{\mathbf{x}} + \omega\mathbf{a}(\mathbf{x}))G_L(\mathbf{x},\mathbf{x}';\beta,\omega)| \leq \frac{\mathcal{C}}{\sqrt{\beta}} G_\infty(\mathbf{x},\mathbf{x}',8\beta), \tag{2.31}$$

where $\mathcal{C}=\mathcal{C}(\beta,\omega)=c\cdot(1+\beta)^5(1+\omega)^3$ and $c>1$ is a numerical constant.

This estimate allows us to define the integral kernels of the operators defined in (2.2); more precisely, for $(\mathbf{x},\mathbf{x}') \in \Lambda_L\times\Lambda_L$, we have

$$\hat{R}_{1,L}(\mathbf{x},\mathbf{x}';\beta,\omega) := \mathbf{a}(\mathbf{x}) \cdot (i\nabla_{\mathbf{x}} + \omega\mathbf{a}(\mathbf{x}))G_L(\mathbf{x},\mathbf{x}';\beta,\omega),$$

$$\hat{R}_{2,L}(\mathbf{x},\mathbf{x}';\beta,\omega) := \frac{1}{2}\mathbf{a}^2(\mathbf{x})G_L(\mathbf{x},\mathbf{x}';\beta,\omega). \tag{2.32}$$

Consider the operator $W_L(\beta,\omega)$ for complex ω, defined by a B_1-convergent complex power series in Theorem 2.3. We will now prove that it has an integral kernel analytic in ω.

Theorem 2.6: *Let $\beta>0$ and fix $\omega_0\geq 0$.*

(i) *The operator $(\partial_\omega^n W_L)(\beta,\omega_0)$* defined in (2.10) *has an integral kernel denoted by $(\partial_\omega^n W_L)\times(\mathbf{x},\mathbf{x}';\beta,\omega_0)$, which is jointly continuous on $(\mathbf{x},\mathbf{x}') \in \bar{\Lambda}_L\times\bar{\Lambda}_L$, and obeys the estimate*

$$\frac{1}{n!}\left|\frac{\partial^n W_L}{\partial\omega^n}(\mathbf{x},\mathbf{x}';\beta,\omega_0)\right| \leq c^n \frac{(1+\omega_0)^{3n}(1+\beta)^{6n}L^n}{\beta^{3/2}\left[\frac{n-1}{4}\right]!}, \quad n\geq 1, \tag{2.33}$$

for some numerical constant $c\geq 1$.

(ii) *For $\omega\in\mathbb{C}$, the operator $W_L(\beta,\omega)$ has an integral kernel $G_L(\mathbf{x},\mathbf{x}';\beta,\omega)$ given by*

$$G_L(\mathbf{x},\mathbf{x}';\beta,\omega) = \sum_{n=0}^{\infty} \frac{(\omega-\omega_0)^n}{n!}\left(\frac{\partial^n W_L}{\partial\omega^n}\right)(\mathbf{x},\mathbf{x}';\beta,\omega_0), \tag{2.34}$$

where the above series is uniformly convergent on $\bar{\Lambda}_L\times\bar{\Lambda}_L$. Thus G_L is jointly continuous on $\bar{\Lambda}_L\times\bar{\Lambda}_L$ and is an entire function of ω.

Proof of Theorem 2.6: Lemma 2.5 obviously implies for $\beta>0$ and $\omega\geq 0$ the estimate

$$|\hat{R}_{1,L}(\mathbf{x},\mathbf{x}';\beta,\omega)| \leq L\frac{\mathcal{C}}{\sqrt{\beta}}G_\infty(\mathbf{x},\mathbf{x}';8\beta). \tag{2.35}$$

We also have

$$|\hat{R}_{2,L}(\mathbf{x},\mathbf{x}';\beta,\omega)| \leq \frac{L^2}{4}G_\infty(\mathbf{x},\mathbf{x}';\beta). \tag{2.36}$$

In the following, we will often use the uniform estimate with respect to the index $i=1,2$:

$$|\hat{R}_{i,L}(\mathbf{x},\mathbf{x}';t,\omega)| \leq L^i\mathcal{C}_1\sqrt{\frac{(1+\beta)}{t}}G_\infty(\mathbf{x},\mathbf{x}';8t), \quad 0<t\leq\beta, \tag{2.37}$$

where $\mathcal{C}_1 := \mathcal{C}_1(\beta,\omega)=2\sqrt{2}\mathcal{C}(\beta,\omega)$.

Let us start by proving (i). Fix $\beta>0,\omega_0\geq 0, L\geq 1$, and consider the operator $\hat{I}_{k,L}(i_1,\ldots,i_k)\times(\beta,\omega_0)$, $k\geq 1$ defined in (2.7). It admits a continuous integral kernel, $\hat{I}_{k,L}(\mathbf{x},\mathbf{x}';\beta,\omega_0) := \hat{I}_{k,L}(i_1,\ldots,i_k)(\mathbf{x},\mathbf{x}';\beta,\omega_0)$ on $\Lambda_L\times\Lambda_L$ given by

$$\begin{aligned}\hat{I}_{k,L}(\mathbf{x},\mathbf{x}';\beta,\omega_0) = \int_{D_k(\beta)} d\tau \int_{\Lambda_L^k} d\mathbf{y}\, G_L(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega_0)\hat{R}_{i_1,L}(\mathbf{y}_1,\mathbf{y}_2;\tau_1 \\ -\tau_2,\omega_0)\cdots\cdots \hat{R}_{i_{k-1},L}(\mathbf{y}_{k-1},\mathbf{y}_n;\tau_{k-1}-\tau_k,\omega_0)\hat{R}_{i_k,L}(\mathbf{y}_k,\mathbf{x}';\tau_k,\omega_0),\end{aligned} \tag{2.38}$$

where $d\mathbf{y}$ denotes the Lebesgue measure on $\mathbb{R}^{3k}$ and $D_k(\beta)$ is defined in (2.6). Let $i_1+i_2+\cdots+i_k=n$. Then by using the Lemma 2.5, the estimate

$$|G_L(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega_0)| \leq 8^{3/2}\sqrt{\frac{\beta}{\beta-\tau_1}}G_\infty(\mathbf{x},\mathbf{y}_1;8(\beta-\tau_1)), \quad 0<\tau_1<\beta,$$

and (2.37), the following estimate holds on $\Lambda_L\times\Lambda_L$:

$$\begin{aligned}|\hat{I}_{k,L}(\mathbf{x},\mathbf{x}';\beta,\omega_0)| \leq 8^{3/2}(1+\beta)^{(k+1)/2}\mathcal{C}_1^k L^n \\ \times\int_{D_k(\beta)} f_k(\tau)d\tau\int_{\Lambda_L^k} d\mathbf{y}G_\infty(\mathbf{x},\mathbf{y}_1;8(\beta-\tau_1))\ldots G_\infty(\mathbf{y}_k,\mathbf{x}';8\tau_k),\end{aligned} \tag{2.39}$$

where the function f_k is defined in (2.22). Notice that by using the semigroup property,

$$\begin{aligned}\int_{\Lambda_L^k} d\mathbf{y}\, G_\infty(\mathbf{x},\mathbf{y}_1;t_1)\ldots G_\infty(\mathbf{y}_k,\mathbf{x}';t_k) \leq \int_{\mathbb{R}^k} d\mathbf{y}\, G_\infty(\mathbf{x},\mathbf{y}_1;t_1)\ldots G_\infty(\mathbf{y}_k,\mathbf{x}';t_k) \\ = G_\infty(\mathbf{x},\mathbf{x}';t_1+\cdots+t_k).\end{aligned} \tag{2.40}$$

Therefore from (2.39) we get

$$|\hat{I}_{k,L}(\mathbf{x},\mathbf{x}';\beta,\omega_0)| \leq 8^{3/2}(1+\beta)^{(k+1)/2}\mathcal{C}_1^k L^n G_\infty(\mathbf{x},\mathbf{x}';8\beta)\int_{D_k(\beta)} f_k(\tau)d\tau. \tag{2.41}$$

Then Theorem 2.3 together with (2.23) and (2.41) show that the operator $(\partial^n W_L/\partial\omega^n)(\beta,\omega_0)$, $n\geq 1$ given by (2.9), admits a continuous integral kernel satisfying

$$\left|\frac{\partial^n W_L}{\partial \omega^n}(\mathbf{x},\mathbf{x}';\beta,\omega_0)\right| \leq (8^3\pi)^{1/2}\mathcal{C}_2^n n!\, L^n G_\infty(\mathbf{x},\mathbf{x}';8\beta)\sum_{k=1}^{n}\sum_{i_j\in\{1,2\}}\frac{\chi_k^n(i_1,\ldots,i_k)}{\Gamma\left(\frac{k+1}{2}\right)},$$

for a new constant $\mathcal{C}_2=\mathcal{C}_2(\beta,\omega_0):=\pi^{1/2}(1+\beta)\mathcal{C}_1(\beta,\omega_0)$. Then by mimicking the proof of (2.26) we get from the last inequality

$$\frac{1}{n!}\left|\frac{\partial^n W_L}{\partial \omega^n}(\mathbf{x},\mathbf{x}';\beta,\omega_0)\right| \leq \frac{c^n(1+\beta)^{6n}(1+\omega_0)^{3n}L^n}{[(n-1)/4]!}G_\infty(\mathbf{x},\mathbf{x}';8\beta), \tag{2.42}$$

where c is a numerical constant. Since $G_\infty(\mathbf{x},\mathbf{x}';8\beta)\leq(16\pi\beta)^{-3/2}$, (2.42) implies the estimate (2.33) and proves (i). Then (ii) follows easily from the previous estimate since $1/[(n-1)/4]!$ has a superexponential decay in n. □

III. REGULARIZED EXPANSION

The bounds obtained in the previous section are not convenient for the proof of the existence of the thermodynamic limit of the magnetic susceptibilities. In particular, the bound on $(\partial^n W_L/\partial\omega^n)(\mathbf{x},\mathbf{x}',\beta,\omega_0)$ given by (2.42) is of order L^n. Then this gives a bound on its trace of order L^{3+n}, while in view of (1.6) we need a bound that goes like L^3.

In this section, we give an improvement of these estimates. In order to do that, we need to introduce the magnetic phase ϕ and the magnetic flux fl defined as [here $\mathbf{x},\mathbf{y},\mathbf{z}\in\Lambda_L$ and $\mathbf{e}=(0,0,1)$]:

$$\phi(\mathbf{x},\mathbf{y}) := \frac{1}{2}\mathbf{e}\cdot(\mathbf{y}\wedge\mathbf{x}) = -\phi(\mathbf{y},\mathbf{x}), \tag{3.1}$$

$$\mathrm{fl}(\mathbf{x},\mathbf{y},\mathbf{z}) := \phi(\mathbf{x},\mathbf{y})+\phi(\mathbf{y},\mathbf{z})+\phi(\mathbf{z},\mathbf{x}) = \frac{1}{2}\mathbf{e}\cdot\{(\mathbf{x}-\mathbf{y})\wedge(\mathbf{z}-\mathbf{y})\}. \tag{3.2}$$

Note that fl is really the magnetic flux through the triangle defined by the three vectors, and we have

$$|\mathrm{fl}(\mathbf{x},\mathbf{y},\mathbf{z})| \leq |\mathbf{x}-\mathbf{y}||\mathbf{y}-\mathbf{z}|. \tag{3.3}$$

For $n\geq 1$ and $\mathbf{x}=\mathbf{y}_0,\mathbf{y}_1,\ldots,\mathbf{y}_n$, some arbitrary vectors in Λ_L, define

$$\mathrm{Fl}_n(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_n) := \phi(\mathbf{y}_n,\mathbf{x})+\sum_{k=0}^{n-1}\phi(\mathbf{y}_k,\mathbf{y}_{k+1}) = \sum_{k=1}^{n-1}\mathrm{fl}(\mathbf{x},\mathbf{y}_k,\mathbf{y}_{k+1}), \quad \text{if } n\geq 2 \tag{3.4}$$

and

$$\mathrm{Fl}_1(\mathbf{x},\mathbf{y}_1)=0.$$

Notice that due to (3.3), we have

$$|\mathrm{Fl}_n(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_n)| \leq \sum_{k=1}^{n-1}\sum_{l=1}^{k}|\mathbf{y}_{l-1}-\mathbf{y}_l||\mathbf{y}_k-\mathbf{y}_{k+1}|. \tag{3.5}$$

Let $\omega\geq 0$. Consider now the bounded operators given by their integral kernels on $\Lambda_L\times\Lambda_L$,

$$R_{1,L}(\mathbf{x},\mathbf{x}';\beta,\omega) := \mathbf{a}(\mathbf{x}-\mathbf{x}')\cdot(i\nabla_{\mathbf{x}}+\omega\mathbf{a}(\mathbf{x}))G_L(\mathbf{x},\mathbf{x}';\beta,\omega).$$

$$R_{2,L}(\mathbf{x},\mathbf{x}';\beta,\omega) := \frac{1}{2}\mathbf{a}^2(\mathbf{x}-\mathbf{x}')G_L(\mathbf{x},\mathbf{x}';\beta,\omega). \tag{3.6}$$

Then by the Lemma 2.5, a straightforward estimate yields to

$$|R_{1,L}(\mathbf{x},\mathbf{x}';\beta,\omega)| \le \frac{\mathcal{C}|\mathbf{x}-\mathbf{x}'|}{2\sqrt{\beta}}G_\infty(\mathbf{x},\mathbf{x}',8\beta) \le 4\mathcal{C}_1 G_\infty(\mathbf{x},\mathbf{x}',16\beta), \tag{3.7}$$

for all $(\mathbf{x},\mathbf{x}')\in\Lambda_L\times\Lambda_L$. Similarly, by (2.30) we have

$$|R_{2,L}(\mathbf{x},\mathbf{x}';\beta,\omega)| \le \frac{|\mathbf{x}-\mathbf{x}'|^2}{8}G_\infty(\mathbf{x},\mathbf{x}',\beta) \le \frac{\beta}{\sqrt{2}}G_\infty(\mathbf{x},\mathbf{x}',2\beta). \tag{3.8}$$

In the sequel for $i=1,2$, we will use the estimate on $\Lambda_L\times\Lambda_L$,

$$|R_{i,L}(\mathbf{x},\mathbf{x}';\beta,\omega)| \le \mathcal{C}_3 G_\infty(\mathbf{x},\mathbf{x}',16\beta), \tag{3.9}$$

where $\mathcal{C}_3=\mathcal{C}_3(\beta,\omega) := 16\mathcal{C}_1(\beta,\omega)$ and $\mathcal{C}_1$ is given in (2.37).

Notice that (3.9) provides a uniform bound wrt. L and β near $\beta=0$ on the operator kernels. This in contrast with the bound on the norm operator of $\hat{R}_{i,L}; i=1,2$ [see Sec. II B, (2.35) and (2.36)]. Using the Schur-Holmgren estimate for the operator norm of an integral operator, (3.9) eventually implies

$$\|R_{i,L}\| \le \mathcal{C}_3, \quad i=1,2. \tag{3.10}$$

Let $\mathbf{x}\in\Lambda_L$. For $k\ge 1$, $m\ge 0$, $\omega\ge 0$, and $\beta>0$, define the continuous function,

$$\begin{aligned} W^m_{k,L}(\mathbf{x};\beta,\omega) := \sum_{j=1}^{k}(-1)^j \sum_{(i_1,\ldots,i_j)\in\{1,2\}^j} \chi^k_j(i_1,\ldots,i_j)\int_{D_j(\beta)} d\tau \int_{\Lambda^j} d\mathbf{y}\frac{(i(\mathrm{Fl}_j(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j)))^m}{m!} \\ \times G_L(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega)R_{i_1,L}(\mathbf{y}_1,\mathbf{y}_2;\tau_1-\tau_2,\omega)\ldots R_{i_{j-1},L}(\mathbf{y}_{j-1},\mathbf{y}_j;\tau_{j-1}-\tau_j,\omega) \\ \times R_{i_j,L}(\mathbf{y}_j,\mathbf{x};\tau_j,\omega), \end{aligned} \tag{3.11}$$

where in the case of $m=0$ we set $0^0\equiv 1$.

The main result of this section gives a new expression for the diagonal of kernel's nth derivative with respect to ω at finite volume.

Theorem 3.1: *Let $\beta>0$ and $\omega\ge 0$. Then for all $\mathbf{x}\in\Lambda_L$, and for all $n\ge 1$, one has*

$$\frac{1}{n!}\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x},\beta,\omega) = \sum_{k=1}^{n} W^{n-k}_{k,L}(\mathbf{x};\beta,\omega), \tag{3.12}$$

and, moreover, uniformly in $L>1$:

$$|W^m_{k,L}(\mathbf{x};\beta,\omega)| \le c(m,k)\frac{(1+\beta)^{7(m+k)+3}}{\beta^{3/2}}(1+\omega)^{3(m+k)+2}, \tag{3.13}$$

where $c(m,k)=c^{m+k}(m^m/m!)\Sigma_{j=1}^{k}\frac{j^{2m}}{j!}$ and c is again a numerical factor.

Proof: We first need to introduce some new notation. Fix $\omega_0\ge 0$. Let $\omega\in\mathbb{C}$, $\delta\omega=\omega-\omega_0$ and $\tilde{R}_{i,L}(\beta,\omega,\omega_0)$, $i=1,2$, $\tilde{W}_L(\beta,\omega,\omega_0)$ be the operators on $\mathcal{H}_L$ defined via their respective integral kernel given on $\Lambda_L\times\Lambda_L$, by

$$\widetilde{R}_{i,L}(\mathbf{x},\mathbf{x}';\beta,\omega,\omega_0) = e^{i\ \delta\omega\ \phi(\mathbf{x},\mathbf{x}')}R_{i,L}(\mathbf{x},\mathbf{x}';\beta,\omega_0), \quad i=1,2,$$

$$\widetilde{W}_L(\mathbf{x},\mathbf{x}';\beta,\omega,\omega_0) = e^{i\delta\omega\phi(\mathbf{x},\mathbf{x}')}G_L(\mathbf{x},\mathbf{x}';\beta,\omega_0), \tag{3.14}$$

where ϕ is defined in (3.1). We also set

$$\widetilde{R}_L(\mathbf{x},\mathbf{x}';\beta,\omega,\omega_0) := \delta\omega\,\widetilde{R}_{1,L}(\mathbf{x},\mathbf{x}';\beta,\omega,\omega_0) + (\delta\omega)^2\widetilde{R}_{2,L}(\mathbf{x},\mathbf{x}';\beta,\omega,\omega_0).$$

Except for a phase factor, the kernel of $\widetilde{W}_L$ and $\widetilde{R}_{i,L}$, $i=1,2$ is the same as the one of W_L, $R_{i,L}$, $i=1,2$, respectively. Then they satisfy (2.30) and (3.9), respectively. Hence, by the same arguments as above, they are bounded operators and

$$\|\widetilde{W}_L\| \leq 1, \|\widetilde{R}_{i,L}\| \leq \mathcal{C}_3 \tag{3.15}$$

[see (3.10)]. Notice also that since $\|\widetilde{W}_L\|_{\mathcal{I}_2} = \|W_L\|_{\mathcal{I}_2} \leq L^{3/2}/(2\pi\beta)^{3/4}$, then by (3.9), $R_{i,L}$, $i=1,2$ as well as $\widetilde{R}_{i,L}$, $i=1,2$ are in the Hilbert-Schmidt class and for $\beta>0$, $\omega_0\geq 0$ and $\omega\in\mathbb{C}$,

$$\|R_{i,L}(\beta,\omega)\|_{\mathcal{I}_2}, \|\widetilde{R}_{i,L}\|_{\mathcal{I}_2}(\beta,\omega,\omega_0) \leq \mathcal{C}_3\|W_L(16\beta,\omega)\|_{\mathcal{I}_2} \leq \mathcal{C}_3\frac{L^{3/2}}{(2\pi\beta)^{3/4}}, \tag{3.16}$$

where $\mathcal{C}_3 = \mathcal{C}_3(\beta,\omega_0)$ was first introduced in (3.9). We now define the following family of bounded operators on $\mathcal{H}_L$. Let $k\geq 1$, $\{i_1,\ldots,i_k\}\in\{1,2\}^k$, $\beta>0$, $\omega_0\geq 0$. For all $\omega\in\mathbb{C}$, set

$$\widetilde{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega,\omega_0) := \int_{D_k(\beta)} d\tau\,\widetilde{W}_L(\beta-\tau_1,\omega,\omega_0)\widetilde{R}_{i_1,L}(\tau_1-\tau_2,\omega,\omega_0)\ldots\widetilde{R}_{i_{k-1},L}(\tau_{k-1} - \tau_k,\omega,\omega_0)\widetilde{R}_{i_k,L}(\tau_k,\omega,\omega_0), \tag{3.17}$$

and for $n\geq 1$,

$$W_{n,L}(\beta,\omega,\omega_0) := \sum_{k=1}^{n}(-1)^k\sum_{i_j\in\{1,2\}}\chi_k^n(i_1,\ldots,i_k)\widetilde{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega,\omega_0), \tag{3.18}$$

where χ_k^n is defined in (2.8).

Lemma 3.2: Let $N\geq 1$, $\beta>0$, $\omega_0\geq 0$. For all $\omega\in\mathbb{C}$, set $\delta\omega=\omega-\omega_0$. Then as bounded operators we can write

$$W_L(\beta,\omega) = \widetilde{W}_L(\beta,\omega,\omega_0) + \sum_{n=1}^{n}(\delta\omega)^n W_{n,L}(\beta,\omega,\omega_0) + \widetilde{\mathcal{R}}^{(1)}_{N+1,L}(\beta,\omega,\omega_0) + \widetilde{\mathcal{R}}^{(2)}_{N+1,L}(\beta,\omega,\omega_0), \tag{3.19}$$

where $\widetilde{\mathcal{R}}^{(1)}_{N+1,L}(\beta,\omega,\omega_0)$ and $\widetilde{\mathcal{R}}^{(2)}_{N+1,L}(\beta,\omega,\omega_0)$ are the following bounded operators on $\mathcal{H}_L$:

$$\widetilde{\mathcal{R}}^{(1)}_{N+1,L}(\beta,\omega,\omega_0) := (-1)^{N+1}\sum_{n=N+1}^{2N+2}(\delta\omega)^n\sum_{i_j\in\{1,2\}}\chi_{N+1}^n(i_1,\ldots,i_n) \times\int_{D_{N+1}(\beta)} d\tau\,W_L(\beta-\tau_1,\omega)\widetilde{\mathcal{R}}_{i_1,L}(\tau_1-\tau_2,\omega,\omega_0)\ldots\widetilde{\mathcal{R}}_{i_{N+1},L}(\tau_{N+1},\omega,\omega_0), \tag{3.20}$$

where $D_{N+1}(\beta)$ is given in (2.6) *and*

$$\tilde{\mathcal{R}}^{(2)}_{N+1,L}(\beta,\omega,\omega_0)=\sum_{n=N+1}^{2N}(\delta\omega)^n\sum_{k=1}^{N}(-1)^k\sum_{i_j\in\{1,2\}}\chi^n_k(i_1,\ldots,i_k)\cdot\tilde{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega,\omega_0). \tag{3.21}$$

Proof of lemma: In this proof we fix $\omega_0\geq 0$ and omit everywhere the ω_0 dependence. We first note that $\tilde{W}_L(\beta,\omega)$ is strongly differentiable with respect to $\beta>0$ [see Cornean (2000)] and satisfies

$$\frac{\partial\tilde{W}_L(\beta,\omega)}{\partial\beta}+H_L(\omega)\tilde{W}_L(\beta,\omega)=\tilde{R}_L(\beta,\omega).$$

By using Proposition 3 from Cornean (2000), we can write the following Dyson-type integral equation:

$$W_L(\beta,\omega)=\tilde{W}_L(\beta,\omega)-\int_0^\beta d\tau\, W_L(\beta-\tau,\omega)\tilde{R}_L(\tau,\omega). \tag{3.22}$$

The above integral is a Riemann integral and converges in the operator norm sense. By iterating (3.22), we obtain

$$\begin{aligned}W_L(\beta,\omega)=\tilde{W}_L(\beta,\omega)+\sum_{n=1}^{N}(-1)^n\int_0^\beta d\tau_1\int_0^{\beta-\tau_1}d\tau_2\ldots\int_0^{\beta-\tau_1-\ldots-\tau_{n-1}}d\tau_n\\ \times\tilde{W}_L(\beta-\tau_1-\ldots-\tau_n,\omega)\tilde{R}_L(\tau_n,\omega)\ldots\tilde{R}_L(\tau_1,\omega)+\tilde{R}^{(1)}_{N+1,L}(\beta,\omega),\end{aligned} \tag{3.23}$$

where

$$\begin{aligned}\tilde{\mathcal{R}}^{(1)}_{N+1,L}(\beta,\omega)=(-1)^{N+1}\int_0^\beta d\tau_1\int_0^{\beta-\tau_1}d\tau_2\cdots\int_0^{\beta-\tau_1-\ldots-\tau_N}d\tau_{N+1}\\ \times W_L(\beta-\tau_1-\ldots-\tau_{N+1},\omega)\cdot\tilde{R}_L(\tau_{N+1},\omega)\ldots\tilde{R}_L(\tau_1,\omega).\end{aligned} \tag{3.24}$$

Then a straightforward change of variables in the integrals of the rhs of the last two formulas yields

$$\begin{aligned}W_L(\beta,\omega)=\tilde{W}_L(\beta,\omega)+\sum_{n=1}^{N}(-1)^n\int_{D_n(\beta)}d\tau\,\tilde{W}_L(\beta-\tau_1,\omega)\tilde{R}_L(\tau_1-\tau_2,\omega)\cdots\tilde{R}_L(\tau_{n-1}-\tau_n,\omega)\tilde{R}_L(\tau_n,\omega)\\ +\tilde{R}^{(1)}_{N+1,L}(\beta,\omega),\end{aligned}$$

with

$$\tilde{\mathcal{R}}^{(1)}_{N+1,L}(\beta,\omega)=(-1)^{N+1}\int_{D_{N+1}(\beta)}d\tau\,W_L(\beta-\tau_1,\omega)\cdot\tilde{R}_L(\tau_1,\omega)\ldots\tilde{R}_L(\tau_{N+1},\omega), \tag{3.25}$$

where $D_n(\beta)$ is defined in (2.6). Recall that $\tilde{R}_L=\delta\omega\tilde{R}_{1,L}+(\delta\omega)^2\tilde{R}_{2,L}$. So (3.25) gives (3.20) and a simple induction argument finishes the proof of the lemma. □

Continuing the proof of Theorem 3.1: From Theorem 2.6, we know that for $\mathbf{x}\in\Lambda_L$, and $\beta>0$, $\mathbb{C}\ni\omega\to G_L(\mathbf{x},\mathbf{x};\beta,\omega)$ is an entire function.

In order to prove (3.12), we will show that for all $\mathbf{x}\in\Lambda_L$, we have

$$G_L(\mathbf{x},\mathbf{x};\beta,\omega) = G_L(\mathbf{x},\mathbf{x};\beta,\omega_0) + \sum_{n=1}^{N} (\delta\omega)^n \sum_{k=1}^{n} W_{k,L}^{n-k}(\mathbf{x};\beta,\omega_0) + \widetilde{\mathcal{R}}_{N+1,L}(\mathbf{x};\beta,\omega,\omega_0), \quad (3.26)$$

where the remainder term satisfies the property that its first N derivatives at ω_0 are zero.

By rewriting Lemma 3.2 in terms of the corresponding integral kernels, and looking at the diagonal of these kernels, we have [remember that $\phi(\mathbf{x},\mathbf{x})=0$]

$$G_L(\mathbf{x},\mathbf{x};\beta,\omega) = G_L(\mathbf{x},\mathbf{x};\beta,\omega_0) + \sum_{n=1}^{N} (\delta\omega)^n W_{n,L}(\mathbf{x},\mathbf{x};\beta,\omega,\omega_0) + \widetilde{\mathcal{R}}^{(1)}_{N+1,L}(\mathbf{x},\mathbf{x};\beta,\omega,\omega_0)$$
$$+ \widetilde{\mathcal{R}}^{(2)}_{N+1,L}(\mathbf{x},\mathbf{x};\beta,\omega,\omega_0). \quad (3.27)$$

By construction, the two remainders are smooth functions that remain smooth, even if they are divided by $(\delta\omega)^{N+1}$; see formulas (3.20) and (3.21). This means that their first N derivatives at ω_0 are all zero. Thus the Nth derivative of $G_L(\mathbf{x},\mathbf{x};\beta,\cdot)$ at ω_0 can only come from the W's.

What we still have to do is to remove the ω dependence from W's. Let us show that for $1 \leq n \leq N$, $\mathbf{x} \in \Lambda_L$ and $|\delta\omega| < 1$,

$$W_{n,L}(\mathbf{x},\mathbf{x};\beta,\omega,\omega_0) = \sum_{m=0}^{N} (\delta\omega)^m W_{n,L}^m(\mathbf{x};\beta,\omega_0) + \widetilde{\mathcal{R}}^{(3)}_{n,N+1}(\mathbf{x};\beta,\omega,\omega_0), \quad (3.28)$$

where $W_{n,L}^m$ were introduced in (3.11), and $\widetilde{\mathcal{R}}^{(3)}_{n,N+1}(\mathbf{x};\beta,\omega,\omega_0)$ has its first N derivatives at ω_0 equal to 0. Indeed, if we replace the integral kernel of $\widetilde{I}_{k,L}$ from (3.17) in the expression of $W_{N,L}$ from (3.18), we see that we can add up all the magnetic phases, and obtain a factor of the type

$$\exp\{\phi(\mathbf{x},\mathbf{y}_1) + \phi(\mathbf{y}_1,\mathbf{y}_2) + \cdots + \phi(y_{k-1},\mathbf{y}_k) + \phi(y_k,\mathbf{x})\}.$$

Then this exponent will equal the magnetic flux defined in (3.4), plus an additional contribution $\phi(\mathbf{x},\mathbf{x})$ *that is zero due to the antisymmetry of the magnetic phase*. Now if we expand $e^{i(\delta\omega)\mathrm{Fl}_j(\mathbf{x},\ldots,\mathbf{y}_j)}$ in Taylor series up to the Nth order we obtain (3.28), where the remainder has again the property that its first N derivatives at ω_0 are zero. Now introduce (3.28) in (3.27), and after some algebra involving the multiplication of two series, we eventually get (3.26). Then we can identify the Nth derivative at ω_0 of the kernel's diagonal as the coefficient multiplying the Nth power of $\delta\omega$. The identity (3.12) is proved.

Now let us prove the second part of the theorem, i.e., the estimate (3.13), which is also linked to the natural question "why is formula (3.12) better than the one from (2.34)?" The answer is that $W_{k,L}^m(\mathbf{x};\beta,\omega_0)$ *does not grow with* L, and we will see in the next section that it even converges when L tends to infinity. Let us show here its uniform boundedness in L.

Looking at its definition given (3.11) and using the estimates from (3.9) together with the diamagnetic inequality, we see that we need to estimate

$$|W_{k,L}^m(\mathbf{x};\beta,\omega)| \leq \mathcal{C}_3^k \sum_{j=1}^{k} (-1)^j \sum_{(i_1,\ldots,i_j)\in\{1,2\}^j} \chi_j^k(i_1,\ldots,i_j) \int_{D_j(\beta)} d\tau \int_{\Lambda^j} d\mathbf{y} \frac{|\mathrm{Fl}_j(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j)|^m}{m!}$$
$$\times G_\infty(\mathbf{x},\mathbf{y}_1;16(\beta-\tau_1)) G_\infty(\mathbf{y}_1,\mathbf{y}_2;16(\tau_1-\tau_2)) \ldots G_\infty(\mathbf{y}_{j-1},\mathbf{y}_j;16(\tau_{j-1}-\tau_j))$$
$$\times G_\infty(\mathbf{y}_j,\mathbf{x};16\tau_j). \quad (3.29)$$

Let $\alpha = 16m$, and identify $\mathbf{x}=\mathbf{y}_0$. In view of (3.5) and the explicit form (2.29) of the heat kernel, for $1 \leq l \leq j-1, 1 \leq l' \leq l$; $\mathbf{y}_0,\mathbf{y}_1,\ldots,\mathbf{y}_j \in \Lambda_L^{j+1}$ and $\{\tau_1,\tau_2,\ldots\tau_j\} \in D_j(\beta)$, we need the straightforward estimate

$$|\mathbf{y}_{l'-1}-\mathbf{y}_{l'}||\mathbf{y}_l-\mathbf{y}_{l+1}|\exp\left(-\frac{|\mathbf{x}-\mathbf{y}_1|^2}{2\alpha(\beta-\tau_1)}\right)\ldots\exp\left(\frac{|\mathbf{y}_k-\mathbf{x}|^2}{2\alpha\tau_k}\right)$$
$$\leq 2\alpha\beta\exp\left(-\frac{|\mathbf{x}-\mathbf{y}_1|^2}{4\alpha(\beta-\tau_1)}\right)\ldots\exp\left(-\frac{|\mathbf{y}_k-\mathbf{x}|^2}{4\alpha\tau_k}\right). \tag{3.30}$$

Thus (3.5) and (3.30) imply

$$|\mathrm{Fl}_j(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j)|^m G_\infty(\mathbf{x},\mathbf{y}_1;16(\beta-\tau_1))\ldots G_\infty(\mathbf{y}_j,\mathbf{x};16\tau_j)$$
$$\leq\left(\sum_{l=1}^{j-1} l\alpha\beta\right)^{m_2 3(j+1)/2} G_\infty(\mathbf{x},\mathbf{y}_1;32(\beta-\tau_1))\ldots G_\infty(\mathbf{y}_j,\mathbf{x};32\tau_j)$$
$$\leq(8j^2m\beta)^{m_2 3(j+1)/2} G_\infty(\mathbf{x},\mathbf{y}_1;32(\beta-\tau_1))\ldots G_\infty(\mathbf{y}_j,\mathbf{x};32\tau_j). \tag{3.31}$$

Integrating over the spatial coordinates, using the semigroup property (2.40), and then integrating over τ variables, one eventually obtains the uniform upper bound in L given in (3.13). □

Remark 3.3: *Theorem 3.1 gives us what we need for the purpose of this paper. One can show that our analysis can be applied in order to get the off-diagonal terms of the integral kernel, i.e.,* $\partial^n G_L/\partial\omega^n(\mathbf{x},\mathbf{x}';\beta,\omega)(\mathbf{x},\mathbf{x}')\in\Lambda_L\times\Lambda_L$, *and* $\beta>0,\omega>0$. *In that case we get*

$$\frac{1}{n!}\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x}';\beta,\omega)=\frac{i^n\phi^n(\mathbf{x},\mathbf{x}')}{n!}G_L(\mathbf{x},\mathbf{x}';\beta,\omega)$$
$$+\sum_{k=1}^{n}\sum_{j=1}^{k}(-1)^j\int_{D_j(\beta)}d\tau\sum_{(i_1,\ldots,i_j)\in\{1,2\}^j}\chi_j^k(i_1,\ldots,i_j)$$
$$\times\int_{\Lambda^j}d\mathbf{y}\frac{(i(\sum_{l=1}^{j-1}\mathrm{fl}(\mathbf{x},\mathbf{y}_l,y_{l+1})+\mathrm{fl}(\mathbf{x},\mathbf{y}_j,\mathbf{x}')+\phi(\mathbf{x},\mathbf{x}')))^{n-k}}{(n-k)!}$$
$$\times G_L(\mathbf{x},\mathbf{y}_1,\beta-\tau_1,\omega)R_{i1,L}(\mathbf{y}_1,\mathbf{y}_2,\tau_1-\tau_2,\omega)\ldots R_{ij,L}(\mathbf{y}_j,\mathbf{x}',\tau_j,\omega). \tag{3.32}$$

Remark 3.4: *Let* $\beta>0$ *and* $\omega_0\geq 0$ *and* $\omega\in\mathbb{C}$. *From* (3.16) *we have* $\|W_L(\beta-\tau,\omega,\omega_0)\widetilde{R}_L(\tau,\omega,\omega_0)\|_1\leq\|W_L(\beta-\tau,\omega,\omega_0)\|_2\|\widetilde{R}_L(\tau,\omega,\omega_0)\|_2$

$$\leq\frac{C(\beta,\omega,\omega_0)L^3}{(\beta-\tau)^{3/4}\tau^{3/4}},$$

where $C(\beta,\omega,\omega_0)=\mathcal{C}_3(\beta,\omega_0)(|\delta\omega|+|(\delta\omega)|^2)$ *and* $\mathcal{C}_3(\beta,\omega_0)$ *is given in* (3.9) *Then the* B_1*-operator valued function* $\tau\in(0,\beta)\to W_L(\beta-\tau,\omega)\widetilde{R}_L(\tau,\omega,\omega_0)$ *is* B_1 *integrable. Denote by* $U_L(\beta,\omega,\omega_0)=\int_0^\beta W_L(\beta-\tau,\omega)\widetilde{R}_L(\tau,\omega,\omega_0)$,

$$\|U_L(\beta,\omega,\omega_0)\|_1\leq CL^3\int_0^\beta\frac{1}{(\beta-\tau)^{3/4}\tau^{3/4}}\leq\frac{16CL^3}{\sqrt{\beta}}. \tag{3.33}$$

The Duhamel-type formula (3.22) *then implies that* $\widetilde{W}_L(\beta,\omega)$ *is of trace class as a sum of the two trace class operators,* W_L *and* U_L. *Consequently, the operators* $\tilde{I}_{k,L}(i_1,\ldots,i_k)(\beta,\omega,\omega_0)$ *defined in* (3.17) *are of trace class because the integrals only involve* B_1*-integrable functions.*

IV. LARGE VOLUME BEHAVIOR

For further applications in Sec. IV, we need to have a similar result as in Theorem 3.1, but with $L=\infty$. The results of Sec. II cannot be applied to this situation. On the contrary, we will show in this section that Theorem 3.1 remains true even if we take $L=\infty$, and the quantities at finite volume converge pointwise to the ones defined on the whole space.

Recall first that the explicit form of the integral kernel of $e^{-\beta H_\infty(\omega)};\beta>0,\omega\geq 0$ is given by

$$G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)=\frac{1}{(2\pi\beta)^{3/2}}\frac{\omega\beta/2}{\sinh(\omega\beta/2)}e^{i\omega\phi(\mathbf{x},\mathbf{x}')}\times\exp\left\{-\frac{1}{2\beta}\left(\frac{\omega\beta/2}{\tanh(\omega\beta/2)}[(x_1-x_1')^2+(x_2-x_2')^2]+(x_3-x_3')^2\right)\right\},\tag{4.1}$$

where the phase ϕ is defined in (3.1).

We start with a technical result. For any $\mathbf{x}\in\Lambda_L$, we denote with $d(\mathbf{x}):=\mathrm{dist}(\mathbf{x},\partial\Lambda_L)$. Let $M:=\{(\mathbf{x},\mathbf{x}')\in\Lambda_L\times\Lambda_L: d(\mathbf{x})\leq 1 \text{ or } d(\mathbf{x}')\leq 1\}$, and denote with χ_M the characteristic function of M.

Theorem 4.1: *Let $\beta>0$ and $\omega\geq 0$. Then for any $(\mathbf{x},\mathbf{x}')\in\Lambda_L\times\Lambda_L$, we have*

$$|G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)|\leq 2\chi_M(\mathbf{x},\mathbf{x}')G_\infty(\mathbf{x},\mathbf{x}';\beta)+\mathcal{C}_4(1-\chi_M)\times(\mathbf{x},\mathbf{x}')G_\infty(\mathbf{x},\mathbf{x}';16\beta)e^{-(d^2(\mathbf{x})/64\beta+d^2(\mathbf{x}')/64\beta)},\tag{4.2}$$

and

$$|(-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(\mathbf{x}))[G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)]|\leq\frac{\mathcal{C}_5}{\sqrt{\beta}}\chi_M(\mathbf{x},\mathbf{x}')G_\infty(\mathbf{x},\mathbf{x}';8\beta)+\mathcal{C}_6(1-\chi_M)G_\infty(\mathbf{x},\mathbf{x}';16\beta)e^{-(d^2(\mathbf{x})/64\beta+d^2(\mathbf{x}')/64\beta)},\tag{4.3}$$

where $\mathcal{C}_4=\mathcal{C}_4(\beta,\omega)=c(1+\beta)^6(1+\omega)^4$, $\mathcal{C}_5=\mathcal{C}_5(\beta,\omega)=c(1+\beta)^5(1+\omega)^3$, $\mathcal{C}_6=\mathcal{C}_6(\beta,\omega)=c(1+\beta)^8(1+\omega)^5$, *and $c>1$ is a numerical constant.*

To prove the theorem, we need the following lemma.

Lemma 4.2: Let $\beta>0$, $\omega\geq 0$ and $\alpha\in\{0,1\}$. Then for every $(\mathbf{x},\mathbf{x}')\in\Lambda_L\times\Lambda_L$ we have

$$\partial_{x_i}^\alpha G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-\partial_{x_i}^\alpha G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)$$

$$\frac{1}{2}\int_0^\beta d\tau\int_{\partial\Lambda_L}d\sigma(\mathbf{y})\partial_{x_i}^\alpha G_\infty(\mathbf{x},\mathbf{y};\tau,\omega)[\mathbf{n}_{\mathbf{y}}\cdot\nabla_{\mathbf{y}}G_L(\mathbf{y},\mathbf{x}';\beta-\tau,\omega)],\tag{4.4}$$

where $d\sigma(\mathbf{y})$ is the measure on $\partial\Lambda_L$ and $\mathbf{n}_{\mathbf{y}}$ is the outer normal to $\partial\Lambda_L$ at $\mathbf{y}$.

Proof: Let $\beta>0$, $\omega\geq 0$. Recall that both Green's functions $G_\infty(\mathbf{x},\mathbf{x}';\tau,\omega)$ and $G_L(\mathbf{x},\mathbf{x}';\tau,\omega)$ satisfy in $\Lambda_L\times\Lambda_L$ in a distributional sense, the equation

$$\text{(i) } \partial_\tau G(\mathbf{x},\mathbf{x}';\tau)=-\frac{1}{2}[-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(\mathbf{x})]^2G(\mathbf{x},\mathbf{x}';\tau);\quad \tau>0,\tag{4.5}$$

$$\text{(ii) } G(\mathbf{x},\mathbf{x}';\tau=0_+)=\delta(\mathbf{x}-\mathbf{x}').\tag{4.6}$$

For $0<\tau<\beta$ and on $\Lambda_L\times\Lambda_L$, define the following quantity:

$$Q(\mathbf{x},\mathbf{x}';\beta,\tau):=\int_{\Lambda_L}d\mathbf{y}\,\overline{G_L(\mathbf{y},\mathbf{x};\beta-\tau,\omega)}G_\infty(\mathbf{y},\mathbf{x}';\tau,\omega).\tag{4.7}$$

Then by (4.5), it is easy to see that

$$\partial_\tau Q(\mathbf{x},\mathbf{x}';\beta,\tau)=\frac{1}{2}\int_{\Lambda_L} d\mathbf{y}\,\{\overline{(-i\nabla_{\mathbf{y}}-\omega\mathbf{a}(\mathbf{y}))^2 G_L(\mathbf{y},\mathbf{x};\beta-\tau,\omega)}G_\infty(\mathbf{y},\mathbf{x}';\tau,\omega)$$
$$-\overline{G_L(\mathbf{y},\mathbf{x};\beta-\tau,\omega)}(-i\nabla_{\mathbf{y}}-\omega\mathbf{a}(\mathbf{y}))^2 G_\infty(\mathbf{y},\mathbf{x}';\tau,\omega)\}. \tag{4.8}$$

Since $G_L(\mathbf{x},\mathbf{x}';\tau,\omega)=0$ if $\mathbf{x}\in\partial\Lambda_L$ or $\mathbf{x}'\in\partial\Lambda_L$, integration by parts gives

$$\partial_\tau Q(\mathbf{x},\mathbf{x}';\beta,\tau)=\frac{1}{2}\int_{\partial\Lambda_L} d\sigma(\mathbf{y})\overline{\mathbf{n}_{\mathbf{y}}\cdot\nabla_{\mathbf{y}}G_L(\mathbf{y},\mathbf{x};\beta-\tau,\omega)}G_\infty(\mathbf{y},\mathbf{x}';\tau,\omega). \tag{4.9}$$

Now, by integrating with respect to τ from 0_+ to β_-, and using (4.6), we obtain

$$G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)=\frac{1}{2}\int_0^\beta d\tau\int_{\partial\Lambda_L} d\sigma(\mathbf{y})\overline{\mathbf{n}_{\mathbf{y}}\cdot\nabla_{\mathbf{y}}G_L(\mathbf{y},\mathbf{x};\beta-\tau,\omega)}G_\infty(\mathbf{y},\mathbf{x}';\tau,\omega). \tag{4.10}$$

Now, using the self-adjointness property of the semigroup, we obtain $G(\mathbf{x},\mathbf{y};\tau)=\overline{G(\mathbf{y},\mathbf{x};\tau)}$; thus, we can rewrite (4.10) as

$$G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)=\frac{1}{2}\int_0^\beta d\tau\int_{\partial\Lambda_L} d\sigma(\mathbf{y})G_\infty(\mathbf{x},\mathbf{y};\tau,\omega)[\mathbf{n}_{\mathbf{y}}\cdot\nabla_{\mathbf{y}}G_L(\mathbf{y},\mathbf{x}';\beta-\tau,\omega)]. \tag{4.11}$$

The lemma now follows from (4.11). □

Proof of Theorem 4.1: Let $\beta>0$, $\omega\geq 0$, and suppose first that $(\mathbf{x},\mathbf{x}')\in M$. Then (4.2) follows from the diamagnetic inequality (2.30). Let us show (4.3) in the same case. We know from (2.31) that

$$|(-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(\mathbf{x}))G_L(\mathbf{x},\mathbf{x}';\beta,\omega)|\leq\frac{\mathcal{C}}{\sqrt{\beta}}G_\infty(\mathbf{x},\mathbf{x}';8\beta). \tag{4.12}$$

On the other hand, using the observation that $-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(\mathbf{x})$ is transformed into $-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(\mathbf{x}-\mathbf{x}')$ after commutation with $e^{i\phi(\mathbf{x},\mathbf{x}')}$; then, by direct computation from (4.1), we get that for all $\eta>0$,

$$|(-i\nabla\mathbf{x}-\omega\mathbf{a}(\mathbf{x}))G_\infty(\mathbf{x},\mathbf{x}';\eta\beta,\omega)|\leq\frac{\mathcal{C}_1'}{\sqrt{\eta\beta}}G_\infty(\mathbf{x},\mathbf{x}';2\eta\beta), \tag{4.13}$$

where $\mathcal{C}_1'=\mathcal{C}_1'(\beta,\omega)=2(1+\eta)(1+\omega)(1+\beta)$. Then (4.12) and (4.13) for $\eta=1$ imply (4.3).

Now suppose that $(\mathbf{x},\mathbf{x}')\notin M$. This means that neither points are near the boundary. For $\mathbf{y}\in\partial\Lambda$ then by (2.31), we have

$$|\nabla_{\mathbf{y}}G_L(\mathbf{y},\mathbf{x};\beta-\tau,\omega)|\leq\frac{\mathcal{C}_1}{\sqrt{\beta-\tau}}G_\infty(\mathbf{y},\mathbf{x},8(\beta-\tau)). \tag{4.14}$$

By applying the estimates (4.14), (2.30), and the Lemma 4.2, we get

$$|G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)|\leq 2^{7/2}\mathcal{C}_1\int_0^\beta d\tau\int_{\partial\Lambda_L} d\sigma(\mathbf{y})\frac{G_\infty(\mathbf{y},\mathbf{x};8(\beta-\tau))}{\sqrt{\beta-\tau}}G_\infty(\mathbf{y},\mathbf{x}';8\tau). \tag{4.15}$$

But if $\mathbf{y}\in\partial\Lambda_L$, $|\mathbf{x}-\mathbf{y}|\geq d(\mathbf{x})$, then a straightforward estimate shows that for $0<t<\beta$, we have $G_\infty(\mathbf{y},\mathbf{x};8t)\leq e^{-d^2(x)/32\beta}G_\infty(\mathbf{y},\mathbf{x};16t)$. Thus, we get the rhs of (4.15),

$$\leq 2^5 \mathcal{C}_1 \int_0^\beta d\tau \frac{e^{-(d^2(x)/32(\beta-\tau)+d^2(x')/32\tau)}}{\sqrt{\beta-\tau}} \int_{\partial\Lambda_L} d\sigma(\mathbf{y}) G_\infty(\mathbf{y},\mathbf{x};16(\beta-\tau)) G_\infty(\mathbf{y},\mathbf{x}';16\tau). \tag{4.16}$$

For any t, $t'>0$, let us look at the integral

$$\int_{\partial\Lambda_L} d\sigma(\mathbf{y}) G_\infty(\mathbf{y},\mathbf{x};t) G_\infty(\mathbf{y},\mathbf{x}';t'). \tag{4.17}$$

Using the convexity of Λ_L, replacing the integrals on the sides of $\partial\Lambda_L$ by integrals on $\mathbb{R}^2$ (thus getting an upper bound), and using the semigroup property in two dimensions, we can show that there exists a numerical constant $C>0$, such that

$$\int_{\partial\Lambda_L} d\sigma(\mathbf{y}) G_\infty(\mathbf{y},\mathbf{x};t) G_\infty(\mathbf{y},\mathbf{x}';t') \leq C \frac{\sqrt{t+t'}}{\sqrt{t}\sqrt{t'}} G_\infty(\mathbf{x},\mathbf{x}';t+t'). \tag{4.18}$$

To be more precise, let us look at the integral on the hyperplane defined by $H := \mathbb{R}^2 + (L/2,0,0)$:

$$\int_H d\sigma(\mathbf{y}) G_\infty(\mathbf{y},\mathbf{x};t) G_\infty(\mathbf{y},\mathbf{x}';t'), \tag{4.19}$$

where $\mathbf{x}$ and $\mathbf{x}'$ are on the same side of $\mathbb{R}^3$ with respect to H. Decompose $\mathbf{x}=\mathbf{x}_1+\mathbf{x}_2$ and $\mathbf{x}'=\mathbf{x}_1'+\mathbf{x}_2'$, where $\mathbf{x}_1$ and $\mathbf{x}_1'$ are the parallel components with H, while $\mathbf{x}_2$ and $\mathbf{x}_2'$ are the orthogonal components on H. Note that here $|\mathbf{x}_2|^2+|\mathbf{x}_2'|^2 \geq |\mathbf{x}_2-\mathbf{x}_2'|^2$. Since $|\mathbf{x}-\mathbf{y}|^2=|\mathbf{x}_1-\mathbf{y}|^2+|\mathbf{x}_2|^2$ if $\mathbf{y}\in H$, we can explicitly integrate with respect to $\mathbf{y}$ and eventually get (4.18).

Then we can write

$$\int_{\partial\Lambda_L} d\sigma(\mathbf{y}) G_\infty(\mathbf{y},\mathbf{x};16(\beta-\tau)) G_\infty(\mathbf{y},\mathbf{x}';16\tau) \leq \mathcal{C}_1' \frac{\sqrt{\beta}}{\sqrt{(\beta-\tau)\tau}} G_\infty(\mathbf{x},\mathbf{x}';16\beta).$$

Therefore, since $\mathbf{x},\mathbf{x}'$ satisfy $d(\mathbf{x})$, $d(\mathbf{x}')\geq 1$, we get

$$\begin{aligned} |G_L(\mathbf{x},\mathbf{x}';\beta,\omega) - G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)| &\leq 2^4 \mathcal{C}_1 \mathcal{C}_1' G_\infty(\mathbf{x},\mathbf{x}';16\beta) e^{-(d^2(\mathbf{x})/64\beta + d^2(\mathbf{x}')/64\beta)} \\ &\quad \times \int_0^\beta d\tau \frac{e^{-(1/64(\beta-\tau)+1/64\tau)}}{\sqrt{\beta-\tau}} \frac{\sqrt{\beta}}{\sqrt{(\beta-\tau)\tau}}. \end{aligned} \tag{4.20}$$

Due the exponential decay, there are no singularities in this integral, and a straightforward estimate gives (4.2).

We now use the same method as above to prove (4.3) in the case when $(\mathbf{x},\mathbf{x}') \notin M$. We know from Lemma 4.2 that

$$\begin{aligned} &(-i\nabla_{\mathbf{x}} - \omega\mathbf{a}(x))(G_L(\mathbf{x},\mathbf{x}';\beta,\omega) - G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)) \\ &\quad = \frac{1}{2}\int_0^\beta d\tau \int_{\partial\Lambda_L} d\sigma(\mathbf{y}) \cdot (-i\nabla_{\mathbf{x}} - \omega\mathbf{a}(x)) G_\infty(\mathbf{x},\mathbf{y};\tau,\omega)[\mathbf{n}_{\mathbf{y}} \cdot \nabla_{\mathbf{y}} G_L(\mathbf{y},\mathbf{x}';\beta-\tau,\omega)]. \end{aligned} \tag{4.21}$$

Then by (4.12) and (4.13),

$$\begin{aligned}&\left|(-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(x))(G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta\omega))\right|\\&\quad\le 4\mathcal{C}_1\mathcal{C}_1'\int_0^\beta d\tau\int_{\partial\Lambda_L}d\sigma(\mathbf{y})\frac{G_\infty(\mathbf{y},\mathbf{x};8(\beta-\tau))}{\sqrt{\beta-\tau}}\frac{G_\infty(\mathbf{y},\mathbf{x}';8\tau)}{\sqrt{\tau}}.\end{aligned}\tag{4.22}$$

Then, by using the same arguments leading to (4.20), we get

$$\begin{aligned}&\left|(-i\nabla_{\mathbf{x}}-\omega\mathbf{a}(x))(G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta\omega))\right|\\&\quad\le 16\sqrt{\beta}\mathcal{C}_1\mathcal{C}_1'^2G_\infty(\mathbf{x},\mathbf{x}';16\beta)e^{-(d^2(x)/64\beta+d^2(x')/64\beta)}\int_0^\beta d\tau\frac{e^{-(1/64(\beta-\tau)+1/64\tau)}}{\tau(\beta-\tau)},\end{aligned}\tag{4.23}$$

from which (4.3) follows. Theorem 4.1 is proved.

We now want to prove that the equality (3.12) stated in Theorem 3.1 remains true, even if L tends to infinity. It is well known (see, e.g., Angelescu and Corciovei (1975)) that for $\beta>0,\omega\ge 0$ and $(\mathbf{x},\mathbf{x}')\in\mathbb{R}^3\times\mathbb{R}^3$,

$$G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)=\lim_{L\to\infty}G_L(\mathbf{x},\mathbf{x}';\beta,\omega).\tag{4.24}$$

Our main goal now is to show that this pointwise convergence holds true for all the derivatives $\partial^n G_L/\partial\omega^n, n\ge 1$.

We need to introduce some notation. Let $\beta>0$ and $\omega\ge 0$. For $(\mathbf{x},\mathbf{x}')\in\mathbb{R}^3\times\mathbb{R}^3$, define

$$R_{1,\infty}(\mathbf{x},\mathbf{x}';\beta,\omega):=\mathbf{a}(\mathbf{x}-\mathbf{x}')\cdot(i\nabla_{\mathbf{x}}+\omega\mathbf{a}(\mathbf{x}))G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega),$$

$$R_{2,\infty}(\mathbf{x},\mathbf{x}';\beta,\omega):=\frac{1}{2}\mathbf{a}^2(\mathbf{x}-\mathbf{x}')G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega).\tag{4.25}$$

Let us note that we again have the same type of estimates as in (3.7), (3.8), and (3.9), i.e., Gaussian localization in the difference of the spatial arguments. The linear growth of the magnetic potential disappears when one commutes $-i\nabla_{\mathbf{x}}$ with the magnetic phase, as we have already seen in (4.13).

Now define for $\mathbf{x}\in\mathbb{R}^3$, $k\ge 1, m\ge 0$:

$$\begin{aligned}W_{k,\infty}^m(\mathbf{x};\beta,\omega):=&\sum_{j=1}^k(-1)^j\sum_{(i_1,\ldots,i_j)\in\{1,2\}^j}\chi_j^k(i_1,\ldots,i_j)\int_{D_j(\beta)}d\tau\int_{\mathbb{R}^{3j}}d\mathbf{y}\\&\times\frac{(i(\mathrm{Fl}_j(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j)))^m}{m!}G_\infty(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega)R_{i_1,\infty}(\mathbf{y}_1,\mathbf{y}_2;\tau_1-\tau_2,\omega)\ldots R_{i_{j-1},\infty}\\&\times(\mathbf{y}_{j-1},\mathbf{y}_k;\tau_{j-1}-\tau_j,\omega)R_{i_j,\infty}(\mathbf{y}_j,\mathbf{x};\tau_j,\omega).\end{aligned}\tag{4.26}$$

Since every integrand is bounded by a free heat kernel and because the flux Fl_j can be bound by *differences* of its arguments [see (3.5)], then the above multiple integrals are absolutely convergent. Also note the important thing that multiplication by $|\mathbf{y}-\mathbf{y}'|^m$ of the free heat kernel only improves the singularity in the time variable due to the estimate

$$|\mathbf{y}-\mathbf{y}'|^m\mathbf{e}^{-|\mathbf{y}-\mathbf{y}'|^2/t}\le\mathrm{const}\cdot t^{m/2}\mathbf{e}^{-|\mathbf{y}-\mathbf{y}'|^2/(2t)}.\tag{4.27}$$

The last important remark about $W_{k,\infty}^m(\mathbf{x};\beta,\omega)$ is that *it does not depend on* $\mathbf{x}$. This can be seen by factorizing all the magnetic phases that enter in the various factors of the integrand, and see that they add up to give another Fl_j, which only depends on differences of variables. The remaining factors are also just functions of differences of variables. Therefore by changing $\mathbf{x}$ we get the same value for $W_{k;\infty}^m$ after a change of variables (a translation) in all integrals, since $W_{k,\infty}^m$ only involves integrals defined on the whole space.

Then we have the following.

Theorem 4.3: *Let* $\beta>0$ *and* $\omega\geq 0$. *Fix* $\mathbf{x}\in\mathbb{R}^3$ *and* $n\geq 1$. *Then we have*

$$\frac{1}{n!}\frac{\partial^n G_\infty}{\partial\omega^n}(\mathbf{x},\mathbf{x};\beta,\omega)=\lim_{L\to\infty}\frac{1}{n!}\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x};\beta,\omega)=\sum_{k=1}^{n}W_{k,\infty}^{n-k}(\mathbf{x};\beta,\omega). \tag{4.28}$$

Proof: Fix $\beta>0$ and $\omega\geq 0$. Let $n\geq 1$ and $(\mathbf{x},\mathbf{x}')\in\mathbb{R}^3$. Choose L large enough such that $\mathbf{x}\in\Lambda_L$. Then from (4.2) and (4.3), we have

$$\left|G_L(\mathbf{x},\mathbf{x}';\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x}';\beta,\omega)\right|\leq \mathcal{C}_4\beta^{-3/2}e^{-(d^2(\mathbf{x})/64\beta+d^2(\mathbf{x}')/64\beta)},$$

$$\left|R_{1,L}(\mathbf{x},\mathbf{x}';\beta,\omega)-R_{1,\infty}(\mathbf{x},\mathbf{x}';\beta,\omega)\right|\leq \mathcal{C}_6\beta^{-1}e^{-(d^2(\mathbf{x})/64\beta+d^2(\mathbf{x}')/64\beta)},$$

$$\left|R_{2,L}(\mathbf{x},\mathbf{x}';\beta,\omega)-R_{2,\infty}(\mathbf{x},\mathbf{x}';\beta,\omega)\right|\leq \mathcal{C}_4\beta^{-1/2}e^{-(d^2(\mathbf{x})/64\beta+d^2(\mathbf{x}')/64\beta)}, \tag{4.29}$$

Then, for all $(\mathbf{x},\mathbf{x}')\in\mathbb{R}^3\times\mathbb{R}^3$, estimates (4.29) show, respectively, that

$$\lim_{L\to\infty}G_L(\mathbf{x},\mathbf{x}',\beta,\omega)=G_\infty(\mathbf{x},\mathbf{x}',\beta,\omega),$$

$$\lim_{L\to\infty}R_{i,L}(\mathbf{x},\mathbf{x}',\beta,\omega)=R_{i,\infty}(\mathbf{x},\mathbf{x}',\beta,\omega),$$

for $i=1,2$. Then

$$\begin{aligned}&\lim_{L\to\infty}G_L(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega)R_{i_1,L}(\mathbf{y}_1,\mathbf{y}_2;\tau_1-\tau_2,\omega)\ldots R_{i_j,L}(\mathbf{y}_j,\mathbf{x};\tau_j,\omega)\\&\quad=G_\infty(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega)R_{i_1,\infty}(\mathbf{y}_1,\mathbf{y}_2;\tau_1-\tau_2,\omega)\ldots R_{i_j,L}(\mathbf{y}_j,\mathbf{x};\tau_j,\omega).\end{aligned}$$

Furthermore, by (3.9) and (2.30), we have

$$\begin{aligned}&\left|G_L(\mathbf{x},\mathbf{y}_1;\beta-\tau_1,\omega)R_{i_1,L}(\mathbf{y}_1,\mathbf{y}_2;\tau_1-\tau_2,\omega)\ldots R_{i_j,L}(\mathbf{y}_j,\mathbf{x};\tau_j,\omega)\right|\\&\quad\leq 4^3C_3^jG_\infty(\mathbf{x},\mathbf{y}_1;16(\beta-\tau_1))G_\infty(\mathbf{y}_1,\mathbf{y}_2;16(\tau_1-\tau_2))\ldots G_\infty(\mathbf{y}_j,\mathbf{x};16\tau_j),\end{aligned}$$

this last quantity is L independent and $\mathbb{R}^3$ integrable by the semigroup property since

$$\int_{\mathbb{R}^{3j}}d\mathbf{y}\;G_\infty(\mathbf{x},\mathbf{y}_1;16(\beta-\tau_1))\ldots G_\infty(\mathbf{y}_j,\mathbf{x};16\tau_j)=G_\infty(\mathbf{x},\mathbf{y}_1;16\beta).$$

Note that the flux Fl_j does not influence anything, since it can be bound by powers of differences between spatial variables, which will meet the Gaussian decay of the free heat kernels. Thus, they will only affect the time integrals (by making them even less singular).

Then, by applying Lebesgue's dominated convergence theorem, we get from (3.11) and (3.12),

$$\lim_{L\to\infty}\frac{1}{n!}\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x},\beta,\omega)=\sum_{k=1}^{n}W_{k,\infty}^{n-k}(\mathbf{x};\beta,\omega). \tag{4.30}$$

Now the remaining thing is to show that this also equals $(1/n!)\,(\partial^n G_\infty/\partial\omega^n)\,(\mathbf{x},\mathbf{x},\beta,\omega)$. Fix $\omega_0\geq 0$ and choose $\omega\in\mathbb{R}$ such that $|\delta\omega|=|\omega-\omega_0|\leq 1$. From the usual Taylor formula, we can write

$$G_L(\mathbf{x},\mathbf{x},\beta,\omega)=\sum_{n=0}^{N}(\delta\omega)^n\frac{1}{n!}\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x},\beta,\omega_0)+(\delta\omega)^{N+1}\frac{1}{(N+1)!}\frac{\partial^{N+1}G_L}{\partial\omega^{N+1}}(\mathbf{x},\mathbf{x},\beta,\omega_1), \tag{4.31}$$

where ω_1 is between ω_0 and ω. Then by taking L to infinity, we easily get the estimate [note that $\Sigma_{k=1}^{N+1}W_{k,L}^{N+1-k}(\mathbf{x};\beta,\omega_1)$ is bounded by a constant independent of L; see the estimate from (3.13)]:

$$\left|G_\infty(\mathbf{x},\mathbf{x},\beta,\omega)-G_\infty(\mathbf{x},\mathbf{x},\beta,\omega_0)-\sum_{n=1}^{N}(\delta\omega)^n\sum_{k=1}^{n}W_{k,\infty}^{n-k}(\mathbf{x};\beta,\omega_0)\right|\le C(N,\beta)|\delta\omega|^{N+1}. \tag{4.32}$$

Since $G_\infty(\mathbf{x},\mathbf{x};\beta,\omega)$ is smooth in ω [see (1.7)], it follows that the coefficient of $(\delta\omega)^n$ must equal $(1/n!)\ (\partial^n G_\infty/\partial\omega^n)(\mathbf{x},\mathbf{x},\beta,\omega_0)$ and we are done. □

V. THERMODYNAMIC LIMIT FOR MAGNETIC SUSCEPTIBILITIES

As a consequence of the analysis of the previous section we are now able to prove the main technical result of this paper.

Theorem 5.1: *Let* $n\ge 1$, $\beta>0$, *and* $w>0$,

$$\int_{\Lambda_L}d\mathbf{x}\left|\frac{\partial^n G_\infty}{\partial\omega^n}(\mathbf{x},\mathbf{x};\beta,\omega)-\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x};\beta,\omega)\right|\le L^2\mathcal{C}(n,\beta,\omega), \tag{5.1}$$

where $\mathcal{C}(n,\beta,\omega):=c(n)[(1+\beta)^{7n+8}/\sqrt{\beta}](1+\omega)^{3n+5}$, *where* $c(n)$ *only depends on* n.

Proof: Let $1\le j\le k$, $1\le k\le n$, $1\le m\le n-k$, and denote the integrand in (4.26) with:

$$\begin{aligned}F_{j,\infty}^m&=F_{j,\infty}^m(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j,\tau_1,\ldots,\tau_j,\beta,\omega)\\&=\frac{(i\mathrm{Fl}_j(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j))^m}{m!}G_\infty(\mathbf{x},\mathbf{y}_1,\beta-\tau_1,\omega)\ldots R_{i_j,\infty}(\mathbf{y}_j,\mathbf{x},\tau_j,\omega).\end{aligned} \tag{5.2}$$

Denote also by

$$F_{j,L}^m=F_{j,L}^m(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j,\tau_1,\ldots,\tau_j,\beta,\omega)=\frac{(i\ \mathrm{Fl}_j(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j))^m}{m!}G_L(\mathbf{x},\mathbf{y}_1,\beta-\tau_1,\omega)\ldots R_{i_j,L}(\mathbf{y}_j,\mathbf{x},\tau_j,\omega). \tag{5.3}$$

Let $n\ge 1$, $\beta\ge 0$, $\omega\ge 0$, and fix $\mathbf{x}\in\mathbb{R}^3$. Then by applying the Theorem 4.3, we can split the integrals from W's in "inner" and "outer" regions:

$$\frac{\partial^n G_\infty}{\partial\omega^n}(\mathbf{x},\mathbf{x},\beta,\omega)=f_L^n(\mathbf{x},\beta,\omega)+g_L^n(\mathbf{x},\beta,\omega), \tag{5.4}$$

where

$$f_L^n(\mathbf{x},\beta,\omega):=n!\sum_{k=1}^{n}\sum_{j=1}^{k}(-1)^j\sum_{(i_1,\ldots,i_j)\in\{1,2\}^j}\chi_j^k(i_1,\ldots,i_j)\int_{D_j(\beta)}d\tau\int_{\Lambda_L^j}d\mathbf{y}$$

$$F_{j,\infty}^{n-k}(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j,\tau_1,\ldots,\tau_j,\beta,\omega), \tag{5.5}$$

$$g_L^n(\mathbf{x},\beta,\omega) := n!\sum_{k=1}^{n}\sum_{j=1}^{k}(-1)^j \sum_{(i_1,\ldots,i_j)\in\{1,2\}^j} \chi_j^k(i_1,\ldots,i_j)\sum_{l=1}^{j}\int_{D_j(\beta)} d\tau \int_{\mathbb{R}^3} d\mathbf{y}_1 \cdots \int_{\mathbb{R}^3\setminus\Lambda_L} \times d\mathbf{y}_l \int_{\mathbb{R}^3} d\mathbf{y}_{l+1}\cdots\int_{\mathbb{R}^3} d\mathbf{y}_j F_{j,\infty}^{n-k}(\mathbf{x},\mathbf{y}_1,\ldots,\mathbf{y}_j,\tau_1,\ldots,\tau_j,\beta,\omega). \tag{5.6}$$

Let us now show that

$$\int_\Lambda d\mathbf{x}\left| f_L^n(\mathbf{x},\beta,\omega) - \frac{\partial^n G_L}{\partial\omega^n}(\mathbf{x},\mathbf{x};\beta,\omega)\right| \le L^2 f(n,\beta,\omega), \tag{5.7}$$

where $f(n,\beta,\omega) := c(n)[(1+\beta)^{7n+3}/\sqrt{\beta}](1+\omega)^{3n+2}$, $c(n)$ depending only on n.

From now, for the sake of simplicity we often omit the explicit dependence of all variables. In view of (3.11), (3.12), (4.26), and (4.28), we need to estimate

$$F_{j,\infty}^m - F_{j,L}^m = \frac{(i\mathrm{Fl}_j)^m}{m!}\left\{(G_\infty - G_L)R_{i_1,\infty}\ldots R_{i_j,\infty} + \sum_{l=1}^{j} G_L R_{i_1,L}\ldots R_{i_{l-1},L}(R_{i_l,\infty} - R_{i_l,L})R_{i_{l+1},\infty}\ldots R_{i_j,\infty}\right\}. \tag{5.8}$$

Denote by $\chi(\mathbf{x})$ the characteristic of $\{\mathbf{x}\in\Lambda, d(\mathbf{x})\le 1\}$. Thanks to the Theorem 4.1, we have

$$\begin{aligned}|(R_{1,\infty} - R_{1,L})(\mathbf{x},\mathbf{x}';\beta,\omega)| &\le |\mathbf{a}(\mathbf{x}-\mathbf{x}')(i\nabla_{\mathbf{x}} + \omega\mathbf{a})(G_\infty - G_L)(\mathbf{x},\mathbf{x}';\beta,\omega)| \\ &\le \mathcal{C}_7 G_\infty(\mathbf{x},\mathbf{x}';32\beta)(\chi(\mathbf{x}) + \chi(\mathbf{x}') + e^{-(d^2(x)/64\beta + d^2(x')/64\beta)}),\end{aligned} \tag{5.9}$$

where $\mathcal{C}_7 = \mathcal{C}_7(\beta,\omega) = c(1+\beta)^9(1+\omega)^5$ for some numerical constant $c>1$. But again by Theorem 4.1, we may use the bound

$$\begin{aligned}|(G_\infty - G_L)(\mathbf{x},\mathbf{x}';\beta,\omega)|, |(R_{2,\infty} - R_{2,L})(\mathbf{x},\mathbf{x}';\beta,\omega)| &\le \mathcal{C}_7 G_\infty(\mathbf{x},\mathbf{x}';32\beta)(\chi(\mathbf{x}) + \chi(\mathbf{x}') \\ &\quad + e^{-(d^2(\mathbf{x})/64\beta + d^2(\mathbf{x}')/64\beta)}).\end{aligned} \tag{5.10}$$

On the other hand, by (3.9), (4.13), and (4.25), the kernel of $R_{i,\infty}$, $i=1,2$ and of $R_{i,L}$, $i=1,2$ satisfy the inequality

$$\max\{|(R_{i,\infty}(\mathbf{x},\mathbf{x}';\beta,\omega)|, |R_{i,L}(\mathbf{x},\mathbf{x}';\beta,\omega)|\} \le \mathcal{C}_3' G_\infty(\mathbf{x},\mathbf{x}';16\beta), \tag{5.11}$$

where $\mathcal{C}_3' = \mathcal{C}_3'\beta,\omega) = c\cdot\mathcal{C}_1$, $\mathcal{C}_1$ is defined in (2.37), and $c>1$ is a numerical constant that is chosen large enough such that we have $G_\infty(\mathbf{x},\mathbf{x}';\beta) \le \mathcal{C}_3' G_\infty(\mathbf{x},\mathbf{x}';16\beta)$.

Set $\mathbf{y}_0 := \mathbf{x}$. Then (2.30), (5.11), together with (5.9) and (5.10), give

$$|F_{j,\infty}^m - F_{j,L}^m| \le \mathcal{C}_7\mathcal{C}_3'^{j-1}\frac{|\mathrm{Fl}_j|^m}{m!} G_\infty(\mathbf{y}_0,\mathbf{y}_1;32(\beta-\tau_1))\cdots G_\infty(\mathbf{y}_j,\mathbf{y}_0;32\tau_j)\sum_{l=0}^{j}(2\chi(\mathbf{x}_l) + e^{-d^2(x_l)/64\beta}). \tag{5.12}$$

Thus, from this inequality and (3.5), we need to estimate the quantity

$$Q := \left(\sum_{l=1}^{j-1}\sum_{l'=1}^{l}|\mathbf{y}_{l'-1} - \mathbf{y}_{l'}||\mathbf{y}_l - \mathbf{y}_{l+1}|\right)^m G_\infty(\mathbf{y}_0,\mathbf{y}_1;32(\beta-\tau_1))\ldots G_\infty(\mathbf{y}_j,\mathbf{y}_0;32\tau_j).$$

By using (4.27), we have

$$Q \le (8\beta j^2)^m m^m 2^{3(j+1)/2} G_\infty(\mathbf{y}_0;\mathbf{y}_1;64(\beta-\tau_1))\cdots, G_\infty(\mathbf{y}_j,\mathbf{y}_0;64\tau_j),$$

and then for $j\le n$,

$$|F^m_{j,\infty} - F^m_{j,L}| \leq 2^{3(n+1)/2}\mathcal{C}_7\mathcal{C}_3'^{n-1}\frac{(8\beta j^2)^m m^m}{m!}G_\infty(\mathbf{y}_0,\mathbf{y}_1;64(\beta-\tau_1))\cdots G_\infty(\mathbf{y}_j,\mathbf{y}_0;64\tau_j)$$
$$\times\sum_{l=0}^{j}(2\chi(\mathbf{x}_l)+e^{-d^2(x_l)/64\beta}). \tag{5.13}$$

By extending the integration with respect to $\mathbf{y}_0,\ldots\mathbf{y}_{l-1},\mathbf{y}_{l+1}\ldots\mathbf{y}_j$ on the whole $\mathbb{R}^3$ space, and using the semigroup property (2.40) and the fact that $G_\infty(\mathbf{x},\mathbf{x};t)=1/(2\pi t)^{3/2}$, we get

$$\left|\int_{\Lambda_L^{j+1}} d\mathbf{y}(F^{n-k}_{j,\infty}-F^{n-k}_{j,L})\right| \leq c^n\mathcal{C}_7\mathcal{C}_3'^{n-1}(j+1)\frac{(\beta_j^2)^{(n-k)}(n-k)^{n-k}}{\beta^{3/2}(n-k)!}\int_{\Lambda_L} d\mathbf{x}(2\chi(\mathbf{x})+e^{-d^2(x)/64\beta}), \tag{5.14}$$

for some positive constant c. Moreover, simple estimates show that

$$\int_{\Lambda_L} d\mathbf{x}(2\chi(\mathbf{x})+e^{-d^2(\mathbf{x})/64\beta}) \leq cL^2(1+\sqrt{\beta}),$$

where c is also some positive numerical constant. From (5.5) and Theorem 3.1,

$$\int_{\Lambda_L} d\mathbf{y}_0\left\{\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{y}_0,\mathbf{y}_0;\beta,\omega)-f_L^n(\mathbf{y}_0,\beta,\omega)\right\} = n!\sum_{k=1}^{n}\sum_{j=1}^{k}(-1)^j\sum_{(i_1,\ldots,i_j)\in\{1,2\}j}\chi_j^k(i_1,\ldots,i_j)\int_{D_j(\beta)}d\tau$$
$$\times\int_{\Lambda^{j+1}} d\mathbf{y}(F^{n-k}_{j,\infty}-F^{n-k}_{j,L})(\mathbf{y}_0,\mathbf{y}_1,\ldots,\mathbf{y}_j,\tau_1,\ldots,\tau_j,\beta,\omega). \tag{5.15}$$

Then (5.14), together with (5.15), lead to

$$\left|\int_{\Lambda_L} d\mathbf{y}_0\left(\frac{\partial^n G_L}{\partial\omega^n}(\mathbf{y}_0,\mathbf{x};\beta,\omega)-f_L^n(\mathbf{y}_0,\beta,\omega)\right)\right| \leq L^2c(n)\frac{(1+\beta)^{7n+3}}{\sqrt{\beta}}(1+\omega)^{3n+2},$$

where $c(n)=(n+1)!\,c^n\Sigma_{k=1}^n\,[(n-k)^{n-k}/(n-k)!\,]\,\Sigma_{j=1}^k\,[j^{2(n-k)}/j!\,]$ and c is again a numerical factor. This last estimate clearly implies (5.7).

Let us now prove that for all $\beta>0$ and $\omega\geq 0$, $g_L^n(\mathbf{y}_0,\beta,\omega)$ given in (5.6) satisfies

$$\left|\int_{\Lambda_L} d\mathbf{y}_0\, g_L^n(\mathbf{y}_0,\beta,\omega)\right| \leq L^2 g(n,\beta,\omega), \tag{5.16}$$

where $g(n,\beta,\omega):=c(n)(1+\beta)^{7n+2}(1+\omega)^{3n+2}$ and $c(n)$ is a positive constant depending only on n. The same arguments as above leading to the estimate (5.13) imply

$$|F^m_{j,\infty}(\mathbf{y}_0,\ldots,\mathbf{y}_j,\tau_1,\ldots,\tau_j,\beta,\omega)| \leq \mathcal{C}_7\mathcal{C}_3'^{j-1}\frac{|\mathrm{Fl}_j|^m}{m!}G_\infty(\mathbf{y}_0,\mathbf{y}_1;32(\beta-\tau_1))\cdots G_\infty(\mathbf{y}_j,\mathbf{y}_0;32\tau_j)$$
$$\leq \mathcal{C}_7\mathcal{C}_3'^{j-1}\frac{(8\beta j^2)^m m^m 2^{3(j+1)/2}}{m!}$$
$$\times G_\infty(\mathbf{y}_0,\mathbf{y}_1;64(\beta-\tau_1))\cdots G_\infty(\mathbf{y}_j,\mathbf{y}_0;64\tau_j). \tag{5.17}$$

On the other hand, by the semigroup property (put $\Lambda_L^c:=\mathbb{R}^3\backslash\Lambda_L$),

$$\int_{\mathbb{R}^3} d\mathbf{y}_1 \dots \int_{\Lambda_L^c} d\mathbf{y}_l \int_{\mathbb{R}^3} d\mathbf{y}_{l+1\dots} \int_{\mathbb{R}^3} d\mathbf{y}_j \, G_\infty(\mathbf{y}_0,\mathbf{y}_1;64(\beta-\tau_1)) \cdots G_\infty(\mathbf{y}_j,\mathbf{y}_0;64\tau_j)$$

$$= \int_{\Lambda_L^c} d\mathbf{y}_l \, G_\infty(\mathbf{y}_0,\mathbf{y}_l;64(\beta-\tau_1)) G_\infty(\mathbf{y}_l,\mathbf{y}_0;64_{\tau l}). \tag{5.18}$$

Then (5.6), (5.17), and (5.18) imply

$$\left| \int_{\Lambda_L} d\mathbf{y}_0 \, g_L^n(\mathbf{y}_0,\beta,\omega) \right| \leq n! \sum_{k=1}^{n} \sum_{j=1}^{k} \mathcal{C}_7 \mathcal{C}_3'^{j-1} 2^{(5j+3)/2} \frac{(8\beta j^2)^{(n-k)}(n-k)^{n-k}}{(n-k)!}$$

$$\times \int_{D_j(\beta)} d\tau \sum_{l=1}^{j} \int_{\Lambda_L} d\mathbf{y}_0 \int_{\Lambda_L^c} d\mathbf{y}_l \, G_\infty(\mathbf{y}_0,\mathbf{y}_l;64(\beta-\tau_l)) G_\infty(\mathbf{y}_l,\mathbf{y}_0;64\tau_l). \tag{5.19}$$

By using the explicit form of the heat kernel given in (2.29), a straightforward computation shows that

$$\int_{\Lambda_L} d\mathbf{y}_0 \int_{\Lambda_L^c} d\mathbf{y}_l \, G_\infty(\mathbf{y}_0,\mathbf{y}_l;64(\beta-\tau_l)) G_\infty(\mathbf{y}_l,\mathbf{y}_0;64\tau_l) \leq c\frac{L^2}{\beta},$$

for some positive constant c. Hence, we get

$$\left| \int_{\Lambda} d\mathbf{y}_0 \, g_L^n(\mathbf{y}_0,\beta,\omega) \right| \leq L^2 c(n)(1+\beta)^{7n+2}(1+\omega)^{3n+2},$$

where $c(n)=n!\,c^n\Sigma_{k=1}^n\Sigma_{j=1}^k[j^{2(n-k)}(n-k)^{n-k}/(n-k)!\,(j-1)!]$ and c is a positive numerical factor. This shows (5.16). Then (5.16) and (5.7) imply the theorem. □

The proof of Theorem 1.2

We are now ready to prove the thermodynamic limit of generalized susceptibilities in the grand-canonical ensemble, when the chemical potential is negative (fugacity z less than one).

Let $L\geq 1$, $\beta>0$, $\omega\geq 0$ and $|z|<1$. We know from (1.8) and (2.27) that

$$P_L(\beta,\omega,z,\epsilon) - P_\infty(\beta,\omega,z,\epsilon) = \frac{\epsilon}{\beta|\Lambda_L|} \sum_{k\geq 1} \frac{(-\epsilon z)^k}{k} \int_{\Lambda_L} d\mathbf{x}\{G_L(\mathbf{x},\mathbf{x};k\beta,\omega) - G_\infty(\mathbf{x},\mathbf{x};k\beta,\omega)\}. \tag{5.20}$$

Then by applying the Theorem 5.1 we get

$$\frac{\partial^n(P_L-P_\infty)}{\partial\omega^n} = \frac{\epsilon}{\beta|\Lambda_L|} \sum_{k\geq 1} \frac{(-\epsilon z)^k}{k} \int_{\Lambda_L} d\mathbf{x} \left(\frac{\partial^n G_L}{\partial\omega^n} - \frac{\partial^n G_\infty}{\partial\omega^n} \right)(\mathbf{x},\mathbf{x};k\beta,\omega).$$

In particular, this also shows that the series from (1.10) must converge. Moreover, by using again the bound (5.1) in the last formula, we have

$$|\chi_L^{(n)} - \chi_\infty^{(n)}| \leq c(n)(1+\omega)^{3n+5} \frac{1}{\beta L} \sum_{k\geq 1} \frac{|z|^k}{k} \frac{(1+k\beta)^{7n+8}}{\sqrt{k\beta}}.$$

Since the series on the rhs of this last inequality is finite and L independent, this proves (1.11).□

(Received 28 March 2006; accepted 2 June 2006; published online 23 August 2006)

A scheme for solving Whitham hierarchies satisfying a special class of string equations is presented. The τ-function of the corresponding solutions is obtained and the differential expressions of the underlying Virasoro constraints are characterized. Illustrative examples of exact solutions of Whitham hierarchies are derived and applications to conformal maps dynamics are indicated. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2218982]

I. INTRODUCTION

Nonlinear integrable models of dispersionless type[1–4] arise in several branches of physics and applied mathematics. They have gained prominence after the discovery of their relevance in the formalism of quantum topological fields,[5,6] and of their role in the theory of deformations of conformal and quasiconformal maps on the complex plane.[7–9] Recently, new applications have been found[10–16] which include dynamics of conformal maps, growth processes of Laplacian type and large N limits of random matrix partition functions.

From the point of view of the theory of integrable systems, these models turn to be furnished by members of the so called *universal Whitham hierarchies* introduced by Krichever in Refs. 4 and 5. A particularly important example of these hierarchies is the dispersionless Toda (dToda) hierarchy.[10–13,17,18] The solutions of dispersionless integrable models underlying many of their applications satisfy special systems of constraints called *string equations*, which posses attractive mathematical properties and interesting physical meaning. Takasaki and Takebe[19–22] showed the relevance of string equations for studying the dispersionless Kadomtsev-Petviashvilii (KP) and Toda hierarchies and, in particular, for characterizing their associated symmetry groups. Nevertheless, although some schemes for solving string equations in the dispersionless KP and Toda hierarchies were provided in Refs. 23–25, general efficient methods of solution for string equations are still lacking.

In a recent work[26] a general formalism of Whitham hierarchies based on a factorization problem on a Lie group of canonical transformations has been proposed. It leads to a natural formulation of string equations in terms of dressing transformations. The present article is concerned with the analysis of these string equations and, in particular, their applications for characterizing exact solutions of Whitham hierarchies. Thus, we provide a solution scheme for a special class of string equations which determines not only the solutions of the algebraic orbits of the Whitham hierarchy,[5] but also the solutions arising in the above-mentioned applications of dispersionless integrable models.[24,25] We characterize the τ-function corresponding to these solutions and, by taking advantage of the string equations, we also derive the differential expressions of the underlying Virasoro constraints.

The elements of the phase space for a zero genus Whitham hierarchy are characterized by a finite set

$$(q_\alpha, z_\alpha^{-1}(p)), \quad \alpha = 0, \ldots, M,$$

of *punctures* q_α, where $q_0 := \infty$, of the complex p-plane and an associated set of local coordinates of the form

$$z_\alpha = \begin{cases} p + \sum_{n=1}^{\infty} \frac{d_{0n}}{p^n}, & \alpha = 0, \\ \frac{d_i}{p - q_i} + \sum_{n=0}^{\infty} d_{in}(p - q_i)^n, & \alpha = i = 1, \ldots, M. \end{cases} \tag{1}$$

The set of flows of the Whitham hierarchy can be formulated as the following infinite system of quasiclassical Lax equations:

$$\frac{\partial z_\alpha}{\partial t_{\mu n}} = \{\Omega_{\mu n}, z_\alpha\}, \tag{2}$$

where the Poisson bracket is defined as

$$\{F, G\} := \frac{\partial F}{\partial p}\frac{\partial G}{\partial x} - \frac{\partial F}{\partial x}\frac{\partial G}{\partial p}$$

and the Hamiltonian functions are

$$\Omega_{\mu n} := \begin{cases} (z_\mu^n)_{(\mu,+)}, & n \geqslant 1, \\ -\log_i(p - q_i), & n = 0, \quad \mu = i = 1, \ldots, M. \end{cases} \tag{3}$$

Here $(\cdot)_{(i,+)}$ and $(\cdot)_{(0,+)}$ stand for the projectors on the subspaces generated by $\{(p-q_i)^{-n}\}_{n=1}^{\infty}$ and $\{p^n\}_{n=0}^{\infty}$ in the corresponding spaces of Laurent series. Henceforth, it will be assumed that appropriate nonintersecting cuts connecting $p=\infty$ with the points q_i are made which allow us to define the logarithmic branches associated with Ω_{i0}. As several of these branches will appear simultaneously in certain equations, to avoid possible misunderstanding we introduce the notation convention $\log_i(p-q_i)$. For $M=0$ and $M=1$ these systems represent the dispersionless versions of the KP and Toda hierarchies, respectively.

In what follows Greek and Latin suffixes will be used to label indices of the sets $\{0, \ldots, M\}$ and $\{1, \ldots, M\}$, respectively. In our analysis we use an extended Lax formalism with Orlov functions

$$m_\alpha(z, \mathbf{t}) = \sum_{n=1}^{\infty} n t_{\alpha n} z_\alpha^{n-1} + \frac{t_{\alpha 0}}{z_\alpha} + \sum_{n \geqslant 2} \frac{v_{\alpha n}}{z_\alpha^n}, \quad t_{00} := -\sum_{i=1}^{M} t_{i0}, \tag{4}$$

such that

$$\{z_\alpha, m_\alpha\} = 1, \quad \forall\, \alpha,$$

and verifying the same Lax equations (2) as the variables z_α.

The basic notions about the Whitham hierarchy which are necessary for the subsequent discussion are introduced in Sec. II. String equations and symmetries are discussed in Sec. III, where the main results concerning the construction of solutions from meromorphic string equations and their Virasoro invariance are proved. Section IV presents a scheme for solving an special class of string equations, which is illustrated with several explicit examples. A formula for the correspond-

ing τ-function is given which generalizes the expression of the τ-function of analytic curves found in Ref. 10. Finally, we analyze the Virasoro symmetries associated to the string equations and obtain the corresponding Virasoro constraints in differential form.

II. THE WHITHAM HIERARCHY

In order to display the main features of the Whitham hierarchy it is convenient to use the following concise formulation in terms of the system of equations:

$$\mathrm{d}z_\alpha \wedge \mathrm{d}m_\alpha = \mathrm{d}\omega, \quad \forall\ \alpha, \tag{5}$$

where ω is the one-form defined by

$$\omega := \sum_{\mu,n} \Omega_{\mu n} \mathrm{d}t_{\mu n}. \tag{6}$$

To see how to get from system (5) to the Whitham hierarchy, note that by identifying the coefficients of $dp \wedge dt_{\mu n}$ and $dx \wedge dt_{\mu n}$ in (5) we obtain

$$\begin{aligned} \frac{\partial z_\alpha}{\partial p}\frac{\partial m_\alpha}{\partial t_{\mu n}} - \frac{\partial m_\alpha}{\partial p}\frac{\partial z_\alpha}{\partial t_{\mu n}} &= \frac{\partial \Omega_{\mu n}}{\partial p}, \\ \frac{\partial z_\alpha}{\partial x}\frac{\partial m_\alpha}{\partial t_{\mu n}} - \frac{\partial m_\alpha}{\partial x}\frac{\partial z_\alpha}{\partial t_{\mu n}} &= \frac{\partial \Omega_{\mu n}}{\partial x}. \end{aligned} \tag{7}$$

and, in particular, a $\Omega_{01}=p$, for $(\mu,n)=(0,1)$, system (7) implies

$$\{z_\alpha, m_\alpha\} = 1.$$

Thus, using this fact and solving (7) for $\partial z_\alpha/\partial t_{\mu n}$ and $\partial m_\alpha/\partial t_{\mu n}$, we deduce

$$\frac{\partial z_\alpha}{\partial t_{\mu n}} = \{\Omega_{\mu n}, z_\alpha\}, \quad \frac{\partial m_\alpha}{\partial t_{\mu n}} = \{\Omega_{\mu n}, m_\alpha\}.$$

It is now natural to introduce the S-functions of the Whitham hierarchy. Indeed as a consequence of (5) we find

$$\mathrm{d}\left(m_\alpha \mathrm{d}z_\alpha + \sum_{\mu,n} \Omega_{\mu n} \mathrm{d}t_{\mu n} \right) = 0, \quad \forall\ \alpha,$$

so that there exist functions $S_\alpha(z_\alpha, \boldsymbol{t})$ such that

$$\mathrm{d}S_\alpha = m_\alpha \mathrm{d}z_\alpha + \sum_{\mu,n} \Omega_{\mu n} \mathrm{d}t_{\mu n}, \quad \forall\ \alpha, \tag{8}$$

and from (4) we see that they admit expansions of the form

$$S_\alpha = \sum_{n\geqslant 1} z_\alpha^n t_{\alpha n} + \log z_\alpha t_{\alpha 0} - v_\alpha(\mathbf{t}) - \sum_{n\geqslant 1} \frac{v_{\alpha n+1}}{n}\frac{1}{z_\alpha^n}, \quad z_\alpha \to \infty. \tag{9}$$

It is important to notice that from (1)–(4) and (8) it follows that

$$\mathrm{d}S_0 = \sum_{n\geqslant 1} (n z_0^{n-1} t_{0n} \mathrm{d}z_0 + (z_0^n)_{(0,+)} \mathrm{d}t_{0n}) + \frac{t_{00}}{z_0}\mathrm{d}z_0 + \mathcal{O}\left(\frac{1}{z_0^2}\right)\mathrm{d}z_0, \quad z_0 \to \infty,$$

and consequently we may take

$$v_0(\mathbf{t}) \equiv 0.$$

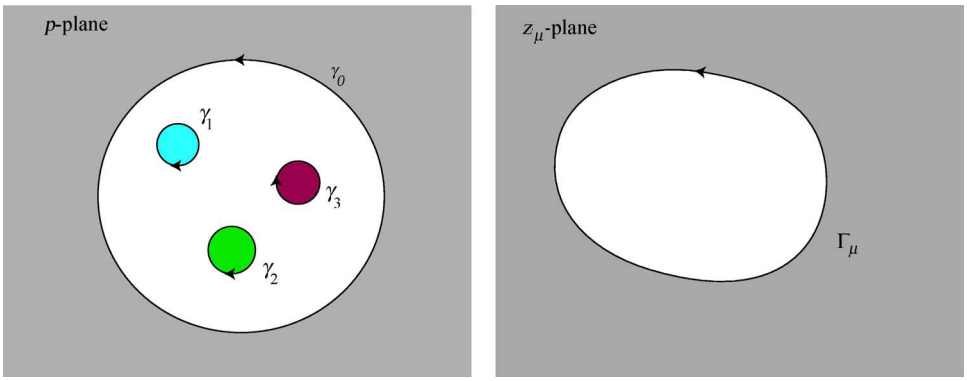

FIG. 1. (Color online) Right exteriors of γ_μ and Γ_μ.

To proceed further some analytic properties of the dynamical variables of the Whitham hierarchy are required. Thus we will henceforth suppose that there exist positively oriented closed curves Γ_μ in the complex planes of the variables z_μ such that each function $z_\mu(p)$ determines a conformal map of the right exterior of a circle $\gamma_\mu := z_\mu^{-1}(\Gamma_\mu)$ on the exterior of Γ_μ. We will assume that the circle γ_0 encircles all the $\gamma_i, (i=1,\ldots M)$ (see Fig. 1). Moreover, for each α the functions S_α and m_α will be assumed to be analytic in the exterior of Γ_α.

Under the previous conditions one can prove that

$$\partial_{\beta,m} v_{\alpha,n+1} = \partial_{\alpha,n} v_{\beta,m+1}, \quad \forall\, \alpha,\beta, \quad n,m \geqslant 0. \tag{10}$$

Here the functions v_{i1} are defined by

$$v_{i1} := v_i - \sum_{j<i} \log_{ji}(-1) t_{j0}, \tag{11}$$

and we are denoting

$$\log_{ji}(-1) := \log_j(q_i - q_j) - \log_i(q_j - q_i) = -\log_{ij}(-1).$$

In other words, it is ensured the existence of a *free-energy function* $F=F(\boldsymbol{t})$, the logarithm $F=\log \tau$ of the *dispersionless* τ-function, verifying

$$\mathrm{d}F = \sum_{(\alpha,n)\neq(0,0)} v_{\alpha n+1} \mathrm{d}t_{\alpha n}. \tag{12}$$

Let us first prove (10) for the case $(\alpha,n)=(i,0),(\beta,m)=(j,0)$. From the equations

$$\partial_{l0} S_k = -\log_l(p - q_l),$$

it follows that

$$\partial_{i0} v_j = \log_i(q_j - q_i), \quad \partial_{j0} v_i = \log_j(q_i - q_j),$$

so that the functions defined in (11) satisfy

$$\partial_{i0} v_{j1} = \partial_{j0} v_{i1}.$$

We indicate the strategy for proving the remaining cases of (10) by considering the choice $\alpha=i,\beta=j\geqslant 1,n,m\geqslant 1$ of (10). From (4) and (8) it follows that

$$v_{i,n+1} = \frac{1}{2\pi i}\oint_{\Gamma_i} z_i^n m_i \mathrm{d}z_i, \quad \partial_{j,m} S_i = (z_j^m)_{(j,+)},$$

so that

$$\partial_{j,m} v_{i,n+1} = \frac{1}{2\pi i}\oint_{\gamma_i} z_i^n \mathrm{d}(z_j^m)_{(j,+)} = \frac{1}{2\pi i}\oint_{\gamma_i} (z_i^n)_{(i,+)} \mathrm{d}(z_j^m)_{(j,+)} = \frac{1}{2\pi i}\oint_{\gamma_j} (z_j^m)_{(j,+)} \mathrm{d}(z_i^n)_{(i,+)} = \partial_{i,n} v_{j,m+1}, \tag{13}$$

where we have taken into account that $(z_i^n)_{(i,+)}\partial_p(z_j^m)_{(j,+)}$ is a rational function of p which has finite poles at q_i and q_j only and a zero residue at ∞.

III. STRING EQUATIONS AND SYMMETRIES

As it was shown in Ref. 26, the analysis of the factorization problem for the Whitham hierarchy shows that this hierarchy admits a natural formulation in terms of systems of string equations of the form

$$\begin{aligned} P_i(z_i,m_i) &= P_0(z_0,m_0), \\ Q_i(z_i,m_i) &= Q_0(z_0,m_0), \end{aligned} \quad i = 1,2,\ldots,M, \tag{14}$$

where $\{P_\alpha, Q_\alpha\}_{\alpha=0}^M$ are pairs of canonically conjugate variables

$$\{P_\alpha(p,x), Q_\alpha(p,x)\} = 1, \quad \forall\ \alpha. \tag{15}$$

In what follows we consider the problem of finding systems of form (14) which are appropriate to generate exact solutions of the Whitham hierarchy.

Given a solution $(z_\alpha(p,\boldsymbol{t}), m_\alpha(p,\boldsymbol{t}))$ of system (14), if we denote

$$\mathcal{P}_\alpha(p,\mathbf{t}) \coloneqq P_\alpha(z_\alpha(p,\mathbf{t}), m_\alpha(p,\mathbf{t})), \quad \mathcal{Q}_\alpha(p,\mathbf{t}) \coloneqq Q_\alpha(z_\alpha(p,\mathbf{t}), m_\alpha(p,\mathbf{t})),$$

then (14) and (15) imply

$$\mathrm{d}\mathcal{P}_\alpha \wedge \mathrm{d}\mathcal{Q}_\alpha = \mathrm{d}\mathcal{P}_\beta \wedge \mathrm{d}\mathcal{Q}_\beta, \quad \forall\ \alpha,\beta \tag{16}$$

and

$$\mathrm{d}\mathcal{P}_\alpha \wedge \mathrm{d}\mathcal{Q}_\alpha = \mathrm{d}z_\alpha \wedge \mathrm{d}m_\alpha, \quad \forall\ \alpha, \tag{17}$$

respectively. Hence solutions of the system of string equations verify

$$\mathrm{d}\mathcal{P}_\alpha \wedge \mathrm{d}\mathcal{Q}_\alpha = \mathrm{d}z_\beta \wedge \mathrm{d}m_\beta, \quad \forall\ \alpha,\beta. \tag{18}$$

The next result provides a convenient framework for our subsequent discussion of solutions of (14).

Theorem 1: *Let* $(z_\alpha(p,\boldsymbol{t}), m_\alpha(p,\boldsymbol{t}))$ *be a solution of* (14) *which admits expansions of forms* (1)–(4) *and such that the coefficients of the two-forms* (18) *are meromorphic functions of the complex variable p with finite poles at* $\{q_1,\ldots,q_M\}$ *only. Then* $(z_\alpha(p,\boldsymbol{t}), m_\alpha(p,\boldsymbol{t}))$ *is a solution of the Whitham hierarchy*.

Proof: In view of the hypothesis of the theorem the coefficients of the two-forms (18) with respect to the basis

$$\{\mathrm{d}p \wedge \mathrm{d}t_{\alpha n}, \quad \mathrm{d}t_{\alpha n} \wedge \mathrm{d}t_{\beta m}\}$$

are determined by their principal parts at $q_\mu, (\mu = 0,\ldots,M)$, so that by taking (18) into account we may write

$$\mathrm{d}z_\alpha \wedge \mathrm{d}m_\alpha = \sum_{\mu=0}^{M} (\mathrm{d}z_\mu \wedge \mathrm{d}m_\mu)_{(\mu,+)}, \quad \forall\, \alpha.$$

Moreover the terms in these decompositions can be found by using expansions (4) of the functions m_μ as follows:

$$\begin{aligned}\mathrm{d}z_\mu \wedge \mathrm{d}m_\mu &= \mathrm{d}z_\mu \wedge \left(\sum_{n=1}^{\infty} n z_\mu^{n-1} \mathrm{d}t_{\mu n} + \frac{\mathrm{d}t_{\mu 0}}{z_\mu} + \sum_{n\geqslant 2} \frac{\mathrm{d}v_{\mu n}}{z_\mu^n} \right) \\ &= \mathrm{d}\left(\sum_{n=1}^{\infty} z_\mu^n \mathrm{d}t_{\mu n} + \log z_\mu \mathrm{d}t_{\mu 0} - \sum_{n\geqslant 2} \frac{1}{n-1} \frac{\mathrm{d}v_{\mu n}}{z_\mu^{n-1}} \right),\end{aligned}$$

so that

$$(\mathrm{d}z_\mu \wedge \mathrm{d}m_\mu)_{(\mu,+)} = \mathrm{d}\left(\sum_{n=1}^{\infty} (z_\mu^n)_{(\mu,+)} \mathrm{d}t_{\mu n} - (1-\delta_{\mu 0}) \log(p - q_\mu) \mathrm{d}t_{\mu 0} \right) = \mathrm{d}\left(\sum_n \Omega_{\mu n} \mathrm{d}t_{\mu n} \right).$$

Thus we find

$$\mathrm{d}z_\alpha \wedge \mathrm{d}m_\alpha = \mathrm{d}\omega = \mathrm{d}\left(\sum_{\mu,n} \Omega_{\mu n} \mathrm{d}t_{\mu n} \right), \quad \forall\, \alpha,$$

and, consequently, this proves that the functions $(z_\alpha(p,\boldsymbol{t}), m_\alpha(p,\boldsymbol{t}))$ determine a solution of the Whitham hierarchy. ■

Following the dressing scheme of Refs. 19–22 it can be shown[26] that each solution of the Whitham hierarchy is determined by an associated system of string equations.

As it was shown in Ref. 26 a complete formulation of the symmetry group of the Whitham hierarchy is obtained by considering deformations of the associated factorization problem. On the other hand, a natural representation of this group is provided by the following symmetries of string equations implemented by Hamiltonian vector fields.

Theorem 2. *Given a vector function*

$$\mathbb{F} := (F_0(z_0,m_0), \ldots, F_M(z_M,m_M)), \tag{19}$$

the infinitesimal deformation

$$\begin{aligned}&\delta_{\mathbb{F}} P_\alpha := \{F_\alpha, P_\alpha\}, \quad \delta_{\mathbb{F}} Q_\alpha := \{F_\alpha, Q_\alpha\}, \\ &\delta_{\mathbb{F}} z_\alpha := \{z_\alpha, (F_\alpha)_-\}, \quad \delta_{\mathbb{F}} m_\alpha := \{m_\alpha, (F_\alpha)_-\},\end{aligned} \tag{20}$$

where

$$(F_\alpha)_- := F_\alpha - \sum_\beta (F_\beta)_{(\beta,+)},$$

determines a symmetry of the system of string equations (14).

Proof: We have to prove that given a solution (z_α, m_α) of (14), then at first order in ϵ

$$\begin{aligned}&(P_i + \epsilon\delta_{\mathbb{F}} P_i)(z_i + \epsilon\delta_{\mathbb{F}} z_i, m_i + \epsilon\delta_{\mathbb{F}} m_i) = (P_0 + \epsilon\delta_{\mathbb{F}} P_0)(z_0 + \epsilon\delta_{\mathbb{F}} z_0, m_0 + \epsilon\delta_{\mathbb{F}} m_0), \\ &(Q_i + \epsilon\delta_{\mathbb{F}} Q_i)(z_i + \epsilon\delta_{\mathbb{F}} z_i, m_i + \epsilon\delta_{\mathbb{F}} m_i) = (Q_0 + \delta_{\mathbb{F}} Q_0)(z_0 + \epsilon\delta_{\mathbb{F}} z_0, m_0 + \epsilon\delta_{\mathbb{F}} m_0),\end{aligned} \tag{21}$$

for all $i = 1, \ldots, M$. Let us consider the first group of equations of (21), they can be rewritten as

$$\frac{\partial P_i}{\partial z_i}\delta_{\mathbb{F}} z_i + \frac{\partial P_i}{\partial m_i}\delta_{\mathbb{F}} m_i + \{F_i, P_i\} = \frac{\partial P_0}{\partial z_0}\delta_{\mathbb{F}} z_0 + \frac{\partial P_0}{\partial m_0}\delta_{\mathbb{F}} m_0 + \{F_0, P_0\},$$

or, equivalently, by taking (20) into account, as

$$\{F_i - (F_i)_-, P_i\} = \{F_0 - (F_0)_-, P_0\}, \quad \forall\, i. \tag{22}$$

By hypothesis $P_i(z_i, m_i) = P_0(z_0, m_0)$. On the other hand

$$F_i - (F_i)_- = F_0 - (F_0)_- = \sum_\beta (F_\beta)_{(\beta,+)},$$

so that (22) is satisfied. The proof for the second group of equations of (21) is identical. □

We note that the condition for a solution (z_α, m_α) of the string equations (14) to be invariant under a symmetry (20) is

$$(F_\alpha(z_\alpha, m_\alpha))_- = 0, \quad \forall\, \alpha, \tag{23}$$

or equivalently

$$F_\alpha = \sum_\mu (F_\mu)_{(\mu,+)}, \quad \forall\, \alpha. \tag{24}$$

In other words, the functions $F_\alpha(z_\alpha, m_\alpha)$ must reduce to a unique meromorphic function of p with finite poles at the punctures q_i only. As a consequence it follows that, under the hypothesis of Theorem 1, solutions of the Whitham hierarchy satisfying a system of string equations (14) are invariant under the symmetries generated by

$$\mathbb{P} = (P_0(z_0, m_0), \ldots, P_M(z_M, m_M)), \quad \mathbb{Q} = (Q_0(z_0, m_0), \ldots, Q_M(z_M, m_M)),$$

and, more generally, they are invariant under the symmetries generated by

$$\mathbb{V}_{rs} = (P_0^{r+1} Q_0^{s+1}, \ldots, P_M^{r+1} Q_M^{s+1}), \quad r \geqslant -1, \quad s \geqslant 0, \tag{25}$$

which determine a Poisson Lie algebra $\mathcal{W}$ of symmetries

$$\{\mathbb{V}_{rs}, \mathbb{V}_{r's'}\} = ((r+1)(s'+1) - (r'+1)(s+1))V_{r+r's+s'}.$$

In particular the functions $\mathbb{V}_r := \mathbb{V}_{r0}$ and $\widetilde{\mathbb{V}}_s := -\mathbb{V}_{0s}$ generate two Virasoro algebras.

$$\{\mathbb{V}_r, \mathbb{V}_{r'}\} = (r - r')\mathbb{V}_{r+r'}, \quad \{\widetilde{\mathbb{V}}_s, \widetilde{\mathbb{V}}_{s'}\} = (s - s')\widetilde{\mathbb{V}}_{s+s'}.$$

IV. A SOLVABLE CLASS OF STRING EQUATIONS

In Ref. 26 a class of string equations was introduced which manifests special properties with respect to the group of dressing transformations. We next provide a scheme of solution for this class.

Let us consider systems of string equations associated to splittings

$$\{1, \ldots, M\} = I \cup J, \quad I \cap J = \emptyset$$

of the form

$$i \in I \begin{cases} z_i^{n_i} = z_0^{n_0} \\ \dfrac{1}{n_i}\dfrac{m_i}{z_i^{n_i-1}} = \dfrac{1}{n_0}\dfrac{m_0}{z_0^{n_0-1}}, \end{cases} \qquad j \in J \begin{cases} -\dfrac{n_0}{n_j}\dfrac{m_j}{z_j^{n_j-1}} = z_0^{n_0} \\ \dfrac{1}{n_0} z_j^{n_j} = \dfrac{1}{n_0}\dfrac{m_0}{z_0^{n_0-1}}, \end{cases} \tag{26}$$

where n_α are arbitrary positive integers. For $J=\emptyset$ these systems furnish the solutions describing the algebraic orbits of the Whitham hierarchy,[5] while the case $I=\emptyset$ includes the systems of string equations considered by Takasaki[18] and Wiegmann-Zabrodin[10–14] in their applications of the dToda hierarchy. The discussion of our scheme for solving (26) requires the consideration of the two cases $J=\emptyset$ and $J\neq\emptyset$ separately. In what follows we consider solutions with only a finite number of times $t_{\mu n}$ different from zero.

A. The case $J=\emptyset$

The corresponding system is given by

$$\begin{aligned} & z_i^{n_i} = z_0^{n_0}, \\ & \frac{1}{n_i}\frac{m_i}{z_i^{n_i-1}} = \frac{1}{n_0}\frac{m_0}{z_0^{n_0-1}}, \qquad i = 1, \dots, M. \end{aligned} \tag{27}$$

The first group of equations (27) is satisfied by setting

$$z_i^{n_i} = z_0^{n_0} = E(p) := p^{n_0} + u_{n_0-2}p^{n_0-2} + \cdots + u_0 + \sum_{i=1}^{M}\sum_{s=1}^{n_i}\frac{v_{is}}{(p-q_i)^s}, \tag{28}$$

and, obviously, appropriate branches of z_μ can be defined which are compatible with the required asymptotic expansions (1). On the other hand, notice that the remaining string equations in (27) can be rewritten as

$$m_i = m_0\frac{\mathrm{d}z_0}{\mathrm{d}z_i}, \tag{29}$$

so that they are verified by taking

$$m_\alpha = \frac{\partial S}{\partial z_\alpha}, \qquad \forall\ \alpha, \tag{30}$$

for a given function $S(p,\mathbf{t})$, which means that all the S_α are equal to S. Moreover, it is straightforward to prove that the expansions (4) are satisfied if we set

$$S = \sum_{n=1}^{N_0} t_{0n}(z_0^n)_{(0,+)} + \sum_{j=1}^{M}\left(\sum_{n=1}^{N_j} t_{jn}(z_j^n)_{(j,+)} - t_{j0}\ln_j(p-q_j)\right). \tag{31}$$

In order to satisfy the hypothesis of Theorem 1, the functions $z_0^{n_0}$ and $m_0/z_0^{n_0-1}$ must be rational functions of p with possible finite poles at the points q_i only. In view of (28) this condition is verified by z_0^n. On the other hand, (27) and (30) imply that

$$\frac{1}{n_0}\frac{m_0}{z_0^{n_0-1}} = \frac{\partial_p S}{\partial_p E}.$$

Therefore, the requirements of Theorem 1 are satisfied provided that

$$\partial_p S(p_r) = 0, \tag{32}$$

where p_r are the zeros of

$$\partial_p E(p_r) = 0.$$

We observe that the number of zeros p_r is

$$M + n_0 - 1 + \sum_{i=1}^{M} n_i,$$

which equals the number of unknowns $\{q_i, u_0, \ldots, u_{n_0-2}, v_{is}\}$. Equation (32) coincides with those formulated by Krichever in Ref. 5 for determining the algebraic orbits of the Whitham hierarchy.

Example: $M=2$, $n_0=n_1=n_2=1$, $N_0=2$, $N_1=N_2=1$.

In this case (28) reads

$$z_\alpha = E(p) = p + \frac{v_1}{p-q_1} + \frac{v_2}{p-q_2}, \quad 0 \leqslant \alpha \leqslant 2,$$

and (32) leads to

$$-t_{10} - t_{20} + 2t_{02}v_1 + 2t_{02}v_2 = 0,$$

$$q_1 t_{10} + 2q_2 t_{10} + 2q_1 t_{20} + q_2 t_{20} + t_{01}v_1 - 4q_2 t_{02}v_1 - t_{11}v_1 + t_{01}v_2 - 4q_1 t_{02}v_2 - t_{21}v_2 = 0,$$

$$-2q_1 q_2 t_{10} - {q_2}^2 t_{10} - {q_1}^2 t_{20} - 2q_1 q_2 t_{20} - 2q_2 t_{01}v_1 + 2{q_2}^2 t_{02}v_1 + 2q_2 t_{11}v_1 - 2q_1 t_{01}v_2 + 2{q_1}^2 t_{02}v_2 + 2q_1 t_{21}v_2 = 0,$$

$$q_1 {q_2}^2 t_{10} + {q_1}^2 q_2 t_{20} + {q_2}^2 t_{01}v_1 - {q_2}^2 t_{11}v_1 + {q_1}^2 t_{01}v_2 - {q_1}^2 t_{21}v_2 = 0.$$

By solving this system we obtain

$$z_\alpha = E(p) = p + \frac{2t_{10} + t_{20}}{4t_{02}\left(p + \dfrac{2t_{01}t_{10} - 2t_{10}t_{11} + 2t_{01}t_{20} - t_{11}t_{20} - t_{20}t_{21}}{4t_{02}(t_{10}+t_{20})}\right)} + \frac{t_{20}}{4t_{02}\left(p - \dfrac{-2t_{01}(t_{10}+t_{20}) + 2t_{20}t_{21} + t_{10}(t_{11}+t_{21})}{4t_{02}(t_{10}+t_{20})}\right)}, \quad 0 \leqslant \alpha \leqslant 2.$$

B. The case $J \neq \emptyset$

Now we consider system (26) for the generic case $J \neq \emptyset$. We look for functions m_α of the form

$$m_\alpha(z,t) = \sum_{n=1}^{N_\alpha} n t_{\alpha n} z_\alpha^{n-1} + \frac{t_{\alpha 0}}{z_\alpha} + \sum_{n \geqslant 2} \frac{v_{\alpha n}}{z_\alpha^n}, \quad t_{00} = -\sum_{i=1}^{M} t_{i0}, \tag{33}$$

for arbitrary positive integers N_α. In order to verify the hypothesis of Theorem 1 and expansions (1), we set

$$z_0^{n_0} = z_i^{n_i} = E_1(p) := p^{n_0} + u_{n_0-2}p^{n_0-2} + \cdots + u_0 + \sum_{l \in I}\sum_{n=1}^{n_l} \frac{a_{ln}}{(p-q_l)^n} + \sum_{k \in J}\sum_{n=1}^{n_{0k}} \frac{b_{kn}}{(p-q_k)^n}, \quad \forall\, i \in I, \tag{34}$$

$$z_j^{n_j} = E_2(p) := \sum_{n=0}^{n_{00}} c_n p^n + \sum_{l\in I}\sum_{n=1}^{n_{0l}} \frac{\widetilde{a}_{ln}}{(p-q_l)^n} + \sum_{k\in J}\sum_{n=1}^{n_k} \frac{\widetilde{b}_{kn}}{(p-q_k)^n}, \quad \forall\, j \in J, \tag{35}$$

where n_{00}, n_{0l}, n_{0k} $(l \in I, k \in J)$, the poles q_i and the coefficients of E_1 and E_2 are to be determined.

By introducing the functions

$$\mathcal{M}_\alpha := m_\alpha z_\alpha, \tag{36}$$

and taking (34) and (35) into account it follows that the system of string equations (26) reduces to

$$\mathcal{M}_0 = \frac{n_0}{n_i}\mathcal{M}_i = -\frac{n_0}{n_j}\mathcal{M}_j = E_1(p)E_2(p), \quad \forall\, i \in I, \quad j \in J. \tag{37}$$

On the other hand, due to their rational character, the functions $\mathcal{M}_\alpha$ can be written in terms of their principal parts at the poles q_β

$$\mathcal{M}_\alpha = \sum_{\beta=0}^{M} (\mathcal{M}_\alpha)_{(\beta,+)},$$

and by taking (4) into account we get

$$(\mathcal{M}_0)_{(0,+)} = \sum_{n=1}^{N_0} n t_{0n} (z_0^n)_{(0,+)} + t_{00}, \quad t_{00} = -\sum_{i=1}^{M} t_{i0},$$

$$(\mathcal{M}_i)_{(i,+)} = \sum_{n=1}^{N_i} n t_{in} (z_i^n)_{(i,+)}.$$

Therefore (37) is satisfied by

$$\begin{gathered}\mathcal{M}_0 = \sum_{n=1}^{N_0} n t_{0n} (z_0^n)_{(0,+)} + t_{00} + \sum_{i\in I} \frac{n_0}{n_i} \sum_{n=1}^{N_i} n t_{in} (z_i^n)_{(i,+)} - \sum_{j\in J} \frac{n_0}{n_j} \sum_{n=1}^{N_j} n t_{jn} (z_j^n)_{(j,+)}, \quad t_{00} = -\sum_{j=1}^{M} t_{j0} \\ \mathcal{M}_i = \frac{n_i}{n}\mathcal{M}_0, \quad \mathcal{M}_j = -\frac{n_j}{n}\mathcal{M}_0, \quad \forall\, i \in I, \quad j \in J,\end{gathered} \tag{38}$$

provided $\mathcal{M}_0$ verifies the equation

$$\mathcal{M}_0 = E_1(p)E_2(p). \tag{39}$$

At this point notice that from (34), (35), and (37) it follows that (39) is the only equation to be satisfied in order to solve the system of string equations (26). Both sides of (39) are rational functions of p with finite poles at $\{q_1, \ldots, q_M\}$ only, so that (39) holds if and only if the principal parts of both members at $\{q_0, q_1, \ldots, q_M\}$ coincide. Now we have that:

(i) At $q_0 = \infty$, the function $\mathcal{M}_0$ has a pole of order N_0, while $E_1(p)E_2(p)$ has a pole of order $n_{00}+n_0$, consequently (39) requires that $n_{00} = N_0 - n_0$, so that identifying the principal parts at q_0 represents $N_0 + 1$ equations.

(ii) At q_i, $(i \in I)$, the function $\mathcal{M}_0$ has a pole of order N_i and $E_1(p)E_2(p)$ has a pole of order $n_i + n_{0i}$. Hence $n_{0i} = N_i - n_i$ and identifying the corresponding principal parts leads to N_i equations.

(iii) At q_j, $(j \in J)$, the function $\mathcal{M}_0$ has a pole of order N_j and $E_1(p)E_2(p)$ has a pole of order $n_{0j} + n_j$. Hence $n_{0j} = N_j - n_j$ and identifying the corresponding principal parts leads to N_j equations.

Thus, Eq. (39) leads to $N_0+\Sigma_{i=1}^{M}N_i+1$ equations. On the other hand we have $N_0+\Sigma_{i=1}^{M}N_i+M$ unknown coefficients given by

$$q_i, \quad i=1,2,\ldots,M,$$

$$a_{i1},\ldots,a_{in_i}, \quad \tilde{a}_{i1},\ldots,\tilde{a}_{iN_i-n_i}, \quad i\in I,$$

$$b_{j1},\ldots,b_{jN_j-n_j}, \quad \tilde{b}_{j1},\ldots,\tilde{b}_{jn_j}, \quad j\in J, \tag{40}$$

$$u_0,\ldots,u_{n_0-2},$$

$$c_0,\ldots,c_{N_0-n_0}.$$

The additional $M-1$ equations required for determining these coefficients arise by imposing the asymptotic behavior (1)–(4) to (z_α,m_α). Note that (34) and (35) imply that the functions z_α have the asymptotic form (1). In what concerns the functions m_α, from the expression (38) for $\mathcal{M}_0$ it follows that

$$\mathcal{M}_0=\sum_{n=1}^{N_0} nt_{0n}z_0^n+t_{00}+\mathcal{O}\left(\frac{1}{z_0}\right), \quad z_0\to\infty,$$

so that m_0 satisfies an expansion of form (4). But in order for m_i $(i=1,2,\ldots,M)$ to satisfy (4) we must impose that

$$\mathrm{Res}(m_i,z_i=\infty)=t_{i0}, \quad i=1,2,\ldots,M. \tag{41}$$

However, let us see that as a consequence of the string equations (26) it follows that

$$\sum_{\alpha=0}^{M}\mathrm{Res}(m_\alpha,z_\alpha=\infty)=0, \tag{42}$$

and, consequently, only $M-1$ of Eq. (41) need to be imposed. Indeed, we have

$$2\pi i\sum_{\alpha=0}^{M}\mathrm{Res}(m_\alpha,z_\alpha=\infty)=\sum_{\alpha=0}^{M}\oint_{\Gamma_\alpha}m_\alpha \mathrm{d}z_\alpha=\sum_{\alpha=0}^{M}\oint_{\gamma_\alpha}m_\alpha\partial_p z_\alpha \mathrm{d}p.$$

On the other hand (34), (35), and (37) imply

$$m_i\partial_p z_i=m_0\partial_p z_0, \quad i\in I,$$

$$m_j\partial_p z_j=m_0\partial_p z_0-\frac{1}{n_0}\partial_p(E_1(p)E_2(p)), \quad j\in J,$$

so that

$$2\pi i\sum_{\alpha=0}^{M}\mathrm{Res}(m_\alpha,z_\alpha=\infty)=\oint_{\gamma}m_0\partial_p z_0\mathrm{d}p=0, \quad \gamma:=\sum_{\alpha=0}^{M}\gamma_\alpha,$$

where we have taken into account that

$$m_0\partial_p z_0 = \frac{1}{n_0}E_2(p)\partial_p E_1(p),$$

is a rational function of p with finite poles at q_i only, and the fact that

$$\gamma \sim 0 \quad \text{in} \quad \mathbb{C}\setminus\{q_1,\ldots,q_M\}.$$

In this way we have a system of

$$N_0 + \sum_{i=1}^{M} N_i + M,$$

equations to determine the same number of unknown coefficients. Therefore, according to Theorem 1, this method furnishes solutions of the Whitham hierarchy.

C. Examples

(1) $M=1$, $I=\emptyset$, $n_0=2$, $n_1=1$, $N_0=N_1=3$. Note that in this case all the equations come from (39). We set

$$z_0^2 = p^2 + u_0 + \frac{a_1}{p-q} + \frac{a_2}{(p-q)^2}, \quad z_1 = \frac{b_1}{p-q} + c_0 + c_1 p.$$

From (39) one obtains the system

$$p^3: \quad 3t_{03} = c_1,$$

$$p^2: \quad 2t_{02} = c_0,$$

$$p^1: \quad t_{01} + \frac{9t_{03}u_0}{2} = b_1 + c_1 u_0,$$

$$p^0: \quad \frac{9a_1 t_{03}}{2} - t_{10} + 2t_{02}u_0 = a_1 c_1 + b_1 q + c_0 u_0,$$

$$(p-q)^{-3}: \quad -6{b_1}^2 t_{13} = a_2,$$

$$(p-q)^{-2}: \quad -2{b_1}^2(2t_{12} + 9(c_0 + c_1 q)t_{13}) = a_1 b_1 + a_2(c_0 + c_1 q),$$

$$\begin{aligned}(p-q)^{-1}: \quad & -2b_1(t_{11} + 4(c_0 + c_1 q)t_{12} + 9(c_0^2 + 2c_0 c_1 q + c_1 b_1 + c_1^2 q^2)t_{13}) \\ & = a_2 c_1 + a_1(c_0 + c_1 q) + b_1(q^2 + u_0),\end{aligned}$$

and by solving these equations we find

$$\begin{aligned}z_0^2 = p^2 & - \frac{2(qt_{01} + t_{10} + 6t_{01}t_{03}t_{12} + 36t_{01}t_{02}t_{03}t_{13} + 54qt_{01}{t_{03}}^2 t_{13})}{3t_{03}(q + 6t_{03}t_{12} + 36t_{02}t_{03}t_{13} + 54q{t_{03}}^2 t_{13})} \\ & + \frac{4t_{10}(t_{12} + 6t_{02}t_{13} + 9qt_{03}t_{13})}{(p-q)(q + 54q{t_{03}}^2 t_{13} + 6t_{03}(t_{12} + 6t_{02}t_{13}))} - \frac{6{t_{10}}^2 t_{13}}{(p-q)^2(q + 54q{t_{03}}^2 t_{13} + 6t_{03}(t_{12} + 6t_{02}t_{13}))^2},\end{aligned}$$

$$z_1 = -\frac{t_{10}}{(p-q)(q+6t_{03}t_{12}+36t_{02}t_{03}t_{13}+54q{t_{03}}^2t_{13})} + 2t_{02} + 3pt_{03},$$

where q is determined by the implicit equation

$$\begin{aligned}
&-2qt_{01}+3q^3t_{03}-2t_{10}+6qt_{03}t_{11}-12t_{01}t_{03}t_{12}+24qt_{02}t_{03}t_{12}+54q^2{t_{03}}^2t_{12}+36{t_{03}}^2t_{11}t_{12}\\
&\quad+144t_{02}{t_{03}}^2{t_{12}}^2+216q{t_{03}}^3{t_{12}}^2-72t_{01}t_{02}t_{03}t_{13}+72q{t_{02}}^2t_{03}t_{13}-108qt_{01}{t_{03}}^2t_{13}+324q^2t_{02}{t_{03}}^2t_{13}\\
&\quad+324q^3{t_{03}}^3t_{13}-108{t_{03}}^2t_{10}t_{13}+216t_{02}{t_{03}}^2t_{11}t_{13}+324q{t_{03}}^3t_{11}t_{13}+1296{t_{02}}^2{t_{03}}^2t_{12}t_{13}\\
&\quad+3888q{t_{02}}{t_{03}}^3t_{12}t_{13}+2916q^2{t_{03}}^4t_{12}t_{13}+2592{t_{02}}^3{t_{03}}^2{t_{13}}^2+11664q{t_{02}}^2{t_{03}}^3{t_{13}}^2\\
&\quad+17496q^2t_{02}{t_{03}}^4{t_{13}}^2+8748q^3{t_{03}}^5{t_{13}}^2=0.
\end{aligned}$$

(2) $M=2$, $I=\emptyset$, $n_0=n_1=n_2=1$, $N_0=N_1=2$, $N_2=1$. In this case there are three punctures $\{q_0=\infty, q_1, q_2\}$ and we have to impose Eq. (41) for $i=1$. We take

$$z_0 = p + \frac{a_1}{p-q_1}, \quad z_1 = z_2 = \frac{b_1}{p-q_1} + \frac{b_2}{p-q_2} + c_0 + c_1p.$$

Then, by identifying powers of p, $(p-q_1)^{-1}$ and $(p-q_2)^{-1}$ in (39) the following system of equations arises

$$p^2: \quad 2t_{02} = c_1,$$

$$p^1: \quad t_{01} = c_0,$$

$$p^0: \quad 4a_1t_{02} - t_{10} - t_{20} = b_1 + b_2 + a_1c_1,$$

$$(p-q_1)^{-2}: \quad -2b_1t_{12} = a_1,$$

$$(p-q_1)^{-1}: \quad -b_1t_{11} - 4b_1\left(c_0 + c_1q_1 + \frac{b_2}{q_1-q_2}\right)t_{12} = b_1q_1 + a_1\left(c_0 + c_1q_1 + \frac{b_2}{q_1-q_2}\right),$$

$$(p-q_2)^{-1}: \quad -t_{21} = q_2 - \frac{a_1}{q_1-q_2}.$$

Moreover, by taking (38) into account, from (41) we get

$$\begin{aligned}
&-q_1t_{01} - 2(2a_1+{q_1}^2)t_{02} - \left(c_0 + c_1q_1 + \frac{b_2}{q_1-q_2}\right)t_{11}\\
&\quad -2\left(2b_1\left(c_1 - \frac{b_2}{(q_1-q_2)^2}\right) + \left(c_0 + c_1q_1 + \frac{b_2}{q_1-q_2}\right)^2\right)t_{12} + t_{20} + \frac{b_2t_{21}}{q_1-q_2} = 0.
\end{aligned}$$

These equations lead to

$$z_0 = p - \frac{1}{2(1+4t_{02}t_{12})(p-q_1)}(r^2(1+4t_{02}t_{12}) - 2t_{12}(t_{10}+t_{20}) + r(t_{11}+2t_{01}t_{12}-t_{21}-4t_{02}t_{12}t_{21})),$$

$$z_1 = \frac{1}{4t_{12}(1+4t_{02}t_{12})(p-q_1)}(r^2(1+4t_{02}t_{12}) - 2t_{12}(t_{10}+t_{20}) + r(t_{11}+2t_{01}t_{12} - t_{21} - 4t_{02}t_{12}t_{21}))$$
$$+ \frac{1}{4t_{12}(p-q_2)}(-r^2(1+4t_{02}t_{12}) - 2t_{12}(t_{10}+t_{20}) + r(-t_{11} - 2t_{01}t_{12} + t_{21} + 4t_{02}t_{12}t_{21}))$$
$$+ t_{01} + 2pt_{02},$$

where

$$q_1 = \frac{1}{2r(1+4t_{02}t_{12})}(r^2(1+4t_{02}t_{12}) + 2t_{12}(t_{10}+t_{20}) - r(t_{11}+2t_{01}t_{12}+t_{21}+4t_{02}t_{12}t_{21})),$$

$$q_2 = -\frac{1}{2r(1+4t_{02}t_{12})}(r^2(1+4t_{02}t_{12}) - 2t_{12}(t_{10}+t_{20}) + r(t_{11}+2t_{01}t_{12}+t_{21}+4t_{02}t_{12}t_{21})),$$

and r is determined by

$$3r^4(1+4t_{02}t_{12})^2 - 4{t_{12}}^2(t_{10}+t_{20})^2 + 4r^3(1+4t_{02}t_{12})(t_{11}+2t_{01}t_{12} - (1+4t_{02}t_{12})t_{21}) + r^2({t_{11}}^2$$
$$+ 4{t_{01}}^2{t_{12}}^2 + 4t_{10}t_{12}(1+4t_{02}t_{12}) - 4t_{12}t_{20} - 16t_{02}{t_{12}}^2t_{20} - 4t_{01}t_{12}t_{21} - 16t_{01}t_{02}{t_{12}}^2t_{21} + {t_{21}}^2$$
$$+ 8t_{02}t_{12}{t_{21}}^2 + 16{t_{02}}^2{t_{12}}^2{t_{21}}^2 + 2t_{11}(2t_{01}t_{12} - (1+4t_{02}t_{12})t_{21})) = 0.$$

(3) $M=2$, $I=\{1\}$, $J=\{2\}$, $n_0=n_1=n_2=N_0=1$, $N_1=N_2=2$. In this case we take

$$z_0 = z_1 = E_1(p) = p + \frac{v_{11}}{p-q_1} + \frac{v_{21}}{p-q_2}, \quad z_2 = E_2(p) = \frac{w_{21}}{p-q_2} + \frac{w_{11}}{p-q_1} + c_0.$$

By equating the coefficients of p^1, p^0, $(p-q_i)^{-j}$, $i,j=1,2$ in (39) one finds

$$p^1: \quad t_{01} = c_0,$$

$$p^0: \quad -t_{10} - t_{20} = w_{11} + w_{21},$$

$$(p-q_1)^{-2}: \quad 2t_{12}{v_{11}}^2 = v_{11}w_{11},$$

$$(p-q_1)^{-1}: \quad v_{11}\left(t_{11} + 4t_{12}\left(q_1 + \frac{v_{21}}{q_1-q_2}\right)\right) = \left(q_1 + \frac{v_{21}}{q_1-q_2}\right)w_{11} + v_{11}\left(c_0 + \frac{w_{21}}{q_1-q_2}\right),$$

$$(p-q_2)^{-2}: \quad -2t_{22}{w_{21}}^2 = v_{21}w_{21},$$

$$(p-q_2)^{-1}: \quad -(t_{21}w_{21}) - 4t_{22}\left(c_0 + \frac{w_{11}}{-q_1+q_2}\right)w_{21} = c_0v_{21} + \frac{v_{21}w_{11} + (-(q_1q_2) + {q_2}^2 + v_{11})w_{21}}{-q_1+q_2},$$

and (41) leads to

$$-q_2t_{01} + t_{10} - \frac{t_{11}v_{11}}{-q_1+q_2} - 2t_{12}\left(\frac{{v_{11}}^2}{(-q_1+q_2)^2} + \frac{2v_{11}\left(q_1 + \frac{v_{21}}{q_1-q_2}\right)}{-q_1+q_2}\right) - t_{21}\left(c_0 + \frac{w_{11}}{-q_1+q_2}\right)$$
$$- 2t_{22}\left(\left(c_0 + \frac{w_{11}}{-q_1+q_2}\right)^2 - \frac{2w_{11}w_{21}}{(q_1-q_2)^2}\right) = 0.$$

By solving these equations one obtains

$$E_1(p) = p - \frac{2r_1{}^2 t_{12} + (t_{10}+t_{20})(1+4t_{12}t_{22}) - r_1(t_{01}-t_{11}+2t_{12}t_{21}+4t_{01}t_{12}t_{22})}{4(p-q_1)t_{12}(1+4t_{12}t_{22})}$$
$$- \frac{t_{22}(2r_1{}^2 t_{12} - (t_{10}+t_{20})(1+4t_{12}t_{22}) - r_1(t_{01}-t_{11}+2t_{12}t_{21}+4t_{01}t_{12}t_{22}))}{(p-q_2)(1+4t_{12}t_{22})},$$

$$E_2(p) = t_{01} - \frac{2r_1{}^2 t_{12} + (t_{10}+t_{20})(1+4t_{12}t_{22}) - r_1(t_{01}-t_{11}+2t_{12}t_{21}+4t_{01}t_{12}t_{22})}{2(p-q_1)(1+4t_{12}t_{22})}$$
$$+ \frac{2r_1{}^2 t_{12} - (t_{10}+t_{20})(1+4t_{12}t_{22}) - r_1(t_{01}-t_{11}+2t_{12}t_{21}+4t_{01}t_{12}t_{22})}{2(p-q_2)(1+4t_{12}t_{22})},$$

where

$$q_1 = \frac{r_1}{2} - \frac{(t_{10}+t_{20})(1+4t_{12}t_{22}) + r_1(t_{11}+2t_{12}t_{21}+t_{01}(-1+4t_{12}t_{22}))}{4r_1 t_{12}},$$

$$q_2 = -\frac{r_1}{2} - \frac{(t_{10}+t_{20})(1+4t_{12}t_{22}) + r_1(t_{11}+2t_{12}t_{21}+t_{01}(-1+4t_{12}t_{22}))}{4r_1 t_{12}},$$

and r_1 satisfies

$$-12r_1{}^4 t_{12}{}^2 + (t_{10}+t_{20})^2(1+4t_{12}t_{22})^2 + 8r_1{}^3 t_{12}(t_{01}-t_{11}+2t_{12}t_{21}+4t_{01}t_{12}t_{22}) - r_1{}^2(t_{11}{}^2 - 4t_{11}t_{12}t_{21}$$
$$- 2t_{01}(t_{11}-2t_{12}t_{21})(1+4t_{12}t_{22}) + (t_{01}+4t_{01}t_{12}t_{22})^2 + 4t_{12}(-t_{10}+t_{20}+t_{12}t_{21}{}^2 - 4t_{10}t_{12}t_{22}$$
$$+ 4t_{12}t_{20}t_{22})) = 0.$$

D. *S*-functions

According to the identities

$$\partial_p S_\alpha = \mathcal{M}_\alpha \partial_p \log z_\alpha, \quad \mathcal{M}_\alpha = m_\alpha z_\alpha,$$

it follows at once from (34), (35), and (37) that the functions $\partial_p S_\alpha$ are rational functions of p with finite poles at the points q_i $(i=1,\ldots,M)$ only. Thus we may decompose the functions $\partial_p S_\alpha$ into their principal parts

$$\partial_p S_\alpha = \sum_\beta (\partial_p S_\alpha)_{(\beta,+)}, \tag{43}$$

and, in view of asymptotic behavior (9), we may write

$$(\partial_p S_\alpha)_{(\alpha,+)} = \partial_p R_\alpha, \tag{44}$$

where

$$R_\alpha := \sum_{n\geqslant 1} (z_\alpha^n)_{(\alpha,+)} t_{\alpha n} - (1-\delta_{\alpha 0}) t_{\alpha 0} \log_\alpha (p-q_\alpha). \tag{45}$$

Further, from (34), (35), and (37) we obtain

$$\partial_p S_i = \partial_p S_0, \quad \forall\, i \in I,$$

$$\partial_p S_j = \partial_p S_0 - \frac{1}{n_0}\partial_p(E_1E_2), \quad \forall\, j \in J, \tag{46}$$

which leads to

$$S_\alpha = \begin{cases} \displaystyle\sum_\beta R_\beta + \frac{1}{n_0}\sum_{j\in J}(E_1E_2)_{(j,+)}, & \alpha \in \{0\}\cup I \\ \displaystyle\sum_\beta R_\beta - \frac{1}{n_0}(E_1E_2)_{(0,+)} - \frac{1}{n_0}\sum_{i\in I}(E_1E_2)_{(i,+)}, & \alpha \in J. \end{cases} \tag{47}$$

In principle, (46) implies the expressions (47) plus additional p-independent terms $w_\alpha(t)$. However these terms can be removed by using (8) and (9). Indeed, assymptotic behavior (9) for S_0 requires $w_0=0$. On the other hand, (8) says that

$$\mathrm{d}S_i - \mathrm{d}S_0 = m_i \mathrm{d}z_i - m_0 \mathrm{d}z_0,$$

so that by using the string equations (26) we deduce

$$\mathrm{d}w_i = \begin{cases} \mathrm{d}S_i - \mathrm{d}S_0 = 0, & i \in I \\ \mathrm{d}S_i - \mathrm{d}S_0 + \dfrac{1}{n_0}\mathrm{d}(E_1E_2) = 0, & i \in J. \end{cases}$$

E. τ-functions

Theorem 3: *The τ-function for the solutions of the Whitham hierarchy associated with the class of string equations* (26) *is given by*

$$\begin{aligned} 2\log\tau &= \sum_\alpha \frac{1}{2\pi i}\oint_{\Gamma_\alpha}\left(\sum_{n\geqslant 1} z_\alpha^n t_{\alpha n}\right) m_\alpha \mathrm{d}z_\alpha - \sum_{j\in J}\frac{1}{4\pi i n_j}\oint_{\Gamma_j} z_j m_j^2 \mathrm{d}z_j + \sum_i t_{i0}v_{i1} \\ &= \sum_\alpha \sum_{n\geqslant 0} t_{\alpha n} v_{\alpha n+1} - \sum_{j\in J}\frac{1}{n_j}\sum_{n\geqslant 1} n t_{jn} v_{jn+1} - \sum_{j\in J}\frac{t_{j0}^2}{2n_j} \end{aligned} \tag{48}$$

Proof: Our strategy to prove (48) is to start from the free-energy function for the algebraic orbits of the Whitham hierarchy[5]

$$F_0 := \sum_\alpha \frac{1}{4\pi i}\oint_{\Gamma_\alpha}\left(\sum_{n\geqslant 1} z_\alpha^n t_{\alpha n}\right) m_\alpha \mathrm{d}z_\alpha + \frac{1}{2}\sum_i t_{i0}v_{i1}, \tag{49}$$

and determine the appropriate modifications to get the free-energy function for the solutions of the class of string equations (26).

By differentiating F_0 with respect to t_{ln}, $n\geqslant 1$ we get

$$\partial_{l,n}F_0 = \frac{1}{4\pi i}\oint_{\Gamma_l} z_l^n m_l \mathrm{d}z_l + \sum_\alpha \frac{1}{4\pi i}\oint_{\gamma_\alpha}\left(\sum_{m\geqslant 1} z_\alpha^m t_{\alpha m}\right)\partial_p((z_l^n)_{(l,+)})\mathrm{d}p + \frac{1}{2}\sum_i t_{i0}\partial_{l,n}v_{i1}, \tag{50}$$

and arguing as in the derivation of (13), we find that

$$\oint_{\gamma_\alpha}\left(\sum_{m\geqslant 1} z_\alpha^m t_{\alpha m}\right)\partial_p((z_l^n)_{(l,+)})\mathrm{d}p = \oint_{\gamma_l} z_l^n \partial_p\left(\sum_{m\geqslant 1}(z_\alpha^m)_{(\alpha,+)} t_{\alpha m}\right)\mathrm{d}p.$$

On the other hand, for $i\neq l$ we have

$$\partial_{l,n}S_i = (z_l^n)_{(l,+)} = -\partial_{l,n}v_{i1} + \mathcal{O}\left(\frac{1}{z_i}\right), \quad p \to q_i,$$

so that

$$\begin{aligned}\partial_{l,n}v_{i1} &= -(z_l^n)_{(l,+)}(q_i)\\ &= \frac{1}{2\pi i}\oint_{\gamma_i}\frac{(z_l^n)_{(l,+)}}{p-q_i}\mathrm{d}p = -\frac{1}{2\pi i}\oint_{\gamma_l}(z_l^n)_{(l,+)}\partial_p\log(p-q_i)\mathrm{d}p\\ &= -\frac{1}{2\pi i}\oint_{\gamma_l} z_l^n\partial_p\log(p-q_i)\mathrm{d}p, \quad i\neq l,\end{aligned}$$

and the same expression turns out to hold for $i=l$. Hence, (50) can be rewritten as

$$\begin{aligned}\partial_{l,n}F_0 &= \frac{1}{2}v_{ln+1} + \frac{1}{4\pi i}\oint_{\gamma_l} z_l^n\sum_\alpha\partial_p\left(\sum_{m\geqslant 1}(z_\alpha^m)_{(\alpha,+)}t_{\alpha m} - (1-\delta_{\alpha 0})t_{\alpha 0}\log(p-q_\alpha)\right)\mathrm{d}p\\ &= v_{ln+1} + \frac{1}{4\pi i}\oint_{\gamma_l} z_l^n\left(\sum_\alpha\partial_p R_\alpha - \partial_p S_l\right)\mathrm{d}p\\ &= v_{ln+1} + \sum_\alpha\frac{1}{4\pi i}\oint_{\gamma_l}(z_l^n)_{(l,+)}(\partial_p R_\alpha - (\partial_p S_l)_{(\alpha,+)})\mathrm{d}p. \end{aligned} \tag{51}$$

Further, we have that

$$\begin{aligned}\frac{1}{4\pi i}\oint_{\gamma_l}(z_l^n)_{(l,+)}(\partial_p R_\alpha - (\partial_p S_l)_{(\alpha,+)})\mathrm{d}p &= -\frac{1}{4\pi i}\oint_{\gamma_\alpha}(z_l^n)_{(l,+)}(\partial_p R_\alpha - (\partial_p S_l)_{(\alpha,+)})\mathrm{d}p\\ &= -\frac{1}{4\pi i}\oint_{\gamma_\alpha}(z_l^n)_{(l,+)}(\partial_p S_\alpha - \partial_p S_l)\mathrm{d}p,\end{aligned}$$

so that from (46) and by taking into account

$$\oint_{\gamma_0}(z_l^n)_{(l,+)}\partial_p(E_1E_2)\mathrm{d}p = -\sum_{i=1}^M\oint_{\gamma_i}(z_l^n)_{(l,+)}\partial_p(E_1E_2)\mathrm{d}p,$$

we get

$$\begin{aligned}\partial_{l,n}F_0 &= v_{ln+1} + \frac{1}{n_0}\sum_{j\in J}\frac{1}{4\pi i}\oint_{\gamma_j}(z_l^n)_{(l,+)}\partial_p(E_1E_2)\mathrm{d}p = v_{ln+1} + \sum_{j\in J}\frac{1}{4\pi i n_j}\oint_{\Gamma_j} z_j m_j\partial_{l,n}m_j\mathrm{d}z_j\\ &= v_{ln+1} + \partial_{l,n}\left(\sum_{j\in J}\frac{1}{8\pi i n_j}\oint_{\Gamma_j} z_j m_j^2\mathrm{d}z_j\right),\end{aligned} \tag{52}$$

which shows that

$$\partial_{l,n}\log\tau = v_{ln+1}.$$

By a similar procedure one finds

$$\partial_{0,n}\log\tau = v_{0n+1}, \quad n\geqslant 1.$$

Nevertheless, proving that

$$\partial_{l,0}\log\tau = v_{l1}, \quad l = 1, \ldots, M \tag{53}$$

requires a more involved analysis. First we differentiate F_0 with respect to t_{l0}

$$\partial_{l,0}F_0 = \sum_\alpha \frac{1}{4\pi i}\oint_{\gamma_\alpha}\left(\sum_{m\geqslant 1} z_\alpha^m t_{\alpha m}\right)\partial_p(-\log(p-q_l))\mathrm{d}p + \frac{1}{2}\sum_i t_{i0}\partial_{l,0}v_{i1} + \frac{1}{2}v_{l1}, \tag{54}$$

and use the following relations:

$$\oint_{\gamma_\alpha}\left(\sum_{m\geqslant 1} z_\alpha^m t_{\alpha m}\right)\frac{1}{p-q_l}\mathrm{d}p = -\oint_{\gamma_l}\left(\sum_{m\geqslant 1}(z_\alpha^m)_{(\alpha,+)}t_{\alpha m}\right)\frac{1}{p-q_l}\mathrm{d}p, \quad \alpha \neq l,$$

$$\oint_{\gamma_l}\left(\sum_{m\geqslant 1} z_l^m t_{lm}\right)\frac{1}{p-q_l}\mathrm{d}p = -2\pi i\lim_{p\to q_l}\left(\sum_{m\geqslant 1}(z_l^m - (z_l^m)_{(l,+)})t_{lm}\right),$$

$$\sum_{i\neq l} t_{i0}\partial_{l0}v_{i1} = \sum_{i\neq l} t_{i0}\log_l(q_i - q_l) - \sum_{i>l} t_{i0}\log_{li}(-1) = \sum_{i\neq l} t_{i0}\log_i(q_l - q_i) - \sum_{i<l} t_{i0}\log_{il}(-1),$$

$$\partial_{l,0}v_{l1} = \lim_{p\to q_l}\log(z_l(p-q_l)).$$

Then (54) becomes

$$\begin{aligned}\partial_{l,0}F_0 = {} & \frac{1}{2}v_{l1} + \frac{1}{4\pi i}\oint_{\gamma_l}\frac{\mathrm{d}p}{p-q_l}\sum_{\alpha\neq l}\left(\sum_{m\geqslant 1}(z_\alpha^m)_{(\alpha,+)}t_{\alpha m} - (1-\delta_{\alpha 0})t_{\alpha 0}\log_\alpha(p-q_\alpha)\right) \\ & + \frac{1}{2}\lim_{p\to q_l}\left(\sum_{m\geqslant 1}(z_l^m - (z_l^m)_{(l,+)})t_{lm} + t_{l0}\log z_l + \ t_{l0}\log_l(p-q_l)\right) - \frac{1}{2}\sum_{i<l} t_{i0}\log_{il}(-1).\end{aligned} \tag{55}$$

Further, from asymptotic expansion (9) of S_l we have that

$$v_l = \lim_{p\to q_l}\left(\sum_{m\geqslant 1} z_l^m t_{lm} + t_{l0}\log z_l - S_l\right),$$

which allows us to rewrite (55) in the form

$$\partial_{l,0}F_0 = v_{l1} + \frac{1}{4\pi i}\oint_{\gamma_l}\frac{\mathrm{d}p}{p-q_l}\sum_{\alpha\neq l} R_\alpha + \frac{1}{2}\lim_{p\to q_l}(S_l - R_l) = v_{l1} + \frac{1}{4\pi i}\oint_{\gamma_l}\frac{\mathrm{d}p}{p-q_l}\left(\sum_\alpha R_\alpha - S_l\right). \tag{56}$$

Now by using (47) it is straightforward to see that

$$\frac{1}{4\pi i}\oint_{\gamma_l}\frac{\mathrm{d}p}{p-q_l}\left(\sum_\alpha R_\alpha - S_l\right) = \frac{1}{n_0}\sum_{j\in J}\frac{1}{4\pi i}\oint_{\gamma_j}\frac{\mathrm{d}p}{p-q_l}E_1E_2 = \sum_{j\in J}\frac{1}{4\pi i n_j}\oint_{\Gamma_j} z_j m_j\partial_{l,0}m_j\mathrm{d}z_j, \tag{57}$$

which shows that (56) is equivalent to (53). □

F. Conformal maps dynamics

We will outline how our scheme applies for characterizing dToda dynamics of conformal maps, and, in particular, how (48) gives rise to the expression of the τ-function of analytic curves found in Ref. 10.

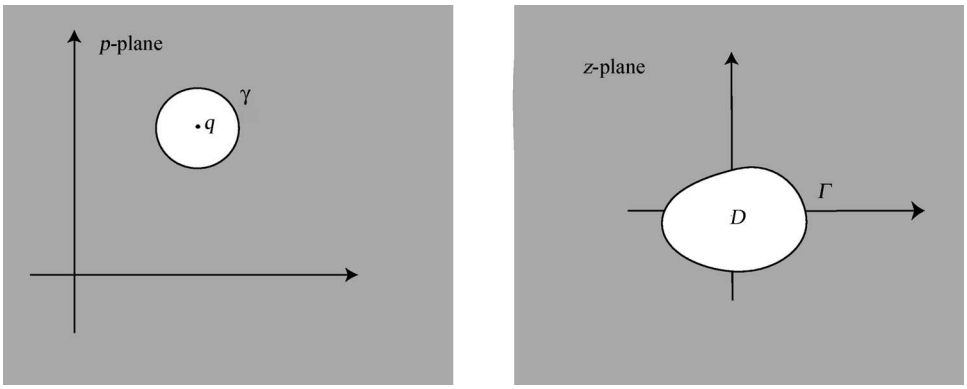

FIG. 2. Conformal map $z=z(p)$.

Given a simply connected domain D bounded by a closed path Γ in the z-plane, there exists[27] a unique circle γ in the p-plane and a unique conformal map $z=z(p)$ satisfying

$$z(p) = p + \sum_{n=1}^{\infty} \frac{d_n}{p^n}, \quad z \to \infty, \tag{58}$$

such that $z=z(p)$ transforms the exterior of γ into the exterior of Γ (see Fig. 2). Note that the conformal map used by Wiegmann-Zabrodin[10] is given by $z(rp+q)$, where q and r are the center and the radius of γ, respectively.

Let us define the function

$$\bar{z}(p) = \overline{z(\mathcal{I}_\gamma(p))}, \tag{59}$$

where $\mathcal{I}_\gamma$ denotes the inversion with respect to the circle γ

$$\mathcal{I}_\gamma(p) := q + \frac{r^2}{\bar{p} - \bar{q}}.$$

It is clear that

$$\bar{z}(p) = \overline{z(p)}, \quad \forall\, p \in \gamma.$$

If Γ is asssumed to be an analytic curve, then it can be described by an equation of the form

$$\bar{z} = \mathcal{S}(z), \tag{60}$$

where $\mathcal{S}(z) := \bar{z}(p(z))$ (the Schwarz function) is analytic in a neigborhood of γ. Thus, if Γ encircles the origin, $\mathcal{S}(z)$ can be expanded as

$$\mathcal{S}(z) = \sum_{n\geqslant 1} n t_n z^{n-1} + \frac{t_0}{z} + \sum_{n\geqslant 1} \frac{v_n(t)}{z^{n+1}}, \tag{61}$$

where the coefficients t_n $(n \geqslant 0)$, the exterior harmonic moments of Γ, determine the curve Γ and conformal map (58). Note, in particular, that the coefficient t_0,

$$t_0 = \frac{1}{2\pi i} \oint_\Gamma \bar{z} \mathrm{d}z = \frac{1}{\pi} \int_D \mathrm{d}x\mathrm{d}y,$$

represents the area of D.

In this way, by considering the harmonic moments as independent complex parameters, if we define

$$q_1 = q, \quad z_0(p) = z(p), \quad z_1(p) = \bar{z}(p),$$

$$t_{0n} := t_n, \quad t_{1n} = -\bar{t}_n, \quad n \geqslant 0,$$

$$m_0 = \mathcal{S}(z_0), \quad m_1 = -z(p(z_1)),$$

we obtain a solution of the system of string equations

$$-m_1 = z_0, \quad z_1 = m_0. \tag{62}$$

Further, by taking into account that

$$v_{1n+1} = -\bar{v}_{0n+1} = -\bar{v}_n, \quad n \geqslant 1,$$

and the identity

$$t_0^2 + 2\sum_{n\geqslant 1} n t_n v_n = \frac{1}{2\pi i}\oint_\Gamma z\mathcal{S}(z)^2 \mathrm{d}z = \frac{1}{2\pi i}\oint_\Gamma z\bar{z}^2 \mathrm{d}z = \frac{1}{\pi}\int_D |z|^2 \mathrm{d}x\mathrm{d}y = \bar{t}_0^2 + 2\sum_{n\geqslant 1} n\bar{t}_n\bar{v}_n,$$

we see that (48) reduces to

$$2\log\tau = \frac{1}{2}\sum_{n\geqslant 1}(2-n)(t_n v_n + \bar{t}_n\bar{v}_n) + t_0 v_0 - \frac{t_0^2}{2}, \tag{63}$$

where $v_0 := -v_{11}$, which is the expression for the τ-function associated to analytic curves obtained in Ref. 10. Notice that (62) is the simplest nontrivial case ($I=\emptyset$, $J=\{1\}$, $n_0=n_1=1$) of the class of string equations (26).

G. Symmetry constraints

As we proved earlier, solutions (z_α, m_α) of systems of string equations (14) are invariant under the symmetries

$$\mathbb{V}_{rs} = (P_0^{r+1}Q_0^{s+1}, \ldots, P_M^{r+1}Q_M^{s+1}), \quad r \geqslant -1, s \geqslant 0.$$

Moreover, as a consequence of (14) we have that the following identities hold:

$$P_0^{r+1}Q_0^{s+1} = P_i^{r+1}Q_i^{s+1} = P_j^{r+1}Q_j^{s+1} = P_0^{r+1}Q_j^{s+1}, \quad \forall\, i \in I, j \in J, \tag{64}$$

for the values of the functions P_μ and Q_μ at a solution (z_α, m_α). In particular these identities lead to the following expressions for the constraints arising from the invariance of (26) under the action of $\mathbb{V}_{rs}$.

Theorem 4: *If* (z_α, m_α) *is a solution of the string equations* (26) *then it satisfies the identities*

$$\sum_{\alpha\in\{0\}\cup I}\oint_{\Gamma_\alpha}\left(\frac{z_\alpha}{n_\alpha}\right)^s z_\alpha^{(r-s)n_\alpha} m_\alpha^{s+1}\mathrm{d}z_\alpha + (-1)^r\frac{s+1}{r+1}n_0^{r-s}\sum_{j\in J}\oint_{\Gamma_j}\left(\frac{z_j}{n_j}\right)^r z_j^{(s-r)n_j} m_j^{r+1}\mathrm{d}z_j = 0, \tag{65}$$

for all $r, s \geqslant 0$.

Proof: From (34)–(37) we find that (64) takes the form

$$z_0^{n_0(r+1)}\left(\frac{1}{n_0}\frac{m_0}{z_0^{n_0-1}}\right)^{s+1}=z_i^{n_i(r+1)}\left(\frac{1}{n_i}\frac{m_i}{z_i^{n_i-1}}\right)^{s+1}=\left(\frac{z_j^{n_j}}{n_0}\right)^{s+1}\left(-\frac{n_0}{n_j}\frac{m_j}{z_j^{n_j-1}}\right)^{r+1}$$

$$=\frac{1}{n_0^{s+1}}E_1^{r+1}E_2^{s+1},\quad \forall\, i\in I, j\in J, \tag{66}$$

and we have that

$$z_0^{n_0(r+1)}\left(\frac{1}{n_0}\frac{m_0}{z_0^{n_0-1}}\right)^{s+1}\partial_p\log E_1=z_i^{n_i(r+1)}\left(\frac{1}{n_i}\frac{m_i}{z_i^{n_i-1}}\right)^{s+1}\partial_p\log E_1=\frac{(\partial_p E_1^{r+1})E_2^{s+1}}{(r+1)n_0^{s+1}}, \tag{67}$$

$$\left(\frac{z_j^{n_j}}{n_0}\right)^{s+1}\left(-\frac{n_0}{n_j}\frac{m_j}{z_j^{n_j-1}}\right)^{r+1}\partial_p\log E_2=-\frac{r+1}{s+1}z_0^{n_0(r+1)}\left(\frac{1}{n_0}\frac{m_0}{z_0^{n_0-1}}\right)^{s+1}\partial_p\log E_1+\partial_p\left(\frac{E_1^{r+1}E_2^{s+1}}{(s+1)n_0^{s+1}}\right),$$

for all $r,s\geqslant 0$ and $i\in I$, $j\in J$. Hence if we proceed as in the proof of (42) and take into account that

$$\partial_p\log E_1=n_0\partial_p\log z_0=n_i\partial_p\log z_i,\quad \forall\, i\in I,$$

$$\partial_p\log E_2=n_j\partial_p\log z_j,\quad \forall\, j\in J,$$

it is straightforward to prove that

$$\sum_{\alpha\in\{0\}\cup I}\oint_{\Gamma_\alpha}z_\alpha^{n_\alpha(r+1)}\left(\frac{1}{n_\alpha}\frac{m_\alpha}{z_\alpha^{n_\alpha-1}}\right)^{s+1}n_\alpha\frac{\mathrm{d}z_\alpha}{z_\alpha}-\sum_{j\in J}\frac{s+1}{r+1}\oint_{\Gamma_j}\left(\frac{z_j^{n_j}}{n_0}\right)^{s+1}\left(-\frac{n_0}{n_j}\frac{m_j}{z_j^{n_j-1}}\right)^{r+1}n_j\frac{\mathrm{d}z_j}{z_j}$$

$$=\oint_\gamma z_0^{n_0(r+1)}\left(\frac{1}{n_0}\frac{m_0}{z_0^{n_0-1}}\right)^{s+1}\partial_p\log E_1\mathrm{d}p=\oint_\gamma\frac{(\partial_p E_1^{r+1})E_2^{s+1}}{(r+1)n_0^{s+1}}\mathrm{d}p=0, \tag{68}$$

where $\gamma:=\Sigma_{\alpha=0}^M\gamma_\alpha$. This proves that the identities (65) hold. □

By evaluating the integrals of the left-hand side we obtain the symmetry constraints in terms of differential equations for the free-energy function $F=\log\tau$.

Examples: For $r=s=0$, Eq. (68) reduces to (42), so that it implies

$$\sum_\alpha t_{\alpha 0}=0.$$

The cases $(r,s)=(1,0)$ and $(r,s)=(2,0)$ correspond to the Virasoro constraints induced by $\mathbb{V}_1$ and $\mathbb{V}_2$, respectively, and lead to the identities

$$\sum_{\alpha\in\{0\}\cup I}\partial_{\alpha,n_\alpha}F-\sum_{j\in J}\frac{n_0}{n_j}\left(\sum_{n-n'=n_j-1}nt_{jn}\partial_{j,n'-1}F+n_jt_{jn_j}t_{j0}+\frac{1}{2}\sum_{n+n'=n_j}nn't_{jn}t_{jn'}\right)=0,$$

$$\sum_{\alpha\in\{0\}\cup I}\partial_{\alpha,2n_\alpha}F+\sum_{j\in J}\left(\frac{n_0}{n_j}\right)^2\left(\sum_{n-n'-n''=2n_j-2}nt_{jn}(\partial_{j,n'-1}F)(\partial_{j,n''-1}F)+2\sum_{n-n'=2n_j-1}nt_{jn}t_{j0}\partial_{j,n'-1}F\right.$$

$$+\sum_{n+n'-n''=2n_j-1}nn't_{jn}t_{jn'}\partial_{j,n''-1}F+2n_jt_{j2n_j}t_{j0}^2+\sum_{n+n'=2n_j}nn't_{jn}t_{jn'}t_{j0}$$

$$\left.+\frac{1}{3}\sum_{n+n'+n''=2n_j}nn'n''t_{jn}t_{jn'}t_{jn''}\right)=0.$$

On solutions of the two-component Camassa-Holm system

Chao-Zhong Wu[a)]
Department of Mathematical Sciences, Tsinghua University, Beijing 100084, People's Republic of China

(Received 31 May 2006; accepted 13 June 2006; published online 24 August 2006)

Following the approach of [Chen *et al.*Lett. Math. Phys. **75**, 1–15 (2006)], we continue the study of the two-component Camassa-Holm system by using its relation with the first negative flow of the AKNS hierarchy. We obtain a more general class of particular solutions including the multisoliton ones. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2234729]

I. INTRODUCTION

The Camassa-Holm equation

$$u_t - u_{xxt} + \kappa u_x + 3uu_x - 2u_x u_{xx} - uu_{xxx} = 0 \tag{1.1}$$

is an integrable system that was derived in Refs. 5 and 6 as a shallow water wave equation. Here κ is a constant, $u=u(x,t)$ and u_x, u_t, etc., denote the partial derivatives of the function u with respect to the variables of the subscripts. Equation (1.1) first appeared in the work of Fuchssteiner and Fokas[10] when they studied the hereditary symmetries of soliton PDEs. Due to its physical background and its special features such as the existence of peakon solutions, the Camassa-Holm equation has drawn much attention among experts in soliton theory during the last ten years. See Refs. 1, 2, 9, 11, 12, and 14–17, and references therein.

Recently a two-component generalization of the Camassa-Holm equation, called the two-component Camassa-Holm (2-CH) system, was proposed by Liu and Zhang in Ref. 15 (see also Ref. 8). It takes the form

$$m_t + um_x + 2mu_x - \rho\rho_x = 0, \tag{1.2}$$

$$\rho_t + (\rho u)_x = 0, \tag{1.3}$$

where $m=u-u_{xx}+\frac{1}{2}\kappa$. This system is reduced to the Camassa-Holm equation when we set $\rho=0$. In Ref. 7, Chen *et al.* proved that the 2-CH system is related to the first negative flow of the AKNS hierarchy through an appropriate reciprocal transformation. By using this relation, they obtained multikink solutions and traveling peakon solutions of the 2-CH system. Some recent works on the properties of the 2-CH system can be found in Refs. 3, 4, 8, and 18.

In this note, we consider the special solutions of the 2-CH system. We obtain a more general class of peakon and multikink solutions and, in particular, its multisoliton solutions by using a relation between the 2-CH system and the first negative flow of the AKNS hierarchy. This relation was first found by Li[13] following the idea of Ref. 7 and is simpler than the one given there. In Sec. II, we explain the relations between the 2-CH system and the first negative flow of the AKNS hierarchy; in Sec. III, we derive the traveling wave solutions of the 2-CH system; in Sec. IV we construct its multikink and multisoliton solutions.

II. RELATIONS TO THE FIRST NEGATIVE FLOW OF THE AKNS HIERARCHY

Let us first recall some results of Ref. 7. Since the parameter κ in (1.2) can be canceled through a Galilean transformation, we assume henceforth that κ vanishes unless otherwise stated. Then the 2-CH system (1.2), (1.3) is equivalent to the compatibility condition of the spectral problem

$$\phi_{xx} + \left(-\tfrac{1}{4} + m\lambda - \rho^2\lambda^2\right)\phi = 0, \tag{2.1}$$

$$\phi_t + \left(\frac{1}{2\lambda} + u\right)\phi_x - \frac{u_x}{2}\phi = 0 \tag{2.2}$$

with the spectral parameter λ. Assume $\rho \neq 0$ and denote $\varphi = \sqrt{\rho}\phi$. Through the reciprocal transformation

$$\mathrm{d}y = \rho \mathrm{d}x - \rho u \mathrm{d}t, \quad \mathrm{d}s = \mathrm{d}t, \tag{2.3}$$

the linear system (2.1), (2.2) is converted to

$$\varphi_{yy} + (Q + P\lambda - \lambda^2)\varphi = 0, \tag{2.4}$$

$$\varphi_s + \frac{\rho}{2\lambda}\varphi_y - \frac{\rho_y}{4\lambda}\varphi = 0 \tag{2.5}$$

with

$$P = \frac{m}{\rho^2}, \quad Q = -\frac{1}{4\rho^2} - \frac{\rho_{yy}}{2\rho} + \frac{\rho_y^2}{4\rho^2}. \tag{2.6}$$

The linear system (2.4), (2.5) is compatible iff there exists a function $f = f(y,s)$ satisfying the following:

$$P = f_y, \quad \rho = f_s, \tag{2.7}$$

$$\partial_y(f_y f_s) + \partial_s\left(\frac{f_y^2}{2} + \frac{f_{ys}^2 - 1}{2f_s^2} - \frac{f_{yys}}{f_s}\right) = 0. \tag{2.8}$$

Any function $f(y,s)$ satisfying Eq. (2.8) is called a *primary solution*[7] of the 2-CH system (1.2), (1.3). It plays a crucial role in constructing parametric solutions of the 2-CH system.

Theorem 2.1 (Ref. 7): *Let $f(y,s)$ be a solution of Eq.* (2.8), *then the functions $x(t,s)$, $u(t,s)$, $\rho(t,s)$ defined by*

$$x = f(t,s), \quad u = \frac{\partial x}{\partial t}, \quad \frac{1}{\rho} = \frac{\partial x}{\partial s} \tag{2.9}$$

give a parametric solution of the 2-CH system (1.2), (1.3).

The first negative flow of the AKNS hierarchy is equivalent to the compatibility condition of the spectral problem

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_y = \begin{pmatrix}\lambda & -q\\ r & -\lambda\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{2.10}$$

$$\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}_s = \frac{1}{4\lambda}\begin{pmatrix}a & b\\ c & -a\end{pmatrix}\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix}, \tag{2.11}$$

where λ is the spectral parameter. This flow is expressed as

$$q_s = \tfrac{1}{2}b, \quad r_s = \tfrac{1}{2}c, \quad b_y = 2aq, \quad c_y = 2ar, \quad a_y + br + cq = 0. \tag{2.12}$$

The 2-CH system is related to it under the constraint

$$a^2 + bc = 1. \tag{2.13}$$

Theorem 2.2 (Ref. 7): *Suppose the functions q,r,a,b,c satisfy the system* (2.12), (2.13). *Then any solution $f(y,s)$ of*

$$2a = be^{-f} - ce^{f} \tag{2.14}$$

is a primary solution of the 2-CH system.

Theorem 2.3 (Ref. 7): *If $f(y,s)$ is a primary solution of the 2-CH system, then a solution (q,r,a,b,c) of the system* (2.12), (2.13) *is given by*

$$q = \frac{e^f}{2}\left(f_y + \frac{\varepsilon - f_{ys}}{f_s}\right), \quad r = \frac{e^{-f}}{2}\left(f_y - \frac{\varepsilon - f_{ys}}{f_s}\right),$$

$$b = 2q_s, \quad c = 2r_s, \quad a = \tfrac{1}{2}(be^{-f} - ce^{f}), \tag{2.15}$$

where $\varepsilon = 1$ or $\varepsilon = -1$.

The above-presented theorems establish an explicit relation between the 2-CH system and the first negative flow of the AKNS hierarchy satisfying (2.13). The following theorem, obtained by Li,[13] gives another relation between these two systems.

Theorem 2.4: *Let the functions $q(y,s)$, $r(y,s)$, $a(y,s)$, $b(y,s)$, $c(y,s)$ give a solution of the system* (2.12), (2.13). *If neither of q, q_s (respectively, r, r_s) vanishes at any point, then the function $f(y,s)$ defined by*

$$f = \ln q \quad (\textit{respectively}, \ f = \ln r) \tag{2.16}$$

is a primary solution of the 2-CH system.

Proof: The functions q,r,a,b,c satisfying the conditions of the theorem determine a compatible linear system (2.10), (2.11). Since the system (2.12), (2.13) is invariant under the transformation $(q,r,a,b,c) \mapsto (r,q,a,c,b)$, we only need to prove the case $f = \ln q$. For this, let

$$\varphi = e^{-f/2}\psi_1, \quad P = f_y = \frac{q_y}{q}, \quad \rho = f_s = \frac{q_s}{q}, \quad Q = \frac{1}{\rho^2}\left(\frac{1}{4}\rho_y^2 - \frac{1}{2}\rho\rho_{yy} - \frac{1}{4}\right). \tag{2.17}$$

With the help of (2.12), (2.13) we can simplify the expression of Q to the form

$$Q = \frac{1}{2}\frac{q_{yy}}{q} - \frac{3}{4}\frac{q_y^2}{q^2} + qr. \tag{2.18}$$

To prove the theorem, we need to check that (2.17) transforms the linear system (2.10), (2.11) to (2.4), (2.5). From (2.10), (2.11) it follows that

$$\varphi_s = -\frac{f_s}{2}e^{-f/2}\psi_1 + e^{-f/2}\left(\frac{a}{4\lambda}\psi_1 + \frac{b}{4\lambda}\psi_2\right) = \left(\left(-\frac{q_s}{2q} + \frac{a}{4\lambda}\right)\psi_1 + \frac{b}{4\lambda}\psi_2\right)e^{-f/2}, \tag{2.19}$$

$$\varphi_y = -\frac{f_y}{2}e^{-f/2}\psi_1 + e^{-f/2}(\lambda\psi_1 - q\psi_2) = \left(\left(-\frac{q_y}{2q} + \lambda\right)\psi_1 - q\psi_2\right)e^{-f/2}. \tag{2.20}$$

They yield the needed result

$$4\lambda\left(\varphi_s + \frac{\rho}{2\lambda}\varphi_y - \frac{\rho_y}{4\lambda}\varphi\right) = \left(-2\lambda\frac{q_s}{q} + a + 2\frac{q_s}{q}\left(-\frac{q_y}{2q} + \lambda\right) - \frac{q_{ys}}{q} + \frac{q_y q_s}{q^2}\right)\psi_1 e^{-f/2} + (b - 2q_s)\psi_2 e^{-f/2} = 0,$$

$$\varphi_{yy} = \left(-\frac{f_y}{2}\left(-\frac{q_y}{2q} + \lambda\right) - \frac{1}{2}\left(\frac{q_{yy}}{q} - \frac{q_y^2}{q^2}\right)\right)\psi_1 e^{-f/2} + \left(\frac{f_y}{2}q - q_y\right)\psi_2 e^{-f/2}$$
$$+ \left(-\frac{q_y}{2q} + \lambda\right)(\lambda\psi_1 - q\psi_2)e^{-f/2} - q(r\psi_1 - \lambda\psi_2)e^{-f/2}$$

$$= \left(\frac{q_y^2}{4q^2} - \frac{q_{yy}}{2q} + \frac{q_y^2}{2q^2} - qr - \frac{q_y}{q}\lambda + \lambda^2\right)\psi_1 e^{-f/2} = -(Q + \lambda P - \lambda^2)\varphi.$$

The theorem is proved. □

Note that the transformation $(q,r,a,b,c) \mapsto (-q,-r,a,-b,-c)$ keeps (2.12), (2.13) invariant, hence without loss of generality we can take q to be always positive. Then by using Theorem 2.3 and Theorem 2.4, the following two corollaries are easily obtained.

Corollary 2.5: Equation (2.8) *is invariant under the following Bäcklund transformations*:

$$\mathcal{Q}_\varepsilon : f \mapsto f + \ln\left(\frac{f_y f_s - f_{ys} + \varepsilon}{2f_s}\right), \quad \varepsilon = 1 \text{ or } \varepsilon = -1. \tag{2.21}$$

Corollary 2.6: For $\varepsilon = 1$ *or* $\varepsilon = -1$, *the system* (2.12), (2.13) *is invariant under the transformation*

$$q \mapsto \tilde{q} = q_y + \frac{q(\varepsilon q - q_{ys})}{2q_s}, \quad r \mapsto \tilde{r} = \frac{1}{2q_s}\left(-\varepsilon + \frac{q_{ys}}{q}\right),$$

$$b \mapsto \tilde{b} = 2\tilde{q}_s, \quad c \mapsto \tilde{c} = 2\tilde{r}_s, \quad a \mapsto \tilde{a} = \frac{\tilde{q}_s}{q} - q\tilde{r}_s. \tag{2.22}$$

Remark 2.7: The Bäcklund transformations (2.21) of Eq. (2.8) correspond to the relation $f = \ln q$ in Theorem 2.4. The Bäcklund transformations of (2.8) corresponding to $f = \ln r$ also take the form (2.21) modulo the trivial Bäcklund transformations: $f \mapsto -f$ and $f \mapsto f + c_0$ (c_0 is any constant).

Proposition 2.8: If $f(y,s)$ *is a primary solution of the 2-CH system*, *then the functions* q,r,a,b,c *defined by*

$$q = e^f, \quad r = \frac{1}{2}\left(\frac{f_y^2}{2} - f_{yy} - \frac{f_{yys}}{f_s} + \frac{f_{ys}^2 - 1}{2f_s^2}\right)e^{-f},$$

$$a = f_{ys} + f_y f_s, \quad b = 2f_s e^f, \quad c = \frac{1 - (f_{ys} + f_y f_s)^2}{2f_s}e^{-f} \tag{2.23}$$

satisfy (2.12), (2.13).

Proof: We only need to check $r_s = \frac{1}{2}c$. It holds true because

$$2r_s = \partial_s\left(\frac{f_y^2}{2} - \frac{f_{yys}}{f_s} + \frac{f_{ys}^2 - 1}{2f_s^2}\right)e^{-f} - f_{yys}e^{-f} - f_s\left(\frac{f_y^2}{2} - f_{yy} - \frac{f_{yys}}{f_s} + \frac{f_{ys}^2 - 1}{2f_s^2}\right)e^{-f}$$

$$=\left(\partial_y(f_y f_s)+\partial_s\left(\frac{f_y^2}{2}+\frac{f_{ys}^2-1}{2f_s^2}-\frac{f_{yys}}{f_s}\right)\right)e^{-f}+\left(-f_y f_{ys}-\frac{f_y^2 f_s}{2}-\frac{f_{ys}^2-1}{2f_s}\right)e^{-f}=c.$$

Here the last equality follows from Eq. (2.8). The proposition is proved. □

Theorem 2.4 together with Theorem 2.1 provides a simple method to construct parametric solutions of the 2-CH system. For example, the multikink solutions like those given in Ref. 7 can be found immediately. This method will be used in Sec. IV to get a more general class of solutions including multisoliton ones.

III. TRAVELING WAVE SOLUTIONS

In this section we keep the parameter κ in the 2-CH system (1.2), (1.3) to be an arbitrary constant. Suppose the 2-CH system has a solution of the form

$$u(x,t)=h(z),\quad \rho(x,t)=g(z)$$

where $z=x+vt$ with v being a constant. Then the 2-CH system (1.2), (1.3) is reduced to

$$v(h'-h''')+3hh'-2h'h''-hh'''+\kappa h'-gg'=0, \tag{3.1}$$

$$vg'+gh'+hg'=0. \tag{3.2}$$

Assume that there exists a constant θ such that as $z\to\pm\infty$,

$$h\to\theta-v,\quad \frac{\mathrm{d}^i h}{\mathrm{d}z^i}\to 0\quad \text{for } i=1,2,\ldots\ . \tag{3.3}$$

Then by integrating Eqs. (3.1), (3.2) we obtain

$$g=\frac{A}{h+v},\quad h'^2=\frac{A^2}{(h+v)^2}-\frac{C}{h+v}+B-(2v-\kappa)(h+v)+(h+v)^2. \tag{3.4}$$

Here A,B,C are constants and because of (3.3) we have

$$B=\frac{A^2}{\theta^2}+2(2v-\kappa)\theta-3\theta^2,\quad C=\frac{2A^2}{\theta}+(2v-\kappa)\theta^2-2\theta^3. \tag{3.5}$$

Denote $\tilde{h}=h+v-\theta$, $\alpha=v-\frac{1}{2}\kappa-2\theta$ and assume

$$\beta^2=\frac{A^2}{\theta^2}-(2v-\kappa)\theta+3\theta^2>0. \tag{3.6}$$

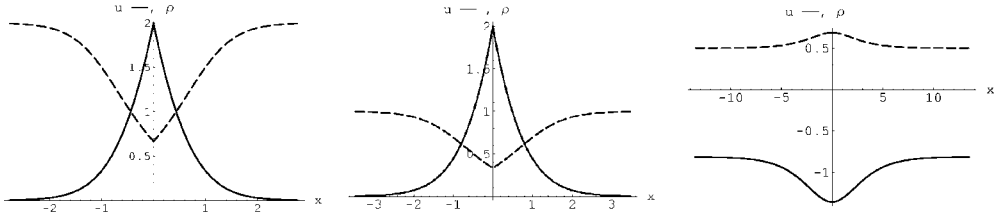
Then we rewrite the second equation in (3.4) to

$$\tilde{h}'^2=\frac{\tilde{h}^2(\tilde{h}^2-2\alpha\tilde{h}+\beta^2)}{(\tilde{h}+\theta)^2} \tag{3.7}$$

with

$$\alpha^2-\beta^2=\left(v-\theta-\frac{1}{2}\kappa\right)^2-\frac{A^2}{\theta^2}. \tag{3.8}$$

From (3.7) we get



(a) $x_0=0, u_0=2, \theta=1, v=1, \kappa=2, A=2, \alpha=-2, \beta=\sqrt{7}, \alpha^2-\beta^2<0$;
(b) $\varepsilon_1=\varepsilon_2=1, x_0=0, u_0=2, \theta=1, v=1, \kappa=2, A=1, \alpha=-2, \beta=2, \alpha^2-\beta^2=0$;
(c) $\varepsilon_3=1, \varepsilon_4=-1, \theta=2, v=45/16, \kappa=0, A=1, \alpha=-19/16, \beta=1, \alpha^2-\beta^2>0$.

FIG. 1. Traveling wave solution (3.10) at $t=0$.

$$\varepsilon z+c_\varepsilon=\begin{cases}\sinh^{-1}\left(\dfrac{\tilde{h}-\alpha}{\sqrt{\beta^2-\alpha^2}}\right)-\dfrac{\theta}{\beta}\sinh^{-1}\left(\dfrac{\beta^2/\tilde{h}-\alpha}{\sqrt{\beta^2-\alpha^2}}\right), & \alpha^2-\beta^2<0\\ \ln(\varepsilon_1(\tilde{h}-\alpha))-\dfrac{\theta}{\beta}\ln\left(\varepsilon_2\left(\dfrac{1}{\tilde{h}}-\dfrac{\alpha}{\beta^2}\right)\right), & \alpha^2-\beta^2=0\\ \cosh^{-1}\left(\varepsilon_3\dfrac{\tilde{h}-\alpha}{\sqrt{\alpha^2-\beta^2}}\right)-\dfrac{\theta}{\beta}\cosh^{-1}\left(\varepsilon_4\dfrac{\beta^2/\tilde{h}-\alpha}{\sqrt{\alpha^2-\beta^2}}\right), & \alpha^2-\beta^2>0.\end{cases} \tag{3.9}$$

Here $\varepsilon, \varepsilon_1, \ldots, \varepsilon_4=1$ or -1; c_{-1}, c_1 are constants.

Since $\tilde{h}$ tends to zero when $z\to\pm\infty$, formula (3.9) shows that

$$|h-(\theta-v)|\sim e^{-\gamma z}$$

for certain $\gamma>0$ as $z\to+\infty$. Thus any traveling wave solution of the 2-CH system satisfying the conditions (3.3), (3.6) decades exponentially at infinity. Whether $\tilde{h}$ in (3.9) can be expressed as an explicit function with respect to z depends on the value of θ/β. For example, the peakon solutions given in Ref. 7 correspond to the special cases $\beta=\theta$ and $\beta=2\theta$, respectively.

Example 3.1: We construct a continuous traveling wave solution of the 2-CH system as

$$x+vt-x_0=\begin{cases}F(u)-F(u_0), & x+vt-x_0<0\\ -F(u)+F(u_0), & x+vt-x_0>0,\end{cases}\qquad \rho=\frac{A}{u+v}. \tag{3.10}$$

Here $F(h)$ is the right-hand side of (3.9) with $\tilde{h}$ replaced by $h+v-\theta$. Formulas (3.10) yield peakon solutions of the 2-CH system whenever $\alpha^2-\beta^2\le 0$. In the case $\alpha^2-\beta^2>0$, let $\tilde{h}$ take its value on either interval

$$\left[\max\left\{\alpha+\sqrt{\alpha^2-\beta^2}, \frac{\beta^2}{\alpha+\sqrt{\alpha^2-\beta^2}}\right\}, 0\right)$$

for $\alpha<0, \varepsilon_3=1, \varepsilon_4=-1$, or

$$\left(0, \min\left\{\alpha+\sqrt{\alpha^2-\beta^2}, \frac{\beta^2}{\alpha+\sqrt{\alpha^2-\beta^2}}\right\}\right]$$

for $\alpha>0, \varepsilon_3=-1, \varepsilon_4=1$, then (3.10) gives a smooth solitary wave solution. See Fig. 1.

IV. MULTIKINK AND MULTISOLITON SOLUTIONS

In this section, we employ the results of Sec. II to look for particular solutions of the 2-CH system. To this end, let us first consider the particular solutions of the system (2.12), (2.13) by using the Darboux transformation of the associated linear system (2.10), (2.11).

In the notations

$$\psi=\begin{pmatrix}\psi_1\\ \psi_2\end{pmatrix},\quad J=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad M=\lambda J+\begin{pmatrix}0 & -q\\ r & 0\end{pmatrix},\quad N=\begin{pmatrix}a & b\\ c & -a\end{pmatrix} \tag{4.1}$$

we can rewrite (2.10), (2.11) in matrix form. It is straightforward to verify the following.

Proposition 4.1: Suppose $\Lambda=\mathrm{diag}(\lambda_1,\lambda_2)$ *with* λ_1,λ_2 *being nonzero constants, and there is given a nondegenerate matrix* $H=(h_{ij})_{2\times 2}$ *satisfying*

$$H_y=JH\Lambda+\begin{pmatrix}0 & -q\\ r & 0\end{pmatrix}H,$$

$$H_s=\frac{1}{4}NH\Lambda^{-1}. \tag{4.2}$$

Let $S=H\Lambda H^{-1}$ *and* I *be the unit matrix of order two, then the linear system* (2.10), (2.11) *has the following Darboux transformation*:

$$\psi\mapsto\tilde{\psi}=(\lambda I-S)\psi,\quad M\mapsto\tilde{M}=M+[J,S],\quad N\mapsto\tilde{N}=SNS^{-1}, \tag{4.3}$$

where $[J,S]=JS-SJ$. *Particularly,* q,r *are transformed to*

$$\tilde{q}=q+\frac{2(\lambda_1-\lambda_2)h_{11}h_{12}}{\det H},\quad \tilde{r}=r-\frac{2(\lambda_1-\lambda_2)h_{21}h_{22}}{\det H}. \tag{4.4}$$

The two columns of H in the proposition are solutions of the linear systems (2.10), (2.11) with $\lambda=\lambda_1$ and $\lambda=\lambda_2$, respectively. Note that $\lambda I-S$ is nondegenerate for general λ. Given a fundamental solution matrix Ψ of the system (2.10), (2.11), then $\tilde{\Psi}=(\lambda I-S)\Psi$ is a fundamental solution matrix of this system with M,N replaced by $\tilde{M},\tilde{N}$. And from $\tilde{\Psi}$ we can find a solution $\tilde{H}$ of (4.2) corresponding to $\tilde{\Lambda}=\mathrm{diag}(\tilde{\lambda}_1,\tilde{\lambda}_2)$. In this way the Darboux transformation can be continued to generate a sequence of solutions of the system (2.12), (2.13) starting from an initial solution of it.

Let us take an initial solution of the system (2.12), (2.13) as

$$q^{(0)}=r^{(0)}=b^{(0)}=c^{(0)}=0,\quad a^{(0)}=1. \tag{4.5}$$

It gives a diagonal system (2.10), (2.11), which has a fundamental solution matrix

$$\Psi^{(0)}(\lambda)=\begin{pmatrix}e^{\omega(\lambda)} & 0\\ 0 & e^{-\omega(\lambda)}\end{pmatrix} \tag{4.6}$$

with $\omega(\lambda)=\lambda y+s/4\lambda$.

The Darboux transformation in Proposition 4.1 yields

$$\Lambda^{(i)}=\mathrm{diag}(-\lambda_i,\lambda_i),\quad \lambda_i>0, \tag{4.7}$$

$$H^{(i)}=\left(\Psi^{(i-1)}(-\lambda_i)\begin{pmatrix}1\\ 0\end{pmatrix},\Psi^{(i-1)}(\lambda_i)\begin{pmatrix}\alpha_i\\ 1\end{pmatrix}\right), \tag{4.8}$$

$$S^{(i)}=H^{(i)}\Lambda^{(i)}(H^{(i)})^{-1}, \tag{4.9}$$

$$\Psi^{(i)}(\lambda) = (\lambda I - S^{(i)})\Psi^{(i-1)}(\lambda), \tag{4.10}$$

where α_i's are nonzero constants for $i=1,2,3,\ldots$. The first formula in (4.4) takes the form

$$q^{(i)} = q^{(i-1)} - 4\lambda_i \frac{h_{12}^{(i)}}{h_{22}^{(i)}}. \tag{4.11}$$

By a direct calculation, we get the results of the first three steps as

$$q^{(1)} = -4\alpha_1\lambda_1 e^{2\omega(\lambda_1)}, \tag{4.12}$$

$$q^{(2)} = 4\frac{\lambda_1+\lambda_2}{\lambda_2-\lambda_1}(\alpha_1\lambda_1 e^{2\omega(\lambda_1)} - \alpha_2\lambda_2 e^{2\omega(\lambda_2)}), \tag{4.13}$$

$$q^{(3)} = 4\frac{\lambda_1+\lambda_3}{\lambda_3-\lambda_1}\left(\frac{\lambda_1+\lambda_2}{\lambda_2-\lambda_1}(-\alpha_1\lambda_1 e^{2\omega(\lambda_1)} + \alpha_2\lambda_2 e^{2\omega(\lambda_2)}) - \frac{\lambda_1+\lambda_3}{\lambda_3-\lambda_1}\alpha_3\lambda_3 e^{2\omega(\lambda_3)}\right). \tag{4.14}$$

Here we can always choose λ_j's pairwise distinct and α_j's with the right signs to make both $q^{(i)}, q_s^{(i)}$ identically positive. Due to Theorem 2.4 and Theorem 2.1 $q^{(i)}$ yield multikink solutions of the 2-CH system when $i \geq 2$. Multikink solutions of this kind were deduced in another way in Ref. 7.

Now let us look for particular solutions of the system (2.12), (2.13) that correspond to multisoliton solutions of the 2-CH system. For this, we denote

$$\xi = \frac{s}{\mu} + \nu y,$$

where μ, ν are constants and $\mu \neq 0$. It is easy to check that

$$q = e^{\xi}, \quad r = \frac{1}{4}(\nu^2 - \mu^2)e^{-\xi}, \quad a = \frac{\nu}{\mu}, \quad b = \frac{2}{\mu}e^{\xi}, \quad c = \frac{\mu^2-\nu^2}{2\mu}e^{-\xi} \tag{4.15}$$

satisfy (2.12), (2.13). The linear system (2.10), (2.11) determined by (4.15) has a fundamental solution matrix

$$\Psi(\lambda) = \begin{pmatrix} e^{\frac{\xi+\zeta(\lambda)}{2}} & e^{\frac{\xi-\zeta(\lambda)}{2}} \\ \frac{2\lambda-\nu-\sqrt{\Delta(\lambda)}}{2}e^{\frac{-\xi+\zeta(\lambda)}{2}} & \frac{2\lambda-\nu+\sqrt{\Delta(\lambda)}}{2}e^{-\frac{\xi+\zeta(\lambda)}{2}} \end{pmatrix} \tag{4.16}$$

with

$$\Delta(\lambda) = 4\lambda^2 - 4\nu\lambda + \mu^2, \quad \zeta(\lambda) = \sqrt{\Delta(\lambda)}\left(y - \frac{1}{2\mu\lambda}s\right).$$

We carry out the Darboux transformation in Proposition 4.1 as

$$\Lambda = \mathrm{diag}(\lambda_1, \lambda_2), \tag{4.17}$$

$$H = \left(\Psi(\lambda_1)\begin{pmatrix}1\\ \beta_1\end{pmatrix}, \Psi(\lambda_2)\begin{pmatrix}1\\ \beta_2\end{pmatrix}\right), \tag{4.18}$$

$$S = H\Lambda H^{-1}, \tag{4.19}$$

$$\tilde{\Psi}(\lambda) = (\lambda I - S)\Psi(\lambda), \tag{4.20}$$

$$\tilde{\Lambda} = \mathrm{diag}(\lambda_3, \lambda_4), \tag{4.21}$$

$$\tilde{H} = \left(\tilde{\Psi}(\lambda_3)\begin{pmatrix}1\\ \beta_3\end{pmatrix}, \tilde{\Psi}(\lambda_4)\begin{pmatrix}1\\ \beta_4\end{pmatrix}\right). \tag{4.22}$$

Here λ_i's are pairwise distinct and β_i's are constants. For the convenience of the straightforward computations, we introduce the following notation:

$$\Delta_j = \Delta(\lambda_j), \quad \zeta_j = \zeta(\lambda_j),$$

$$g_{1j} = e^{\zeta_j/2} + \beta_j e^{-\zeta_j/2}, \quad g_{2j} = \frac{2\lambda_j - \nu - \sqrt{\Delta_j}}{2} e^{\zeta_j/2} + \beta_j \frac{2\lambda_j - \nu + \sqrt{\Delta_j}}{2} e^{-\zeta_j/2},$$

$$K_j = \frac{g_{2j}}{g_{1j}} = \left(\lambda_j - \frac{\nu + \sqrt{\Delta_j}}{2}\right) + \frac{\beta_j \sqrt{\Delta_j}}{e^{\zeta_j} + \beta_j},$$

where $j = 1, 2, 3, 4$. By using the first formula in (4.4) we get

$$\tilde{q} = q + \frac{2(\lambda_1 - \lambda_2)}{\dfrac{h_{22}}{h_{12}} - \dfrac{h_{21}}{h_{11}}} = e^{\xi}\left(1 + \frac{2(\lambda_2 - \lambda_1)}{K_1 - K_2}\right), \tag{4.23}$$

$$\tilde{\tilde{q}} = \tilde{q} + \frac{2(\lambda_3 - \lambda_4)}{\dfrac{\tilde{h}_{22}}{\tilde{h}_{12}} - \dfrac{\tilde{h}_{21}}{\tilde{h}_{11}}} = e^{\xi}\left(1 + \frac{2(\lambda_2 - \lambda_1)}{K_1 - K_2} + \frac{2(\lambda_4 - \lambda_3)}{R_3 - R_4}\right), \tag{4.24}$$

where

$$R_j = \frac{(\lambda_2 - \lambda_1) g_{21} g_{22} g_{1j} + (\lambda_j - \lambda_2) g_{11} g_{22} g_{2j} - (\lambda_j - \lambda_1) g_{12} g_{21} g_{2j}}{(\lambda_j - \lambda_1) g_{11} g_{22} g_{1j} - (\lambda_j - \lambda_2) g_{12} g_{21} g_{1j} + (\lambda_1 - \lambda_2) g_{11} g_{12} g_{2j}}$$

$$= \frac{(\lambda_2 - \lambda_1) K_1 K_2 + (\lambda_j - \lambda_2) K_2 K_j + (\lambda_1 - \lambda_j) K_j K_1}{(\lambda_j - \lambda_1) K_2 + (\lambda_2 - \lambda_j) K_1 + (\lambda_1 - \lambda_2) K_j}, \quad j = 3, 4.$$

Due to Theorem 2.4 and Theorem 2.1, formulas (4.23), (4.24) yield solutions of the 2-CH system. When the parameters involved are chosen appropriately we can get multisoliton solutions.

Example 4.2: Formula (4.23) is written as

$$\tilde{q} = e^{\xi}\left(1 + \frac{2(\lambda_2 - \lambda_1)}{\lambda_1 - \lambda_2 - \dfrac{1}{2}(\sqrt{\Delta_1} - \sqrt{\Delta_2}) + \dfrac{\beta_1 \sqrt{\Delta_1}}{e^{\zeta_1} + \beta_1} - \dfrac{\beta_2 \sqrt{\Delta_2}}{e^{\zeta_2} + \beta_2}}\right). \tag{4.25}$$

By a careful analysis of the parameters, we know that

$$\nu > \mu > 0, \quad \lambda_1 > \lambda_2 > \frac{1}{2}(\nu + \sqrt{\nu^2 - \mu^2}), \quad \beta_1 < 0, \quad \beta_2 > 0 \tag{4.26}$$

is a sufficient condition for both $\tilde{q}$ and $\tilde{q}_s$ being identically positive. Under this condition formula (4.25) gives a 2-soliton solution of the 2-CH system. If we change (4.26) by setting $\beta_2 = 0$, then

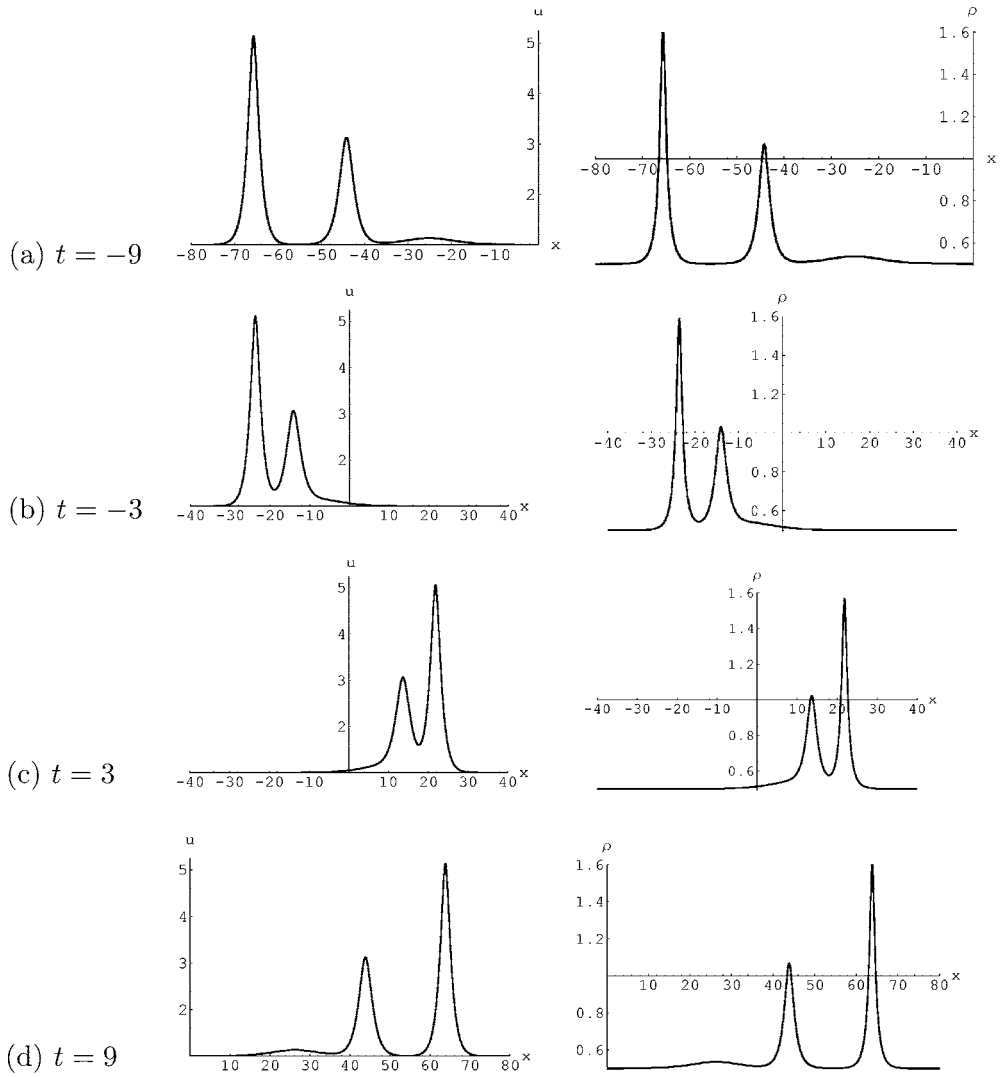


FIG. 2. 3-soliton solution of 2-CH by (4.24) with $\mu=1/2, \nu=1, \lambda_1=2, \lambda_2=1, \lambda_3=5, \lambda_4=3, \beta_1=-1, \beta_2=1, \beta_3=0, \beta_4=1$.

$$\tilde{q}|_{\beta_2=0} = e^{\xi}\left(1 + \frac{4(\lambda_2-\lambda_1)(e^{\zeta_1}+\beta_1)}{(2(\lambda_1-\lambda_2)-(\sqrt{\Delta_1}-\sqrt{\Delta_2}))e^{\zeta_1}+\beta_1(2(\lambda_1-\lambda_2)+\sqrt{\Delta_1}+\sqrt{\Delta_2})}\right) \tag{4.27}$$

gives a solitary wave solution of the 2-CH system. With a little further argument, we know that formula (4.27) yields a traveling wave solution of the 2-CH system. It corresponds to the case $\alpha^2-\beta^2>0$ of (3.9). This also implies that the solitary wave solutions given by (3.10) are smooth.

From formula (4.24) we can obtain 3-soliton or 4-soliton solutions of the 2-CH system whenever the parameters are appropriately chosen. See Fig. 2.

V. CONCLUSION

Theorem 2.1 and Theorem 2.4 provide a simple method to find parametric solutions of the 2-CH system (1.2), (1.3) from solutions of the first negative flow (2.12), (2.13) of the AKNS hierarchy. We have shown that apart from the peakon and multikink solutions, the 2-CH system also possesses n-soliton solutions for $n\leqslant 4$. We expect that for any positive integer n, the n-soliton

solution of the 2-CH system can also be obtained by using the Darboux transformation given in Proposition 4.1, with the seed solution (4.15), (4.16) and appropriately chosen parameters involved in the Darboux transformation.

Evaluation representations of quantum affine algebras at roots of unity

Yuuki Abe[a] and Toshiki Nakashima[b]
Department of Mathematics, Sophia University, Tokyo, 102-8554, Japan

(Received 29 June 2006; accepted 29 June 2006; published online 25 August 2006)

The purpose of this paper is to compute the Drinfel'd polynomials for two types of evaluation representations of quantum affine algebras at roots of unity and construct those representations as the submodules of evaluation Schnizer modules. Moreover, we obtain the necessary and sufficient condition for that the two types of evaluation representations are isomorphic to each other. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2235047]

I. INTRODUCTION

For a generic q, let $U_q(\mathfrak{g})$ be the quantum algebra associated with a simple Lie algebra $\mathfrak{g}$ and $U_q(\tilde{\mathfrak{g}})$ be the nontwisted quantum loop algebra of $\mathfrak{g}$. It is known that every finite-dimensional irreducible $U_q(\mathfrak{g})$ (respectively, $U_q(\tilde{\mathfrak{g}})$) modules are highest-weight module and classified by highest weights. Moreover, there exists one to one correspondence from the set of their highest weights to $\mathbb{Z}_+^n$ (respectively, polynomials $\mathbb{C}_0[t]^n$), where $\mathbb{Z}_+ := \{0,1,2,\ldots\}$ (respectively, $\mathbb{C}_0[t] := \{P \in \mathbb{C}[t] | P$ is monic and $P(0) \neq 0\}$). The theory of finite-dimensional $U_q(\tilde{\mathfrak{g}})$-modules is introduced in Ref. 10. We denote the $U_q(\mathfrak{g})$ (respectively, $U_q(\tilde{\mathfrak{g}})$) module corresponding to $\lambda \in \mathbb{Z}_+^n$ (respectively, $\mathbf{P} \in \mathbb{C}_0[t]^n$) by $V_q(\lambda)$ (respectively, $V_q(\mathbf{P})$), where the polynomial $\mathbf{P}$ of $\tilde{V}_q(\mathbf{P})$ is called "Drinfel'd polynomial."

In the case $\mathfrak{g} = \mathfrak{sl}_{n+1}$, there exist $\mathbb{C}$-algebra homomorphisms $ev_{\mathbf{a}}^+$, $ev_{\mathbf{a}}^-$: $U_q(\widetilde{\mathfrak{sl}_{n+1}}) \to U_q(\mathfrak{sl}_{n+1})$ for $\mathbf{a} \in \mathbb{C}^\times$ (see Refs. 17 and 8). By using these homomorphisms, we can regard $V_q(\lambda)$ as a $U_q(\widetilde{\mathfrak{sl}_{n+1}})$-module, which are called "evaluation representations" and denoted by $V_q(\lambda)_{\mathbf{a}}^{\pm}$. By the classification theorem of finite-dimensional $U_q(\widetilde{\mathfrak{sl}_{n+1}})$-modules, (Ref. 10) there exists a unique polynomial $\mathbf{P}_{\mathbf{a}}^{\pm} \in \mathbb{C}_0[t]^n$ such that $V_q(\lambda)_{\mathbf{a}}^{\pm}$ is isomorphic to $\tilde{V}_q(\mathbf{P}_{\mathbf{a}}^{\pm})$ as a $U_q(\widetilde{\mathfrak{sl}_{n+1}})$-module. The Drinfel'd polynomials $\mathbf{P}_{\mathbf{a}}^{\pm}$ are computed by Chari and Pressley in Ref. 8. In this paper we shall consider evaluation representations at roots of unity.

Let ε be a primitive lth root of unity. The representation theory of quantum algebras at roots of unity is divided into two types. One is for $U_\varepsilon(\mathfrak{g})$, $U_\varepsilon(\tilde{\mathfrak{g}})$ defined by De Concini-Kac (=nonrestricted type) in Ref. 13 and the other is for $U_\varepsilon^{\mathrm{res}}(\mathfrak{g})$, $U_\varepsilon^{\mathrm{res}}(\tilde{\mathfrak{g}})$ defined by Lusztig (=restricted type) in Ref. 18.

$U_\varepsilon^{\mathrm{res}}(\mathfrak{g})$ (respectively, $U_\varepsilon^{\mathrm{res}}(\tilde{\mathfrak{g}})$ has the $\mathbb{C}$-subalgebra $U_\varepsilon^{\mathrm{fin}}(\mathfrak{g})$ (respectively, $U_\varepsilon^{\mathrm{fin}}(\tilde{\mathfrak{g}})$) which is called "small quantum algebra." By the tensor product theorem (see Refs. 18 and 11), in order to understand the representation theory of $U_\varepsilon^{\mathrm{res}}(\mathfrak{g})$ (respectively, $U_\varepsilon^{\mathrm{res}}(\tilde{\mathfrak{g}})$), we may consider the one of $U_\varepsilon^{\mathrm{fin}}(\mathfrak{g})$ (respectively, $U_\varepsilon^{\mathrm{fin}}(\tilde{\mathfrak{g}})$). Indeed, every finite-dimensional irreducible $U_\varepsilon^{\mathrm{fin}}(\mathfrak{g})$ (respectively, $U_\varepsilon^{\mathrm{fin}}(\tilde{\mathfrak{g}})$) module is a highest-weight module and classified by highest weight. Moreover, there exists one to one correspondence from the set of their highest weights to $\mathbb{Z}_l^n$ (respectively, polynomials $\mathbb{C}_l[t]^n$), where $\mathbb{Z}_l := \{0,1,\cdots,l-1\}$ (respectively, $\mathbb{C}_l[t] := \{P \in \mathbb{C}_0[t] | P$ is not divisible by $(1-ct^l)$ for any $c \in \mathbb{C}^\times\}$). We denote the $U_\varepsilon^{\mathrm{fin}}(\mathfrak{g})$ (respectively, $U_\varepsilon^{\mathrm{fin}}(\tilde{\mathfrak{g}})$) module corresponding to $\lambda \in \mathbb{Z}_l^n$ (respectively, $\mathbf{P} \in \mathbb{C}_l[t]^n$) by $V_\varepsilon^{\mathrm{fin}}(\lambda)$ (respectively, $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$).

[a]Electronic mail: yu-abe@sophia.ac.jp
[b]Electronic mail: toshiki@mm.sophia.ac.jp

We also obtain the evaluation representations of $V_\varepsilon^{\mathrm{fin}}(\lambda)$ in the case of $U_\varepsilon^{\mathrm{fin}}(\widetilde{\mathfrak{sl}}_{n+1})$. We denote them by $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}}^{\pm}$. We can compute the Drinfel'd polynomials of $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}}^{\pm}$ by a similar method to Ref. 8 (see Theorem 4.13 in this paper). Moreover, for $\mathbf{a}_\pm \in \mathbb{C}^\times$, we shall show that $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_+}^{+}$ is isomorphic to $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_-}^{-}$ if and only if

$$\mathbf{a}_+ = \mathbf{a}_- \varepsilon^{2(\sum_{k=1}^{i-1}\lambda_k - \sum_{k=i+1}^{n}\lambda_{k+i})} \text{ for all } i \in \mathrm{supp}(\lambda), \tag{1.1}$$

where $\mathrm{supp}(\lambda) := \{1 \leqslant i \leqslant n \,|\, \lambda_i \neq 0\}$. If q is generic, condition (1.1) never occurs for $\#(\mathrm{supp}(\lambda)) > 1$. But, in this case, there exists $\lambda \in \mathbb{Z}_l^n$ which satisfies (1.1) for $\#(\mathrm{supp}(\lambda)) > 1$ (see Propositions 4.14, 4.15).

On the other hand, many finite-dimensional irreducible $U_\varepsilon(\mathfrak{g})$ (respectively, $U_\varepsilon(\widetilde{\mathfrak{g}})$) modules are no longer highest- or lowest-weight modules and they are characterized by several continuous parameters (see Refs. 13 and 6). For $\mathfrak{g} = \mathfrak{sl}_{n+1}$, such $U_\varepsilon(\mathfrak{sl}_{n+1})$-modules are constructed explicitly in Ref. 12, which are called "maximal cyclic representation." For an arbitrary simple Lie algebra $\mathfrak{g}$, Schnizer introduced an alternative construction of such $U_\varepsilon(\mathfrak{g})$-modules in Refs. 23 and 24, which we call "Schnizer modules."

By using the theory of the quantum algebra of restricted type, we obtain that every finite-dimensional irreducible "nilpotent" $U_\varepsilon(\mathfrak{sl}_{n+1})$-modules are highest-weight module and classified by highest weight (see Secs. III D and V B). Moreover, there exists one to one correspondence from the set of their highest weights to $\mathbb{Z}_l^n$ (respectively, $\mathbb{C}_l[t]^n$). We denote the $U_\varepsilon(\mathfrak{sl}_{n+1})$ (respectively, $U_\varepsilon(\widetilde{\mathfrak{sl}}_{n+1})$) module corresponding to $\lambda \in \mathbb{Z}_l^n$ (respectively, $\mathbf{P} \in \mathbb{C}_l[t]^n$) by $V_\varepsilon^{\mathrm{nil}}(\lambda)$ (respectively, $\widetilde{V}_\varepsilon^{\mathrm{nil}}(\mathbf{P})$). We also obtain the evaluation representations of $V_\varepsilon^{\mathrm{nil}}(\lambda)$, which are denoted by $V_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}}^{\pm}$. The module $V_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}}^{\pm}$ is regraded as a $U_\varepsilon^{\mathrm{fin}}(\widetilde{\mathfrak{sl}}_{n+1})$-module and $V_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}}^{\pm}$ is isomorphic to $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}}^{\pm}$ as a $U_\varepsilon^{\mathrm{fin}}(\widetilde{\mathfrak{sl}}_{n+1})$-module (see Sec. V B). Therefore, for $\mathbf{a}_\pm \in \mathbb{C}^\times$, we obtain

$$V_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_+}^{+} \text{ is isomorphic to } V_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_-}^{-} \text{ if and only if (1.1) holds.} \tag{1.2}$$

We can also prove (1.2) without using the theory of the quantum algebra of restricted type. In Ref. 22, T.N. showed that one can construct $V_\varepsilon^{\mathrm{nil}}(\lambda)$ as the subrepresentation of a maximal cyclic representation by specializing their parameters properly for type A. Similarly, in Ref. 2, we found that we can construct $V_\varepsilon^{\mathrm{nil}}(\lambda)$ as a submodule of a Schnizer module if $\mathfrak{g} = A$, B, C, or D, and then we can construct $V_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}}^{\pm}$ as the submodule of evaluation of a Schnizer module. By using this fact, we can prove (1.2) (see Sec. V alternative proof of Proposition 5.11(b)).

The organization of this paper is as follows. In Sec. II, we introduce basic properties of quantum algebras for generic q. In Sec. III, we introduce quantum algebras at roots of unity of nonrestricted type and restricted type. Moreover, we prove the isomorphisn theorem of these algebras. In Sec. IV (respectively, Sec. V), we discuss the evaluation representations of restricted (respectively, nonrestricted) type.

II. QUANTUM ALGEBRAS (GENERIC CASE)

A. Notations

We fix the following notations (see Refs. 3 and 6). Let $\mathfrak{sl}_{n+1}$ be the finite-dimensional simple Lie algebra over $\mathbb{C}$ of type A_n and $\widetilde{\mathfrak{sl}}_{n+1} = \mathfrak{sl}_{n+1} \otimes \mathbb{C}[t, t^{-1}]$ be the loop algebra of $\mathfrak{sl}_{n+1}$. We set $I := \{1, 2, \ldots, n\}$ and $\widetilde{I} := I \sqcup \{0\}$. Let $(\mathfrak{a}_{i,j})_{i,j\in\widetilde{I}}$ be the generalized Cartan matrix of $\widetilde{\mathfrak{sl}}_{n+1}$, that is, $\mathfrak{a}_{i,i} = 2$, $\mathfrak{a}_{i,j} = -1$ if $|i-j| = 1$ or n, and $\mathfrak{a}_{i,j} = 0$ otherwise. Then $(\mathfrak{a}_{i,j})_{i,j\in I}$ is the Cartan matrix of $\mathfrak{sl}_{n+1}$. Let $\Pi := \{\alpha_i\}_{i\in I}$ (respectively, $\widetilde{\Pi} := \{\alpha_i\}_{i\in\widetilde{I}}$) be the set of the simple roots of $\mathfrak{sl}_{n+1}$ (respectively, $\widetilde{\mathfrak{sl}}_{n+1}$) and $\Pi^\vee := \{\alpha_i^\vee\}_{i\in I}$ (respectively, $\widetilde{\Pi}^\vee := \{\alpha_i^\vee\}_{i\in\widetilde{I}}$) be the set of the simple coroots of $\mathfrak{sl}_{n+1}$ (respectively, $\widetilde{\mathfrak{sl}}_{n+1}$). Let $\mathfrak{h}$ be the Cartan subalgebra of $\mathfrak{sl}_{n+1}$ and $\mathfrak{h}^*$ be the $\mathbb{C}$-dual space of $\mathfrak{h}$. Then $\Pi^\vee$ (respectively, Π) is a $\mathbb{C}$-basis of $\mathfrak{h}$ (respectively, $\mathfrak{h}^*$). We have a $\mathbb{C}$-bilinear map $\langle , \rangle : \mathfrak{h}^* \times \mathfrak{h} \to \mathbb{C}$ such that $\langle \alpha_j, \alpha_i^\vee \rangle = \mathfrak{a}_{i,j}$ for any $i, j \in I$. Define the root lattice $Q := \oplus_{i\in I}\mathbb{Z}\alpha_i$ (respectively,

the coroot lattice $Q^\vee := \oplus_{i\in I}\mathbb{Z}\alpha_i^\vee$) and the affine root lattice $\widetilde{Q} := \mathbb{Z}\alpha_0 \oplus Q$ (respectively, the affine coroot lattice $\widetilde{Q}^\vee := \mathbb{Z}\alpha_0^\vee \oplus Q^\vee$). For $i \in I$, we define the fundamental weights $\{\Lambda_i\}_{i\in I} \subset \mathfrak{h}^*$ by

$$\Lambda_i := \frac{1}{n+1}\left\{(n-i+1)\sum_{k=1}^{i} k\alpha_k + i\sum_{k=i+1}^{n}(n-k+1)\alpha_k\right\}. \tag{2.1}$$

Similarly, we define the fundamental coweights $\{\Lambda_i^\vee\}_{i\in I} \subset \mathfrak{h}$ by replacing α in Λ_i with $\alpha^\vee$. Then we have $\langle \Lambda_i, \alpha_j^\vee\rangle = \delta_{i,j}$ (respectively, $\langle \alpha_j, \Lambda_i^\vee\rangle = \delta_{i,j}$) for any $i,j \in I$. Define the weight lattice $P := \oplus_{i\in I}\mathbb{Z}\Lambda_i$ (respectively, the coweight lattice $P^\vee := \oplus_{i\in I}\mathbb{Z}\Lambda_i^\vee$) and define a symmetric bilinear form $(,)$: $\mathfrak{h}^* \times \mathfrak{h}^* \to \mathbb{C}$ determined by $(\alpha_i, \alpha_j) = \mathfrak{a}_{i,j}$ for any $i,j \in I$.

Let Δ (respectively, Δ_+) be the set of roots (respectively, positive roots) of $\widetilde{\mathfrak{sl}_{n+1}}$ and $\theta := \Sigma_{i\in I}\alpha_i$ be the highest root in Δ. We set $\delta := \alpha_0 + \theta$. Let $\widetilde{\Delta}$ be the affine root system of $\widetilde{\mathfrak{sl}_{n+1}}$. Then we have $\widetilde{\Delta} = \widetilde{\Delta}^{\mathrm{re}} \sqcup \widetilde{\Delta}^{\mathrm{im}}$, where

$$\widetilde{\Delta}^{\mathrm{re}} := \{\alpha + n\delta | \alpha \in \Delta, n \in \mathbb{Z}\}, \quad \Delta^{\mathrm{im}} := \{n\delta | n \in \mathbb{Z}^\times := (\mathbb{Z}\setminus\{0\})\},$$

and $\widetilde{\Delta} = \widetilde{\Delta}_+ \sqcup (-\widetilde{\Delta}_+)$, where

$$\widetilde{\Delta}_+ := \widetilde{\Delta}_+^{\mathrm{re}} \sqcup \widetilde{\Delta}_+^{\mathrm{im}}, \quad \widetilde{\Delta}_+^{\mathrm{re}} := \{\alpha + n\delta | \alpha \in \Delta, n \in \mathbb{N} := \{1,2,\dots\}\} \sqcup \Delta_+, \quad \widetilde{\Delta}_+^{\mathrm{im}} := \{n\delta | n \in \mathbb{N}\}.$$

Moreover, we set

$$\widetilde{\Delta}_+^{\mathrm{im}}(I) := I \times \widetilde{\Delta}_\times^{\mathrm{im}} = \{(i,n\delta) | i \in I, n \in \mathbb{N}\}, \quad \widetilde{\Delta}_+(I) := \widetilde{\Delta}_+^{\mathrm{re}} \sqcup \widetilde{\Delta}_+^{\mathrm{im}}(I),$$

$$\widetilde{\Delta}^{\mathrm{im}}(I) := \{(i,n\delta) | i \in I, n \in \mathbb{Z}^\times\}, \quad \widetilde{\Delta}(I) := \widetilde{\Delta}^{\mathrm{re}} \sqcup \widetilde{\Delta}^{\mathrm{im}}(I).$$

For $i \in \widetilde{I}$, let s_i be the simple reflection on $\mathfrak{h}^*$, that is, $s_i(\lambda) = \lambda - \langle \lambda, \alpha_i^\vee\rangle\alpha_i$ for any $\lambda \in \mathfrak{h}^*$. The affine Weyl group $\widetilde{\mathcal{W}}$ of $\widetilde{\mathfrak{sl}_{n+1}}$ (respectively, Weyl group $\mathcal{W}$ of $\mathfrak{sl}_{n+1}$) is generated by $\{s_i\}_{i\in\widetilde{I}}$ (respectively, $\{s_i\}_{i\in I}$). For $x \in \mathfrak{h}$, we define $t_x: \mathfrak{h}^* \to \mathfrak{h}^*$ by $t_x(\lambda) = \lambda - \langle \lambda, x\rangle\delta$ and set $T_{P^\vee} := \{t_x | x \in P^\vee\}$, $T_{Q^\vee} := \{t_x | x \in Q^\vee\}$. Consider the extended affine Weyl group $\hat{\mathcal{W}} := \mathcal{W}\widetilde{\times}T_{P^\vee}$, where the structure of the semi-direct product is given by $(s,t_x)(s',t_y) = (ss', t_{s'^{-1}x}t_y)$ for any $s,s' \in \mathcal{W}$, and $x,y \in P^\vee$. We set $\mathcal{T} := \{\tau: \widetilde{I} \to \widetilde{I}; \text{permutation} \,|\, \mathfrak{a}_{\tau(i),\tau(j)} = \mathfrak{a}_{i,j} \text{ for any } i,j \in \widetilde{I}\}$ and define the semi-direct product $\mathcal{T}\widetilde{\times}\widetilde{\mathcal{W}}$ by $\tau s_i \tau^{-1} = s_{\tau(i)}$ for $\tau \in \mathcal{T}$, $i \in \widetilde{I}$. It is known that $\hat{\mathcal{W}} \cong \mathcal{T}\widetilde{\times}\widetilde{\mathcal{W}}$ and $\widetilde{\mathcal{W}} \cong \mathcal{W}\widetilde{\times}T_{Q^\vee}$. In particular, the latter isomorphism is given by $s_i \mapsto (s_i, id_{\mathfrak{h}^*})$ for $i \in I$ and $s_0 \mapsto (s_\theta, t_{\theta^\vee})$, where $\theta^\vee := \Sigma_{i\in I}\alpha_i^\vee$. The length of an element $\tau w \in \hat{\mathcal{W}}$ ($\tau \in \mathcal{T}, w \in \widetilde{\mathcal{W}}$) is given by $l_{\widetilde{\mathcal{W}}}(\tau w) := l_{\widetilde{\mathcal{W}}}(w)$, where $l_{\widetilde{\mathcal{W}}}$ is the length function of $\widetilde{\mathcal{W}}$.

Let q be an indeterminate. For $r \in \mathbb{Z}$, $m \in \mathbb{N}$, we define q-integers and Gaussian binomial coefficients in the rational function field $\mathbb{C}(q)$ by

$$[r] := \frac{q^r - q^{-r}}{q - q^{-1}}, \quad [m]! := [m][m-1]\cdots[1], \quad \begin{bmatrix} r \\ m \end{bmatrix} := \frac{[r][r-1]\cdots[r-m+1]}{[1][2]\cdots[m]}.$$

Similarly, for $c \in \mathbb{C}$ ($c \neq 0, \pm 1$), we define

$$[r]_c := \frac{c^r - c^{-r}}{c - c^{-1}}, \quad [m]_c! := [m]_c[m-1]_c\cdots[1]_c, \quad \begin{bmatrix} r \\ m \end{bmatrix}_c := \frac{[r]_c[r-1]_c\cdots[r-m+1]_c}{[1]_c[2]_c\cdots[m]_c}.$$

We set $[0]! := [0]_c! := 1$.

B. Definitions

Definition 2.1: The quantum loop algebra $\widetilde{U}_q := U_q(\widetilde{\mathfrak{sl}_{n+1}})$ (respectively, the quantum algebra $U_q := U_q(\mathfrak{sl}_{n+1})$, the extended quantum algebra $U_q' := U_q'(\mathfrak{sl}_{n+1})$) is an associative $\mathbb{C}(q)$-algebra generated by $\{E_i, F_i, K_\mu | i \in \widetilde{I}$ (respectively, $i \in I$, $i \in I$), $\mu \in \widetilde{Q}$ (respectively, $\mu \in Q$, $\mu \in P$)$\}$ with the relations

$$K_\mu K_\nu = K_{\mu+\nu}, \quad K_0 = 1, \quad K_{\alpha_0} = K_\theta^{-1},$$

$$K_\mu E_j K_\mu^{-1} = q^{(\mu,\alpha_j)} E_j, \quad K_\mu F_j K_\mu^{-1} = q^{-(\mu,\alpha_j)} F_j,$$

$$E_i F_j - F_j E_i = \delta_{i,j} \frac{K_{\alpha_i} - K_{\alpha_i}^{-1}}{q - q^{-1}},$$

$$\sum_{r=0}^{1-\mathfrak{a}_{ij}} (-1)^r E_i^{(r)} E_j E_i^{(1-\mathfrak{a}_{i,j}-r)} = \sum_{r=0}^{1-\mathfrak{a}_{ij}} (-1)^r F_i^{(r)} F_j F_i^{(1-\mathfrak{a}_{i,j}-r)} = 0, \quad i \neq j,$$

where

$$E_i^{(r)} := \frac{1}{[r]!} E_i^r, \quad F_i^{(r)} := \frac{1}{[r]!} F_i^r \quad (r \in \mathbb{Z}_+ := \{0,1,2,\dots\}).$$

Let $\widetilde{U}_q^+$ (respectively, $\widetilde{U}_q^-$, $\widetilde{U}_q^0$) be the $\mathbb{C}(q)$-subalgebra of $\widetilde{U}_q$ generated by $\{E_i\}_{i\in\widetilde{I}}$ (respectively, $\{F_i\}_{i\in\widetilde{I}}$, $\{K_\mu\}_{\mu\in Q}$). Similarly, let U_q^+ (respectively, U_q^-, U_q^0) be the $\mathbb{C}(q)$-subalgebra of U_q generated by $\{E_i\}_{i\in I}$ (respectively, $\{F_i\}_{i\in I}$, $\{K_\mu\}_{\mu\in Q}$).

It is well known that $\widetilde{U}_q$ (respectively, U_q) have a Hopf algebra structure and its comultiplication is given by

$$\Delta(E_i) = E_i \otimes 1 + K_{\alpha_i} \otimes E_i, \quad \Delta(F_i) = F_i \otimes K_{\alpha_i}^{-1} + 1 \otimes F_i, \quad \Delta(K_\mu) = K_\mu \otimes K_\mu,$$

where $i \in \widetilde{I}$ (respectively, I), $\mu \in Q$.

We have a $\mathbb{C}$-algebra anti-automorphism $\Omega : \widetilde{U}_q \to \widetilde{U}_q$ and a $\mathbb{C}(q)$-algebra anti-automorphism $\Phi : \widetilde{U}_q \to \widetilde{U}_q$ such that

$$\Omega(q) = q^{-1}, \quad \Omega(E_i) = F_i, \quad \Omega(F_i) = E_i, \quad \Omega(K_\mu) = K_\mu^{-1}, \tag{2.2}$$

$$\Phi(E_i) = E_i, \quad \Phi(F_i) = F_i, \quad \Phi(K_\mu) = K_\mu^{-1}, \tag{2.3}$$

for $i \in \widetilde{I}$, $\mu \in Q$. Let T_i be the $\mathbb{C}(q)$-algebra automorphism of $\widetilde{U}_q$ introduced by Lusztig (Ref. 21, Chap. 37):

$$T_i(E_i^{(m)}) = (-1)^m q^{-m(m-1)} F_i^{(m)} K_{\alpha_i}^m, \quad T_i(F_i^{(m)}) = (-1)^m q^{m(m-1)} K_{\alpha_i}^{-1} E_i^{(m)},$$

$$T_i(E_j^{(m)}) = \sum_{r=0}^{-m\mathfrak{a}_{i,j}} (-1)^{r-m\mathfrak{a}_{i,j}} q^{-r} E_i^{(-m\mathfrak{a}_{i,j}-r)} E_j^{(m)} E_i^{(r)} \quad (i \neq j),$$

$$T_i(F_j^{(m)}) = \sum_{r=0}^{-m\mathfrak{a}_{i,j}} (-1)^{r-m\mathfrak{a}_{i,j}} q^{r} F_i^{(r)} F_j^{(m)} F_i^{(-m\mathfrak{a}_{i,j}-r)} \quad (i \neq j),$$

$$T_i(K_\mu) = K_{s_i(\mu)}, \tag{2.4}$$

where $i \in \widetilde{I}$, $m \in \mathbb{N}$, $\mu \in Q$. For $\tau \in \mathcal{T}$, we define $\widetilde{U}_q$-automorphism T_τ by

$$T_\tau(E_i) := E_{\tau(i)}, \quad T_\tau(F_i) := F_{\tau(i)}, \quad T_\tau(K_{\alpha_i}^{\pm 1}) := K_{\alpha_{\tau(i)}}^{\pm 1} \quad (i \in \widetilde{I}). \tag{2.5}$$

We obtain that

$$T_i^{-1} = \Phi T_i \Phi^{-1}, \quad T_i \Omega = \Omega T_i, \quad T_\tau \Omega = \Omega T_\tau. \tag{2.6}$$

Let $w \in \hat{\mathcal{W}}$ and $w = \tau s_{i_1} \cdots s_{i_m}$ ($\tau \in \mathcal{T}, i_1, \ldots, i_m \in \widetilde{I}, m \in \mathbb{N}$) be a reduced expression of w. Then $T_w := T_\tau T_{i_1} \cdots T_{i_m}$ is a well-defined $\widetilde{U}_q$-automorphism, that is, T_w does not depend on the choice of reduced expression of w.

C. Drinfel'd realization

It is known that $\widetilde{U}_q$ has another realization which is called Drinfel'd realization.

Definition 2.2 (Ref. 14): Let $\mathcal{D}_q$ be an associative $\mathbb{C}(q)$-algebra generated by $\{X_{i,r}^{\pm}, H_{i,s}, K_\mu | i \in I, r, s \in \mathbb{Z}, s \neq 0, \mu \in Q\}$ with the relations

$$K_\mu K_\nu = K_{\mu+\nu}, \quad K_0 = 1, \quad [K_\mu, H_{j,s}] = [H_{i,r}, H_{j,s}] = 0,$$

$$K_\mu X_{i,r}^{\pm} K_\mu^{-1} = q^{\pm(\mu,\alpha_i)} X_{i,r}^{\pm}, \quad [H_{j,s}, X_{i,r}^{\pm}] = \pm \frac{[r\mathfrak{a}_{i,j}]}{r} X_{i,r+s},$$

$$X_{i,r+1}^{\pm} X_{j,s}^{\pm} - q^{\pm \mathfrak{a}_{i,j}} X_{j,s}^{\pm} X_{i,r+1}^{\pm} = q^{\pm \mathfrak{a}_{i,j}} X_{i,r}^{\pm} X_{j,s+1}^{\pm} - X_{j,s+1}^{\pm} X_{i,r}^{\pm},$$

$$[X_{i,r}^{+}, X_{j,s}^{-}] = \delta_{i,j} \frac{\Psi_{i,r+s}^{+} - \Psi_{i,r+s}^{-}}{q - q^{-1}},$$

$$\sum_{\pi \in \mathcal{S}_m} \sum_{k=0}^{\mathbf{m}} (-1)^k \begin{bmatrix} \mathbf{m} \\ k \end{bmatrix} X_{i,r_{\pi}(1)}^{\pm} \cdots X_{i,r_{\pi(1)}}^{\pm} X_{j,s}^{\pm} X_{i,r_{\pi(k+1)}}^{\pm} \cdots X_{i,r_{\pi(\mathbf{m})}}^{\pm} = 0 \quad (i \neq j),$$

for $r_1, \ldots, r_{\mathbf{m}} \in \mathbb{Z}$, where $\mathbf{m} := 1 - \mathfrak{a}_{i,j}$, $\mathcal{S}_{\mathbf{m}}$ is the symmetric group on $\mathbf{m}$ letters, and $\Psi_{i,r}^{\pm}$ are determined by

$$\sum_{r=0}^{\infty} \Psi_{i,\pm r}^{\pm} u^{\pm r} := K_{\alpha_i}^{\pm 1} \exp\left(\pm (q - q^{-1}) \sum_{s=1}^{\infty} H_{i,\pm s} u^{\pm s} \right),$$

and $\Psi_{i,\pm r}^{\pm} := 0$ if $r < 0$.

For $i \in I$, let $t_{\Lambda_i^\vee} = \tau s_{j_1} \cdots s_{j_r}$ ($\tau \in \mathcal{T}, j_1, \cdots j_r \in \widetilde{I}$) be a reduced expression of $t_{\Lambda_i^\vee}$ (see Sec. II A). Then we set $T_{\Lambda_i^\vee} := T_\tau T_{j_1} \cdots T_{j_r}$.

Theorem 2.3 (Ref. 3): *There exists a $\mathbb{C}(q)$-algebra isomorphism $T: \mathcal{D}_q \to \widetilde{U}_q$ such that*

$$T(X_{i,r}^{+}) = (-1)^{ir} T_{\Lambda_i^\vee}^{-r}(E_i), \quad T(X_{i,r}^{-}) = (-1)^{ir} T_{\Lambda_i^\vee}^{r}(F_i) \quad (i \in I, r \in \mathbb{Z}). \tag{2.7}$$

In particular, by Ref. 3, Sec. 4 Remark and Ref. 8, Sec. 2.5, we obtain the inverse map of T:

$$T^{-1}(E_i) = X_{i,0}^{+}, \quad T^{-1}(F_i) = X_{i,0}^{-}, \quad T^{-1}(K_\mu) = K_\mu,$$

$$T^{-1}(E_0) = (-1)^{m+1} q^{n+1} [X_{n,0}^{-}, \cdots [X_{m+1,0}^{-}, [X_{i,0}^{-}, \cdots [X_{m-1,0}^{-} X_{m,1}^{-}]_{q^{-1}} \cdots]_{q^{-1}} \quad K_\theta^{-1},$$

$$T^{-1}(F_0) = (-1)^{m+n}[X^+_{n,0}, \cdots [X^+_{m+1,0}, [X^+_{1,0}, \cdots [X^+_{m-1,0}, X^+_{m,-1}]_{q^{-1}} \cdots]_{q^{-1}} \quad K_\theta, \tag{2.8}$$

for $m, i \in I$, where $[u,v]_{q^{\pm 1}} := uv - q^{\pm 1}vu$ for $u, v \in \widetilde{U}_q$ (T is independent of the choice of m). We identify $\mathcal{D}_q$ with $\widetilde{U}_q$ by this isomorphism T.

D. PBW basis

Let w_0 be the longest element in $\mathcal{W}$ and $w_0 = s_{i_1} \cdots s_{i_N}$ be a reduced expression of w_0. We set $\gamma_1 := \alpha_{i_1}$, $\gamma_2 := s_{i_1}(\alpha_{i_2}), \ldots, \gamma_N := s_{i_1} \cdots s_{i_{N-1}}(\alpha_{i_N})$. By the theory of the classical Lie algebra, we have $\Delta_+ = \{\gamma_1, \ldots, \gamma_N\}$. Define the root vectors in U_q by

$$\bar{E}_{\gamma_k} := T_{i_1}, \cdots T_{i_{k-1}}(E_{\alpha_{i_k}}), \quad \bar{F}_{\gamma_k} := \Omega(E_{\gamma_k}), \tag{2.9}$$

for $1 \leqslant k \leqslant N$, where $E_{\alpha_i} := E_i$, $F_{\alpha_i} := F_i (i \in I)$. We set

$$\mathbb{Z}_+^{\Delta_+} := \{c : \Delta_+ \to \mathbb{Z}_+; \text{map}\}, \quad B_q^0 := \{K_\mu | \mu \in Q\},$$

$$B_q^+ := \left\{ \prod_{\gamma \in \Delta_+}^{<} \bar{E}_\gamma^{c(\gamma)} | c \in \mathbb{Z}_+^{\Delta_+} \right\}, \quad B_q^- := \Omega(B_q^+), \quad B_q := B_q^- B_q^0 B_q^+, \tag{2.10}$$

where $<$ means that the product is ordered by $\gamma_1 < \cdots < \gamma_N$.

Theorem 2.4 (Ref. 19, Sec. 1): *$B_q^\star$ (respectively, B_q) is a $\mathbb{C}(q)$-basis of $U_q^\star$ (respectively, U_q) for $\star \in \{-, 0, +\}$.*

The following notations and facts are given in Ref. 5. Let $\rho^\vee := \frac{1}{2}\sum_{\alpha \in \Delta_+} \alpha^\vee (\in P^\vee)$ and $t_{2\rho^\vee} = s_{j_1} \cdots s_{j_{\tilde{N}}}$ be a reduced expression of $t_{2\rho^\vee} (2\rho^\vee \in Q^\vee)$. Define the doubly infinite sequence $(\ldots, i_{-1}, i_0, i_1, \ldots)$ by $i_k := j_{k'}$ if $k \equiv k' \pmod{\tilde{N}}$ for all $k \in \mathbb{Z}$, $1 \leqslant k' \leqslant \tilde{N}$. We set

$$\beta_k := s_{i_0} s_{i_{-1}} \cdots s_{i_{k+1}}(\alpha_{i_k}) \quad (k \leqslant 0) \quad \beta_k := s_{i_1} s_{i_2} \cdots s_{i_{k-1}}(\alpha_{i_k}) \quad (k > 0).$$

Then we have $\widetilde{\Delta}_+^{\text{re}} = \{\beta_k\}_{k \in \mathbb{Z}}$. Define a total order on $\widetilde{\Delta}_+(I)$ by

$$\beta_0 < \beta_{-1} < \beta_{-2} < \cdots < (1, \delta) < \cdots < (n, \delta) < (1, 2\delta) < \cdots < (n, 2\delta) < \cdots < \beta_2 < \beta_1. \tag{2.11}$$

We set $E_{\alpha_i} := E_i$, $F_{\alpha_i} := F_i$ $(i \in \widetilde{I})$. Define the positive real root vectors in $\widetilde{U}_q$ by

$$E_{\beta_k} := T_{i_0}^{-1} T_{i_{-1}}^{-1} \cdots T_{i_{k+1}}^{-1}(E_{\alpha_{i_k}}) \quad (k \leqslant 0) \quad E_{\beta_k} := T_{i_1} T_{i_2} \cdots T_{i_{k-1}}(E_{\alpha_{i_k}}) \quad (k > 0), \tag{2.12}$$

and the positive imaginary root vectors $E_{(i,r\delta)}$ by

$$\exp\left((q - q^{-1}) \sum_{s=1}^{\infty} E_{(i,s\delta)} u^k \right) := 1 + \sum_{s=1}^{\infty} (q - q^{-1}) \hat{E}_{(i,s\delta)} u^k, \tag{2.13}$$

where $\hat{E}_{(i,s\delta)} := E_{-\alpha_i + s\delta} E_i - q^{-2} E_i E_{-\alpha_i + s\delta}$ for $i \in I$, $s \in \mathbb{N}$. Define the negative root vectors by $F_\beta := \Omega(E_\beta)$ for $\beta \in \widetilde{\Delta}_+(I)$. We set

$$\mathbb{Z}_+^{\widetilde{\Delta}_+(I)} := \{c : \widetilde{\Delta}_+(I) \to \mathbb{Z}_+; \text{map} | \, \#\{c(\beta) \neq 0\} < \infty\}, \quad \widetilde{B}_q^0 := \{K_\mu | \mu \in Q\},$$

$$\widetilde{B}_q^+ := \left\{ \prod_{\beta \in \widetilde{\Delta}_+(I)}^{<} E_\beta^{c(\beta)} | c \in \mathbb{Z}_+^{\widetilde{\Delta}_+(I)} \right\}, \quad \widetilde{B}_q^- := \Omega(\widetilde{B}_q^+), \quad \widetilde{B}_q := \widetilde{B}_q^- \widetilde{B}_q^0 \widetilde{B}_q^+, \tag{2.14}$$

where $<$ is the total order as in (2.11).

Theorem 2.5 (Ref. 4): $\widetilde{B}_q^{\star}$ (*respectively*, $\widetilde{B}_q$) *is a* $\mathbb{C}(q)$*-basis of* $\widetilde{U}_q^{\star}$ (*respectively*, $\widetilde{U}_q$) *for* $\star \in \{-,0,+\}$.

By Ref. 5 Lemma 1.5, we obtain

$$X_{i,r}^{+} = (-1)^{ir} E_{\alpha_i + r\delta} \quad (r \geqslant 0), \quad X_{i,r}^{+} = (-1)^{ir-1} F_{-\alpha_i - r\delta} K_i^{-1} \quad (r < 0),$$

$$X_{i,r}^{-} = (-1)^{ir-1} K_i E_{-\alpha_i + r\delta} \quad (r > 0), \quad X_{i,r}^{-} = (-1)^{ir} F_{\alpha_i - r\delta} \quad (r \leqslant 0),$$

$$H_{i,s} = (-1)^{is} E_{(i,s\delta)}, \quad \Psi_{i,s}^{+} = (-1)^{is}(q - q^{-1}) K_i \hat{E}_{(i,s\delta)}, \tag{2.15}$$

for $i \in I$, $r \in \mathbb{Z}$, $s \in \mathbb{N}$.

E. Evaluation homomorphisms

There exists a $\mathbb{C}(q)$-algebra homomorphism $U_q(\mathfrak{sl}_{n+1}) \to U_q(\widetilde{\mathfrak{sl}_{n+1}})$ such that

$$E_i \mapsto X_{i,0}^{+}, \quad F_i \mapsto X_{i,0}^{-}, \quad K_\mu \mapsto K_\mu, \tag{2.16}$$

for $i \in I$, $\mu \in Q$. Moreover, for $m \in I$, $0 \leqslant k \leqslant n-m$, there exists a $\mathbb{C}(q)$-algebra homomorphism $U_q(\widetilde{\mathfrak{sl}_{m+1}}) \to U_q(\widetilde{\mathfrak{sl}_{n+1}})$ such that

$$X_{i,r}^{\pm} \mapsto X_{i+k,r}^{\pm}, \quad H_{i,s} \mapsto H_{i+k,s}, \quad K_{\alpha_i} \mapsto K_{\alpha_{i+k}}, \tag{2.17}$$

for $1 \leqslant i \leqslant m$, r, $s \in \mathbb{Z}(s \neq 0)$. Hence we can regard any $U_q(\widetilde{\mathfrak{sl}_{n+1}})$-module as a $U_q(\mathfrak{sl}_{n+1})$-module and $U_q(\widetilde{\mathfrak{sl}_{m+1}})$-module. Let $U_q'(\mathfrak{sl}_{n+1})$ be the extended quantum algebra in Definition 2.1. By the following proposition, we can regard any $U_q'(\mathfrak{sl}_{n+1})$-module as a $U_q(\widetilde{\mathfrak{sl}_{n+1}})$- module.

Proposition 2.6: (Ref. 17, Sec. 2, Ref. 8, Proposition 3.4): For any $\mathbf{a} \in \mathbb{C}^{\times}$, *there exist* $\mathbb{C}(q)$*- algebra homomorphisms* $\mathrm{ev}_{\mathbf{a}}^{\pm}$: $U_q(\widetilde{\mathfrak{sl}_{n+1}}) \to U_q'(\mathfrak{sl}_{n+1})$ *such that*

$$\mathrm{ev}_{\mathbf{a}}^{\pm}(E_i) = E_i, \quad \mathrm{ev}_{\mathbf{a}}^{\pm}(F_i) = F_i, \quad \mathrm{ev}_{\mathbf{a}}^{\pm}(K_\mu) = K_\mu,$$

$$\mathrm{ev}_{\mathbf{a}}^{+}(E_0) = q^{-1}\mathbf{a} K_{\Lambda_1} K_{\Lambda_n}^{-1} [F_n, [F_{n-1}, \ldots, [F_2, F_1]_{q^{-1}} \cdots]_{q^{-1}},$$

$$\mathrm{ev}_{\mathbf{a}}^{-}(E_0) = q^{-1}\mathbf{a} K_{\Lambda_1}^{-1} K_{\Lambda_n} [F_1, [F_2, \ldots, [F_{n-1}, F_n]_{q^{-1}} \cdots]_{q^{-1}},$$

$$\mathrm{ev}_{\mathbf{a}}^{+}(F_0) = (-1)^{n-1} q^n \mathbf{a}^{-1} K_{\Lambda_1}^{-1} K_{\Lambda_n} [E_n, [E_{n-1}, \ldots, [E_2, E_1]_{q^{-1}} \cdots]_{q^{-1}},$$

$$\mathrm{ev}_{\mathbf{a}}^{-}(F_0) = (-1)^{n-1} q^n \mathbf{a}^{-1} K_{\Lambda_1} K_{\Lambda_n}^{-1} [E_1, [E_2, \ldots, [E_{n-1}, E_n]_{q^{-1}} \cdots]_{q^{-1}},$$

for $i \in I$ and $\mu \in P$. By (2.4) and (2.6), we obtain

$$\mathrm{ev}_{\mathbf{a}}^{+}(E_0) = q^{-n}\mathbf{a} K_{\Lambda_1} K_{\Lambda_n}^{-1} T_1^{-1} \cdots T_{n-1}^{-1}(F_n), \quad \mathrm{ev}_{\mathbf{a}}^{-}(E_0) = q^{-n}\mathbf{a} K_{\Lambda_1}^{-1} K_{\Lambda_n} T_n^{-1} \cdots T_2^{-1}(F_1),$$

$$\mathrm{ev}_{\mathbf{a}}^{+}(F_0) = q^{n}\mathbf{a}^{-1} K_{\Lambda_1}^{-1} K_{\Lambda_n} T_1^{-1} \cdots T_{n-1}^{-1}(E_n), \quad \mathrm{ev}_{\mathbf{a}}^{-}(F_0) = q^{n}\mathbf{a}^{-1} K_{\Lambda_1} K_{\Lambda_n}^{-1} T_n^{-1} \cdots T_2^{-1}(E_1). \tag{2.18}$$

III. QUANTUM ALGEBRAS AT ROOTS OF UNITY

In the rest of this paper, we fix the following notations. Let l be an odd integer greater than 2 and ε be a primitive lth root of unity. Moreover, we assume $\gcd(l, n+1) = 1$. By Ref. 6 Lemma 2.1 and Corollary 2.1, we obtain that $\gcd(l, n+1) = 1$ if and only if $\det([k\mathfrak{a}_{i,j}])_{i,j \in I} \neq 0$ for any $k \in \mathbb{Z}$ such that $k \not\equiv 0 \bmod l$.

A. Quantum algebras of nonrestricted type

Let $\mathcal{A}:=\mathbb{C}[q,q^{-1}]$ be the Laurent polynomial ring and $\widetilde{U}_{\mathcal{A}}$ (respectively, $U_{\mathcal{A}}$) be the $\mathcal{A}$-subalgebra of $\widetilde{U}_q$ (respectively, U_q) generated by $\{E_i,F_i,K_{\alpha_j},[K_{\alpha_j};0]\,|\,i\in\widetilde{I}$ (respectively, $i\in I),j\in I\}$, where $[K_{\alpha_j};0]:=(K_{\alpha_j}-K_{\alpha_j}^{-1})/(q-q^{-1})$ for $j\in I$. Let $\widetilde{U}_{\mathcal{A}}^+$ (respectively, $\widetilde{U}_{\mathcal{A}}^-$, $\widetilde{U}_{\mathcal{A}}^0$) be the $\mathcal{A}$-subalgebra of $\widetilde{U}_{\mathcal{A}}$ generated by $\{E_i\}_{i\in\widetilde{I}}$ (respectively, $\{F_i\}_{i\in\widetilde{I}}$, $\{K_{\alpha_i},[K_{\alpha_i};0]\}_{i\in I}$) and $U_{\mathcal{A}}^+$ (respectively, $U_{\mathcal{A}}^-$, $U_{\mathcal{A}}^0$) be the $\mathcal{A}$-subalgebra of $U_{\mathcal{A}}$ generated by $\{E_i\}_{i\in I}$ (respectively, $\{F_i\}_{i\in I}$, $\{K_{\alpha_i},[K_{\alpha_i};0]\}_{i\in I}$). We have triangular decompositions $\widetilde{U}_{\mathcal{A}}=\widetilde{U}_{\mathcal{A}}^-\widetilde{U}_{\mathcal{A}}^0\widetilde{U}_{\mathcal{A}}^+$ and $U_{\mathcal{A}}=U_{\mathcal{A}}^-U_{\mathcal{A}}^0U_{\mathcal{A}}^+$. We set

$$\widetilde{B}_{\mathcal{A}}^+:=\widetilde{B}_q^+,\quad \widetilde{B}_{\mathcal{A}}^-:=\widetilde{B}_q^-,\quad \widetilde{B}_{\mathcal{A}}^0:=\left\{\prod_{i\in I}K_{\alpha_i}^{\delta_i}[K_{\alpha_i};0]^{m_i}\,|\,m_i\in\mathbb{Z}_+,\delta_i=0\text{ or }1\right\},\quad \widetilde{B}_{\mathcal{A}}:=\widetilde{B}_{\mathcal{A}}^-\widetilde{B}_{\mathcal{A}}^0\widetilde{B}_{\mathcal{A}}^+,$$

$$B_{\mathcal{A}}^+:=B_q^+,\quad B_{\mathcal{A}}^-=B_q^-,\quad B_{\mathcal{A}}^0:=\left\{\prod_{i\in I}K_{\alpha_i}^{\delta_i}[K_{\alpha_i};0]^{m_i}\,|\,m_i\in\mathbb{Z}_+,\delta_i=0\text{ or }1\right\},\quad B_{\mathcal{A}}:=B_{\mathcal{A}}^-B_{\mathcal{A}}^0B_{\mathcal{A}}^+.$$

We have $T_i(\widetilde{U}_{\mathcal{A}})\subset\widetilde{U}_{\mathcal{A}}$ by (2.4) and $T_i^{-1}(\widetilde{U}_{\mathcal{A}})\subset\widetilde{U}_{\mathcal{A}}$ by (2.6) for $i\in I$. Hence, by (2.12) and (2.15), we have E_β, F_β, $X_{i,r}^\pm$, $H_{i,s}\in\widetilde{U}_{\mathcal{A}}$ for all $\beta\in\widetilde{\Delta}_+(I)$, $i\in I$, r, $s\in\mathbb{Z}(s\neq 0)$. Similarly, we obtain $T_i^{\pm 1}(U_{\mathcal{A}})\subset U_{\mathcal{A}}$ and $\bar{E}_\gamma$, $\bar{F}_\gamma\in U_{\mathcal{A}}$ for all $\gamma\in\Delta_+$ by (2.9). Thus we obtain $\widetilde{B}_{\mathcal{A}}^\star$, $\widetilde{B}_{\mathcal{A}}\subset\widetilde{U}_{\mathcal{A}}$ and $B_{\mathcal{A}}^\star$, $B_{\mathcal{A}}\subset U_{\mathcal{A}}$ ($\star\in\{-,0,+\}$).

Proposition 3.1: $B_{\mathcal{A}}^\star$ (respectively, $B_{\mathcal{A}}$) is an $\mathcal{A}$-basis of $U_{\mathcal{A}}^\star$ (respectively, $U_{\mathcal{A}}$) for $\star\in\{-,0,+\}$.

Proof: By Theorem 2.4, $B_q^\star$ (respectively, B_q) is $\mathbb{C}$-linearly independent in $U_q^\star$ (respectively, U_q) for $\star\in\{-,0,+\}$. Thus $B_{\mathcal{A}}^\star$ (respectively, $B_{\mathcal{A}}$) is $\mathcal{A}$-linearly independent in $U_{\mathcal{A}}^\star$ (respectively, $U_{\mathcal{A}}$). Let $V_{\mathcal{A}}^\star$ (respectively, $V_{\mathcal{A}}$) be the $\mathcal{A}$-subalgebra of $U_{\mathcal{A}}^\star$ (respectively, $U_{\mathcal{A}}$) generated by $B_{\mathcal{A}}^\star$ (respectively, $B_{\mathcal{A}}$). It is enough to prove that $U_{\mathcal{A}}^\star V_{\mathcal{A}}^\star\subset V_{\mathcal{A}}^\star$ for all $\star\in\{-,0,+\}$. Indeed, if we can prove this claim, then we obtain $U_{\mathcal{A}}^\star=V_{\mathcal{A}}^\star$ and $U_{\mathcal{A}}=U_{\mathcal{A}}^-U_{\mathcal{A}}^0U_{\mathcal{A}}^+=V_{\mathcal{A}}^-V_{\mathcal{A}}^0V_{\mathcal{A}}^+=V_{\mathcal{A}}$. So $U_{\mathcal{A}}^\star$ (respectively, $U_{\mathcal{A}}$) is generated by $B_{\mathcal{A}}^\star$ (respectively, $B_{\mathcal{A}}$) as $\mathcal{A}$-module.

By the following formula, we have $K_{\alpha_i}^{\pm 1}(\Pi_{i\in I}K_{\alpha_i}^{\delta_i}[K_{\alpha_i};0]^{m_i})\in V_{\mathcal{A}}^0$ for all $i\in I$, $m_i\in\mathbb{Z}_+$:

$$K_{\alpha_i}^2=K_{\alpha_i}(K_{\alpha_i}-K_{\alpha_i}^{-1})+1=(q-q^{-1})K_{\alpha_i}[K_{\alpha_i};0]+1\in V_{\mathcal{A}}^0,$$

$$K_{\alpha_i}^{-1}=K_{\alpha_i}-(K_{\alpha_i}-K_{\alpha_i}^{-1})=K_{\alpha_i}-(q-q^{-1})[K_{\alpha_i};0]\in V_{\mathcal{A}}^0.$$

Thus we obtain $U_{\mathcal{A}}^0V_{\mathcal{A}}^0\subset V_{\mathcal{A}}^0$. By Ref. 13 Lemma 1.7, we get the following formula: for α, $\beta\in\Delta_+$ such that $\beta>\alpha$,

$$E_\beta E_\alpha=\sum_{c\in\mathbb{Z}_+^{\Delta_+}}a_c\prod_{\gamma\in\Delta_+}^{<}E_\gamma^{c(\gamma)},$$

where $a_c\in\mathcal{A}$. So we obtain the case of $\star=+$. Similarly, by using the automorphism Ω (see (2.2)), we obtain the case of $\star=-$. □

By Ref. 6 Proposition 1.7(c), we obtain the following formula: for $\alpha,\beta\in\widetilde{\Delta}_+(I)$ such that $\beta>\alpha$,

$$E_\beta E_\alpha=q^{(\alpha,\beta)}E_\alpha E_\beta+\sum_{\alpha<\gamma_1<\cdots<\gamma_m<\beta}c_\gamma E_{\gamma_1}^{a_1}\cdots E_{\gamma_m}^{a_m},$$

where $c_\gamma\in\mathcal{A}$ for $\gamma=(\gamma_1,\ldots,\gamma_m)\in\widetilde{\Delta}_+(I)^m$. So, in a similar way to the proof of Proposition 3.1, we obtain the following proposition.

Proposition 3.2: $\widetilde{B}_{\mathcal{A}}^\star$ (respectively, $\widetilde{B}_{\mathcal{A}}$) is an $\mathcal{A}$-basis of $\widetilde{U}_{\mathcal{A}}^\star$ (respectively, $\widetilde{U}_{\mathcal{A}}$) for $\star\in\{-,0,+\}$.

Now we define the quantum algebras of nonrestricted type. We regard $\mathbb{C}$ as $\mathcal{A}$-module by $g(q).c := g(\varepsilon)c$ for $g(q) \in \mathcal{A}$, $c \in \mathbb{C}$ and denote it by $\mathbb{C}_\varepsilon$. We define

$$\widetilde{U}_\varepsilon := \widetilde{U}_\mathcal{A} \otimes_\mathcal{A} \mathbb{C}_\varepsilon \quad (\text{respectively, } U_\varepsilon := U_\mathcal{A} \otimes_\mathcal{A} \mathbb{C}_\varepsilon).$$

Then we call $\widetilde{U}_\varepsilon$ (respectively, U_ε) "quantum loop algebra (respectively, quantum algebra) of nonrestricted type (or De Concini-Kac type)" (see Refs. 6 and 13). For $\star \in \{-,0,+\}$, we set $\widetilde{U}^\star_\varepsilon := \widetilde{U}^\star_\mathcal{A} \otimes_\mathcal{A} 1$ (respectively, $U^\star_\varepsilon := U^\star_\mathcal{A} \otimes_\mathcal{A} 1$). We simply denote $u \otimes 1$ by u for $u \in \widetilde{U}_\mathcal{A}$ (respectively, $U_\mathcal{A}$).

Remark 3.3: (a) In Ref. 6 (respectively, Ref. 13), $\widetilde{U}_\varepsilon$ (respectively, U_ε) is defined by $\widetilde{U}_\varepsilon := \widetilde{U}_{\mathcal{A}^\varepsilon}/(q-\varepsilon)\widetilde{U}_{\mathcal{A}^\varepsilon}$ (respectively, $U_\varepsilon := U_\mathcal{A}/(q-\varepsilon)U_\mathcal{A}$), where $\mathcal{A}^\varepsilon := \{g(q) \in \mathbb{C}(q) \,|\, g(q) \text{ has no poles at } q=\varepsilon\} (\supset \mathcal{A})$ and $(q-\varepsilon)\widetilde{U}_{\mathcal{A}^\varepsilon}$ (respectively, $(q-\varepsilon)U_\mathcal{A}$) is the two-sided ideal of $\mathbb{C}$-algebra $\widetilde{U}_{\mathcal{A}^\varepsilon}$ (respectively, $U_\mathcal{A}$) generated by $(q-\varepsilon)$. But, by the universality of tensor product, we obtain

$$\widetilde{U}_\mathcal{A} \otimes_\mathcal{A} \mathbb{C}_\varepsilon \cong \widetilde{U}_\mathcal{A}/(q-\varepsilon)\widetilde{U}_\mathcal{A} \cong \widetilde{U}_{\mathcal{A}^\varepsilon}/(q-\varepsilon)\widetilde{U}_{\mathcal{A}^\varepsilon} \quad (\text{as } \mathbb{C}\text{-algebra}),$$

$$U_\mathcal{A} \otimes_\mathcal{A} \mathbb{C}_\varepsilon \cong U_\mathcal{A}/(q-\varepsilon)U_\mathcal{A} \cong U_{\mathcal{A}^\varepsilon}/(q-\varepsilon)U_{\mathcal{A}^\varepsilon} \quad (\text{as } \mathbb{C}\text{-algebra}).$$

(b) $\widetilde{U}_\varepsilon$ (respectively, U_ε) is the associative algebra over $\mathbb{C}$ on generators $\{E_i, F_i, K_\mu \,|\, i \in \widetilde{I}$ (respectively, I), $\mu \in \widetilde{Q}$ (respectively, $Q)\}$ and defining relations in Definition 2.1 replaced q by ε (see Ref. 6, Sec. 1.9 and Ref. 13, Sec. 1.5).

We set $\widetilde{B}^\star_\varepsilon := \widetilde{B}_\mathcal{A} \otimes_\mathcal{A} 1$ ($\star \in \{-,0,+\}$). Similarly, we define $\widetilde{B}_\varepsilon$, $B^\star_\varepsilon$ and B_ε.

Lemma 3.4: Let $\{v_j\}_j$ be an $\mathcal{A}$-basis in $\widetilde{U}_\mathcal{A}$ (respectively, $U_\mathcal{A}$). Then $\{v_j + (q-\varepsilon)\widetilde{U}_\mathcal{A}\}_j$ (respectively, $\{v_j + (q-\varepsilon)U_\mathcal{A}\}_j$) is a $\mathbb{C}$-basis of $\widetilde{U}_\mathcal{A}/(q-\varepsilon)\widetilde{U}_\mathcal{A}$ (respectively, $U_\mathcal{A}/(q-\varepsilon)U_\mathcal{A}$).

Proof: $\widetilde{U}_\mathcal{A}/(q-\varepsilon)\widetilde{U}_\mathcal{A}$ is spanned by $\{v_j + (q-\varepsilon)\widetilde{U}_\mathcal{A}\}_j$ as $\mathbb{C}$-vector space. So we shall prove that $\{v_j + (q-\varepsilon)\widetilde{U}_\mathcal{A}\}_j$ is linearly independent over $\mathbb{C}$ in $\widetilde{U}_\mathcal{A}/(q-\varepsilon)\widetilde{U}_\mathcal{A}$. We assume that $\Sigma_j c_j (v_j + (q-\varepsilon)\widetilde{U}_\mathcal{A}) = 0$ ($c_j \in \mathbb{C}, \#\{j \,|\, c_j \neq 0\} < \infty$). Then $\Sigma_j c_j v_j \in (q-\varepsilon)\widetilde{U}_\mathcal{A}$. Since $\widetilde{U}_\mathcal{A}$ is generated by $\{v_j\}_j$ as an $\mathcal{A}$-module, there exist $c_{j,m} \in \mathbb{C} (m \in \mathbb{Z}, \#\{(j,m) \,|\, c_{j,m} \neq 0\} < \infty)$ such that $\Sigma_j c_j v_j = (q-\varepsilon)\Sigma_{j,m} c_{j,m} q^m v_j$ in $\widetilde{U}_\mathcal{A}$. Since $\{v_j\}_j$ is linearly independent over $\mathcal{A}$ in $\widetilde{U}_\mathcal{A}$, we obtain $c_j = (q-\varepsilon)\Sigma_{m \in \mathbb{Z}} c_{j,m} q^m$ for all j. Therefore we obtain $c_j = c_{j,m} = 0$ for any j and m. Similarly, we obtain the case of $U_\mathcal{A}$. □

By this lemma, Proposition 3.2, and Remark 3.3(a), we obtain the following proposition.

Proposition 3.5: $\widetilde{B}^\star_\varepsilon$ (respectively, $\widetilde{B}_\varepsilon$) is a $\mathbb{C}$-basis of $\widetilde{U}^\star_\varepsilon$ (respectively, $\widetilde{U}_\varepsilon$) for $\star \in \{-,0,+\}$.

The classical case of this proposition is given in Ref. 13, Sec. 1.7.

Proposition 3.6: $B^\star_\varepsilon$ (respectively, B_ε) is a $\mathbb{C}$-basis of $U^\star_\varepsilon$ (respectively, U_ε) for $\star \in \{-,0,+\}$.

Let $Z(\widetilde{U}_\varepsilon)$ (respectively $Z(U_\varepsilon)$) be the center of $\widetilde{U}_\varepsilon$ (respectively, U_ε) and $\widetilde{Z}_0$ (respectively, Z_0) be the $\mathbb{C}$-subalgebra of $\widetilde{U}_\varepsilon$ (respectively, U_ε) generated by $\{E^l_\beta, F^l_\beta, E_{(i,sl\delta)}, F_{(i,sl\delta)}, K^l_\mu \,|\, \beta \in \widetilde{\Delta}^{\mathrm{re}}_+, i \in I, s \in \mathbb{N}, \mu \in Q\}$ (respectively, $\{\bar{E}^l_\gamma, \bar{F}^l_\gamma, K^l_\mu \,|\, \gamma \in \Delta_+, \mu \in Q\}$).

Proposition 3.7 (Ref. 6, Lemma 2.2, Proposition 2.3): $\widetilde{Z}_0 = Z(\widetilde{U})$.

Proposition 3.8 (Ref. 13, Corollary 3.1): $Z_0 \subset Z(U_\varepsilon)$.

For $m \in \mathbb{N}$, we set $\mathbb{Z}_m := \{0,1,\ldots,m-1\} \subset \mathbb{Z}_+$ and $Q_m := \oplus_{i \in I} \mathbb{Z}_m \alpha_i$. Let I_ε be the two-sided ideal of U_ε generated by $\{\bar{E}^l_\gamma, \bar{F}^l_\gamma, K^{2l}_\mu - 1 \,|\, \gamma \in \Delta_+, \mu \in Q\}$ and set $(U_\varepsilon/I_\varepsilon)^\star := \{u + I_\varepsilon \,|\, u \in U^\star_\varepsilon\} \subset U_\varepsilon/I_\varepsilon$ for $\star \in \{-,0,+\}$. We set

$$\mathbb{Z}_l^{\Delta_+} := \{c : \Delta_+ \to \mathbb{Z}_l; \text{map}\}, \quad B^+_l := \left\{ \left(\prod_{\gamma \in \Delta_+}^{<} \bar{E}_\gamma \right) + I_\varepsilon \,|\, \gamma \in \mathbb{Z}_l^{\Delta_+} \right\},$$

$$B^-_l := \Omega(B^+_l), \quad B^0_l := \{K_\mu + I_\varepsilon \,|\, \mu \in Q_{2l}\}, \quad B_l := B^-_l B^0_l B^+_l. \tag{3.1}$$

Proposition 3.9: $B_l^\star$ (*respectively*, B_l) *is a* $\mathbb{C}$*-basis of* $(U_\varepsilon/I_\varepsilon)^\star$ (*respectively*, $U_\varepsilon/I_\varepsilon$) *for* $\star \in \{-,0,+\}$.

Proof: We shall prove that B_l^+ is a $\mathbb{C}$-basis of $(U_\varepsilon/I_\varepsilon)^+$. We can also prove the other cases similarly. Let V_l^+ be the $\mathbb{C}$-subspace of $(U_\varepsilon/I_\varepsilon)^+$ spanned by B_l^+ and $u+I_\varepsilon \in (U_\varepsilon/I_\varepsilon)^+$. By Theorem 2.4, there exist $a_c \in \mathbb{C}(c \in \mathbb{Z}_+^{\Delta_+})$ such that $u+I_\varepsilon=\Sigma_{c\in\mathbb{Z}_+^{\Delta_+}} a_c \Pi_{\gamma\in\Delta_+}^{<} \bar{E}_\gamma^{c(\gamma)}+I_\varepsilon$. If c is an element in $\mathbb{Z}_+^{\Delta_+}\backslash\mathbb{Z}_l^{\Delta_+}$, then there exists $\gamma_0 \in \Delta_+$ such that $c(\gamma_0) \geqslant l$. Then we have $\Pi_{\gamma\in\Delta_+}^{<} \bar{E}_\gamma^{c(\gamma)} \in I_\varepsilon$. Hence $u+I_\varepsilon=\Sigma_{c\in\mathbb{Z}_l^{\Delta_+}} a_c \Pi_{\gamma\in\Delta_+}^{<} \bar{E}_\gamma^{c(\gamma)}+I_\varepsilon \in V_l^+$. So $(U_\varepsilon/I_\varepsilon)^+$ is spanned by B_l^+.

Let $u=\Sigma_{c\in\mathbb{Z}_l^{\Delta_+}} a_c \Pi_{\gamma\in\Delta_+}^{<} \bar{E}_\gamma^{c(\gamma)} \in U_\varepsilon^+(a_c \in \mathbb{C}, c \in \mathbb{Z}_l^{\Delta_+})$. We assume $u+I_\varepsilon=0$ in $(U_\varepsilon/I_\varepsilon)^+$. Then we have $u \in I_\varepsilon \cap U_\varepsilon^+$. By Theorem 2.4, we obtain

$$I_\varepsilon \cap U_\varepsilon^+ = \left(\sum_{\gamma\in\Delta_+} U_\varepsilon \bar{E}_\gamma^l + \sum_{\mu\in Q} U_\varepsilon (K_\mu^{2l}-1) + \sum_{\gamma\in\Delta_+} U_\varepsilon \bar{F}_\gamma^l \right) \cap U_\varepsilon^+ = \sum_{\gamma\in\Delta_+} U_\varepsilon^+ \bar{E}_\gamma^l.$$

Hence there exists $u'=\Sigma_{c'\in\mathbb{Z}_+^{\Delta_+}} b_{c'} \Pi_{\gamma\in\Delta_+}^{<} \bar{E}_\beta^{c'(\beta)} \in U_\varepsilon^+(b_{c'} \in \mathbb{C}, c' \in \mathbb{Z}_l^{\Delta_+})$ such that $u=\Sigma_{\gamma\in\Delta_+} u' \bar{E}_\gamma^l$. Since $\bar{E}_\gamma^l$ is a central element in U_ε (see Proposition 3.8), we have

$$\sum_{\gamma\in\Delta_+} u' \bar{E}_\gamma^l \in \sum_{c\in\mathbb{Z}_+^{\Delta_+}\backslash\mathbb{Z}_l^{\Delta_+}} \mathbb{C}\left(\prod_{\gamma\in\Delta_+}^{<} \bar{E}_\gamma^{c(\gamma)} \right).$$

Thus, by Proposition 3.6, we get $a_c=0$ for any $c \in \mathbb{Z}_l^{\Delta_+}$. Therefore B_l^+ is linearly independent in $(U_\varepsilon/I_\varepsilon)^+$.

Let $\tilde{I}_\varepsilon$ be the two-sided ideal of $\tilde{U}_\varepsilon$ generated by $\{E_\beta^l, F_\beta^l, E_{(i,sl\delta)}, F_{(i,sl\delta)}, K_\mu^{2l}-1 \,|\, \beta \in \tilde{\Delta}_+^{\mathrm{re}}, i \in I, s \in \mathbb{N}, \mu \in Q\}$ and set $(\tilde{U}_\varepsilon/\tilde{I}_\varepsilon)^\star := \{u+\tilde{I}_\varepsilon \,|\, u \in \tilde{U}_\varepsilon^\star\}$ for $\star \in \{-,0,+\}$. We define

$$\mathbb{Z}_l^{\tilde{\Delta}_+(I)} := \{c \in \mathbb{Z}_+^{\tilde{\Delta}_+(I)} | c(\beta) \in \mathbb{Z}_l, c((i,sl\delta))=0 (\beta \in \tilde{\Delta}_+^{\mathrm{re}}, i \in I, s \in \mathbb{N})\},$$

$$\tilde{B}_l^+ := \left\{ \prod_{\beta\in\tilde{\Delta}_+(I)}^{<} E_\beta^{c(\beta)} + \tilde{I}_\varepsilon | c \in \mathbb{Z}_l^{\tilde{\Delta}_+(I)} \right\}, \quad \tilde{B}_l^- := \Omega(\tilde{B}_l^+),$$

$$\tilde{B}_l^0 := \{K_\mu + \tilde{I}_\varepsilon | \mu \in Q_{2l}\}, \quad \tilde{B}_l := \tilde{B}_l^- \tilde{B}_l^0 \tilde{B}_l^+. \tag{3.2}$$

Then, by Theorem 2.5 and Proposition 3.7, we obtain the following proposition.

Proposition 3.10: $\tilde{B}_l^\star$ (*respectively*, $\tilde{B}_l$) *is a* $\mathbb{C}$*-basis of* $(\tilde{U}_\varepsilon/\tilde{I}_\varepsilon)^\star$ (*respectively*, $(\tilde{U}_\varepsilon/\tilde{I}_\varepsilon)$) *for* $\star \in \{-,0,+\}$.

The proof of this proposition is similar to the one of Proposition 3.9.

B. Quantum algebras of restricted type

Let $\tilde{U}_{\mathcal{A}}^{\mathrm{res}}$ (respectively, $U_{\mathcal{A}}^{\mathrm{res}}$) be the $\mathcal{A}$-subalgebra of $\tilde{U}_q$ (respectively, U_q) generated by $\{E_i^{(m)}, F_i^{(m)}, K_\mu | i \in \tilde{I}$ (respectively, I), $m \in \mathbb{N}, \mu \in Q\}$. We set

$$\begin{bmatrix} K_{\alpha_i}; r \\ m \end{bmatrix} := \prod_{s=1}^{m} \frac{K_{\alpha_i} q^{r-s+1} - K_{\alpha_i}^{-1} q^{-r+s-1}}{q^s - q^{-s}},$$

for $m \in \mathbb{N}$, $r \in \mathbb{Z}$, $i \in I$. It is known that $\begin{bmatrix} K_{\alpha_i}; r \\ m \end{bmatrix} \in U_{\mathcal{A}}^{\mathrm{res}}$ (see Ref. 9, Sec. 9.3A). By (2.4) and (2.6), we have $T_i^{\pm 1}(\tilde{U}_{\mathcal{A}}^{\mathrm{res}}) \subset \tilde{U}_{\mathcal{A}}^{\mathrm{res}}$ (respectively, $T_{\mathbf{i}}^{\pm 1}(U_{\mathcal{A}}^{\mathrm{res}}) \subset U_{\mathcal{A}}^{\mathrm{res}}$) for any $i \in \tilde{I}$ (respectively, I). Hence we obtain $E_\beta, F_\beta, X_{i,r}^\pm, H_{i,s} \in \tilde{U}_{\mathcal{A}}^{\mathrm{res}}$ for $\beta \in \tilde{\Delta}_+(I)$, $i \in I$, $r, s \in \mathbb{Z}(s \neq 0)$ by (2.12) and (2.15). Similarly, we obtain $\bar{E}_\gamma, \bar{F}_\gamma \in U_{\mathcal{A}}^{\mathrm{res}}$ for any $\gamma \in \Delta_+$ by (2.9). We define

$$\widetilde{U}_{\varepsilon}^{\mathrm{res}} := \widetilde{U}_{\mathcal{A}}^{\mathrm{res}} \otimes_{\mathcal{A}} \mathbb{C}_{\varepsilon} \quad (\text{respectively, } U_{\varepsilon}^{\mathrm{res}} := U_{\mathcal{A}}^{\mathrm{res}} \otimes_{\mathcal{A}} \mathbb{C}_{\varepsilon}).$$

Then we call $\widetilde{U}_{\varepsilon}^{\mathrm{res}}$ (respectively, $U_{\varepsilon}^{\mathrm{res}}$) "quantum loop algebra (respectively, quantum algebra) of restricted type (or Lusztig type)" (see Refs. 18 and 11). We denote $E_{\beta} \otimes 1$ by e_{β} for $\beta \in \widetilde{\Delta}_{+}(I)$. Similarly, we set $f_{\beta} := F_{\beta} \otimes 1$, $k_{\mu} := K_{\mu} \otimes 1$, $x_{i,r} := X_{i,r} \otimes 1, \ldots$. Moreover, we set

$$\dot{e}_{\beta} := e_{\beta}, \quad \dot{f}_{\beta} := \Omega(\dot{e}_{\beta}), \quad \dot{e}_{(i,m\delta)} := \left(\frac{1}{[m]} E_{(i,m\delta)} \right) \otimes 1, \quad \dot{f}_{(i,m\delta)} := \Omega(\dot{e}_{(i,m\delta)}),$$

$$\dot{h}_{i,s} := \left(\frac{1}{[s]} H_{i,s} \right) \otimes 1, \quad \begin{bmatrix} k_{\alpha_i}; r \\ m \end{bmatrix} := \begin{bmatrix} K_{\alpha_i}; r \\ m \end{bmatrix} \otimes 1,$$

for $\beta \in \widetilde{\Delta}_{+}^{\mathrm{re}}$, $i \in I$, $m \in \mathbb{N}$, $r, s \in \mathbb{Z}(s \neq 0)$. Let $(\widetilde{U}_{\varepsilon}^{\mathrm{res}})^{\pm}$ (respectively, $(\widetilde{U}_{\varepsilon}^{\mathrm{res}})^{0}$) be the $\mathbb{C}$-subalgebra of $\widetilde{U}_{\varepsilon}^{\mathrm{res}}$ generated by $\{(x_{i,r}^{\pm})^{(m)} | i \in I, r \in \mathbb{Z}, m \in \mathbb{N}\}$ (respectively, $\left\{ k_{\mu}, \begin{bmatrix} k_{\alpha_i}; r \\ m \end{bmatrix}, \dot{h}_{i,s} \middle| \mu \in Q, i \in I, r \in \mathbb{Z}, m \in \mathbb{N}, s \in \mathbb{Z}^{\times} \right\}$) and $(U_{\varepsilon}^{\mathrm{res}})^{+}$ (respectively, $(U_{\varepsilon}^{\mathrm{res}})^{-}, (U_{\varepsilon}^{\mathrm{res}})^{0}$) be the $\mathbb{C}$-subalgebra of $U_{\varepsilon}^{\mathrm{res}}$ generated by $\{e_i^{(m)} | i \in I, m \in \mathbb{N}\}$ (respectively, $\{f_i^{(m)} | i \in I, m \in \mathbb{N}\}$, $\left\{ k_{\mu}, \begin{bmatrix} k_{\alpha_i}; r \\ m \end{bmatrix} \middle| \mu \in Q, i \in I, r \in \mathbb{Z}, m \in \mathbb{N} \right\}$). We obtain that $\begin{bmatrix} k_{\alpha_i}; r \\ m \end{bmatrix}$ is generated by $\left\{ k_{\alpha_i}, \begin{bmatrix} k_{\alpha_i}; 0 \\ l \end{bmatrix} \right\}$ for $i \in I$, $r \in \mathbb{Z}$, $m \in \mathbb{N}$. It is known that $U_{\varepsilon}^{\mathrm{res}}$ has the triangular decomposition, that is, the multiplication map defines an isomorphism of $\mathbb{C}$-vector spaces:

$$(U_{\varepsilon}^{\mathrm{res}})^{-} \otimes (U_{\varepsilon}^{\mathrm{res}})^{0} \otimes (U_{\varepsilon}^{\mathrm{res}})^{+} \xrightarrow{\sim} U_{\varepsilon}^{\mathrm{res}} \quad (u^{-} \otimes u^{0} \otimes u^{+} \mapsto u^{-} u^{0} u^{+}). \tag{3.3}$$

Moreover, by Ref. 11, Proposition 6.1, we have

$$(\widetilde{U}_{\varepsilon}^{\mathrm{res}})^{-} \otimes (\widetilde{U}_{\varepsilon}^{\mathrm{res}})^{0} \otimes (\widetilde{U}_{\varepsilon}^{\mathrm{res}})^{+} \xrightarrow{\sim} \widetilde{U}_{\varepsilon}^{\mathrm{res}} \quad (\widetilde{u}^{-} \otimes \widetilde{u}^{0} \otimes \widetilde{u}^{+} \mapsto \widetilde{u}^{-} \widetilde{u}^{0} \widetilde{u}^{-}). \tag{3.4}$$

We set

$$(\widetilde{B}_{\varepsilon}^{\mathrm{res}}) := \left\{ \prod_{\beta \in \widetilde{\Delta}_{+}(I)}^{<} \dot{e}_{\beta}^{(c(\beta))} | c \in \mathbb{Z}_{l}^{\widetilde{\Delta}_{+}(I)} \right\}, \quad (\widetilde{B}_{\varepsilon}^{\mathrm{res}})^{-} := \Omega((\widetilde{B}_{\varepsilon}^{\mathrm{res}})^{+}),$$

$$(\widetilde{B}_{\varepsilon}^{\mathrm{res}})^{0} := \left\{ \prod_{i \in I} k_{\alpha_i}^{\delta_i} \begin{bmatrix} k_{\alpha_i}; 0 \\ m_i \end{bmatrix} | m_i \in \mathbb{N}, \delta_i = 0 \text{ or } 1 \right\}, \quad \widetilde{B}_{\varepsilon}^{\mathrm{res}} := (\widetilde{B}_{\varepsilon}^{\mathrm{res}})^{-} (\widetilde{B}_{\varepsilon}^{\mathrm{res}})^{0} (\widetilde{B}_{\varepsilon}^{\mathrm{res}})^{+},$$

(see (2.14)). By Ref. 16, we obtain the following theorem.

Theorem 3.11: *$\widetilde{B}_{\varepsilon}^{\mathrm{res}}$ is a $\mathbb{C}$-basis of $\widetilde{U}_{\varepsilon}^{\mathrm{res}}$.*

Proof: By Ref. 16, we obtain a PBW basis of $\widetilde{U}_{\mathcal{A}}^{\mathrm{res}}$. Since any $\mathcal{A}$-basis of $\widetilde{U}_{\mathcal{A}}^{\mathrm{res}}$ becomes $\mathbb{C}$-basis of $\widetilde{U}_{\mathcal{A}}^{\mathrm{res}} \otimes_{\mathcal{A}} \mathbb{C}_{\varepsilon}$ canonically (see Lemma 3.4), we obtain this theorem. □

C. Small quantum algebras

Let $\widetilde{U}_{\varepsilon}^{\mathrm{fin}}$ (respectively, $U_{\varepsilon}^{\mathrm{fin}}$) be the $\mathbb{C}$-subalgebra of $\widetilde{U}_{\varepsilon}^{\mathrm{res}}$ (respectively, $U_{\varepsilon}^{\mathrm{res}}$) generated by $\{e_i, f_i, k_{\mu} | i \in \widetilde{I}$ (respectively, I), $\mu \in Q\}$). Then we call $\widetilde{U}_{\varepsilon}^{\mathrm{fin}}$ (respectively, $U_{\varepsilon}^{\mathrm{fin}}$) "small quantum loop algebra (respectively, small quantum algebra)." Let $\mathcal{D}_{\varepsilon}^{\mathrm{fin}}$ be the $\mathbb{C}$-subalgebra of $\widetilde{U}_{\varepsilon}^{\mathrm{res}}$ generated by $\{x_{i,r}^{\pm}, h_{i,s}, k_{\mu} | i \in I, r, s \in \mathbb{Z}(s \neq 0), \mu \in Q\}$. By (2.8), we obtain $e_0, f_0 \in \mathcal{D}_{\varepsilon}^{\mathrm{fin}}$. So we have $\mathcal{D}_{\varepsilon}^{\mathrm{fin}} = \widetilde{U}_{\varepsilon}^{\mathrm{fin}}$. Let $(\widetilde{U}_{\varepsilon}^{\mathrm{fin}})^{\pm}$ (respectively, $(\widetilde{U}_{\varepsilon}^{\mathrm{fin}})^{0}$) be the $\mathbb{C}$-subalgebra of $\widetilde{U}_{\varepsilon}^{\mathrm{fin}}$ generated by $\{x_{i,r}^{\pm} | i \in I, r \in \mathbb{Z}\}$ (respectively, $\{h_{i,s}, k_{\mu} | i \in I, s \in \mathbb{Z}^{\times}, \mu \in Q\}$) and $(U_{\varepsilon}^{\mathrm{fin}})^{+}$ (respectively, $(U_{\varepsilon}^{\mathrm{fin}})^{-}, (U_{\varepsilon}^{\mathrm{fin}})^{0}$) be the $\mathbb{C}$-subalgebra of $U_{\varepsilon}^{\mathrm{fin}}$ generated by $\{e_i\}_{i \in I}$ (respectively, $\{f_i\}_{i \in I}$, $\{k_{\mu}\}_{\mu \in Q}$). Let $\mathbb{Z}_{l}^{\Delta_{+}}$ be as in (3.1). We set

$$(B_\varepsilon^{\mathrm{fin}})^+ := \left\{ \prod_{\gamma\in\Delta_+}^{<} \overline{e}_\gamma^{c(\gamma)} | c \in \mathbb{Z}_l^{\Delta_+} \right\}, \quad (B_\varepsilon^{\mathrm{fin}})^- := \Omega((B_\varepsilon^{\mathrm{fin}})^+),$$

$$(B_\varepsilon^{\mathrm{fin}})^0 := \{k_\mu | \mu \in Q_{2l}\}, \quad B_\varepsilon^{\mathrm{fin}} := (B_\varepsilon^{\mathrm{fin}})^-(B_\varepsilon^{\mathrm{fin}})^0(B_\varepsilon^{\mathrm{fin}})^+. \tag{3.5}$$

Theorem 3.12 (Ref. 19, Sec. 5, Ref. 20, Sec. 8): $(B_\varepsilon^{fin})^\star$ *(respectively,* B_ε^{fin}*) is a* $\mathbb{C}$*-basis of* $(U_\varepsilon^{\mathrm{fin}})^\star$ *(respectively,* $U_\varepsilon^{\mathrm{fin}}$*) for* $\star \in \{-,0,+\}$.

Since e_β, f_β are generated by $\{e_i\}_{i\in\tilde{I}}, \{f_i\}_{i\in\tilde{I}}$, respectively, we get e_β, $f_\beta \in \tilde{U}_\varepsilon^{\mathrm{fin}}$ for any $\beta \in \tilde{\Delta}_+(I)$. For $\beta \in \tilde{\Delta}_+^{\mathrm{re}}$, $i \in I$, $m \in \mathbb{N}$, we have

$$e_\beta^l = [l]_\varepsilon! \dot{e}_\beta^{(l)}, \quad f_\beta^l = [l]_\varepsilon! \dot{f}_\beta^{(l)}, \quad e_{(i,ml\delta)} = [l]_\varepsilon \dot{e}_{(i,ml\delta)}, \quad f_{(i,ml\delta)} = [l]_\varepsilon \dot{f}_{(i,ml\delta)},$$

$$\prod_{r=1}^{l} (k_{\alpha_i}\varepsilon^{1-r} - k_{\alpha_i}\varepsilon^{r-1}) = \prod_{r=1}^{l} (\varepsilon^r - \varepsilon^{-r}) \begin{bmatrix} k_{\alpha_i}; 0 \\ l \end{bmatrix},$$

(see Ref. 18, Lemma 4.4). So we obtain

$$e_\beta^l = f_\beta^l = e_{(i,sl\delta)} = f_{(i,sl\delta)} = k_{\alpha_i}^{2l} - 1 = 0, \tag{3.6}$$

for any $\beta \in \tilde{\Delta}_+^{\mathrm{re}}$, $s \in \mathbb{N}$, $i \in I$. Let $\mathbb{Z}_l^{\tilde{\Delta}_+(I)}$ be as in (3.2). Define

$$(\tilde{B}_\varepsilon^{\mathrm{fin}})^+ := \left\{ \prod_{\beta\in\tilde{\Delta}_+(I)}^{<} e_\beta^{c(\beta)} | c \in \mathbb{Z}_l^{\tilde{\Delta}_+(I)} \right\}, \quad (\tilde{B}_\varepsilon^{\mathrm{fin}})^- := \Omega((\tilde{B}_\varepsilon^{\mathrm{fin}})^+),$$

$$(\tilde{B}_\varepsilon^{\mathrm{fin}})^0 := \{k_\mu | \mu \in Q_{2l}\}, \quad \tilde{B}_\varepsilon^{\mathrm{fin}} := (\tilde{B}_\varepsilon^{\mathrm{fin}})^-(\tilde{B}_\varepsilon^{\mathrm{fin}})^0(\tilde{B}_\varepsilon^{\mathrm{fin}})^+.$$

Since $e_\beta, f_\beta \in \tilde{U}_\varepsilon^{\mathrm{fin}}$ for any $\beta \in \tilde{\Delta}_+(I)$, we have $\tilde{B}_\varepsilon^{\mathrm{fin}} \subset \tilde{U}_\varepsilon^{\mathrm{fin}}$. Therefore, by Theorem 3.11, we obtain the following lemma.

Proposition 3.13: $\tilde{B}_\varepsilon^{\mathrm{fin}}$ *is linearly independent in* $\tilde{U}_\varepsilon^{\mathrm{fin}}$.

D. Isomorphism theorem

Proposition 3.14 (Ref. 2, Lemma 4.8): There exists a $\mathbb{C}$*-algebra isomorphism* $\bar{\phi}: U_\varepsilon/I_\varepsilon \to U_\varepsilon^{\mathrm{fin}}$ *such that* $\bar{\phi}(E_i+I_\varepsilon)=e_i$, $\bar{\phi}(F_i+I_\varepsilon)=f_i$ and $\bar{\phi}(K_\mu+I_\varepsilon)=k_\mu$ *for* $i \in I$, $\mu \in Q$.

We obtain an affine version of the above-noted result:

Theorem 3.15: *There exists a* $\mathbb{C}$*-algebra isomorphism* $\tilde{\phi}: \tilde{U}_\varepsilon/\tilde{I}_\varepsilon \to \tilde{U}_\varepsilon^{\mathrm{fin}}$ *such that* $\tilde{\phi}(E_i+\tilde{I}_\varepsilon) = e_i$, $\tilde{\phi}(F_i+\tilde{I}_\varepsilon)=f_i$ *and* $\tilde{\phi}(K_\mu+\tilde{I}_\varepsilon)=k_\mu$ *for* $i \in \tilde{I}$, $\mu \in Q$. *In particular,* $\tilde{B}_\varepsilon^{\mathrm{fin}}$ *is a* $\mathbb{C}$*-basis of* $\tilde{U}_\varepsilon^{\mathrm{fin}}$.

Proof: Elements in $\{e_i, f_i, k_\mu | i \in \tilde{I}, \mu \in Q\} (\subset \tilde{U}_\varepsilon^{\mathrm{fin}})$ satisfy the relations of Definition 2.1. So, by the universality of $\tilde{U}_\varepsilon$ (see Remark 3.3 (b)), there exists a surjective $\mathbb{C}$-algebra homomorphism $\phi: \tilde{U}_\varepsilon \to \tilde{U}_\varepsilon^{\mathrm{fin}}$ such that $E_i \mapsto e_i$, $F_i \mapsto f_i$, $K_\mu \mapsto k_\mu$ for $i \in \tilde{I}$, $\mu \in Q$. Since $e_\beta = E_\beta \otimes 1$ and $f_\beta = F_\beta \otimes 1$ $(\beta \in \tilde{\Delta}_+(I))$, we obtain $\phi(E_\beta)=e_\beta$ and $\phi(F_\beta)=f_\beta$. Then, by (3.6), we have $\phi(\tilde{I}_\varepsilon)=0$. Hence there exists a surjective $\mathbb{C}$-algebra homomorphism $\tilde{\phi}: \tilde{U}_\varepsilon/\tilde{I}_\varepsilon \to \tilde{U}_\varepsilon^{\mathrm{fin}}$ such that $\tilde{\phi}(E_\beta+\tilde{I}_\varepsilon)=e_\beta$, $\tilde{\phi}(F_\beta+\tilde{I}_\varepsilon) = f_\beta$ and $\tilde{\phi}(K_\mu+\tilde{I}_\varepsilon)=k_\mu$ for $\beta \in \tilde{\Delta}_+(I)$, $\mu \in Q$.

Let $u \in \mathrm{Ker}(\tilde{\phi})$. By Proposition 3.10, we have

$$u = \sum_{\mu\in Q_{2l}} \sum_{c,c' \in \mathbb{Z}_l^{\tilde{\Delta}_+(I)}} a(c,\mu,c') \left(\prod_{\beta\in\tilde{\Delta}_+(I)}^{<} E_\beta^{c(\beta)} + \tilde{I}_\varepsilon \right) (K_\mu + \tilde{I}_\varepsilon) \left(\prod_{\beta\in\tilde{\Delta}_+(I)}^{<} F_\beta^{c'(\beta)} + \tilde{I}_\varepsilon \right),$$

where $a(c,\mu,c') \in \mathbb{C}$. Then we get

$$0=\tilde{\phi}(u)=\sum_{\mu\in Q_{2l}}\sum_{c,c'\in\mathbb{Z}_l^{\tilde{\Delta}_+(I)}}a(c,\mu,c')\left(\prod_{\beta\in\tilde{\Delta}_+(I)}^{<}e_\beta^{c(\beta)}\right)k_\mu\left(\prod_{\beta\in\tilde{\Delta}_+(I)}^{<}f_\beta^{c'(\beta)}\right).$$

Hence, by Lemma 3.13, we obtain $a(c,\mu,c')=0$ for any $c,c'\in\mathbb{Z}_l^{\tilde{\Delta}_+(I)}$, $\mu\in Q_{2l}$. Thus $\tilde{\phi}$ is injective. Therefore $\tilde{\phi}$ is an isomorphism and $\tilde{B}_\varepsilon^{\mathrm{fin}}$ is a $\mathbb{C}$-basis of $\tilde{U}_\varepsilon^{\mathrm{fin}}$. □

IV. EVALUATION REPRESENTATIONS OF RESTRICTED TYPE

A. Representation theory of restricted type

We call a $\tilde{U}_\varepsilon^{\mathrm{res}}$-module (respectively, $U_\varepsilon^{\mathrm{res}}$-module) V "type **1**" if $k_\mu^l=1$ on V for any $\mu\in Q$. In general, finite-dimensional irreducible $\tilde{U}_\varepsilon^{\mathrm{res}}$-modules (respectively, $U_\varepsilon^{\mathrm{res}}$-modules) are classified into 2^n types according to $\{\sigma:Q\to\{\pm1\};$ group homomorphism$\}$. It is known that for any $\sigma:Q\to\{\pm1\}$, the category of finite-dimensional $\tilde{U}_\varepsilon^{\mathrm{res}}$-modules (respectively, $U_\varepsilon^{\mathrm{res}}$-modules) of type σ is essentially equivalent to the category of the finite-dimensional $\tilde{U}_\varepsilon^{\mathrm{res}}$-modules (respectively, $U_\varepsilon^{\mathrm{res}}$-modules) of type **1**.

Let $U=U_\varepsilon^{\mathrm{res}}$, $U_\varepsilon^{\mathrm{fin}}$, $\tilde{U}_\varepsilon^{\mathrm{res}}$, or $\tilde{U}_\varepsilon^{\mathrm{fin}}$.

Definition 4.1: Let V be a U-module and v be a nonzero vector in V. Suppose that v satisfies

$$e_i^{(m)}v=0 \text{ for any } i\in I,\quad m\in\mathbb{N} \text{ if } U=U_\varepsilon^{\mathrm{res}},\quad e_iv=0 \text{ for any } i\in I \text{ if } U=U_\varepsilon^{\mathrm{fin}},$$

$$(x_{i,r}^+)^{(m)}v=0 \text{ for any } i\in I,\quad m\in\mathbb{N},\quad r\in\mathbb{Z} \text{ if } U=\tilde{U}_\varepsilon^{\mathrm{res}},$$

$$x_{i,r}^+v=0 \text{ for any } i\in I,\quad r\in\mathbb{Z} \text{ if } U=\tilde{U}_\varepsilon^{\mathrm{fin}}.$$

We call v a "primitive vector" in V.

Definition 4.2: Let V be a U-module and $\Lambda:U^0\to\mathbb{C}$ be a $\mathbb{C}$-algebra homomorphism. We assume that V is generated as a U-module by a primitive vector $v_\Lambda\in V$ such that

$$u_0v_\Lambda=\Lambda(u_0)v_\Lambda,$$

for any $u_0\in U^0$. Then we call V a "highest-weight U-module" generated by a "highest-weight vector" v_Λ with "highest weight Λ."

Proposition 4.3: For any $\mathbb{C}$-algebra homomorphism $\Lambda:U^0\to\mathbb{C}$, there exists a unique (up to isomorphism) irreducible highest-weight U-module V with highest weight Λ.

Proof: For any $U_\varepsilon^{\mathrm{res}}$-module (respectively, $\tilde{U}_\varepsilon^{\mathrm{res}}$-module) V, we can define the weight spaces on V by

$$V_\mu:=\left\{v\in V\,|\,k_\alpha v=\varepsilon^{\langle\mu,\alpha_i^\vee\rangle}v,\quad \begin{bmatrix}k_{\alpha_i};0\\ l\end{bmatrix}v=\begin{bmatrix}\langle\mu,\alpha_i^\vee\rangle\\ l\end{bmatrix}_\varepsilon v \text{ for any } i\in I\right\},\tag{4.1}$$

where $\mu\in P$ (see Refs. 18 and 11). Then, by the theory of highest-weight modules, we obtain this proposition in the case of $U=U_\varepsilon^{\mathrm{res}}$ or $\tilde{U}_\varepsilon^{\mathrm{res}}$ (see Ref. 11, Proposition 7.3). So we shall prove the case of $\tilde{U}_\varepsilon^{\mathrm{fin}}$. We can prove the case of $U_\varepsilon^{\mathrm{fin}}$ similarly.

Let $\hat{U}_\varepsilon^{\mathrm{fin}}$ be the $\mathbb{C}$-subalgebra of $\tilde{U}_\varepsilon^{\mathrm{res}}$ generated by $\tilde{U}_\varepsilon^{\mathrm{fin}}\cup\left\{\begin{bmatrix}k_{\alpha_i};0\\ l\end{bmatrix}\,\middle|\, i\in I\right\}$. For any $\mathbb{C}$-algebra homomorphism $\Lambda:(\tilde{U}_\varepsilon^{\mathrm{fin}})^0\to\mathbb{C}$, let $\hat{I}_\varepsilon^{\mathrm{fin}}(\Lambda)$ (respectively, $\tilde{I}_\varepsilon^{\mathrm{fin}}(\Lambda)$) be the left ideal of $\hat{U}_\varepsilon^{\mathrm{fin}}$ (respectively, $\tilde{U}_\varepsilon^{\mathrm{fin}}$) generated by $\left\{x_{i,r}^+,u_0-\Lambda(u_0),\begin{bmatrix}k_{\alpha_i};0\\ l\end{bmatrix}\,\middle|\, i\in I,r\in\mathbb{Z},u_0\in(\tilde{U}_\varepsilon^{\mathrm{fin}})^0\right\}$ (respectively, $\{x_{i,r}^+,u_0-\Lambda(u_0)\,|\,i\in I,r\in\mathbb{Z},u_0\in(\tilde{U}_\varepsilon^{\mathrm{fin}})^0\}$). We define a $\hat{U}_\varepsilon^{\mathrm{fin}}$-module $\hat{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$ and a $\tilde{U}_\varepsilon^{\mathrm{fin}}$-module $\tilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$, respectively, by

$$\hat{M}_\varepsilon^{\mathrm{fin}}(\Lambda) := \hat{U}_\varepsilon^{\mathrm{fin}}/\hat{I}_\varepsilon^{\mathrm{fin}}(\Lambda), \quad \widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda) := \widetilde{U}_\varepsilon^{\mathrm{fin}}/\widetilde{I}_\varepsilon^{\mathrm{fin}}(\Lambda).$$

We set $\hat{v}_\Lambda := 1+\hat{I}_\varepsilon^{\mathrm{fin}}(\Lambda) \in \hat{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$ and $\tilde{v}_\Lambda := 1+\widetilde{I}_\varepsilon^{\mathrm{fin}}(\Lambda) \in \widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$. Let $\hat{N}_\varepsilon^{\mathrm{fin}}(\Lambda)$ be the $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-submodule of $\hat{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$ generated by $\hat{v}_\Lambda$. Then, by the universality of the $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module $\widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$, there exists a surjective $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module homomorphism $\phi: \widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda) \to \hat{N}_\varepsilon^{\mathrm{fin}}(\Lambda)$ such that $\phi(\tilde{v}_\Lambda) = \hat{v}_\Lambda$. Let B be a $\mathbb{C}$-basis of $(\widetilde{U}_\varepsilon^{\mathrm{fin}})^-$. Then, by (3.4), we obtain that $\{u\hat{v}_\Lambda \,|\, u \in B\}$ (respectively, $\{u\tilde{v}_\Lambda \,|\, u \in B\}$) is a $\mathbb{C}$-basis of $\hat{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$ (respectively, $\widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$). Hence ϕ is an isomorphism of $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module. So we can regard $\widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$ as $\hat{U}_\varepsilon^{\mathrm{fin}}$-module. In a similar way to (4.1), we can define the weight spaces on this module. Then, by the theory of the highest-weight module, $\widetilde{M}_\varepsilon^{\mathrm{fin}}(\Lambda)$ has a unique simple quotient of $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module and it is the unique irreducible highest-weight $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module with highest weight Λ. □

For any $\mathbb{C}$-algebra homomorphism $\Lambda: U^0 \to \mathbb{C}$, we denote the unique irreducible highest weight U-module with highest weight Λ by $V_\varepsilon^{\mathrm{res}}(\Lambda)$ if $U = U_\varepsilon^{\mathrm{res}}$, $V_\varepsilon^{\mathrm{fin}}(\Lambda)$ if $U = U_\varepsilon^{\mathrm{fin}}$, $\widetilde{V}_\varepsilon^{\mathrm{res}}(\Lambda)$ if $U = \widetilde{U}_\varepsilon^{\mathrm{res}}$, and $\widetilde{V}_\varepsilon^{\mathrm{fin}}(\Lambda)$ if $U = \widetilde{U}_\varepsilon^{\mathrm{fin}}$. Then, by Proposition 4.3 and the uniqueness of the primitive vectors, we obtain the following proposition.

Proposition 4.4: Let Λ and $\Lambda': U^0 \to \mathbb{C}$ be $\mathbb{C}$-algebra homomorphisms. Then $V_\varepsilon^{res}(\Lambda)$ (respectively, $V_\varepsilon^{fin}(\Lambda)$, $\widetilde{V}_\varepsilon^{res}(\Lambda)$, $\widetilde{V}_\varepsilon^{fin}(\Lambda)$) is isomorphic to $V_\varepsilon^{res}(\Lambda')$ (respectively, $V_\varepsilon^{fin}(\Lambda')$, $\widetilde{V}_\varepsilon^{res}(\Lambda')$, $\widetilde{V}_\varepsilon^{fin}(\Lambda')$) if and only if $\Lambda = \Lambda'$.

Now, we define $\mathcal{P}_{i,m} \in \widetilde{U}_q$ inductively by

$$\mathcal{P}_{i,0} := 1, \quad \mathcal{P}_{i,m} := -\frac{K_{\alpha_i}^{-1}}{1-q^{-2m}} \sum_{s=1}^{m} \Psi_{i,s}^{+} \mathcal{P}_{i,m-s}, \quad \mathcal{P}_{i,-m} := \Omega(\mathcal{P}_{i,m}),$$

where Ω as in (2.2). We have $\Omega(\Psi_{i,s}^{+}) = \Psi_{i,-s}^{-}$.

Proposition 4.5 (Ref. 11, Sec. 3): For any $i \in I$, $r \in \mathbb{Z}$, we have $\mathcal{P}_{i,r} \in \widetilde{U}_{\mathcal{A}}^{res}$. Moreover, $(\widetilde{U}_\varepsilon^{\mathrm{res}})^0$ is generated by $\left\{k_{\alpha_i}, \begin{bmatrix} k_{\alpha_i};0 \\ l \end{bmatrix}, \mathcal{P}_{i,r} \otimes 1 \,\middle|\, i \in I, r \in \mathbb{Z}\right\}$ as a $\mathbb{C}$-algebra.

We simply denote $\mathcal{P}_{i,r} \otimes 1 \in \widetilde{U}_\varepsilon^{\mathrm{res}}$ by $\mathcal{P}_{i,r}$. We set

$$\mathbb{C}_0[t] := \{P \in \mathbb{C}_0[t] \,|\, P \text{ is monic, } P(0) \neq 0\}.$$

We call a polynomial $P \in \mathbb{C}[t]$ "l-acyclic" if it is not divisible by $(1-ct^l)$ for any $c \in \mathbb{C}^\times$ (see Ref. 15) and set

$$\mathbb{C}_l[t] := \{P \in \mathbb{C}_0[t] \,|\, P \text{ is } l\text{-acyclic}\}.$$

Definition 4.6: (a) For $\lambda = (\lambda_i)_{i\in I} \in \mathbb{Z}_+^n$, let $\lambda_i^{(0)} \in \mathbb{Z}_l$ and $\lambda_i^{(1)} \in \mathbb{Z}_+$ such that $\lambda_i = \lambda_i^{(0)} + l\lambda_i^{(1)}$ ($i \in I$). We define a $\mathbb{C}$-algebra homomorphism $\Lambda_\lambda^{\mathrm{res}}: (U_\varepsilon^{\mathrm{res}})^0 \to \mathbb{C}$ by

$$\Lambda_\lambda^{\mathrm{res}}(k_{\alpha_i}) := \varepsilon^{\lambda_i^{(0)}}, \quad \Lambda_\lambda^{\mathrm{res}}\left(\begin{bmatrix} k_{\alpha_i};0 \\ l \end{bmatrix}\right) := \lambda_i^{(1)} \quad (i \in I).$$

(b) For $\lambda = (\lambda_i)_{i\in I} \in \mathbb{Z}_l^n$, we define a $\mathbb{C}$-algebra homomorphism $\Lambda_\lambda^{\mathrm{fin}}: (U_\varepsilon^{\mathrm{fin}})^0 \to \mathbb{C}$ by

$$\Lambda_\lambda^{\mathrm{fin}}(k_{\alpha_i}) := \varepsilon^{\lambda_i} \quad (i \in I).$$

(c) For $\mathbf{P} = (P_i)_{i\in I} \in \mathbb{C}_0[t]^n$, let $p_i^{(0)} \in \mathbb{Z}_l$ and $p_i^{(1)} \in \mathbb{Z}_+$ such that $\deg(P_i) = p_i^{(0)} + lp_i^{(1)}$ ($i \in I$). We define a $\mathbb{C}$-algebra homomorphism $\widetilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}}: (\widetilde{U}_\varepsilon^{\mathrm{res}})^0 \to \mathbb{C}$ by

$$\widetilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}}(k_{\alpha_i}) := \varepsilon^{p_i^{(0)}}, \quad \widetilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}}\left(\begin{bmatrix} k_{\alpha_i};0 \\ l \end{bmatrix}\right) := p_i^{(1)} \quad (i \in I),$$

$$\sum_{m=0}^{\infty} \tilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}}(\mathcal{P}_{i,m})t^m := \frac{P_i(t)}{P_i(0)}, \quad \sum_{m=0}^{\infty} \tilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}}(\mathcal{P}_{i,-m})t^m := t^{\deg(P_i)}P_i(t^{-1}),$$

(see Ref. 11, Sec. 8).

(d) For $\mathbf{P}=(P_i)_{i\in I}\in \mathbb{C}_l[t]^n$, we define a $\mathbb{C}$-algebra homomorphism $\tilde{\Lambda}_{\mathbf{P}}^{\mathrm{fin}}:(\tilde{U}_\varepsilon^{\mathrm{fin}})^0\to\mathbb{C}$ by

$$\sum_{m=0}^{\infty} \tilde{\Lambda}_{\mathbf{P}}^{\mathrm{fin}}(\psi_{i,m}^{+})t^m := \varepsilon^{\deg(P_i)}\frac{P_i(\varepsilon^{-2}t)}{P_i(t)} := \sum_{m=0}^{\infty} \tilde{\Lambda}_{\mathbf{P}}^{\mathrm{fin}}(\psi_{i,-m}^{-})t^{-m},$$

in the sense that the left- and right-hand sides are the Laurent expansions of the middle term about $t=0$ and $t=\infty$, respectively (see Ref. 11, Sec. 8).

By Ref. 11, Sec. 8, we obtain $\tilde{\Lambda}_{\mathbf{P}}^{\mathrm{fin}}=\tilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}}|_{(\tilde{U}_\varepsilon^{\mathrm{fin}})^0}$ ($\mathbf{P}\in\mathbb{C}_l[t]^n$). For $\lambda\in\mathbb{Z}_+^n$ (respectively, $\mathbb{Z}_l^n$), we set $V_\varepsilon^{\mathrm{res}}(\lambda):=V_\varepsilon^{\mathrm{res}}(\Lambda_\lambda^{\mathrm{res}})$ (respectively, $V_\varepsilon^{\mathrm{fin}}(\lambda):=V_\varepsilon^{\mathrm{fin}}(\Lambda_\lambda^{\mathrm{fin}})$). Similarly, for $\mathbf{P}\in\mathbb{C}_0[t]^n$ (respectively, $\mathbb{C}_l[t]^n$), we set $\tilde{V}_\varepsilon^{\mathrm{res}}(\mathbf{P}):=\tilde{V}_\varepsilon^{\mathrm{res}}(\tilde{\Lambda}_{\mathbf{P}}^{\mathrm{res}})$ (respectively, $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P}):=\tilde{V}_\varepsilon^{\mathrm{fin}}(\tilde{\Lambda}_{\mathbf{P}}^{\mathrm{fin}})$) and call $\mathbf{P}$ "Drinfel'd polynomial" of $\tilde{V}_\varepsilon^{\mathrm{res}}(\mathbf{P})$ (respectively, $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$).

Theorem 4.7 (Refs. 18 and 9, Proposition 11.2.10): *For any* $\lambda\in\mathbb{Z}_+^n$ (*respectively*, $\mathbb{Z}_l^n$), $V_\varepsilon^{\mathrm{res}}(\lambda)$ (*respectively*, $V_\varepsilon^{\mathrm{fin}}(\lambda)$) *is a finite-dimensional irreducible* $U_\varepsilon^{\mathrm{res}}$*-module* (*respectively*, $U_\varepsilon^{\mathrm{fin}}$*-module*) *of type* **1**. *Conversely, for any finite-dimensional irreducible* $U_\varepsilon^{\mathrm{res}}$*-module* (*respectively*, $U_\varepsilon^{\mathrm{fin}}$*-module*) *V of type* **1**, *there exists a unique* $\lambda\in\mathbb{Z}_+^n$ (*respectively*, $\mathbb{Z}_l^n$) *such that V is isomorphic to* $V_\varepsilon^{\mathrm{res}}(\lambda)$ (*respectively*, $V_\varepsilon^{\mathrm{fin}}(\lambda)$) *as a* $U_\varepsilon^{\mathrm{res}}$*-module* (*respectively*, $U_\varepsilon^{\mathrm{fin}}$*-module*). *In particular, for any* $\lambda\in\mathbb{Z}_l^n$, $V_\varepsilon^{\mathrm{fin}}(\lambda)$ *is isomorphic to* $V_\varepsilon^{\mathrm{res}}(\lambda)$ *as a* $U_\varepsilon^{\mathrm{fin}}$*-module*.

Theorem 4.8 (Ref. 11, Theorem 8.2, 9.2, Ref. 15, Theorem 2.6): *For any* $\mathbf{P}\in\mathbb{C}_0[t]^n$ (*respectively*, $\mathbb{C}_l[t]^n$), $\tilde{V}_\varepsilon^{\mathrm{res}}(\mathbf{P})$ (*respectively*, $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$) *is a finite-dimensional irreducible* $\tilde{U}_\varepsilon^{\mathrm{res}}$*-module* (*respectively*, $\tilde{U}_\varepsilon^{\mathrm{fin}}$*-module*) *of type* **1**. *Conversely, for any finite-dimensional irreducible* $\tilde{U}_\varepsilon^{\mathrm{res}}$*-module* (*respectively*, $\tilde{U}_\varepsilon^{\mathrm{fin}}$*-module*) *V of type* **1**, *there exists a unique* $\mathbf{P}\in\mathbb{C}_0[t]^n$ (*respectively*, $\mathbb{C}_l[t]^n$) *such that V is isomorphic to* $\tilde{V}_\varepsilon^{\mathrm{res}}(\mathbf{P})$ (*respectively*, $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$) *as a* $\tilde{U}_\varepsilon^{\mathrm{res}}$*-module* (*respectively*, $\tilde{U}_\varepsilon^{\mathrm{fin}}$*-module*). *In particular, for any* $\mathbf{P}\in\mathbb{C}_l[t]^n$, $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$ *is isomorphic to* $\tilde{V}_\varepsilon^{\mathrm{res}}(\mathbf{P})$ *as a* $\tilde{U}_\varepsilon^{\mathrm{fin}}$*-module*.

By the tensor product theorem, in order to understand the representation theory of $\tilde{U}_\varepsilon^{\mathrm{res}}$ (respectively, $U_\varepsilon^{\mathrm{res}}$), it is sufficient to consider $\tilde{U}_\varepsilon^{\mathrm{fin}}$ (respectively $U_\varepsilon^{\mathrm{fin}}$) (see Refs. 11 and 18).

B. Drinfel'd polynomials of evaluation representations

For $m\in\mathbb{Z}_+$, let $V_\varepsilon^{\mathrm{fin}}(m)$ be the $(m+1)$-dimensional irreducible $U_\varepsilon^{\mathrm{fin}}(\mathfrak{sl}_2)$-module. By (2.16), we can regard $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$ as a $U_\varepsilon^{\mathrm{fin}}(\mathfrak{sl}_{n+1})$-module ($\mathbf{P}\in\mathbb{C}_l[t]^n$). Then, by Ref. 11, Secs. 7–9 (in particular, p. 321), we obtain the following theorem.

Theorem 4.9 (Ref. 11): *For any* $P\in\mathbb{C}_l[t](P\neq 1)$, *there exist* r, $m_s\in\mathbb{N}$ *and* $c_s\in\mathbb{C}^\times(1\leqslant s\leqslant r)$ *such that*

$$\tilde{V}_\varepsilon^{fin}(P)\cong\tilde{V}_\varepsilon^{fin}(P_1)\otimes\cdots\otimes\tilde{V}_\varepsilon^{fin}(P_r)\quad(\textit{as a } U_\varepsilon^{\mathrm{fin}}(\widetilde{\mathfrak{sl}_2})-\textit{module}),$$

where $P=\prod_{s=1}^r P_s$, $P_s(t)=\prod_{p=1}^{m_s}(t-c_s\varepsilon^{m_s+1-2p})\in\mathbb{C}_l[t]$ $(1\leqslant s\leqslant r)$. *In particular,* $\tilde{V}_\varepsilon^{fin}(P_s)$ *is isomorphic to* $V_\varepsilon^{fin}(m_s)$ *as a* $U_\varepsilon^{\mathrm{fin}}(\mathbf{sl}_2)$*-module*.

By this theorem, we obtain the following lemma.

Lemma 4.10: Let $P\in\mathbb{C}_l[t]$, $m\in\mathbb{N}$. *If* $\tilde{V}_\varepsilon^{fin}(P)$ *is isomorphic to* $V_\varepsilon^{fin}(m)$ *as a* $U_\varepsilon^{\mathrm{fin}}(\mathbf{sl}_2)$*-module, then there exists* $c\in\mathbb{C}^\times$ *such that* $P(t)=\prod_{p=1}^m(t-c\varepsilon^{m+1-2p})$.

By using this lemma, we can prove the following lemma.

Lemma 4.11: Let $\mathbf{P}=(P_i)_{i\in I}\in\mathbb{C}_l[t]^n$, $\lambda=(\lambda_i)_{i\in I}\in\mathbb{Z}_l^n$. *We assume* $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$ *is isomorphic to* $V_\varepsilon^{\mathrm{fin}}(\lambda)$ *as a* $U_\varepsilon^{\mathrm{fin}}$*-module. Then, for any* $i\in I(P_i\neq 1)$, *there exists* $c_i\in\mathbb{C}^\times$ *such that* $P_i(t)=\prod_{p=1}^{\lambda_i}(t-c_i\varepsilon^{\lambda_i+1-2p})$.

Proof: Let $v_{\mathbf{P}}$ be a highest-weight vector in $\tilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P})$. Then $v_{\mathbf{P}}$ is also a highest-weight vector in $V_\varepsilon^{\mathrm{fin}}(\lambda)$. For $i\in I$, let $(\tilde{U}_\varepsilon^{\mathrm{fin}})_i$ (respectively, $(U_\varepsilon^{\mathrm{fin}})_i$) be the $\mathbb{C}$-subalgebra of $\tilde{U}_\varepsilon^{\mathrm{fin}}$ (respectively, $U_\varepsilon^{\mathrm{fin}}$)

generated by $\{x^{\pm}_{i,r}, h_{i,s}, k_{\alpha_i} | r,s \in \mathbb{Z}, s \neq 0\}$ (respectively, $\{e_i, f_i, k_{\alpha_i}\}$) and $\widetilde{W}_i$ (respectively, W_i) be the $(\widetilde{U}^{\mathrm{fin}}_{\varepsilon})_i$-submodule (respectively, $(U^{\mathrm{fin}}_{\varepsilon})_i$-submodule) of $\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P})$ generated by $v_{\mathbf{P}}$. By (2.17) (respectively, (2.16)), we can regard $\widetilde{W}_i$ (respectively W_i) as a $U^{\mathrm{fin}}_{\varepsilon}(\widetilde{\mathfrak{sl}}_2)$-module (respectively, $U^{\mathrm{fin}}_{\varepsilon}(\widetilde{\mathfrak{sl}}_2)$-module). Then, by Lemma 7.6 in Ref. 11, we obtain $\widetilde{W}_i \cong \widetilde{V}^{\mathrm{fin}}_{\varepsilon}(P_i)$ as a $U^{\mathrm{fin}}_{\varepsilon}(\widetilde{\mathfrak{sl}}_2)$-module. Similarly (more easily), we obtain $W_i \cong V^{\mathrm{fin}}_{\varepsilon}(\lambda_i)$ as a $U^{\mathrm{fin}}_{\varepsilon}(\mathfrak{sl}_2)$-module. So, by Lemma 4.10, it is enough to prove $\widetilde{W}_i = W_i$ for $i \in I$ such that $P_i \neq 1$.

By (3.4), $\widetilde{W}_i$ is spanned by $\{x^{-}_{i,r_1} \cdots x^{-}_{i,r_m} v_{\mathbf{P}} | r_1, \cdots r_m \in \mathbb{Z}, m \in \mathbb{Z}_+\}$ as a $\mathbb{C}$-vector space. By Theorem 4.8, we can regard $\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P})$ as a $\widetilde{U}^{\mathrm{res}}_{\varepsilon}$-module and define the weight spaces on $\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P})$ in a similar way to (4.1). Then, by the relations of Drinfel'd realization, we have $x^{-}_{i,r_1} \cdots x^{-}_{i,r_m} v_{\mathbf{P}} \in (\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P}))_{\lambda - m\alpha_i}$ for any $m \in \mathbb{N}, r_1, \cdots r_m \in \mathbb{Z}$. So we obtain $\widetilde{W}_i \subset \oplus_{m \geqslant 0} (\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P}))_{\lambda - m\alpha_i}$. On the other hand, by the assumption of this lemma, $\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P})$ is isomorphic to $V^{\mathrm{fin}}_{\varepsilon}(\lambda)$ as a $U^{\mathrm{fin}}_{\varepsilon}$-module. Hence, by (3.3), $\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P})$ is spanned by $\{\Pi^{<}_{\gamma \in \Delta_+} \overline{f}^{c(\gamma)}_{\gamma} v_{\mathbf{P}} | c \in \mathbb{Z}_l^{\Delta_+}\}$. Since $\Pi^{<}_{\gamma \in \Delta_+} \overline{f}^{c(\gamma)}_{\gamma} v_{\mathbf{P}} \in (\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P}))_{\Sigma_{\gamma \in \Delta_+} c(\gamma)\gamma}$, we have

$$\bigoplus_{m \geqslant 0} (\widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P}))_{\lambda - m\alpha_i} = \bigoplus_{m \in \mathbb{Z}_l} \mathbb{C} f_i^m v_{\mathbf{P}} \subset W_i.$$

Then we have $\widetilde{W}_i = W_i$. □

Let $(U^{\mathrm{res}}_{\mathcal{A}})'$ (respectively, $(U^{\mathrm{fin}}_{\varepsilon})'$) be the extended algebra of $U^{\mathrm{res}}_{\mathcal{A}}$ (respectively, $U^{\mathrm{fin}}_{\varepsilon}$) defined by replacing $\{K_\mu | \mu \in Q\}$ with $\{K_\mu | \mu \in P\}$ (see Definition 2.1). By (2.18), we obtain $\mathrm{ev}^{\pm}_{\mathbf{a}}(\widetilde{U}^{\mathrm{res}}_{\mathcal{A}}) \subset (U^{\mathrm{res}}_{\mathcal{A}})'$ $(\mathbf{a} \in \mathbb{C}^{\times})$. Hence, by Proposition 2.6, we obtain the evaluation $\widetilde{U}^{\mathrm{fin}}_{\varepsilon}$-homomorphisms $(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{\pm}: \widetilde{U}^{\mathrm{fin}}_{\varepsilon} \to (U^{\mathrm{fin}}_{\varepsilon})'$ defined by

$$(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{\pm}(e_i) := e_i, \quad (\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{\pm}(f_i) := f_i \quad (\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{\pm}(k_\mu) := k_\mu,$$

$$(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{+}(e_0) := \mathbf{a}\varepsilon^{-1} k_{\Lambda_1} k^{-1}_{\Lambda_n} [f_n, [f_{n-1}, \ldots, [f_2 f_1]_{\varepsilon^{-1}} \cdots]_{\varepsilon^{-1}},$$

$$(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{+}(f_0) := \mathbf{a}^{-1}(-1)^{n-1} \varepsilon^n k^{-1}_{\Lambda_1} k_{\Lambda_n} [e_n, [e_{n-1}, \ldots, [e_2, e_1]_{\varepsilon^{-1}} \cdots]_{\varepsilon^{-1}},$$

$$(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{-}(e_0) := \mathbf{a}\varepsilon^{-1} k^{-1}_{\Lambda_1} k_{\Lambda_n} [f_1, [f_2, \ldots, [f_{n-1}, f_n]_{\varepsilon^{-1}} \cdots]_{\varepsilon^{-1}},$$

$$(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}})^{-}(f_0) := \mathbf{a}^{-1}(-1)^{n-1} \varepsilon^n k_{\Lambda_1} k^{-1}_{\Lambda_n} [e_1, [e_2, \ldots, [e_{n-1}, e_n]_{\varepsilon^{-1}} \cdots]_{\varepsilon^{-1}}, \tag{4.2}$$

for $i \in I$, $\mu \in Q$. For any $\lambda \in \mathbb{Z}_l^n$, we regard $V^{\mathrm{fin}}_{\varepsilon}(\lambda)$ as a $(U^{\mathrm{fin}}_{\varepsilon})'$-module through these homomorphisms. Then the evaluation $\widetilde{U}^{\mathrm{fin}}_{\varepsilon}$-representations are defined by the following method.

Definition 4.12: Let $\mathbf{a} \in \mathbb{C}^{\times}$, $\lambda = (\lambda_i)_{i \in I} \in \mathbb{Z}_l^n$. We set

$$\lambda_{\Lambda_i} := \sum_{j \in I} \lambda_j (\Lambda_i, \Lambda_j) \quad (i \in I), \tag{4.3}$$

$$\mathbf{a}^{\lambda}_{+} := \mathbf{a}\varepsilon^{-\lambda_{\Lambda_1} + \lambda_{\Lambda_n} + n}, \quad \mathbf{a}^{\lambda}_{-} := \mathbf{a}(-1)^{n+1} \varepsilon^{\lambda_{\Lambda_1} - \lambda_{\Lambda_n} + 2n + 1}. \tag{4.4}$$

We regard $V^{\mathrm{fin}}_{\varepsilon}(\lambda)$ as a $\widetilde{U}^{\mathrm{fin}}_{\varepsilon}$-module by using $(\mathrm{ev}^{\mathrm{fin}}_{\mathbf{a}^{\lambda}_{\pm}})^{\pm}$ and denote it by $V^{\mathrm{fin}}_{\varepsilon}(\lambda)^{\pm}_{\mathbf{a}}$.

Since $V^{\mathrm{fin}}_{\varepsilon}(\lambda)$ is irreducible as a $U^{\mathrm{fin}}_{\varepsilon}$-module, $V^{\mathrm{fin}}_{\varepsilon}(\lambda)^{\pm}_{\mathbf{a}}$ is a finite-dimensional irreducible $\widetilde{U}^{\mathrm{fin}}_{\varepsilon}$-module of type **1**. Thus, by Theorem 4.8, there exists a unique $\mathbf{P}^{\pm}_{\mathbf{a}} = (P^{\pm}_{i,\mathbf{a}})_{i \in I} \in \mathbb{C}_l[t]^n$ such that $V^{\mathrm{fin}}_{\varepsilon}(\lambda)^{\pm}_{\mathbf{a}} \cong \widetilde{V}^{\mathrm{fin}}_{\varepsilon}(\mathbf{P}^{\pm}_{\mathbf{a}})$ as a $\widetilde{U}^{\mathrm{fin}}_{\varepsilon}$-module. Let $i \in I$ such that $P^{\pm}_{i,\mathbf{a}} \neq 1$. Then, by Lemma 4.11, there exist $\mathbf{a}_{(\pm,i)} \in \mathbb{C}^{\times}$ such that $P^{(\pm)}_{i,\mathbf{a}}(t) = \Pi^{\lambda_i}_{p=1}(t - \mathbf{a}_{(\pm,i)} \varepsilon^{\lambda_i + 1 - 2p})$. Around $t = 0$, we have

$$\varepsilon^{\lambda_i}+(\varepsilon^{\lambda_i}-\varepsilon^{-\lambda_i})\sum_{m=1}^{\infty}(\mathbf{a}_{(\pm,i)}^{-1}\varepsilon^{\lambda_i-1}t)^m=\frac{\varepsilon^{\lambda_i}-\mathbf{a}_{(\pm,i)}^{-1}\varepsilon^{-1}t}{1-\mathbf{a}_{(\pm,i)}^{-1}\varepsilon^{\lambda_i-1}t}=\varepsilon^{\lambda_i}\frac{\varepsilon^{-2\lambda_i}(t-\mathbf{a}_{(\pm,i)}\varepsilon^{\lambda_i+1})}{t-\mathbf{a}_{(\pm,i)}\varepsilon^{-\lambda_i+1}}=\varepsilon^{\deg(P_{i,\mathbf{a}}^{\pm})}\frac{P_{i,\mathbf{a}}^{\pm}(\varepsilon^{-2}t)}{P_{i,\mathbf{a}}^{\pm}(t)}$$

(see Ref. 7, Corollary 4.2). Thus, by Definition 4.6(d), we obtain

$$\sum_{m=0}^{\infty}\tilde{\Lambda}_{\mathbf{P}_{\mathbf{a}}^{\pm}}^{\mathrm{fin}}(\psi_{i,m}^{+})t^m=\varepsilon^{\deg}(P_{i,\mathbf{a}}^{\pm})\frac{P_{i,\mathbf{a}}^{\pm}(\varepsilon^{-2}t)}{P_{i,\mathbf{a}}^{\pm}(t)}=\varepsilon^{\lambda_i}+(\varepsilon^{\lambda_i}-\varepsilon^{-\lambda_i})\sum_{m=1}^{\infty}(\mathbf{a}_{(\pm,i)}^{-1}\varepsilon^{\lambda_i-1}t)^m. \tag{4.5}$$

Hence we can calculate $\mathbf{a}_{(\pm,i)}$ explicitly by the computation of $\tilde{\Lambda}_{\mathbf{P}_{\mathbf{a}}^{\pm}}^{\mathrm{fin}}(\psi_{i,1}^{+})$. Therefore, in a similar way to the proof of Ref. 8, Theorem 3.5, we obtain the following theorem.

Theorem 4.13: *For* $\lambda=(\lambda_i)_{i\in I}\in\mathbb{Z}_{l}^{n}$, $\mathbf{a}\in\mathbb{C}^{\times}$, *let* $\mathbf{P}_{\mathbf{a}}^{\pm}=(P_{i,\mathbf{a}}^{\pm})_{i\in I}\in\mathbb{C}_l[t]^n$ *such that* $\tilde{V}_{\varepsilon}^{\mathrm{fin}}(\mathbf{P}_{\mathbf{a}}^{\pm})\cong V_{\varepsilon}^{\mathrm{fin}}(\lambda)_{\mathbf{a}}^{\pm}$. *Then, for any* $i\in I$ *such that* $P_{i,\mathbf{a}}^{\pm}\neq 1$, *we obtain*

$$P_{i,\mathbf{a}}^{\pm}=\prod_{p=1}^{\lambda_i}(t-\varepsilon^{\lambda_i-2p+1}\mathbf{a}_{(\pm,i)}), \tag{4.6}$$

where

$$\mathbf{a}_{(\pm,i)}:=\mathbf{a}^{-1}\varepsilon^{\pm(\lambda^{(i)}+i)}, \tag{4.7}$$

$$\lambda^{(i)}:=\sum_{k=1}^{i-1}\lambda_k-\sum_{k=i+1}^{n}\lambda_k. \tag{4.8}$$

Proof: We shall prove the case of $P_{i,\mathbf{a}}^{+}$. We can also prove the case of $P_{i,\mathbf{a}}^{-}$ similarly. Let v_+ be the highest-weight vector in $\tilde{V}_{\varepsilon}^{\mathrm{fin}}(\mathbf{P}_{\mathbf{a}}^{+})$. By (2.8), for any $i\in I$, we have

$$e_0v_+=(-1)^{i+1}\varepsilon^{n+1}[f_n,\cdots[f_{i+1},[f_1,\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}k_{\theta}^{-1}v_+.$$

Then we get

$$\begin{aligned}
e_ne_0v_+&=(-1)^{i+1}\varepsilon^{-\sum_{k\in I}\lambda_k+n+1}\{e_nf_n[f_{n-1},[\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}\\
&\quad-\varepsilon^{-1}[f_{n-1},[\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}e_nf_n\}v_+\\
&=(-1)^{i+1}\varepsilon^{-\sum_{k\in I}\lambda_k+n+1}\left\{\left(\frac{k_{\alpha_n}-k_{\alpha_n}^{-1}}{\varepsilon-\varepsilon^{-1}}\right)[f_{n-1},[\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}\right.\\
&\quad\left.-\varepsilon^{-1}[f_{n-1},[\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}\left(\frac{k_{\alpha_n}-k_{\alpha_n}^{-1}}{\varepsilon-\varepsilon^{-1}}\right)\right\}v_+\\
&=(-1)^{i+1}\varepsilon^{-\sum_{k\in I}\lambda_k+n+1}([\lambda_n+1]_{\varepsilon}-\varepsilon^{-1}[\lambda_n]_{\varepsilon})[f_{n-1},[\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}v_+\\
&=(-1)^{i+1}\varepsilon^{\lambda_n-\sum_{k\in I}\lambda_k+n+1}[f_{n-1},[\cdots[f_{i-1},x_{i,1}^{-}]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}v_+.
\end{aligned}$$

By repeating this, we obtain

$$e_i\cdots e_1e_{i+1}\cdots e_ne_0v_+=e_i\{(-1)^{i+1}\varepsilon^{-\lambda_i+n+1}x_{i,1}^{-}v_+\}=(-1)^{i+1}\varepsilon^{-\lambda_i+n+1}x_{i,0}^{+}x_{i,1}^{-}v_+. \tag{4.9}$$

On the other hand, by (4.2), we have

$$e_0v_+=(\mathrm{ev}_{\mathbf{a}_+^{\lambda}}^{\mathrm{fin}})^{+}(e_0)v_+=\mathbf{a}_+^{\lambda}\varepsilon^{-1}k_{\Lambda_1}k_{\Lambda_n}^{-1}[f_n,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]\ {}_{\varepsilon^{-1}}v_+.$$

Since $(\Lambda_1-\Lambda_n,\theta)=0$, we have

$$k_{\Lambda_1}k_{\Lambda_n}^{-1}[f_n,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}=[f_n,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}k_{\Lambda_1}k_{\Lambda_n}^{-1}.$$

Moreover, we have $k_{\Lambda_1}v_+=\varepsilon^{\lambda_{\Lambda_1}}v_+$, $k_{\Lambda_n}v_+=\varepsilon^{\lambda_{\Lambda_n}}v_+$. So, by (4.4), we obtain

$$e_0v_+=\mathbf{a}\varepsilon^{n-1}[f_n,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}v_+.$$

In a similar way to the above-noted proof, we have

$$e_{i+1}\cdots e_ne_0v_+=\mathbf{a}\varepsilon^{\sum_{k=i+1}\lambda_k+n-1}[f_i,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}v_+.$$

Here, we obtain

$$\begin{aligned}e_1[f_i,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}v_+&=[f_i,[\cdots[f_2,e_1f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}v_+=\left\{[f_i,[\cdots[f_2,f_1e_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}\right.\\&\quad\left.+\left[f_{i,}\left[\cdots\left[f_2,\frac{k_{\alpha_1}-k_{\alpha_1}^{-1}}{\varepsilon-\varepsilon^{-1}}\right]_{\varepsilon^{-1}}\cdots\right]_{\varepsilon^{-1}}\right\}v_+\right.\\&=\{[f_i,[\cdots[f_2,f_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}e_1+[f_i,[\cdots[f_3,f_2]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}(-\varepsilon^{-1}k_{\alpha_1}^{-1})\}v_+\\&=\varepsilon^{-\lambda_1-1}[f_i,[\cdots[f_3,f_2]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}v_+.\end{aligned}$$

By repeating this, we get

$$e_i\cdots e_1e_{i+1}\cdots e_ne_0v_+=(-1)^{i-1}\mathbf{a}\varepsilon^{-\sum_{k=1}^{i-1}\lambda_k-(i-1)+\sum_{k=i+1}^{n}\lambda_k+n-1}e_if_iv_+=(-1)^{i-1}\mathbf{a}\varepsilon^{-\lambda^{(i)}-i+n}[\lambda_i]_\varepsilon v_+. \tag{4.10}$$

Thus, by (4.9) and (4.10), we obtain

$$\psi_{i,1}v_+=(\varepsilon-\varepsilon^{-1})x_{i,0}^+x_{i,1}^-v_+=\mathbf{a}\varepsilon^{\lambda_i-\lambda^{(i)}-i-1}(\varepsilon^{\lambda_i}-\varepsilon^{-\lambda_i})v_+.$$

On the other hand, by (4.5), we have $\psi_{i,1}^+v_+=\tilde{\Lambda}_{\mathbf{P}_\mathbf{a}^+}^{\mathrm{fin}}(\psi_{i,1}^+)v_+=\mathbf{a}_{(+,i)}^{-1}\varepsilon^{\lambda_i-1}(\varepsilon^{\lambda_i}-\varepsilon^{-\lambda_i})$. Therefore we obtain $\mathbf{a}_{(+,i)}=\mathbf{a}^{-1}\varepsilon^{\lambda^{(i)}+i}$.

For $\lambda=(\lambda_i)_{i\in I}\in\mathbb{Z}_l^n$, we set $\mathrm{supp}(\lambda):=\{i\in I\,|\,\lambda_i\neq 0\}$.

Proposition 4.14: Let $\lambda=(\lambda_i)_{i\in I}\in\mathbb{Z}_l^n$, $\mathbf{a}_\pm\in\mathbb{C}^\times$.

(*a*) *If* $\lambda=0$, *then* $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_+}^+$ *is isomorphic to* $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_-}^-$ *as a* $\tilde{U}_\varepsilon^{\mathrm{fin}}$*-module*.

(*b*) *In the case of* $\lambda\neq 0$, $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_+}^+$ *is isomorphic to* $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_-}^-$ *as a* $\tilde{U}_\varepsilon^{\mathrm{fin}}$*-module if and only if* $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ *for any* $i\in\mathrm{supp}(\lambda)$.

Proof: (a) is obvious. So we shall prove (b). By Theorem (4.8), $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_+}^+$ is isomorphic to $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_-}^-$ if and only if $\mathbf{P}_{\mathbf{a}_+}^+=\mathbf{P}_{\mathbf{a}_-}^-$. By (4.5) and Theorem 4.13, we obtain $\mathbf{P}_{\mathbf{a}_+}^+=\mathbf{P}_{\mathbf{a}_-}^-$ if and only if $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ for any $i\in\mathrm{supp}(\lambda)$.

Proposition 4.15: Let $\lambda=(\lambda_i)_{i\in I}\in\mathbb{Z}_l^n(\lambda\neq 0)$, $\mathbf{a}_\pm\in\mathbb{C}^\times$. *Let* $i_1,\ldots,i_m\in I$ *such that* $\mathrm{supp}(\lambda)=\{i_1,\ldots,i_m\}$ *and* $i_1<\ldots<i_m$. *Then* $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ *for any* $i\in\mathrm{supp}(\lambda)$ *if and only if the following conditions* (*a*) *and* (*b*) *hold*.

(*a*) *For any* $2\leqslant r\leqslant m$,

$$\lambda_{i_r}\equiv(-1)^{r-1}\lambda_{i_1}+(-1)^ri_1-i_r+2\sum_{k=2}^{r-1}(-1)^{r-1+k}i_k\equiv 0\quad(mod\ l).$$

(*b*)

$$\mathbf{a}_+=\begin{cases}\mathbf{a}_-\varepsilon^{2\sum_{k=1}^m(-1)^{k-1}i_k} & \text{if } m \text{ is odd}\\ \mathbf{a}_-\varepsilon^{2(\lambda_{i_1}+\sum_{k=2}^m(-1)^ki_k)} & \text{if } m \text{ is even}.\end{cases}$$

Proof: We assume $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ for any $i\in\mathrm{supp}(\lambda)$. Then $\varepsilon^{2(\lambda^{(i)}+i)}=\varepsilon^{2(\lambda^{(j)}+j)}$ for any $i,j\in\mathrm{supp}(\lambda)$. Hence, for $2\leqslant r\leqslant m$, we have $\lambda^{(i_r)}-\lambda^{(i_{r-1})}+i_r-i_{r-1}\equiv 0(\mathrm{mod}\, l)$. By (4.8), for $1\leqslant r\leqslant m$, we obtain

$$\lambda^{(i_r)}=\sum_{k=1}^{i_r-1}\lambda_k-\sum_{k=i_r+1}^{n}\lambda_k=\sum_{k=1}^{r-1}\lambda_{i_k}-\sum_{k=r+1}^{m}\lambda_{i_k}.$$

Thus, for $2\leqslant r\leqslant m$, we get

$$\lambda^{(i_r)}-\lambda^{(i_{r-1})}+i_r-i_{r-1}=\lambda_{i_r}+\lambda_{i_{r-1}}+i_r-i_{r-1}\equiv 0 \pmod{l}.$$

Hence $(-1)^r\lambda_{i_r}-(-1)^{r-1}\lambda_{i_{r-1}}\equiv(-1)^{r-2}i_{r-1}+(-1)^{r-1}i_r$. Therefore, we obtain

$$\begin{aligned}(-1)^r\lambda_{i_r}&\equiv-\lambda_{i_1}+\sum_{k=2}^{r}\{(-1)^k\lambda_{i_k}-(-1)^{k-1}\lambda_{i_{k-1}}\}\\&\equiv-\lambda_{i_1}+\sum_{k=2}^{r}\{(-1)^{k-1}i_k+(-1)^{k-2}i_{k-1}\}\\&\equiv-\lambda_{i_1}+i_1+(-1)^{r-1}i_r+2\sum_{k=2}^{r-1}(-1)^{k-1}i_k\quad(2\leqslant r\leqslant m).\end{aligned}$$

Thus we have (a). In particular, if λ_{i_r} is as in (a), then $\lambda_{i_{r-1}}+\lambda_{i_r}\equiv i_{r-1}-i_r$ for any $2\leqslant r\leqslant m$ and $\lambda^{(i)}+i\equiv\lambda^{(j)}+j$ for any $i,j\in\mathrm{supp}(\lambda)$. Hence, for $1\leqslant r\leqslant m$, we have $\lambda^{(i_r)}+i_r\equiv\lambda^{(1)}+i_1\equiv-\sum_{k=2}^{m}\lambda_{i_k}+i_1$. If m is odd, then we get

$$\begin{aligned}-\sum_{k=2}^{m}\lambda_{i_k}+i_1&\equiv-(\lambda_{i_2}+\lambda_{i_3})-\cdots-(\lambda_{i_{m-1}}+\lambda_{i_m})+i_1\\&\equiv(-i_2+i_3)+\cdots+(-i_{m-1}+i_m)+i_1\\&\equiv\sum_{k=1}^{m}(-1)^{k-1}i_k.\end{aligned}$$

Similarly, we have the case that m is even. Therefore we obtain (b). So we can prove "only if part" of this proposition. The proof of "if part" follows the proof of "only if part." □

Remark 4.16: For $\lambda=(\lambda_i)_{i\in I}\in\mathbb{Z}_+^n$, let $V_q(\lambda)$ be the finite-dimensional irreducible U_q-module with highest weight λ of type **1**. For $\mathbf{a}\in\mathbb{C}^\times$, let $V_q(\lambda)_{\mathbf{a}}^{\pm}$ be the evaluation representation of $V_q(\lambda)$ arising from $\mathrm{ev}_{\mathbf{a}}^{\pm}$ (see Ref. 8). In the case that q is not a root of unity, for any $\mathbf{a}_\pm\in\mathbb{C}^\times$, $V_q(\lambda)_{\mathbf{a}_+}^{+}$ is not isomorphic to $V_q(\lambda)_{\mathbf{a}_-}^{-}$ if $\#(\mathrm{supp}(\lambda))>1$. But, in the case that q is a root of unity, there exist $\lambda\in\mathbb{Z}_l^n$ and $\mathbf{a}_\pm\in\mathbb{C}^\times$ such that $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_+}^{+}$ is isomorphic to $V_\varepsilon^{\mathrm{fin}}(\lambda)_{\mathbf{a}_-}^{-}$ even if $\#(\mathrm{supp}(\lambda))>1$ by Propositions 4.14, 4.15.

V. EVALUATION REPRESENTATIONS OF NONRESTRICTED TYPE

A. Schnizer modules and evaluation representations

We fix the following notations. Let $N:=\frac{1}{2}n(n+1)$ be the number of the positive roots of $\mathfrak{sl}_{n+1}$. Let V_N be an l^N-dimensional $\mathbb{C}$-vector space and $\{v(m)\in V_N|m=(m_{i,j})_{1\leqslant i\leqslant j\leqslant n}\in\mathbb{Z}_l^N\}$ be a $\mathbb{C}$-basis of V_N. For $m\in\mathbb{Z}_l^N$, $m'\in\mathbb{Z}^N$, we set $v(m+lm'):=v(m)$. For $i,j\in I$, we define $\epsilon_{i,j}$, $\alpha_{i,j}\in\mathbb{Z}_l^N$ by

$$\epsilon_{i,j} := (\delta_{i,r}\delta_{j,s})_{1\leqslant r\leqslant s\leqslant n} \quad (i \leqslant j), \quad \alpha_{i,j} := \sum_{k=j+1}^{i} \epsilon_{k-1,n-i+k} - \sum_{k=j}^{i} \epsilon_{k,n-i+k} \quad (j \leqslant i), \tag{5.1}$$

where $\delta_{i,j}$ is Kronecker's symbol. For $i,j \in I$, $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in (\mathbb{C}^{\times})^N$, $c=(c_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{C}^N$, we define

$$M_{i,j}(c) := \sum_{k=i-1}^{j-1} (c_{i,k} - c_{i-1,k}) + \sum_{k=i}^{j} (c_{i,k} - c_{i+1,k}) \quad (i \leqslant j), \tag{5.2}$$

$$N_{i,j}(c) := c_{j-1,n-i+j} - c_{j,n-i+j} \quad (j \leqslant i), \tag{5.3}$$

$$\mu_i(c) := \sum_{k=i-1}^{n} c_{i-1,k} - 2\sum_{k=i}^{n} c_{i,k} + \sum_{k=i+1}^{n} c_{i+1,k}, \tag{5.4}$$

$$a(c) := \prod_{1\leqslant i\leqslant j\leqslant n} a_{i,j}^{c_{i,j}}, \tag{5.5}$$

where $c_{i,j}=0$ if the index (i,j) is out of the range.

Theorem 5.1 (Ref. 24, Theorem 3.2, Ref. 23). *Let* $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in (\mathbb{C}^{\times})^N$, $b=(b_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{C}^n$, and $\lambda=(\lambda_i)_{i\in I} \in \mathbb{C}^n$. Then there exists a $\mathbb{C}$ algebra homomorphism $\rho:=\rho(a,b,\lambda)$: $U_\varepsilon \to End(V_N)$ *such that for* $i \in I$ *and* $m \in \mathbb{Z}_l^N$,

$$\rho(E_i)(v(m)) = \sum_{j=1}^{i} a(\alpha_{i,j})[N_{i,j}(m+b)]_\varepsilon v(m+\alpha_{i,j}), \tag{5.6}$$

$$\rho(F_i)(v(m)) = \sum_{j=i}^{n} a_{i,j}[M_{i,j}(m+b) - \lambda_i]_\varepsilon v(m+\epsilon_{i,j}), \tag{5.7}$$

$$\rho(K_{\alpha_i})(v(m)) = \varepsilon^{\mu_i(m+b)+\lambda_i} v(m). \tag{5.8}$$

We denote the l^N-dimensional U_ε-module associated with $(\rho(a,b,\lambda),V_N)$ by $V_\varepsilon(a,b,\lambda)$. We call $V_\varepsilon(a,b,\lambda)$ a "Schnizer module."

Now, for $i \in I$ and $r=(r_1,\ldots,r_i) \in I^i$, we set

$$F_{\theta_i} := [F_i,[\cdots[F_2,F_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}, \quad E_{\theta_i} := [E_i,[\cdots[E_2,E_1]_{\varepsilon^{-1}}\cdots]_{\varepsilon^{-1}}, \tag{5.9}$$

$$\epsilon_r := \sum_{k=1}^{i} \epsilon_{k,r_k}, \quad \alpha_r := \sum_{k=1}^{i} \alpha_{k,r_k}. \tag{5.10}$$

For $1 \leqslant s \leqslant i$, we set

$$R_{s,i} := \{r_i^s = (r_{1,i}^s,\ldots,r_{i,i}^s) \in I^i | r_{1,i}^s \geqslant \cdots \geqslant r_{s-1,i}^s \geqslant r_{s,i}^s < r_{s+1,i}^s < \cdots < r_{i,i}^s\},$$

$$R_{s,i}^F := \{r_i^s = (r_{1,i}^s,\ldots,r_{i,i}^s) \in R_{s,i} | k \leqslant r_{k,i}^s \text{ for } 1 \leqslant k \leqslant i\},$$

$$R_{s,i}^E := \{r_i^s = (r_{1,i}^s,\ldots,r_{i,i}^s) \in R_{s,i} | r_{k,i}^s \leqslant k \text{ for } 1 \leqslant k \leqslant i\},$$

$$R_i^F := \bigsqcup_{s=1}^{i} R_{s,i}^F, \quad R_i^E := \bigsqcup_{s=1}^{i} R_{s,i}^E. \tag{5.11}$$

Moreover, for $c \in \mathbb{C}^N$, set

$$C_i(c, r_i^s) := \sum_{k=1}^{s-1} M_{k,r_{k,i}^s}(c) - \sum_{k=s+1}^{i} M_{k,r_{k,i}^s}(c) \quad (r_i^s \in R_{i,s}^F).$$

$$D_i(c, r_i^s) := \sum_{k=1}^{s-1} N_{k,r_{k,i}^s}(c) - \sum_{k=s+1}^{i} N_{k,r_{k,i}^s}(c) \quad (r_i^s \in R_{i,s}^E). \tag{5.12}$$

Lemma 5.2: Let $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in (\mathbb{C}^\times)^N$, $b=(b_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{C}^N$, $\lambda=(\lambda_i)_{i\in I} \in \mathbb{C}^n$, $i \in I$, *and* $m=(m_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{Z}_l^N$. *We have*

$$F_{\theta_i} v(m) = \sum_{r_i^s \in R_i^F} (-1)^{i+s} a(\epsilon_{r_i^s}) \varepsilon^{C_i(m+b, r_i^s) - \lambda^{(s,i)} + 1 - s} [M_{s,r_{s,i}^s}(m+b) - \lambda_s]_\varepsilon v(m + \epsilon_{r_i^s}),$$

$$E_{\theta_i} v(m) = \sum_{r_i^s \in R_i^E} (-1)^{i+s} a(\alpha_{r_i^s}) \varepsilon^{D_i(m+b, r_i^s) + 1 - s} [N_{s,1}(m+b) - \lambda_s]_\varepsilon v(m + \alpha_{r_i^s}),$$

in $V_\varepsilon(a,b,\lambda)$, *where* $\lambda^{(s,i)} := \Sigma_{k=1}^{s-1} \lambda_k - \Sigma_{k=s+1}^{i} \lambda_k$.

Proof: We shall prove the F_{θ_i}-case by the induction on i. We can prove the E_{θ_i}-case similarly. If $i=1$, then we have

$$F_{\theta_1} v(m) = \sum_{r_1^1 \in R_1^F} a(\epsilon_{1,r_{1,1}^1}) [M_{1,r_{1,1}^1}(m+b) - \lambda_1]_\varepsilon v(m + \epsilon_{1,r_{1,1}^1}).$$

We replace $r_{1,1}^1$ with j. Then we obtain

$$F_{\theta_1} v(m) = \sum_{j=1}^{n} a(\epsilon_{1,j}) [M_{1,j}(m+b) - \lambda_1]_\varepsilon v(m + \epsilon_{1,j}) = F_1 v(m).$$

Now we assume that $i>1$ and the case of $(i-1)$ holds. For $i \leqslant j \leqslant n$, $r_{i-1}^s \in R_{i-1}^F$, we set

$$\begin{aligned} \mathbf{M}(r_{i-1}^s, j) := {} & [M_{s,r_{s,i-1}^s}(m+b) - \lambda_s]_\varepsilon [M_{i,j}(m+b) - \lambda_i + M_{i,j}(\epsilon_{r_{i-1}^s})]_\varepsilon - \varepsilon^{C_{i-1}(\epsilon_{i,j}, r_{i-1}^s) - 1} [M_{s,r_{s,i-1}^s}(m+b) \\ & - \lambda_s + M_{s,r_{s,i-1}^s}(\epsilon_{i,j})]_\epsilon [M_{i,j}(m+b) - \lambda_i]_\varepsilon. \end{aligned}$$

Then, by the assumption of the induction, we have

$$\begin{aligned} F_{\theta_i} v(m) &= [F_i, F_{\theta_{i-1}}]_{\varepsilon^{-1}} v(m) \\ &= \sum_{j=i}^{n} \sum_{r_{i-1}^s \in R_{i-1}^F} (-1)^{i+s-1} a_{i,j} a(\epsilon_{r_{i-1}^s}) \varepsilon^{C_{i-1}(m+b, r_{i-1}^s) - \lambda^{(s,i-1)} + 1 - s} \mathbf{M}(r_{i-1}^s, j) v(m + \epsilon_{r_{i-1}^s} + \epsilon_{i,j}). \end{aligned}$$

Now we set

$$\xi(j > j') := \begin{cases} 1 & \text{if } j > j' \\ 0 & \text{if } j \leqslant j', \end{cases} \qquad \xi(j \leqslant j') := \begin{cases} 1 & \text{if } j \leqslant j' \\ 0 & \text{if } j > j'. \end{cases}$$

Then, for any $1 \leqslant i \leqslant j \leqslant n$, $1 \leqslant i' \leqslant j' \leqslant n$, we get

$$M_{i,j}(\epsilon_{i',j'}) = -\delta_{i-1,i'}\xi(j > j') + \delta_{i,i'}\xi(j > j') + \delta_{i,i'}\xi(j \geqslant j') - \delta_{i+1,i'}\xi(j \geqslant j'),$$

Hence, for any $i \leqslant j \leqslant n$, $1 \leqslant s \leqslant i-1$, $r^s_{i-1} \in R^F_{i-1}$, we have

$$M_{i,j}(\epsilon_{r^s_{i-1}}) = -\xi(j > r^s_{i-1,i-1}), \quad M_{s,r^s_{s,i-1}}(\epsilon_{i,j}) = -\delta_{s,i-1}\xi(r^{i-1}_{i-1,i-1} \geqslant j),$$

$$C_{i-1}(\epsilon_{i,j}, r^s_{i-1}) = \xi(i-1 > s)\xi(r^s_{i-1,i-1} \geqslant j).$$

Thus, we have

$$\begin{aligned}\mathbf{M}(r^s_{i-1}, j) = {} & [M_{s,r^s_{s,i-1}}(m+b) - \lambda_s]_\varepsilon [M_{i,j}(m+b) - \lambda_i - \xi(j > r^s_{i-1,i-1})]_\varepsilon \\ & - \varepsilon^{\xi(i-1>s)\xi(r^s_{i-1,i-1} \geqslant j)-1}[M_{s,r^s_{s,i-1}}(m+b) - \lambda_s - \delta_{s,i-1}\xi(r^{i-1}_{i-1,i-1} \geqslant j)]_\varepsilon [M_{i,j}(m+b) - \lambda_i]_\varepsilon.\end{aligned}$$

Since $[c]_\varepsilon - \varepsilon^{-1}[c-1]_\varepsilon = \varepsilon^{c-1}$ and $[c-1]_\varepsilon - \varepsilon^{-1}[c]_\varepsilon = -\varepsilon^{-c}$ for any $c \in \mathbb{C}$, we have

$$\mathbf{M}(r^s_{i-1}, j) = -\varepsilon^{M_{i,j}(m+b)+\lambda_i}[M_{s,r^s_{s,i-1}}(m+b) - \lambda_s]_\varepsilon \quad (s \leqslant i-1, r^s_{i-1,i-1} < j),$$

$$\mathbf{M}(r^s_{i-1}, j) = 0 \quad (s < i-1, j \leqslant r^s_{i-1,i-1}),$$

$$\mathbf{M}(r^{i-1}_{i-1}, j) = \varepsilon^{\tilde{M}(r^{i-1}_{i-1},j)}[M_{i,j}(m+b) - \lambda_i]_\varepsilon \quad (j \leqslant r^{i-1}_{i-1,i-1}),$$

where $\tilde{M}(r^{i-1}_{i-1}, j) := M_{i-1,r^{i-1}_{i-1,i-1}}(m+b) - \lambda_{i-1} - 1$. Therefore we obtain

$$\begin{aligned}F_{\theta_i} v(m) = {} & \sum_{j > r^s_{i-1,i-1}} \sum_{r^s_{i-1} \in R^F_{i-1}} (-1)^{i+s} a(\epsilon_{r^s_{i-1}} + \epsilon_{i,j}) \varepsilon^{C_{i-1}(m+b, r^s_{i-1}) - M_{i,j}(m+b) - \lambda^{(s,i)} + 1 - s}[M_{s,r^s_{s,i-1}}(m+b) \\ & - \lambda_s]_\varepsilon v(m + \epsilon_{r^s_{i-1}} + \varepsilon_{i,j}) + \sum_{j \leqslant r^s_{i-1,i-1}} \sum_{r^{i-1}_{i-1} \in R^F_{i-1,i-1}} (-1)^{i+i} a(\epsilon_{r^{i-1}_{i-1}} \\ & + \epsilon_{i,j}) \varepsilon^{C_{i-1}(m+b, r^{i-1}_{i-1}) - M_{i,j}(m+b) - \lambda^{(i,i)} + 1 - i}[M_{i,j}(m+b) - \lambda_i]_\varepsilon v(m + \epsilon_{r^{i-1}_{i-1}} + \varepsilon_{i,j}).\end{aligned}$$

Here, if we set

$$r^s_i = (r^s_{1,i}, \ldots, r^s_{i,i}) := \begin{cases} (r^s_{1,i-1}, \ldots, r^s_{i-1,i-1}, j) & \text{if } s \leqslant i-1 \text{ and } j > r^s_{i-1,i-1} \\ (r^{i-1}_{1,i-1}, \ldots, r^{i-1}_{i-1,i-1}, j) & \text{if } s = i \text{ and } j \leqslant r^{i-1}_{i-1,i-1}, \end{cases}$$

then we have F_{θ_i}-case. □

For $s \in I$, we set

$$R_s := \{r^s = (r^s_k)_{k \in I} \in I^n \,|\, r^s_1 \geqslant \cdots \geqslant r^s_{s-1} \geqslant r^s_s < r^s_{s+1} < \cdots < r^s_n\},$$

$$R^F_s := \{r^s = (r^s_i)_{i \in I} \in R_s \,|\, k \leqslant r^s_k \text{ for any } k \in I\},$$

$$R^E_s := \{r^s = (r^s_i)_{i \in I} \in R_s \,|\, r^s_k \leqslant k \text{ for any } k \in I\},$$

$$R^F := \bigsqcup_{s=1}^{n} R^F_s, \quad R^E := \bigsqcup_{s=1}^{n} R^E_s. \tag{5.13}$$

Note if $r^s = (r^s_k)_{k \in I} \in R^F_s$ (respectively, R^E_s), then $r^s_k = k$ for any $s \leqslant k \leqslant n$ (respectively, $r^s_k = 1$ for any $1 \leqslant k \leqslant s$). Moreover, for $c \in \mathbb{C}^N$, we set

$$C(c,r^s) := c_{s-1,s-1} - c_{n,n} + \sum_{k=1}^{n} c_{1,k} + \sum_{k=1}^{s-1} \sum_{p=r_{k+1}^s}^{r_k^s - 1} c_{k,p} - \sum_{k=1}^{s} \sum_{p=r_k^s+1}^{r_{k-1}^s} c_{k,p} \quad (r^s \in R_s^F),$$

$$D(c,r^s) := - \sum_{k=n-s+2}^{n} c_{1,k} - \sum_{k=s+1}^{n} (c_{r_k^s-1,n-k+r_k^s} - c_{r_k^s,n-k+r_k^s}) \quad (r^s \in R_s^E), \tag{5.14}$$

where $r_0^s := n$. Then, by Lemma 5.2, we obtain the following lemma.

Lemma 5.3: Let $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in (\mathbb{C}^\times)^N$, $b=(b_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{C}^N$, $\lambda=(\lambda_i)_{i\in I} \in \mathbb{C}^n$, *and* $m=(m_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{Z}_l^N$. *We have*

$$F_{\theta_n} v(m) = \sum_{r^s \in R^F} (-1)^{s+n} a(\epsilon_{r^s}) \varepsilon^{C(m+b,r^s)-\lambda^{(s)}+1-s} [-m_{s-1,s-1} + m_{s,s} - b_{s-1,s-1} + b_{s,s} - \lambda_s]_\varepsilon v(m+\epsilon_{r^s}),$$

$$E_{\theta_n} v(m) = \sum_{r^s \in R^E} (-1)^{s+n} a(\alpha_{r^s}) \varepsilon^{D(m+b,r^s)+1-s} [-m_{1,n-s+1} - b_{1,n-s+1}]_\varepsilon v(m+\alpha_{r^s}),$$

in $V_\varepsilon(a,b,\lambda)$, *where* $\lambda^{(s)}$ *as in (4.8).*

Let $U'_{\mathcal{A}}$ (respectively, U'_ε) be the extended algebra of $U_{\mathcal{A}}$ (respectively, U_ε) defined by replacing $\{K_\mu | \mu \in Q\}$ with $\{K_\mu | \mu \in P\}$ (see Definition 2.1). By (2.18), we have $\mathrm{ev}_{\mathbf{a}}^{\pm}(\widetilde{U}_{\mathcal{A}}) \subset U'_{\mathcal{A}}(\mathbf{a} \in \mathbb{C}^\times)$. So we obtain the evaluation homomorphisms $\mathrm{ev}_{\mathbf{a}}^{\pm}: \widetilde{U}_\varepsilon \to U'_\varepsilon$ as in Proposition 2.6. On the other hand, by (2.1), we can regard an arbitrary Schnizer module $V_\varepsilon(a,b,\lambda)$ as a U'_ε-module if we define

$$K_{\Lambda_i} v(m) := \varepsilon^{-\sum_{k=i}^{n} (m_{i,k}+b_{i,k})+\lambda_{\Lambda_i}} v(m), \tag{5.15}$$

for any $i \in I$, $m \in \mathbb{Z}_l^N$, where λ_{Λ_i} as in (4.3).

Definition 5.4: Let $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in (\mathbb{C}^\times)^N$, $b=(b_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{C}^N$, $\lambda=(\lambda_i)_{i\in I} \in \mathbb{C}^n$, and $\mathbf{a} \in \mathbb{C}^\times$. Then we define $\widetilde{\mathrm{ev}}_{\mathbf{a}}^{\pm} := \widetilde{\mathrm{ev}}_{\mathbf{a}}^{\pm}(a,b,\lambda) := \rho(a,b,\lambda) \circ \mathrm{ev}_{\mathbf{a}_\pm^\lambda}^{\pm}: \widetilde{U}_\varepsilon \to \mathrm{End}(V_N)$, where $\rho=\rho(a,b,\lambda)$ is as in Theorem 5.1 and $\mathbf{a}_\pm^\lambda$ are as in (4.4). We denote the l^N-dimensional $\widetilde{U}_\varepsilon$-module associated with $(\widetilde{\mathrm{ev}}_{\mathbf{a}}^{\pm}, V_N)$ by $V_\varepsilon(a,b,\lambda)_{\mathbf{a}}^{\pm}$.

For $c \in C^N$, we set

$$C_E(c,r^s) := c_{s-1,s-1} + \sum_{k=1}^{s-1} \sum_{p=r_{k+1}^s}^{r_k^s - 1} c_{k,p} - \sum_{k=1}^{s} \sum_{p=r_k^s+1}^{r_{k-1}^s} c_{k,p} \quad (r^s \in R_s^F),$$

$$D_F(c,r^s) := - c_{n,n} + \sum_{k=1}^{n-s+1} c_{1,k} - \sum_{k=s+1}^{n} (c_{r_k^s-1,n-k+r_k^s} - c_{r_k^s,n-k+r_k^s}) \quad (r^s \in R_s^E). \tag{5.16}$$

Proposition 5.5: Let $a=(a_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in (\mathbb{C}^\times)^N$, $b=(b_{i,j})_{1\leqslant i\leqslant j\leqslant n} \in \mathbb{C}^N$, $\lambda=(\lambda_i)_{i\in I} \in \mathbb{C}^n$, *and* $\mathbf{a} \in \mathbb{C}^\times$. *Then, for any* $i \in I$ *and* $m \in \mathbb{Z}_l^N$, *we obtain*

$$\widetilde{\mathrm{ev}}_{\mathbf{a}}^{\pm}(E_i)(v(m)) = \rho(E_i)(v(m)), \quad \widetilde{\mathrm{ev}}_{\mathbf{a}}^{\pm}(F_i)(v(m)) = \rho(F_i)(v(m)),$$

$$\widetilde{\mathrm{ev}}_{\mathbf{a}}^{\pm}(K_{\alpha_i})(v(m)) = \rho(K_{\alpha_i})(v(m)),$$

$$\widetilde{\mathrm{ev}}^{\pm}_{\mathbf{a}}(E_0)(v(m)) = \mathbf{a} \sum_{r^s \leqslant R^F} (-1)^{s+n} a(\epsilon_{r^s}) \varepsilon^{\pm(C_E(m+b,r^s)-\lambda^{(s)}-s)+n}[-m_{s-1,s-1}+m_{s,s}-b_{s-1,s-1}+b_{s,s}-\lambda_s]_\varepsilon \times v(m+\epsilon_{r^s}),$$

$$\widetilde{\mathrm{ev}}^{\pm}_{\mathbf{a}}(F_0)(v(m)) = \mathbf{a}^{-1} \sum_{r^s \leqslant R^E} (-1)^{s-1} a(\alpha_{r^s}) \varepsilon^{\pm(D_F(m+b,r^s)-s+n+1)-n}[-m_{1,n-s+1}-b_{1,n-s}]_\varepsilon v(m+\alpha_{r^s}),$$

where ϵ_{r^s}, α_{r^s} *are as in (5.10),* R^F, R^E *are as in (5.13), and* $C_E(m+b,r^s)$, $D_F(m+b,r^s)$ *are as in (5.16).*

Proof: By Proposition 2.6, Theorem 5.1, Lemma 5.3, and (5.15), we obtain the $\widetilde{\mathrm{ev}}^{+}_{\mathbf{a}}$-case. Similarly, we obtain the $\widetilde{\mathrm{ev}}^{-}_{\mathbf{a}}$-case. □

B. Nilpotent modules

Definition 5.6: Let V be a $\widetilde{U}_\varepsilon$-module (respectively, U_ε-module). We assume $E^l_\beta = F^l_\beta = E_{(i,sl\delta)} = F_{(i,sl\delta)} = 0$ on V for any $\beta \in \widetilde{\Delta}^{\mathrm{re}}_+$, $i \in I$, $s \in \mathbb{N}$ (respectively, $\bar{E}^l_\gamma = \bar{F}^l_\gamma = 0$ on V for any $\gamma \in \Delta_+$). Then we call V a "nilpotent" $\widetilde{U}_\varepsilon$-module (respectively, U_ε-module). In particular, if $K^l_\mu = 1$ on V for any $\mu \in Q$, then we call V a nilpotent $\widetilde{U}_\varepsilon$-module (respectively U_ε-module) of "type **1**."

For $\lambda \in \mathbb{Z}^n_l$, let $V^{\mathrm{fin}}_\varepsilon(\lambda)$ be the $U^{\mathrm{fin}}_\varepsilon$-module in Sec. IV A. By Proposition 3.14, we can regard $V^{\mathrm{fin}}_\varepsilon(\lambda)$ as a nilpotent U_ε-module. We denote U_ε-module $V^{\mathrm{fin}}_\varepsilon(\lambda)$ by $V^{\mathrm{nil}}_\varepsilon(\lambda)$. By Proposition 3.14 and Theorem 4.7, we obtain the following proposition.

Proposition 5.7: For any $\lambda \in \mathbb{Z}^n_l$, $V^{\mathrm{nil}}_\varepsilon(\lambda)$ *is a finite-dimensional irreducible nilpotent* U_ε*-module of type* **1**. *Conversely, for any finite-dimensional irreducible nilpotent* U_ε*-module* V *of type* **1**, *there exists a unique* $\lambda \in \mathbb{Z}^n_l$ *such that* V *is isomorphic to* $V^{\mathrm{nil}}_\varepsilon(\lambda)$.

We can construct $V^{\mathrm{nil}}_\varepsilon(\lambda)$ as a U_ε-submodule of Schnizer module $V_\varepsilon(a,b,\lambda)$ as follows (Refs. 1, 2, and 22). For $i,j \in I (i \leqslant j)$, $\lambda \in \mathbb{Z}^n_l$, we set

$$a^{(0)}_{i,j} := 1, \quad b^{(0)}_{i,j} := 0, \quad a^{(0)} := (a^{(0)}_{i,j})_{1 \leqslant i \leqslant j \leqslant n}, \quad b^{(0)} := (b^{(0)}_{i,j})_{1 \leqslant i \leqslant j \leqslant n}, \tag{5.17}$$

$$\rho^0_\lambda := \rho(a^{(0)}, b^{(0)}, \lambda), \quad V^0_\varepsilon(\lambda) := V_\varepsilon(a^{(0)}, b^{(0)}, \lambda). \tag{5.18}$$

We denote $v(0)$ in $V^0_\varepsilon(\lambda)$ by $v_\lambda(0)$. For $\lambda = (\lambda_i)_{i \in I} \in \mathbb{Z}^n_l$, we define $m^\lambda = (m^\lambda_{i,j})_{1 \leqslant i \leqslant j \leqslant n} \in \mathbb{Z}^n_l$ by

$$m^\lambda_{i,j} \equiv \sum_{k=1}^{i} \lambda_{j-k+1} \pmod{l} \quad 1 \leqslant i \leqslant j \leqslant n. \tag{5.19}$$

Proposition 5.8: Let $\lambda \in \mathbb{Z}^n_l$ *and* $v \in V^0_\varepsilon(\lambda)$.
(*a*) $E_i v = 0$ *for any* $i \in I$ *if and only if* $v \in \mathbb{C} v_\lambda(0)$.
(*b*) $F_i v = 0$ *for any* $i \in I$ *if and only if* $v \in \mathbb{C} v(m^\lambda)$.

Proof: By Ref. 2, we obtain (a). So we shall prove (b). "If part." By (5.19), we have

$$m^\lambda_{i,i} - m^\lambda_{i-1,i-1} = \lambda_i, \quad m^\lambda_{i,j} - m^\lambda_{i-1,j} = \lambda_{j-i+1}, \quad m^\lambda_{i,j} - m^\lambda_{i+1,j} = -\lambda_{j-i}, \tag{5.20}$$

for any $1 \leqslant i \leqslant j \leqslant n$. Hence, by (5.2), we get

$$M_{i,j}(m^\lambda) = m^\lambda_{i,i} - m^\lambda_{i-1,i-1} + \sum_{k=i}^{j-1} (m^\lambda_{i,k} - m^\lambda_{i-1,k}) + \sum_{k=i+1}^{j} (m^\lambda_{i,k} - m^\lambda_{i+1,k})$$
$$= \lambda_i + \left(\sum_{k=i}^{j-1} \lambda_{k-i+1} - \sum_{k=i+1}^{j} \lambda_{k-i} \right) = \lambda_i,$$

for any $1 \leqslant i \leqslant j \leqslant n$. Therefore, by (5.7), we obtain

$$F_i v(m^\lambda) = \sum_{j=i}^{n} [M_{i,j}(m^\lambda) - \lambda_i]_\varepsilon v(m^\lambda + \epsilon_{i,j}) = \sum_{j=i}^{n} [\lambda_i - \lambda_i]_\varepsilon v(m^\lambda + \epsilon_{i,j}) = 0 \quad (i \in I).$$

"Only if part." Let $v = \Sigma_{m \in \mathbb{Z}_l^n} c_m v(m) \in V(\lambda) (c_m \in \mathbb{C})$. We assume that $F_i v = 0$ for any $i \in I$. Set

$$\mathbb{Z}_l^n(r) := \{m = (m_{i,j})_{1 \leqslant i \leqslant j \leqslant n} \in \mathbb{Z}_l^n | m_{i,j} = m_{i,j}^\lambda \text{ if } j - i < r\} \ (r = 1, \ldots, n), \quad \mathbb{Z}_l^n(0) := \mathbb{Z}_l^n.$$

Then we have

$$\mathbb{Z}_l^n = \mathbb{Z}_l^n(0) \supset \mathbb{Z}_l^n(1) \supset \cdots \supset \mathbb{Z}_l^n(n) = \{m^\lambda\}.$$

We shall prove that $v = \Sigma_{m \in \mathbb{Z}_l^n(r)} c_m v(m)$ for all $0 \leqslant r \leqslant n$ by the induction on r. Indeed, if we can prove this claim, then we obtain $v = c_{m^\lambda} v(m^\lambda) \in \mathbb{C} v(m^\lambda)$. If $r = 0$, then there is nothing to prove. So we assume that $r > 0$ and the case of $(r-1)$ holds.

In a similar way to the proof of "if part," for any $m \in \mathbb{Z}_l^n(r-1)$, we have $M_{i,j}(m) = \lambda_i$ if $j - i < r - 1$. Moreover, for any $m \in \mathbb{Z}_l^n(r-1)$ and $i \in I$ such that $i + r - 1 \leqslant n$, we get

$$M_{i,i+r-1}(m) = \sum_{k=i}^{i+r-2} m_{i,k} - \sum_{k=i-1}^{i+r-2} m_{i-1,k} + \sum_{k=i}^{i+r-1} m_{i,k} - \sum_{k=i+1}^{i+r-1} m_{i+1,k} = M_{i,i+r-1}(m^\lambda) - m_{i-1,i+r-2} + m_{i,i+r-1}$$
$$+ m_{i-1,i+r-2}^\lambda - m_{i,i+r-1}^\lambda = \lambda_i - m_{i-1,i+r-2} + m_{i,i+r-1} - \lambda_{i+r-1}.$$

Therefore, by (5.7), we get

$$F_i v = \sum_{m \in \mathbb{Z}_l^n(r-1)} c_m [m_{i,i+r-1} - m_{i-1,i+r-2} - \lambda_{i+r-1}]_\varepsilon v(m + \epsilon_{i,i+r-1})$$
$$+ \sum_{j=i+r}^{n} \sum_{m \in \mathbb{Z}_l^n(r-1)} c_m [M_{i,j}(m) - \lambda_i]_\varepsilon v(m + \epsilon_{i,j}) = 0 \quad (i \leqslant n - r + 1). \tag{5.21}$$

Now, for $1 \leqslant s \leqslant n - r + 1$, we set

$$\mathbb{Z}_l^n(r-1, s) := \{m = (m_{i,j})_{1 \leqslant i \leqslant j \leqslant n} \in \mathbb{Z}_l^n(r-1) | m_{i,i+r-1} - m_{i-1,i+r-2} \equiv \lambda_{i+r-1} \pmod{l} \text{ if } s \leqslant i \leqslant n - r + 1\}.$$

We have $m_{i,i+r-1} - m_{i-1,i+r-2} \equiv \lambda_{i+r-1}$ for any $1 \leqslant i \leqslant n - r + 1$ if and only if $m_{i,i+r-1} = m_{i,i+r-1}^\lambda$ for any $1 \leqslant i \leqslant n - r + 1$. Hence we get

$$\mathbb{Z}_l^n(r-1) \supset \mathbb{Z}_l^n(r-1, n-r+1) \supset \cdots \supset \mathbb{Z}_l^n(r-1, 1) = \mathbb{Z}_l^n(r).$$

So it is enough to prove that $v = \Sigma_{m \in \mathbb{Z}_l^n(r-1,s)} c_m v(m)$ for all $1 \leqslant s \leqslant n - r + 1$. We shall prove this claim by the induction on s. By (5.21), we obtain

$$F_{n-r+1} v = \sum_{m \in \mathbb{Z}_l^n(r-1)} c_m [m_{n-r+1,n} - m_{n-r,n-1} - \lambda_n]_\varepsilon v(m + \epsilon_{n-r+1,n}) = 0.$$

Thus, $c_m [m_{n-r+1,n} - m_{n-r,n-1} - \lambda_n]_\varepsilon = 0$ for any $m \in \mathbb{Z}_l^n(r-1)$. So if $c_m \neq 0$ for any $m \in \mathbb{Z}_l^n(r-1)$, then $m_{n-r+1,n} - m_{n-r,n-1} \equiv \lambda_n$. Hence $v = \Sigma_{m \in \mathbb{Z}_l^n(r-1,n-r+1)} c_m v(m)$.

Now we assume that $s < n - r + 1$ and the case of $(s+1)$ holds. By (5.21), we get

$$F_s v = \sum_{m \in \mathbb{Z}_l^n(r-1,s+1)} c_m [m_{s,s+r-1} - m_{s-1,s+r-2} - \lambda_{s+r-1}]_\varepsilon v(m + \epsilon_{s,s+r-1}) + \sum_{j=s+r}^{n} \sum_{m \in \mathbb{Z}_l^n(r-1,s+1)} c_m [M_{s,j}(m)$$
$$- \lambda_s]_\varepsilon v(m + \epsilon_{s,j}) = 0.$$

Here, for $m = (m_{i,j})_{1 \leqslant i \leqslant j \leqslant n} \in \mathbb{Z}_l^n(r-1, s+1)$, we obtain

$$(m+\epsilon_{s,s+r-1})_{s+1,s+r}-(m+\epsilon_{s,s+r-1})_{s,s+r-1}\equiv(m_{s+1,s+r}-m_{s,s+r-1})-1\equiv\lambda_{s+r}-1,$$

$$(m+\epsilon_{s,j})_{s+1,s+r}-(m+\epsilon_{s,j})_{s,s+r-1}\equiv m_{s+1,s+r}-m_{s,s+r-1}\equiv\lambda_{s+r}\ (s+r\leqslant j\leqslant n).$$

Hence, by the linear independence, we obtain $c_m[m_{s,s+r-1}-m_{s-1,s+r-2}-\lambda_{s+r-1}]_\varepsilon=0$ for any $m\in\mathbb{Z}_l^n(r-1,s+1)$. So if $c_m\neq 0$, then $m_{s,s+r-1}-m_{s-1,s+r-2}\equiv\lambda_{s+r-1}$ for any $m\in\mathbb{Z}_l^n(r-1,s+1)$. Then we have $v=\Sigma_{m\in\mathbb{Z}_l^n(r-1,s)}c_m v(m)$. □

For $\lambda\in\mathbb{Z}_l^n$, let $V_\varepsilon^0(\lambda)$ be as in (5.18) and $L_\varepsilon^{\mathrm{nil}}(\lambda)$ be the U_ε-submodule of $V_\varepsilon^0(\lambda)$ generated by $v_\lambda(0)$.

Proposition 5.9 (Refs. 2 and 22): For any $\lambda\in\mathbb{Z}_l^n$, $L_\varepsilon^{\mathrm{nil}}(\lambda)$ *is isomorphic to* $V_\varepsilon^{\mathrm{nil}}(\lambda)$ *as a* U_ε*-module*.

For $\mathbf{a}\in\mathbb{C}^\times$, $\lambda\in\mathbb{Z}_l^n$, let $V_\varepsilon^0(\lambda)_\mathbf{a}^\pm$ (respectively, $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^\pm$) be the evaluation representation of $V_\varepsilon^0(\lambda)$ (respectively, $L_\varepsilon^{\mathrm{nil}}(\lambda)$) (see Definition 5.4). Then $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^\pm$ is the $\widetilde{U}_\varepsilon$-submodule of $V_\varepsilon^0(\lambda)_\mathbf{a}^\pm$ generated by $v_\lambda(0)$, respectively.

Now, let $\widetilde{\phi}:\widetilde{U}_\varepsilon/\widetilde{I}_\varepsilon\to\widetilde{U}_\varepsilon^{\mathrm{fin}}$ (respectively, $\bar{\phi}:U_\varepsilon/I_\varepsilon\to U_\varepsilon^{\mathrm{fin}}$) be the isomorphism in Theorem 3.15 (respectively, Proposition 3.14). Let I_ε' be the two-sided ideal of U_ε' generated by $\{\widetilde{E}_\gamma^l,\widetilde{F}_\gamma^l,K_\mu^{2l}-1\,|\,\gamma\in\Delta_+,\mu\in P\}$. Then we can regard $\bar{\phi}$ as an isomorphism from $U_\varepsilon'/I_\varepsilon'$ to $(U_\varepsilon^{\mathrm{fin}})'$. Let $\widetilde{\pi}:\widetilde{U}_\varepsilon\to\widetilde{U}_\varepsilon/\widetilde{I}_\varepsilon$ (respectively, $\pi:U_\varepsilon'\to U_\varepsilon'/I_\varepsilon'$) be the projection and $\mathrm{ev}_\mathbf{a}^\pm:\widetilde{U}_\varepsilon\to U_\varepsilon'$ (respectively, $(\mathrm{ev}_\mathbf{a}^{\mathrm{fin}})^\pm:\widetilde{U}_\varepsilon^{\mathrm{fin}}\to(U_\varepsilon^{\mathrm{fin}})'$) be the evaluation homomorphism in Proposition 2.6 (respectively, (4.2))). Then, by the definition of these maps, the following diagram commutes:

$$\begin{array}{ccc}
\widetilde{U}_\varepsilon & \xrightarrow{\mathrm{ev}_\mathbf{a}^\pm} & U_\varepsilon' \\
\widetilde{\pi}\downarrow & & \downarrow\pi \\
\widetilde{U}_\varepsilon/\widetilde{I}_\varepsilon & & U_\varepsilon'/I_\varepsilon' \\
\widetilde{\phi}\downarrow & & \uparrow\widetilde{\phi}^{-1} \\
\widetilde{U}_\varepsilon^{\mathrm{fin}} & \xrightarrow{(\mathrm{ev}_\mathbf{a}^{\mathrm{fin}})^\pm} & (U_\varepsilon^{\mathrm{fin}})'
\end{array} \tag{5.22}$$

Proposition 5.10: For any $\mathbf{a}\in\mathbb{C}^\times$ *and* $\lambda\in\mathbb{Z}_l^n$, $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^\pm$ *is a finite-dimensional irreducible nilpotent* $\widetilde{U}_\varepsilon$*-module of type* **1**.

Proof: We shall prove the case of $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+$. Since we can prove the case of $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^-$ similarly. By Theorem 5.9, $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+$ is a finite-dimensional irreducible $\widetilde{U}_\varepsilon$-module of type **1**. So we shall prove, that $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+$ is a nilpotent $\widetilde{U}_\varepsilon$-module.

For $\lambda\in\mathbb{Z}_l^n$, let ρ_λ^0 as in (5.18). We define $\bar{\rho}_\lambda^0:U_\varepsilon'/I_\varepsilon'\to\mathrm{End}(L_\varepsilon^{\mathrm{nil}}(\lambda))$ by $\bar{\rho}_\lambda^0(u+I_\varepsilon):=\rho_\lambda^0(u)$ for any $u\in U_\varepsilon'$. Since $L_\varepsilon^{\mathrm{nil}}(\lambda)$ is a nilpotent U_ε-module, $\bar{\rho}_\lambda^0$ is well-defined. Then, for any $u\in U_\varepsilon'$, $v\in L_\varepsilon^{\mathrm{nil}}(\lambda)$, we have $u.v=\bar{\rho}_\lambda^0\circ\pi(u)(v)$ on $L_\varepsilon^{\mathrm{nil}}(\lambda)$. Hence, for any $u\in\widetilde{U}_\varepsilon$ and $v\in L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+$, we get

$$u.v=\bar{\rho}_\lambda^0\circ\pi\circ\mathrm{ev}_\mathbf{a}^+(u)(v)=\bar{\rho}_\lambda^0\circ(\bar{\phi}')^{-1}\circ(\mathrm{ev}_\mathbf{a}^{\mathrm{fin}})^+\circ\widetilde{\phi}\circ\widetilde{\pi}(u)(v)\ \text{on}\ L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+,$$

by (5.22). Since $\widetilde{\pi}(\widetilde{I}_\varepsilon)=0$, we obtain $\widetilde{I}_\varepsilon=0$ on $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+$. Therefore $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^+$ is a nilpotent $\widetilde{U}_\varepsilon$-module. □

By Theorem 3.15 and Proposition 5.10, we can regard $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^\pm$ as a $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module. We denote $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module $L_\varepsilon^{\mathrm{nil}}(\lambda)_\mathbf{a}^\pm$ by $L_\varepsilon^{\mathrm{fin}}(\lambda)_\mathbf{a}^\pm$. Let $\mathbf{P}_\mathbf{a}^\pm$ be as in (4.6) and $\widetilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P}_\mathbf{a}^\pm)$ be the evaluation representation of $\widetilde{U}_\varepsilon^{\mathrm{fin}}$ in Sec. IV. Then, by Theorem 4.13, 5.9, $L_\varepsilon^{\mathrm{fin}}(\lambda)_\mathbf{a}^\pm$ is isomorphic to $\widetilde{V}_\varepsilon^{\mathrm{fin}}(\mathbf{P}_\mathbf{a}^\pm)$ as a $\widetilde{U}_\varepsilon^{\mathrm{fin}}$-module. Hence, by Proposition 4.14, we obtain the following proposition.

Proposition 5.11: Let $\lambda=(\lambda_i)_{i\in l}\in\mathbb{Z}_l^n$, $\mathbf{a}_\pm\in\mathbb{C}^\times$.

(*a*) *If* $\lambda=0$, *then* $L_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_+}^+$ *is isomorphic to* $L_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_-}^-$ *as a* $\widetilde{U}_\varepsilon$*-module*.

(*b*) *In the case of* $\lambda\neq 0$, $L_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_+}^+$ *is isomorphic to* $L_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_-}^-$ *as a* $\widetilde{U}_\varepsilon$*-module if and only if* $\mathbf{a}_+$

$=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ *for any* $i\in\mathrm{supp}(\lambda)$.

C. Alternative proof of Proposition 5.11(b)

We can also prove Proposition 5.11(b) without using the theory of restricted type. We give here the alternative proof.

"*Proof of only if part:*" We assume that $L_\varepsilon^{\mathrm{nil}}(\lambda)^+_{\mathbf{a}_+}\cong L_\varepsilon^{\mathrm{nil}}(\lambda)^-_{\mathbf{a}_-}$. Then there exists a $\widetilde{U}_\varepsilon$-module isomorphism $\phi: L_\varepsilon^{\mathrm{nil}}(\lambda)^+_{\mathbf{a}_+}\to L_\varepsilon^{\mathrm{nil}}(\lambda)^-_{\mathbf{a}_-}$. By Proposition 5.8(a), there exists $d\in\mathbb{C}^\times$ such that $\phi(v_\lambda(0))=dv_\lambda(0)$. Since $L_\varepsilon^{\mathrm{nil}}(\lambda)^+_{\mathbf{a}_+}$ is generated by $v_\lambda(0)$ as a $\widetilde{U}_\varepsilon$-module, we obtain $\phi(v)=dv$ for any $v\in L_\varepsilon^{\mathrm{nil}}(\lambda)_{\mathbf{a}_+}$. Hence we have

$$\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)v_\lambda(0)=d^{-1}\phi(\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)v_\lambda(0))=d^{-1}\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)\phi(v_\lambda(0))=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)v_\lambda(0). \tag{5.23}$$

For $c=(c_{i,j})_{1\leqslant i\leqslant j\leqslant n}\in\mathbb{C}^N$, $r^s\in R^F$, let $C_E(c,r^s)$ be as in (5.16). Then $C_E(0,r^s)=0$ for $r^s\in R^F$. By Theorem 5.5, we obtain

$$\widetilde{\mathrm{ev}}^\pm_{\mathbf{a}_\pm}(E_0)v_\lambda(0)=\mathbf{a}_\pm\sum_{r^s\in R^F}(-1)^{s+n}\varepsilon^{\mp(\lambda^{(s)}+s)+n}[-\lambda_s]_\varepsilon v(\epsilon_{r^s}). \tag{5.24}$$

Since $\{v(\epsilon_{r^s})\,|\,r^s\in R^F\}$ is linearly independent, by (5.23) and (5.24), we have $\mathbf{a}_+\varepsilon^{-\lambda^{(s)}-s}[\lambda_s]_\varepsilon=\mathbf{a}_-\varepsilon^{\lambda^{(s)}+s}[\lambda_s]_\varepsilon$ for any $s\in I$. Hence $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ for any $i\in\mathrm{supp}(\lambda)$.

"*Proof of if part:*" We assume that $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(i)}+i)}$ for any $i\in\mathrm{supp}(\lambda)$. By the definition of $\widetilde{\mathrm{ev}}^\pm_{\mathbf{a}_\pm}$, we have $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_i)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_i)$, $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(F_i)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(F_i)$, and $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(K_{\alpha_i})=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(K_{\alpha_i})$ on $V_\varepsilon^{\mathrm{nil}}(\lambda)$ for any $i\in I$. So it is enough to prove that $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)$ and $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(F_0)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(F_0)$ on $V_\varepsilon^{\mathrm{nil}}(\lambda)$. By (5.24), we obtain $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)v_\lambda(0)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)v_\lambda(0)$. On the other hand, for any $j_1,\cdots j_r\in I(r\in\mathbb{N})$, we get

$$\begin{aligned}\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)(F_{j_1}\cdots F_{j_r}v_\lambda(0))&=\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(F_{j_1}\cdots F_{j_r})(\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)v_\lambda(0))=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(F_{j_1}\cdots F_{j_r})(\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)v_\lambda(0))\\&=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)(F_{j_1}\cdots F_{j_r}v_\lambda(0)).\end{aligned}$$

Since $L_\varepsilon^{\mathrm{nil}}(\lambda)$ is spanned by $U_\varepsilon^-v_\lambda(0)$ as a $\mathbb{C}$-vector space, we obtain $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(E_0)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(E_0)$ on $V_\varepsilon^{\mathrm{nil}}(\lambda)$.

Now, for $c=(c_{i,j})_{1\leqslant i\leqslant j\leqslant n}\in\mathbb{C}^N$, $r^s\in R^E$, let $D_F(c,r^s)$ be as in Proposition 5.5 and m^λ be as in (5.19). Then, for any $r^s\in R^E$, we have

$$\begin{aligned}D_F(m^\lambda,r^s)&=-m^\lambda_{n,n}+\sum_{k=1}^{n-s+1}m^\lambda_{1,k}-\sum_{k=s+1}^{n}(m^\lambda_{r^s_k-1,n-k+r^s_k}-m^\lambda_{r^s_k,n-k+r^s_k})\\&=-\sum_{k=1}^{n}\lambda_{n-k+1}+\sum_{k=1}^{n-s+1}\lambda_k+\sum_{k=s+1}^{n}\lambda_{n-k+1}=\lambda^{(n-s+1)},\end{aligned}$$

(see (5.20)). Hence, by Theorem 5.5, we get

$$\widetilde{\mathrm{ev}}^\pm_{\mathbf{a}_\pm}(F_0)v(m^\lambda)=\mathbf{a}_\pm^{-1}\sum_{r^s\in R^E}(-1)^{s-1}\varepsilon^{\pm(\lambda^{(n-s+1)}-s+n+1)-n}[-\lambda_{n-s+1}]_\varepsilon v(m^\lambda+\alpha_{r^s}).$$

By the assumption, if $\lambda_{n-s+1}\neq 0$, then we have $\mathbf{a}_+=\mathbf{a}_-\varepsilon^{2(\lambda^{(n-s+1)}+(n-s+1))}$. So we obtain

$$\mathbf{a}_+^{-1}\varepsilon^{\lambda^{(n-s+1)}-s+n+1}=\mathbf{a}_-^{-1}\varepsilon^{-2\lambda^{(n-s+1)}-2(n-s+1)+\lambda^{(n-s+1)}-s+n+1}=\mathbf{a}_-^{-1}\varepsilon^{-(\lambda^{(n-s+1)}-s+n+1)}.$$

We have that $\widetilde{\mathrm{ev}}^+_{\mathbf{a}^+}(F_0)v(m^\lambda)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(F_0)v(m^\lambda)$.

On the other hand, in a similar way to the proof of Proposition 5.6 in Ref. 22, we obtain that there exists a nonzero vector $v_L\in L_\varepsilon^{\mathrm{nil}}(\lambda)$ such that $F_iv_L=0$ for any $i\in I$. Hence, by Proposition 5.8(b), we obtain $v(m^\lambda)\in L_\varepsilon^{\mathrm{nil}}(\lambda)$. Then $L_\varepsilon^{\mathrm{nil}}(\lambda)$ is spanned by $U_\varepsilon^+v(m^\lambda)$ as a $\mathbb{C}$-vector space. Therefore, in a similar way to the proof of E_0-case, we obtain $\widetilde{\mathrm{ev}}^+_{\mathbf{a}_+}(F_0)=\widetilde{\mathrm{ev}}^-_{\mathbf{a}_-}(F_0)$ on $L_\varepsilon^{\mathrm{nil}}(\lambda)$.

In this paper, we study Miura transformations $u \mapsto v$ from partial differential equations $u_{xxx}=\mathcal{F}(u,u_x,u_t)$ to nonlinear partial differential equations $\mathcal{G}(v,v_x,v_t,\ldots,\partial_x^l v,\ldots,\partial_t^l v)=0$ defined using integrable systems on v. We classify all such Miura transformations under some restrictions, and hence generalize the classical Miura transformation to a large class of nonlinear partial differential equations. For some examples, by applying Miura transformations found in this paper, we derive exact solutions v from known solutions u. In particular, kink and soliton-kink solutions of $v_t=\frac{3}{2}v_x \sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$ are obtained from constant solutions and soliton solutions of the MKdV equation. As another application of Miura transformations of this paper, we deduce a new Bäcklund transformation for each of $v_t=\frac{3}{2}v_x \sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$ and $v_t=-\frac{3}{2}v_x \sinh^2 v-\frac{1}{2}v_x^3+v_{xxx}$ from the known Bäcklund transformations for the MKdV equations. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2234727]

I. INTRODUCTION

It is now well known that if v is a solution of the negative MKdV equation

$$v_t = v_{xxx} - 6v^2 v_x, \tag{1.1}$$

then $u=v_x-v^2$ is a solution of the KdV equation

$$u_t = u_{xxx} + 6uu_x. \tag{1.2}$$

The transformation $v \mapsto u=v_x-v^2$ from solutions of the negative MKdV equation to solutions of the KdV equation is the classical Miura transformation.[6]

On the other hand, if u is a solution of the KdV equation, then the system

$$\begin{aligned} v_x &= v^2 + u, \\ v_t &= 2v^2 u + 2u^2 + 2vu_x + u_{xx} \end{aligned} \tag{1.3}$$

on v is integrable and yields a solution v (with a constant of integration) of the negative MKdV equation.

*Dedicated to the memory of our great mentor, Professor Shiing-Shen Chern.

a)Electronic mail: xfcao@yzu.edu.cn

So, the classical Miura transformation $v \mapsto u = v_x - v^2$ and this second transformation $u \mapsto v$ defined using (1.3) together give a local equivalence between the negative MKdV equation and the KdV equation.

Motivated by this example, we give the following general definition of Miura transformations of the type $u \mapsto v$ above.

Let $n > 0$ and $k \geqslant 0$ be integers. Consider a system

$$\begin{aligned} \Phi_x &= \Omega(\phi_1, \ldots, \phi_n, u, u_x, u_t, \ldots, \partial_x^k u, \ldots, \partial_t^k u), \\ \Phi_t &= \Theta(\phi_1, \ldots, \phi_n, u, u_x, u_t, \ldots, \partial_x^k u, \ldots, \partial_t^k u) \end{aligned} \tag{1.4}$$

on the (row) vector Φ of n functions $\phi_1, \ldots, \phi_n$. Following Ref. 6, we say that (1.4) is an *integrable system* associated with a partial differential equation (PDE)

$$\mathcal{F}(u, u_x, u_t, \ldots, \partial_x^l u, \ldots, \partial_t^l u) = 0 \tag{1.5}$$

if it is integrable on a nonempty open subset of the Φ space when and only when u is a solution to a fixed set of PDEs implied by (1.5).

The functions defined by integrable systems associated with a PDE were called *pseudopotentials* of the equation by Wahlquist and Estabrook in Ref. 13, and they have been studied extensively in the literature.

Let (1.4) be an integrable system associated with (1.5). A map

$$u \mapsto v = F(\phi_1, \ldots, \phi_n, u, u_x, u_t, \ldots, \partial_x^k u, \ldots, \partial_t^k u) \tag{1.6}$$

is called a *Miura-transformation* (MT) from (1.5) to a nonlinear PDE

$$\mathcal{G}(v, v_x, v_t, \ldots, \partial_x^l v, \ldots, \partial_t^l v) = 0 \tag{1.7}$$

defined using (1.4) if it is nonconstant with respect to at least one of $\phi_1, \ldots, \phi_n$, and v is always a solution of (1.7) for each solution u of (1.5) and every solution $\Phi = (\phi_1, \ldots, \phi_n)$ of the corresponding system (1.4).

In general, given a solution u of (1.5), investigating (1.4) is much easier than solving (1.7). This is the reason for why MTs are useful. When (1.5) and (1.7) are the same equation, a MT is then called a *Bäcklund transformation* (BT) for the equation. There is a huge literature on such transformations (see, e.g., Refs. 8, 5, 14, 10, and 7).

In this paper, we explicitly determine all MTs $u \mapsto v$ from PDEs of the form

$$u_{xxx} = \mathcal{F}(u, u_x, u_t) \tag{1.8}$$

to nonlinear PDEs of the form

$$\mathcal{G}(v, v_x, v_t, \ldots, \partial_x^l v, \ldots, \partial_t^l v) = 0 \tag{1.9}$$

defined using integrable systems of the form

$$\begin{aligned} v_x &= \omega(v) + u, \\ v_t &= \Theta(v, u, u_x, u_{xx}) \end{aligned} \tag{1.10}$$

associated with (1.8). For the main classification results of this paper, see Theorems 2.4 and 2.6.

In each of such situations, the map $v \mapsto u = v_x - \omega(v)$ is a MT from (1.9) to (1.8), and the transformations $u \mapsto v$ and $v \mapsto u = v_x - \omega(v)$ together give a local equivalence between (1.8) and (1.9). This motivates our choice of the special format of the associated integrable system (1.10).

This work is a continuation of Ref. 14. Our method originated from the work[2] of Chern and Tenenblat and relies on the requirement that *the source* PDE $u_{xxx} = \mathcal{F}(u, u_x, u_t)$ *in question has enough solutions so that at each point in a nonempty open subset of the xt space, the values of u*,

u_x, u_t, and u_{xx} are independent from each other; *hence*, *we can treat them as independent variables in the functions* $\mathcal{F}$, $\mathcal{G}$, ω, *and* Θ *when we want to determine these functions*. We will always omit this requirement from the statements of our results.

Most papers in this area are about constructions of BTs, MTs, and solutions, and there are several results on classifications of such transformations. However, all these classification results (see, e.g., Ref. 9) assume that the PDEs considered satisfy certain integrability conditions, such as Lax pairs, symmetries, or high order conservation laws; moreover, some authors allow transformations that are more general than those which we use. As a feature of this paper, we do not assume that the PDEs studied have any structures.

The organization of this paper is as follows. In Sec. II, we prove this paper's classification of MTs. Section III is devoted to exact solutions obtained using MTs of this paper, with soliton-kink solutions presented in Examples 3.7 and 3.8; while Sec. IV deals with BTs deduced in terms of such MTs, with two new BTs given in Examples 4.6 and 4.7.

II. MIURA TRANSFORMATIONS

First, we have the following complete classification of all the integrable systems of the form (1.10) associated with PDEs of the form (1.8). Recall that a linear coordinate change of the xt space has the form $\tilde{x}=a_1x+b_1t+c_1$ and $\tilde{t}=a_2x+b_2t+c_2$ with $a_1b_2\neq a_2b_1$, while a linear coordinate change of the u axis can be written as $u\mapsto au+b$ with $a\neq 0$.

Theorem 2.1: *Up to linear coordinate changes of the* xt, u, *and* v *spaces*, (1.10) *is an integrable system associated with* (1.8) *if and only if*: *when* ω *is linear*,

$$\mathcal{F}(u,u_x,u_t)=p(u)+q(u)u_x+\frac{3\delta Q'(u)}{2Q(u)}u_x^2+s(u)u_x^3+Q(u)u_t, \tag{2.1}$$

$$\omega(v)=\delta v, \tag{2.2}$$

$$\Theta(v,u,u_x,u_{xx})=\widetilde{\Theta}(v,u)+\frac{\delta}{Q(u)}u_x+\frac{Q'(u)}{2Q(u)^2}u_x^2+\frac{1}{Q(u)}u_{xx} \tag{2.3}$$

for some smooth functions q *and* Q *such that* $Q\neq 0$, *where* $\delta=0$ *or* 1,

$$p(u)=Q(u)\left(\delta\theta_0-\theta_1u+\delta\int\frac{\delta-q(u)}{Q(u)}\mathrm{d}u\right), \tag{2.4}$$

$$s(u)=\frac{Q'(u)^2}{Q(u)^2}-\frac{Q''(u)}{2Q(u)}, \tag{2.5}$$

$$\widetilde{\Theta}(v,u)=\theta_0+\theta_1v+\int\frac{\delta-q(u)}{Q(u)}\mathrm{d}u \tag{2.6}$$

for some constants θ_0 *and* θ_1; *when* ω *is nonlinear*,

$$\mathcal{F}(u,u_x,u_t)=-6uu_x+u_t, \tag{2.7}$$

$$\omega(v)=v^2, \tag{2.8}$$

$$\Theta(v,u,u_x,u_{xx})=2v^2u+2u^2+2vu_x+u_{xx}, \tag{2.9}$$

or

$$\mathcal{F}(u,u_x,u_t)=-\tfrac{3}{2}u^2u_x+u_t, \tag{2.10}$$

$$\omega(v) = \sin v, \tag{2.11}$$

$$\Theta(v,u,u_x,u_{xx}) = \sin v + u + \tfrac{1}{2}u^2\sin v + \tfrac{1}{2}u^3 + u_x\cos v + u_{xx}, \tag{2.12}$$

or

$$\mathcal{F}(u,u_x,u_t) = \tfrac{3}{2}u^2u_x + u_t, \tag{2.13}$$

$$\omega(v) = \sinh v, \tag{2.14}$$

$$\Theta(v,u,u_x,u_{xx}) = \sinh v + u - \tfrac{1}{2}u^2\sinh v - \tfrac{1}{2}u^3 + u_x\cosh v + u_{xx}. \tag{2.15}$$

Proof: If (1.10) is an integrable system associated with (1.8), then by Lemma 2.11 of Ref. 14,

$$\Theta(v,u,u_x,u_{xx}) = \check{\Theta}(v,u,u_x) + \hat{\Theta}(v,u)u_{xx}, \tag{2.16}$$

$$\mathcal{F}(u,u_x,u_t) = P(u,u_x) + Q(u)u_t \tag{2.17}$$

for some smooth functions $\check{\Theta}$, $\hat{\Theta}$, P, and Q satisfying $\hat{\Theta}(v,u)Q(u)\equiv 1$. Hence, $\hat{\Theta}$ does not depend on v, $Q\neq 0$, and $\hat{\Theta}=1/Q$. Applying Lemma 2.11 of Ref. 14 again, (1.10) is an integrable system associated with (1.8) if and only if

$$\mathcal{F}(u,u_x,u_t) = p(u) + q(u)u_x + r(u)u_x^2 + s(u)u_x^3 + Q(u)u_t, \tag{2.18}$$

$$\Theta(v,u,u_x,u_{xx}) = \widetilde{\Theta}(v,u) + \frac{\omega'(v)}{Q(u)}u_x + \frac{Q'(u)}{2Q(u)^2}u_x^2 + \frac{1}{Q(u)}u_{xx} \tag{2.19}$$

for some smooth functions p, q, r, s, and $\widetilde{\Theta}$ satisfying

$$-Q''(u)Q(u) + 2Q'(u)^2 = 2s(u)Q(u)^2, \tag{2.20}$$

$$3\omega'(v)Q'(u) = 2r(u)Q(u), \tag{2.21}$$

$$\omega'^2(v) = (\omega(v)+u)\omega''(v) + Q(u)\frac{\partial\widetilde{\Theta}(v,u)}{\partial u} + q(u), \tag{2.22}$$

$$\omega'(v)\widetilde{\Theta}(v,u) = (\omega(v)+u)\frac{\partial\widetilde{\Theta}(v,u)}{\partial v} + p(u)/Q(u). \tag{2.23}$$

From (2.21) we see that either ω is linear, or Q is (nonzero and) constant.

Case 1: *ω is linear*. Then, $\omega(v)=\omega_0+\omega_1 v$ for some constants ω_0 and ω_1. Replacing u by $u-\omega_0$ if necessary, we can assume that $\omega_0=0$. When $\omega_1\neq 0$, after replacing x by x/ω_1 and u by $\omega_1 u$, we have that $\omega_1=1$. So, up to a shift in the u direction and a rescaling of the x and u directions, we can always assume that $\omega(v)=\delta v$, where $\delta=0$ or 1. Then, from (2.20)–(2.22) we deduce (2.5) and that $r=3\delta Q'/(2Q)$,

$$\widetilde{\Theta}(v,u) = \theta(v) + \int\frac{\delta - q(u)}{Q(u)}\mathrm{d}u \tag{2.24}$$

for some smooth function θ. Differentiating (2.23) with respect to v yields that $(\omega+u)\theta''=0$, and hence $\theta(v)=\theta_0+\theta_1 v$ for some constants θ_0 and θ_1. Then, (2.23) and (2.24) imply (2.4) and (2.6), respectively.

Case 2: Q is constant. Replacing t by Qt, we can assume that $Q=1$. Then $\widehat{\Theta}=1$. Now, (2.20) and (2.21) are equivalent to $s=0$ and $r=0$, respectively. So, (2.18), (2.19), (2.22), and (2.23) can be rewritten as

$$\mathcal{F}(u,u_x,u_t)=p(u)+q(u)u_x+u_t, \tag{2.25}$$

$$\Theta(v,u,u_x,u_{xx})=\widetilde{\Theta}(v,u)+\omega'(v)u_x+u_{xx}, \tag{2.26}$$

$$\frac{\partial\widetilde{\Theta}(v,u)}{\partial u}=\omega'(v)^2-\omega(v)\omega''(v)-\omega''(v)u-q(u), \tag{2.27}$$

$$p(u)=\omega'(v)\widetilde{\Theta}(v,u)-(\omega(v)+u)\frac{\partial\widetilde{\Theta}(v,u)}{\partial v}, \tag{2.28}$$

respectively. From (2.27) we have that

$$\widetilde{\Theta}(v,u)=\theta(v)+(\omega'(v)^2-\omega(v)\omega''(v))u-\tfrac{1}{2}\omega''(v)u^2-\int q(u)\mathrm{d}u \tag{2.29}$$

for some smooth function θ. In particular, $\partial\widetilde{\Theta}(v,u)/\partial v$ is polynomial in u of degree $\leqslant 2$. Taking the v derivative of (2.28) yields that

$$(\omega(v)+u)\frac{\partial^2\widetilde{\Theta}(v,u)}{\partial v^2}=\omega''(v)\widetilde{\Theta}(v,u). \tag{2.30}$$

Since ω is not linear, from (2.30) and (2.29) one then deduces that q is a polynomial of degree $\leqslant 2$, i.e., $q(u)=q_0+q_1u+q_2u^2$ for some constants q_0, q_1, and q_2. When $q_2\neq 0$, using a shift in the u direction, we can always have that $q_1=0$. By applying the coordinate change $\tilde{x}=x-q_0t$ and $\tilde{t}=t$ if necessary, we can assume that $q_0=0$. Thus,

$$q(u)=q_1u+q_2u^2, \tag{2.31}$$

and hence (2.27) is equivalent to that

$$\widetilde{\Theta}(v,u)=\theta(v)+(\omega'(v)^2-\omega(v)\omega''(v))u-\tfrac{1}{2}(\omega''(v)+q_1)u^2-\frac{q_2}{3}u^3 \tag{2.32}$$

for some smooth function θ. By (2.28), p is a polynomial of degree $\leqslant 3$, i.e., $p(u)=p_0+p_1u+p_2u^2+p_3u^3$ for some constants p_0, p_1, p_2, and p_3. So, (2.28) can be rewritten as

$$p_3=-\frac{q_2}{3}\omega'(v)+\frac{1}{2}\omega'''(v), \tag{2.33}$$

$$p_2=-\frac{q_1}{2}\omega'(v)-\frac{3}{2}\omega'(v)\omega''(v)+\frac{3}{2}\omega(v)\omega'''(v), \tag{2.34}$$

$$p_1=\omega'(v)^3-2\omega(v)\omega'(v)\omega''(v)+\omega(v)^2\omega'''(v)-\theta'(v), \tag{2.35}$$

$$p_0=\omega'(v)\theta(v)-\omega(v)\theta'(v). \tag{2.36}$$

By taking the v derivative of (2.33) we obtain that

$$\omega''''(v) = \frac{2q_2}{3}\omega''(v). \tag{2.37}$$

If $q_2<0$ (and hence one can assume that $q_1=0$), by a rescaling in the u direction, one has that $q_2=-3/2$. So, $q(u)=-3u^2/2$. Thus, (2.37) implies that up to a shift in the v direction, $\omega''(v)=-c\sin v$ for some constant $c\neq 0$, and hence $\omega(v)=a+bv+c\sin v$ for some constants a and b. After replacing x by x/c, t by t/c^3 and u by cu, the PDE on u stays invariant, while in the new system on ϕ, $\omega(v)=a/c+bv/c+\sin v$. So, we can assume that $c=1$. Then, (2.33)–(2.36) together are equivalent to $a=b=0$ and $p=\theta=0$. Therefore, in this subcase, up to linear coordinate changes of the xt, u, and v spaces, (2.25)–(2.28) can be rewritten as (2.7)–(2.9).

If $q_2=0$, then (2.33) implies that $\omega(v)=a+bv+cv^2+p_3v^3/3$ for some constants a, b, and c. By comparing the v^3 coefficients in (2.34) one gets that $p_3=0$. Hence, $c\neq 0$. By rescaling the x and u variables, we can assume that $c=1$; then after a shift in the v direction, one can reach the situation where $b=0$; and finally a shift in the u direction can make $\omega(v)=v^2$. Then, (2.33)–(2.36) together are equivalent to $q_1=-6$, i.e., $q(u)=-6u$, and $p=\theta=0$. Therefore, in this subcase, up to linear coordinate changes of the xt, u, and v spaces, (2.25)–(2.28) can be rewritten as (2.10)–(2.12).

If $q_2>0$, one can show similarly that up to linear coordinate changes of the xt, u, and v spaces, (2.25)–(2.28) can be rewritten as (2.13)–(2.15). This finishes the proof. ■

The case of a linear ω in Theorem 2.1 includes the following class of examples.

Example 2.2: Let $\delta=0$ or 1, and $n\in\mathbb{N}$. For any real constants θ_0, θ_1, $q_1,\ldots,q_n$ satisfying $q_n\neq 0$, the nonlinear PDE

$$u_{xxx} = \delta\theta_0 + (\delta-\theta_1)u - \frac{\delta q_1}{2}u^2 - \cdots - \frac{\delta q_n}{n+1}u^{n+1} + (q_1u+\cdots+q_nu^n)u_x + u_t \tag{2.38}$$

has the associated integrable system

$$\begin{aligned} v_x &= \delta v + u,\\ v_t &= \theta_0 + \theta_1 v + \delta u - \frac{q_1}{2}u^2 - \cdots - \frac{q_n}{n+1}u^{n+1} + \delta u_x + u_{xx}. \end{aligned} \tag{2.39}$$

The following principle gives a general way for obtaining Miura transformations among PDEs from associated integrable systems of forms similar to that of (1.10).

Principle 2.3: *If*

$$\begin{aligned} v_x &= \omega(v) + u,\\ v_t &= \Theta(v,u,u_x,u_t,\ldots,\partial_x^k u,\ldots,\partial_t^k u) \end{aligned} \tag{2.40}$$

is an integrable system associated with a partial differential equation

$$\mathcal{F}(u,u_x,u_t,\ldots,\partial_x^l u,\ldots,\partial_t^l u) = 0, \tag{2.41}$$

then $u\mapsto v$ *is a Miura transformation from* (2.41) *to the partial differential equation*

$$v_t = \Theta(v,v_x-\omega(v),\ldots,\partial_x^l(v_x-\omega(v)),\ldots,\partial_t^l(v_x-\omega(v))) \tag{2.42}$$

defined using (2.40).

In this case, the Miura transformations $u\mapsto v$ *and* $v\mapsto u=v_x-\omega(v)$ *together give a local equivalence between* (2.41) and (2.42).

Applying Principle 2.3 to the case in Theorem 2.1 with a linear ω immediately yields the following classification.

Theorem 2.4: *Assume that* ω *in* (1.10) *is linear. Then,* $u\mapsto v$ *is a Miura transformation from a partial differential equation* (1.8) *to a nonlinear partial differential equation* (1.9) *defined using an integral system* (1.10) *associated with* (1.8) *if and only if up to linear coordinate changes of the*

xt, *u*, *and v spaces*, (1.8)–(1.10) *can be written as*

$$u_{xxx} = p(u) + q(u)u_x + \frac{3\delta Q'(u)}{2Q(u)}u_x^2 + s(u)u_x^3 + Q(u)u_t, \tag{2.43}$$

$$v_t = \widetilde{\Theta}(v, v_x - \delta v) + \frac{\delta}{Q(v_x - \delta v)}(v_{xx} - \delta v_x) + \frac{Q'(v_x - \delta v)}{2Q(v_x - \delta v)^2}(v_{xx} - \delta v_x)^2 + \frac{1}{Q(v_x - \delta v)}(v_{xxx} - \delta v_{xx}) \tag{2.44}$$

and

$$\begin{aligned} v_x &= \delta v + u, \\ v_t &= \widetilde{\Theta}(v, u) + \frac{\delta}{Q(u)}u_x + \frac{Q'(u)}{2Q(u)^2}u_x^2 + \frac{1}{Q(u)}u_{xx} \end{aligned} \tag{2.45}$$

for some smooth functions q and Q such that $Q \neq 0$ *and one of them is nonconstant*, *where* $\delta = 0$ *or* 1, *and p*, *s*, *and* $\widetilde{\Theta}$ *are given by* (2.4)–(2.6).

Example 2.5: When (2.43) is (2.38), (2.44) becomes

$$v_t = \theta_0 + (\theta_1 - \delta)v - \frac{q_1}{2}(v_x - \delta v)^2 - \cdots - \frac{q_n}{n+1}(v_x - \delta v)^{n+1} + v_{xxx}, \tag{2.46}$$

which also does not involve the second-order *x* derivative.

From Principle 2.3 and the case of Theorem 2.1 with a nonlinear ω, we immediately obtain the following classification.

Theorem 2.6: *Assume that* ω *in* (1.10) *is nonlinear. Then*, $u \mapsto v$ *is a Miura transformation from a partial differential equation* (1.8) *to a nonlinear partial differential equation* (1.9) *defined using an integrable system* (1.10) *associated with* (1.8) *if and only if up to linear coordinate changes of the xt*, *u*, *and v spaces*, *either* (1.8)–(1.10) *are the KdV equation* (1.2), *the negative MKdV equation* (1.1), *and the integrable system* (1.3), *respectively*, *or they form one of the following two cases*:

Case 1.

$$u_t = \tfrac{3}{2}u^2u_x + u_{xxx}, \tag{2.47}$$

$$v_t = \tfrac{3}{2}v_x\sin^2 v + \tfrac{1}{2}v_x^3 + v_{xxx}, \tag{2.48}$$

and

$$\begin{aligned} v_x &= \sin v + u, \\ v_t &= \sin v + u + \tfrac{1}{2}u^2 \sin v + \tfrac{1}{2}u^3 + u_x \cos v + u_{xx}. \end{aligned} \tag{2.49}$$

Case 2.

$$u_t = -\tfrac{3}{2}u^2u_x + u_{xxx}, \tag{2.50}$$

$$v_t = -\tfrac{3}{2}v_x \sinh^2 v - \tfrac{1}{2}v_x^3 + v_{xxx}, \tag{2.51}$$

and

$$v_x = \sinh v + u, \tag{2.52}$$

$$v_t = \sinh v + u - \tfrac{1}{2}u^2 \sinh v - \tfrac{1}{2}u^3 + u_x \cosh v + u_{xx}.$$

Remark 2.7: Note that (2.48) is a real form of

$$u_t + u_{xxx} - \tfrac{1}{8}u_x^3 + u_x(ae^u + be^{-u}) + c = 0, \tag{2.53}$$

which was found by Fokas in Ref. 3, and by Calogero and Degasperis in Ref. 1. In Ref. 14, a BT for (2.48) was found.

III. EXACT SOLUTIONS

If $u \mapsto v$ is a MT from a PDE (1.8) to a nonlinear PDE (1.9) defined using an integrable system (1.10), then from a solution u of (1.8), by solving the integrable system (1.10), one gets a one-parameter family of solutions v of (1.9). In the following, we give eight examples, the first two of which correspond to the case of a linear ω, and the others the case of a nonlinear ω.

In general, it is not easy (if possible) to get explicit formulas for the solutions v of (1.10) when a solution u of (1.8) is given, even though u can be explicit and simple. In such a situation, using an ordinary differential equation (ODE) solver, one can usually obtain numerical approximations of these solutions of (1.10), and hence of exact solutions of (1.9). Sometimes, even u can be given via an ODE. We will use this method whenever needed.

Example 3.1: In Example 2.2, let $\delta=1$ and $n=1$. Using a linear coordinate change of the u axis and one of the xt plane we can bring (2.38) into the form

$$u_{xxx} = \theta_0 - u^2 + 2uu_x + u_t. \tag{3.1}$$

Then, the associated integrable system (2.39) becomes

$$\begin{aligned} v_x &= v + u, \\ v_t &= \theta_0 + v + u - u^2 + u_x + u_{xx}, \end{aligned} \tag{3.2}$$

while the corresponding PDE (2.46) on v takes the form

$$v_t = \theta_0 - (v_x - v)^2 + v_{xxx}. \tag{3.3}$$

The x-independent solution of (3.1) are

$$u(x,t) = c_1 \tan(c_1 t + \alpha) \tag{3.4}$$

if $\theta_0 < 0$,

$$u(x,t) = -\frac{1}{t+\alpha}, \quad u = 0 \tag{3.5}$$

if $\theta_0 = 0$, and

$$u(x,t) = -c_2 \tanh(c_2 t + \alpha), \quad u(x,t) = -c_2 \coth(c_2 t + \alpha), \quad u = \pm c_2 \tag{3.6}$$

if $\theta_0 > 0$, where $c_1 = \sqrt{-\theta_0}$, $c_2 = \sqrt{\theta_0}$, and α is an arbitrary real constant. Note that the tanh solutions are x-steady solutions *antikink* in the t variable, starting from (the constant solution) c_2 at $t=-\infty$ and strictly decreasing to (the constant solution) $-c_2$ at $t=+\infty$. Moreover, the tanh solutions have exactly one inflection point.

For such a u, the solutions of (3.2), i.e., the corresponding solutions of (3.3), are

$$v(x,t) = ce^{x+t} - u(x,t), \tag{3.7}$$

where c is also an arbitrary real constant. We mention that when u is one of the tanh-solutions above, the corresponding v with $c=0$ is an x-steady solution *kink* in the t variable. Figure 1 shows the u with $\theta_0=1$ and $\alpha=0$ together with the corresponding v with $c=0$.

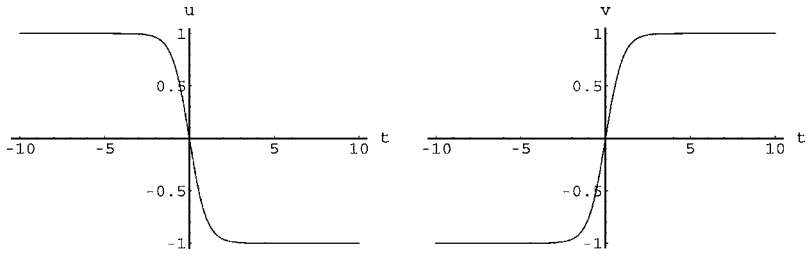

FIG. 1. Solutions antikink and kink in the t variable.

The following example generalizes the main parts of Example 3.1 to the case with an $n \geqslant 2$.

Example 3.2: Let $\delta=1$ and $n \in \mathbb{N}$ such that $n \geqslant 2$. Then, (2.38), (2.39), and (2.46) become

$$u_{xxx} = \theta_0 + (1-\theta_1)u - \frac{q_1}{2}u^2 - \cdots - \frac{q_n}{n+1}u^{n+1} + (q_1 u + \cdots + q_n u^n)u_x + u_t, \tag{3.8}$$

$$\begin{aligned} v_x &= v + u, \\ v_t &= \theta_0 + \theta_1 v + u - \frac{q_1}{2}u^2 - \cdots - \frac{q_n}{n+1}u^{n+1} + u_x + u_{xx}, \end{aligned} \tag{3.9}$$

$$v_t = \theta_0 + (\theta_1 - 1)v - \frac{q_1}{2}(v_x - v)^2 - \cdots - \frac{q_n}{n+1}(v_x - v)^{n+1} + v_{xxx}, \tag{3.10}$$

respectively. The x-steady solutions $u(x,t)=f(t)$ of (3.8) are given by the ODE

$$f'(t) = \frac{q_n}{n+1}f(t)^{n+1} + \cdots + \frac{q_1}{2}f(t)^2 + (\theta_1 - 1)f(t) - \theta_0. \tag{3.11}$$

For each such u, the solutions of (3.9), i.e., the corresponding solutions of (3.10), are

$$v(x,t) = c\mathrm{e}^{x+\theta_1 t} - f(t), \tag{3.12}$$

where c is an arbitrary real constant.

Assume that the polynomial on the right-hand side of (3.11) has $k \geqslant 2$ distinct real roots. Then, (3.8) has $k-1$ one-parameter families of x-steady solutions between these roots and kink or antikink in the t variable. For each such u, the corresponding v with $c=0$ is also an x-steady solution kink or antikink in the t variable; and when $\theta_1=0$, the corresponding v's with $c<0$ are solutions kink or antikink in the t variable and moving down in the x direction, and those v's with $c>0$ are solutions kink or antikink in the t variable and moving up in the x direction.

As a particular example, if we let $n=3$, $\theta_0=(1.42^2-1)^2-1$, $\theta_1=1$, $q_1=-4$, $q_2=0$ and $q_3=4$, then (3.8)–(3.10) take the form

$$u_{xxx} = \theta_0 + 2u^2 - u^4 + (-4u + 4u^3)u_x + u_t, \tag{3.13}$$

$$\begin{aligned} v_x &= v + u, \\ v_t &= \theta_0 + v + u + 2u^2 - u^4 + u_x + u_{xx}, \end{aligned} \tag{3.14}$$

$$v_t = \theta_0 + 2(v_x - v)^2 - (v_x - v)^4 + v_{xxx}, \tag{3.15}$$

respectively. In this case, the real constant solutions of (3.13) are $u=\pm 1.42$, the x-steady solution

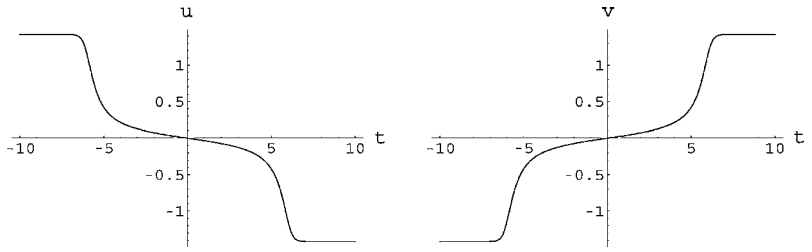

FIG. 2. A 2-antikink and a 2-kink.

u satisfying $u(0,0)=0$ is a *2-antikink*, i.e., an antikink having exactly $2(2)-1=3$ infection points, and the corresponding v with $c=0$ is a *2-kink*. Figure 2 indicates them.

Multikink and *multi-antikink* solutions with more than two "steps" can be obtained similarly. We omit the details.

Next, we discuss the solution of the nonlinear PDE (2.48) obtained from known solutions of the MKdV equation (2.47) and in terms of the MT from (2.47) to (2.48) defined using (2.49). We divide our discussion into several parts according to the complexity of the known solutions of the MKdV equation used. Note that v *is a solution of* (2.49) *if and only if* $v+2\pi$ *is*.

Example 3.3: The MKdV equation (2.47) has the trivial solution $u=0$. Substituting this solution into (2.49) gives that

$$\begin{aligned} v_x &= \sin v, \\ v_t &= \sin v. \end{aligned} \tag{3.16}$$

Solving this system yields the solutions $v=n\pi$ and

$$v(x,t) = 2n\pi + 2\arctan(\alpha e^{x+t}) = (2n+1)\pi \pm \arccos\tanh(x+t+\beta) \tag{3.17}$$

of (2.48), where $n \in \mathbb{Z}$, α is a nonzero real constant, and β is an arbitrary real constant. The above-mentioned nonconstant solutions are kink or antikink solutions, whose profiles are illustrated in Fig. 3.

Example 3.4: Let $c \in (-1,1)$ be nonzero. Substituting the constant solution $u=c$ of (2.47) into (2.49) gives that

$$\begin{aligned} v_x &= \sin v + c, \\ v_t &= (1 + c^2/2)(\sin v + c). \end{aligned} \tag{3.18}$$

Solving this system yields the solutions

$$v = 2n\pi + \arcsin(-c), \quad v = (2n+1)\pi - \arcsin(-c), \tag{3.19}$$

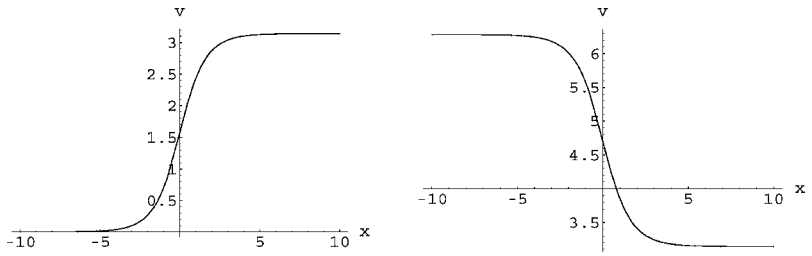

FIG. 3. Profiles of kink and antikink solutions of $v_t=\frac{3}{2}v_x\sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

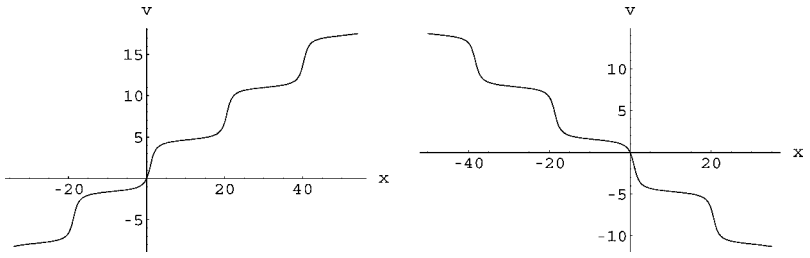

FIG. 4. Profiles of up- and down-stair solutions of $v_t=\frac{3}{2}v_x\sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

$$v(x,t)=2n\pi+2\arctan\frac{c_1+c_2\alpha\exp\left((\operatorname{sgn}c)\sqrt{1-c^2}(x+c_3t)\right)}{1+\alpha\exp((\operatorname{sgn}c)\sqrt{1-c^2}(x+c_3t))} \tag{3.20}$$

of 2.48, where $n\in\mathbb{Z}$, α is a nonzero real constant, and

$$c_1=-1/c+\sqrt{1/c^2-1},\quad c_2=-1/c-\sqrt{1/c^2-1},\quad c_3=1+c^2/2. \tag{3.21}$$

The above-noted nonconstant solutions are also kink or antikink solutions.

Example 3.5: Substituting the constant solution $u=\pm1$ of (2.47) into (2.49) gives the system (3.18) with $c=\pm1$. Solving this system yields the solutions

$$v=(2n\mp1/2)\pi,\quad v(x,t)=(2n\mp1/2)\pi-2\operatorname{arccot}(\alpha\pm x\pm3t/2) \tag{3.22}$$

of (2.48), where $n\in\mathbb{Z}$, and α is a real constant. The above-noted nonconstant solutions are also kink or antikink solutions.

Therefore, from constant solutions of the MKdV equation (2.47), one gets three classes of kink and antikink solutions of (2.48).

Example 3.6: From the constant solution $u=c$ of the MKdV equation (2.47) satisfying $|c|>1$, we get the solution

$$v(x,t)=2n\pi+2\arctan\left(\frac{\sqrt{c^2-1}}{c}\tan\left(\frac{\sqrt{c^2-1}}{2}\left[x+\left(1+\frac{c^2}{2}\right)t+\alpha\right]\right)-\frac{1}{c}\right) \tag{3.23}$$

of (2.48), where $n\in\mathbb{Z}$, and α is a real constant. Note that v is smooth on $\mathbb{R}^2$, and the formula (3.23) should be understood as its continuous extension to $\mathbb{R}^2$. When $c>1$ (respectively, $c<-1$), the profiles of these solutions look like stairs going up (respectively, down) in the x increasing direction, and hence we call these solutions *up-stair solutions* (respectively, *down-stair solutions*), see Fig. 4 for illustrations with $c=\pm1.05$.

Example 3.7: The MKdV equation (2.47) has one-soliton solutions

$$u(x,t)=\pm2k\operatorname{sech}(kx+k^3t+\alpha), \tag{3.24}$$

where k and α are arbitrary real constants satisfying $k>0$. Figure 5 shows a profile of the positive one-soliton solution with $k=1$ and $\alpha=0$.

From this one-soliton solution, we obtain two types of solutions of (2.49), i.e., solutions of (2.48): the majority of these solutions are kink-like solutions carrying a one-soliton and hence are called *one-soliton-kink* solutions, and the remaining ones are countably many kink solutions between the one-soliton-kink solutions and given by

$$v(x,t)=2n\pi-\arccos\tanh(x+t), \tag{3.25}$$

where $n\in\mathbb{Z}$. Figure 6 illustrates these solutions at $t=0$, while Fig. 7 consists of the wave forms of the one-soliton-kink solution v with $v(0,0)=\pi/2$ at $t=-4$, -2, -1 (first row) and at $t=0$, 1, 3 (second row).

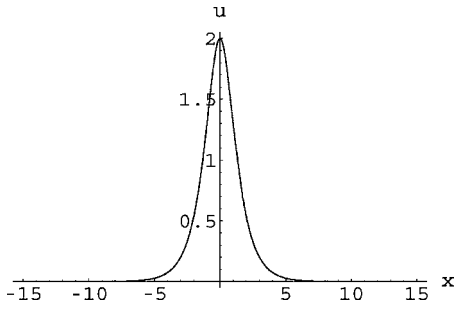

FIG. 5. Profile of a one-soliton solution of $u_t=\frac{3}{2}u^2u_x+u_{xxx}$.

The solutions v satisfying $v(0,0)=(2n+1)\pi$ with $n\in\mathbb{Z}$ are x-attractors, i.e., all nearby solutions approach these solutions as $x\to\pm\infty$; while the kink solutions are unstable in the x direction. Note that when t is sufficiently negative, the effect of the one-soliton u is a solitary valley in v; and when t is sufficiently large, the effect is a solitary peak. Moreover, if a negative soliton solution is used, then the solutions v so obtained are *one-soliton-antikink* solutions and antikink solutions.

Example 3.8: The MKdV equation (2.47) has two-soliton solutions

$$u(x,t)=\frac{2(k_1^2-k_2^2)(k_1\cosh g(x,t)+k_2\cosh f(x,t))}{(k_1^2+k_2^2)\cosh f(x,t)\cosh g(x,t)-2k_1k_2(\sinh f(x,t)\sinh g(x,t)-1)}, \tag{3.26}$$

where

$$f(x,t)=k_1x+k_1^3t+\alpha,\quad g(x,t)=k_2x+k_2^3t+\beta, \tag{3.27}$$

and k_1, k_2, α, and β are arbitrary real constants such that $k_1\neq 0\neq k_2$ and $|k_1|\neq|k_2|$ (either $k_1=0$ or $k_2=0$ for one-soliton solutions). Figure 8 shows the profiles of the two-soliton solution with $k_1=2$, $k_2=1$, $\alpha=-10$, and $\beta=0$ at $t=-2$, 0, 1 (first row) and at $t=2$, 3, 5 (second row).

From this two-soliton solution, we obtain two types of solutions of (2.49), i.e., solutions of (2.48): the majority of these solutions are two-kink-like solutions carrying a one-soliton and hence are called *one-soliton-two-kink* solutions, and the remaining ones are countably many two-kink solutions between the one-soliton-two-kink solutions (no formula for them). Figure 9 illustrates these solutions at $t=0$; while Fig. 10 consists of the wave forms of the one-soliton-two-kink solution v with $v(0,0)=\pi/2$ at $t=-3$, -1, 0 (first row), at $t=1$, 2, 3 (second row), and at $t=4$, 5, 7 (third row).

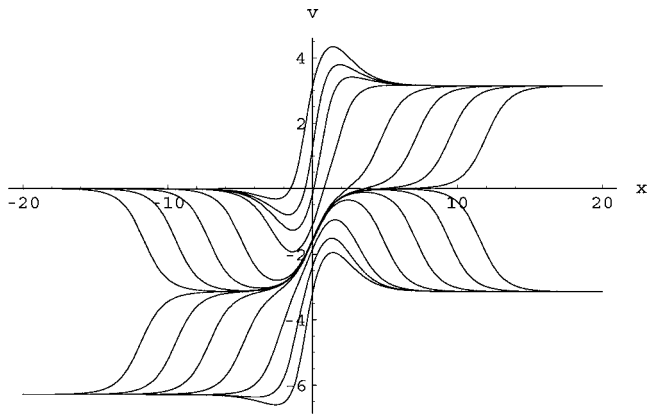

FIG. 6. Profiles of one-soliton-kink and kink solutions of $v_t=\frac{3}{2}v_x\sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

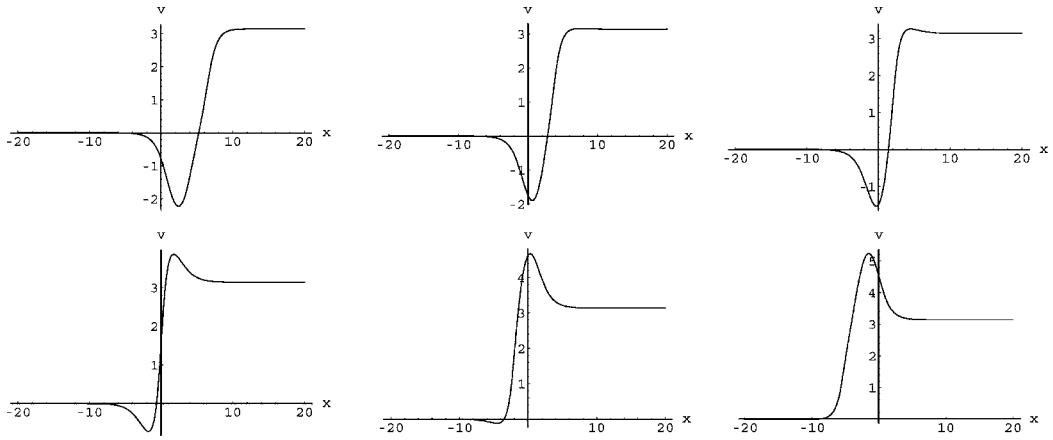

FIG. 7. Profiles of a one-soliton-kink solution of $v_t=\frac{3}{2}v_x \sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

When $k_1=k_2$ and $\alpha=\beta$, the countably many two-kink solutions look almost like kink solutions. Figure 11 shows such a solution together with nearby one-soliton-two-kink solutions at $t=0$ for the situation of $k_1=k_2=1$ and $\alpha=\beta=0$.

Again, the solutions v satisfying $v(0,0)=(2n+1)\pi$ with $n\in\mathbb{Z}$ are x-attractors; while the two-kink solutions are unstable in the x direction. Note that when t is sufficiently negative, the effects of the wider soliton and the narrower one in u are a solitary valley in v and a step in v, respectively; and when t is sufficiently large, the effects are a solitary peak and a step, respectively. Moreover, if a negative two-soliton solution is used, then the solutions v so obtained are *one-soliton-two-antikink* solutions and two-antikink solutions.

In general, an n-soliton solution u of the MKdV equation (2.47) gives countably many one-parameter families of *one-soliton-n-kink* or *one-soliton-n-antikink* solutions and countably many *n-kink* or *n-antikink* solutions of (2.48).

The exact solutions of (2.51) obtained from known solutions of the negative MKdV equation (2.50) and via the integrable system (2.52) can be discussed similarly. However, all the solutions v so defined seem to blow up, even for the ones deduced from $u=0$. So, we omit the details.

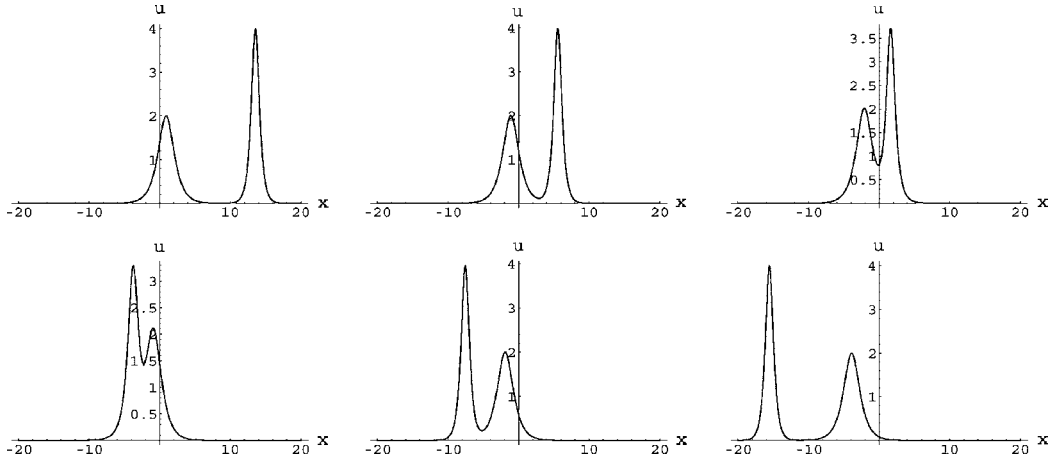

FIG. 8. Profiles of a two-soliton solution of $u_t=\frac{3}{2}u^2u_x+u_{xxx}$.

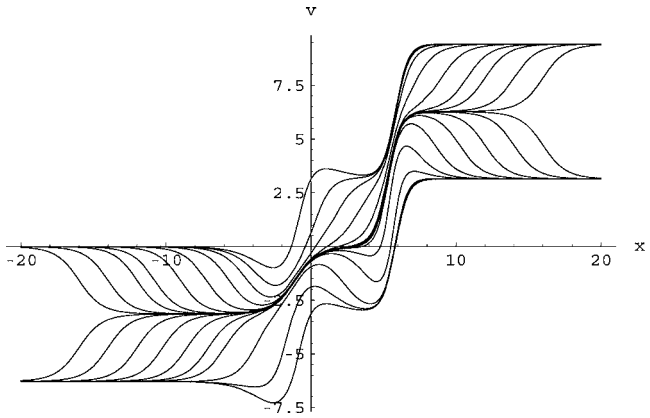

FIG. 9. Profiles of one-soliton-two-kinks and a two-kink of $v_t=\frac{3}{2}v_x\sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

IV. BÄCKLUND TRANSFORMATIONS

In this section, we present a general method for obtaining new BTs from known ones using MTs, and apply the method to deduce BTs for PDEs in Theorems 2.4 and 2.6.

Theorem 4.1: *Assume that there is a local equivalence between a partial differential equation*

$$\mathcal{F}(u,u_x,u_t,\ldots,\partial_x^j u,\ldots,\partial_t^j u)=0 \tag{4.1}$$

and another partial differential equation

$$\mathcal{G}(v,v_x,v_t,\ldots,\partial_x^j v,\ldots,\partial_t^j v)=0 \tag{4.2}$$

given by Miura transformations $u\mapsto v$, defined using an integrable system

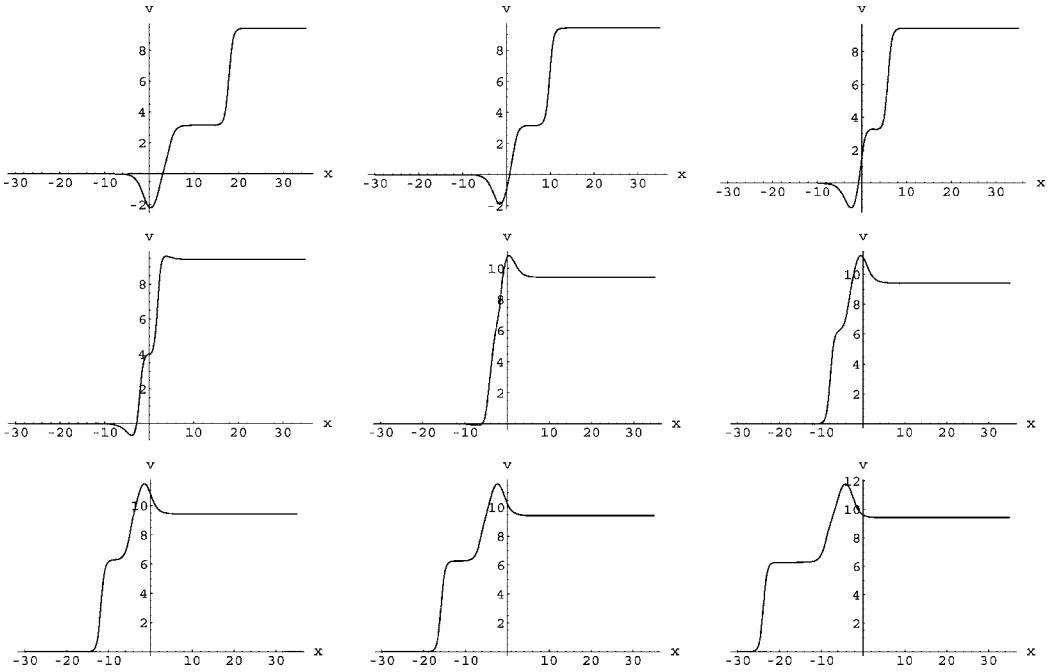

FIG. 10. Profiles of a one-soliton-two-kink solution of $v_t=\frac{3}{2}v_x\sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

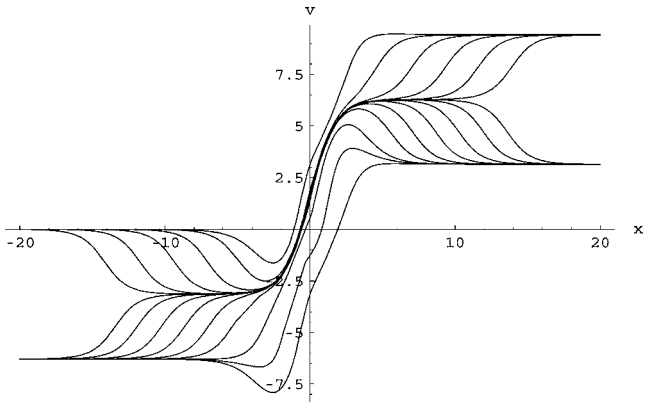

FIG. 11. Profiles of one-soliton-two-kinks and an almost kink of $v_t=\frac{3}{2}v_x\sin^2 v+\frac{1}{2}v_x^3+v_{xxx}$.

$$\begin{aligned} v_x &= \omega(v)+u,\\ v_t &= \Theta(v,u,u_x,u_t,\ldots,\partial_x^k u,\ldots,\partial_t^k u) \end{aligned} \tag{4.3}$$

associated with (4.1), *and* $v\mapsto u=v_x-\omega(v)$.

(i) *If* (4.1) *has a Bäcklund transformation*

$$u\mapsto \tilde{u}=F(\phi_1,\ldots,\phi_n,u,u_x,u_t,\ldots,\partial_x^k u,\ldots,\partial_t^k u) \tag{4.4}$$

defined using its associated integrable system

$$\begin{aligned} \Phi_x &= \Gamma(\phi_1,\ldots,\phi_n,u,u_x,u_t,\ldots,\partial_x^k u,\ldots,\partial_t^k u),\\ \Phi_t &= \Delta(\phi_1,\ldots,\phi_n,u,u_x,u_t,\ldots,\partial_x^k u,\ldots,\partial_t^k u), \end{aligned} \tag{4.5}$$

then (4.2) *also has a Bäcklund transformation*, *i.e.*,

$$v\mapsto u=v_x-\omega(v)\mapsto \tilde{u}=F(\phi_1,\ldots,\partial_t^k(v_x-\omega(v)))\mapsto \tilde{v} \tag{4.6}$$

defined using its associated integrable system

$$\begin{aligned} \Phi_x &= \Gamma(\phi_1,\ldots,\phi_n,v_x-\omega(v),\ldots,\partial_t^k(v_x-\omega(v))),\\ \tilde{v}_x &= w(\tilde{v})+F(\phi_1,\ldots,\partial_t^k(v_x-\omega(v))),\\ \Phi_t &= \Delta(\phi_1,\ldots,\phi_n,v_x-\omega(v),\ldots,\partial_t^k(v_x-\omega(v))),\\ \tilde{v}_t &= \Theta(\tilde{v},\ldots,\partial_t^k F(\phi_1,\ldots,\partial_t^k(v_x-\omega(v)))). \end{aligned} \tag{4.7}$$

(ii) *If* (4.2) *has a Bäcklund transformation*

$$v\mapsto \tilde{v}=F(\phi_1,\ldots,\phi_n,v,v_x,v_t,\ldots,\partial_x^k v,\ldots,\partial_t^k v) \tag{4.8}$$

defined using its associated integrable system

$$\begin{aligned} \Phi_x &= \Gamma(\phi_1,\ldots,\phi_n,v,v_x,v_t,\ldots,\partial_x^k v,\ldots,\partial_t^k v),\\ \Phi_t &= \Delta(\phi_1,\ldots,\phi_n,v,v_x,v_t,\ldots,\partial_x^k v,\ldots,\partial_t^k v), \end{aligned} \tag{4.9}$$

then (4.1) *also has a Bäcklund transformation*, *i.e.*,

$$u \mapsto v \mapsto \tilde{v} = F(\phi_1, \ldots, \partial_t^k v) \mapsto \tilde{u} = \tilde{v}_x - \omega(\tilde{v}) \tag{4.10}$$

defined using its associated integrable system

$$\begin{gathered} v_x = \omega(v) + u, \\ \Phi_x = \Gamma(\phi_1, \ldots, \phi_n, v, v_x, v_t, \ldots, \partial_x^k v, \ldots, \partial_t^k v), \\ v_t = \Theta(v, u, u_x, u_t, \ldots, \partial_x^k u, \ldots, \partial_t^k u), \\ \Phi_t = \Delta(\phi_1, \ldots, \phi_n, v, v_x, v_t, \ldots, \partial_x^k v, \ldots, \partial_t^k v). \end{gathered} \tag{4.11}$$

Note that the new BT is defined using $n+1$ pseudopotentials, i.e., $\phi_1, \ldots, \phi_n$, $\tilde{v}$ in (i) and v, $\phi_1, \ldots, \phi_n$ in (ii). Sometimes, the new BT can be equivalently defined using an associated integrable system of a lower degree (i.e., with less pseudopotentials, see Sec. I in Ref. 14 for the definition of degree).

Combining Theorems 4.1 and (2.4) we immediately get the following fact.

Corollary 4.2: *If one of the nonlinear partial differential equations* (2.43) and (2.44) *has a Bäcklund transformation*, *then the other one also has a Bäcklund transformation*.

A special case of Corollary 4.2 is the following classical example.

Example 4.3: In Ref. 12, Wahlquist and Estabrook found a BT $v \mapsto \tilde{v}$ for the potential KdV equation

$$v_t = 3v_x^2 + v_{xxx} \tag{4.12}$$

defined by

$$\begin{gathered} \tilde{v}_x = \lambda - v_x - \tfrac{1}{2}(v - \tilde{v})^2, \\ \tilde{v}_t = -v_t + (v - \tilde{v})(v_{xx} - \tilde{v}_{xx}) - 2(v_x^2 + v_x \tilde{v}_x + \tilde{v}_x^2), \end{gathered} \tag{4.13}$$

where λ is an arbitrary constant. From this BT, they deduced the now well-known BT $u \mapsto \tilde{u}$ for the KdV equation (1.2) defined by

$$u \mapsto v = \int u \, \mathrm{d}x \mapsto \tilde{v} \mapsto \tilde{u} := \tilde{v}_x. \tag{4.14}$$

So, the BT $u \mapsto \tilde{u} = \tilde{v}_x$ for the KdV equation is defined using the integrable system

$$\begin{gathered} v_x = u, \\ \tilde{v}_x = \lambda - u - \tfrac{1}{2}(v - \tilde{v})^2, \\ v_t = 2v^2 u + 2u^2 + 2v u_x + u_{xx}, \\ \tilde{v}_t = -3u^2 - u_{xx} + (v - \tilde{v})(u_x - \tilde{v}_{xx}) - 2(u^2 + u\tilde{v}_x + \tilde{v}_x^2) \end{gathered} \tag{4.15}$$

associated with the KdV equation.

Note that the transformation $u \mapsto v$ from the KdV equation (1.2) to the potential KdV equation (4.12) defined using $v_x = u$ and $v_t = 3u^2 + u_{xx}$ is an easy example of the MT given by Theorem 2.4 with $\delta = 0$, $Q = 1$ and $\tilde{\Theta}(v, u) = 3u^2$.

In Ref. 11, it is shown that the above BT $u \mapsto \tilde{u}$ for the KdV equation can also be defined as follows. Let ϕ be the solution of the associated integrable system

$$\phi_x = -\lambda + \phi^2 + u,$$
$$\phi_t = 4\lambda(-\lambda + \phi^2) + 2(\lambda + \phi^2)u + 2u^2 + 2\phi u_x + u_{xx}, \tag{4.16}$$

where λ is an arbitrary constant, then

$$u \mapsto \tilde{u} = 2\lambda - 2\phi^2 - u \tag{4.17}$$

is the BT.

Generalizing the above-presented example, we have the following fact.

Corollary 4.4: If one of a partial differential equation

$$u_t = \partial_x f(u, u_x, u_t, \ldots, \partial_x^j u, \ldots, \partial_t^j u) \tag{4.18}$$

and its potential equation

$$v_t = f(v_x, v_{xx}, v_{xt}, \ldots, \partial_x^j v_x, \ldots, \partial_t^j v_x) \tag{4.19}$$

has a Bäcklund transformation, then the other one also has a Bäcklund transformation.

Proof: This is because that there is a MT $u \mapsto v$ from (4.18) to (4.19) defined using the integrable system

$$v_x = u,$$
$$v_t = f(u, u_x, u_t, \ldots, \partial_x^j u, \ldots, \partial_t^j u) \tag{4.20}$$

associated with (4.18). ■

Example 4.5: Using Theorem 4.1 and the local equivalence between the KdV equation and the MKdV equation mentioned at the beginning of this paper, one can get the known BT for the KdV equation from that for the MKdV equation, and vis versa. We omit the details.

Example 4.6: In Ref. 4, Lamb obtained the following BT

$$u \mapsto \tilde{u} = \frac{4\lambda\phi}{1 + \phi^2} + u \tag{4.21}$$

for the MKdV equation (2.47), where λ is an arbitrary nonzero constant, and ϕ is the solution of the associated integrable system

$$\phi_x = \lambda\phi + \tfrac{1}{2}(1 + \phi^2)u,$$
$$\phi_t = \lambda^3 + \tfrac{1}{2}\lambda^2(1 + \phi^2)u + \tfrac{1}{2}\lambda\phi u^2 + \tfrac{1}{4}(1 + \phi^2)u^3 + \tfrac{1}{2}\lambda(1 - \phi^2)u_x + \tfrac{1}{2}(1 + \phi^2)u_{xx}. \tag{4.22}$$

Using this BT together with the MTs $u \mapsto v$ from (2.47) to (2.48), defined using (2.49), and $v \mapsto u = v_x - \sin v$ from (2.48) to (2.47), we deduce a BT $v \mapsto \tilde{v}$ for the nonlinear PDE (2.48):

$$v \mapsto u = v_x - \sin v \mapsto \tilde{u} = \frac{4\lambda\phi}{1 + \phi^2} + (v_x - \sin v) \mapsto \tilde{v} \tag{4.23}$$

defined using the integrable system

$$\phi_x = \lambda\phi + \tfrac{1}{2}(1 + \phi^2)u,$$
$$\tilde{v}_x = \sin\tilde{v} + \tilde{u},$$
$$\phi_t = \lambda^3 + \tfrac{1}{2}\lambda^2(1 + \phi^2)u + \tfrac{1}{2}\lambda\phi u^2 + \tfrac{1}{4}(1 + \phi^2)u^3 + \tfrac{1}{2}\lambda(1 - \phi^2)u_x + \tfrac{1}{2}(1 + \phi^2)u_{xx},$$

$$\tilde{v}_t = \sin\tilde{v} + \tilde{u} + \tfrac{1}{2}\tilde{u}^2 \sin\tilde{v} + \tfrac{1}{2}\tilde{u}^3 + \tilde{u}_x \cos\tilde{v} + \tilde{u}_{xx} \tag{4.24}$$

associated with (2.48). Note that u and $\tilde{u}$ in (4.24) are expressions in ϕ and v and are given by (4.23).

In Ref. 14, a BT for (2.48) using one pseudopotential was found. Now, (4.23) is another BT for (2.48), using two pseudopotentials. Moreover, a new BT for the MKdV equation can be deduced similarly, see Ref. 15.

Example 4.7: In Ref. 14, the BT

$$u \mapsto \tilde{u} = 2\sinh\phi + u \tag{4.25}$$

for the negative MKdV equation (2.50) defined using its associated integrable system

$$\begin{aligned} \phi_x &= \sinh\phi + u, \\ \phi_t &= \sinh\phi + u - \tfrac{1}{2}u^2 \sinh\phi - \tfrac{1}{2}u^3 + u_x \cosh\phi + u_{xx} \end{aligned} \tag{4.26}$$

has been deduced. From this BT for (2.50) and the local equivalence between (2.50) and (2.51) given in Theorem 2.6, we obtain the BT

$$v \mapsto u = v_x - \sinh v \mapsto \tilde{u} = 2\sinh\phi - \sinh v + v_x \mapsto \tilde{v} \tag{4.27}$$

for (2.51) defined using the integrable system

$$\begin{aligned} \phi_x &= \sinh\phi + u, \\ \tilde{v}_x &= \sinh\tilde{v} + \tilde{u}, \\ \phi_t &= \sinh\phi + u - \tfrac{1}{2}u^2 \sinh\phi - \tfrac{1}{2}u^3 + u_x \cosh\phi + u_{xx}, \\ \tilde{v}_t &= \sinh\tilde{v} + \tilde{u} - \tfrac{1}{2}\tilde{u}^2 \sinh\tilde{v} - \tfrac{1}{2}\tilde{u}^3 + \tilde{u}_x \cosh\tilde{v} + \tilde{u}_{xx} \end{aligned} \tag{4.28}$$

associated with (2.51).

We believe that this is the first time that a BT for (2.51) is found. By Theorem 2.43 in Ref. 14 this BT cannot be defined using an associated integrable system of the form

$$\begin{aligned} \phi_x &= \Gamma(\phi, u, u_x, u_{xx}), \\ \phi_t &= \Delta(\phi, u, u_x, u_{xx}). \end{aligned} \tag{4.29}$$

(Received 19 January 2006; accepted 4 July 2006; published online 31 August 2006)

Heat-kernel expansion and zeta function regularization are discussed for Laplace-type operators with discrete spectrum in noncompact domains. Since a general theory is lacking, the heat-kernel expansion is investigated by means of several examples. It is pointed out that for a class of exponential (analytic) interactions, generically the noncompactness of the domain gives rise to logarithmic terms in the heat-kernel expansion. Then, a meromorphic continuation of the associated zeta function is investigated. A simple model is considered, for which the analytic continuation of the zeta function is not regular at the origin, displaying a pole of higher order. For a physically meaningful evaluation of the related functional determinant, a generalized zeta function regularization procedure is proposed. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2259580]

I. INTRODUCTION

Within the so-called one-loop approximation in quantum field theory, the Euclidean one-loop effective action can be expressed in terms of the sum of the classical action and a contribution depending on a functional determinant of an elliptic differential operator, the so-called fluctuation operator. The ultraviolet one-loop divergences which are present need to be regularized by means of a suitable technique (for recent reviews, see Refs. 1–5).

In general, one works in Euclidean spacetime and deals with a self-adjoint, non-negative, second-order differential operator of the form

$$L = -\Delta + V, \tag{1.1}$$

where Δ is the Laplace-Beltrami operator and V a potential depending on the classical background solution and containing, in general, a mass term. It is well known that the one-loop effective action $W \equiv W[\Phi]$, is related to the functional determinant of the field operator L by

[a)]Electronic mail: cognola@science.unitn.it
[b)]Electronic mail: elizalde@ieec.uab.es
[c)]Electronic mail: zerbini@science.unitn.it

$$W = -\ln Z = S + \frac{1}{2}\ln\det\frac{L}{\mu^2}, \tag{1.2}$$

S being the classical action and μ^2 a renormalization parameter, which appears for dimensional reasons.

The one-loop divergences may be dealt with by using a variant of the zeta-function regularization method.[6–8] One namely introduces the regularization parameter ε and considers

$$W(\varepsilon) = S - \frac{1}{2}\int_0^\infty \mathrm{d}t\,\frac{t^{\varepsilon-1}}{\Gamma(1+\varepsilon)}\mathrm{Tr}\,e^{-tL/\mu^2} = S - \frac{1}{2\varepsilon}\zeta(\varepsilon|L/\mu^2), \tag{1.3}$$

where, as usual, for the elliptic operator L the zeta function is defined by means of the Mellin-type transform

$$\zeta(s|L) = \frac{1}{\Gamma(s)}\int_0^\infty \mathrm{d}t\,t^{s-1}\mathrm{Tr}\,e^{-tL}, \quad \zeta(s|L/\mu^2) = \mu^{2s}\zeta(s|L). \tag{1.4}$$

Here the heat trace $\mathrm{Tr}\,e^{-tL}$ plays a preeminent role. Recall that, for a second-order elliptic nonnegative operator L in a *compact* d-dimensional manifold without boundary, one has the small-t asymptotic expansion

$$\mathrm{Tr}\,e^{-tL} \simeq \sum_{j=0}^{\infty} A_j(L)t^{j-d/2}, \tag{1.5}$$

where $A_j(L)$ are the Seeley-DeWitt coefficients.[9,10] As a result, for a second-order differential operator in d-dimensions, the integral (1.4) is convergent in the domain $\mathrm{Re}\,s > d/2$.

In the compact case, $\zeta(s|L)$ is regular at the origin and one has the well-known result $\zeta(0|L) = A_{d/2}(L)$. The latter quantity is computable (see, for example, the recent reviews (Refs. 11 and 12) and depends on the potential and on geometric invariants. In particular, for odd dimensional manifolds without boundaries, $\zeta(0|L) = 0$. Performing a Taylor expansion of the zeta function we obtain

$$W(\varepsilon) = S - \frac{1}{2\varepsilon}\zeta(0|L) + \frac{\zeta(0|L)}{2}\ln\mu^2 + \frac{\zeta'(0|L)}{2} + O(\varepsilon). \tag{1.6}$$

Thus, the one-loop divergences as well as finite contributions to the one-loop effective action are expressed in terms of the zeta function and its derivative evaluated at the origin.

In this paper, we would like to discuss a more general situation where *logarithmic terms* in the heat-trace asymptotics are present. First, we recall a well-known but crucial fact concerning the local heat-kernel expansion associated with a Laplace type operator in R^d of the kind

$$H = -\Delta + V(x). \tag{1.7}$$

If the potential is real and non-negative, with an additional, rather mild hypothesis, the operator H is essentially self-adjoint in $C_0^\infty(R^d)$. We will be interested in confining potentials which, with the additional hypothesis of being also smooth functions, give rise to a discrete spectrum. As has been shown in Refs. 13 and 14, the local heat-kernel expansion can be partially summed over and rewritten under the form

$$K_t(x,x) = \frac{1}{(4\pi t)^{d/2}}e^{-tV(x)}\sum_{n=0}^{\infty} b_n(x)t^n, \tag{1.8}$$

where the new coefficients $b_n(x)$ can easily be computed and depend only on the derivatives of the potential $V(x)$. The first few read

$$b_0(x) = 1, \quad b_1(x) = 0,$$

$$b_2(x) = -\frac{1}{6}\Delta V, \quad b_3(x) = -\frac{\Delta^2 V}{60} + \frac{\nabla_k V \nabla_k V}{12}, \tag{1.9}$$

$$b_4(x) = -\frac{\Delta^3 V}{840} + \frac{(\Delta V)^2}{72} + \frac{\nabla_i \nabla_j V \nabla_i \nabla_j V}{90} + \frac{\nabla_k V \nabla_k \Delta V}{30}. \tag{1.10}$$

We will make use of such a resummation for obtaining the heat-kernel trace asymptotics in Sec. II.

If one is dealing with smooth compact manifolds, the passage to the heat-kernel trace is accomplished by integrating term by term over the coordinates, and no logarithmic contribution in the heat-trace expansion appears. However, in the case of nonsmooth manifolds one may get logarithmic terms in the heat-kernel trace, e.g., when one considers the Laplace operator on higher-dimensional cones,[15,16] but also in four-dimensional spacetimes with a three-dimensional, noncompact, hyperbolic spatial section of finite volume,[17] and in the case of general pseudo-differential operators.[18] More recently, the presence of logarithmic terms in self-interacting scalar field theory defined on manifolds with noncommutative coordinates has also been pointed out.[19–21] This goes together with a nontypical behavior of the corresponding zeta function: possibly a simple pole at the origin and higher-order poles at other places.

Here we would like to investigate the case of Laplace-type self-adjoint operators defined on *noncompact* manifolds. To our knowledge, for the general case of a confining potential and discrete spectrum, a systematic theory has yet to be formulated. A pioneering investigation along this line can be found in Ref. 22. Other studies involve one-dimensional problems on the real half-line[23] and the Barnes zeta functions.[24] With regard to the presence of logarithmic terms in heat-trace asymptotics, one should note that they have been considered in the abstract context of regularized products in many places.

Recall that, under certain conditions, the regularized product associated with an infinite sequence of nonzero complex numbers $\{\lambda_n\}$ has a related Dirichlet series $\Sigma_n \lambda_n^{-s}$ (the zeta-function). In this paper, we are only interested in the case when the λ_n are eigenvalues of *non-negative* differential operators and the zeta function converges absolutely for Re s sufficiently large. When this zeta-function is holomorphic at the origin, the regularized product is defined as $\exp[-\zeta'(0)]$. A general theory is presented in Refs. 27 and 28 and other relevant papers are Refs. 29–31 and references quoted therein. It is worth mentioning that the case of noncompact domains but with scattering potentials, namely the ones for which a continuous spectrum exists, is well understood and the S-matrix or the phase shift function then enter the game (see, for instance, Ref. 32). In this context, delta-like potentials have also been considered (see, e.g., Refs. 33–35, and references therein). If the potential is singular, for instance, proportional to $1/x^2$, the presence of logarithmic terms in the local heat-kernel expansion is also possible, their coefficients becoming distributions[25] (see also the recent paper (Ref. 26) and references therein). Here, we will not deal with situations of this kind. Moreover, for the sake of simplicity, we will limit ourselves to the R^d flat case.

The content of the paper is as follows. In Sec. II, local heat-kernel asymptotics are reviewed for the simple case we are going to deal with. In Sec. III, the heat-trace asymptotics are investigated and the possibility for the presence of logarithmic terms is pointed out explicitly. The consequences of such unusual terms are discussed in Sec. IV in some detail. Finally, in Sec. V, a simple model of confinement is proposed and a generalization of the zeta-function regularization method is constructed to deal with this case. The paper ends with some conclusions and an Appendix.

II. HEAT-KERNEL TRACE ASYMPTOTICS IN NONCOMPACT DOMAINS

In this section we will show that, for suitable classes of potentials in noncompact domains, logarithmic terms can actually be present in the heat-trace expansion. Under the usual hypothesis

concerning the potential $V(x)$—namely $V(x)$ smooth enough, non-negative, and going to infinity for $|x|\to\infty$—the heat trace can be shown to exist and the heat kernel asymptotics is given by

$$\mathrm{Tr}\, e^{-tH} = \int_{R^d} \mathrm{d}x\, K_t(x,x) = \frac{1}{(4\pi t)^{d/2}} \int_{R^d} \mathrm{d}x\, e^{-tV(x)}[1 + t^2 b_2(x) + t^3 b_3(x) + \cdots]. \tag{2.1}$$

In particular we shall focus our attention on the class of spherical potentials, $V(x)=V(r)$, $r \in [0,\infty)$, and thus

$$\mathrm{Tr}\, e^{-tH} = \frac{\Omega_d}{(4\pi t)^{d/2}} \int_0^\infty \mathrm{d}r\, r^{d-1} e^{-tV(r)}[1 + O(t^2)], \tag{2.2}$$

where $\Omega_d = 2\pi^{d/2}/\Gamma(d/2)$. The latter expression will be our starting point for further discussions.

As a first family of potentials, let us consider $V(r)$ to be a positive polynomial of degree Q. In this case, we will show that logarithmic terms are absent, but the leading term goes as $O(t^{-d/2-d/Q})$, in contrast to the leading behavior $O(t^{-d/2})$ associated with the compact case. To prove this, since we are interested in the short-t leading term, it is sufficient to consider the leading term of the potential, namely $V(r)=r^Q+\cdots$. Thus, the leading term in the heat trace reads

$$\mathrm{Tr}\, e^{-tH} \simeq \frac{\Omega_d}{(4\pi t)^{d/2}} \int_0^\infty \mathrm{d}r\, r^{d-1} e^{-tr^Q} = \frac{2^{1-d}\Gamma(d/Q)}{Q\Gamma(d/2)t^{d/2+d/Q}}. \tag{2.3}$$

One can check that this result holds true for the case $Q=2$, for which the heat trace is well known, since it corresponds to the partition function of a harmonic oscillator in d-dimensions. In fact one has eigenvalues $2n+1$ for each dimension and then

$$\mathrm{Tr}\, e^{-tH} = \left(\sum_0^\infty e^{-t(2n+1)}\right)^d = \frac{1}{(2\sinh t)^d} \simeq \frac{1}{(2t)^d} + \cdots, \tag{2.4}$$

in agreement with Eq. (2.3) (note that here $m=1/2$ and $\omega=2$). Our results also agree with those for the one-dimensional case investigated in Ref. 23.

The situation drastically changes if one considers exponential confining potentials which, for large r, go asymptotically as $V(r)\simeq e^{r^Q}$. We will show that in these cases logarithmic terms are present. In fact, we have

$$\mathrm{Tr}\, e^{-tH} \simeq \frac{\Omega_d}{(4\pi)^{d/2}t^{d/2}} \int_0^\infty \mathrm{d}r\, r^{d-1} e^{-te^{r^Q}} = \frac{\Omega_d}{(4\pi)^{d/2}t^{d/2}Q} \int_1^\infty \mathrm{d}y\, y^{-1} e^{-ty} (\ln y)^{d/Q-1}. \tag{2.5}$$

For simplicity, let us now assume d/Q to be an integer. In such case we can use (A4) and (A6), thus obtaining the leading term in the form

$$\mathrm{Tr}\, e^{-tH} \simeq \frac{(-1)^{d/Q}}{2^d Q\Gamma(d/2+1)t^{d/2}} (\ln t)^{d/Q}. \tag{2.6}$$

It has to be noted that with respect to the compact case, for such class of potentials on noncompact manifolds, the leading term in the trace is modified by the presence of the logarithmic factor $(\ln t)^{d/Q}$. We also note that, for $Q=1$, (2.6) yields the same result obtained by Nash in Ref. 22 using a different method. Let us emphasize that those comparisons are essential both for consistency reasons and in view of its application to real situations in physics.

Equations (2.3) and (2.5) give only the leading term in the trace of the heat kernel, but in principle it is possible to go on in the expansion by integrating other terms of the local asymptotics. However it should be stressed that more terms in the local expansion can give contributions of the same order to the trace asymptotics. This can be easily seen by considering, for instance, the one-dimensional harmonic oscillator described by the Hamiltonian

$$H = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + \frac{\omega^2 x^2}{4}, \quad \hbar = 1, \quad m = \frac{1}{2}. \tag{2.7}$$

For this model, one has

$$\mathrm{Tr}\, e^{-tH} = \frac{1}{2\sinh(\omega t/2)} = \frac{1}{\omega t} - \frac{\omega t}{24} + O(t^3), \tag{2.8}$$

$$K_t(x,x) = \sqrt{\frac{\omega}{4\pi \sinh \omega t}} e^{-\omega x^2(\cosh \omega t - 1)/2 \sinh \omega t} = \frac{e^{-tV}}{\sqrt{4\pi t}}(1 + b_2 t^2 + b_3 t^3 + \cdots),$$

$$b_2 = -\frac{\omega^2}{12}, \quad b_3 = \frac{\omega^4 x^2}{48}. \tag{2.9}$$

In order to get the expansion (2.8) up to order t, one needs to integrate the local expansion up to order $t^{5/2}$. This means that both b_2 and b_3 give a contribution of order t in the trace asymptotics. To obtain the subsequent term t^3, one has to consider all b_n coefficients up to b_6.

III. MEROMORPHIC EXTENSION OF THE ZETA-FUNCTION

With respect to the compact case, the meromorphic structure of the zeta-function associated with the operator H is generically quite complicated and it is strictly related to the form of the potential. In order to show this, we first consider the polynomial case $V(r)=r^Q$ and assume $Q=2P$ to be an even number. Under such assumption all b_n coefficients are polynomials in r and the heat-trace asymptotics are of the form

$$\mathrm{Tr}\, e^{-tH} = \sum_n C_n t^{\alpha_n - (d/2 + d/Q)}, \quad C_0 = \frac{\Gamma(d/Q)}{2^{d-1} Q \Gamma(d/2)}, \quad \alpha_0 = 1 < \alpha_1 < \alpha_2 < \cdots, \tag{3.1}$$

where the C_n are numerical coefficients obtained by integrating the local expansion, and the α_n are rational numbers. Making use of (1.4) and splitting the integration over t into $(0,1]$ and $[1,\infty)$, we get

$$\zeta(s|H) = \frac{1}{\Gamma(s)} \sum_n \frac{C_n}{s + \alpha_n - \left(\frac{d}{2} + \frac{d}{Q}\right)} + \frac{J(s)}{\Gamma(s)}, \tag{3.2}$$

where $J(s)$ is an analytic function. It follows that for such class of potentials the zeta function admits only simple poles—as it happens in the compact case—but whose location strictly depends on the form of the potential, since the α_n are not universal powers. Moreover, we see that $\zeta(0|H)$ is not vanishing if and only if $\alpha_n = d/2 + d/Q$ for some n and the corresponding coefficient C_n is different from zero (note that if this coefficient $C_n=0$, then the corresponding term is absent from the sum, for any s).

The situation becomes more complicated for the class of exponential potentials we have considered in Sec. II. In fact, in such case one obtains in general an asymptotic expansion with terms of the kind $t^\alpha (\ln t)^\beta$, α and β being rational numbers which depend on the potential, and this means that the meromorphic extension of the zeta function will have poles or branch points of order β at $s=-\alpha$ (see (A8)).

In order to compute the nonholomorphic structure of the zeta function for this class of potentials it is convenient to proceed as follows. We use the general expression (1.8) in (1.4) and thus, for $\mathrm{Re}\, s$ sufficiently large and $V(x)=V(r)>0$, we can write

$$\zeta(s|H) \sim \frac{1}{(4\pi)^{d/2}\Gamma(s)}\sum_n \int_0^\infty \mathrm{d}t\, t^{s+n-d/2-1}\int_{R^d}\mathrm{d}x\, b_n(x)e^{-tV(x)} = \sum_n \frac{\Gamma(s+n-d/2)}{(4\pi)^{d/2}\Gamma(s)}\int_{R^d}\mathrm{d}x\, b_n(x) \times [V(x)]^{-(s+n-d/2)}, \tag{3.3}$$

which is well defined for even Q, since in such case all coefficients $b_n(x)$ are regular everywhere. Since $V(r)$ is exponential like and spherically symmetric, we may assume that

$$b_n = \sum_{pq} C_{pq}^n r^p V^q, \quad 0 \leqslant p \leqslant 2(n-1)(Q-1), \quad 1 \leqslant q < n, \quad n \geqslant 2. \tag{3.4}$$

Now, the integration can be performed and we obtain for the nonholomorphic part

$$\zeta(s|H) \sim \frac{\Omega_d}{(4\pi)^{d/2}\Gamma(s)}\left[\Gamma(s-d/2)\int_0^\infty \mathrm{d}r\, r^{d-1}e^{-(s-d/2)r^Q} + \sum_{n\geqslant 2;pq} C_{pq}^n \Gamma(s+n-d/2)\int_0^\infty \mathrm{d}r\, r^{d+p-1}e^{-(s+n-q-d/2)r^Q}\right] = \frac{\Omega_d}{(4\pi)^{d/2}Q\Gamma(s)}\left[\frac{\Gamma(s-d/2)\Gamma(d/Q)}{(s-d/2)^{d/Q}} + \sum_{n\geqslant 2;pq} C_{pq}^n \frac{\Gamma(s+n-d/2)\Gamma((d+p)/Q)}{(s+n-q-d/2)^{(d+p)/Q}}\right]. \tag{3.5}$$

As a consequence, it follows that generically the zeta function may have poles and branch points of any order. It should also be noted that in the case of even dimension it is not holomorphic at the origin.

For example, in the simplest case $d=Q=2$, $V(r)=e^{r^2}$, by straightforward dimensional analysis one can see that only the term proportional to C_{21}^2 contributes to the singularity at the origin and we get (see Sec. IV)

$$\zeta(s|H) = \frac{C_{21}^2}{4s} + \cdots, \quad C_{21}^2 = -\frac{2}{3}. \tag{3.6}$$

We conclude this section by studying the asymptotics of the spectral density associated with the operator H. We can define the spectral density via the spectral representation of the heat trace, namely

$$\mathrm{Tr}\, e^{-tH} = \int_0^\infty e^{-t\lambda}\mathrm{d}N(\lambda) = \int_0^\infty \mathrm{d}\lambda e^{-t\lambda}\rho(\lambda). \tag{3.7}$$

For the polynomial interaction, the Tauberian theorems (see the Appendix) and the short-t leading terms of the heat-trace expansion give

$$N(\lambda) \simeq \lambda^{(dQ+2d)/2Q}, \quad \rho(\lambda) \simeq \lambda^{(dQ+2d)/2Q-1}, \quad \lambda \to \infty, \tag{3.8}$$

while for the exponential interaction, with d/Q an integer,

$$N(\lambda) \simeq \lambda^{d/Q}(\ln\lambda)^{d/Q}, \quad \rho(\lambda) \simeq \lambda^{d/Q-1}(\ln\lambda)^{d/Q}, \quad \lambda \to \infty. \tag{3.9}$$

In particular, when $Q=d$, one has

$$N(\lambda) \simeq \lambda(\ln\lambda), \quad \rho(\lambda) \simeq \ln\lambda, \quad \lambda \to \infty. \tag{3.10}$$

In this last case the distribution of the eigenvalues of the operator H resembles the asymptotic behavior which one meets in number theory, namely the asymptotic distribution of the nontrivial zeroes of the Riemann zeta function.[22] With regard to this important issue we refer the reader to the literature, mentioning the relevance of the method based on Cramer's V-function (Ref. 36 and references therein). Other related papers are Refs. 37 and 38.

IV. A SIMPLE MODEL OF CONFINEMENT

In this section we investigate an explicit model, namely a massive scalar field defined on a flat spacetime $R\times R^3$ in an external static field described by a confining potential which is asymptotically exponential in two dimensions. In the Euclidean version, we may compactify the "time" coordinate and the *zeta* spatial coordinate, assuming periodic boundary conditions with periods β and l, respectively. As a result, the relevant operator reads

$$L=-\frac{\mathrm{d}^2}{\mathrm{d}^2\tau}-\frac{\mathrm{d}^2}{\mathrm{d}z^2}+H_2+M^2,\quad H_2=-\Delta_2+V(r),\quad V(r)=g^2e^{\alpha^2r^2}, \tag{4.1}$$

g and α being dimensional parameters. Making use of Poisson's resummation formula, the heat trace can be written as

$$\mathrm{Tr}\, e^{-tL}=\frac{Se^{-tM^2}}{4\pi t}\mathrm{Tr}\, e^{-tH_2}+\ldots, \tag{4.2}$$

where $S=\beta l$ and the dots stand for exponentially small terms in the parameter t.

In this model, the zeta function can be computed by using the method described in Sec. III, but one now obtains an expression which is different from (3.3), since the potential is defined only on R^2 and one needs to take the factor $e^{-tM^2/t}$ into account. As a result, we get

$$\zeta(s|L)\sim\frac{S}{(4\pi)^2\Gamma(s)}\sum_n\int_0^\infty \mathrm{d}t\, t^{s+n-3}\int_{R^2}\mathrm{d}x\,\tilde{b}_n(x)e^{-tV(r)}=\sum_n\frac{\Gamma(s+n-2)}{(4\pi)^2\Gamma(s)}\int_{R^2}\mathrm{d}x\,\tilde{b}_n(x)[V(r)]^{-(s+n-2)}, \tag{4.3}$$

where the $\tilde{b}_n$ are related to the b_n in (3.4) by

$$\tilde{b}_n=\sum_{j+k=n}\frac{(-1)^kb_jM^{2k}}{k!},\quad n\geqslant 2,\quad \tilde{b}_0=1,\quad \tilde{b}_1=-M^2. \tag{4.4}$$

The $\tilde{b}_n$ have again the same structure as in Eq. (3.4), but now q can vanish, namely

$$\tilde{b}_n=\sum_{pq}\tilde{C}^n_{pq}r^pa^qe^{qbr^2},\quad 0\leqslant p\leqslant 2(n-1),\quad 0\leqslant q<n,\quad n\geqslant 0, \tag{4.5}$$

$$\tilde{C}^n_{00}=\frac{(-1)^nM^{2n}}{n!}. \tag{4.6}$$

The b_n coefficients which appear in Eq. (4.5) can be evaluated by making use of (1.9) and (1.10); the first nontrivial ones read

$$b_2=-\frac{2g\alpha e^{\alpha r^2}}{3}(1+\alpha r^2),$$

$$b_3=-\frac{4g\alpha^2e^{\alpha r^2}}{15}(2+4\alpha r^2+\alpha^2r^4)+\frac{g^2\alpha^2e^{2\alpha r^2}}{3},$$

$$b_4=-\frac{8g\alpha^3e^{\alpha r^2}}{105}(6+18\alpha r^2+9\alpha^2r^4+\alpha^3r^6)+\frac{2g^2\alpha^2e^{2\alpha r^2}}{45}(7+38\alpha r^2+21\alpha^2r^4), \tag{4.7}$$

from which we can read off the C^n_{pq} coefficients up to $n=4$.

By integrating (4.3), the nonholomorphic contribution to the zeta function reads

$$\zeta(s|L) = \frac{S}{16\pi\Gamma(s)} \sum_{n\geqslant 0;pq} \tilde{C}^n_{pq} \frac{\Gamma(s+n-2)\Gamma(1+p/2)a^{-(s+n-q-2)}}{b^{1+p/2}(s+n-q-2)^{1+p/2}}. \tag{4.8}$$

Since in our specific example p is even, the zeta function has only poles of oder $p/2$. In particular, in a neighborhood of $s=0$ the pole structure is

$$\zeta(s|L) = \frac{S}{16\pi\alpha}\left[\frac{M^4}{2s} + \sum_{n=3}^{6} \frac{\tilde{C}^n_{2,n-2}\Gamma(n-2)}{\alpha s} + 2\sum_{n=3}^{6} \frac{\tilde{C}^n_{4,n-2}\Gamma(n-2)}{\alpha^2 s^2}\right] + \cdots . \tag{4.9}$$

Thus, the zeta function $\zeta(s|L)$ is *not* regular at the origin: a pole of second-order appears. Within a physical context (restricted most of the time to the realm of pseudodifferential operators in compact domains), this is a very unusual behavior for the zeta function.[19–21] In these cases, as far as the one-loop effective action is concerned, the otherwise well-established zeta function regularization procedure needs to be modified.[5,39]

Our proposal, which extends in a natural way the one formulated in Refs. 19–21, consists in the introduction of an additional spectral function which depends on the order of the pole at the origin of the initial zeta function. Thus, in the case of a pole of order N, the auxiliary spectral function reads

$$\omega(s) = s^N \zeta(s|L), \tag{4.10}$$

and the definition of the regularized determinant is generalized as

$$\ln\det\frac{L}{\mu^2} = -\frac{1}{(N+1)!}\lim_{s\to 0}\frac{\mathrm{d}^{N+1}}{\mathrm{d}s^{N+1}}[\mu^{2s}\omega(s)], \tag{4.11}$$

with the normalization chosen in such a way that when $\zeta(s|L)$ is regular at the origin, one does recover the ordinary definition of regularized functional determinant. This is an essential condition in order to preserve the well-established properties defining the zeta function regularization procedure.

Recalling our example before, we have seen that in this model a second-order pole will generically appear. Then, the new spectral function, which is regular at the origin, will be given by

$$\omega(s) = s^2 \zeta(s|L). \tag{4.12}$$

We correspondingly define

$$\ln\det\frac{L}{\mu^2} = -\frac{1}{3!}\lim_{s\to 0}\frac{\mathrm{d}^3}{\mathrm{d}s^3}[\mu^{2s}\omega(s)]. \tag{4.13}$$

It has to be mentioned here that, within the context of a general theory of regularized products (see, e.g., Ref. 27), in the case when the related zeta function is not holomorphic at the origin but has a first-order pole—and we have stressed this to happen when logarithmic terms are present in the heat-trace asymptotics—a new definition of regularized product was proposed recently.[40] It reads

$$\prod_{k=1}^{\infty}\lambda_k \equiv \exp\left[-\mathrm{Res}\left(\frac{\zeta(s)}{s^2}\right)_{s=0}\right], \quad \zeta(s) = \sum_{k=1}^{\infty}\lambda_k^{-s}. \tag{4.14}$$

Recalling the definition of residue, it is straightforward to conclude that this prescription is equivalent to ours, Eq. (4.11). This is a further consistency check and inscribes our result in a very general context.

We conclude with the following remark. The one-loop renormalization group equations associated with the presence of the renormalization scale μ can be treated along the same lines as in Ref. 39. This shows both the power and flexibility of the zeta-function method to easily cope with

nonstandard and unexpected situations, without ever losing contact with the fundamental issue of its applicability to actual physical problems. This means, in particular, that the results obtained with the method must be checked to be physically meaningful and to reproduce measured experimental values.

V. CONCLUSION

In this paper we have considered several examples of the determination of heat-kernel traces associated with operators of Laplace type defined on noncompact domains. For the sake of simplicity, we have restricted our analysis to R^d and to analytic but confining potentials, thus dealing with discrete spectra only. However, the adequacy of the procedure to treat more general settings has been exhibited. In particular, although for the sake of simplicity we have postponed the treatment of the case when d/Q is noninteger, with some extra effort this can be dealt with along the same lines. New branching points appear there.

We have shown that for confining potentials of exponential behavior at infinity, the asymptotics of the heat-kernel trace contain generically logarithmic terms. As a consequence, the meromorphic structure of the associated zeta function develops higher-order poles as well as branching points. In particular, we have exhibited some cases where the zeta function is not regular at the origin.

In these situations, one is confronted with the nontrivial task of having to define the corresponding regularized functional determinant or the one-loop effective potential. In fact, in the example of an apparently reasonable model of confinement, constructed by means of an asymptotically exponential potential, we have proven that the meromorphic continuation of the zeta function already develops a higher-order pole at the origin. This, as far as we know, is an absolutely novel finding in the field, even more since it comes from such an apparently harmless model.

In order to deal with these special cases, we have proposed a generalization of the zeta function regularization procedure, consisting in the introduction of a new, auxiliary zeta function which is still regular at the origin, together with a correspondingly new definition for the zeta-regularized determinant (thus extending Ray and Singer's definition). This general prescription—which naturally extends particular cases already considered by some of us before[19–21]—turns out to be equivalent to the one recently proposed by Hirano *et al.*[40] in a more generic context of a theory of regularized products. In accordance with our fundamental aim never to abandon the already established connections with the physical world (e.g., the many uses of zeta regularization in experimental physics), all the new quantities have been defined in such a way as to recover the celebrated results of zeta-function regularization in the absence of poles at the origin.

Still pending is the task to construct an explicit general theory to deal with the whole class of Laplacian-type operators in noncompact domains, which we leave for further work.

APPENDIX: SOME USEFUL FORMULAS

Here we list some expressions that have been employed in the text. We start with the incomplete gamma function, useful in order to reveal the presence of logarithmic terms in the heat-kernel trace expansion. Its definition reads

$$\Gamma(s,t) = \int_t^\infty \mathrm{d}y\, y^{s-1}e^{-y} = \Gamma(s) - \frac{t^s}{s} - t^s\sum_{r=1}^{\infty}\frac{t^n}{n!(s+n)}, \tag{A1}$$

and thus

$$\Gamma(0,t) = -\ln t - \gamma - t - \frac{t^2}{4} + O(t^3), \tag{A2}$$

γ being Euler's constant. Taking the derivative of order n of $\Gamma(s,t)$ with respect to s, one gets

$$\frac{\mathrm{d}^n}{\mathrm{d}s^n}\Gamma(s,t) = \int_t^\infty \mathrm{d}y(\ln y)^n y^{s-1}e^{-y}, \tag{A3}$$

from which it follows that

$$\int_1^\infty \mathrm{d}y(\ln y)^n y^{s-1}e^{-ty} = \frac{\mathrm{d}^n}{\mathrm{d}s^n}\frac{\Gamma(s,t)}{t^s} = \sum_{k=0}^{n} f_k(s)\Gamma(s)\frac{(\ln t)^k}{t^s} - \frac{(-1)^n n!}{s^{n+1}} + O(t), \tag{A4}$$

where the $f_k(s)$ are computable functions. In particular,

$$f_n(s) = (-1)^n, \quad f_{n-1}(s) = (-1)^{n+1}\psi(s), \tag{A5}$$

$\psi(s)$ being the digamma function. In the limit $s\to 0$ we finally have

$$\int_1^\infty \mathrm{d}y(\ln y)^n y^{-1}e^{-ty} = \sum_{k=0}^{n+1} c_k(\ln t)^k + O(t), \tag{A6}$$

where

$$c_{n+1} = \frac{(-1)^{n+1}}{n+1}, \quad c_n = (-1)^{n+1}\gamma. \tag{A7}$$

With a view to the analytic continuation of zeta functions, the following formulas are useful too. If α is a complex number with positive real part, and β such that Re $\beta > -1$, one has

$$\int_0^1 \mathrm{d}t\, t^{\alpha-1}(\ln t)^\beta = \frac{(-1)^\beta\Gamma(\beta+1)}{\alpha^{\beta+1}}. \tag{A8}$$

To prove this, it is sufficient to perform the change of variable $u=-\ln t$ and recall the definition of the Euler gamma function.

Furthermore, for the asymptotics of the spectral density for large λ, one has

$$t^{-s} = \int_0^\infty e^{-t\lambda}\frac{\lambda^{s-1}}{\Gamma(s)}. \tag{A9}$$

Taking the derivative with respect to s,

$$\ln t t^{-s} = \int_0^\infty e^{-t\lambda}\lambda^{s-1}\left[-\frac{\ln\lambda}{\Gamma(s)} + \frac{\Gamma'(s)}{\Gamma(s)}\right], \tag{A10}$$

and

$$\ln^2 tt^{-s} = \int_0^\infty e^{-t\lambda}\lambda^{s-1}\left[\frac{\ln^2\lambda}{\Gamma(s)} + 2\frac{\Gamma'(s)}{\Gamma^2(s)}\ln\lambda - \frac{\Gamma''(s)}{\Gamma(s)} - \frac{\Gamma'(s)}{\Gamma^2(s)}\right]. \tag{A11}$$

The above-noted identities are compatible with the Karamata Tauberian theorems, which can be stated as follows. Suppose we deal with

$$\int_0^\infty e^{-t\lambda} dN(\lambda) = K(t). \tag{A12}$$

(i) If

$$K(t) \simeq At^{-r}, \quad t \to 0, \tag{A13}$$

then

$$N(\lambda) \simeq A\frac{\lambda^r}{\Gamma(r+1)}, \quad \lambda \to \infty. \tag{A14}$$

(ii) If

$$K(t) \simeq At^{-r}\ln^N t, \quad t \to 0, \tag{A15}$$

then

$$N(\lambda) \simeq A\frac{\lambda^r \ln^N \lambda}{\Gamma(r+1)}, \quad \lambda \to \infty. \tag{A16}$$

Is weak pseudo-Hermiticity weaker than pseudo-Hermiticity?

Ali Mostafazadeh[a)]
Department of Mathematics, Koç University, 34450 Sariyer, Istanbul, Turkey

(Received 2 May 2006; accepted 18 July 2006; published online 5 September 2006)

For a weakly pseudo-Hermitian linear operator, we give a spectral condition that ensures its pseudo-Hermiticity. This condition is always satisfied whenever the operator acts in a finite-dimensional Hilbert space. Hence weak pseudo-Hermiticity and pseudo-Hermiticity are equivalent in finite-dimensions. This equivalence extends to a much larger class of operators. Quantum systems whose Hamiltonian is selected from among these operators correspond to pseudo-Hermitian quantum systems possessing certain symmetries. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2338144]

I. INTRODUCTION

References 1 and 2 discuss a notion of a pseudo-Hermitian operator that has proven to be a convenient tool in the study of $\mathcal{PT}$-symmetric Hamiltonians.[3–7] It also plays a central role in solving some of the basic problems of relativistic quantum mechanics and quantum cosmology[8] and revealing some interesting analogies between quantum mechanics and general relativity.[9] The following is a mathematically precise description of this notion.[1]

Definition 1: A densely defined linear operator $H:\mathcal{H}\to\mathcal{H}$ acting in a separable Hilbert space $\mathcal{H}$ is said to be *pseudo-Hermitian* if there exists a Hermitian automorphism $\eta:\mathcal{H}\to\mathcal{H}$ satisfying

$$H^\dagger = \eta H \eta^{-1}, \tag{1}$$

where $H^\dagger$ denotes the adjoint of H. (Throughout this paper, "Hermitian" means "self-adjoint," e.g., $\eta^\dagger=\eta$.)

For a discussion of the earlier uses of the term pseudo-Hermitian in the context of indefinite-metric theories see Ref. 10.

Note that an automorphism is by definition an everywhere-defined, one-to-one, and onto linear operator. Moreover, an everywhere-defined Hermitian linear operator is necessarily bounded (this is known as the Hellinger-Toeplitz theorem[11]), and a bounded one-to-one onto linear map has a bounded inverse (this is known as the inverse mapping theorem[11] or Banach's theorem[12]). As a result, if one adopts the definition of an invertible operator that identifies the latter with a one-to-one, onto linear map with a bounded inverse,[13–15] then *a linear operator is everywhere-defined, Hermitian, and invertible if and only if it is a Hermitian automorphism*. Usually in physics literature one ignores the technical issues associated with the domain of the operators and uses "Hermitian automorphism" and "Hermitian invertible linear map" synonymously. Another more familiar term used for such an operator particularly in the context of pseudo-Hermitian operators is "*pseudo-metric*."

The operator equation (1) in particular implies that the domain of its both sides must coincide. In light of the fact that η is everywhere-defined, this means

a)Electronic mail: amostafazadeh@ku.edu.tr

$$\eta(\mathcal{D}(H)) = \mathcal{D}(H^\dagger), \tag{2}$$

where $\mathcal{D}(L)$ denotes the domain of a linear operator $L:\mathcal{H}\to\mathcal{H}$, and $L(\mathcal{S})$ stands for the image of a subset $\mathcal{S}\subseteq\mathcal{H}$ under L.

Definition 1 is a direct generalization of the notion of a self-adjoint operator, for the latter corresponds to a pseudo-Hermitian operator admitting the identity operator $I:\mathcal{H}\to\mathcal{H}$ as a pseudo-metric. (We may similarly generalize the notion of a *symmetric operator*[11] by replacing (2) with $\eta(\mathcal{D}(H))\subseteq\mathcal{D}(H^\dagger)$ and requiring that (1) holds in $\eta(\mathcal{D}(H))$.)

In Ref. 4, Solombrino has slightly weakened the defining condition of a pseudo-Hermitian operator by relaxing the requirement of the Hermiticity of η. This leads to the following notion of weak pseudo-Hermiticity.

Definition 2: A linear operator $H:\mathcal{H}\to\mathcal{H}$ acting in a separable Hilbert space $\mathcal{H}$ is said to be *weakly pseudo-Hermitian* if there exists an everywhere-defined, bounded, invertible, linear map (i.e., a bounded automorphism) $\eta_w:\mathcal{H}\to\mathcal{H}$ satisfying

$$H^\dagger = \eta_w H \eta_w^{-1}. \tag{3}$$

Again (3) implies

$$\eta_w(\mathcal{D}(H)) = \mathcal{D}(H^\dagger). \tag{4}$$

The basic motivation for introducing weak pseudo-Hermiticity is that the Hermiticity of η in (1) does not play any significant role in establishing the spectral characterization theorem(s) for diagonalizable pseudo-Hermitian operators with a discrete spectrum.[1,2,4] This suggests, at least for diagonalizable operators with a discrete spectrum, that pseudo-Hermiticity and weak pseudo-Hermiticity are equivalent conditions.[4] In Ref. 5 Bagchi and Quesne explore the relationship between these two concepts and use the term "complementary" to describe it. Though it is not made explicit in their analysis, their approach can be consistently applied only to a restricted class of bounded automorphisms η, namely to those for which $\eta+\eta^\dagger$ is also an automorphism. More recently, Znojil[7] has suggested that considering weak-pseudo-Hermitian Hamiltonians may provide further insight into the current search for potential applications of non-Hermitian Hamiltonians in quantum mechanics.

The purpose of this paper is to conduct a careful reexamination of the relationship between weak pseudo-Hermiticity and pseudo-Hermiticity for a general not necessarily diagonalizable linear operator. We will establish the equivalence of these concepts for a large class of linear operators including all linear operators that act in a finite-dimensional Hilbert space, i.e., matrix Hamiltonians.

Before starting our analysis we introduce our conventions and notation.

- $\mathcal{H}$ denotes a separable Hilbert space.
- For any linear operator $H:\mathcal{H}\to\mathcal{H}$, $\mathfrak{U}_H$ stands for the set of all bounded automorphisms $\eta_w:\mathcal{H}\to\mathcal{H}$ satisfying (3). Therefore, H is weakly pseudo-Hermitian if $\mathfrak{U}_H\neq\emptyset$. It is pseudo-Hermitian if $\mathfrak{U}_H$ contains a Hermitian element.
- For any bounded operator $B:\mathcal{H}\to\mathcal{H}$, $\|B\|$ denotes the norm of B.

II. A CAREFUL LOOK AT WEAK PSEUDO-HERMITICITY

First we present some useful facts.

Proposition 1: Let $H:\mathcal{H}\to\mathcal{H}$ be a weakly pseudo-Hermitian linear operator. Then for all η_w, $\eta_w'\in\mathfrak{U}_H$, $\eta_w^{-1}\eta_w'$ is a bounded automorphism commuting with H.

Proof: Let η_w, $\eta_w'\in\mathfrak{U}_H$. Because both η_w and η_w' are bounded, one-to-one, and onto, so are η_w^{-1} and $\eta_w^{-1}\eta_w'$. Furthermore, as shown in Ref. 1, in view of (3) and its analog satisfied by η_w', we have $[\eta_w^{-1}\eta_w', H]=0$. □

Proposition 2: Let $H:\mathcal{H}\to\mathcal{H}$ be a closed weakly pseudo-Hermitian linear operator and $\eta_w\in\mathfrak{U}_H$. Then $\eta_w^\dagger\in\mathfrak{U}_H$ provided that $\eta_w^\dagger\mathcal{D}(H)=\mathcal{D}(H^\dagger)$. In this case

$$A := \eta_w^{-1}\eta_w^\dagger \tag{5}$$

is a bounded automorphisms commuting with H. (Although Definitions 1 and 2 do not require H to be a closed operator, this requirement is necessary to derive many of the useful properties of pseudo-Hermitian and weakly pseudo-symmetric operators. Here we need it to assure that $H^{\dagger\dagger}=H$.[16])

Proof: Let $\eta_w \in \mathfrak{U}_H$ be such that $\eta_w^\dagger \mathcal{D}(H)=\mathcal{D}(H^\dagger)$. η_w satisfies (3) or equivalently

$$\eta_w H = H^\dagger \eta_w. \tag{6}$$

This in particular implies

$$\eta_w^{-1}\mathcal{D}(H^\dagger) = \mathcal{D}(H^\dagger \eta_w) = \mathcal{D}(\eta_w H) = \mathcal{D}(H). \tag{7}$$

Now, take the adjoint of both sides of this equation. [Note that for a pair of (densely defined) linear operators $A,B:\mathcal{H}\to\mathcal{H}$ that are not bounded and everywhere-defined, the relation $(AB)^\dagger=B^\dagger A^\dagger$ does not hold in general (Ref. 14, Sec. 7.7).] Because $\mathcal{D}(\eta_w H)=\mathcal{D}(H)$ is dense and η_w is bounded and everywhere-defined, we have (Ref. 14, Sec. 7.7)

$$(\eta_w H)^\dagger = H^\dagger \eta_w^\dagger, \tag{8}$$

or alternatively

$$H^\dagger = (\eta_w H)^\dagger \eta_w^{\dagger -1}. \tag{9}$$

Furthermore, as explained in Ref. 14, Sec. 7.7, because $\mathcal{D}(H^\dagger \eta_w)=\eta_w^{-1}\mathcal{D}(H^\dagger)=\mathcal{D}(H)$ is dense, $\mathcal{D}(\eta_w^\dagger H)\subseteq\mathcal{D}((H^\dagger\eta_w)^\dagger)$ and

$$(H^\dagger\eta_w)^\dagger\psi = \eta_w^\dagger H\psi \quad \text{for all } \psi\in\mathcal{D}(\eta_w^\dagger H)=\mathcal{D}(H). \tag{10}$$

This in turn means that

$$(H^\dagger\eta_w)^\dagger\eta_w^{\dagger -1}\phi = \eta_w^\dagger H\eta_w^{\dagger -1}\phi \quad \text{for all } \phi\in\eta_w^\dagger\mathcal{D}(H). \tag{11}$$

Therefore, in view of the hypothesis: $\eta_w^\dagger\mathcal{D}(H)=\mathcal{D}(H^\dagger)$ and Eqs. (6), (9), and (10) (as envisaged in Ref. 5)

$$H^\dagger = \eta_w^\dagger H \eta_w^{\dagger -1}. \tag{12}$$

This together with the fact that the adjoint $(\eta_w^\dagger)$ of a bounded automorphism (η_w) is a bounded automorphism establish $\eta_w^\dagger\in\mathfrak{U}_H$. The fact that $[A,H]=0$ follows from Proposition 1. □

Proposition 3: Let H and A be as in Proposition 2 and $r_A := \lim_{n\to\infty}\|A^n\|^{1/n}$ be the spectral radius[17] of A. Then the spectrum σ_A of A lies in the annulus centered at $0\in\mathbb{C}$ and having as its inner and outer radii r_A^{-1} and r_A, respectively, i.e.,

$$\sigma_A \subseteq \{z\in\mathbb{C}\,|\,r_A^{-1}\leqslant|z|\leqslant r_A\}. \tag{13}$$

In particular, $\|A\|\geqslant r_A\geqslant 1$.

Proof: According to Proposition 2, A is a bounded invertible linear map. This implies that $A^\dagger$ and A^{-1} are bounded operators, and the following identities are satisfied:[17,14]

$$\sigma_{A^\dagger}=\{\lambda\in\mathbb{C}\,|\,\lambda^*\in\sigma_A\},\quad \sigma_{A^{-1}}=\{\lambda\in\mathbb{C}\,|\,\lambda^{-1}\in\sigma_A\}. \tag{14}$$

Furthermore, because $A^{-1}=\eta_w^{\dagger -1}\eta_w$, $A^\dagger=\eta_w\eta_w^{-1\dagger}=\eta_w A^{-1}\eta_w^{-1}$, and η_w is invertible, we have $\sigma_{A^\dagger}=\sigma_{A^{-1}}$.[15] Combining this result with (14), we find that for all $\lambda\in\sigma_A$, $1/\lambda^*\in\sigma_A$. Next, we recall that for all $\mu\in\sigma_A$, $|\mu|\leqslant r_A$. Applying this inequality for $\mu=\lambda$ and $1/\lambda^*$, we then find $r_A^{-1}\leqslant|\lambda|\leqslant r_A$ for all $\lambda\in\sigma_A$. (Because there is always $\Lambda\in\sigma_A$ such that $|\Lambda|=r_A$ and $1/\Lambda^*\in\sigma_A$, σ_A intersects both the circles $|z|=r_A$ and $|z|=r_A^{-1}$.) This establishes (13). Finally, because the spectrum of every bounded operator is nonempty, we must have $r_A^{-1}\leqslant r_A$, which in turn implies $r_A\geqslant 1$. The fact that

$r_A \leqslant \|A\|$ is well-known.[17] □

The following is our main result. It links the equivalence of weak pseudo-Hermiticity and pseudo-Hermiticity of a large class of linear operators H with the existence of an $\eta_w \in \mathfrak{U}_H$ such that the unit circle $S^1 := \{e^{i\varphi} \in \mathbb{C} \,|\, \varphi \in [0, 2\pi)\}$ is not a subset of σ_A. Note that Proposition 3 does not rule out this possibility.

Theorem 1: Let $H: \mathcal{H} \to \mathcal{H}$ be a closed weakly pseudo-Hermitian linear operator acting in a separable Hilbert space $\mathcal{H}$. Then H is pseudo-Hermitian, if there is $\eta_w \in \mathfrak{U}_H$ such that $\eta_w^\dagger \mathcal{D}(H) = \mathcal{D}(H^\dagger)$ and the unit circle S^1 is not a subset of the spectrum σ_A of $A := \eta_w^{-1} \eta_w^\dagger$.

Proof: Let $\eta_w \in \mathfrak{U}_H$ be such that $\eta_w^\dagger \mathcal{D}(H) = \mathcal{D}(H^\dagger)$, and $\vartheta \in [0, 2\pi)$ be arbitrary. Then according to Proposition 2, $\eta_w^\dagger \in \mathfrak{U}_H$, and both (3) and (12) hold. Expressing these equations in the form

$$\eta_w H = H^\dagger \eta_w, \tag{15}$$

$$\eta_w^\dagger H = H^\dagger \eta_w^\dagger, \tag{16}$$

multiplying both sides of (15) and (16), respectively, by $ie^{i\vartheta}$ and $-ie^{-i\vartheta}$, and adding the resulting equations side by side, we find

$$\eta(\vartheta) H = H^\dagger \eta(\vartheta), \tag{17}$$

where

$$\eta(\vartheta) := i(e^{i\vartheta} \eta_w - e^{-i\vartheta} \eta_w^\dagger) \quad \text{for all } \vartheta \in [0, 2\pi). \tag{18}$$

The operator $\eta(\vartheta)$ is manifestly Hermitian. It is also everywhere-defined and bounded, because both η_w and $\eta_w^\dagger$ share these properties. But it need not be invertible. We can express $\eta(\vartheta)$ in the form

$$\eta(\vartheta) = -ie^{-i\vartheta} \eta_w (A - e^{2i\vartheta} I), \tag{19}$$

where I stands for the identity operator acting on $\mathcal{H}$. Clearly because η_w is invertible, $\eta(\vartheta)$ is invertible if and only if $A - e^{2i\vartheta} I$ is invertible. By the definition of the spectrum of a linear operator,[11–17] the latter condition is equivalent to $e^{2i\vartheta} \notin \sigma_A$. If $S^1 \subseteq \sigma_A$, there is $\vartheta_\star \in [0, \pi)$ such that $e^{2i\vartheta_\star} \notin \sigma_A$. Therefore, $\eta_\star := \eta(\vartheta_\star)$ is invertible; $\mathfrak{U}_H$ includes a Hermitian operator $\eta_\star$; and H is pseudo-Hermitian. □

Corollary: A linear operator acting in a finite-dimensional Hilbert space is weakly pseudo-Hermitian if and only if it is pseudo-Hermitian. (As pointed out by the referee, this is a known result.[18])

Proof: According to Definitions 1 and 2, every pseudo-Hermitian operator is weakly pseudo-Hermitian. The converse holds for an operator acting in a finite-dimensional Hilbert space, because in this case all the operators are everywhere-defined (bounded and hence closed) and σ_A of Theorem 1 is a finite set. Hence, it cannot include S^1 as a subset. □

In summary, a weakly pseudo-Hermitian linear operator may fail to be pseudo-Hermitian, if it acts in an infinite-dimensional space and for every $\eta_w \in \mathfrak{U}_H$ either $\eta_w^\dagger \mathcal{D}(H) \neq \mathcal{D}(H^\dagger)$ or $S^1 \subseteq \sigma_A$ where $A := \eta_w^{-1} \eta_w^\dagger$. The latter condition seems to be very difficult to satisfy.

III. EXAMPLES

Consider the following bounded automorphism that is employed in Ref. 7:

$$\eta_w = \begin{pmatrix} 0 & 0 & \mathcal{P} \\ \mathcal{P} & 0 & 0 \\ 0 & \mathcal{P} & 0 \end{pmatrix}, \tag{20}$$

where $\mathcal{P}$ is the usual parity operator acting in $L^2(\mathbb{R})$, the Hilbert space is $L^2(\mathbb{R}) \oplus L^2(\mathbb{R}) \oplus L^2(\mathbb{R})$, a three-component representation of the state vectors is used, and $H = (H_{ij})$ is a 3×3 matrix of

differential operators H_{ij} such that $\mathcal{P}\mathcal{D}(H)=\mathcal{D}(H)=\mathcal{D}(H^\dagger)$. It is not difficult to see that $\vartheta_\star=3\pi/2$ fulfills the conditions of Theorem 1, and

$$\eta_\star := \eta\left(\frac{3\pi}{2}\right) = \eta_w + \eta_w^\dagger = \begin{pmatrix} 0 & \mathcal{P} & \mathcal{P} \\ \mathcal{P} & 0 & \mathcal{P} \\ \mathcal{P} & \mathcal{P} & 0 \end{pmatrix} \tag{21}$$

is a genuine pseudo-metric belonging to $\mathfrak{U}_H$. Indeed, it is not only everywhere-defined, bounded, Hermitian, and one-to-one, but it is also onto and its inverse is bounded. This can be directly checked. Alternatively, we may apply Theorem 1 and show that $S^1 \nsubseteq \sigma_A$. It is very easy to compute the symmetry generator (5):

$$A = \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \tag{22}$$

where 1 is viewed as the identity operator acting in $L^2(\mathbb{R})$. Clearly, $\sigma_A=\{1, e^{2i\pi/3}, e^{4i\pi/3}\}$. Hence $S^1 \nsubseteq \sigma_A$ and $\eta_\star$ is invertible.

This calculation shows that the systems considered in Ref. 7 can be identified with $\eta_\star$-pseudo-Hermitian Hamiltonians acting in $L^2(\mathbb{R})\oplus L^2(\mathbb{R})\oplus L^2(\mathbb{R})$ and commuting with A, where $\eta_\star$ and A are, respectively, given by (21) and (22). *These systems can be studied without any reference to weak pseudo-Hermiticity*.

Another probably more interesting example is $\eta_w:\mathbb{C}^2\to\mathbb{C}^2$ that is defined by its standard matrix representation according to

$$\eta_w = \begin{pmatrix} 1 & 1 \\ -1 & i \end{pmatrix}. \tag{23}$$

The symmetry generator (5) and the most general Hamiltonian $H:\mathbb{C}\to\mathbb{C}$ satisfying (6) have the following standard matrix representations:

$$A = \begin{pmatrix} i & 0 \\ 1-i & -1 \end{pmatrix} = -iM_1 - M_2, \tag{24}$$

$$H = \begin{pmatrix} a & 0 \\ ib & a+b \end{pmatrix} = aI + bM_1, \tag{25}$$

where

$$M_1 := \begin{pmatrix} 0 & 0 \\ i & 1 \end{pmatrix}, \quad M_2 := \begin{pmatrix} 1 & 0 \\ -i & 0 \end{pmatrix},$$

I is the identity matrix, and $a,b\in\mathbb{R}$ are arbitrary. Clearly, A and H commute for all $a,b\in\mathbb{R}$.

We can also easily compute $A-e^{2i\vartheta}I$. It turns out to be noninvertible only for $\vartheta=\pi/4,\pi/2,5\pi/4,3\pi/2$. This in turn means that $\eta(\vartheta)$ is noninvertible for these four values of ϑ. In particular, $\eta(3\pi/2)=\eta_w+\eta_w^\dagger$ that is considered in Ref. 5 is not invertible. (The possibility that given an invertible operator η_w the operators $\eta_w\pm\eta_w^\dagger$ may fail to be invertible seems to be overlooked in Ref. 5.)

In general, $\eta(\vartheta)$ has the following explicit form:

$$\eta(\vartheta)=2c\begin{pmatrix}-t & i\\ -i & -1\end{pmatrix}, \tag{26}$$

where $c:=\cos\vartheta$ and $t:=\tan\vartheta$. In terms of c and t the invertibility condition: $\vartheta\notin\{\pi/4,\pi/2,5\pi/4,3\pi/2\}$, takes the simple form: $c\neq 0$ and $t\neq 1$.

Having obtained an infinite class of pseudo-metric operators $\eta(\vartheta)$ that render the Hamiltonians of the form (25) pseudo-Hermitian, we can construct the following family of symmetry generators:[1,6]

$$A(r,t_1,t_2):=\eta(\vartheta_2)^{-1}\eta(\vartheta_1)=r\begin{pmatrix}1-t_1 & 0\\ i(t_1-t_2) & 1-t_2\end{pmatrix}=r(I-t_2M_1-t_1M_2), \tag{27}$$

where $r:=\cos\vartheta_1/(\cos\vartheta_2-\sin\vartheta_2)\neq 0$ and $t_i:=\tan\vartheta_i\neq 1$ for $i=1,2$. Comparing (25) and (27), we see that the only nontrivial symmetry generator for the system is M_2. We could reach the same conclusion using (24).

Finally, we note that $\eta(\alpha)$ is positive-definite whenever $c<0$ and $t>1$ which corresponds to $5\pi/4<\vartheta<3\pi/2$. In particular, H is pseudo-Hermitian with respect to a set of positive-definite metric operators. According to Ref. 2, this implies that it is quasi-Hermitian[19] and has real eigenvalues. The latter is easily seen from (25) where the eigenvalues appear as diagonal entries.

IV. CONCLUDING REMARKS

In this paper, we have examined the relation between the notions of pseudo-Hermiticity and weak pseudo-Hermiticity. We have found a sufficient spectral condition that ensures whether a given weakly pseudo-Hermitian operator is pseudo-Hermitian. This condition which is not sensitive to the diagonalizability of the operator in question is trivially satisfied in finite-dimensional Hilbert spaces. Hence weak pseudo-Hermiticity and pseudo-Hermiticity are equivalent in finite dimensions. This equivalence extends to a large class of operators acting in infinite-dimensional Hilbert spaces. Our general results seem to indicate that further investigation of weak pseudo-Hermiticity is not likely to produce any substantial insight into the current study of the possible applications of non-Hermitian Hamiltonians in quantum mechanics.

ACKNOWLEDGMENTS

During the course of this work I have benefitted from helpful discussions with Varga Kalantarov. I would also like to thank the anonymous referee for bringing Ref. 18 to my attention and for correcting an error in a previous version of the paper.

It is well known that n bits of entropy are necessary and sufficient to perfectly encrypt n bits (one-time pad). Even if we allow the encryption to be approximate, the amount of entropy needed does not asymptotically change. However, this is not the case when we are encrypting quantum bits. For the perfect encryption of n quantum bits, $2n$ bits of entropy are necessary and sufficient (quantum one-time pad), but for approximate encryption one asymptotically needs only n bits of entropy. In this paper, we provide the optimal trade-off between the approximation measure ϵ and the amount of classical entropy used in the encryption of single quantum bits. Then, we consider n-qubit encryption schemes which are a composition of independent single-qubit ones and provide the optimal schemes both in the 2- and the ∞-norm. Moreover, we provide a counterexample to show that the encryption scheme of Ambainis-Smith [Proceedings of RANDOM '04, pp. 249–260] based on small-bias sets does not work in the ∞-norm. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2339014]

I. INTRODUCTION

Secure transmission of information is a subject that has been studied extensively. In this model, Alice wants to securely transmit a message to Bob using a secret key that they both share, in such a way that any eavesdropper gets absolutely no information about the message sent. In the classical world, Shannon[11,12] has shown that for the perfect encryption of n classical bits, it is necessary and sufficient to use n bits of classical entropy (one-time pad). By performing a bitwise XOR between the n-bit message and the n-bit secret key, the view of any eavesdropper that has no knowledge of the key is just a uniformly random n-bit string. Ambainis *et al.*[2] showed that $2n$ classical bits of entropy are necessary and sufficient for the transmission of n quantum bits.

Let us briefly sketch how one can perfectly encrypt a quantum bit. Let ρ be the state of an arbitrary qubit and let I,X,Y,Z be the four Pauli matrices. Then, by using two bits of classical entropy we can uniformly pick one of the four matrices and apply it to our qubit. The state of the qubit after the encryption is

$$\mathcal{E}(\rho) = \tfrac{1}{4}(\rho + X\rho X + Y\rho Y + Z\rho Z).$$

It is easy to verify that for all states $\rho, \mathcal{E}(\rho) = \frac{1}{2}\mathbb{I}$ and hence the view of the eavesdropper is the completely mixed state, i.e., she gets no information about the encrypted state ρ. The scheme easily generalizes to n-qubit states by using $2n$ classical bits of entropy.

The entropy needed for the perfect encryption of quantum states is two times what is needed for the perfect encryption of classical bits. Interestingly, this is no longer true, when we look at *approximate encryption*. Let $\rho \in \mathbb{C}^{d\times d}$ be the state of a $(\log d)$-qubit message, $\{U_k \in \mathbb{C}^{d\times d} | k \in [N]\}$ be a set of N unitary operations acting on $\log d$ qubits and $\mathcal{D}=\{w_1,\ldots,w_N\}$ be a distribu-

b)Electronic mail: jkeren@math.mit.edu

tion on $[N]$. Imagine the encryption scheme, where Alice picks a unitary U_k with probability w_k and applies it to the message. The ciphertext can be written as

$$\mathcal{E}(\rho) = \sum_{k\epsilon[N]} w_k \rho U_k^\dagger$$

and the entropy of the scheme is defined as the Shannon entropy $H(\mathcal{D})$.

Definition 1: The map $\mathcal{E}$ is an (ϵ,H)-approximate encryption scheme for the ∞-norm, if the entropy of the scheme is H and for all states ρ

$$\left\| \mathcal{E}(\rho) - \frac{\mathbb{I}}{d} \right\|_\infty \leqslant \frac{\epsilon}{d}.$$

Similarly, the map $\mathcal{E}$ is an (ϵ,H)-approximate encryption scheme for the 2-norm, if the entropy of the scheme is H and for all states ρ

$$\left\| \mathcal{E}(\rho) - \frac{\mathbb{I}}{d} \right\|_2 \leqslant \frac{\epsilon}{\sqrt{d}}.$$

Hayden, *et al.*[5] found an $(\epsilon, n+o(n))$-approximate encryption scheme for n qubits. Specifically, they showed that an encryption scheme that applies a unitary on ρ picked uniformly from a random set of unitaries of size $2^{n+o(n)}$ achieves ϵ-approximation. Ambainis and Smith[3] derandomized this construction using small-bias sets and constructed deterministically a set of $2^{n+o(n)}$ unitaries that achieves an $(\epsilon, n+o(n))$-approximation for the 2-norm.

On the other hand, it is not hard to see that for the classical case, one needs at least $n - \log(1-\epsilon/2)$ bits of entropy for an ϵ-approximation scheme. Hence, the entropy needed for the approximate encryption of classical and quantum states is asymptotically equal.

In this paper, we start by investigating the approximate encryption of single qubits and find the optimal trade-off between the approximation measure ϵ and the amount of classical entropy H, i.e., we calculate the least amount of classical entropy which is necessary and sufficient to achieve an ϵ-approximation. Our proof is constructive in the sense that for any given ϵ we describe the encryption scheme that achieves the optimal H and vice versa. The following theorem holds both for the ∞- and 2-norm. Note the weights in the distributions are in decreasing order.

Theorem 1: *Let $\mathcal{E}(\rho)$ be the optimal (ϵ,H)-approximate encryption scheme for a qubit. Then,*

1. The encryption is of the form $\mathcal{E}(\rho)=w\rho+xX\rho X+yY\rho Y+zZ\rho Z$.
2. For any fixed ϵ, the optimal distribution $\mathcal{D}$ (and hence the minimum entropy H) is:

(i) $\epsilon \leqslant 1/6 : \mathcal{D} = \left\{\frac{1}{4}+\frac{\epsilon}{2}, \frac{1}{4}+\frac{\epsilon}{2}, \frac{1}{4}+\frac{\epsilon}{2}, \frac{1}{4}-\frac{3\epsilon}{2}\right\}$,
(ii) $1/6 \leqslant \epsilon \leqslant 0.287 : \mathcal{D} = \left\{2\epsilon, \frac{1}{2}-\epsilon, \frac{1}{2}-\epsilon, 0\right\}$,
(iii) $\epsilon \geqslant 0.287 : \mathcal{D} = \left\{\frac{1}{4}+\frac{3\epsilon}{2}, \frac{1}{4}-\frac{\epsilon}{2}, \frac{1}{4}-\frac{\epsilon}{2}, \frac{1}{4}-\frac{\epsilon}{2}\right\}$.

In Sec. II we find the optimal Pauli encryption scheme for a qubit and in Sec. III we show that Pauli encryption schemes are no worse than general encryption schemes.

Next, in Sec. IV we consider n-qubit encryption schemes which are a composition of independent single-qubit schemes that each use entropy H. In general, such questions are not easy to tackle, since they hinge on notoriously hard questions on the additivity of quantum channels. However, in this case we only consider unitary operations and hence we can use a result of King[6] in order to find the optimal schemes.

Theorem 2: *Let P be the single-qubit Pauli encryption scheme, which achieves the optimal approximation ϵ for the given entropy H. Then, the optimal n-qubit independent encryption scheme $R(\rho)$ is the same for both the 2- and the ∞-norm and has the following properties*:

1. $R(\rho)=P^{\otimes n}(\rho)$.
2. $\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_2 \leqslant \sqrt{n}\frac{\epsilon}{2^{n/2}}+\frac{o(\epsilon\sqrt{n})}{2^{n/2}}$.
3. $\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_\infty \leqslant n\frac{\epsilon}{2^n}+\frac{o(n\epsilon)}{2^n}$.

The above-mentioned bounds are tight and hence for any encryption scheme that acts independently on each qubit, $2n-o(n)$ bits of entropy are necessary for approximate encryption.

Finally, in Sec. V we discuss nonindependent n-qubit encryption schemes. In particular, we are interested in the Ambainis-Smith small-bias set based scheme. In Ref. 3, they found an $(\epsilon, n+o(n))$-approximate encryption scheme for the 2-norm. Their scheme uses a deterministically constructed small-bias set of $2n$-bit strings of size $2^{n+o(n)}$, where each string corresponds to a unitary which is a tensor product of n Pauli matrices. The message is encrypted by picking uniformly a unitary from this set. One of the open questions in their paper is whether this scheme is also an $(\epsilon, n+o(n))$-approximate encryption scheme for the ∞-norm. We resolve this by finding an example of an asymptotically optimal small-bias set, for which the encryption scheme of Ambainis-Smith fails in the ∞-norm. However, it is possible that an $(\epsilon, n+o(n))$-approximate encryption scheme for the ∞-norm can be constructed in a different way, for example by using a small-bias set with some extra properties.

II. THE OPTIMAL PAULI ENCRYPTION SCHEME

The input state to our encryption scheme is a quantum bit which can be described by a density matrix ρ, i.e., a Hermitian matrix with unit trace

$$\rho = \tfrac{1}{2}(\mathbb{I} + r_x X + r_y Y + r_z Z), \tag{1}$$

where $(\vec{r}=r_x, r_y, r_z)$ is a unit vector, and the four Pauli matrices are

$$\mathbb{I}=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}, \quad X=\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix}, \quad Y=\begin{bmatrix}0 & -i\\ i & 0\end{bmatrix}, \quad Z=\begin{bmatrix}1 & 0\\ 0 & -1\end{bmatrix}.$$

Let us denote +1 eigenvectors of the matrices X, Y and Z by $|x+\rangle, |y+\rangle$, and $z+\rangle$.

A *Pauli encryption scheme* for single qubits is described by a probability distribution on the four Pauli matrices, i.e., by a probability vector $\mathcal{D}=(w,x,y,z)$, such that the encryption of a qubit ρ is given by

$$\mathcal{E}_{IXYZ}(\rho) = w\rho + xX\rho X + yY\rho Y + zZ\rho Z. \tag{2}$$

Without loss of generality, we can assume the weights $\{w,x,y,z\}$ obey $w \geqslant z \geqslant x \geqslant y \geqslant 0$. The reason for this is that these four unitaries are freely interchangeable by picking a suitable $\rho = U\rho' U^\dagger$. If the original qubit ρ was encoded by $\mathcal{E}(\rho)$, with weights $\{w,x,y,z\}$, we can achieve the same encoding $E'(\rho')$ on the transformed qubit ρ', just with $\{w,x,y,z\}$ permuted.

The classical entropy used by the encryption scheme is the entropy of the probability distribution, i.e., $H(\{p_i\})=-\Sigma_i p_i \log_2 p_i = -w \log w - x \log x - y \log y - z \log z$.

To test how good the encryption scheme is, we want to know how much the encrypted state differs from the completely mixed state in the 2- and the operator norm. For any d-dimensional matrix A, the 2- and operator norm are related to the eigenvalues of the matrix, namely

$$\|A\|_2^2 = \sum_{k=1}^{d} \lambda_k^2, \quad \|A\|_\infty = \max_k |\lambda_k|.$$

Thus, for the operator norm we need to examine the maximum of the absolute value of the eigenvalues of

$$I(\rho) = \mathcal{E}_{IXYZ}(\rho) - \tfrac{1}{2}\mathbb{I}.$$

Note, that since the matrix $I(\rho)$ has trace equal to 0, the two eigenvalues are of the form $\pm\lambda$ and hence, the 2-norm is maximized simultaneously with the operator norm.

A. The maximum eigenvalue of $I(\rho)$

After applying the channel (2) to the density matrix described by (1), we obtain

$$\mathcal{E}_{IXYZ}(\rho) = \tfrac{1}{2}(\mathbb{I} + r'_x X + r'_y Y + r'_z Z),$$

where the new parameters can be easily determined from (2) using the anticommutation relations for Pauli matrices,

$$r'_x = (w + x - z - y)r_x = (2(w + x) - 1)r_x,$$

$$r'_y = (w + y - z - x)r_y = (2(w + y) - 1)r_y,$$

$$r'_z = (w + z - x - y)r_z = (2(w + z) - 1)r_z.$$

This shows that the parameters r_x, r_y, and r_z shrink according to the above-presented relations. The factors can be negative, but because have $w \geqslant z \geqslant x \geqslant y$ and $w+z+x+y=1$, with a little work one can verify that the magnitude of the shrinking factor $|2(w+z)-1|$ in front of r_z is the largest of the three.

Using the geometric description (1) of ρ, we can express the matrix $I(\rho)$ as

$$I(\rho) = \mathcal{E}(\rho) - \tfrac{1}{2}\mathbb{I} = \tfrac{1}{2}(r'_x X + r'_y Y + r'_z Z).$$

Its eigenvalues are then simply

$$\lambda_{I(\rho)} = \pm\tfrac{1}{2}|\vec{r}'|.$$

Our goal is to find the maximum eigenvalue $|\lambda_{I(\rho)}|$ over all states ρ as a function of the probability distribution $\mathcal{D}=(w,z,x,y)$ and then pick the distribution that minimizes it. Already knowing that the shrinking factor in front of r_z is the largest, we can maximize $|\lambda_{I(\rho)}| = \frac{1}{2}(1+|\vec{r}'|)$ by picking ρ with $\vec{r}=(0,0,1)$. This gives us $\vec{r}'=(0,0,2(w+z)-1)$, and

$$\max_\rho |\lambda_{I(\rho)}| = \left|w + z - \tfrac{1}{2}\right|. \tag{3}$$

Note that w and z are the two largest weights and therefore we always have $w+z \geqslant \frac{1}{2}$.

B. The optimal trade-off between approximation and entropy

In Sec. II A, we found an upper bound on the maximum eigenvalue of $I(\rho)$ as a function of the probability distribution used by the Pauli encryption scheme. Note also that Eq. (3) shows that for a perfect encryption the only possible scheme is the one that uses a uniform distribution over the four Pauli matrices.

The natural question is to find the optimal Pauli encryption scheme when we can only use a fixed amount H of classical entropy. Turning the question around, we fix the approximation parameter ϵ and calculate the necessary entropy to achieve it.

Let us fix $\epsilon = \max_\rho |\lambda| = w+z-1/2$. In addition, the condition $w \geqslant z$ implies that $1/4+\epsilon/2 \geqslant z$. Our goal is to minimize the classical entropy needed to achieve approximation ϵ:

$$H(\epsilon) = \min_{\mathcal{D}}(-w \log w - z \log z - x \log x - y \log y).$$

Keeping x, y, and ϵ fixed, the entropy as a function of z is concave, with a maximum at $z=w$. Because $z \leqslant w$, the entropy decreases with decreasing z. Specifically, if $z > x+y$, one can decrease

the entropy by setting $z=x+y$ (and increasing w accordingly, to keep ϵ fixed). Without loss of generality, one can then assume that $z \leqslant x+y$ for the optimal $\mathcal{D}$. Now, let us minimize the entropy as a function of x. It is concave in x, with a maximum at $x=y=(1-w-z)/2$ and possible minima at the end points. Because $x \geqslant y$, we want to pick x as large as possible. Because $x \leqslant z$ and $z \leqslant x+y$, this results in $x=z$. The weights that minimize the entropy for a fixed ϵ thus are (as a function of z)

$$w = 1/2 + \epsilon - z, \quad x = z, \quad y = 1/2 - \epsilon - z.$$

To find the optimal $H(\epsilon)$, one thus needs to minimize

$$H(\epsilon,z) = -\left(\tfrac{1}{2}+\epsilon-z\right)\log\left(\tfrac{1}{2}+\epsilon-z\right) - 2z\log z - \left(\tfrac{1}{2}-\epsilon-z\right)\log\left(\tfrac{1}{2}-\epsilon-z\right)$$

with respect to z, remembering the constraints collected so far ($w \geqslant z \geqslant x \geqslant y \geqslant 0, x+y \geqslant z$):

$$\frac{1}{4}+\frac{\epsilon}{2} \geqslant z \geqslant \frac{1}{4}-\frac{\epsilon}{2}, \tag{4}$$

$$\tfrac{1}{2}-\epsilon \geqslant z. \tag{5}$$

We perform this minimization in the first section of the Appendix and conclude that for $\epsilon \leqslant 1/6$, picking the three larger weights to be equal is the entropy-minimizing strategy. For $1/6 \leqslant \epsilon \leqslant \epsilon_0$, picking only three unitaries, with two of the lower weights equal is the best choice. For $\epsilon_0 \leqslant \epsilon \leqslant 1/2$, it is optimal to pick the three smaller weights to be equal.

Turning the argument around—given entropy H, what is the optimal Pauli encryption scheme? There is a unique way to pick the probability distribution with the given entropy that minimizes the parameter ϵ,

$$(i) H \geqslant \log_2 3 : \mathcal{D} = (z,z,z,1-3z),$$

$$(ii) \log_2 3 \geqslant H \geqslant H_0 : \mathcal{D} = (1-2z,z,z,0),$$

$$(iii) H_0 \geqslant H : \mathcal{D} = (1-3z,z,z,z). \tag{6}$$

Note that the weights are in descending order and that the approximation ϵ is given by the sum of the largest two weights minus $\frac{1}{2}$. Also, one should not expect the optimal distribution parameters to be continuous at H_0. These two ways of picking the weights come from different regions in the parameter space $\{w,z,x,y\}$, and the choice of the optimal distribution is simply a numerical minimum of these two functions. The point H_0 (or equivalently ϵ_0) does not have an obvious special meaning.

III. THE OPTIMALITY OF PAULI ENCRYPTION SCHEMES

In this section we give an elementary constructive proof that the Pauli encryption schemes are no worse than any general encryption scheme. For any encryption scheme $\mathcal{E}(\rho)=\Sigma_k p_k U_k \rho U_k^\dagger$ with arbitrary unitaries and weights, we give a Pauli encryption scheme with weights $\{w,z,x,y\}$ that has lower entropy, and is no worse than $\mathcal{E}(\rho)$. We show this by finding a density matrix ρ_0, for which the maximum eigenvalue of $I(\rho_0)$ is the same as in (3), which is the worst case for the newly found Pauli scheme. Hence, the Pauli encryption scheme of Sec. II is optimal amongst all possible encryption schemes.

After completion of this work, we learned of an alternative proof of optimality of Pauli encryption for a single qubit by Bouda and Ziman.[4] They investigated perfect encryption of a subspace of the Bloch sphere, while we are interested in approximate encryption of the whole Bloch sphere. Their proof uses the Kraus representation of the quantum channel, showing that the representation of a channel using orthogonal matrices requires the least amount of entropy.

Using the fact that every channel can be expressed also as a Pauli channel,[10] we can utilize a clever trick by Nielsen[8] to prove that the weights of this Pauli channel majorize the weights of the original channel. Knowing that the entropy is concave, we can conclude that the Pauli realization of the channel requires the least amount of entropy. The details of this proof are given in the second section of Appendix. Let us now continue with our proof.

Let T be an encryption scheme with distribution $\{w_1, w_2, \ldots, w_N\}$ over N unitaries U_k, where the weights are in decreasing order. We parametrize the unitaries as $U_k = e^{i\alpha_k} e^{i\phi_k(\vec{n}_k \cdot \vec{\sigma})}$, where $(\vec{n}_k = x_k, y_k, z_k)$ and $\vec{\sigma} = (X, Y, Z)$. The phases α_k are not important in our analysis and hence, we denote the parametrization of U_k only as $U(\phi_k, \vec{n}_k)$.

We have the following three cases:

Case 1: $w_1 + w_2 - 1/2 \leqslant 0$. We show that the entropy H of the encryption scheme T is greater or equal to 2, and for $H = 2$, we already know a perfect encoding with four unitaries and $w_k = 1/4$. It is clear that if $w_1 < 1/4$ then the entropy is larger than 2. Let us assume that $w_1 \geqslant 1/4$. From the concavity of the Shannon entropy, we know that the entropy of a distribution that contains two weights (w_k, w_l) with $w_k \geqslant w_l$ decreases if we change them into $(w_k + \Delta, w_l - \Delta)$.

Hence we can decrease the entropy of the initial distribution $\{w_1, w_2, \ldots, w_N\}$ by increasing the weight w_2 to make it equal to $w_2' = 1/2 - w_1$ and decreasing some of the smaller weights. We can further decrease the entropy by making the middle weights all equal, i.e. $\{w_1, w_2', w_2', \ldots, w_2', w_N\}$. Picking $w_1 = x$ fully determines the distribution, giving $w_2' = 1/2 - x$ and $w_N = (4 - N)/2 + (N - 3)x$. The constraints $1/2 \geqslant w_1 \geqslant w_2 \geqslant w_N \geqslant 0$ give us

$$\frac{N-3}{2(N-2)} \geqslant x \geqslant \frac{N-4}{2(N-3)}. \tag{7}$$

The entropy as a function of x is concave (the second derivative is negative) and therefore, we look for the minimum entropy at the end points, given in (7). These end points correspond to choosing the distribution as $\{w_1, w_2, \ldots, w_2\}$ with $w_2 = (1 - w_1)/(N - 1)$. The entropy of such distributions as a function of N is

$$H(N) = -w_1 \log w_1 - (N-1) w_2 \log w_2 = -\frac{N-3}{2(N-2)} \log(N-3) + 1 + \log(N-2).$$

It is easy to see that this function is a monotone, growing function of N with a minimum for $H(4) = 2$. We conclude that any encryption scheme with $n \geqslant 5$ unitaries and $w_1 + w_2 - 1/2 < 0$ uses entropy $H \geqslant 2$ and hence is worse than the perfect encryption scheme with four unitaries.

Case 2: $w_1 + w_2 - 1/2 \geqslant 0$ and $\Sigma_{k=3}^{n} w_k \leqslant 2w_2$. We show that there exists a Pauli encryption scheme that is no worse than T and uses less entropy. Let P be the Pauli scheme that uses the distribution $\{w_1, w_2, w_2, w_3'\}$. This is possible by the constraint $\Sigma_{k=3}^{n} w_k \leqslant 2w_2$ and from the concavity of the entropy, P uses less entropy. We also know from Eq. (3) that for the encryption scheme P,

$$\max_\rho |\lambda_{I(\rho)}| = \left| w_1 + w_2 - \tfrac{1}{2} \right|.$$

Without loss of generality, when encoding an input density matrix ρ with the set of unitaries

$$U(\phi_1, \vec{n}_1), U(\phi_2, \vec{n}_2), U(\phi_3, \vec{n}_3), \ldots, U(\phi_n, \vec{n}_n)$$

one can equivalently analyze the encoding of the density matrix $\rho' = U_1^\dagger \rho U_1$ with a related set of unitaries:

$$\mathbb{I}, U(\phi_2', \vec{n}_2'), U(\phi_3', \vec{n}_3'), \ldots, U(\phi_n', \vec{n}_n').$$

The approximation parameter ϵ of the encoding scheme is basis independent, it is now convenient to pick a basis in which the unitaries are of the form

$$\mathbb{I}, Z_{\alpha_2}, (z_3 Z + x_3 X + y_3 Y)_{\alpha_3}, \ldots, (z_n Z + x_n X + y_n Y)_{\alpha_n},$$

where $x_k^2 + y_k^2 + z_k^2 = 1$, and Z_{α_2} denotes a rotation about the z-axis, namely $Z_{\alpha_2} = e^{-i\alpha_2 Z} = (\cos \alpha_2)\mathbb{I} - i(\sin \alpha_2)Z$.

Let us now check how well the $|z+\rangle$ state is encoded,

$$\rho = |z+\rangle\langle z+| = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}.$$

Note that since ρ is an eigenstate of Z, it commutes with Z_{α_2}. After some algebraic manipulations, we have

$$I(\rho) = \mathcal{E}(\rho) - \frac{1}{2}\mathbb{I} = \begin{bmatrix} \left(w_1 + w_2 - \frac{1}{2}\right) + \left(\sum_{k=3}^n w_k A_k\right) & \left(\sum_{k=3}^n w_k B_k\right)^* \\ \left(\sum_{k=3}^n w_k B_k\right) & -\left(w_1 + w_2 - \frac{1}{2}\right) - \left(\sum_{k=3}^n w_k A_k\right) \end{bmatrix},$$

where

$$A_k = \cos^2 \alpha_k + z_k^2 \sin^2 \alpha_k,$$

$$B_k = (\cos \alpha_k + i z_k \sin \alpha_k)(x_k - i y_k) i \sin \alpha_k.$$

The eigenvalues of $I(\rho)$ are now

$$\lambda_{I(\rho)}^2 = \left[\left(w_1 + w_2 - \frac{1}{2}\right) + \left(\sum_{k=3}^n w_k A_i\right)\right]^2 + \left|\sum_{k=3}^n w_k B_k\right|^2.$$

We know that $w_1 + w_2 - 1/2 \geq 0$ and $A_k \geq 0$. Thus we can bound the eigenvalues as

$$\lambda_{I(\rho)}^2 \geq \left(w_1 + w_2 - \tfrac{1}{2}\right)^2,$$

with w_1 and w_2 the two largest weights. The equality is achieved if we pick our unitaries with $z_k = 0$ and $\cos \alpha_k = 0$, which imply $A_k = B_k = 0$.

This is the same result as in Eq. (3) and hence no matter how we pick the unitaries, the encryption cannot be better than in the Pauli encryption scheme.

Case 3: $w_1 + w_2 - 1/2 \geq 0$ and $\Sigma_{k=3}^n w_k \geq 2w_2$. Since $w_1 + w_2 \geq 1/2$, we conclude that $w_1 \geq 1/4 \geq \frac{1}{3}(w_2 + \Sigma_{k=3}^n w_k)$ and so, it is possible to consider the Pauli scheme P that uses the distribution $\left\{w_1, \frac{1}{3}(w_2 + \Sigma_{k=3}^n w_k), \frac{1}{3}(w_2 + \Sigma_{k=3}^n w_k), \frac{1}{3}(w_2 + \Sigma_{k=3}^n w_k)\right\}$. Moreover, the constraint $\Sigma_{k=3}^n w_k \geq 2w_2$ implies that $\frac{1}{3}(w_2 + \Sigma_{k=3}^n w_k) \geq w_2$ and hence from the concavity of the entropy, P uses less entropy than T. From Eq. (3), we know that for the encryption scheme P,

$$\max_\rho |\lambda_{I(\rho)}| = \left| w_1 + \frac{1}{3}\left(w_2 + \sum_{k=3}^n w_k\right) - \frac{1}{2} \right|. \tag{8}$$

In what follows, we calculate how well the states $|z+\rangle, |x+\rangle$ and $|y+\rangle$ are encrypted by T and prove that at least one of them is encoded worse than in the Pauli scheme P.

We pick the unitaries of T to be

$$\mathbb{I}, Z_{\alpha_2}, (z_3 Z + x_3 X + y_3 Y)_{\alpha_3}, \ldots, (z_n Z + x_n X + y_n Y)_{\alpha_n}.$$

Similar to Case 2, the $|z+\rangle$ state is encoded no better than with

$$\lambda_z^2 \geqslant \left(w_1 + w_2 + \sum_{k=3}^{n} w_k(\cos^2 \alpha_k + \sin^2 \alpha_k \cos^2 \beta_k) - \frac{1}{2} \right)^2,$$

where we named $z_k = \cos \beta_k$, $x_k = \sin \beta_k \cos \gamma_k$, and $y_k = \sin \beta_k \sin \gamma_k$. Let us now check how well the $|x+\rangle$ state is encoded,

$$\rho_x = \frac{1}{2}\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix},$$

$$Z_{\alpha_2} \rho_x Z_{\alpha_2}^\dagger = \frac{1}{2}\begin{bmatrix} 1 & e^{-2i\alpha_2} \\ e^{2i\alpha_2} & 1 \end{bmatrix},$$

$$U_k \rho_x U_k^\dagger = \frac{1}{2}\begin{bmatrix} 1 + C_k & D_k - iE_k \\ D_k + iE_k & 1 - C_k \end{bmatrix},$$

where $D_k = (-1 + 2\cos^2 \alpha_k + 2 \sin^2 \alpha_k \sin^2 \beta_k \cos^2 \gamma_k)$ and C_k, E_k are functions of $\alpha_k, \beta_k, \gamma_k$ which do not affect the bounds. The encoding of ρ_x becomes

$$I(\rho_x) = \mathcal{E}(\rho_x) - \frac{\mathbb{I}}{2} = w_1 \mathbb{I} \rho_x \mathbb{I} + w_2 Z_{\alpha_2} \rho_x Z_{\alpha_2} + \sum_{k \geqslant 3} w_k U_k \rho_x U_i^\dagger - \frac{\mathbb{I}}{2}$$

$$= \frac{1}{2}\begin{bmatrix} \sum_{k \geqslant 3} w_k C_k & F - iG \\ F + iG & -\sum_{k \geqslant 3} w_k C_k \end{bmatrix},$$

where $F = w_1 - w_2 + 2w_2 \cos^2 \alpha_2 + \Sigma_{k \geqslant 3} w_k D_k$ and $G = w_1 \sin 2\alpha + \Sigma_{k \geqslant 3} w_k E_k$. We are ready to bound the eigenvalue:

$$\lambda_x^2 = \frac{1}{4}\left(\sum_{k \geqslant 3} w_k C_k \right)^2 + \frac{1}{4} G^2 + \frac{1}{4} F^2 \geqslant \frac{1}{4} F^2 = \frac{1}{4}\Big(w_1 - w_2 + 2w_2 \cos^2 \alpha_2 + \sum_{k \geqslant 3} w_k (-1 + 2\cos^2 \alpha_k$$
$$+ 2 \sin^2 \alpha_k \sin^2 \beta_k \cos^2 \gamma_k) \Big)^2 = \left(w_1 + w_2 \cos^2 \alpha_2 + \sum_{k \geqslant 3} w_k \cos^2 \alpha_k \right.$$
$$\left. + \sum_{k=3}^{n} w_k \sin^2 \alpha_k \sin^2 \beta_k \cos^2 \gamma_k - \frac{1}{2} \right)^2.$$

Using the same type of computation as above, we encode the $|y+\rangle$ state and obtain a bound for the eigenvalues of $I(\rho_y) = \mathcal{E}(\rho_y) - \mathbb{I}/2$:

$$\lambda_y^2 \geqslant \left(w_1 + w_2 \cos^2 \alpha_2 + \sum_{k \geqslant 3} w_k \cos^2 \alpha_k + \sum_{k=3}^{n} w_k \sin^2 \alpha_k \sin^2 \beta_k \sin^2 \gamma_k - \frac{1}{2} \right)^2.$$

Summing the three inequalities of the eigenvalues, we obtain that

$$|\lambda_x| + |\lambda_y| + |\lambda_z| \geqslant \left(3w_1 + w_2 + \sum_{k=3}^{n} w_k + \left(2 \sum_{k \geqslant 2} w_k \cos^2 \alpha_k \right) - \frac{3}{2} \right) \geqslant \left(3w_1 + w_2 + \sum_{k=3}^{n} w_k - \frac{3}{2} \right),$$

which implies that at least one of the three λ is greater or equal to (8). This means the Pauli encryption scheme P is no worse than T, while using less entropy.

This concludes the proof that Pauli encryption schemes are no worse than general encryption schemes. This also concludes the proof of Theorem 1.

IV. *N*-QUBIT INDEPENDENT ENCRYPTION SCHEMES

In this section we consider n-qubit encryption schemes which are composed of independent single-qubit schemes, each using H amount of classical entropy. For clarity of exposition, we assume that for each qubit we use the same amount of classical entropy. All the results go through in the more general case where for each qubit k we use entropy H_k. By independent we mean that the encryption has the form $R(\rho)=(R_1\otimes\cdots\otimes R_n)(\rho)$.

Theorem 2: *Let P be the single-qubit Pauli encryption scheme, which achieves the optimal approximation* ϵ *for the given entropy H. Then, the optimal n-qubit independent encryption scheme* $R(\rho)$ *is the same for both the 2- and the* ∞*-norm and has the following properties*:

1. $R(\rho)=P^{\otimes n}(\rho)$.
2. $\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_2\leqslant\sqrt{n}\frac{\epsilon}{2^{n/2}}+\frac{o(\epsilon\sqrt{n})}{2^n/2}$.
3. $\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_\infty\leqslant n\frac{\epsilon}{2^n}+\frac{o(n\epsilon)}{2^n}$.

Proof: We first employ a result by King[6] to show that product states are the worst encoded states for independent encryption schemes. King proved that the p-norm of a product of unital channels is multiplicative, i.e., for $p\geqslant 1$,

$$\max_\rho\|R(\rho)\|_p=\prod_{i=1}^n\left(\max_{\xi_i}\|R_i(\xi_i)\|_p\right). \tag{9}$$

A quantum channel Φ is *unital* if it preserves unity, i.e., $\Phi(\mathbb{I})=\mathbb{I}$. The encryption schemes we consider here are unital. The p-norm of a channel R is the maximum of $\|R(\rho)\|_p$ over all input states ρ. Note that the multiplicativity of the p-norms, and hence the additivity of the capacities of nonunital channels is a main open question.[13] This shows that the norm $\|R(\rho)\|_p$ is maximized by a product state $\rho=\xi_1\otimes\cdots\otimes\xi_n$, where ξ_i is the state of the ith qubit. In our encryption schemes we measure the quality of the approximation by the maximum of the norm $\|R(\rho)-\mathbb{I}/2^n\|_p$, for $p=2$ and $p=\infty$. Let λ_k be the eigenvalues of $R(\rho)$; then, the eigenvalues of $R(\rho)-\mathbb{I}/2^n$ are $(\lambda_k-1/2^n)$ and we have

$$\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_2^2=\sum_{k=1}^{2^n}\left(\lambda_k-\frac{1}{2^n}\right)^2=\sum_{k=1}^{2^n}\left(\lambda_k^2-2\frac{\lambda_k}{2^n}+\frac{1}{2^{2n}}\right)=\|R(\rho)\|_2^2-\frac{1}{2^n}, \tag{10}$$

$$\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_\infty=\max_k\left(\lambda_k-\frac{1}{2^n}\right)=\|R(\rho)\|_\infty-\frac{1}{2^n}. \tag{11}$$

It is clear that the norm of $R(\rho)-\mathbb{I}/2^n$ is maximized when the norm of $R(\rho)$ is maximized and, therefore, for any independent encryption scheme the worst encoded state is a product state.

Hence, in order to find the optimal independent encryption scheme, one needs to find the scheme that encrypts product states optimally. The encryption of a product state $R(\xi_1\otimes\cdots\otimes\xi_n)=R_1(\xi_1)\otimes\cdots\otimes R_n(\xi_n)$ is also a product state and the eigenvalues of $R(\xi_1\otimes\cdots\otimes\xi_n)$ are simply products of the eigenvalues of $R_k(\xi_k)$. Without loss of generality, let us now encrypt a state $\xi_1\otimes\rho_{2\ldots n}$ using $R=R_1\otimes R_{2\ldots n}$. The eigenvalues of the single-qubit encryption $R_1(\xi_1)$ can be expressed as $\mu_{1,2}=(1\pm\epsilon_1)/2$ and the eigenvalues of $R_{2\ldots n}(\rho_{2\ldots n})$ as $\nu_{k=1,\ldots,2^{n-1}}=(1+\delta_k)/2^{n-1}$. Hence, the eigenvalues and 2-norm of $R(\xi_1\otimes\rho_{2\ldots n})-\mathbb{I}/2^n$ are

$$\lambda_{i,k}=\mu_i\nu_k-\frac{1}{2^n}=\frac{\delta_k\pm\epsilon_1(1+\delta_k)}{2^n},$$

$$\left\| R(\xi_1 \otimes \rho_{2\ldots n}) - \frac{\mathbb{I}}{2^n} \right\|_2^2 = \sum_{k=1}^{2^{n-1}} \sum_{i=1}^{2} \lambda_{i,k}^2 = \sum_{k=1}^{2^{n-1}} \frac{\delta_k^2 + \epsilon_1^2 (1+\delta_k)^2}{2^{2n}}. \tag{12}$$

The last expression is a growing function of ϵ_1 and, therefore, the optimal n-qubit encryption scheme has to be optimal (i.e., Pauli) on the first qubit, giving the smallest possible upper bound ϵ_1. After going through this procedure for all qubits, we see that the optimal encryption scheme for product states in the 2-norm is the Pauli scheme $P^{\otimes n}$. It is straightforward to obtain the same statement for the ∞-norm using (12). This concludes the proof that the optimal n-qubit independent encryption scheme for both the 2- and the operator norm is the Pauli scheme $P^{\otimes n}(\rho)$.

We now prove tight upper bounds for the quality of the approximation of the Pauli encryption scheme. For the 2-norm, Eq. (9) and induction imply

$$\max_{\rho} \|P^{\otimes n}(\rho)\|_2 = \left(\max_{\xi} \|P(\xi)\|_2 \right)^n.$$

Let us pick ξ to be the worst encoded single-qubit state for P. The eigenvalues of $P(\xi)$ are $(1 \pm \epsilon)/2$ and therefore:

$$\|P^{\otimes n}(\rho)\|_2 \leq \max_{\rho} \|P^{\otimes n}(\rho)\|_2 = \left(\left(\frac{1+\epsilon}{2} \right)^2 + \left(\frac{1-\epsilon}{2} \right)^2 \right)^{n/2} = \left(\frac{1+\epsilon^2}{2} \right)^{n/2}.$$

From Eq. (10), we bound the 2-norm of $P^{\otimes n}(\rho) - \mathbb{I}/2^n$ as

$$\left\| P^{\otimes n}(\rho) - \frac{\mathbb{I}}{2^n} \right\|_2 = \left[\|P^{\otimes n}(\rho)\|_2^2 - \frac{1}{2^n} \right]^{1/2} \leq \left[\left(\frac{1+\epsilon^2}{2} \right)^n - \frac{1}{2^n} \right]^{1/2} = \frac{\epsilon\sqrt{n}}{2^{n/2}} + \frac{o(\epsilon\sqrt{n})}{2^{n/2}}.$$

For the ∞-norm, multiplicativity of norms (9) implies

$$\|P^{\otimes n}(\rho)\|_\infty \leq \max_{\rho} \|P^{\otimes n}(\rho)\|_\infty = \max_{\xi} \|P(\xi)\|_\infty^n = \left(\frac{1+\epsilon}{2} \right)^n,$$

and therefore Eq. (11) gives us

$$\left\| P^{\otimes n}(\rho) - \frac{\mathbb{I}}{2^n} \right\|_\infty = \|P^{\otimes n}(\rho)\|_\infty - \frac{1}{2^n} \leq \left(\frac{1+\epsilon}{2} \right)^n - \frac{1}{2^n} = \frac{n\epsilon}{2^n} + \frac{o(n\epsilon)}{2^n}.$$

Note that both bounds are tight and achieved for product states. □

Since the bounds in Theorem 2 are tight, any good independent encryption scheme requires that the approximation parameter for each single qubit is $\epsilon = O(1/\sqrt{n})$ for the 2-norm and $\epsilon = O(1/n)$ for the ∞-norm. Hence, from Eq. (15) we conclude that the amount of entropy needed for the encryption of n-qubit states is $2n - o(n)$.

V. GENERAL *N*-QUBIT ENCRYPTION SCHEMES

In Sec. IV, we found the optimal way to independently compose single-qubit encryption schemes in order to encrypt n-qubit states. However, one can do better with encryption schemes that do not act independently on each qubit. For example, the encryption scheme in Ref. 5 uniformly picks an n-qubit unitary from a set of $O(n2^n)$ random ones and hence it is not an independent encoding. Note also that it only uses $n + \log n + O(1)$ bits of entropy.

Ambainis and Smith[3] managed to derandomize the encryption scheme of Ref. 5 by explicitly describing the set of unitaries. In particular, they use a set of $2n$-bit strings, where each string corresponds to a product of n Pauli matrices (the bits $\{2j-1, 2j\}$ define the Pauli matrix for the jth qubit). They prove that if the set of strings is a small-bias set of size $O(n2^n)$, then picking a random unitary from this set gives an $(\epsilon, n + 2\log n + 2\log(1/\epsilon))$ encryption scheme in the 2-norm.

A δ-biased set is a set of k-bit strings such that for all possible subsets of bits, the probability over the set that the parity of the subset is 0, is $\left[\frac{1}{2}-\delta,\frac{1}{2}+\delta\right]$. Naor and Naor[7] gave the first such construction with size polynomial in k and $1/\delta$. Alon *et al.*[1] showed a lower bound on the size of a δ-biased set

$$N(k,\delta)\geqslant\Omega\left(\min\left\{\frac{k}{\delta^2\log(1/\delta)},2^k\right\}\right).$$

Since we are interested in encryption schemes which use less than 2n bits of entropy, we only consider δ-biased sets of size $o(2^{2n})$ and hence $\delta=\omega(1/2^n)$. Ambainis and Smith showed the following:

There exists a function $\delta(n)=\omega(1/2^n)$ such that any $O(\delta(n))$-biased set gives rise to a good encryption scheme in the 2-norm and moreover it has size $N=o(2^{2n})$.

In fact, their result holds for any $\delta(n)=1/\alpha(n)2^{n/2}$, where $\alpha(n)$ is any slowly growing function of n (e.g., $\log n$). Note that there are explicit constructions of such small-bias sets of size $N=\mathrm{poly}(\alpha(n),n)2^n$. However, it was an open question whether the same holds for the case of ∞-norm. Here, we resolve this question by providing a counterexample. We show that

For any $\delta(n)=\omega(1/2^n)$ there exists a $O(\delta(n))$-biased set of size $N=o(2^{2n})$ which is not good in the ∞-norm.

Let us, first, compute the norm $\|R(\rho)-\mathbb{I}/2^n\|_\infty$, where R is a Pauli encryption scheme and $\rho=|z+\rangle^{\otimes n}\langle z+|^{\otimes n}$. The density matrix of this state in the z-basis is

$$\rho=\left(\frac{\mathbb{I}+Z}{2}\right)^{\otimes n}=\begin{pmatrix}1&0&\cdots\\0&0&\cdots\\\vdots&\vdots&\ddots\end{pmatrix}.$$

The unitaries in the encryption scheme can be written as $U^k=U_1^k\otimes\cdots\otimes U_n^k$ with $U_i^k\in\{\mathbb{I},X,Y,Z\}$. For each unitary U^k we define a string $\chi^k\in\{0,1\}^n$ with $\chi_i^k=0$ if $U_i^k\in\{\mathbb{I},Z\}$, and $\chi_i^k=1$ if $U_i^k\in\{X,Y\}$. Note that $XZX=YZY=-Z$ and $ZZZ=\mathbb{I}Z\mathbb{I}=Z$, and hence

$$R(\rho)=\frac{1}{N}\sum_{k=1}^{N}\left(\frac{\mathbb{I}+(-1)^{\chi_1^k}Z}{2}\right)\otimes\cdots\otimes\left(\frac{\mathbb{I}+(-1)^{\chi_n^k}Z}{2}\right).$$

The density matrix of the encrypted state is again diagonal in the z-basis and therefore its eigenvalues are simply its diagonal elements. The size of each eigenvalue λ_χ is exactly the number of unitaries U^k with the same corresponding string χ divided by N. Thus,

$$\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_\infty=\max_\chi\left|\lambda_\chi-\frac{1}{2^n}\right|=\max_\chi\left|\frac{1}{N}(\#\textit{of unitaries with the same }\chi)-\frac{1}{2^n}\right|.$$

It is easy to see that starting from any small-bias set we can create a set which is asymptotically as good as the initial one and it has the extra property that it contains at least a $\delta(n)$ fraction of the unitaries with $\chi=0$. We start with a $O(\delta(n))$-biased set of size N and add $\delta(n)N$ unitaries with $\chi=0$ to the initial set. The new set has size $N'=O(N)$ and bias $O(\delta(n))$, and therefore, it is asymptotically as good as the original set. Hence

$$\left\|R(\rho)-\frac{\mathbb{I}}{2^n}\right\|_\infty=\max_\chi\left|\frac{1}{N'}(\#\textit{of unitaries with the same }\chi)-\frac{1}{2^n}\right|\geqslant O(\delta(n))-\frac{1}{2^n}=w\left(\frac{1}{2^n}\right),$$

which means that the encryption scheme R is not good in the ∞-norm. In other words, we show that although a δ-biased set encryption scheme is always good for the 2-norm, this is not the case for the ∞-norm. However, it is still conceivable that one might be able to use δ-biased sets with some extra properties in order to achieve good encryption for the ∞-norm.

ACKNOWLEDGMENTS

We would like to thank Eddie Farhi and Debbie Leung for stimulating discussions, and the journal referees for pointing out Refs. 8 and 10 and for the simplified proofs in Sec. II A and the second section of the Appendix. We thank the referees for pointing out a geometric view of the Pauli encoding in Ref. 9. We also thank the anonymous referee for providing us with another shorter proof. I. K. acknowledges professor Peter w. Shor who has supported his research from his appointment as the holder of the H. A. Morss and H. A. Morss, Jr. Professorship and from NSF CCF-0431787. D.N. gratefully acknowledges support from the National Security Agency (NSA) and Advanced Research and Development Activity (ARDA) under Army Research Office (ARO) Contract No. W911NF-04-1-0216.

APPENDIX

1. Minimization of the entropy $H(\epsilon,z)$

Here, we provide details for the minimization of the function $H(\epsilon,z)$ with respect to z that concludes the proof of the optimal trade-off between approximation and entropy. Recall that

$$H(\epsilon,z) = -\left(\tfrac{1}{2}+\epsilon-z\right)\log\left(\tfrac{1}{2}+\epsilon-z\right) - 2z\log z - \left(\tfrac{1}{2}-\epsilon-z\right)\log\left(\tfrac{1}{2}-\epsilon-z\right)$$

and the constraints are

$$\frac{1}{4}+\frac{\epsilon}{2} \geqslant z \geqslant \frac{1}{4}-\frac{\epsilon}{2}, \tag{A1}$$

$$\frac{1}{2}-\epsilon \geqslant z. \tag{A2}$$

The entropy as a function of z is again a concave function and hence, in order to find the minimum we investigate the end points of the allowed interval for z. There are two cases:

Case 1: for $\epsilon \leqslant 1/6$, the constraint (4) is tighter. The left end point is $\{\frac{1}{4}+\epsilon/2, \frac{1}{4}+\epsilon/2, \frac{1}{4}+\epsilon/2, \frac{1}{4}-3\epsilon/2\}$, giving

$$H_1(\epsilon) = -3\left(\frac{1}{4}+\frac{\epsilon}{2}\right)\log\left(\frac{1}{4}+\frac{\epsilon}{2}\right) - \left(\frac{1}{4}-\frac{3\epsilon}{2}\right)\log\left(\frac{1}{4}-\frac{3\epsilon}{2}\right) = 2 - \frac{6}{\ln 2}\epsilon^2 + O(\epsilon^3).$$

The right end point is $\{\frac{1}{4}+3\epsilon/2, \frac{1}{4}-\epsilon/2, \frac{1}{4}-\epsilon/2, \frac{1}{4}-\epsilon/2\}$, giving

$$H_2(\epsilon) = -\left(\frac{1}{4}+\frac{3\epsilon}{2}\right)\log\left(\frac{1}{4}+\frac{3\epsilon}{2}\right) - 3\left(\frac{1}{4}-\frac{\epsilon}{2}\right)\log\left(\frac{1}{4}-\frac{\epsilon}{2}\right).$$

At $\epsilon=0$, $H_1=H_2=2$. At $\epsilon=1/6$, $H_1 \leqslant H_2$. The derivative of H_2-H_1 is always negative,

$$\frac{\mathrm{d}(H_2-H_1)}{\mathrm{d}\epsilon} = \frac{3}{2}\log\frac{(1-2\epsilon)(1-6\epsilon)}{(1+2\epsilon)(1+6\epsilon)} \leqslant 0,$$

so we conclude that H_1 is the best choice for $\epsilon \leqslant 1/6$. At $\epsilon=1/6$, H_1 achieves the value of $\log_2 3$, which means only three equally weighed unitaries are used.

Case 2: for $\epsilon \geqslant 1/6$, the constraint (5) is tighter, changing the left end point of z to $z=1/2-\epsilon$. This sets $y=0$, which is the regime of using only three unitaries, i.e., the distribution is $\{2\epsilon, \frac{1}{2}-\epsilon, \frac{1}{2}-\epsilon, 0\}$ and the entropy

$$H_3(\epsilon) = -2\epsilon\log 2\epsilon - 2\left(\tfrac{1}{2}-\epsilon\right)\log\left(\tfrac{1}{2}-\epsilon\right).$$

The second derivative of H_3-H_2 is always negative,

$$\frac{\mathrm{d}^2}{\mathrm{d}\epsilon^2}(H_3 - H_2) = -2[\epsilon(1-2\epsilon)(1+6\epsilon)\ln 2]^{-1},$$

so the function $H_3 - H_2$ is concave. That allows for only two points where $H_3 = H_2$. One of them is at $\epsilon = 1/2$, the other is found numerically to be $\epsilon_0 \approx 0.287$ with $H_0 \approx 1.41$. We conclude that for $1/6 \leqslant \epsilon \leqslant \epsilon_0$, the choice of H_3 is optimal, whereas for $\epsilon_0 \leqslant \epsilon \leqslant 1/2$, the best choice is H_2.

2. Another proof of optimality of Pauli encryption schemes

It is known[10] that every unital channel $\mathcal{E}$ with weights $\{w_k\}$ and unitaries U_k is equivalent to a Pauli channel with some other weights $\{x_m\}$, that is

$$\mathcal{E}(\rho) = \sum_k w_k U_k \rho U_k^\dagger, \tag{A3}$$

$$\mathcal{E}(\rho) = x_1\rho + x_2 X\rho X + x_3 Y\rho Y + x_4 Z\rho Z. \tag{A4}$$

This channel is an ϵ-randomizing map. We will prove that the Pauli realization of it has smaller entropy.

Suppose we act with this channel on one half of the Bell state $|\psi^+\rangle = (1/\sqrt{2})(|00\rangle + |11\rangle)$. The first definition of $\mathcal{E}$ will give us

$$\rho' = \mathcal{E}(\rho) = \sum_k w_k (U_k \otimes \mathbb{I})|\psi^+\rangle\langle\psi^+|(U_k \otimes \mathbb{I})^\dagger = \sum_k w_k |\psi_k\rangle\langle\psi_k|, \tag{A5}$$

where $|\psi_k\rangle = (U_k \otimes \mathbb{I})|\psi^+\rangle$ are pure states. On the other hand, the second realization of $\mathcal{E}$ (with Pauli operations) acting on one half of the state $|\psi^+\rangle$ will transform it into a state with density matrix diagonal in the Bell basis, $\rho' = \mathrm{diag}(x_1, x_2, x_3, x_4)$.

In Ref. 8, Nielsen showed that when a density matrix can be expressed as $\rho' = \Sigma_k w_k |\varphi_k\rangle\langle\varphi_k|$, where $|\varphi_k\rangle$ are normalized states, the (ordered) vector of probabilities w_k is majorized by the vector of eigenvalues of ρ', that is $(w_k) \prec \lambda(\rho')$.

In our case, the vector of eigenvalues of ρ' is (x_m), and the majorization $(w_k) \prec (x_m)$ means $\Sigma_{m=1}^n w_m \leqslant \Sigma_{m=1}^n x_m$ for any $n \geqslant 1$. Note that if the length of (w_k) is greater than four, we pad the vector (x_m) by zero entries to make the lengths of the vectors equal.

The entropy function is concave. Because the vector of weights for the Pauli realization (x_k) majorizes the vector of weights for the original realization (w_k), the Pauli realization of the channel has smaller entropy, $S(\{x_k\}) \leqslant S(\{w_k\})$. This means the Pauli channel is the optimal (entropy-wise) realization of any unital channel.

Sheaf-theoretic representation of quantum measure algebras

Elias Zafiris[a)]
University of Athens, Institute of Mathematics, Panepistimiopolis, 15784 Athens, Greece

(Received 5 April 2006; accepted 11 July 2006; published online 15 September 2006)

We construct a sheaf-theoretic representation of quantum probabilistic structures, in terms of covering systems of Boolean measure algebras. These systems coordinatize quantum states by means of Boolean coefficients, interpreted as Boolean localization measures. The representation is based on the existence of a pair of adjoint functors between the category of presheaves of Boolean measure algebras and the category of quantum measure algebras. The sheaf-theoretic semantic transition of quantum structures shifts their physical significance from the orthoposet axiomatization at the level of events, to the sheaf-theoretic gluing conditions at the level of Boolean localization systems. © *2006 American Institute of Physics.*

I. INTRODUCTION

The groundbreaking 1936 paper by von Neumann and Birkhoff entitled "The Logic of Quantum Mechanics" introduced for the first time the notion of logic of a physical theory. For classical theories the appropriate logic is a Boolean algebra; but for quantum theories a non-Boolean logical structure is necessary, which can be an orthocomplemented lattice, or a partial Boolean algebra, or some other structure of a related form. The logic of a physical theory reflects the structure of the propositions describing the behavior of a physical system in the domain of the corresponding theory.

Naturally, the typical mathematical structure associated with logic is an ordered structure. The original quantum logical formulation of quantum theory[1,2] depends in an essential way on the identification of propositions with projection operators on a complex Hilbert space. A nonclassical, non-Boolean logical structure is effectively induced which has its origins in quantum theory. More accurately, the Hilbert space quantum logic has been initially axiomatized as a complete, atomic, orthomodular lattice. Equivalently, it could be cast isomorphic to the partial Boolean algebra of closed subspaces of the Hilbert space associated with the quantum system, or alternatively the partial Boolean algebra of projection operators of the system. On the contrary, the propositional logic of classical mechanics is Boolean logic, meaning that the class of models over which validity and associated semantic notions are defined for the propositions of classical mechanics is the class of Boolean logic structures.

The notion of logic of a physical theory essentially reflects the structure of events being observed in the context of that theory. Associated with such an events structure, there always exists a corresponding probabilistic structure, defined by means of convex sets of measures on that logic. In this sense, the probabilistic structure of a classical system is described by convex sets of probability measures on the Boolean algebra of events of the system, whereas the probabilistic structure of a quantum system is described by convex sets of probability measures on the quantum logic structure of that system. More accurately, in the case of quantum systems, if the quantum events logic is denoted by L, each quantum probability measure, called quantum state, is defined by a mapping;

[a)]Electronic mail: ezafiris@math.uoa.gr

$$p:L \to [0,1]$$

such that the following conditions are satisfied: $p(1)=1$ and $p(x\vee y)=p(x)+p(y)$, if $x\perp y$, where, $x, y \in L$. In the Hilbert space formulation of quantum theory, L denotes the Hilbert space quantum logic, whereas a quantum state is defined by the Hilbert space inner product,

$$\langle \varphi, Px\varphi \rangle,$$

where $x \in L$, φ is a normalized vector in the Hilbert space, and Px is the orthogonal projection operator corresponding to $x \in L$. We remind that there exists a bijective correspondence between elements of L, or equivalently closed subspaces of the Hilbert space, and orthogonal projection operators.

In this work we will develop the idea that in quantum theory, Boolean localization measures can be understood as providing a coordinatization of a quantum probabilistic structure by establishing a principle of contextuality. More concretely, we shall argue that the covering coordinatization process induced by Boolean localization systems, being formed from families of collated compatible local Boolean measures, leads naturally to a contextual description of quantum events, and their associated quantum probabilities of a corresponding global quantum structure, with respect to local Boolean reference frames of measurement.

An intuitive flavor of this insight is provided by Kochen-Specker theorem,[3] according to which the complete comprehension of a quantum mechanical system is impossible, in case that a single system of Boolean devices is only used globally. On the other side, in every concrete measurement context, the set of events that have been actualized in this context form a Boolean algebra. This fact motivates the assertion that a Boolean algebra in the lattice of quantum events serves as a local reference frame, conceived in a precise category-theoretical sense, relative to which a measurement result is being coordinatized. The conceptual meaning of the proposed scheme implies that a quantum logical or quantum probabilistic structure is being construed by means of covering Boolean reference frames, regulated by our measurement localization procedures, which interlock to form a global coherent picture in a nontrivial way. Hence Boolean descriptive contexts are not abandoned once and for all, but instead are used locally, accomplishing the task of providing partial congruent relations with globally non-Boolean objects, the internal structure and functioning of which are being hopefully recovered by the interconnecting machinery governing the local objects. In this work we propose a mathematical scheme for the implementation of the above-mentioned assertion, in relation to quantum measure algebras, based on categorical and sheaf-theoretic methods.[4–8] Contextual category theoretical approaches to quantum structures have also been considered, from a different viewpoint in Refs. 9 and 10, and discussed in Refs. 11 and 12. A remarkable conceptual affinity to the viewpoint of the present paper, although not based on categorical methods, can be found in Refs. 13 and 14. For a general mathematical and philosophical discussion of sheaves, variable sets, and related structures, the interested reader should consult Ref. 15. Recently, there has also appeared in the literature a complete treatment of the dynamical aspects of physical theories, and in particular gauge theories, along topological sheaf-theoretic lines,[16,17] as an application of the framework of Mallios's abstract differential geometry.[18] Finally, it is worth mentioning that a sheaf-theoretic approach to quantum structures has been initiated independently by de Groote in a series of preprints.[19–22] In a general setting, de Groote constructs a theory of presheaves on the quantum lattice of closed subspaces of a complex Hilbert space, by transposing literally and generalizing the corresponding constructions from the lattice of open sets of a topological space to the quantum lattice. In comparison, our approach emphasizes the crucial role of Boolean localization systems in the global formation of quantum structures, and, thus, shifts the focus of relevant constructions to sheaves over suitable Grothendieck topologies on a base category of Boolean subalgebras of global quantum algebras.

The development of the conceptual and technical machinery of localization systems for generating a nontrivial global event and observable structures, as has been recently demonstrated in Refs. 23 and 24, effectuates a transition in the semantics of events and observables from a

set-theoretic to a sheaf-theoretic one. This is a crucial semantic difference that characterizes the present approach in comparison to the vast literature on quantum measurement and quantum logic. In Sec. II we will attempt to motivate physically the necessity of this transition on the basis of appropriate requirements that generalized procedures of physical measurement should respect, referring to the apprehension of physical information in terms of observables.

II. PHYSICAL MOTIVATION AND GENERAL CONCEPTUAL FRAMEWORK

Procedures of physical measurement presuppose, at the fundamental level, the existence of a localization process for extracting information related with the local behavior of a physical system, and, thus, discerning observable events. In a general setting, a localization process is usually being implemented physically by the preparation of suitable local reference domains for measurement of observable attributes. Subsequently, these reference domains instantiate local physical contexts for observation of events, which takes place by means of events-registering measurement devices, operating locally within these contexts. In a broad perspective, it is important to notice that registering an event, which has been observed in the context of a prepared reference domain, is not always equivalent to conferring a numerical identity to it, expressed in terms of some real value corresponding to a physical attribute. On the contrary, the latter is only a limited case of the localization process, when, in particular, it is assumed that all local reference contexts can be contracted to points, meaning that points are considered as unique measures of localization in the physical "continuum."

This is exactly the crucial assumption underlying the employment of the set-theoretic structure of the real line as a model of the physical continuum. The semantics of the physical continuum in the standard interpretation of physical theories is associated with the codomain of valuation of physical attributes. Usually the notion of continuum is tied to the attribute of position, serving as the range of values characterizing this particular attribution. In this sense, the model adopted to represent these values is the real line, specified as a set-theoretic structure of points that are independent and possess the property of infinite distinguishability with absolute precision. The adoption of the set theoretical real line model is usually justified on the basis of arguments, stipulating that quantities admissible as measured results must be real numbers, since the resort to real numbers has the advantage of securing our empirical access to the external world. Essentially, the basic semantic assumption underlying the employment of the set theoretic structure of the real line for the modeling of the localization structure of the physical continuum is that real number representability constitutes our global form of observation.

The success of this localizing philosophy for classical theories is due to the association of the notion of physical continuum with the attribute of position and the theoretical fact that all classical observables can be determined precisely and simultaneously at the unique measure of localization of that attribute, viz., at a spatial point, parametrized by the field of real numbers. Nevertheless, the major foundational difference between classical and quantum physical systems from the perspective of the modeling scheme by observables is a consequence of a single principle that can be termed principle of simultaneous observability. According to this, in the classical description of physical systems all their observables are theoretically compatible, or else they can be simultaneously specified in a single local measurement context. On the other side, the quantum description of physical systems is based on the assertion of incompatibility of all theoretical observables in a single local measurement context, and as a consequence quantum-theoretically the simultaneous specification of all observables is not possible. The conceptual roots of the violation of the principle of simultaneous observability in the quantum regime is tied with Heisenberg's uncertainty principle and Bohr's principle of complementarity of physical descriptions.

In this train of thought, a fruitful fundamental strategy implied by quantum theory would ideally fulfill the following objectives: First, it should disassociate the physical meaning of the notion of localization from its restricted spatial connotation reference context. Second, it should allow the functional dependence of observables on generalized localization measures induced by the preparation of suitably structured domains of measurement, not necessarily based on the existence of an underlying set-theoretic structure of points on the real line. Regarding the imple-

mentation of this strategy, it should be essential to interpret any local observable as a relational information algebraic number-like object with respect to the corresponding local context of measurement. At a further stage, it should be necessary to establish appropriate compatibility conditions for gluing the information content of local observables globally. Mathematically, the implementation of this strategy is being precisely captured by the concept of a sheaf-theoretic fibered structure, explained in the sequel. The primary physical motivation of this paper concerns the possibility of constructing explicitly an appropriate localization process suited to quantum physical observation, along the objectives of the above-stated strategy, and study in particular its consequences referring to the interpretation of quantum probabilistic structures. For this purpose, the focus is shifted from point-set to topological localization models of partially ordered global quantum event structures.

Before embarking on a qualitative discussion of the relevance of the concept of sheaf for this endeavor, it is initially instructive to clarify that the functioning of a localization process amounts to filtering the information content of a global structure of partially ordered physical events, through a concretely specified structure of observation domains determined by a homologous operational physical procedure. The latter is defined by the requirement that the reference contexts of measurement, together with their structural transformations, should form a mathematical category. Thus, the localization process should be implemented in terms of an action of the category of reference contexts on a set-theoretic global structure of physical events. The latter is then partitioned into sorts parametrized by the objects of the category of contexts. In this sense, the functioning of a localization process can be represented by means of a fibered construct, understood geometrically as a presheaf, or equivalently, as a variable set over the base category of contexts. The fibers of this construct may be thought of, in analogy to the case of the action of a group on a set of points, as the "generalized orbits" of the action of the category of contexts. The notion of functional dependence incorporated in this action, forces the ordered structure of physical events to fiber over the base category of reference contexts. Most important, the presheaf fibered construct incorporates the physical requirement of uniformity of observed events. More concretely, for any two events observed over the same domain of measurement, the structure of all reference contexts that relate to the first cannot be distinguished in any possible way from the structure of contexts relating to the second. Consequently, all the events observed within any particular reference context, implementing a localization process, are uniformly equivalent to each other. Equivalently stated, the compatibility of the localization process with the physical requirement of uniformity, demands that the relation of (partial) order in a global set-theoretic universe of events is induced by lifting appropriately a structured family of arrows from the base category of reference contexts to the fibers. It is precisely that condition of compatibility being formalized by the construction of the category of elements of the corresponding presheaf.

The disassociation of the physical meaning of a localization process from its restricted spatial connotation reference context requires, first of all, the abstraction of the constitutive properties of localization in appropriate categorical terms, and then, the effectuation of these properties for the definition of localization systems of global event structures. Regarding these objectives, the sought abstraction is being implemented by means of covering devices on the base category of reference contexts, called in categorical terminology covering sieves. The constitutive properties of localization being abstracted categorically in terms of sieves, being qualified as covering ones, satisfy the following basic requirements:

(i) The covering sieves are covariant under pullback operations, viz. they are stable under change of a base reference context. Most important, the stability conditions are functorial. This requirement means, in particular, that the intersection of covering sieves is also a covering sieve, for each reference context in the base category.
(ii) The covering sieves are transitive, such that, intuitively stated, covering sieves of figures of a context in covering sieves of this context are also covering sieves of the context themselves.

From a physical perspective, the consideration of covering sieves as generalized measures of localization of events in a global partially ordered structure of events gives rise to localization systems of the latter. More specifically, the operation which assigns to each reference context of the base category a collection of covering sieves satisfying the closure conditions stated previously gives rise to the notion of a Grothendieck topology on the category of contexts. The construction of a suitable Grothendieck topology on the base category of contexts is significant for the following reasons: First, it elucidates precisely and unquestionably the conception of local in a categorical measurement environment, such that this conception becomes detached from its restricted spatial connotation, and thus, expressed exclusively in relational information terms. Second, it permits the collation of local observable information into global ones by utilization of the notion of sheaf for that Grothendieck topology. The definition of sheaf essentially expresses gluing conditions, providing the means for studying the global consequences of locally defined properties. The transition from locally defined observable information into global ones is being effectuated via a compatible family of elements over a localization system of a global event structure. A sheaf assigns a set of elements to each reference context of a localization system, representing local observable data colected within that context. A choice of elements from these sets, one for each context, forms a compatible family if the choice respects the mappings induced by the restriction functions among contexts, and moreover, if the elements chosen agree whenever two contexts of the localization system overlap. If such a locally compatible choice induces a unique choice for a global event structure being localized, viz. a global choice, then the condition for being a sheaf is satisfied. We note that, in general, there will be more locally defined or partial choices than globally defined ones, since not all partial choices need be extendible to global ones, but a compatible family of partial choices uniquely extends to a global one, or in other words, any presheaf uniquely defines a sheaf.

Having explained in detail the physical motivation, as well as the key conceptual prerequisites and ideas underlying the modeling of localization processes for acquisition and efficient handling of observable information related with the behavior of physical systems in a broad perspective, in the sequel, we focus our attention on the implementation of a concrete localization process of quantum probabilistic structures effectuated by Boolean localization systems of quantum measurement.

III. CATEGORICAL PROBABILISTIC STRUCTURES

According to the category-theoretic approach to each kind of mathematical structure, there corresponds a *category* whose objects have that structure, and whose morphisms preserve it. Moreover to any natural construction on structures of one kind, yielding structures of another kind, there corresponds a *functor* from the category of the first kind to the category of the second.

A *classical event structure* is a small category, denoted by $\mathcal{B}$, which is called the category of Boolean event algebras. Its objects are Boolean algebras of events, and its arrows are Boolean algebraic morphisms.

A *quantum event structure* is a small category, denoted by $\mathcal{L}$, which is called the category of quantum event algebras.

Its objects, denoted by L, are quantum algebras of events, that is orthomodular σ-orthoposets. More concretely, each object L in $\mathcal{L}$ is considered as a partially ordered set of quantum events, endowed with a maximal element 1, and with an operation of orthocomplementation $[-]^*: L \to L$, which satisfy, for all $l \in L$, the following conditions: (a) $l \leqslant 1$, (b) $l^{**} = l$, (c) $l \vee l^* = 1$, (d) $l \leq \acute{l} \Rightarrow \acute{l}^* \leq l^*$, (e) $l \perp \acute{l} \Rightarrow l \vee \acute{l} \in L$, (f) for $l, \acute{l} \in L$, $l \leqslant \acute{l}$ implies that l and $\acute{l}$ are compatible, where $0 := 1^*$, $l \perp \acute{l} := l \leqslant \acute{l}^*$, and the operations of meet $\wedge$ and join $\vee$ are defined as usually. We also recall that $l, \acute{l} \in L$ are compatible if the sublattice generated by $\{l, l^*, \acute{l}, \acute{l}^*\}$ is a Boolean algebra, namely if it is a Boolean sublattice. The σ-completeness condition, namely that the join of countable families of pairwise orthogonal events must exist, is also required in order to have a well-defined theory of observables over L.

Its arrows are quantum algebraic morphisms, that is maps $L \xrightarrow{H} K$, which satisfy, for all $k \in K$, the following conditions: (a) $H(1)=1$, (b) $H(k^*)=[H(k)]^*$, (c) $k \leq \acute{k} \Rightarrow H(k) \leq H(\acute{k})$, (d) $k \perp \acute{k} \Rightarrow H(k \vee \acute{k}) \leq H(k) \vee H(\acute{k})$.

Next we introduce the categories associated with probabilistic structures.

A *quantum convex measure structure* is a small category, denoted by Σ, which is called the category of convex sets of quantum probability measures.

Its objects are the convex sets Θ of quantum states or quantum probability measures on a quantum event algebra L. Each quantum probability measure, or quantum state, is defined by a mapping;

$$p: L \to [0,1]$$

such that the following conditions are satisfied: $p(1)=1$ and $p(x \vee y)=p(x)+p(y)$, if $x \perp y$, where x, $y \in L$. On each set Θ, there is defined the operation of convex mixing by means of the mappings,

$$\sigma^n: E^n \times \Theta^n \to \Theta$$

for each natural number n, such that

$$\sigma^n(\underline{e},\underline{p}) := \sum_i e_i p_i,$$

where $\underline{e}=\langle e_1, \ldots, e_n \rangle$, is a vector of real numbers, with $e_i \geq 0$ and $\Sigma_i e_i = 1$, and also, $\underline{p}=\langle p_1 \ldots p_n \rangle$ is a vector of quantum states. The unique quantum state $\Sigma_i e_i p_i$ is called the convex mixture of $\underline{p}$. The convex mixture of $\underline{p}$, evaluated at $x \in L$, is the superposition of probabilities $\Sigma_i e_i p_i(x)$. For a quantum state p_i and an event $x \in L$, $p_i(x)$ denotes the probability of occurrence of x in state p_i.

The arrows in the category Σ are morphisms of convex sets of probability measures, that is morphisms of sets $[\,]^h: \Theta \to \Phi$ which commute with the operation of convex mixing, that is,

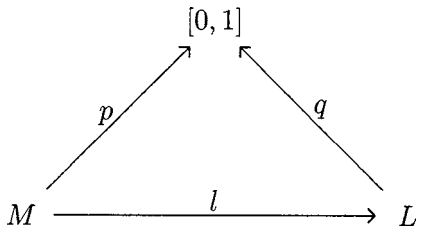
$$[\sigma^n(\underline{e},\underline{p})]^h = \sigma^n(\underline{e},\underline{p}^h).$$

We note that Θ and Φ are regarded as defined over the same quantum event algebra L, otherwise we have to take into account the quantum algebraic morphisms as well.

Using the information encoded in the categories of quantum event algebras $\mathcal{L}$, and quantum probabilistic structures Σ, it is possible to construct a new category, called the category of quantum probabilities, constructed as a category fibered in groupoids over the category of quantum event algebras $\mathcal{L}$, as follows:

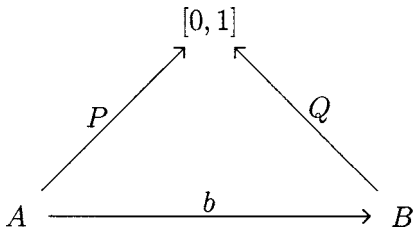
A *quantum probabilistic structure* is a small category, denoted by $\mathcal{Q}$, which is called the category of quantum states or quantum probabilities.

Its objects are the quantum measure algebras $\langle M,p \rangle := {}^pM$, where M is a quantum event algebra and p is a quantum probability measure on M, defined by the measurable mapping $p: M \to [0,1]$. The arrows in $\mathcal{Q}$, denoted by ${}^pM \xrightarrow{l} {}^qL$, are commutative triangles, or equivalently, are those quantum logic morphisms $M \xrightarrow{l} L$ in $\mathcal{L}$, such that $p=q \circ l$ in the diagram to follow is again a quantum probability measure.



Correspondingly, a *Boolean probabilistic structure* is a small category, denoted by $\mathcal{C}$, which is called the category of Boolean probability measures, or classical states.

Its objects are the Boolean measure algebras $\langle A,P\rangle := {}^{P}A$, where A is a Boolean event algebra and P is a Boolean probability measure on M, defined by the measurable mapping $P:A\to[0,1]$. The arrows in $\mathcal{C}$, denoted by ${}^{P}A\xrightarrow[b]{}{}^{Q}B$, are commutative triangles, or equivalently, are those Boolean logic morphisms $A\to B$ in $\mathcal{B}$, such that $P=Q\circ b$ in the diagram to follow is again a classical state.



IV. PRESHEAF AND COEFFICIENTS BOOLEAN FUNCTORS

A. Presheaves of Boolean probability measures

If $\mathcal{C}^{\mathrm{op}}$ is the opposite category of $\mathcal{C}$, then $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$ denotes the functor category of presheaves on Boolean measure algebras. Its objects are all functors $\mathbf{X}:\mathcal{C}^{\mathrm{op}}\to\mathbf{Sets}$, and its morphisms are all natural transformations between such functors. Each object $\mathbf{X}$ in this category is a contravariant set-valued functor on $\mathcal{C}$, called a presheaf of Boolean probability measures on $\mathcal{C}$.

A functor $\mathbf{X}$ is a structure-preserving morphism of these categories, that it preserves composition and identities. A functor in the category $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$ can be understood as a contravariant translation of the language of $\mathcal{C}$ into that of **Sets**. Given another such translation (contravariant functor) $\acute{\mathbf{X}}$ of $\mathcal{C}$ into **Sets** we need to compare them. This can be done by giving, for each object ${}^{P}A$ in $\mathcal{C}$ a transformation $\tau_{{}^{P}A}:\mathbf{X}({}^{P}A)\to\acute{\mathbf{X}}({}^{P}A)$ which compares the two images of the object ${}^{P}A$. Not any morphism will do, however, as it would be necessary for the construction to be parametric in ${}^{P}A$, rather than ad hoc. Since ${}^{P}A$ is an object in $\mathcal{C}$ while $\mathbf{X}({}^{P}A)$ is in **Sets** we cannot link them by a morphism. Rather the goal is that the transformation should respect the morphisms of $\mathcal{C}$, or in other words the interpretations of $v:{}^{P}A\to{}^{Q}B$ by $\mathbf{X}$ and $\acute{\mathbf{X}}$ should be compatible with the transformation under τ. Then τ is a natural transformation in the category of presheaves $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$.

For each Boolean measure algebra ${}^{P}A$ of $\mathcal{C}$, $\mathbf{X}({}^{P}A)$ is a set, and for each arrow $f:{}^{Q}B\to{}^{P}A$, $\mathbf{X}(f):\mathbf{X}({}^{P}A)\to\mathbf{X}({}^{Q}B)$ is a set function. If $\mathbf{X}$ is a presheaf on $\mathcal{C}$ and $x\in\mathbf{X}(O)$, the value $\mathbf{X}(f)(x)$ for an arrow $f:{}^{Q}B\to{}^{P}A$ in $\mathcal{C}$ is called the restriction of x along f and is denoted by $\mathbf{X}(f)(x)=x\cdot f$.

Each object ${}^{P}A$ of $\mathcal{C}$ gives rise to a contravariant Hom-functor $y[{}^{P}A]:=\mathrm{Hom}_{\mathcal{C}}(-,{}^{P}A)$. This functor defines a presheaf on $\mathcal{C}$. Its action on an object ${}^{Q}B$ of $\mathcal{C}$ is given by

$$y[{}^{P}A]({}^{Q}B) := \mathrm{Hom}_{\mathcal{C}}({}^{Q}B,{}^{P}A)$$

whereas its action on a morphism ${}^{R}C\xrightarrow{w}{}^{Q}B$, for $v:{}^{Q}B\to{}^{P}A$ is given by

$$y[{}^{P}A](w):\quad \mathrm{Hom}_{\mathcal{C}}({}^{Q}B,{}^{P}A)\to\mathrm{Hom}_{\mathcal{C}}({}^{R}C,{}^{P}A),$$

$$y[{}^{P}A](w)(v)=v\circ w.$$

Furthermore y can be made into a functor from $\mathcal{C}$ to the contravariant functors on $\mathcal{C}$,

$$y:\quad \mathcal{C}\to\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}},$$

such that ${}^{P}A\mapsto\mathrm{Hom}_{\mathcal{C}}(-,{}^{P}A)$. This is an embedding, called the Yoneda embedding,[5] and it is a full and faithful functor.

The functor category of presheaves on Boolean measure algebras $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$, provides an instantiation of a structure known as topos.[6–8] A topos exemplifies a well-defined notion of a categorical universe of variable sets. It can be conceived as a local mathematical framework corresponding to a generalized model of set theory or as a generalized space. Moreover it provides a natural example of a many-valued truth structure, which remarkably is not ad hoc, but reflects genuine constraints of the surrounding universe.

B. Boolean measure algebras fibrations

Since $\mathcal{C}$ is a small category, there is a set consisting of all the elements of all the sets $\mathbf{X}({}^{P}A)$, and similarly there is a set consisting of all the functions $\mathbf{X}(f)$. This observation regarding $\mathbf{X}:\mathcal{C}^{\mathrm{op}}\rightarrow\mathbf{Sets}$ permits us to take the disjoint union of all the sets of the form $\mathbf{X}({}^{P}A)$ for all objects ${}^{P}A$ of $\mathcal{C}$. The elements of this disjoint union can be represented as pairs $({}^{P}A,\chi)$ for all objects ${}^{P}A$ of $\mathcal{C}$ and elements $\chi\in\mathbf{X}({}^{P}A)$. Thus the disjoint union of sets is made by labeling the elements. Now we can construct a category whose set of objects is the disjoint union just mentioned. This structure is called the category of elements of the presheaf $\mathbf{X}$, denoted by $\int(\mathbf{X},\mathcal{C})$. Its objects are all pairs $({}^{P}A,\chi)$, and its morphisms $({}^{R}C,\acute{\chi})\rightarrow({}^{P}A,\chi)$ are those morphisms $u:{}^{R}C\rightarrow{}^{P}A$ of $\mathcal{C}$ for which $\chi\cdot u=\acute{\chi}$. Projection on the second coordinate of $\int(\mathbf{X},\mathcal{C})$, defines a functor $\int_{\mathbf{X}}:\int(\mathbf{X},\mathcal{C})\rightarrow\mathcal{C}$. $\int(\mathbf{X},\mathcal{C})$ together with the projection functor $\int_{\mathbf{X}}$ is equivalent to the discrete fibration induced by $\mathbf{X}$, and $\mathcal{C}$ is the base category of the fibration. We note that the fibration is discrete because the fibers are categories in which the only arrows are identity arrows. If ${}^{P}A$ is a Boolean measure algebra of $\mathcal{C}$, the inverse image under $\int_{\mathbf{X}}$ of ${}^{P}A$ is simply the set $\mathbf{X}({}^{P}A)$, although its elements are written as pairs so as to form a disjoint union. The instantiation of the fibration induced by $\mathbf{X}$ is an application of the general Grothendieck construction.[8]

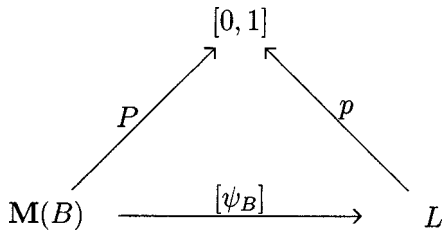
$$\begin{array}{ccc} \int(\mathbf{X},\mathcal{C}) & & \\ \Big\downarrow{\scriptstyle \int_{\mathbf{X}}} & & \\ \mathcal{C} & \xrightarrow{\ \mathbf{X}\ } & \mathbf{Sets} \end{array}$$

The split discrete fibration induced by $\mathbf{X}$, where $\mathcal{C}$ is the base category of the fibration, provides a well-defined notion of a uniform homologous fibered structure in the following sense: First, by the arrows specification defined in the category of elements of $\mathbf{X}$, any element χ, determined over the measure algebra ${}^{P}A$, is homologously related with any other element $\acute{\chi}$ over the measure algebra ${}^{R}C$, and so on, by variation over all the contexts of the base category. Second, all the elements χ of $\mathbf{X}$, of the same sort ${}^{P}A$, viz. determined over the same measure algebra ${}^{P}A$, are uniformly equivalent to each other, since all the arrows in $\int(\mathbf{X},\mathcal{C})$ are induced by lifting arrows from the base category $\mathcal{C}$.

C. Functor of Boolean measure coefficients

We define a modeling Boolean coefficients functor, $\mathbf{M}:\mathcal{C}\rightarrow\mathcal{Q}$, which assigns to Boolean measure algebras in $\mathcal{C}$, that instantiates a model category, the underlying quantum measure algebras from $\mathcal{Q}$, and to Boolean measurable morphisms the underlying quantum measurable morphisms. Hence $\mathbf{M}$ acts as a forgetful functor, forgetting the extra Boolean structure of $\mathcal{C}$.

Equivalently the Boolean coefficients functor can be characterized as $\mathbf{M}:\mathcal{B}\rightarrow\mathcal{L}$, which assigns to Boolean event algebras in $\mathcal{B}$ the underlying quantum event algebras from $\mathcal{L}$, and to Boolean morphisms the underlying quantum algebraic morphisms, such that the following diagram commutes:



V. ADJOINT FUNCTORIAL RELATION

We consider the category of quantum measure algebras $\mathcal{Q}$ and the modeling functor **M**, and we define the functor **R** from $\mathcal{Q}$ to the topos of presheaves on Boolean measure algebras $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$, given by

$$\mathbf{R}({}^{p}L):{}^{P}A \mapsto \mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}({}^{P}A),{}^{p}L).$$

A natural transformation τ in the topos of presheaves on Boolean measure algebras $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$ between **X** and $\mathbf{R}({}^{p}L)$, $\tau:\mathbf{X}\to\mathbf{R}({}^{p}L)$ is a family $\tau_{{}^{p}A}$ indexed by Boolean measure algebras ${}^{P}A$ of $\mathcal{C}$ for which each $\tau_{{}^{p}A}$ is a map

$$\tau_{{}^{p}A}:\mathbf{X}({}^{P}A) \to \mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}({}^{P}A),{}^{p}L)$$

of sets, such that the diagram of sets to follow, commutes for each Boolean morphism $u:{}^{R}\mathcal{C} \to {}^{P}A$ of $\mathcal{C}$,

$$\begin{array}{ccc} \mathbf{X}({}^{P}A) & \xrightarrow{\tau_{{}^{P}A}} & Hom_{\mathcal{Q}}(\mathbf{M}({}^{P}A),{}^{p}L) \\ \Big\downarrow{\scriptstyle \mathbf{X}(u)} & & \Big\downarrow{\scriptstyle \mathbf{M}(u)} \\ \mathbf{X}({}^{R}C) & \xrightarrow{\tau_{{}^{R}C}} & Hom_{\mathcal{Q}}(\mathbf{M}({}^{R}C),{}^{p}L) \end{array}$$

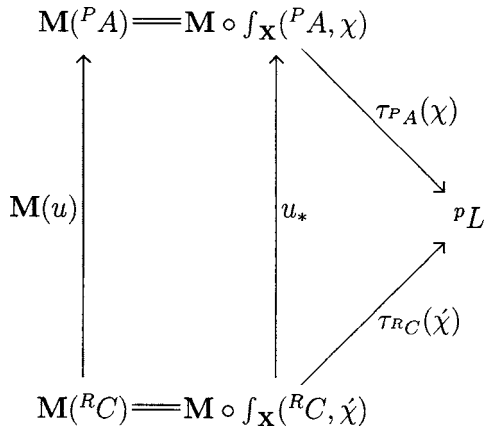
If we make use of the category of elements of the Boolean measure algebras-variable set X, being an object in the topos of presheaves $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$, then the map $\tau_{{}^{p}A}$, defined earlier, can be characterized as

$$\tau_{{}^{p}A}:({}^{P}A,\chi) \to \mathrm{Hom}_{\mathcal{Q}}\left(\mathbf{M}\circ\int_{\mathbf{X}}({}^{P}A,\chi),{}^{p}L\right).$$

Equivalently such a τ can be seen as a family of arrows of $\mathcal{Q}$ which is being indexed by objects $({}^{P}A,\chi)$ of the category of elements of the presheaf of Boolean measure algebras **X**, namely

$$\{\tau_{{}^{p}A}(\chi):\mathbf{M}({}^{P}A) \to {}^{p}L\}_{({}^{P}A,\chi)}.$$

From the perspective of the category of elements of **X**, the condition of the commutativity of the above-presented diagram is equivalent to the condition that for each Boolean morphism $u:{}^{R}\mathcal{C} \to {}^{P}A$ of $\mathcal{C}$, the following diagram commutes.



From the diagram above-presented, we conclude that the arrows $\tau^{P}{}_{A}(\chi)$ form a cocone from the functor $\mathbf{M}\circ\int_{\mathbf{X}}$ to the quantum measure algebra ${}^{P}L$. Making use of the definition of the colimit, we conclude that each such cocone emerges by the composition of the colimiting cocone with a unique arrow from the colimit $\mathbf{LX}$ to the quantum measure algebra object ${}^{P}L$. In other words, there is a bijection which is natural in $\mathbf{X}$ and ${}^{P}L$,

$$\mathrm{Nat}(\mathbf{X},\mathbf{R}({}^{P}L)) \cong \mathrm{Hom}_{\mathcal{Q}}(\mathbf{LX},{}^{P}L).$$

From the above-noted bijection we are driven to the conclusion that the functor $\mathbf{R}$ from $\mathcal{Q}$ to the topos of presheaves $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$, given by

$$\mathbf{R}({}^{P}L):{}^{P}A \mapsto \mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}({}^{P}A),{}^{P}L),$$

has a left adjoint $\mathbf{L}:\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}\to\mathcal{Q}$, which is defined for each presheaf of Boolean measure algebras $\mathbf{X}$ in $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$ as the colimit

$$\mathbf{L}(\mathbf{X}) = \mathrm{Colim}\left\{\int (\mathbf{X},\mathcal{C}) \xrightarrow{\int_{\mathbf{X}}} \mathcal{C} \xrightarrow{\mathbf{M}} \mathcal{Q}\right\}.$$

Consequently there is a *pair of adjoint functors* $\mathbf{L}\dashv\mathbf{R}$ as follows:

$$\mathbf{L}:\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}} \leftrightarrows \mathcal{Q}:\mathbf{R}.$$

Thus we have constructed an adjunction which consists of the functors $\mathbf{L}$ and $\mathbf{R}$, called left and right adjoints with respect to each other, respectively, as well as the natural bijection:

$$\begin{array}{ccc} Nat(\mathbf{X},\mathbf{R}({}^{p}L)) & \xrightarrow{\ \mathbf{r}\ } & Hom_{\mathcal{Q}}(\mathbf{LX},{}^{p}L) \\ \| & & \| \\ Nat(\mathbf{X},\mathbf{R}({}^{p}L)) & \xleftarrow{\ \mathbf{l}\ } & Hom_{\mathcal{Q}}(\mathbf{LX},{}^{p}L) \end{array}$$

$$\mathrm{Nat}(\mathbf{X},\mathbf{R}({}^{p}L)) \cong \mathrm{Hom}_{\mathcal{Q}}(\mathbf{LX},{}^{p}L).$$

In the above-described adjunction, between the topos of presheaves of Boolean measure algebras and the category of quantum measure algebras, the map $\mathbf{r}$ is called the right adjoint operator and the map $\mathbf{l}$ the left adjoint operator.

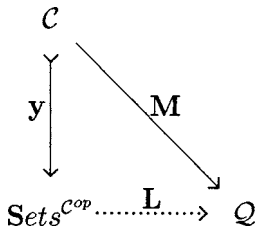
If in the bijection defining the adjunction we use as $\mathbf{X}$ the representable presheaf of the topos of Boolean measure algebras $\mathbf{y}[{}^{P}A]$, it takes the form:

$$\mathrm{Nat}(\mathbf{y}[{}^{P}A],\mathbf{R}({}^{p}L)) \cong \mathrm{Hom}_{\mathcal{Q}}(\mathbf{Ly}[{}^{P}A],{}^{p}L).$$

We note that when $\mathbf{X}=\mathbf{y}[{}^{P}A]$ is representable, then the corresponding category of elements $\int(\mathbf{y}[{}^{P}A],\mathcal{C})$ has a terminal object, namely the element $1:{}^{P}A\to{}^{P}A$ of $\mathbf{y}[{}^{P}A]({}^{P}A)$. Therefore the colimit of the composite $\mathbf{M}\circ\int_{\mathbf{y}[{}^{P}A]}$ is going to be just the value of $\mathbf{M}\circ\int_{\mathbf{y}[{}^{P}A]}$ on the terminal object. Thus we have

$$\mathbf{Ly}[{}^{P}A]({}^{P}A) \cong \mathbf{M}\circ\int_{\mathbf{y}[{}^{P}A]}({}^{P}A,1) = \mathbf{M}({}^{P}A).$$

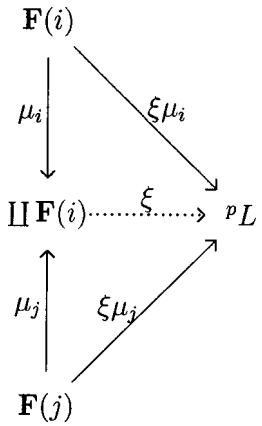
Thus we can characterize $\mathbf{M}({}^{P}A)$ as the colimit of the representable presheaf on the category of Boolean measure algebras,



VI. TENSOR PRODUCT REPRESENTATION OF THE COLIMIT

The content of the adjunction between the topos of presheaves of Boolean measure algebras and the category of quantum measure algebras can be analyzed if we make use of the categorical construction of the above-defined colimit, as a coequalizer of a coproduct. We consider the colimit of any functor $\mathbf{F}:\mathcal{I}\to\mathcal{Q}$ from some index category $\mathcal{I}$ to $\mathcal{Q}$. Let $\mu_i:\mathbf{F}(i)\to\amalg_i\mathbf{F}(i)$, $i\in I$, be the injections into the coproduct. A morphism from this coproduct, $\xi:\amalg_i\mathbf{F}(i)\to{}^{p}L$, is determined uniquely by the set of its components $\xi_i=\xi\mu_i$. These components ξ_i are going to form a cocone over $\mathbf{F}$ to the quantum measure algebra vertex ${}^{p}L$ only when for all arrows $v:i\to j$ of the index category $\mathcal{I}$ the following conditions are satisfied:

$$(\xi\mu_j)\mathbf{F}(v) = \xi\mu_i$$

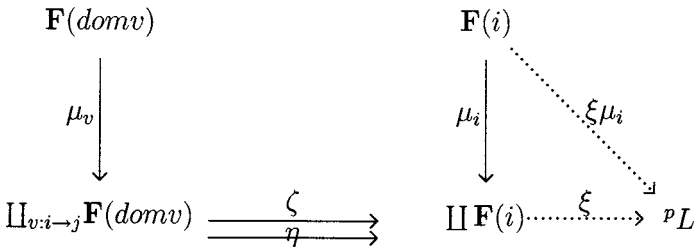


So we consider all $\mathbf{F}(\mathrm{dom}\,v)$ for all arrows v with its injections ν_v and obtain their coproduct $\amalg_{v:i\to j}\mathbf{F}(\mathrm{dom}\,v)$. Next we construct two arrows ζ and η, defined in terms of the injections ν_v and μ_i, for each $v:i\to j$ by the conditions

$$\zeta\nu_v = \mu_i,$$

$$\eta\nu_v = \mu_j \mathbf{F}(v)$$

as well as their coequalizer ξ;



The coequalizer condition $\xi\zeta = \xi\eta$ tells us that the arrows $\xi\mu_i$ form a cocone over $\mathbf{F}$ to the quantum measure algebra vertex ${}^{P}L$. We further note that since ξ is the coequalizer of the arrows ζ and η this cocone is the colimiting cocone for the functor $\mathbf{F}: I \to \mathcal{Q}$ from some index category $\mathcal{I}$ to $\mathcal{Q}$. Hence the colimit of the functor $\mathbf{F}$ can be constructed as a coequalizer of coproduct according to the following diagram:

$$\coprod_{v:i\to j} \mathbf{F}(domv) \underset{\eta}{\overset{\zeta}{\rightrightarrows}} \coprod \mathbf{F}(i) \xrightarrow{\xi} Colim\mathbf{F}$$

In the case considered the index category is the category of elements of the presheaf of Boolean measure algebras $\mathbf{X}$ and the functor $\mathbf{M} \circ G_{\mathbf{X}}$ plays the role of the functor $\mathbf{F}: \mathcal{I} \to \mathcal{Q}$. In the above-presented diagram the second coproduct is over all the objects $({}^{P}A, \chi)$ with $\chi \in \mathbf{X}({}^{P}A)$ of the category of elements, while the first coproduct is over all the maps $v: ({}^{R}C, \acute{\chi}) \to ({}^{P}A, \chi)$ of that category, so that $v: {}^{R}C \to {}^{P}A$ and the condition $\chi v = \acute{\chi}$ is satisfied. We conclude that the colimit $\mathbf{L}_M(\mathbf{X})$ can be equivalently presented as the following coequalizer:

$$\coprod_{v:{}^{R}C\to{}^{P}A} \mathbf{M}({}^{R}C) \underset{\eta}{\overset{\zeta}{\rightrightarrows}} \coprod_{({}^{P}A,\chi)} \mathbf{M}({}^{P}A) \xrightarrow{\xi} \mathbf{X}\otimes_{\mathcal{C}}\mathbf{M}$$

The coequalizer presentation of the colimit shows that the Hom-functor $\mathbf{R}$ has a left adjoint which can be characterized categorically as the tensor product $-\otimes_{\mathcal{C}}\mathbf{M}$.

In order to clarify the above-presented observation, we forget for the moment that the discussion concerns the category of quantum measure algebras $\mathcal{Q}$, and we consider instead the category **Sets**. Then the coproduct $\coprod_p \mathbf{M}({}^{P}A)$ is a coproduct of sets, which is equivalent to the product $\mathbf{X}({}^{P}A) \times \mathbf{M}({}^{P}A)$ for ${}^{P}A \in \mathcal{C}$. The coequalizer is thus the definition of the tensor product $\mathbf{X}\otimes_{\mathcal{C}}\mathbf{M}$ of the set valued functors:

$$\mathbf{X}: \mathcal{C}^{\mathrm{op}} \to \mathbf{Sets}, \quad \mathbf{M}: \mathcal{C} \to \mathbf{Sets}$$

$$\mathbf{X}: \mathcal{C}^{op} \longrightarrow \mathbf{Sets}, \qquad \mathbf{M}: \mathcal{C} \longrightarrow \mathbf{Sets}$$

$$\coprod_{{}^{P}A,{}^{R}C} \mathbf{X}({}^{P}A) \times Hom({}^{R}C, {}^{P}A) \times \mathbf{M}({}^{R}C) \underset{\eta}{\overset{\zeta}{\rightrightarrows}} \coprod_{{}^{P}A} \mathbf{X}({}^{P}A) \times \mathbf{M}({}^{P}A) \xrightarrow{\xi} \mathbf{X}\otimes_{\mathcal{C}}\mathbf{M}$$

According to the above-presented diagram for elements $\chi \in \mathbf{X}({}^{P}A)$, $v: {}^{R}C \to {}^{P}A$ and $\acute{y} \in \mathbf{M}({}^{R}C)$ the following equations hold:

$$\zeta(\chi, v, \acute{y}) = (\chi v, \acute{y}), \quad \eta(\chi, v, \acute{y}) = (\chi, v\acute{y})$$

symmetric in $\mathbf{X}$ and $\mathbf{M}$. Hence the elements of the set $\mathbf{X}\otimes_{\mathcal{C}}\mathbf{M}$ are all of the form $\xi(\chi, y)$. This element can be written as

$$\xi(\chi, y) = \chi \otimes y, \quad \chi \in \mathbf{X}({}^{P}A), y \in \mathbf{M}({}^{P}A).$$

Thus if we take into account the above-presented definitions of ζ and η, we obtain

$$\chi v \otimes \acute{y} = \chi \otimes v\acute{y}.$$

Furthermore if we define the arrows

$$k_{^PA}:\mathbf{X}\otimes_{\mathcal{C}}\mathbf{M} \to {}^{p}L, \quad l_{^PA}:\mathbf{X}({}^{P}A) \to \mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}({}^{P}A),{}^{p}L)$$

they are related under the fundamental adjunction by

$$k_{^PA}(\chi,y) = l_{^PA}(\chi)(y), \quad {}^{P}A \in \mathcal{C}, \chi \in \mathbf{X}({}^{P}A), y \in \mathbf{M}({}^{P}A).$$

Here we consider k as a function on $\amalg_{^PA}\mathbf{X}({}^{P}A)\times\mathbf{M}({}^{P}A)$ with components $k_{^PA}:\mathbf{X}({}^{P}A)\times\mathbf{M}({}^{P}A) \to {}^{p}L$ satisfying

$$k_{^RC}(\chi v, y) = k_{^PA}(\chi, vy)$$

in agreement with the above-defined equivalence relation.

Now we replace the category **Sets** by the category of quantum measure algebras $\mathcal{Q}$ under study. The element y in the set $\mathbf{M}({}^{P}A)$ is replaced by a generalized element $y:\mathbf{M}({}^{R}C)\to\mathbf{M}({}^{P}A)$ from some modeling object $\mathbf{M}({}^{R}C)$ of $\mathcal{Q}$. Then we consider k as a function $\amalg_{({}^{P}A,\chi)}\mathbf{M}({}^{P}A)\to{}^{p}L$ with components $k_{({}^{P}A,\chi)}:\mathbf{M}({}^{P}A)\to{}^{p}L$ for each $\chi\in\mathbf{X}({}^{P}A)$, that for all arrows $v:{}^{R}C\to{}^{P}A$ satisfy

$$k_{({}^{R}C,\chi v)} = k_{({}^{P}A,\chi)} \circ \mathbf{M}(v).$$

Then the condition defining the bijection holding by virtue of the fundamental adjunction is given by

$$k_{({}^{P}A,\chi)} \circ y = l_{^PA}(\chi) \circ y:\mathbf{M}({}^{R}C) \to {}^{p}L.$$

This argument, being natural in the object $\mathbf{M}({}^{R}C)$, is determined by setting $\mathbf{M}({}^{R}C)=\mathbf{A}({}^{P}A)$ with y being the identity map. Hence the bijection takes the form $k_{({}^{P}A,\chi)}=l_{^PA}(\chi)$, where $k:\amalg_{({}^{P}A,\chi)}\mathbf{M}({}^{P}A)\to{}^{p}L$, and $l_{^PA}:\mathbf{X}({}^{P}A)\to\mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}({}^{P}A),{}^{p}L)$.

VII. SYSTEM OF LOCALIZATIONS FOR QUANTUM MEASURE ALGEBRAS

The notion of a system of localizations for a quantum measure algebra, which will be defined in the sequel, is conceptually based on the expectation that a quantum measure algebra ${}^{p}L$ in $\mathcal{Q}$ is possible to be comprehended by means of certain structure preserving maps $\mathbf{M}({}^{P}A)\to{}^{p}L$ with local or modeling objects Boolean measure algebras ${}^{P}A$ in $\mathcal{C}$ as their domains. It is obvious that any single map from any modeling Boolean measure algebra to a quantum measure algebra is not adequate to determine it entirely, and hence, it contains only a fraction of the total information content included in it. This problem may be tackled, only if we employ many appropriate structure preserving maps from the modeling Boolean measure algebras to a quantum measure algebra simultaneously, so as to cover it completely. In turn the information available about each map of the specified kind may be used to determine the quantum measure algebra itself. In this case we conceive the family of such maps as the generator of a system of localizations for a quantum measure algebra. The notion of local is characterized using a notion of topology on $\mathcal{C}$, the axioms of which express closure conditions on the collection of modeling algebras of Boolean coefficient probability measures.

A. The notion of Grothendieck topology on $\mathcal{C}$

We start our discussion by explicating the notion of a topology on the category of Boolean measure algebras $\mathcal{C}$. A topology on $\mathcal{C}$ is a system of arrows $\mathbf{\Lambda}$, where for each object ${}^{P}A$ there is a set $\mathbf{\Lambda}({}^{P}A)$ that contains indexed families of $\mathcal{C}$-morphisms,

$$\mathbf{\Lambda}({}^{P}A) = \{\psi_i : {}^{R}C_i \to {}^{P}A, i \in I\}$$

that is, Boolean homomorphisms to ${}^{P}A$, such that certain appropriate conditions are satisfied.

The notion of a topology on the category of Boolean measure algebras $\mathcal{C}$ is a categorical generalization of a system of set-theoretical covers on a topology $\mathbf{T}$, where a cover for $U \in \mathbf{T}$ is a set $\{U_i : U_i \in \mathbf{T}, \mathbf{i} \in \mathbf{I}\}$ such that $\cup U_i = U$. The generalization is achieved by noting that the topology ordered by inclusion is a poset category and that any cover corresponds to a collection of inclusion arrows $U_i \to U$. Given this fact, any family of arrows contained in $\mathbf{\Lambda}({}^{P}A)$ of a topology is a cover as well.

The specification of a categorial or Grothendieck topology on the category of Boolean measure algebras takes place through the introduction of appropriate covering devices, called covering sieves. For an object ${}^{P}A$ in $\mathcal{C}$, a ${}^{P}A$-sieve is a family ϱ of $\mathcal{C}$-morphisms with codomain ${}^{P}A$, such that if ${}^{R}C \to {}^{P}A$ belongs to ϱ and ${}^{Q}D \to {}^{R}C$ is any $\mathcal{C}$-morphism, then the composite ${}^{Q}D \to {}^{R}C \to {}^{P}A$ belongs to ϱ.

A Grothendieck topology on the category of Boolean measure algebras $\mathcal{C}$ is a system J of sets, $J({}^{P}A)$ for each ${}^{P}A$ in $\mathcal{C}$, where each $J({}^{P}A)$ consists of a set of ${}^{P}A$-sieves (called the covering sieves), which satisfy the following conditions:

1. For any ${}^{P}A$ in $\mathcal{C}$ the maximal sieve $\{g : \mathrm{cod}(g) = {}^{P}A\}$ belongs to $J({}^{P}A)$ (maximality condition).
2. If ϱ belongs to $J({}^{P}A)$ and $f : {}^{R}C \to {}^{P}A$ is a $\mathcal{C}$-morphism, then $f^{*}(\varrho) = \{h : {}^{R}C \to {}^{P}A, f \cdot h \in \varrho\}$ belongs to $J({}^{R}C)$ (stability condition).
3. If ϱ belongs to $J({}^{P}A)$ and S is a sieve on ${}^{R}C$, where for each $f : {}^{R}C \to {}^{P}A$ belonging to ϱ, we have $f^{*}(S)$ in $J({}^{R}C)$, then S belongs to $J({}^{P}A)$ (transitivity condition).

The small category $\mathcal{C}$ together with a Grothendieck topology $\mathbf{J}$ is called a Boolean measure algebras site.

B. The Grothendieck topology of epimorphic families

We consider $\mathcal{C}$ as a model category, whose set of objects $\{{}^{P_i}A_i : i \in I\}$, I: index set, generate $\mathcal{Q}$, in the sense that

$$\mathbf{M}({}^{P_i}A_i) \xrightarrow{w_i} {}^{p}L \underset{u}{\overset{v}{\rightrightarrows}} {}^{t}K$$

the identity $v \circ w_i = u \circ w_i$, for every arrow $w_i : \mathbf{M}({}^{P_i}A_i) \to {}^{p}L$, and every ${}^{P_i}A_i$, implies that $v = u$. Equivalently we can say that the set of all arrows $w_i : \mathbf{M}({}^{P_i}A_i) \to {}^{p}L$, constitute an epimorphic family.

The consideration that $\mathcal{C}$ is a generating model category of $\mathcal{Q}$ points exactly to the depiction of the appropriate Grothendieck topology on $\mathcal{C}$.

We assert that a sieve S on a Boolean measure algebra ${}^{P}A$ in $\mathcal{C}$ is to be a covering sieve of ${}^{P}A$, when the arrows $s : {}^{R}C \to {}^{P}A$ belonging to the sieve S together form an epimorphic family in $\mathcal{Q}$. This requirement may be equivalently expressed in terms of a map

$$\Phi_S : \amalg_{(s:{}^{R}C \to {}^{P}A) \in S} {}^{R}C \to {}^{P}A$$

being an epi in $\mathcal{Q}$.

We will show that the choice of covering sieves on Boolean measure algebras ${}^{P}A$ in $\mathcal{C}$, as being epimorphic families in $\mathcal{Q}$, does indeed define a Grothendieck topology on $\mathcal{C}$.

First of all we notice that the maximal sieve on each Boolean measure algebra ${}^{P}A$ includes the identity ${}^{P}A \to {}^{P}A$, thus it is a covering sieve. Next, the transitivity property of the depicted covering sieves is obvious. It remains to demonstrate that the covering sieves remain stable under pullback. For this purpose we consider the pullback of such a covering sieve S on ${}^{P}A$ along any arrow $h : {}^{Q}D \to {}^{P}A$ in $\mathcal{C}$

$$\begin{array}{ccc} \amalg_{s\in S}{}^{R}C\times_{P_A}{}^{Q}D & \longrightarrow & {}^{Q}D \\ \downarrow & & \downarrow h \\ \amalg_{s\in S}{}^{R}C & \xrightarrow{\Phi} & {}^{P}A \end{array}$$

The Boolean measure algebras ${}^{P}A$ in $\mathcal{C}$ generate the category of quantum measure algebras $\mathcal{Q}$, hence, there exists for each arrow $s:{}^{R}C\to{}^{P}A$ in S, an epimorphic family of arrows $\amalg[{}^{T}E]^{s}\to{}^{R}C\times_{P_A}{}^{Q}D$, or equivalently $\{[{}^{T}E]^{s}_{j}\to{}^{R}C\times_{P_A}{}^{Q}D\}_{j}$, with each domain $[{}^{T}E]^{s}$ a Boolean measure algebra.

Consequently the collection of all the composites:

$$[{}^{T}E]^{s}_{j}\to{}^{R}C\times_{P_A}{}^{Q}D\to{}^{Q}D$$

for all $s:{}^{R}C\to{}^{P}A$ in S, and all indices j together form an epimorphic family in $\mathcal{Q}$, that is contained in the sieve $h^{*}(S)$, being the pullback of S along $h:{}^{Q}D\to{}^{P}A$. Therefore the sieve $h^{*}(S)$ is a covering sieve.

C. Covering sieves as localization systems

If we consider a quantum measure algebra ${}^{p}L$, and all quantum algebraic morphisms of the form $\psi_{P_A}:\mathbf{M}({}^{P}A)\to{}^{p}L$, with domains ${}^{P}A$, in the generating model category of Boolean measure algebras $\mathcal{C}$, then the family of all these maps ψ_{P_A}, constitute an epimorphism:

$$S:\amalg_{({}^{P}A\in\mathcal{C},\psi_{P_A}:\mathbf{M}({}^{P}A)\to{}^{p}L)}\mathbf{M}({}^{P}A)\to{}^{p}L.$$

We say that a sieve on a quantum measure algebra defines a covering sieve by objects of its generating model category $\mathcal{C}$, when the quantum algebraic morphisms belonging to the sieve define the preceding epimorphism.

From a physical perspective covering sieves by Boolean measure algebras are equivalent to Boolean localization systems of quantum measure algebras. These localization systems filter the information of a quantum measure algebra through Boolean domains, associated with procedures of localization in measurement environments. We will discuss localizations systems in detail, in order to unravel the physical meaning of the requirements underlying the notion of Grothendieck topology, and subsequently, the notion of covering sieves defined previously. It is instructive to begin with the notion of a system of prelocalizations for a quantum measure algebra.

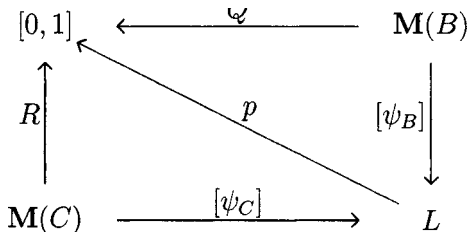
A *system of prelocalizations* for a quantum measure algebra ${}^{p}L$ in $\mathcal{Q}$ is a subfunctor of the Hom-functor $\mathbf{R}({}^{p}L)$ of the form $\mathbf{S}:\mathcal{C}^{\mathrm{op}}\to\mathbf{Sets}$, namely for all ${}^{P}A$ in $\mathcal{C}$ it satisfies $\mathbf{S}({}^{P}A)\subseteq[\mathbf{R}({}^{p}L)]({}^{P}A)$. Hence a system of prelocalizations for quantum measure algebra ${}^{p}L$ in $\mathcal{Q}$ is an ideal $\mathbf{S}({}^{P}A)$ of quantum algebraic morphisms of the form

$$\psi_{P_A}:\mathbf{M}({}^{P}A)\to{}^{p}L,\quad {}^{P}A\in\mathcal{C},$$

such that $\{\psi_{P_A}:\mathbf{M}({}^{P}A)\to{}^{p}L$ in $\mathbf{S}({}^{P}A)$, and $\mathbf{A}(v):\mathbf{M}({}^{R}C)\to\mathbf{M}({}^{P}A)$ in $\mathcal{Q}$ for $v:{}^{R}C\to{}^{P}A$ in $\mathcal{C}$, implies $\psi_{P_A}\circ\mathbf{M}(v):\mathbf{M}({}^{R}C)\to\mathcal{Q}$ in $\mathbf{S}({}^{P}A)\}$.

The introduction of the notion of a system of prelocalizations is forced on the basis of operational physical arguments. According to Kochen-Specker theorem it not possible to understand completely a quantum mechanical system with the use of a single system of Boolean devices. On the other side, in every concrete experimental context, the set of events that have been actualized in this context forms a Boolean algebra. In light of this we can say that any Boolean domain object $(B,[\psi_{B}]:\mathbf{M}(B)\to L)$ in a system of prelocalizations for a quantum event algebra L, making the diagram below commutative, corresponds to a set of Boolean classical events that

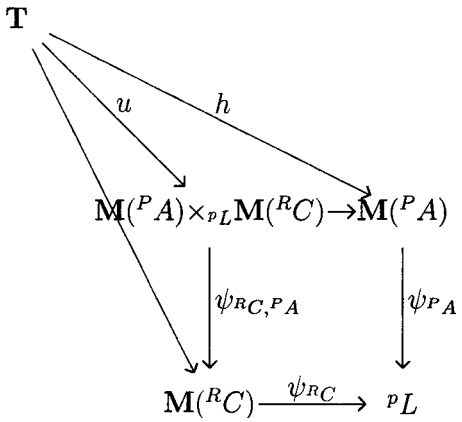
become actualized in the experimental context of B. These Boolean domains play the role of localizing devices in a quantum event structure, which are induced by measurement situations. The above-noted observation is equivalent to the statement that a measurement-induced Boolean algebra serves as a reference frame, in a topos-theoretical environment, relative to which a measurement result is being coordinatized. Correspondingly, by commutativity of the diagram to follow, we obtain naturally the notion of coordinatizing Boolean measure algebras in a system of prelocalizations for a quantum measure algebra over a quantum event algebra L. The same notion suggests an effective way of comprehending quantum theory in a contextual perspective, pointing to a relativity principle of a topos-theoretical origin. Concretely it supports the assertion that the quantum world is the universe of varying Boolean reference frames, which interconnect to form a coherent picture in a nontrivial way.



Adopting the aforementioned perspective on quantum measure algebraic structures, the operation of the Hom-functor $\mathbf{R}({}^{p}L)$ is equivalent to depicting an ideal of morphisms which are to play the role of local coverings of a quantum measure algebra by modeling objects. The notion of a system of prelocalizations formalizes an intuitive idea, according to which, if we sent many coordinatizing Boolean measure algebras into the quantum measure algebra homomorphically, then we would expect that these modeling objects would prove to be enough for the complete determination of the quantum measure algebra. If we consider a geometrical viewpoint, we may legitimately characterize metaphorically the maps $\psi^{p}{}_{A}:\mathbf{M}({}^{P}A)\rightarrow{}^{p}L$, where ${}^{P}A$ in $\mathcal{C}$, in a system of prelocalizations for quantum measure algebra ${}^{p}L$ as Boolean measure algebra charts. Correspondingly the modeling Boolean domain objects $(A,[\psi_A]:\mathbf{M}(A)\rightarrow L)$ in a system of prelocalizations for a quantum event algebra, making the above-presented diagram commutative, may be characterized as measurement charts. Subsequently, their domains A may be called Boolean coefficient domains induced by measurement, the elements of A measured local Boolean coefficients, and the elements of L quantum events (or quantum propositions in a logical interpretation), coordinatized by Boolean coefficients. Finally, the Boolean morphisms $\upsilon:D\rightarrow A$ in $\mathcal{B}$ play the equivalent role of transition maps.

Under these intuitive identifications, we say that a family of Boolean measure algebra charts $\psi^{p}{}_{A}:\mathbf{M}({}^{P}A)\rightarrow{}^{p}L$, ${}^{P}A$ in $\mathcal{C}$ (or correspondingly a family of Boolean measurement charts $[\psi_A]:\mathbf{M}(A)\rightarrow L$ making the above-presented diagram commutative), is the generator of the system of prelocalization $\mathbf{S}$ iff this system is the smallest among all that contains that family. It is evident that a quantum measure algebra, and correspondingly the quantum event algebra over which it is defined, can have many systems of measurement prelocalizations, that, remarkably, form an ordered structure. More specifically, systems of prelocalization constitute a partially ordered set under inclusion. Furthermore, the intersection of any number of systems of prelocalization is again a system of prelocalizations. We emphasize that the minimal system is the empty one, namely $\mathbf{S}({}^{P}A)=\emptyset$, for all ${}^{P}A$ in $\mathcal{C}$, whereas the maximal system is the Hom-functor $\mathbf{R}({}^{p}L)$ itself, or equivalently, all quantum algebraic morphisms $\psi^{p}{}_{A}:\mathbf{M}({}^{P}A)\rightarrow{}^{p}L$, for all ${}^{P}A$ in $\mathcal{C}$.

The transition from a system of prelocalizations to a system of localizations for a quantum measure algebra can be effected under the restriction that certain compatibility conditions have to be satisfied on the overlap of the modeling Boolean coefficient domains covering the quantum measure algebra under investigation. In order to accomplish this we use a pullback diagram in $\mathcal{Q}$ as follows:



The pullback of the Boolean charts $\psi_{^PA}:\mathbf{M}(^PA)\to{}^pL$, ^PA in $\mathcal{C}$, and $\psi_{^RC}:\mathbf{M}(^RC)\to{}^pL$, $^RC\in\mathcal{C}$ with common codomain the quantum measure algebra ^pL consists of the object $\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC)$ and two arrows $\psi_{^PA^RC}$ and $\psi_{^RC^PA}$, called projections, as shown in the above-presented diagram. The square commutes and for any object T and arrows h and g that make the outer square commute, there is a unique $u:T\to\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC)$ that makes the whole diagram commutative. Hence we obtain the condition:

$$\psi_{^RC}\circ g=\psi_{^PA}\circ h.$$

The pullback of the Boolean measure algebra charts $\psi_{^PA}:\mathbf{A}(^PA)\to{}^pL$, ^PA in $\mathcal{C}$, and $\psi_{^RC}:\mathbf{M}(^RC)\to{}^pL$, ^RC in $\mathcal{C}$, is equivalently characterized as their fiber product, because $\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC)$ is not the whole product $\mathbf{A}(^PA)\times\mathbf{M}(^RC)$ but the product taken fiber by fiber. We notice that if $\psi_{^PA}$ and $\psi_{^RC}$ are injective, then their pullback is isomorphic with the intersection $\mathbf{M}(^PA)\cap\mathbf{M}(^{P'}A)$. Then we can define the pasting map, which is an isomorphism, as follows:

$$\Omega_{^PA,^RC}:\psi_{^RC^PA}(\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC))\to\psi_{^PA^RC}(\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC))$$

by putting

$$\Omega_{^PA,^RC}=\psi_{^PA^RC}\circ\psi^RC^PA^{-1}.$$

Then we have the following cocycle conditions:

$$\Omega_{^PA,^PA}=1_{^PA},\quad 1_{^PA}:=id_{^PA}$$

$$\Omega_{^PA,^RC}\circ\Omega_{^RC,^TE}=\Omega_{^PA,^TE}\quad if\ \mathbf{M}(^PA)\cap\mathbf{M}(^RC)\cap\mathbf{M}(^TE)\neq 0,$$

$$\Omega_{^PA,^RC}=\Omega^{-1}_{^RC,^PA}\quad if\ \mathbf{M}(^PA)\cap\mathbf{M}(^RC)\neq 0.$$

The pasting map assures that the mapping $\psi_{^RC^PA}(\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC))$ and also $\psi_{^PA^RC}(\mathbf{M}(^PA)\times_{^pL}\mathbf{M}(^RC))$ are going to cover the same part of the quantum measure algebra in a compatible way. It is obvious that the above-mentioned compatibility conditions are translated immediately to corresponding compatibility conditions concerning Boolean measurement charts on the quantum event structure.

Given a system of prelocalizations for a quantum measure algebra ^pL in $\mathcal{Q}$, and correspondingly for the quantum event algebra over which it is defined, we call it a *system of localizations* iff the above-noted compatibility conditions are satisfied and moreover the quantum algebraic structure is preserved.

We assert that the above-noted compatibility conditions provide the necessary relations for understanding a system of localizations for a quantum measure algebra as a structure sheaf or sheaf of Boolean coefficients, consisting of local Boolean measure algebras. This is related to the observation that systems of localizations are actually subfunctors of the representable Hom-functor $\mathbf{R}({}^{p}L)$ of the form $\mathbf{S}:\mathcal{C}^{\mathrm{op}}\rightarrow\mathbf{Sets}$, namely for all ${}^{P}A$ in $\mathcal{C}$ satisfy $\mathbf{S}({}^{P}A)\subseteq[\mathbf{R}({}^{p}L)]({}^{P}A)$. In this sense the pullback compatibility conditions express gluing relations on overlaps of Boolean measure algebra charts and convert a presheaf subfunctor of the Hom-functor into a sheaf for the Grothendieck topology specified. The concept of sheaf expresses exactly the pasting conditions that local Boolean coefficients algebras have to satisfy, namely, the way by which local data can be collated together into global ones. We stress the point that the transition from locally defined properties to global consequences happens via a compatible family of elements over a cover of the global object. A cover, or equivalently a localization system of the global, object, being a quantum measure algebra structure in the present scheme, can be viewed as providing a decomposition of that object into simpler modeling objects.

The comprehension of a localization system as a sheaf of Boolean coefficients permits the conception of a quantum measure algebra (or of its associated quantum event algebra) as a generalized Boolean manifold, obtained by pasting the $\psi_{{}^{R}C{}^{P}A}(\mathbf{M}({}^{P}A)\times_{{}^{p}L}\mathbf{M}({}^{R}C))$ and $\psi_{{}^{P}A{}^{P'}A}(\mathbf{M}({}^{P}A)\times_{{}^{p}L}\mathbf{M}({}^{R}C))$ covers together by the transition functions $\Omega_{{}^{P}A,{}^{R}C}$.

More specifically, the equivalence relations in the category of elements of such a structure sheaf, represented by a Boolean system of Boolean probabilities coefficients, have to be taken into account according to the analysis of the adjoint relation presented in Sec. VI. Equivalence relations of this form give rise to congruences in the structure sheaf of Boolean coefficients, which are expressed categorically as a colimit in the category of elements of such a structure sheaf. In this perspective the generalized manifold, which represents categorically a quantum measure algebra, is understood as a colimit in a sheaf of Boolean coefficients, which contains compatible families of modeling Boolean measure algebras. It is instructive to emphasize that the organization of Boolean coordinatizing objects in localization systems takes the form of interconnection of these modeling objects through the categorical construction of colimit, the latter being the means to comprehend an object of complex structure (quantum measure algebra) from simpler coefficient objects (Boolean measure algebras).

The above-noted ideas provide the basis for the formulation of a sheaf-theoretic representation theorem concerning quantum measure algebras as we shall present in the following section.

VIII. REPRESENTATION OF QUANTUM MEASURE ALGEBRAS

A. Unit and counit of the adjoint relation

We again focus our attention on the fundamental adjoint relation established, and investigate the unit and the counit of it. For any presheaf $\mathbf{X}$ in the topos $\mathbf{Sets}^{\mathcal{C}^{\mathrm{op}}}$, the **unit** $\delta_{\mathbf{X}}:\mathbf{X}\rightarrow\mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}(\_),\mathbf{X}\otimes_{\mathcal{C}}\mathbf{M})$ has components:

$$\delta_{\mathbf{X}}({}^{P}A):\mathbf{X}({}^{P}A)\rightarrow\mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}({}^{P}A),\mathbf{X}\otimes_{\mathcal{C}}\mathbf{M})$$

for each Boolean measure algebra ${}^{P}A$ in $\mathcal{C}$.

If we make use of the representable presheaf $y[{}^{P}A]$ we obtain

$$\delta_{\mathbf{y}[{}^{P}A]}:\mathbf{y}[{}^{P}A]\rightarrow\mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}(\_),\mathbf{y}[{}^{P}A]\otimes_{\mathcal{C}}\mathbf{M}).$$

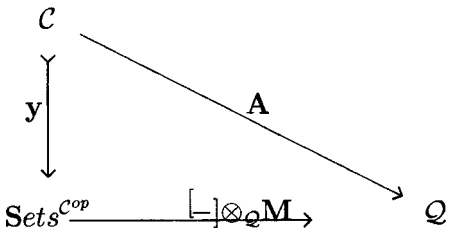
Hence for each object ${}^{P}A$ of $\mathcal{C}$ the unit, in the case considered, corresponds to a map

$$\mathbf{M}({}^{P}A)\rightarrow\mathbf{y}[{}^{P}A]\otimes_{\mathcal{C}}\mathbf{M}.$$

But since

$$\mathbf{y}[{}^{P}A]\otimes_{\mathcal{C}}\mathbf{M}\cong\mathbf{M}({}^{P}A)$$

the unit for the representable presheaf of Boolean measure algebras is clearly an isomorphism. By the preceding discussion we conclude that the following diagram commutes:

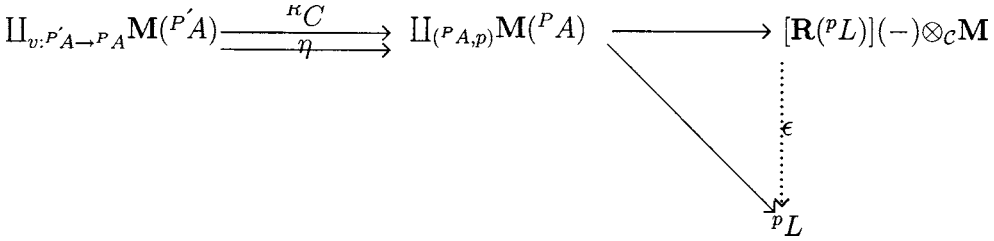


Thus the unit of the fundamental adjunction referring to the representable presheaf of the category of Boolean measure algebras provides a quantum algebraic morphism, $\mathbf{M}({}^{P}A)\rightarrow\mathbf{y}[{}^{P}A]\otimes_{\mathcal{C}}\mathbf{M}$, which is an isomorphism.

On the other side, for each quantum measure algebra ${}^{p}L$ in $\mathcal{Q}$ the *counit* is defined as follows:

$$\epsilon_{{}^{p}L}:\mathrm{Hom}_{\mathcal{Q}}(\mathbf{M}(\_),{}^{p}L)\otimes_{\mathcal{C}}\mathbf{M}\rightarrow{}^{p}L.$$

The counit corresponds to the vertical map in the following diagram:

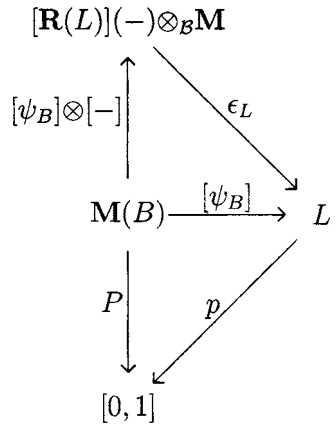


B. Boolean representation

The sheaf-theoretic representation of a quantum measure algebra in terms of Boolean measure localization systems is formulated in terms of the following proposition, effectuated by means of the vertical counit map in the preceding diagram.

The representation of a quantum measure algebra ${}^{p}L$ in $\mathcal{Q}$, in terms of a coordinatization system of Boolean measure algebra localizations **S**, consisting of Boolean probability coefficients, is full and faithful, if and only if the counit of the established adjoint relation, restricted to that system, is an isomorphism, that is, structure-preserving, 1-1 and onto.

It is easy to see that the counit of the adjunction, restricted to a system of Boolean measure algebra localizations is a quantum algebraic isomorphism, iff the right adjoint functor is full and faithful, or equivalently, iff the cocone from the functor $\mathbf{M}\circ\int_{\mathbf{R}({}^{p}L)}$ to the quantum measure algebra ${}^{p}L$ is universal for each ${}^{p}L$ in $\mathcal{Q}$. In the latter case we characterize the Boolean measure coefficients functor $\mathbf{M}:\mathcal{C}\rightarrow\mathcal{Q}$, a proper modeling functor. As a consequence if we consider as $\mathcal{B}$ the category of Boolean subalgebras of a quantum event algebra L of ordinary quantum mechanics, that is an orthomodular σ-orthoposet of orthogonal projections of a Hilbert space, together with a proper modeling inclusion functor $\mathbf{M}:\mathcal{B}\rightarrow\mathcal{L}$, such that the diagram to follow commutes, the counit of the established adjunction restricted to a system of Boolean localizations is an isomorphism



$$\epsilon_L : \mathbf{R}(L)\otimes_{\mathcal{B}}\mathbf{M}\rightarrow^{\cong}L$$

$$\epsilon_L{:}\mathbf{R}(L)\otimes_{\mathcal{B}}\mathbf{M}\rightarrow^{\cong}L$$

such that

$$[\psi_B] = \epsilon_L \circ ([\psi_B] \otimes \_)$$

or in the notation of elements equivalently:

$$\epsilon_L([\psi_B] \otimes a) = [\psi_B](a), \quad a \in \mathbf{M}(B),$$

where $p([\psi_B](a))=(P(a))$, for all $[\psi_B]{:}\mathbf{M}(B)\rightarrow L$ according to the above-presented commutative diagram.

IX. CONCLUSIONS

The primary physical motivation of this paper has been the implementation and explicit construction of an appropriate localization process suited to quantum physical observation, and in particular, the study of its consequences referring to the interpretation of quantum probabilistic structures. The crucial ideas and techniques related to the objective of interpreting quantum measure algebras sheaf-theoretically in the topos-theoretic environment of Grothendieck sites are based on extension and elaboration of previous works of the author, communicated, both conceptually and technically, in the literature.[23–27] The defining characteristic of the topos-theoretic perspective enunciated by the author in this endeavor has been the change of resolution focus form point-set to variable topological localization models of quantum algebraic structures, which effectively induce a transition in the semantics of global quantum event observable and probability algebras from a set-theoretic to a sheaf-theoretic one. The significance and semantic differentiation of this work in relation to the foundations of quantum theory can be cast in the form of the following statements:

1. Conceptually, the physical meaning of the notion of localization is being disassociated from its restricted spatial connotation reference context. We have argued that this is an essential and necessary reconceptualization of the meaning of locality in relational information terms forced by the quantum description of physical systems.
2. A suitable localization process of global quantum event and probabilistic structures that respects the premises of the quantum theory of measurement is being formulated in terms of Boolean localization systems, described categorically in terms of an appropriate Grothendieck topology, which incorporate the constitutive requirements of the notion of Boolean localization in functorial relational terms.

3. Global quantum event and probabilistic structures are being functionally and functorially dependent on generalized topological localization measures induced by the preparation of Boolean structured domains of measurement, not necessarily based on the existence of an underlying set-theoretic structure of points on the real line.
4. The sheaf-theoretic semantic transition of quantum measure algebras has been forced by means of gluing cocycle conditions over an explicitly constructed uniform and homologous fibered representation of quantum states with respect to local Boolean reference frames for the Grothendieck topology of epimorphic families. According to this representation, quantum states have been conceptualized as equivalence classes of local Boolean coordinates with respect to those reference frames. Subsequently, an isomorphic representation of quantum measure algebras with colimits taken in the categories of elements of sheaves of Boolean reference frames has been constructed.
5. The physical significance of the sheaf-theoretic representation of quantum measure algebras is encapsulated in the realization that the whole information content of a quantum measure algebra is preserved by the action of some covering system, if and only if that system forms a Boolean localization system. Hence, the significance of a quantum measure algebra is shifted from the orthoposet axiomatization at the level of events, to the sheaf-theoretic gluing conditions at the level of Boolean localization systems.
6. The preservation of quantum information property according to the above is being formally established by the counit of the related adjunction isomorphism. More specifically, the surjective property of the counit guarantees that the Boolean localization measures, representing objects in the category of elements of the sheaf $\int(\mathbf{R}(^{p}L),\mathcal{C})$, cover entirely a quantum measure algebra ^{p}L, whereas its injective property guarantees that any two covers are compatible in a system of localizations. Moreover, since the counit is also a homomorphism, it preserves the algebraic structure.
7. The physical content of the sheaf-theoretic representation of quantum events algebras can be formulated in terms of a functoriality property. According to this, the information content of a quantum measure algebra is covariant under the groupoid of gluing isomorphisms between overlapping local Boolean reference frames, along their intersections, in a Boolean localization system.
8. In the physical state of affairs, each cover corresponds to a Boolean measure algebra of events realized locally (with respect to the Grothendieck topology of epimorphic families) in a measurement situation. The equivalence classes of local Boolean measure coefficients represent quantum states in ^{p}L, via the sheaf-theoretic pullback compatibility conditions. In this sense, the notion of quantum probability is basically classical when interpreted locally *à la Grothendieck*. Moreover, the probabilities of actualization of events in equivalent local measurement environments are equal.
9. Conclusively, the structure of a quantum measure algebra is being generated by the information that its structure preserving morphims, encoded as Boolean covers in localization systems carry, as well as their compatibility relations. Most significantly, the same compatibility conditions provide the necessary relations for understanding a system of localizations for a quantum probabilistic structure, as a structure sheaf of Boolean measure coefficients associated with local contexts of measurement.

Finally, it would be instructive to comment briefly on the possible implications of the proposed topos-theoretic interpretation schema of quantum structures, based on a reconceptualization of the notion of physical localization, in relation to the ongoing research on quantum relativity and quantum gravity. A preliminary account of the attempt to establish a connective link with the conception of a categorical theory of covariant quantum gravitational dynamics based on the utilization of topological localization systems in the physical "continuum" is in the phase of intense development, while some basic ideas and results related with this program have already been communicated.[28] In the context of that work we initiate a sheaf-theoretic dynamical analysis of quantum observable structures by synthesizing the flexible categorical machinery of Grothendieck topoi, together with the powerful sheaf-theoretic methodology of Mallios's abstract differential geometry.[18]

The crucial physical issue incorporated in the idea of generalized topological localization processes, conceived in the sense of Grothendieck topologies on a base category of structured reference contexts, is related to a novel topos-theoretic conception of the physical "continuum." According to this conception the quantum regime of observable dynamical phenomena should be understood in functorial terms of categorically localized information, and not in the restricted classical localization terms conceived by means of metrical properties on a pre-existing smooth set-theoretic spacetime manifold. Subsequently, that semantic transition can be implemented conceptually and technically by the replacement of the classical variable metrical ruler of localization on a smooth background spacetime manifold, with a variable sheaf-cohomological ruler of categorical localization in a Grothendieck topos, that captures the relational information of observables in the quantum regime, filtered through local reference frames in that topos. Then, the dynamical properties of quantum structures can be addressed to the global topos-theoretic dynamics generated by interlocking diagrams of local frames in that topos, giving rise to generalized De Rham complexes of sheaves encapsulating cohomologically the corresponding dynamical behavior.

Galois quantum systems, irreducible polynomials and Riemann surfaces

A. Vourdas[a)]
Department of Computing, University of Bradford, Bradford BD7 1DP, United Kingdom

(Received 8 June 2006; accepted 29 July 2006; published online 19 September 2006)

Finite quantum systems in which the position and momentum take values in the Galois field GF(p^ℓ), are studied. Ideas from the subject of field extension are transferred in the context of quantum mechanics. The Frobenius automorphisms in Galois fields lead naturally to the "Frobenius formalism" in a quantum context. The Hilbert space splits into "Frobenius subspaces" which are labeled with the irreducible polynomials associated with the $y^{p^\ell}-y$. The Frobenius maps transform unitarily the states of a Galois quantum system and leave fixed all states in some of its Galois subsystems (where the position and momentum take values in subfields of GF(p^ℓ)). An analytic representation of these systems in the ℓ-sheeted complex plane shows deeper links between Galois theory and Riemann surfaces. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2345111]

I. INTRODUCTION

Quantum systems with finite-dimensional Hilbert spaces were studied originally by Weyl[1] and Schwinger,[2] and later by many authors (for a review with an extensive list of references see Ref. 3). In this case the position and momentum take values in the ring $\mathcal{Z}_d$ (the integers modulo d) and the phase space of the system is the toroidal lattice $\mathcal{Z}_d\times\mathcal{Z}_d$. We can try to develop a phase space formalism which is similar to the one for the harmonic oscillator. For example, we can define displacements and show that they form a Heisenberg-Weyl group.

An important class of transformations in the harmonic oscillator $R\times R$ phase space are the symplectic Sp$(2,R)$ transformations. Apart from their theoretical importance, they are intimately related to more practical areas like squeezing and quantum tomography in quantum optics. In finite quantum systems, the $\mathcal{Z}_d\times\mathcal{Z}_d$ phase space is in general a collection of points with no geometrical structure and we cannot define symplectic transformations. The root of these difficulties is that $\mathcal{Z}_d$ is a ring. However when d is the power of a prime number p (i.e., $d=p^\ell$) the $\mathcal{Z}_d$ (with appropriate multiplication rule) becomes the Galois field GF(p^ℓ). We call them Galois quantum systems. In this case the phase space is a finite geometry[4] and we can define the group of symplectic transformations Sp$(2,GF(p^\ell))$.[5–7]

There are some other remarkable properties of the Galois quantum systems. Mutually unbiased bases are important in quantum information processing and have been studied extensively in the last few years.[8–18] It is known that the number of such bases cannot exceed $d+1$; and it is also known that for systems where d is the power of a prime, the number of such bases is indeed $d+1$. Similar ideas appear in the so-called "mean king's problem."[19–21] Applications of these ideas to quantum coding have been discussed in Refs. 22 and 23.

A central concept in a Galois field is the Frobenius automorphisms which leave fixed all elements in some of its subfields. Galois quantum systems inherit the properties of Galois fields and in this paper we develop a "Frobenius formalism" in a quantum context. Preliminary work in this direction has been presented in Ref. 7 for the case where ℓ is a prime number. In this simple case there is only one proper subfield of GF(p^ℓ) which is the $\mathcal{Z}_p$ and we get a two layer structure.

[a)]Electronic mail: a.vourdas@bradford.ac.uk

Here we consider the more complicated case of general ℓ and get a multilayer structure. In order to do this we first construct a labeling method for the irreducible polynomials associated with the $y^{p^\ell}-y$. To each irreducible polynomial corresponds a Frobenius subspace comprised of position states labeled with the Galois conjugates corresponding to this polynomial. We then introduce the Frobenius transformations $\mathcal{G}$ which leave these subspaces invariant. The powers of $\mathcal{G}$ form a cyclic group of order ℓ. We explain how the Frobenius transformations leave fixed all states in Galois subsystems (where the position and momentum take values in subfields of GF(p^ℓ)).

There are deep connections between Riemann surfaces and Galois theory. Roughly speaking, the multivaluedness in coverings of Riemann surfaces can be related to the Galois conjugates. An example of this relationship has been discussed in Ref. 24, in a very different context from ours. Here we introduce an analytic representation of Galois quantum systems in the ℓ-sheeted complex plane. We show how various aspects of the Frobenius transformations are elegantly expressed in the language of analytic functions.

II. GALOIS FIELDS

We consider the Galois field GF(p^ℓ). The elements of the Galois field GF(p^ℓ) can be written as polynomials

$$\alpha=\alpha_0+\alpha_1\epsilon+\cdots+\alpha_{\ell-1}\epsilon^{\ell-1},\quad \alpha_0,\alpha_1,\ldots,\alpha_{\ell-1}\in\mathcal{Z}_p. \tag{1}$$

These polynomials are defined modulo an irreducible polynomial of degree ℓ:

$$P(\epsilon)\equiv c_0+c_1\epsilon+\cdots+c_{\ell-1}\epsilon^{\ell-1}+\epsilon^{\ell},\quad c_0,c_1,\ldots,c_{\ell-1}\in\mathcal{Z}_p. \tag{2}$$

Different irreducible polynomials of the same degree ℓ lead to isomorphic finite fields.

The α, $\alpha^p,\ldots,\alpha^{p^{\ell-1}}$ are Galois conjugates. The trace of α is defined as

$$\mathrm{Tr}(\alpha)=\alpha+\alpha^p+\cdots+\alpha^{p^{\ell-1}},\quad \mathrm{Tr}(\alpha)\in\mathcal{Z}_p. \tag{3}$$

All conjugates have the same trace. Elements of the base field $\mathcal{Z}_p$ are Galois self-conjugates.

As in Ref. 7, for practical calculations we introduce the $\ell\times\ell$ matrices

$$g_{\lambda\kappa}\equiv\mathrm{Tr}(\epsilon^{\lambda+\kappa}),\quad G\equiv g^{-1},\quad g_{\lambda\kappa},G_{\lambda\kappa}\in\mathcal{Z}_p. \tag{4}$$

We also introduce a dual basis $E_0,E_1,\ldots,E_{\ell-1}$, as follows:

$$E_\kappa=\sum_\lambda G_{\kappa\lambda}\epsilon^\lambda,\quad \mathrm{Tr}(\epsilon^\kappa E_\lambda)=\delta_{\kappa\lambda}. \tag{5}$$

A number $\alpha\in\mathrm{GF}(p^\ell)$ can be expressed in the two bases as

$$\begin{gathered}\alpha=\sum_{\lambda=0}^{\ell-1}\alpha_\lambda\epsilon^\lambda=\sum_{\lambda=0}^{\ell-1}\overline{\alpha_\lambda}E_\lambda,\\ \alpha_\lambda=\mathrm{Tr}[\alpha E_\lambda];\quad \overline{\alpha_\lambda}=\mathrm{Tr}[\alpha\epsilon^\lambda].\end{gathered} \tag{6}$$

We refer to α_λ and $\overline{\alpha_\lambda}$ as the components and dual components of α, correspondingly. They are related as follows:

$$\alpha_\lambda=\sum_\kappa G_{\lambda\kappa}\overline{\alpha_\kappa},\quad \overline{\alpha_\lambda}=\sum_\kappa g_{\lambda\kappa}\alpha_\kappa. \tag{7}$$

The trace of the product $\alpha\beta$ is given in terms of the components of these numbers as

$$\mathrm{Tr}(\alpha\beta)=\sum_{\lambda,\kappa}g_{\lambda\kappa}\alpha_\lambda\beta_\kappa=\sum_{\lambda,\kappa}G_{\lambda\kappa}\overline{\alpha_\lambda}\overline{\beta_\kappa}=\sum_\lambda\alpha_\lambda\overline{\beta_\lambda}=\sum_\lambda\overline{\alpha_\lambda}\beta_\lambda. \tag{8}$$

We also introduce the $\ell \times \ell$ matrix $\mathcal{C}$ with elements in $\mathcal{Z}_p$, through the relations:

$$\epsilon^{\mu p} = \sum_{\kappa=0}^{\ell-1} \epsilon^{\kappa} \mathcal{C}_{\kappa\mu}. \tag{9}$$

κ, μ take values from 0 to $\ell-1$. We can show that

$$\mathcal{C}^{\ell} = \mathbf{1}, \quad \mathcal{C}_{\kappa 0} = \delta(\kappa, 0), \tag{10}$$

where δ is the Kronecker delta. The conjugates of an arbitrary number α can now be written in terms of its components as

$$\alpha^{p^{\lambda}} = \sum_{\kappa,\mu} \epsilon^{\kappa} (\mathcal{C}^{\lambda})_{\kappa\mu} \alpha_{\mu}. \tag{11}$$

A. Characters

We consider the following complex-valued function which is an additive character in GF(p^{ℓ}):

$$\chi(\alpha) = \omega[\mathrm{Tr}(\alpha)], \quad \chi(\alpha)\chi(\beta) = \chi(\alpha + \beta), \tag{12}$$

where

$$\omega = \exp\left(i\frac{2\pi}{p}\right), \quad \omega(m) \equiv \omega^{m}, \quad m \in \mathcal{Z}_p. \tag{13}$$

We can easily show that for $n, m, r \in \mathrm{GF}(p^{\ell})$:

$$\frac{1}{p^{\ell}} \sum_{n} \omega[\mathrm{Tr}(nm - nr)] = \delta(m, r). \tag{14}$$

A more general relation is

$$\frac{1}{p^{\ell}} \sum_{n} \omega[\mathrm{Tr}(nm - n^{p^{\lambda}} r)] = \delta(m, r^{p^{\ell-\lambda}}) = \delta(m^{p^{\lambda}}, r). \tag{15}$$

We can also rewrite this in terms of the components of the $m^{p^{\lambda}}, r$:

$$\delta(m^{p^{\lambda}}, r) = \prod_{\kappa=0}^{\ell-1} \delta\left(\sum_{\mu} (\mathcal{C}^{\lambda})_{\kappa\mu} m_{\mu}, r_{\kappa}\right). \tag{16}$$

B. Labeling of the irreducible polynomials

The Frobenius map

$$\sigma: \alpha \to \alpha^{p}, \quad \sigma^{\ell} = \mathbf{1} \tag{17}$$

defines an automorphism in GF(p^{ℓ}). It maps the Galois conjugates to each other and leave all elements of the base field $\mathcal{Z}_p$ fixed. The Frobenius map can be written in terms of the components of α and α^{p} as

$$\sigma: \alpha_{\kappa} \to \sum_{\mu} \mathcal{C}_{\kappa\mu} \alpha_{\mu}. \tag{18}$$

The

$$\Sigma_1 = \{\mathbf{1}, \sigma, \ldots, \sigma^{\ell-1}\} \tag{19}$$

form the Galois group which is a cyclic group of order ℓ. It comprises all automorphisms of GF(p^ℓ) which leaves the elements of the subfield $\mathcal{Z}_p$ fixed.

The product

$$f(y) \equiv (y-\alpha)(y-\alpha^p)\cdots(y-\alpha^{p^{d-1}}) \tag{20}$$

involves all the Galois conjugates and is an irreducible polynomial of degree d in $\mathcal{Z}_p[y]$ (the polynomials with coefficients in $\mathcal{Z}_p$). It is known that the number of such irreducible polynomials of degree d is given in terms of the Möbius μ-function as

$$n(d,p) = \frac{1}{d}\sum_{e|d} \mu(e) p^{d/e}, \tag{21}$$

where the summation is over all e which are divisors of d (we denote this as $e|d$). It is easily seen that

$$n(1,p) = p. \tag{22}$$

We label the various irreducible polynomials of degree d as $f_{d\kappa}(y)$ where κ takes values from 1 to $n(d,p)$. The product of all distinct irreducible polynomials in $\mathcal{Z}_p[y]$ of degree d, where d is a divisor of ℓ, is

$$\prod_{d|\ell} \prod_{\kappa=1}^{n(d,p)} f_{d\kappa}(y) = y^{p^\ell} - y. \tag{23}$$

From the degrees of these polynomials we easily show that

$$\sum_{d|\ell} d n(d,p) = p^\ell. \tag{24}$$

We call $\mathfrak{q}_\ell$ the number of divisors of ℓ and we write them in ascending order as

$$d_1 = 1 < d_2 < \cdots < d_{\mathfrak{q}_{\ell-1}} < d_{\mathfrak{q}_\ell} = \ell\ . \tag{25}$$

We introduce the

$$w(\ell,d,p) = \sum_{d_i<d} n(d_i,p). \tag{26}$$

Here the summation is over all divisors d_i of ℓ (given in Eq. (25)), which are smaller than d.

The total number of irreducible polynomials entering in the factorization of $y^{p^\ell}-y$ in Eq. (29) is

$$\mathfrak{M}(\ell,p) = \sum_{d|\ell} n(d,p). \tag{27}$$

Therefore an alternative labeling system for these polynomials is to use a single index $\mathfrak{N}$:

$$f_{\mathfrak{N}}(y) \equiv f_{d\kappa}(y), \quad \mathfrak{N} = 1, \ldots, \mathfrak{M}(\ell,p). \tag{28}$$

There is one-to-one map between the (d,κ) and $\mathfrak{N}$. When (d,κ) are given we calculate the corresponding $\mathfrak{N}$ as

$$\mathfrak{N} = w(\ell,d,p) + \kappa. \tag{29}$$

When the $\mathfrak{N}$ is given we can calculate the corresponding (d,κ) by finding the *largest* d_i among the divisors of ℓ (in Eq. (25)), such that the $w(\ell,d_i,p)$ is smaller than $\mathfrak{N}$ and then

$$d = d_{i+1}, \quad \kappa = \mathfrak{N} - w(\ell, d_i, p). \tag{30}$$

We introduce a notation which indicates for each number m in the Galois field GF(p^ℓ) the corresponding irreducible polynomial $f_{d\kappa}(y)$. We stress that this depends on the choice of the irreducible polynomial $P(\epsilon)$ in Eq. (2); but different choices lead to isomorphic results. We first take any of the d Galois conjugates corresponding to $f_{d\kappa}(y)$, and denote it as $m(d,\kappa,1)$. We then denote the rest of them as

$$m(d,\kappa,\nu) = [m(d,\kappa,1)]^{p^{\nu-1}}, \quad \kappa = 1, \ldots, n(d,p), \quad \nu = 1, \ldots, d. \tag{31}$$

The index ν labels the various Galois conjugates corresponding to a given irreducible polynomial $f_{d\kappa}(y)$. In the special case $d=1$ it is easily seen that $m(1,\kappa,1)=\kappa$ where $\kappa \in \mathcal{Z}_p$.

It is clear from our above-presented discussion that an alternative labeling system for these numbers is

$$m(d,\kappa,\nu) = m(\mathfrak{N},\nu), \tag{32}$$

where the relation between (d,κ) and $\mathfrak{N}$ has been given in Eqs. (29) and (30).

C. Subfields

When d is a divisor of ℓ the GF(p^d) is a subfield of GF(p^ℓ). The GF(p^d) contains the Galois conjugates corresponding to all irreducible polynomials $f_{e\kappa}(y)$ where e is a divisor of d. Then:

$$\prod_{e|d} \prod_{\kappa=1}^{n(e,p)} f_{e\kappa}(y) = y^{p^d} - y. \tag{33}$$

The $y^{p^d}-y$ is a divisor of $y^{p^\ell}-y$.

Using the other labeling method of the irreducible polynomials we rewrite Eq. (33) as

$$\prod_{\mathfrak{N}=1}^{\mathfrak{M}(d,p)} f_{\mathfrak{N}}(y) = y^{p^d} - y. \tag{34}$$

When the label $\mathfrak{N}$ takes all values from 1 to $\mathfrak{M}(d,p)$, we get all the irreducible polynomials $f_{\mathfrak{N}}(y)$ contained in $y^{p^d}-y$.

The

$$\Sigma_d = \{\mathbf{1}, \sigma^d, \ldots, \sigma^{\ell-d}\} \tag{35}$$

form a cyclic group of order ℓ/d. It is a subgroup of Σ_1 and comprises all automorphisms of GF(p^ℓ) which leave the elements of the subfield GF(p^d) fixed.

D. Example

We consider the field GF(16). Practical calculations depend on the choice of the irreducible polynomial and we choose $P(\epsilon)=\epsilon^4+\epsilon+1$. The matrices g, G, and $\mathcal{C}$ are in this example:

$$g = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix}, \quad G = \begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix}, \quad \mathcal{C} = \begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{36}$$

The irreducible polynomials are

$$f_{11}(y)=y,$$

$$f_{12}(y)=y-1,$$

$$\begin{aligned} f_{21}(y)&=y^2+y+1=(y-\epsilon-\epsilon^2)(y-1-\epsilon-\epsilon^2),\\ f_{41}(y)&=y^4+y+1=(y-\epsilon)(y-\epsilon^2)(y-1-\epsilon)(y-1-\epsilon^2),\end{aligned} \tag{37}$$

$$f_{42}(y)=y^4+y^3+y^2+y+1=(y-\epsilon^3)(y-\epsilon^2-\epsilon^3)(y-1-\epsilon-\epsilon^2-\epsilon^3)(y-\epsilon-\epsilon^3),$$

$$f_{43}(y)=y^4+y^3+1=(y-1-\epsilon^3)(y-1-\epsilon^2-\epsilon^3)(y-\epsilon-\epsilon^2-\epsilon^3)(y-1-\epsilon-\epsilon^3).$$

In this case the labeling of the elements of this field introduced in Eq. (31) is as follows:

$$m(1,1,1)=0,\quad m(1,2,1)=1,$$

$$m(2,1,1)=\epsilon+\epsilon^2,\quad m(2,1,2)=1+\epsilon+\epsilon^2,$$

$$m(4,1,1)=\epsilon,\quad m(4,1,2)=\epsilon^2,\quad m(4,1,3)=1+\epsilon,\quad m(4,1,4)=1+\epsilon^2, \tag{38}$$

$$m(4,2,1)=\epsilon^3,\quad m(4,2,2)=\epsilon^2+\epsilon^3,\quad m(4,2,3)=1+\epsilon+\epsilon^2+\epsilon^3,\quad m(4,2,4)=\epsilon+\epsilon^3,$$

$$m(4,3,1)=1+\epsilon^3,\quad m(4,3,2)=1+\epsilon^2+\epsilon^3,\quad m(4,3,3)=\epsilon+\epsilon^2+\epsilon^3,\quad m(4,3,4)=1+\epsilon+\epsilon^3.$$

It is easy to check that the four elements $m(1,1,1)$, $m(1,2,1)$, $m(2,1,1)$, $m(2,1,2)$ associated to the irreducible polynomials $f_{11}(y)$, $f_{12}(y)$, $f_{21}(y)$, form a subfield which is the GF(4).

III. GALOIS QUANTUM SYSTEMS

A. Finite quantum systems with phase space $\mathcal{Z}_d\times\mathcal{Z}_d$

We consider a quantum system with a d-dimensional Hilbert space $\mathcal{H}$ and an orthonormal basis of "position states" $|\mathcal{X};m\rangle$ where m takes values in the ring $\mathcal{Z}_d$. The Fourier operator is defined as

$$\mathcal{F}=d^{-1/2}\sum_{m=0}^{d-1}\sum_{n=0}^{d-1}\Omega_d(mn)|\mathcal{X};m\rangle\langle\mathcal{X};n|,\quad \mathcal{F}^4=\mathbf{1}, \tag{39}$$

where we use the notation

$$\Omega_d=\exp\left[i\frac{2\pi}{d}\right],\quad \Omega_d(m)\equiv\Omega_d^m,\quad m\in\mathcal{Z}_d. \tag{40}$$

Acting with the Fourier operators on the position states we get the momentum states

$$|\mathcal{P};m\rangle=\mathcal{F}|\mathcal{X};m\rangle=d^{-1/2}\sum_n\Omega_d(mn)|\mathcal{X};n\rangle. \tag{41}$$

Position and momentum operators $\hat{x}$ and $\hat{p}$ are defined as

$$\mathfrak{x} = \sum_{n=0}^{d-1} n|\mathcal{X};n\rangle\langle\mathcal{X};n|, \quad \mathfrak{p} = \mathcal{F}\hat{x}\mathcal{F}^{\dagger} = \sum_{n=0}^{d-1} n|\mathcal{P};n\rangle\langle\mathcal{P};n|. \tag{42}$$

All numbers in $\mathcal{Z}_p$ obey the relation $m^p = m$ and the Cayley-Hamilton theorem can be used to prove that::

$$\mathfrak{x}^p = \mathfrak{x}; \quad \mathfrak{p}^p = \mathfrak{p}. \tag{43}$$

The position-momentum phase space is the toroidal lattice $\mathcal{Z}_d \times \mathcal{Z}_d$ and in it we define displacement operators which form the Heisenberg-Weyl group:

$$\mathcal{Z} = \Omega_d^{\mathfrak{x}} = \sum_{n=0}^{d-1} \Omega_d(n)|\mathcal{X};n\rangle\langle\mathcal{X};n|,$$

$$\mathcal{X} = \Omega_d^{-\mathfrak{p}} = \sum_{n=0}^{d-1} \Omega_d(-n)|\mathcal{P};n\rangle\langle\mathcal{P};n|, \tag{44}$$

$$\mathcal{X}^d = \mathcal{Z}^d = \mathbf{1}, \quad \mathcal{X}^\beta\mathcal{Z}^\alpha = \mathcal{Z}^\alpha\mathcal{X}^\beta\Omega_d(-\alpha\beta), \quad \alpha,\beta \in \mathcal{Z}_d.$$

General displacement operators are defined as

$$\mathcal{D}(\alpha,\beta) = \mathcal{Z}^\alpha\mathcal{X}^\beta\Omega_d(-2^{-1}\alpha\beta). \tag{45}$$

B. Galois quantum systems with phase space GF(p^ℓ)×GF(p^ℓ)

We next consider the case that d is a prime p in which case $\mathcal{Z}_p$ is a Galois field and the phase space $\mathcal{Z}_p \times \mathcal{Z}_p$ is a finite geometry. This is an example of a Galois quantum system. Following Ref. 7 we construct bigger Galois quantum systems with dimension p^ℓ by considering the tensor product

$$H = \mathcal{H} \otimes \cdots \otimes \mathcal{H} \tag{46}$$

of ℓ such spaces. We use calligraphic letters for operators and states on the various p-dimensional Hilbert spaces $\mathcal{H}$; and ordinary letters for operators and states on the p^ℓ-dimensional Hilbert space H.

The position states in H are labeled with $m \in \mathrm{GF}(p^\ell)$:

$$|X;m\rangle \equiv |\mathcal{X};m_0\rangle \otimes \cdots \otimes |\mathcal{X};m_{\ell-1}\rangle. \tag{47}$$

The system is in the position state $m = m_0 + m_1\epsilon + \cdots + m_{\ell-1}\epsilon^{\ell-1}$ when its first component is in the position state m_0, its second component in the position state m_1, etc.

The Fourier transform is given by

$$F = (p^\ell)^{-1/2}\sum_{m,n} \omega[\mathrm{Tr}(mn)]|X;m\rangle\langle X;n|, \quad F^4 = \mathbf{1}, \tag{48}$$

where $\omega = \Omega_p$ (see also Eq. (13)). We note that F is different from the operator $\mathcal{F}\otimes\cdots\otimes\mathcal{F}$ which performs independent Fourier transforms on each of the component systems. A Galois quantum system with Hilbert space H, Fourier transform F, and positions (and momenta) in GF(p^ℓ) has much more structure than a "simple" tensor product system which has the same Hilbert space H, Fourier transform $\mathcal{F}\otimes\cdots\otimes\mathcal{F}$ and positions (and momenta) in $\mathcal{Z}_p \times \cdots \times \mathcal{Z}_p$. An element m of the Galois field GF(p^ℓ) is *not* just an ℓ-dimensional vector $(m_0,\ldots,m_{\ell-1})$; there is a lot of extra structure related to the Galois multiplication. And this enters in the Fourier transform Fwhich uses

the trace of the Galois product mn and which according to Eq. (8) is $\Sigma g_{\lambda\kappa} m_\lambda n_\kappa$. In contrast, the Fourier transform $\mathcal{F}\otimes\cdots\otimes\mathcal{F}$ uses the $\Sigma m_\lambda n_\lambda$:

$$F=(p^\ell)^{-1/2}\sum_{m,n}\omega\Big[\sum g_{\lambda\kappa}m_\lambda n_\kappa\Big]|\mathcal{X};m_0\rangle\langle\mathcal{X};n_0|\otimes\cdots\otimes|\mathcal{X};m_{\ell-1}\rangle\langle\mathcal{X};n_{\ell-1}|,$$
$$\mathcal{F}\otimes\cdots\otimes\mathcal{F}=(p^\ell)^{-1/2}\sum_{m,n}\omega\Big[\sum m_\lambda n_\lambda\Big]|\mathcal{X};m_0\rangle\langle\mathcal{X};n_0|\otimes\cdots\otimes|\mathcal{X};m_{\ell-1}\rangle\langle\mathcal{X};n_{\ell-1}| \tag{49}$$

Momentum states are defined as

$$|P;m\rangle=F|X;m\rangle=(p^\ell)^{-1/2}\sum_n\omega[\mathrm{Tr}(mn)]|X;n\rangle=|\mathcal{P};\overline{m_0}\rangle\otimes\cdots\otimes|\mathcal{P};\overline{m}_{\ell-1}\rangle. \tag{50}$$

The dual components $\overline{m_i}$ of m enter in the momentum states, while the components m_i enter in the position states.

The position and momentum operators are given by

$$\hat{x}=\sum_m m|X;m\rangle\langle X;m|,\quad \hat{p}=F\hat{x}F^\dagger=\sum_m m|P;m\rangle\langle P;m|. \tag{51}$$

All numbers in $\mathrm{GF}(p^\ell)$ obey the relation $m^{p^\ell}=m$ and the Cayley–Hamilton theorem can be used to prove that

$$\hat{x}^{p^\ell}=\hat{x},\quad \hat{p}^{p^\ell}=\hat{p}. \tag{52}$$

C. Displacements in Galois quantum systems

Displacement operators in Galois quantum systems have been discussed in Ref. 7. They are given by

$$Z^\alpha=\sum_n\omega[\mathrm{Tr}(\alpha n)]|X;n\rangle\langle X;n|,$$
$$X^\beta=\sum_n\omega[-\mathrm{Tr}(\beta n)]|P;n\rangle\langle P;n|, \tag{53}$$

where $\alpha,\beta\in\mathrm{GF}(p^\ell)$. We can show that

$$Z^\alpha|P;m\rangle=|P;m+\alpha\rangle,\quad Z^\alpha|X;m\rangle=\omega[\mathrm{Tr}(\alpha m)]|X;m\rangle, \tag{54}$$

$$X^\beta|P;m\rangle=\omega[-\mathrm{Tr}(m\beta)]|P;m\rangle,\quad X^\beta|X;m\rangle=|X;m+\beta\rangle, \tag{55}$$

and also that

$$X^\beta Z^\alpha=Z^\alpha X^\beta\omega[-\mathrm{Tr}(\alpha\beta)]. \tag{56}$$

The displacement operators form a Heisenberg-Weyl group.

General displacement in the $\mathrm{GF}(p^\ell)\times\mathrm{GF}(p^\ell)$ phase space is defined as

$$D(\alpha,\beta)=Z^\alpha X^\beta\omega\Big[-\tfrac{1}{2}\,\mathrm{Tr}(\alpha\beta)\Big]. \tag{57}$$

The displacement operators acting on H are expressed in terms of the displacement operators $\mathcal{D}$ acting on the various components of the system as

$$D(\alpha,\beta)=\mathcal{D}(\overline{\alpha_0},\beta_0)\otimes\cdots\otimes\mathcal{D}(\overline{\alpha}_{\ell-1},\beta_{\ell-1}). \tag{58}$$

Here $\overline{\alpha_i}$ are the dual components of α and β_i are the components of β as in Eq. (6).

IV. FROBENIUS FORMALISM

A. Frobenius subspaces

We split the Hilbert space H into subspaces, each of which is spanned by conjugate position states, i.e., position states labeled with Galois conjugate numbers. All Galois conjugates correspond to a particular irreducible polynomial and we label each of these subspaces with the indices of the corresponding irreducible polynomial. For the irreducible polynomial $f_{d\kappa}(y)$ we consider the d-dimensional space

$$\mathfrak{H}_{d\kappa} = \text{span}\{|X;m(d,\kappa,1)\rangle, |X;m(d,\kappa,2)\rangle, \ldots, |X;m(d,\kappa,d)\rangle\}. \tag{59}$$

We have explained earlier that d is a divisor of ℓ and takes $\mathfrak{q}_\ell$ values; and that κ takes $n(d,p)$ values. An alternative to the indices (d,κ) is the index $\mathfrak{N}$ as explained in Eqs. (29) and (30). Therefore Eq. (59) can be rewritten as

$$\mathfrak{H}_{\mathfrak{N}} = \text{span}\{|X;m(\mathfrak{N},1)\rangle, |X;m(\mathfrak{N},2)\rangle, \ldots, |X;m(\mathfrak{N},d)\rangle\}. \tag{60}$$

We call $\pi_{d\kappa}$ (or $\pi_{\mathfrak{N}}$) the projection operators to the spaces $\mathfrak{H}_{d\kappa}$. In the special case $d=1$ we have p one-dimensional spaces $\mathfrak{H}_{1\kappa}$ and

$$\pi_{1\kappa} = |X;\kappa\rangle\langle X;\kappa|, \quad \kappa \in \mathcal{Z}_p. \tag{61}$$

The spaces $\mathfrak{H}_{d\kappa}$ have been defined with respect to position states. If we use the states $U|X;m\rangle$ where U is any unitary operator we will get different Frobenius subspaces which we denote as $U\mathfrak{H}_{d\kappa}$. For example, the Frobenius subspaces with respect to momentum states are $F\mathfrak{H}_{d\kappa}$ and they are different from $\mathfrak{H}_{d\kappa}$. Only in the special case the U commutes with $\pi_{d\kappa}$, the spaces $U\mathfrak{H}_{d\kappa}$ and $\mathfrak{H}_{d\kappa}$ are the same:

$$[U,\pi_{d\kappa}] = 0 \rightarrow U\mathfrak{H}_{d\kappa} = \mathfrak{H}_{d\kappa}. \tag{62}$$

We call $\overline{\mathfrak{H}}_d$ the Hilbert space which is the direct sum of all $\mathfrak{H}_{d\kappa}$:

$$\overline{\mathfrak{H}}_d = \bigoplus_{\kappa=1}^{n(d,p)} \mathfrak{H}_{d\kappa} = \bigoplus_{\mathfrak{N}=w(\ell,d,p)+1}^{w(\ell,d,p)+n(d,p)} \mathfrak{H}_{\mathfrak{N}}, \tag{63}$$

where $w(\ell,d,p)$ has been defined in Eq. (26). The dimension of $\overline{\mathfrak{H}}_d$ is $dn(d,p)$. We call $\overline{\pi}_d$ the projection operators to the spaces $\overline{\mathfrak{H}}_d$.

The Frobenius subspace $\mathfrak{H}_{d\kappa}$ is the null space of the corresponding irreducible polynomial operator $f_{d\kappa}(\hat{x})$,

$$f_{d\kappa}(\hat{x})\,\pi_{d\kappa} = 0. \tag{64}$$

B. Galois subsystems

Let d be a divisor of ℓ. We call H_d the Hilbert space which is the direct sum of all $\overline{\mathfrak{H}}_e$ where e is any of the $\mathfrak{q}_d$ divisors of d:

$$H_d = \bigoplus_{e|d} \overline{\mathfrak{H}}_e. \tag{65}$$

This space is spanned by position states labeled with numbers in the subfield $\text{GF}(p^d)$. Indeed we have included here position states labeled with Galois numbers corresponding to all irreducible polynomials $f_{e\kappa}(y)$ where e is a divisor of d; and we have seen in Eq. (33) that they form the subfield $\text{GF}(p^d)$. Therefore the space H_d describes a Galois subsystem. In the special case $d=1$ the space H_1 is p-dimensional and is spanned by position states labeled with integers in $\mathcal{Z}_p$. In the other extreme special case $d=\ell$ it is easily seen that $H_\ell = H$.

We note that the spaces $\mathfrak{H}_{d\kappa}$ and $\overline{\mathfrak{H}}_d$ describe subsystems which are *not* Galois subsystems because the position does not take all values in a Galois subfield.

We call Π_d the projection operator to the space H_d. Then:

$$\Pi_d = \sum_{e|d} \sum_{\kappa=1}^{n(e,p)} \pi_{e\kappa} = \sum_{e|d} \overline{\pi}_e. \tag{66}$$

In the special cases $d=1$ and $d=\ell$ we get

$$\Pi_1 = \sum_{\kappa \in \mathcal{Z}_p} |X;\kappa\rangle\langle X;\kappa|, \quad \Pi_\ell = \mathbf{1}. \tag{67}$$

C. Frobenius transformations

Frobenius transformations in $\mathfrak{H}_{d\kappa}$ are the following unitary transformations:

$$\mathcal{G}_{d\kappa} = \sum_{\nu \in \mathcal{Z}_d} |X;m(d,\kappa,\nu+1)\rangle\langle X;m(d,\kappa,\nu)|,$$
$$\mathcal{G}_{d\kappa}^d = \pi_{d\kappa}. \tag{68}$$

The summation is over all the Galois conjugates corresponding to the irreducible polynomial $f_{d\kappa}$. In the special case $d=1$ we get

$$\mathcal{G}_{1\kappa} = \pi_{1\kappa} = |X;\kappa\rangle\langle X;\kappa|, \quad \kappa \in \mathcal{Z}_p. \tag{69}$$

The $\{\mathbf{1}, \mathcal{G}_{d\kappa}, \mathcal{G}_{d\kappa}^2, \ldots, \mathcal{G}_{d\kappa}^{d-1}\}$ form a cyclic group of order d.

We sum all the transforms $\mathcal{G}_{d\kappa}$ and we get the following unitary transformations in H:

$$\mathcal{G} = \sum_{d,\kappa} \mathcal{G}_{d\kappa}, \quad \mathcal{G}^\ell = \mathbf{1}, \quad [\mathcal{G}, \pi_{d\kappa}] = 0, \quad \mathcal{G}\pi_{d\kappa} = \mathcal{G}_{d\kappa}. \tag{70}$$

As above, d are the divisors of ℓ; and κ takes values from 1 to $n(d,p)$. These transformations are the analogue in the present context of the transformations σ in Eq. (17) for Galois fields, and we call them Frobenius transformations. More general relations than $\mathcal{G}^\ell = \mathbf{1}$ are the following:

$$\mathcal{G}^d \overline{\pi}_d = \overline{\pi}_d, \quad \mathcal{G}^d \Pi_d = \Pi_d. \tag{71}$$

We have explained earlier that the spaces $\mathfrak{H}_{d\kappa}$ have been defined with respect to position states; and that if we use more general states $U|X;m\rangle$ we get different Frobenius subspaces $U\mathfrak{H}_{d\kappa}$. The corresponding Frobenius transformations in these spaces, are $U\mathcal{G}U^\dagger$. Only in the special case

$$[\mathcal{G}, U] = 0 \tag{72}$$

the Frobenius transformations are the same in both sets of Frobenius subspaces $\mathfrak{H}_{d\kappa}$ and $U\mathfrak{H}_{d\kappa}$. An example of this is the Frobenius subspaces $F\mathfrak{H}_{d\kappa}$, with respect to momentum states. Using Eq. (16) we prove that in this case

$$[\mathcal{G}, F] = 0. \tag{73}$$

Therefore the Frobenius transformations are the same in both $F\mathfrak{H}_{d\kappa}$ and $\mathfrak{H}_{d\kappa}$. Acting with $\mathcal{G}^\lambda$ on position and momentum states we get

$$\mathcal{G}^\lambda |X;m\rangle = |X;m^{p^\lambda}\rangle, \quad \mathcal{G}^\lambda |P;m\rangle = |P;m^{p^\lambda}\rangle, \tag{74}$$

where $\lambda \in \mathcal{Z}_\ell$. We can also show that

$$\mathcal{G}^{\lambda}X^{\beta}(\mathcal{G}^{\dagger})^{\lambda}=X^{\beta^{p^{\lambda}}},\quad \mathcal{G}^{\lambda}Z^{\alpha}(\mathcal{G}^{\dagger})^{\lambda}=Z^{\alpha^{p^{\lambda}}} \tag{75}$$

and more generally that

$$\mathcal{G}^{\lambda}D(\alpha,\beta)(\mathcal{G}^{\dagger})^{\lambda}=D(\alpha^{p^{\lambda}},\beta^{p^{\lambda}}). \tag{76}$$

When $m,\alpha,\beta\in\mathcal{Z}_p$ we get

$$\begin{gathered} m\in\mathcal{Z}_p\rightarrow\mathcal{G}^{\lambda}|X;m\rangle=|X;m\rangle,\quad \mathcal{G}^{\lambda}|P;m\rangle=|P;m\rangle,\\ \alpha,\beta\in\mathcal{Z}_p\rightarrow\mathcal{G}^{\lambda}D(\alpha,\beta)(\mathcal{G}^{\dagger})^{\lambda}=D(\alpha,\beta). \end{gathered} \tag{77}$$

From Eqs. (74)–(76) it is tempting to interpret Frobenius transformations as magnifying the "area" of the phase space by a power (from A to $A^{p^{\lambda}}$). We note that the phase space here is *not* a continuum; that magnification is simply one-to-one relabeling; and that $\mathcal{G}^{\ell}=\mathbf{1}$.

The

$$\mathfrak{G}_1=\{\mathbf{1},\mathcal{G},\mathcal{G}^2,\ldots,\mathcal{G}^{\ell-1}\} \tag{78}$$

form a cyclic group of order ℓ whose elements leave fixed all the states in the Galois subsystem described with the space H_1. This is the analogue of the Galois group of Eq. (19) in the present context. If d is a divisor of ℓ the

$$\mathfrak{G}_d=\{\mathbf{1},\mathcal{G}^d,\mathcal{G}^{2d},\ldots,\mathcal{G}^{\ell-d}\} \tag{79}$$

form a cyclic subgroup of $\mathfrak{G}_1$ of order ℓ/d. Its elements leave fixed all states in the Galois subsystem described with the space H_d. This is the analogue of the group Σ_d in Eq. (35). We consider the subfield GF(p^d) of GF(p^{ℓ}). For m,α,β in the subfield GF(p^d) of GF(p^{ℓ}), we get

$$\begin{gathered} m\in GF(p^d)\rightarrow\mathcal{G}^{\lambda d}|X;m\rangle=|X;m\rangle,\quad \mathcal{G}^{\lambda d}|P;m\rangle=|P;m\rangle,\\ \alpha,\beta\in GF(p^d)\rightarrow\mathcal{G}^{\lambda d}D(\alpha,\beta)(\mathcal{G}^{\dagger})^{\lambda d}=D(\alpha,\beta). \end{gathered} \tag{80}$$

V. ANALYTIC REPRESENTATION OF GALOIS QUANTUM SYSTEMS IN RIEMANN SURFACES

Various analytic representations have been used in quantum mechanics (for a review see Ref. 25). Here we show that an analytic representation of quantum states in the space H can be defined in the ℓ-sheeted complex plane. This analytic representation is related to the one discussed in Ref. 26, which was introduced from a Riemann surfaces point of view and did not involve Galois theory. The aim here is to show the conceptual link between the multivaluedness in coverings of Riemann surfaces and the multivaluedness related to the conjugates in Galois theory.

A. Bargmann representation of a harmonic oscillator in the ℓ-sheeted complex plane

We consider a harmonic oscillator described with the infinite-dimensional Hilbert space h. In the number state basis $\{|N\rangle\}$, a general state $|f\rangle$ can be written as

$$|s\rangle=\sum_{N=0}^{\infty}s(N)|N\rangle,\quad \sum_{N=0}^{\infty}|s(N)|^2=1. \tag{81}$$

In the Bargmann representation this state is represented with the function

$$S_1(z) = \sum_{N=0}^{\infty} s(N) z^N (N!)^{-1/2}, \tag{82}$$

which is analytic in the complex plane C. The scalar product of two states $|s\rangle$ and $|q\rangle$ represented with the functions $S_1(z)$ and $Q_1(z)$ is given by

$$\langle q|s\rangle = \int_C d\mu_1(z) \exp(-|z|^2)[Q_1(z)]^* S_1(z), \quad d\mu_1(z) = \frac{dz_R dz_I}{\pi}, \tag{83}$$

where z_R, z_I are the real and imaginary parts of z, correspondingly.

Following Ref. 26 we consider the Riemann surface $C^*/\mathcal{Z}_\ell$ associated with the map $z^{1/\ell}$. Here $C^* = C - \{0\}$ is the punctured complex plane and $\mathcal{Z}_\ell$ the discrete group of transformations

$$z \to \Omega_\ell z, \tag{84}$$

which is isomorphic to the integers modulo ℓ. The covering surface of this Riemann surface is the ℓ-sheeted complex plane with the following cuts T_m and sheets Ξ_m:

$$\begin{aligned} T_m &= \{z = r\Omega_\ell^m; r \geqslant 0\}, \quad m = 0, \ldots, \ell - 1, \\ \Xi_m &= \left\{ z = r \exp(i\phi); r \geqslant 0; \frac{2\pi m}{\ell} < \phi < \frac{2\pi(m+1)}{\ell} \right\}. \end{aligned} \tag{85}$$

The sheet number of a complex number z is defined as

$$\tau(z) = \mathrm{IP}\left(\frac{\ell \arg(z)}{2\pi} \right), \quad \tau(z) \in \mathcal{Z}_\ell, \tag{86}$$

where IP stands for the integer part of the number. We split the Hilbert space h into ℓ subspaces as follows:

$$h = \bigoplus_{m=0}^{\ell-1} h_m, \quad h_m = \mathrm{span}\{|m\rangle, |m + \ell\rangle, |m + 2\ell\rangle, \ldots\}. \tag{87}$$

We call ϖ_m the projection operator to the space h_m. We introduce an analytic representation in the ℓ-sheeted complex plane where the general state $|s\rangle$ of Eq. (81) is represented with the function

$$S_\ell(z) = \sum_{N=0}^{\infty} s(\tau(z) + N\ell) z^{N\ell} (N!)^{-1/2}. \tag{88}$$

We note that in the m-sheet Ξ_m, this function represents only the projection $\varpi_m|s\rangle$ of the state $|s\rangle$ in the subspace h_m. But when we consider the function $S_\ell(z)$ in all the ℓ sheets we get all the projections $\varpi_m|s\rangle$ and therefore the full state $|s\rangle$.

The function $S_\ell(z)$ is analytic in the interior of all sheets Ξ_m and has discontinuities across the cuts T_m given by

$$\Delta_m(z) = \sum_{N=0}^{\infty} [s(m + N\ell) - s(m + N\ell - 1)] z^{\ell N} (N!)^{-1/2}. \tag{89}$$

The scalar product of two states $|s\rangle$ and $|q\rangle$ represented with the functions $S_\ell(z)$ and $Q_\ell(z)$ is given by

$$\langle q|s\rangle = \int_C d\mu_\ell(z)\exp(-|z|^{2\ell})[Q_\ell(z)]^* S_\ell(z), \quad d\mu_\ell(z) = \ell^2|z|^{2(\ell-1)}\frac{dz_R dz_I}{\pi}. \tag{90}$$

More details about this formalism are given in Ref. 26.

B. Analytic representation of Galois quantum systems in the ℓ-sheeted complex plane

We now apply the general formalism of the previous section in our context. We consider a Galois quantum system described with the Hilbert space H. Using the orthonormal basis $|X;m(\mathfrak{N},\nu)\rangle$ which we introduced earlier, we express the general state of this system as

$$|s\rangle = \sum_{\mathfrak{N}=1}^{\mathfrak{M}(\ell,p)} \sum_{\nu=1}^{d} s(\mathfrak{N},\nu)|X;m(\mathfrak{N},\nu)\rangle. \tag{91}$$

In the summation ν takes values from 1 to d (which is given in terms of $\mathfrak{N}$ in Eq. (30)). We will describe how this state is represented by an analytic function, in three steps.

In the first step we consider the projection of this state to the d-dimensional space $\mathfrak{H}_\mathfrak{N}$,

$$\pi_\mathfrak{N}|s\rangle = \sum_{\nu=1}^{d} s(\mathfrak{N},\nu)|X;m(\mathfrak{N},\nu)\rangle. \tag{92}$$

This is represented in the ℓ-sheeted complex plane with the function

$$\mathfrak{S}_\mathfrak{N}(z) = s[\mathfrak{N},\nu=\tau(z)(\mathrm{mod}\ d)]z^{\ell\mathfrak{N}}(\mathfrak{N}\,!\,)^{-1/2}. \tag{93}$$

In the first d sheets we have d functions which represent the d components of this state (for ν equal 1 to d). The fact that $\nu=\tau(z)$ modulo d, implies that there is periodicity in the next d sheets, which continues up to the last d sheets (the d is a divisor of ℓ). Therefore

$$\mathfrak{S}_\mathfrak{N}(z\Omega_\ell^d) = \mathfrak{S}_\mathfrak{N}(z). \tag{94}$$

In the second step we consider the projection of the state $|s\rangle$ to the $dn(d,p)$-dimensional space $\overline{\mathfrak{H}}_d$:

$$\overline{\pi}_d|s\rangle = \sum_{\mathfrak{N}=w(\ell,d,p)+1}^{w(\ell,d,p)+n(d,p)} \sum_{\nu} s(\mathfrak{N},\nu)|X;m(\mathfrak{N},\nu)\rangle, \tag{95}$$

where $w(\ell,d,p)$ has been defined in Eq. (26). This is represented in the ℓ-sheeted complex plane with the function

$$\overline{\mathfrak{S}}_d(z) = \sum_{\mathfrak{N}=w(\ell,d,p)+1}^{w(\ell,d,p)+n(d,p)} \mathfrak{S}_\mathfrak{N}(z) = \sum_{\mathfrak{N}=w(\ell,d,p)+1}^{w(\ell,d,p)+n(d,p)} s[\mathfrak{N},\nu=\tau(z)(\mathrm{mod}\ d)]z^{\ell\mathfrak{N}}(\mathfrak{N}\,!\,)^{-1/2}. \tag{96}$$

As above, d different functions in the first d sheets represent this state and there is periodicity in the rest of the sheets:

$$\overline{\mathfrak{S}}_d(z\Omega_\ell^d) = \overline{\mathfrak{S}}_d(z). \tag{97}$$

We note that Frobenius transformations on the state $\overline{\pi}_d|s\rangle$ are easily implemented in this representation as

$$\mathcal{G}^\kappa\overline{\pi}_d|s\rangle \to \overline{\mathfrak{S}}_d(z\Omega_\ell^\kappa). \tag{98}$$

Then Eq. (97) expresses in this representation the relation $\mathcal{G}^d\overline{\pi}_d=\overline{\pi}_d$ given in Eq. (71).

In the third step we consider the full state $|s\rangle$. It is represented with the function

$$S(z)=\sum_d \overline{\mathfrak{S}}_d(z)=\sum_{\mathfrak{N}=1}^{\mathfrak{M}(\ell,,p)} s[\mathfrak{N},\nu=\pi(z)(\mathrm{mod}\ d)]z^{\ell\mathfrak{N}}(\mathfrak{N}\,!\,)^{-1/2}. \tag{99}$$

The function $S(z)$ is analytic in the interior of all sheets Ξ_m and has discontinuities across the cuts T_m given by

$$\Delta_m(z)=\sum_{\mathfrak{N}=1}^{\mathfrak{M}(\ell,,p)} \{s[\mathfrak{N},\nu=m(\mathrm{mod}\ d)]-s[\mathfrak{N},\nu=m-1(\mathrm{mod}\ d)]\}z^{\ell\mathfrak{N}}(\mathfrak{N}\,!\,)^{-1/2}. \tag{100}$$

The scalar product of two states is given by Eq. (90).

Frobenius transformations on the state $|s\rangle$ are easily implemented in this representation as

$$\mathcal{G}^\kappa|s\rangle\rightarrow S(z\Omega_\ell^\kappa). \tag{101}$$

The relation $\mathcal{G}^\ell=\mathbf{1}$ of Eq. (70), is seen in this representation through the fact that $\Omega_\ell^\ell=1$.

The projection $\Pi_d|s\rangle$ of the state $|s\rangle$ in the space H_d is represented with the function

$$S_d(z)=\sum_{e|d} \overline{\mathfrak{S}}_e(z). \tag{102}$$

The summation is over all divisors e of d. Using Eq. (97) we easily show that

$$S_d(z\Omega_\ell^d)=S_d(z). \tag{103}$$

This expresses in this representation the relation $\mathcal{G}^d\Pi_d=\Pi_d$ given in Eq. (71) which expresses the fact that the transformations of Eq. (79) leave fixed all the states in the Galois subsystem described with the space H_d.

VI. DISCUSSION

In this paper we brought ideas from the subject of field extension in the context of finite quantum systems. Field extension constructs large fields from smaller ones. We have constructed the Hilbert space H as the tensor product of ℓ Hilbert spaces $\mathcal{H}$ and used the Fourier transform of Eq. (48) which contains the trace of the Galois product, and this provides the system with Galois structure.

One important aspect of a Galois theory is the Frobenius automorphisms σ of $\mathrm{GF}(p^\ell)$ which are given in Eq. (17). Powers of these automorphisms leave fixed the elements of the subfield $\mathcal{Z}_p$ and form the cyclic group Σ_1 of Eq. (19) of order ℓ. More generally the powers of σ in Eq. (35) leave fixed the elements of the subfield $\mathrm{GF}(p^d)$ and form the cyclic group Σ_d of order ℓ/d. We have studied in detail the implications of this in our context. We have introduced the Frobenius transformations $\mathcal{G}$ of Eq. (70) and shown that its powers in Eq. (78) leave fixed all the states in the Galois subsystem described with the space H_1 and form the cyclic group $\mathfrak{G}_1$ of order ℓ. More generally the powers of $\mathcal{G}$ in Eq. (79) leave fixed all the states in the Galois subsystem described with the space H_d and form the cyclic group $\mathfrak{G}_d$ of order ℓ/d.

We have also studied an analytic representation of Galois quantum systems in the ℓ-sheeted complex plane. The purpose is to show connections between Riemann surfaces and Galois theory. The basic idea is that multivaluedness in Riemann surfaces can be related to the Galois conjugates. We have seen in Eq. (101) how the Frobenius transformations are implemented in this language; and how the fact that the transformations of Eq. (79) leave fixed all the states in the Galois subsystem described with the space H_d is easily proved using Eq. (103).

Galois fields have previously been used in quantum mechanics with a physical motivation: in order to have well-defined symplectic transformations; or in the context of mutually unbiased bases; or in the context of quantum coding. The present paper studied more mathematical aspects

of this structure and in particular the Frobenius formalism and its links to Riemann surfaces. Potential applications include quantum coding, quantum information processing, the magnetic translation group in condensed matter, quantum chaos, etc.

(Received 21 June 2006; accepted 29 July 2006; published online 20 September 2006)

It is well known that the Berry phase of a cyclic adiabatic dynamical system appears formally as the flux of a magnetic field in the control parameter manifold. In this electromagnetic picture a level crossing appears as a Dirac magnetic monopole in this manifold. We make an extensive study of the magnetic monopole model of eigenvalue crossings. We show that the properties of the monopole magnetic field in the control manifold are determined by the immersion of the control manifold in a space given by the universal classifying theorem of fiber bundles. We give a detailed illustrative study of the simple but instructive case of a two level crossing of a system controlled by a two-dimensional manifold. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2345473]

I. INTRODUCTION

In 1984, Berry Ref. 1 proved, in the context of the standard adiabatic approximation, that the wave function of a quantum dynamical system takes the form

$$\psi(t) = \exp\left(- i\hbar^{-1} \int_0^t E_a(\vec{R}(t'))\mathrm{d}t' - \int_0^t \langle a,\vec{R}(t')|\partial_{t'}|a,\vec{R}(t')\rangle \mathrm{d}t' \right) |a,\vec{R}(t)\rangle, \tag{1}$$

where E_a is a nondegenerate instantaneous eigenvalue which is isolated from the rest of the Hamiltonian spectrum and has the instantaneous eigenvector $|a,\vec{R}(t)\rangle$. $\vec{R}$ is a set of classical control parameters used to model the time-dependent environment of the system. The set of all configurations of $\vec{R}$ is assumed to form a $\mathcal{C}^\infty$-manifold $\mathcal{M}$. The important result is the presence of an extra phase term $\exp(-\int_0^t \langle a,\vec{R}(t')|\partial_{t'}|a,\vec{R}(t')\rangle \mathrm{d}t')$ called the Berry phase. Simon[2] later found that the mathematical structure which models the Berry phase phenomenon is a principal bundle with base space $\mathcal{M}$ and with structure group U(1). If we eliminate the dynamical phase by a gauge transformation, which involves redefining the eigenvector at each time, then the expression [Eq. (1)) is the horizontal lift of the curve $\mathcal{C}$ described by $t \mapsto \vec{R}(t)$ with gauge potential $A = \langle a,\vec{R}|d_{\mathcal{M}}|a,\vec{R}\rangle$. If $\mathcal{C}$ is closed then the Berry phase $\exp(-\oint_{\mathcal{C}} A) \in \mathrm{U}(1)$ is the holonomy of the horizontal lift.

In 1984, Wilczek and Zee[3] introduced the concept of a non-Abelian Berry phase in the context of the adiabatic approximation. Let $E_a(\vec{R}(t))$ be an M-fold degenerate instantaneous eigenvalue isolated from the rest of the spectrum and $\{|a,i,\vec{R}(t)\rangle\}_{i=1,\ldots,M}$ be an orthonormal basis for the associated eigensubspace. If the initial state is $\psi(0)=|a,i,\vec{R}(0)\rangle$, then the wave function is

[a)]Electronic mail: viennot@obs-besancon.fr

$$\psi(t) = \sum_{j=1}^{M} \exp\left(-i\hbar^{-1} \int_0^t E_a(\vec{R}(t'))\mathrm{d}t' \right) \left[\mathbb{T} e^{-\int_0^t A(\vec{R}(t'))} \right]_{ji} |a, j, \vec{R}(t)\rangle, \tag{2}$$

where the matricial one-form A has the elements $A_{ij} = \langle a, i, \vec{R} | d_{\mathcal{M}} | a, j, \vec{R} \rangle$, and $\mathbb{T}$ is the time-ordering operator. By elimination of the dynamical phase this expression becomes a horizontal lift of the curve $\mathcal{C}$ described by $t \mapsto \vec{R}(t)$ into a principal bundle with base space $\mathcal{M}$ and structure group $\mathrm{U}(M)$. If $\mathcal{C}$ is closed then $\mathbb{P} \exp(-\oint_{\mathcal{C}} A(\vec{R})) \in \mathrm{U}(M)$ is the holonomy of the horizontal lift, $\mathbb{P}$ being the path-ordering operator.

More generally for a quantum dynamical system, let $\{E_a(\vec{R}(t))\}_{a \in I}$ be a set of eigenvalues indexed by I, and isolated from the rest of the spectrum. Suppose that $\psi(0) = |a, \vec{R}(0)\rangle$; the wave function is then

$$\psi(t) = \sum_{b \in I} \left[\mathbb{T} e^{-i\hbar^{-1} \int_0^t E(\vec{R}(t'))\mathrm{d}t' - \int_0^t A(\vec{R}(t'))} \right]_{ba} |b, \vec{R}(t)\rangle, \tag{3}$$

where we have the matrices $E(\vec{R}(t))_{ab} = E_a(\vec{R}(t))\,\delta_{ab}$ and $A(\vec{R})_{ab} = \langle a, \vec{R} | d_{\mathcal{M}} | b, \vec{R} \rangle$. When the matrices E and A do not commute then the mathematical structure which models the non-Abelian phase phenomenon is a principal composite bundle with base space $\mathcal{M} \times \mathbb{R}$, where $\mathbb{R}$ models the time (see Ref. 4).

For each of the three preceding cases, an appropriate gauge potential $A \in \Omega^1(\mathcal{M}, \mathfrak{u}(M))$ has been defined, to be associated with the principal bundle $\mathcal{P}$ with base space $\mathcal{M}$ and with structure group $\mathrm{U}(M)$ (where $M = 1$ for the Berry's orginal case; M is the degenerate order for Wilczek's case, and $M = \mathrm{card} I$ for the general case). In the one-dimensional case, the bundle curvature is defined by $B = d_{\mathcal{M}} A$ and it satisfies the equation $d_{\mathcal{M}} B = 0$. It is easy to prove that this equation is the analog in $\mathcal{M}$ to half of the Maxwell equations. We can then identify B with a magnetic field existing in $\mathcal{M}$ and A with its magnetic potential. In this picture, for any closed curve $\mathcal{C}$ for which there exists a surface $\mathcal{S} \subset \mathcal{M}$ such that $\partial_{\mathcal{M}} \mathcal{S} = \mathcal{C}$, the holonomy term can be written (using the Stokes theorem) as the flux of the magnetic field B through $\mathcal{S}$: $\oint_{\mathcal{C}} A = \int_{\mathcal{S}} B$. By using the expression for A, it is easy to show that

$$B = \mathrm{d}_{\mathcal{M}} A = 2i\mathfrak{I} \frac{\partial \langle a, \vec{R}|}{\partial R^\mu} \frac{\partial |a, \vec{R}\rangle}{\partial R^\nu} \mathrm{d}R^\mu \wedge \mathrm{d}R^\nu. \tag{4}$$

By using the closure relation one can write

$$B = i\mathfrak{I} \sum_{b \neq a} \frac{\langle a, \vec{R} | \partial_\mu H(\vec{R}) | b, \vec{R} \rangle \langle b, \vec{R} | \partial_\nu H(\vec{R}) | a, \vec{R} \rangle}{(E_b(\vec{R}) - E_a(\vec{R}))^2} \mathrm{d}R^\mu \wedge \mathrm{d}R^\nu, \tag{5}$$

where $H(\vec{R})$ is the system Hamiltonian. We cannot strictly apply the one-dimensional adiabatic approximation if the eigenvalue E_a is not isolated from the rest of the spectrum. Nevertheless, the formal use of this approximation in the case where two eigenvalues E_a and E_c cross at $\vec{R}_{ac} \in \mathcal{M}$, produces the result $B(\vec{R}_{ac}) = +\infty$. This magnetic field divergence must be interpreted as a magnetic monopole at $\vec{R}_{ac}$ in $\mathcal{M}$. In the M-dimensional case the field defined by the Cartan structure equation $F = d_{\mathcal{M}} A + \frac{1}{2}[A, A]$ satisfies the Bianchi identity $d_{\mathcal{M}} F + [A, F] = 0$. The Bianchi identity is analogous in $\mathcal{M}$ to half of the Yang-Mills equations. The eigenvalue crossings then appear as non-Abelian monopoles (so-called colored monopoles in the case where the structure group is SU(3), see Refs. 5 and 6), as has already been pointed by Wilczek and Zee.[3]

This paper studies the properties of the adiabatic magnetic monopoles, with special attention to the monopole magnetic field distribution in $\mathcal{M}$ and on the apparent charge of the monopole. We show that these properties are determined by the immersion of $\mathcal{M}$ in a universal space associated with the topology of the adiabatic bundle.

The concept of the virtual magnetic monopole is today very important for nonrelativistic quantum physics. In 1986, Moody *et al.*[7] showed the possibility of realizing a magnetic monopole via the precession of a diatomic molecule. Fang *et al.*[8] showed that a trapped Λ-type atom induced a magnetic monopole. Recently Zhong *et al.*[9,10] observed experimentally a magnetic monopole in the crystal momentum space related to the anomalous Hall effect in the $SrRuO_3$ crystal. These examples show the importance of understanding the properties of the adiabatic magnetic monopoles.

Section II recalls the definition and the properties of the universal classifying space for the general case. Section III is devoted to the Dirac magnetic monopole theory, in particular its link with Berry's original example of a geometric phase. A more complete discussion of the results reviewed in these sections can be found in Ref. 11. Originally $\mathcal{M}$ is a soft manifold (i.e., one without a natural metric), because it is a set of classical control parameters of the environment which do not necessarily have the same physical nature. Section IV shows that $\mathcal{M}$ can be rigidified (endowed with a metric) by an appropriate immersion. This rigidification is needed to describe the monopole magnetic field distribution in $\mathcal{M}$. Section V is devoted to the analysis of the apparent monopole charge in $\mathcal{M}$. Section VI generalizes the discussion to the case of the non-Abelian monopoles. In most of this paper we suppose that $\dim \mathcal{M}=2$ and restrict our attention to the monopole (level crossing) neighborhood. We discuss the effect of these assumptions in the last section.

II. THE UNIVERSAL SPACE OF QUANTUM ADIABATIC DYNAMICS

Bohm and Mostafazadeh showed in Refs. 12 and 13 that the Berry phase phenomena are related to the nonadiabatic geometric phases of cyclic dynamical quantum systems discovered by Aharonov and Anandan.[14] This relationship is given by the universal classifying theorem of principal bundles (see Refs. 15 and 16). Here we recall this theorem, and the associated induced geometric structure of quantum mechanics.

A. The universal classifying theorem

Let $\mathcal{B}=(B,X,G,\pi_B)$ be a principal bundle with base space X, total space B, structure group G, and projection π_B. We say that $\mathcal{B}$ is n-universal if for every cell n-complex K (see Refs. 15 and 16), for every cell subcomplex $L\subset K$, for every principal bundle $\mathcal{B}'=(B',K,G,\pi_{B'})$ and for every map $h:(\pi_{B'}^{-1}(L),L,G,\pi_{B'})\to(B,X,G,\pi_B)$, there exists an extension of h to $(B',K,G,\pi_{B'})\to(B,X,G,\pi_B)$.

If $\mathcal{B}=(B,X,G,\pi_B)$ is $(n+1)$-universal and if K is a cell n-complex then there exists a map $f:K\to X$ such that the following diagram commutes

$$\begin{array}{ccc} f^*B & \overset{f^*}{\leftarrow} & B \\ \pi_{f^*B}\downarrow & & \downarrow\pi_B \\ K & \overset{f}{\rightarrow} & X \end{array},$$

where $f^*\mathcal{B}$ is the bundle induced by f. X is called the universal manifold of K and f is called the universal map. In the case of the adiabatic bundle $\mathcal{P}$, the situation is as follows. Suppose that the Hilbert space is n-dimensional. In the case of the one-dimensional adiabatic approximation, the universal manifold of $\mathcal{P}$ is the projective space $\mathbb{C}P^{n-1}$, and the universal map can be written:

$$f:\begin{array}{c}\mathcal{M}\to\mathbb{C}P^{n-1}\\ \vec{R}\mapsto|a,\vec{R}\rangle\langle a,\vec{R}|\end{array}.$$

In the m-dimensional adiabatic approximation, the universal manifold is the Grassmanian manifold $G_m(\mathbb{C}^n)=U(n)/(U(m)\times U(m-n))$ and the universal map is

$$\mathcal{M} \to G_m(\mathbb{C}^n)$$
$$f: \vec{R} \mapsto \sum_{a \in I} |a,\vec{R}\rangle\langle a,\vec{R}|$$

(see Ref. 13). In the following we will restrict our attention to $\mathbb{C}P^{n-1}$ and will analyze its structure.

B. The Kählerian structure of quantum dynamics

The physical reason which explains why $\mathbb{C}P^{n-1}$ is the universal space of quantum mechanics is the following. We know that the mathematical structure of quantum mechanics is a separable $\mathbb{C}$-Hilbert space $\mathcal{H}$ which models the state space. The probabilistic interpretation of quatum mechanics states that a physical state ψ is a probability amplitude, and so we must have $\|\psi\|=1$. In this way two proportional vectors represent the same physical state. Moreover, the phase of a vector does not give physical information; only the phase difference between two vectors has a physical meaning (quantum interference theory). We then see that the Hilbert space $\mathcal{H}$ contains a lot of "nonphysical" information, so that it is not the most efficient structure to describe quantum mechanics. To define the "true" space of quantum mechanics we first consider $\mathcal{H}$. If $\psi=\alpha\phi$ with $\alpha \in \mathbb{R}^+$ and $\alpha \neq 0$ then the two vectors ψ and ϕ define the same physical state (they have only a different norm). This previous relation is an equivalence relation $\sim$, which signifies that a physical state is an equivalence class. So the physical space is

$$\mathcal{N} = (\mathcal{H} \setminus \{0\})/\sim, \tag{6}$$

which is called the space of normed rays. Suppose that the question of interference is ignored; then two vectors which are only different by a phase factor represent the same physical state. We define the group action of U(1) on $\mathcal{N}$ by

$$\forall e^{i\varphi} \in U(1), \forall [\psi] \in \mathcal{N}, \quad e^{i\varphi}[\psi] = [e^{i\varphi}\psi]. \tag{7}$$

Since two vectors represent the same state if they belong to the same orbit, then the physical space is the homogeneous space of the orbits

$$\mathcal{R} = \mathcal{N}/U(1), \tag{8}$$

which is called the complex projective space. If $\mathcal{H}$ is finite dimensional, $\dim \mathcal{H}=n$, we have $\mathcal{R}=\mathbb{C}P^{n-1}$ (it is a $(n-1)$-dimensional $\mathbb{C}^\infty$-differential complex manifold). In the case $n=2$ there exists an exceptional diffeomorphism

$$\mathbb{C}P^1 \simeq S^3/S^1 \simeq S^2. \tag{9}$$

Thus the space of a quantum two-level system (a spin for example) is the sphere.

Let $\psi \in \mathcal{H}$, with $\psi=(\psi^0,\psi^1,\ldots,\psi^{n-1})$. We set $w^i=\psi^i/\psi^0$ for all $i=1,\ldots,n-1$. The complex numbers $\{w^i\}_i$ are called the homogeneous coordinates of ψ in $\mathbb{C}P^{n-1}$. We can write the gauge potential by using these coordinates:

$$A = \frac{\psi^\dagger \mathrm{d}\psi}{\psi^\dagger\psi} = \frac{i}{2}\frac{\psi^\dagger \mathrm{d}\psi - \psi \mathrm{d}\psi^\dagger}{\psi^\dagger\psi} \tag{10}$$

$$= \frac{i}{2}\frac{\bar{\psi}_\alpha \mathrm{d}\psi^\alpha - \psi^\alpha \mathrm{d}\bar{\psi}_\alpha}{\bar{\psi}_\gamma\psi^\gamma} \tag{11}$$

$$= \frac{i}{2} \frac{\bar{w}_i \mathrm{d}w^i - w^i \mathrm{d}\bar{w}_i}{1 + \bar{w}_j w^j}. \tag{12}$$

Einstein's notation has been adopted for the sum, with the convention that the Greek indices take the values $0, \ldots, n-1$ and that the Latin indices take the values $1, \ldots, n-1$. The magnetic field (the curvature of the universal bundle) can be written

$$F = \mathrm{d}A = i \frac{\bar{w}_i w^j - (1 + \bar{w}_k w^k)\delta_i^j}{(1 + \bar{w}_l w^l)^2} \mathrm{d}w^i \wedge \mathrm{d}\bar{w}_j. \tag{13}$$

We introduce the function

$$K = \tfrac{1}{2} \mathrm{Ln}(1 + \bar{w}_k w^k), \tag{14}$$

where Ln is the multivalued complex logarithm. We also introduce the Dolbeault operators of the complex manifold ∂ and $\bar{\partial}$ ($\bar{\partial} + \partial = d$) (a presentation of complex differential geometry can be found in Ref. 17). It is easy to see that

$$\bar{\partial}\partial K = \frac{1}{2} \frac{\bar{w}_i w^j - (1 + \bar{w}_k w^k)\delta_i^j}{(1 + \bar{w}_l w^l)^2} \mathrm{d}w^i \wedge \mathrm{d}\bar{w}_j \tag{15}$$

and we then have $F = 2i\bar{\partial}\partial K$. We recognize here the structure of a Kählerian geometry (see Ref. 17); K is the Kähler potential and F is the Kähler form of $\mathbb{C}P^{n-1}$. We know that a Kählerian manifold is endowed with a natural metric, which in this case is the Fubini-Study metric

$$\eta = \mathrm{d}l^2 = \frac{(1 + \bar{w}_k w^k)\delta_i^j - \bar{w}_i w^j}{(1 + \bar{w}_l w^l)^2} \mathrm{d}w^i \mathrm{d}\bar{w}_j. \tag{16}$$

This Kählerian structure of quantum mechanics was indicated by Anandan and Aharonov in Ref. 18.

III. MAGNETIC MONOPOLE

We have seen that the divergence of the magnetic field of $\mathcal{M}$ relates a level crossing to the presence of a magnetic monopole in the electromagnetic picture. We recall here the theory of the Dirac magnetic monopole[19] and also the direct relationship between this theory and the Berry phase phenomenon.

A. The Dirac magnetic monopole theory

We consider a magnetic monopole with magnetic charge g, at the position (0, 0, 0) in a three-dimensional space. The first aspect of the Dirac model is that we do not consider $\mathbb{R}^3$ as being the fundamental manifold, but as a foliation $(S^2, \mathbb{R}^+)$, where S^2 is a sphere centered on the monopole and $\mathbb{R}^+$ is the foliation parameter space which describes the radius of the sphere. We consider the $U(1)$-principal bundle with base space S^2. We know that an atlas of S^2 must have at least two local charts. We choose the following charts:

$$U^N = \{(\theta, \varphi), \theta \in [0, \pi/2 + \epsilon], \varphi \in [0, 2\pi[\},$$

$$U^S = \{(\theta, \varphi), \theta \in [\pi/2 - \epsilon, \pi], \varphi \in [0, 2\pi[\}.$$

In these charts of the north and south hemispheres (the choice of the equator S^1 being arbitrary) ϵ is a small parameter which is used to ensure the nonvanishing intersection of the charts. On S^2 we introduce the local potential

$$A^N = ig(1 - \cos\theta)\mathrm{d}\varphi, \tag{17}$$

$$A^S = -ig(1+\cos\theta)\mathrm{d}\varphi. \tag{18}$$

By using the vector formalism of $\mathbb{R}^3$ we have

$$\vec{A}^N = \frac{g(1-\cos\theta)}{r\sin\theta}\vec{e}_\varphi, \tag{19}$$

$$\vec{A}^S = -\frac{g(1+\cos\theta)}{r\sin\theta}\vec{e}_\varphi. \tag{20}$$

(We should note that A^N is singular if we extend it at $\theta=\pi$ and A^S is singular if we extend it at $\theta=0$.)

The magnetic field (the curvature) is then $F=\mathrm{d}A$. We compute the magnetic flux through S^2; by using Stokes theorem we find

$$\Phi = \int_{S^2} F \tag{21}$$

$$= \lim_{\epsilon\to 0}\left(\int_{U^N}\mathrm{d}A^N + \int_{U^S}\mathrm{d}A^S\right) \tag{22}$$

$$= \lim_{\epsilon\to 0}\left(\int_{\partial U^N}A^N + \int_{\partial U^S}A^S\right) \tag{23}$$

$$= \int_{S^1} A^N - A^S \tag{24}$$

$$= \int_{S^1} 2g\mathrm{d}\varphi \tag{25}$$

$$= 4\pi g. \tag{26}$$

This is, effectively, the flux of a central field with charge g. We introduce the transition function $g^{NS}=e^{2ig\varphi}$, and we then have

$$A^N = A^S + (g^{NS})^{-1}\mathrm{d}g^{NS}. \tag{27}$$

To have a single transition one should require that $g^{NS}(\varphi=0)=g^{NS}(\varphi=\pi)\Leftrightarrow 2g\in\mathbb{Z}$. This is the Dirac quantization condition.

By the foliation we extend this result to all of $\mathbb{R}^3$ and we have

$$A^N = -ig\frac{y\mathrm{d}x - x\mathrm{d}y}{r(r+z)}, \tag{28}$$

$$A^S = ig\frac{y\mathrm{d}x - x\mathrm{d}y}{r(r-z)}, \tag{29}$$

$$F = ig\frac{x\mathrm{d}y \wedge \mathrm{d}z + y\mathrm{d}z \wedge \mathrm{d}x + z\mathrm{d}x \wedge \mathrm{d}y}{r^3} \tag{30}$$

with $r=\sqrt{x^2+y^2+z^2}$. By using the Hodge duality we find the correct expression in the vector formalism for the magnetic field: $\vec{F}=g\vec{r}/r^3$.

On the z axis A^N is singular at $z\leqslant 0$ and A^S is singular at $z\geqslant 0$. We call these two semilines the Dirac strings. We note that by a gauge transformation (with another choice of equator) the Dirac strings rotate in the space.

B. The magnetic monopole of a simple two-level system

We consider the system originally considered by Berry a spin $\frac{1}{2}$ particle interacting with a magnetic field, described by the Hamiltonian

$$H(\vec{x}) = x^i\sigma_i = \begin{pmatrix} x^3 & x^1 - ix^2 \\ x^1 + ix^2 & -x^3 \end{pmatrix}. \tag{31}$$

The eigenvalues of $H(\vec{x})$ are $E_\pm(\vec{x})=\pm r=\pm\sqrt{(x^1)^2+(x^2)^2+(x^3)^2}$. We thus have a level crossing at $\vec{x}=\vec{0}$. The eigenvector associated with E_+ is

$$|+,\vec{x}\rangle^N = \frac{1}{\sqrt{2r(r+x^3)}}\begin{pmatrix} r+x^3 \\ x^1+ix^2 \end{pmatrix} = \begin{pmatrix} \cos\dfrac{\theta}{2} \\ e^{i\varphi}\sin\dfrac{\theta}{2} \end{pmatrix}, \tag{32}$$

where $\theta=\arctan\sqrt{(x^1)^2+(x^2)^2}/x^3$ and $\varphi=\arctan x^2/x^1$ are, together with r, the spherical coordinates of $\mathbb{R}^3$. With another convention for the matrix representation, the eigenstate is

$$|+,\vec{x}\rangle^S = \frac{1}{\sqrt{2r(r-x^3)}}\begin{pmatrix} x^1-ix^2 \\ r-x^3 \end{pmatrix} = \begin{pmatrix} e^{-i\varphi}\cos\dfrac{\theta}{2} \\ \sin\dfrac{\theta}{2} \end{pmatrix}. \tag{33}$$

We compute the adiabatic gauge potential

$$A^N = {}^N\langle +,\vec{x}|\mathrm{d}|+,\vec{x}\rangle^N = -\frac{i}{2}\frac{x^2\mathrm{d}x^1 - x^1\mathrm{d}x^2}{r(r+x^3)} = \frac{i}{2}(1-\cos\theta)\mathrm{d}\varphi, \tag{34}$$

$$A^S = {}^S\langle +,\vec{x}|\mathrm{d}|+,\vec{x}\rangle^S = \frac{i}{2}\frac{x^2\mathrm{d}x^1 - x^1\mathrm{d}x^2}{r(r-x^3)} = -\frac{i}{2}(1+\cos\theta)\mathrm{d}\varphi. \tag{35}$$

We recognize here the magnetic potential associated with a magnetic monopole of charge $\frac{1}{2}$ at $\vec{x}=\vec{0}\in\mathbb{R}^3$. We see that a level crossing leads to the equations appropriate to a Dirac magnetic monopole. Let us consider that r is constant; the manifold describing the system is the sphere $S^2=\mathbb{C}P^1$ with coordinate system (θ,φ). We see that the present representation is in fact the universal model of quantum mechanics. We designate S^2 by the term "universal manifold," and $\mathbb{R}^3$ foliated by S^2 by the term "generalized universal space."

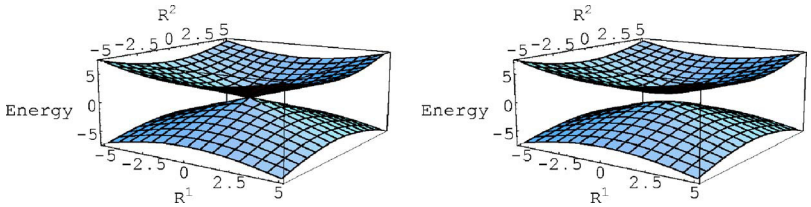

FIG. 1. (Color online) Representations of two levels with respect to the control manifold $\mathcal{M}$, the immersions being defined by, left: $f^1(\vec{R})=R^1$, $f^2(\vec{R})=R^2$, $f^3(\vec{R})=0$, right: $f^1(\vec{R})=R^1$, $f^2(\vec{R})=R^2$, $f^3(\vec{R})=1$. For the left panel, the monopole is in $f(\mathcal{M})$, and we have a crossing for $f(\vec{R})=0$. In the right panel, the monopole is not in $f(\mathcal{M})$, but $f(\mathcal{M})$ passes by the neighborhood of the monopole for $\vec{R}=0$; at this position we see an avoided crossing.

IV. THE ADIABATIC MAGNETIC MONOPOLE FIELD ASSOCIATED WITH A TWO LEVEL CROSSING

A. Immersion of the control manifold, level crossings, and avoided level crossings

We consider an adiabatic quantum dynamical system described by the Hamiltonian $H(\vec{R})$, with $\vec{R}\in\mathcal{M}$. The control manifold $\mathcal{M}$ is supposed to be two dimensional. We consider a crossing between two nondegenerate eigenvalues E_1 and E_2 of $H(\vec{R})$. In the neighborhood $\mathcal{U}$ of this crossing we consider the effective Hamiltonian associated with this crossing:

$$\forall \vec{R}\in\mathcal{U},\quad H^{\text{eff}}(\vec{R})=\begin{pmatrix} f^3(\vec{R}) & f^1(\vec{R})-if^2(\vec{R}) \\ f^1(\vec{R})+if^2(\vec{R}) & -f^3(\vec{R}) \end{pmatrix}. \tag{36}$$

H^{eff} is obtained by a partitioning technique,[20] arising from a quantum KAM method,[21] an adiabatic elemination method,[21] or a Bloch wave operator method.[20,22] Comparing the Hamiltonian [Eq. (36)] with the Hamiltonian Eq. (31) of the universal model, we see that we have a map f from the control manifold $\mathcal{M}$ to the generalized universal space $\mathbb{R}^3$, with $f(\vec{R})=(f^1(\vec{R}),f^2(\vec{R}),f^3(\vec{R}))\in\mathbb{R}^3$. In order to respect the geometric framework we suppose that f is a $\mathcal{C}^\infty$-map. Let $f_*:T_{\vec{R}}\mathcal{M}\to T_{f(\vec{R})}\mathbb{R}^3$ be the push-forward map (which is a linear map between two vector spaces for a fixed $\vec{R}$). We suppose that $\ker f_*=\{0\}$ (f_* is an injective map), and f is then an immersion of $\mathcal{M}$ in $\mathbb{R}^3$ (we will discuss this assumption later). There is no reason to suppose that f is an embedding; several points of $\mathcal{M}$ can be associated with the same point in the universal space and we will use this possibility in the later discussion.

We have a level crossing at $\vec{R}_0\in\mathcal{M}$ if and only if $f(\vec{R}_0)=0$. Although only one magnetic monopole is present in the generalized universal space $\mathbb{R}^3$, it is possible that several monopoles (crossings between E_1 and E_2) exist at several points $\{\vec{R}_i\}_{i=1,\ldots,n}$ if $f(\vec{R}_1)=f(\vec{R}_2)=\cdots=f(\vec{R}_n)=0$.

An avoided crossing manifests itself in this geometric analysis by virtue of the fact that the immersed manifold $f(\mathcal{M})$ does not include 0 but passes through a neighborhood of 0, i.e., $\forall\vec{R}\in\mathcal{U}$, $f(\vec{R})\neq 0$, but $\exists\vec{R}_0$ and $\exists\epsilon$ a small positive constant such that $\|f(\vec{R}_0)\|=\sqrt{(f^1(\vec{R}_0))^2+(f^2(\vec{R}_0))^2+(f^3(\vec{R}_0))^2}=\epsilon$ and $\forall\vec{R}\in\mathcal{U}$, $\vec{R}\neq\vec{R}_0$, $\|f(\vec{R}_0)\|>\epsilon$ ($\vec{R}_0$ is a local minimum of the vector norm). Note that 2ϵ is the energy gap of the avoided crossing (Fig. 1).

B. The Riemannian structure of the control manifold

The control manifold $\mathcal{M}$ is not endowed with a natural metric. The Euclidian metric defined by the scalar product $\vec{R}\cdot\vec{Q}=R^\mu Q^\nu\delta_{\mu\nu}$ does not have a physical meaning, because the control parameters can have different physical natures. However, we know that the universal manifold is endowed with a metric which is natural for the quantum mechanics, the Fubini-Study metric. We will use this metric and the immersion f to rigidify the manifold $\mathcal{M}$.

The universal manifold is a sphere $S^2 \simeq \mathbb{C}P^1$ considered as a sheaf of the foliation of $\mathbb{R}^3$. Let $\psi=(\psi^0,\psi^1)=\psi^0(1,w^1)$ be a vector of the space spanned by the eigenvectors of the Hamiltonian [Eq. (36)]. $w^1 \in \mathbb{C}$ is the coordinate on $\mathbb{C}P^1$. The Fubini-Study metric of $\mathbb{C}P$ (to be closer to the usual electromagnetic formalism, we have removed the factor i in order to have real fields in place of purely imaginary fields) is

$$\eta = \frac{(1+\bar{w}_1 w^1)-\bar{w}_1 w^1}{(1+\bar{w}_1 w^1)^2} \mathrm{d}\bar{w}_1 \mathrm{d}w^1 = \frac{\mathrm{d}\bar{w}_1 \mathrm{d}w^1}{(1+\bar{w}_1 w^1)^2}. \tag{37}$$

This expression is precisely the conformal representation of the Riemannian metric of the sphere (see Ref. 23). The Kählerian structure of $\mathbb{C}P^1$ is equivalent to the Riemannian structure of S^2. We can then write, with the standard coordinate system of S^2,

$$\eta = r^2 \sin^2 \varphi \mathrm{d}\theta^2 + r^2 \mathrm{d}\varphi^2. \tag{38}$$

We know that the Riemannian metric of S^2 centered on 0 in $\mathbb{R}^3$ is obtained as being the metric induced by the Euclidian metric of $\mathbb{R}^3$. We write δ for this metric ($\delta_{ij}=0$ if $i \neq j$ or $=1$ if $i=j$). We see that the rigidification of $\mathcal{M}$ is obtained by the metric induced by the immersion of $\mathcal{M}$ in $\mathbb{R}^3$ endowed with δ. The natural metric of $\mathcal{M}$ is then

$$g = g_{\mu\nu} \mathrm{d}R^\mu \mathrm{d}R^\nu = \delta_{ij} \frac{\partial f^i}{\partial R^\mu} \frac{\partial f^j}{\partial R^\nu} \mathrm{d}R^\mu \mathrm{d}R^\nu. \tag{39}$$

Moreover, we can write $H^{\mathrm{eff}}(\vec{R})=f^i(\vec{R})\sigma_i$ where $\{\sigma_1,\sigma_2,\sigma_2\}$ are the Pauli matrices. Since $\frac{1}{2}\mathrm{tr}(\sigma_i\sigma_j)=\delta_{ij}$ we obtain

$$g_{\mu\nu} = \frac{1}{2}\mathrm{tr}\left(\frac{\partial H^{\mathrm{eff}}}{\partial R^\mu} \frac{\partial H^{\mathrm{eff}}}{\partial R^\nu} \right). \tag{40}$$

We have supposed that f is an immersion, i.e., that f_* is injective. If this is not the case, then the bilinear form g defined by Eq. (39) is not a metric in a rigorous mathematical sense. g is then not positively defined (if f_* is not injective, then there exists an isotropic tangent vector of $\mathcal{M}$, i.e., $\exists X^\mu \partial_\mu \in T\mathcal{M}$ such that $g_{\mu\nu}X^\mu X^\nu=0$). In this case, by an abuse of language, we will continue to call g a metric, and we will continue to consider that

$$\int_{\mathcal{C}} \sqrt{g_{\mu\nu} \frac{\mathrm{d}\eta^\mu}{\mathrm{d}s} \frac{\mathrm{d}\eta^\nu}{\mathrm{d}s}} \mathrm{d}s$$

is the length of $\mathcal{C}$ parametrized by $s \mapsto \eta(s)$ in $\mathcal{M}$. This abuse of language is standard in physics; for example, in the context of special relativity we call a metric the bilinear form defined by $\eta_{\mu\nu}=0$ if $\mu \neq \nu$, $\eta_{ii}=1$ if $i=1,2,3$ and $\eta_{00}=-1$. The Minkwoski metric η is also not positively defined and is not a metric in the mathematical sense.

C. Magnetic field of the control manifold

In the universal space $\mathbb{R}^3$ we have the gauge potential (we choose one of the two conventions) (to be closer to the usual electromagnetic formalism, we have removed the factor i in order to have real fields in place of purely imaginary fields)

$$A = \frac{1}{2} \frac{x^2 \mathrm{d}x^1 - x^1 \mathrm{d}x^2}{r(r-x^3)} \in \Omega^1 \mathbb{R}^3 \tag{41}$$

and the magnetic monopole field is

$$B = \mathrm{d}A = \frac{1}{2} \frac{x^1 \mathrm{d}x^2 \wedge \mathrm{d}x^3 + x^2 \mathrm{d}x^3 \wedge \mathrm{d}x^1 + x^3 \mathrm{d}x^1 \wedge \mathrm{d}x^2}{r^3} \in \Omega^2 R^3 \tag{42}$$

By using the identity

$$\mathrm{d}x^i \leftrightarrow \begin{pmatrix} \delta_{1i} \\ \delta_{2i} \\ \delta_{3i} \end{pmatrix},$$

we can write $A \in \Omega^1\mathbb{R}^3$ as being a vector field of $\mathbb{R}^3$:$\vec{A}$. We recall the definition of the Hodge star operator associated with a metric q in a n-dimensional manifold X:

$$*_q : \Omega^r X \to \Omega^{n-r} X$$

$$*_q(\mathrm{d}x^{i_1} \wedge \cdots \wedge \mathrm{d}x^{i_r}) = \frac{\sqrt{|\det q|}}{(n-r)!} q^{i_1 j_1} \cdots q^{i_r j_r} \epsilon_{j_1,\ldots,j_n} \mathrm{d}x^{j_{r+1}} \wedge \cdots \wedge \mathrm{d}x^{j_n},$$

where ϵ is the Levi-Civita symbol, $q^{ij}q_{jk} = \delta^i_k$ and $\det q = q_{1i_1}q_{2i_2}\ldots q_{ni_n}\epsilon^{i_1 i_2 \ldots i_n}$.

In $\mathbb{R}^3$ we have simply $*_\delta : \Omega^2\mathbb{R}^3 \to \Omega^1\mathbb{R}^3$, with $*_\delta(\mathrm{d}x^1 \wedge \mathrm{d}x^2) = \mathrm{d}x^3$. Then $*_\delta B \in \Omega^1\mathbb{R}^3$ and we can consider it as being a magnetic vector field $\vec{B}$. The relation $B = \mathrm{d}A$ is then $\vec{B} = \vec{\mathrm{curl}}\vec{A}$.

Consider the pullback $f^* : \Omega^*\mathbb{R}^3 \to \Omega^*\mathcal{M}$. The gauge potential in $\mathcal{M}$ is

$$f^*A = A_i \frac{\partial f^i}{\partial R^\mu} \mathrm{d}R^\mu. \tag{43}$$

Note that we can compute f^*A directly with the eigenvector of [Eq. (36)]:

$$f^*A = \langle 1, \vec{R} | \mathrm{d}_{\mathcal{M}} | 1, \vec{R} \rangle = f^*(\langle +, \vec{x} | \mathrm{d} | + \vec{x} \rangle)_{\vec{x}=f(\vec{R})}. \tag{44}$$

As f^* is a chain map for the exterior differential, then the magnetic field is

$$f^*B = f^*\mathrm{d}A = \mathrm{d}_{\mathcal{M}} f^*A = B_{ij} \frac{\partial f^i}{\partial R^\mu} \frac{\partial f^j}{\partial R^\nu} \mathrm{d}R^\mu \wedge \mathrm{d}R^\nu = 2B_{ij} \frac{\partial f^i}{\partial R^1} \frac{\partial f^j}{\partial R^2} \mathrm{d}R^1 \wedge \mathrm{d}R^2. \tag{45}$$

In the same way that in $\mathbb{R}^3$ the field associated with the usual electromagnetic formalism is not $f^*B \in \Omega^2\mathcal{M}$ but $*_g f^*B \in \Omega^0\mathcal{M}$, we see that

$$*_g(\mathrm{d}R^1 \wedge \mathrm{d}R^2) = \sqrt{|\det g|} g^{1\mu} g^{2\nu} \epsilon_{\mu\nu} \tag{46}$$

$$= \sqrt{|\det g|}(g^{11}g^{22} - g^{12}g^{21}) \tag{47}$$

$$= \sqrt{|\det g|} \det g^{-1} \tag{48}$$

$$= \frac{\sqrt{|\det g|}}{\det g} \tag{49}$$

$$= \frac{\mathrm{sgn}(\det g)}{\sqrt{|\det g|}}. \tag{50}$$

As g is a Riemannian metric (because it is induced by the Euclidian metric) $\det g > 0$, and then

$$*_g f^*B = 2B_{ij} \frac{\partial f^i}{\partial R^1} \frac{\partial f^j}{\partial R^2} \frac{1}{\sqrt{\det g}}. \tag{51}$$

Consider the two-coform

$$N = \frac{\partial f^i}{\partial R^1}\frac{\partial f^j}{\partial R^2}\frac{\partial}{\partial x^i} \wedge \frac{\partial}{\partial x^j}. \tag{52}$$

It is clear that $\vec{N} = *_{\delta} N$ is a vector normal to the immersed manifold $f(\mathcal{M})$. We compute the norm of $\vec{N}$:

$$\|\vec{N}\|^2 = \delta_{kl}(*_{\delta}N)^k(*_{\delta}N)^l \tag{53}$$

$$= \delta_{kl}\frac{\partial f^i}{\partial R^1}\frac{\partial f^j}{\partial R^2}\epsilon_{ij}{}^{k}\frac{\partial f^n}{\partial R^1}\frac{\partial f^m}{\partial R^2}\epsilon_{nm}{}^{l} \tag{54}$$

$$= (\delta_{in}\delta_{jm} - \delta_{im}\delta_{jn})\frac{\partial f^i}{\partial R^1}\frac{\partial f^j}{\partial R^2}\frac{\partial f^n}{\partial R^1}\frac{\partial f^m}{\partial R^2}, \tag{55}$$

where we have used the following property of the Levi-Civita symbol: $\epsilon_{ij}{}^{k}\epsilon_{nm}{}^{l}\delta_{kl} = \delta_{in}\delta_{jm} - \delta_{im}\delta_{jn}$ (see Ref. 24). We also have the result:

$$\det g = g_{1\mu}g_{2\nu}\epsilon^{\mu\nu} \tag{56}$$

$$= \delta_{in}\frac{\partial f^i}{\partial R^1}\frac{\partial f^n}{\partial R^\mu}\delta_{jm}\frac{\partial f^j}{\partial R^2}\frac{\partial f^m}{\partial R^\nu}\epsilon^{\mu\nu} \tag{57}$$

$$= \delta_{in}\delta_{jm}\frac{\partial f^i}{\partial R^1}\frac{\partial f^j}{\partial R^2}\left(\frac{\partial f^n}{\partial R^1}\frac{\partial f^m}{\partial R^2} - \frac{\partial f^m}{\partial R^1}\frac{\partial f^n}{\partial R^2}\right) \tag{58}$$

$$= (\delta_{in}\delta_{jm} - \delta_{im}\delta_{jn})\frac{\partial f^i}{\partial R^1}\frac{\partial f^j}{\partial R^2}\frac{\partial f^n}{\partial R^1}\frac{\partial f^m}{\partial R^2}. \tag{59}$$

We see that $\|\vec{N}\| = \sqrt{\det g}$. Let $\vec{u}_N = (1/\sqrt{\det g})\vec{N}$ be the unit normal vector to $f(\mathcal{M})$. The density of the flux of $\vec{B}$ through $f(\mathcal{M})$ is then

$$\vec{B}\cdot\vec{u}_N = \frac{1}{\sqrt{\det g}}\langle B, N\rangle = 2B_{ij}\frac{\partial f^i}{\partial R^1}\frac{\partial f^j}{\partial R^2}\frac{1}{\sqrt{\det g}}. \tag{60}$$

Here $\langle .,. \rangle$ is the duality product between tangent and cotangent spaces (i.e. $\langle dx^i, \partial/\partial x^j\rangle = \delta^i_j$). To summarize, we have the results

$$*_g f^* dA = *_g f^* B = *_g d_{\mathcal{M}} f^* A = \vec{B}\cdot\vec{u}_N. \tag{61}$$

The magnetic field in $\mathcal{M}(*_g f^* B)$ is equal to the density of the flux of the magnetic field of $\mathbb{R}^3$ through the immersed manifold $f(\mathcal{M})$.

D. Examples

The charts of the magnetic field $d_{\mathcal{M}} f^* A$ can be used to analyze the adiabatic properties of a quantum dynamical system, since this field makes monopoles appear at the eigenvalue crossings and since it is proportional to the nonadiabatic transitions. It is sometimes difficult to interpret these charts; the immersion property of the control manifold can help us with that interpretation.

In order to illustrate the effects of the control manifold immersion we consider three simple examples of three level systems. To simplify the analysis our chosen method of producing an effective Hamiltonian is the partioning method by adiabatic elimination.[21] Let H be the total Hamiltonian matrix with the form

$$H = \begin{pmatrix} H_{00} & H_{10} \\ H_{01} & H_{11} \end{pmatrix}, \tag{62}$$

where H_{ij} are matrix blocs, H_{00} being the bloc corresponding to the considered crossing. The effective Hamiltonian after the adiabatic elimination process is

$$H^{\text{eff}} = H_{00} - H_{01}H_{11}^{-1}H_{10}. \tag{63}$$

Moreover we can redefine $H^{\text{eff}} \to H^{\text{eff}} - (\text{tr}H^{\text{eff}}/\text{tr}I)I$ (I is the identity matrix) in order to have a traceless effective Hamiltonian.

The first example we study is the Hamiltonian

$$H_1(u,\theta) = \begin{pmatrix} 0 & 0 & ue^{i\theta} \\ 0 & 1 & 1 \\ ue^{-i\theta} & 1 & 1 \end{pmatrix}. \tag{64}$$

This Hamiltonian corresponds to the RWA description of a three level atom interacting with two lasers such that the first laser is quasiresonant with the transition $|1\rangle$ to $|3\rangle$ and the second laser is quasiresonant with the transition $|2\rangle$ to $|3\rangle$ ($|i\rangle$ is the bare atom basis, the basis in which the matrix (Eq. (64) is written). u and ϕ are the amplitude and the phase of the first laser and constitute the control parameters; its polarization is constant. The second laser is constant with an amplitude equal to 1 in reduced units. For $u=0$,

$$H_1(0,\theta) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

has the eigenvalues {0,0,2}. In the neighborhood of the crossing the effective Hamiltonian (with adiabatic elimination of the state 3) is

$$H_1^{\text{eff}} = \begin{pmatrix} -\dfrac{u^2}{2} & ue^{i\theta} \\ ue^{-i\theta} & \dfrac{u^2}{2} \end{pmatrix}. \tag{65}$$

The immersion of the control manifold is then

$$f_1(u,\theta) = \begin{pmatrix} u\cos\theta \\ u\sin\theta \\ -\dfrac{u^2}{2} \end{pmatrix}. \tag{66}$$

The first immersed manifold is then diffeomorphic to an elliptic paraboloid.

The second example is the Hamiltonian

$$H_2(\theta,\phi) = \begin{pmatrix} 0 & 2(e^{i\phi}-1) & \cos\theta \\ 2(e^{-i\phi}-1) & 1 & e^{-i\phi} \\ \cos\theta & e^{i\phi} & 1 \end{pmatrix}. \tag{67}$$

This Hamiltonian corresponds to the RWA description of a three level atom interacting with four lasers such that the first and the second laser are quasiresonant with the transition $|1\rangle$ to $|2\rangle$, the third laser is quasiresonant with the transition $|1\rangle$ to $|3\rangle$ and the fourth laser is quasiresonant with the transition $|2\rangle$ to $|3\rangle$. The second laser is constant with an amplitude equal to 2 in reduced units, the first laser presents a phase modulation with a constant amplitude equal to 2, the third laser

presents a polarization modulation with a constant amplitude equal to 1, and the fourth laser presents a phase modulation synchronized with the phase modulation of the second laser. The control parameters are ϕ (the phase of the second and of the fourth lasers) and θ (the angle between the polarization of the third laser and the atom electric dipole moment). For $(\theta,\phi)=(\pi/2,0)$,

$$H_2\left(\frac{\pi}{2},0\right)=\begin{pmatrix}0&0&0\\0&1&1\\0&1&1\end{pmatrix}$$

and in the neighborhood of the crossing, the effective Hamiltonian (with adiabatic elimination of the state 3) is

$$H_2^{\text{eff}}(\theta,\phi)=\begin{pmatrix}-\dfrac{\sin^2\theta}{2} & 2(e^{i\phi}-1)-\cos\theta e^{i\phi}\\ 2(e^{-i\phi}-1)-\cos\theta e^{-i\phi} & \dfrac{\sin^2\theta}{2}\end{pmatrix}. \tag{68}$$

The immersion of the control manifold is then

$$f_2(\theta,\phi)=\begin{pmatrix}(2-\cos\theta)\cos\phi-2\\(2-\cos\theta)\sin\phi\\-\dfrac{\sin^2\theta}{2}\end{pmatrix}. \tag{69}$$

The second immersed manifold is then diffeormorphic to a half torus.

The third example is the Hamiltonian

$$H_3(u,\theta)=\begin{pmatrix}0 & 2(e^{i\theta}-1) & u\cos\dfrac{\theta}{2}\\ 2(e^{-i\theta}-1) & 0 & ue^{-i\theta}\\ u\cos\dfrac{\theta}{2} & ue^{i\theta} & 1\end{pmatrix}. \tag{70}$$

This Hamiltonian corresponds to the RWA description of a three level atom interacting with four lasers such that the first and the second laser are quasiresonant with the transition $|1\rangle$ to $|2\rangle$, the third laser is quasiresonant with the transition $|1\rangle$ to $|3\rangle$, and the fourth laser is quasiresonant with the transition $|2\rangle$ to $|3\rangle$. The second laser is constant with an amplitude equal to 2 in reduced units, the first laser presents a phase modulation with a constant amplitude equal to 2, the third laser presents a polarization modulation synchronized with the phase modulation of the first laser and it presents an amplitude modulation; finally, the fourth laser presents a phase modulation synchronized with the phase modulation of the second laser. The control parameters are u (the amplitude of the third laser) and θ (the phase of the second and of the fourth lasers, $\theta/2$ being the angle between the synchronized polarization of the third laser and the atom electric dipole moment). For $(u,\theta)=(0,0)$,

$$H_3(0,0)=\begin{pmatrix}0&0&0\\0&0&0\\0&0&1\end{pmatrix},$$

and in the neighborhood of the crossing, the effective Hamiltonian (with adiabatic elimination of the state 3) is

$$H_3^{\text{eff}}(u,\theta)=\begin{pmatrix} \dfrac{u^2\sin^2\dfrac{\theta}{2}}{2} & 2(e^{i\theta}-1)-u^2\cos\dfrac{\theta}{2}e^{i\theta} \\ 2(e^{-i\theta}-1)-u^2\cos\dfrac{\theta}{2}e^{-i\theta} & -\dfrac{u^2\sin^2\dfrac{\theta}{2}}{2} \end{pmatrix}. \tag{71}$$

The immersion of the control manifold is then

$$f_3(u,\theta)=\begin{pmatrix} \left(2-u^2\cos\dfrac{\theta}{2}\right)\cos\theta-2 \\ \left(2-u^2\cos\dfrac{\theta}{2}\right)\sin\theta \\ \dfrac{u^2\sin^2\dfrac{\theta}{2}}{2} \end{pmatrix}. \tag{72}$$

The third immersed manifold is then diffeomorphic to a half Moebius strip.

For these three examples we have computed $\langle 1,\vec{R}|d_{\mathcal{M}}|1,\vec{R}\rangle$, which is equal to f^*A, and we have drawn the magnetic field of the control manifold $d_{\mathcal{M}}f^*A$. We have moreover drawn the flux density of a monopole magnetic field through the immersed surfaces. The results are represented in Fig. 2.

We see with these figures that the immersion can be used to interpret the magnetic field chart, particularly for the third example, where the sign inversion of the field is explained by the nonorientability (the twist) of the Moebius strip, and for the second example, where the existence of the two lobes of the field is explained.

V. THE APPARENT CHARGE OF A TWO LEVEL CROSSING MAGNETIC MONOPOLE IN THE CONTROL MANIFOLD

In the universal model the monopole has a charge equal to $\frac{1}{2}$. Experimentally, it is the magnetic field on $\mathcal{M}$ that we see, and the apparent charge of the monopole in $\mathcal{M}$ can be different from $\frac{1}{2}$. Leboeuf and Mouchet[25] proposed a physical realization of nonelementary magnetic monopoles in quantum adiabatic dynamics by introducing constraint parameters. They explored the properties of their nonelementary monopoles by an analysis of Dirac strings. In this paper we want to exhibit nonelementary monopoles in a different way, using the immersion of the control manifold in the generalized universal space. Although our analysis is similar to the method followed by Leboeuf and Mouchet, we present it briefly, without repeating the discussion about Dirac strings. The interested reader can see Ref. 25

A. The geometry of a level crossing

In the universal model the single monopole has a magnetic charge equal to $\frac{1}{2}$. For the Hamiltonian [Eq. (31)] that corresponds to the conical crossing of the eigenvalues $\pm\sqrt{(x^1)^2+(x^2)^2+(x^3)^2}$, a conical crossing being a zero-order contact between the energy surfaces. We recall that a contact at $\vec{R}_0$ between two surfaces defined by the equations $z=E_+(R^1,R^2)$ and $z=E_-(R^1,R^2)$ in the space (R_1,R_2,z) is said to be of order r if and only if the function $E_+(\vec{R})-E_-(\vec{R})$ and each of its derivatives of order $\leqslant r$ vanish at $\vec{R}_0$. We know that the concept of contact order is invariant under diffeomorphism, so this notion is well defined even without endowing $\mathcal{M}$ with a metric (Fig. 2). To have a complete exposition of contact manifold theory, the reader can see Ref. 26.

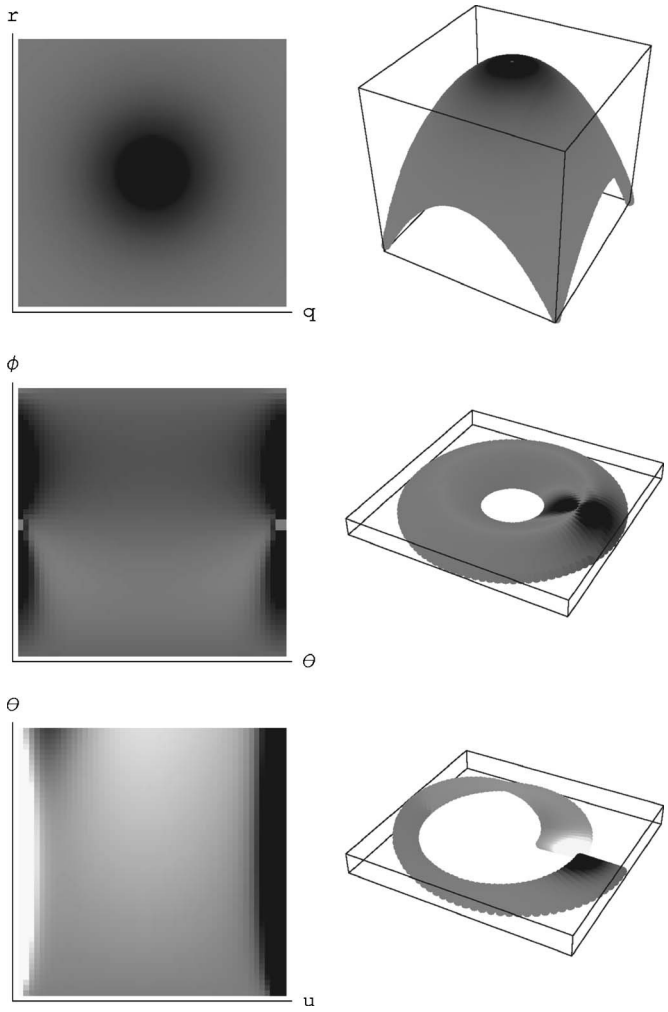

FIG. 2. Left: the magnetic field of the control manifold $d_{\mathcal{M}}\langle 1,\vec{R}|d_{\mathcal{M}}|1,\vec{R}\rangle$, Right: the immersed manifold and the flux density of a central field centered on (0, 0, 0), from top to bottom: the first example [Eq. (64)], the second example [Eq. (67)], and the third example [Eq. (70)]. The colors of the fields density are such that a strong positive field (or a strong positive flux) is black, a strong negative field (or a strong negative flux) is white, a vanishing field is gray. For the first example: $q=u\cos\theta$ and $r=u\sin\theta$.

For the generic Hamiltonian [Eq. (36)], the contact order between the energy surfaces (the order of the intersection) depends of the immersion f. Let $E_{\pm}=\pm\sqrt{f^i(\vec{R})f^j(\vec{R})\delta_{ij}}$ be the eigenvalues of the effective Hamiltonian. Let $\epsilon(\vec{R})=[E_+(\vec{R})-E_-(\vec{R})]/2$. By definition if $\vec{R}_0$ is the position of a level crossing then $\epsilon(\vec{R}_0)=0$ (i.e., $\forall i$, $f^i(\vec{R}_0)=0$). We have:

$$\frac{\partial\epsilon}{\partial R^\mu}=\frac{\frac{\partial f^i}{\partial R^\mu}f^j\delta_{ij}}{\sqrt{f^if^j\delta_{ij}}} \tag{73}$$

$$=\frac{\frac{\partial f^1}{\partial R^\mu}f^1}{\sqrt{(f^1)^2+(f^2)^2+(f^3)^2}}+\frac{\frac{\partial f^2}{\partial R^\mu}f^2}{\sqrt{(f^1)^2+(f^2)^2+(f^3)^2}}+\frac{\frac{\partial f^3}{\partial R^\mu}f^3}{\sqrt{(f^1)^2+(f^2)^2+(f^3)^2}}. \tag{74}$$

It is then clear that

$$\forall i, \quad \left.\frac{\partial f^i}{\partial R^\mu}\right]_{\vec{R}=\vec{R}_0} = 0 \Rightarrow \left.\frac{\partial \epsilon}{\partial R^\mu}\right]_{\vec{R}=\vec{R}_0} = 0. \tag{75}$$

The contact order between the energy surfaces is $\geqslant 1$ if $\forall i$, $\forall \mu$ $\partial f^i/\partial R^\mu]_{\vec{R}=\vec{R}_0}=0$. More generally, we can prove that

$$\frac{\partial^n \epsilon}{\partial R^{\mu_1} \dots \partial R^{\mu_n}} = \frac{1}{2}\sum_{p=0}^{n-1} \sum_{\sigma \in S_n} \frac{1}{(n-p)!p!} \frac{\partial^{n-p} f^i}{\partial R^{\mu_{\sigma(1)}} \dots \partial R^{\mu_{\sigma(n-p)}}} \frac{\partial^p f^j}{\partial R^{\mu_{\sigma(n-p+1)}} \dots \partial R^{\mu_{\sigma(n)}}} \delta_{ij}$$
$$- \frac{1}{2\epsilon}\sum_{p=1}^{n-1} \sum_{\sigma \in S_n} \frac{1}{(n-p)!p!} \frac{\partial^{n-p} \epsilon}{\partial R^{\mu_{\sigma(1)}} \dots \partial R^{\mu_{\sigma(n-p)}}} \frac{\partial^p \epsilon}{\partial R^{\mu_{\sigma(n-p+1)}} \dots \partial R^{\mu_{\sigma(n)}}}, \tag{76}$$

where S_n is the nth group of permutations. Then, the order of the crossing is greater than or equal to r if $\forall n \leqslant r$, $\forall i$, $\forall \mu_1, \dots, \mu_n$ $\partial^n f^i/\partial R^{\mu_1} \dots \partial R^{\mu_n}]_{\vec{R}=\vec{R}_0}=0$.

B. Perturbative analysis

We will see that the apparent charge of the magnetic monopole in $\mathcal{M}$ is related to the order of the eigenvalue crossing and thereby is related to the number of zero derivatives of f at $\vec{R}_0$. We consider a neighborhood $\mathcal{U}$ of $\vec{R}_0$. We suppose that $f(\mathcal{U})$ is tangent to the plane $x^3=0$ in $\mathbb{R}^3$, i.e., that the Dirac strings are orthogonal to $f(\mathcal{U})$. If this is not the case, we can always use a gauge transformation such that the Dirac strings rotate to be orthogonal to $f(\mathcal{U})$; in other words we change the coordinates system such that the x^3 axis coincides with the Dirac strings. In agreement with this hypothesis, and with $\mathcal{U}$ sufficiently small, we can consider that $\forall \vec{R} \in \mathcal{U} f^3(\vec{R}) \simeq 0$. In the plane $x^3=0$ we have the gauge potential

$$A = \frac{i}{2}\frac{x^2 \mathrm{d}x^1 - x^1 \mathrm{d}x^2}{(x^1)^2 + (x^2)^2} = \frac{i}{2}\frac{x^i \mathrm{d}x^j \epsilon_{ij}}{x^i x^j \delta_{ij}}. \tag{77}$$

Note that in this expression the Kronecker symbol δ_{ij} plays the role of the metric tensor of the Euclidian plane and the Levi-Civita symbol ϵ_{ij} plays the role of the vector cross product in the Euclidian space. They are then metric dependent tensors (contrary to the previous parts of this paper where the Levi-Civita symbol has been used to represent the sum over the permutations).

The gauge potential in $\mathcal{M}$ in the neighborhood of $\vec{R}_0$ is

$$f^* A = \frac{i}{2}\frac{f^i(\vec{R})\dfrac{\partial f^j}{\partial R^\mu}\epsilon_{ij}\mathrm{d}R^\mu}{f^i(\vec{R}) f^j(\vec{R})\delta_{ij}}. \tag{78}$$

But in the neighborhood of $\vec{R}_0$ we can use a Taylor expansion:

$$f^i(\vec{R}) = f^i(\vec{R}_0) + (R^\mu - R_0^\mu) \left.\frac{\partial f^i}{\partial R^\mu}\right]_{\vec{R}=\vec{R}_0} + \left.\frac{(R^\mu - R_0^\mu)(R^\nu - R_0^\nu)}{2}\frac{\partial^2 f^i}{\partial R^\mu \partial R^\nu}\right]_{\vec{R}_0}$$
$$+ \dots + \frac{(R^{\mu_1} - R_0^{\mu_1}) \dots (R^{\mu_n} - R_0^{\mu_n})}{n!} \left.\frac{\partial^n f^i}{\partial R^{\mu_1} \dots \partial R^{\mu_n}}\right]_{\vec{R}_0} + \mathcal{O}(((R^\mu - R_0^\mu)(R^\nu - R_0^\nu)\delta_{\mu\nu})^{n/2}). \tag{79}$$

Now we suppose that $\forall r \leqslant n-1$, $\forall i$, $\forall \mu_1, \dots, \mu_r$ $\partial^r f^i/\partial R^{\mu_1} \dots \partial R^{\mu_r}]_{\vec{R}=\vec{R}_0}=0$; the contact order of the level crossing is then equal to $n-1$. It is clear that any Taylor expansion must be of an order equal to n. $\forall \vec{R}$ in the neighborhood of $\vec{R}_0$ we have

$$f^i(\vec{R}) \simeq \frac{(R^{\mu_1} - R_0^{\mu_1}) \ldots (R^{\mu_n} - R_0^{\mu_n})}{n!} \left. \frac{\partial^n f^i}{\partial R^{\mu_1} \ldots \partial R^{\mu_n}} \right]_{\vec{R}_0}, \tag{80}$$

$$\frac{\partial f^i}{\partial R^\nu} \simeq \frac{(R^{\mu_1} - R_0^{\mu_1}) \ldots (R^{\mu_{n-1}} - R_0^{\mu_{n-1}})}{(n-1)!} \left. \frac{\partial^n f^i}{\partial R^{\mu_1} \ldots \partial R^{\mu_{n-1}} \partial R^\nu} \right]_{\vec{R}_0}, \tag{81}$$

$$g_{\mu\nu}(\vec{R}) = \frac{\partial f^i}{\partial R^\mu} \frac{\partial f^j}{\partial R^\nu} \delta_{ij} \tag{82}$$

$$\simeq \frac{(R^{\mu_1} - R_0^{\mu_1}) \ldots (R^{\mu_{n-1}} - R_0^{\mu_{n-1}})}{(n-1)!} \left. \frac{\partial^n f^i}{\partial R^{\mu_1} \ldots \partial R^{\mu_{n-1}} \partial R^\mu} \right]_{\vec{R}_0} \times \frac{(R^{\nu_1} - R_0^{\nu_1}) \ldots (R^{\nu_{n-1}} - R_0^{\nu_{n-1}})}{(n-1)!} \left. \frac{\partial^n f^i}{\partial R^{\nu_1} \ldots \partial R^{\nu_{n-1}} \partial R^\nu} \right]_{\vec{R}_0} \delta_{ij}, \tag{83}$$

$$f^i f^j \delta_{ij} \simeq \frac{(R^{\mu_1} - R_0^{\mu_1}) \ldots (R^{\mu_n} - R_0^{\mu_n})(R^{\nu_1} - R_0^{\nu_1}) \ldots (R^{\nu_n} - R_0^{\nu_n})}{(n!)^2} \left. \frac{\partial^n f^i}{\partial R^{\mu_1} \ldots \partial R^{\mu_n}} \right]_{\vec{R}_0} \times \left. \frac{\partial^n f^j}{\partial R^{\nu_1} \ldots \partial R^{\nu_n}} \right]_{\vec{R}_0} \delta_{ij} \tag{84}$$

$$\simeq \frac{(R^{\mu_n} - R_0^{\mu_n})(R^{\nu_n} - R_0^{\nu_n})}{n^2} g_{\mu_n \nu_n} \tag{85}$$

$$\simeq \frac{\mathcal{N}}{n^2}. \tag{86}$$

We then have

$$f^* A \simeq \frac{in^2}{2\mathcal{N}} \left(\frac{(R^{\mu_1} - R_0^{\mu_1}) \ldots (R^{\mu_n} - R_0^{\mu_n})}{n!} \left. \frac{\partial^n f^i}{\partial R^{\mu_1} \ldots \partial R^{\mu_n}} \right]_{\vec{R}_0} \times \frac{(R^{\nu_1} - R_0^{\nu_1}) \ldots (R^{\nu_{n-1}} - R_0^{\nu_{n-1}})}{(n-1)!} \left. \frac{\partial^n f^j}{\partial R^{\nu_1} \ldots \partial R^{\nu_n}} \right]_{\vec{R}_0} \epsilon_{ij} \right). \tag{87}$$

However, the cross product in $\mathcal{M}$ induced by the Euclidian cross product is defined by

$$(R^\mu - R_0^\mu) \mathrm{d}R^\nu \epsilon^g_{\mu\nu} = (R^\mu - R_0^\mu) \mathrm{d}R^\nu \frac{\partial f^i}{\partial R^\mu} \frac{\partial f^j}{\partial R^\nu} \epsilon_{ij} \tag{88}$$

$$\simeq (R^\mu - R_0^\mu) \mathrm{d}R^\nu \frac{(R^{\mu_1} - R_0^{\mu_1}) \ldots (R^{\mu_{n-1}} - R_0^{\mu_{n-1}})}{(n-1)!} \left. \frac{\partial^n f^i}{\partial R^{\mu_1} \ldots \partial R^{\mu_{n-1}} \partial R^\mu} \right]_{\vec{R}_0} \times \frac{(R^{\nu_1} - R_0^{\nu_1}) \ldots (R^{\nu_{n-1}} - R_0^{\nu_{n-1}})}{(n-1)!} \left. \frac{\partial^n f^j}{\partial R^{\nu_1} \ldots \partial R^{\nu_{n-1}} \partial R^\nu} \right]_{\vec{R}_0} \epsilon_{ij}. \tag{89}$$

In summary, we have the result

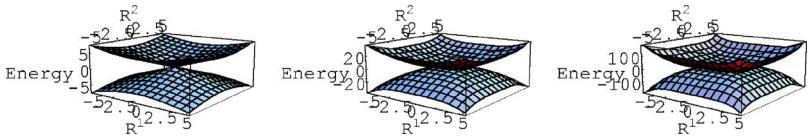

FIG. 3. (Color online) The energy surfaces drown with respect to the coordinates of $\mathcal{M}$ for (from left to right): the immersion $f(\vec{R})=(R^1,R^2,0)$ (a monopole with charge $\frac{1}{2}$), the immersion $f(\vec{R})=((R^1)^2,(R^2)^2,0)$ (a monopole with charge 1), and the immersion $f(\vec{R})=((R^1)^3,(R^2)^3,0)$ (a monopole with charge $\frac{3}{2}$).

$$f^*A \simeq \frac{ni}{2}\frac{(R^\mu - R_0^\mu)\mathrm{d}R^\nu \epsilon^g_{\mu\nu}}{(R^\lambda - R_0^\lambda)(R^\rho - R_0^\rho)g_{\lambda\rho}}. \tag{90}$$

By comparing this expression with Eq. (77), we see that f^*A is the gauge potential of a monopole with magnetic charge equal to $n/2$ in the curved space $\mathcal{M}$ with metric g. We conclude that if the magnetic monopole in $\mathcal{M}$ has a charge equal to n then the contact order of the energy surface crossing is equal to $n-1$ (Fig. 3).

C. Topological analysis

The previous analysis has the advantage that it exhibits the monopole gauge potential in $\mathcal{M}$, but a shorter analysis is possible using a topological result. Let S^1 be a circle in the plane $x^3=0$ centered over 0. We have (see Ref. 27, p. 152)

$$\frac{-i}{2\pi}\oint_{S^1} A = \frac{1}{4\pi}\oint_{S^1}\frac{x^2\mathrm{d}x^1 - x^1\mathrm{d}x^2}{(x^1)^2+(x^2)^2} = \frac{1}{2} \tag{91}$$

more generally for any loop $\mathcal{C}$ in the plane $\mathcal{M}$ (a loop is a closed path) we have

$$\frac{1}{2\pi}\oint_{\mathcal{C}}\frac{x^2\mathrm{d}x^1 - x^1\mathrm{d}x^2}{(x^1)^2+(x^2)^2} = n, \tag{92}$$

where n is the number of oriented turns of $\mathcal{C}$ around 0. This number is a topological character of the loop in $\mathbb{R}^2\backslash\{0\}$: it is invariant by homotopy and is called the winding number. We can use this invariant to characterize the monopole charge. Let S^1 be a circle on $\mathcal{M}$ centered on $\vec{R}_0$. $f(\mathcal{M})$ is not a plane, but if the radius of S^1 is sufficiently small we can consider that $f(\mathcal{M})$ is approximately flat in the neighborhood of $f(S^1)$. We use the complex coordinate of $\mathcal{M}$, $z=R^1+iR^2$,

$$f(z) = \sqrt{(f^1(z))^2+(f^2(z))^2}\exp\left(i\arctan\frac{f^2(z)}{f^1(z)}\right) \tag{93}$$

$$= \epsilon(z)\exp\left(i\arctan\frac{f^2(z)}{f^1(z)}\right). \tag{94}$$

If the contact order is equal to $n-1$, then ϵ has a zero of order n at z_0. We can then write $f(z)=(z-z_0)^n h(z)$, where $h(z)$ is a holomorphic function and where $(z-z_0)^n=r^n e^{in\theta}$. We have:

$$\arg f(z) = \arg(z-z_0)^n + \arg h(z) = n\theta + \arg h(z), \tag{95}$$

$$\frac{1}{2\pi}\oint_{S^1} \mathrm{d}\arg f = \frac{1}{2\pi}\oint_{S^1} n\mathrm{d}\theta + \frac{1}{2\pi}\mathrm{d}\arg h(z) \tag{96}$$

$$= n + \underbrace{\frac{1}{2\pi}\oint_{S^1} \frac{\partial h(z)}{\partial z}\mathrm{d}z}_{=0 \text{ by the residus lemma}} \tag{97}$$

$$= n. \tag{98}$$

We also have

$$\mathrm{d}\arg f = \mathrm{d}\arctan\frac{f^2}{f^1} = \frac{f^1\mathrm{d}f^2 - f^2\mathrm{d}f^1}{(f^1)^1 + (f^2)^2} = -i2f^*A \tag{99}$$

and so conclude that

$$\frac{-i}{2\pi}\oint_{S^1} f^*A = \frac{-i}{2\pi}\oint_{f(S^1)} A = \frac{n}{2}. \tag{100}$$

The monopole in $\mathcal{M}$ thus has an apparent charge equal to $n/2$.

VI. NON-ABELIAN MONOPOLE ASSOCIATED WITH A MULTILEVEL CROSSING

In the previous parts we have considered only two-level crossings between nondegenerate states. Now we consider multilevel crossings, for example the crossing of three nondegenerate states or the crossing of a doubly degenerate state with a nondegenerate state.

A. Immersion of the control manifold

By elimination of the other states, we suppose that the Hamiltonian can be written in the neighborhood of the multilevel crossing as

$$H^{\mathrm{eff}}(\vec{R}) = f^i(\vec{R})J_i, \tag{101}$$

where $\{J_i\}$ is a set of generators of a real Lie algebra $\mathfrak{g}$ associated with a Lie group G (the Hamiltonian symmetry group). Usually we have $G=\mathrm{U}(m)$, where m is the number of levels involved in the crossing (or the sum of the degeneracy degrees of the levels involved in the crossing). But we know that the physics of an m-level system can be described simply by $G=\mathrm{SU}(m)$ (see Refs. 28 and 29). Let d be the number of generators of G ($d=\dim\mathfrak{g}$). The immersion f defined by $f(\vec{R})=(f^1(\vec{R}),\ldots,f^d(\vec{R}))$ is then a map from $\mathcal{M}$ to $\mathbb{R}^d$. $\mathbb{R}^d$ plays the role of the generalized universal space in place of $\mathbb{R}^3$. Let $\{H_i,E_\alpha\}_{i,\alpha}$ be the Cartan basis of $\mathfrak{g}$. The Cartan subalgebra (the algebra generated by $\{H_i\}_i$) is the Lie algebra of the maximal torus T of G. Let $E(\vec{R})$ be the diagonal matrix of the eigenvalues of $H(\vec{R})$ (the matrix of levels involved in the crossing). As the diagonal matrix group is Abelian, we have $E(\vec{R})=b^i(\vec{R})H_i$. Then the diagonalization of H^{eff} can be written

$$H^{\text{eff}}(\vec{R}) = e^{i\chi^{\alpha}(\vec{R})E_{\alpha}} E(\vec{R}) e^{-i\chi^{\alpha}(\vec{R})E_{\alpha}} \tag{102}$$

$$= \exp\left(i \sum_{\alpha>0} (z^{\alpha}(\vec{R})E_{\alpha} + \overline{z}^{\alpha}(\vec{R})E_{-\alpha}) \right) E(\vec{R})$$
$$\times \exp\left(- i \sum_{\alpha>0} (\overline{z}^{\alpha}(\vec{R})E_{\alpha} + z^{\alpha}(\vec{R})E_{-\alpha}) \right), \tag{103}$$

where $T(\vec{R}) = e^{i\chi^{\alpha}(\vec{R})E_{\alpha}}$ is the diagonalizing matrix for $H^{\text{eff}}(\vec{R})$. The Berry phase depends only on $z^{\alpha}(\vec{R})$ or equivalently on $\chi^{\alpha}(\vec{R})$. Moreover it is clear that $\{\chi^{\alpha}\}_{\alpha}$ and $\{z^{\alpha}\}_{\alpha}$ are, respectively, real and complex coordinates systems for the manifold G/T. This manifold is called a flag manifold, Mostafazadeh[30] has shown that it is also the universal manifold for the system with symmetry group G, and $\chi: \mathcal{M} \to G/T$ defined by $\chi(\vec{R}) = (\chi^{\alpha}(\vec{R}))_{\alpha}$ is the universal map. Clearly the flag manifold G/T is a complex manifold which has a Riemannian structure induced by the embedding $G/T \hookrightarrow \mathbb{C}P^{n-1}$ (see Ref. 30), where n is the dimension of the original Hilbert space. The Kählerian structure of $\mathbb{C}P^{n-1}$ induces the Riemannian structure of G/T considered as a real manifold. Let r be the rank of $\mathfrak{g}$ (the dimension of the Cartan subalgebra). $\mathbb{R}^d$ is foliated with leafs which are diffeomorphic to G/T and with the foliation parameters $\{b^i(\vec{R})\}_{i=1,\ldots,r}$, $(G/T, \mathbb{R}^r) \simeq \mathbb{R}^d$. Considering a particular leaf G/T, we have the following commutative diagram:

$$\begin{array}{ccc} \mathcal{M} & \overset{\chi^{\alpha}}{\to} & G/T \\ f^i \downarrow & \Phi^{\alpha} \swarrow & \downarrow \hookrightarrow \\ \mathbb{R}^d & \underset{\hookrightarrow}{\to} & \mathbb{C}P^{n-1} \end{array}$$

where Φ is defined by

$$H^{\text{eff}}(\vec{R}) = \text{Ad}(e^{i\chi^{\alpha}(\vec{R})E_{\alpha}}) b^i(\vec{R}) H_i = e^{i\chi^{\alpha}(\vec{R})\text{ad}(E_{\alpha})} b^i(\vec{R}) H_i = \Phi^i(\vec{R}) H_i + \Phi^{\beta}(\chi(\vec{R})) E_{\beta}., \tag{104}$$

Here Ad is the adjoint action of the Lie group on its Lie algebra, and ad is the adjoint action of the Lie algebra on itself. We suppose that G is compact and semisimple; then the Killing form of its *complex* Lie algebra $\mathfrak{g}_{\mathbb{C}}$ is positively defined. Following the commutativity structure of the previous diagram, the Riemannian structure of G/T is also induced by the Killing form of $\mathfrak{g}_{\mathbb{C}}$ considered as a scalar product on $\mathbb{R}^d$. If $G = \text{SU}(N)$ then $2NK$ is the Euclidian metric of $\mathbb{R}^d$ (where K is the Killing form of $\text{SU}(N)$).

In the case of a two-level crossing, $G = \text{SU}(2)$, $d = 3$ and the maximal torus is $\text{U}(1)$; the flag manifold is then $\text{SU}(2)/\text{U}(1) \simeq S^2$ in agreement with the discussion in previous sections. In the case of a three-level crossing, $G = \text{SU}(3)$, the universal space is $\mathbb{R}^8$, the maximal torus is $T^2 = \text{U}(1) \times \text{U}(1)$ and the flag manifold is $\text{SU}(3)/(\text{U}(1) \times \text{U}(1))$. For the generic case of an N-level crossing, the symmetry group is $\text{SU}(N)$, its dimension is $d = N^2 - 1$, and the standard monopole exists in the universal space $\mathbb{R}^{N^2-1}$. The flag manifold (the universal manifold) is $\text{SU}(N)/T^{N-1} \simeq \mathbb{C}P^{N-1} \ltimes \mathbb{C}P^{N-2} \ltimes \ldots \ltimes \mathbb{C}P^1$ where T^{N-1} is the $(N-1)$-torus:

$$T^{N-1} = \underbrace{\text{U}(1) \times \cdots \times \text{U}(1)}_{N-1 \text{ times}}$$

and where $\ltimes$ denotes a possible nontrivial topological product. The induced metric on $\mathcal{M}$ is

$$g_{\mu\nu} = \delta_{ij} \frac{\partial f^i}{\partial R^{\mu}} \frac{\partial f^j}{\partial R^{\nu}} \tag{105}$$

with $i = 1, \ldots, N^2 - 1$ and $\mu = 1, 2$.

B. An analogy with the field theory

The monopole gauge potential is $A \in \Omega^1(\mathbb{R}^{N^2-1}, \mathfrak{su}(N))$. The monopole field is obtained by the Cartan structure equation $F = \mathrm{d}A + \frac{1}{2}[A,A] \in \Omega^2(\mathbb{R}^{N^2-1}, \mathfrak{su}(N))$ and satisfies half of the Yang-Mills equations, i.e., the Bianchi identity $\mathrm{d}F + [A,F] = 0$. In $\mathcal{M}$, $f^*A \in \Omega^1(\mathcal{M}, \mathfrak{su}(N))$ and $f^*F \in \Omega^2(\mathcal{M}, \mathfrak{su}(N))$ satisfy similar equations. Consider the Abelian case of a pure adiabatic transport. We suppose that the evolution of the system is a path $\mathcal{C}$ on $\mathcal{M}$ which passes in the neighborhood of a two-level crossing but is sufficiently far away or is traversed at such a speed that no population transfer occurs. The path $\mathcal{C}$ is parametrized by a function $t \mapsto \vec{R}(t)$. Let $\{|+,\vec{R}\rangle^N, |-,\vec{R}\rangle^N\}$ be the two eigenvectors. If we suppose that $\psi(0) = |+,\vec{R}(0)\rangle^N$ then we have

$$\psi(t) = \exp\left(- i\hbar^{-1} \int_0^t E_+(\vec{R}(t'))\mathrm{d}t' - \int_{\vec{R}(0)}^{\vec{R}(t)} A_+^N(\vec{R}) \right) |+,\vec{R}(t)\rangle^N, \tag{106}$$

where $A_+^N = {}^N\langle +,\vec{R}|d_{\mathcal{M}}|+,\vec{R}\rangle^N$. The gauge group associated with this situation is U(1). We have a complete analogy with electrodynamics, where ψ is the matter field of a charged particle which is moving on the path $\mathcal{C}$ in $\mathcal{M}$ and which is subject to the monopole magnetic field. Indeed, Ezawa[31] notes that a single matter field $\phi(x)$ cannot be used in the whole space-time in the presence of a magnetic monopole. He uses a path-dependent formalism with $\phi(x,\mathcal{P}) = \exp(\int_\infty^x A)\phi(x)$ where $\mathcal{P}$ is a path from infinity to x. This new field is gauge invariant. In the same way, in the generalized universal space $\mathbb{R}^3$ we cannot use a single field $|+,\vec{x}\rangle$ as a matter field because

$$|+,\vec{x}\rangle^N = \frac{1}{\sqrt{2r(r+x^3)}} \begin{pmatrix} r + x^3 \\ x^1 + ix^2 \end{pmatrix}$$

is not defined for $x^3 \leqslant 0$ and

$$|+,\vec{x}\rangle^S = \frac{1}{\sqrt{2r(r-x^3)}} \begin{pmatrix} x^1 - ix^2 \\ r - x^3 \end{pmatrix}$$

is not defined for $x^3 \geqslant 0$. Following Ezawa, by elimination of the dynamical phase, we set $\tilde{\psi}(\vec{x},\mathcal{C}) = \exp(-\int_{\vec{x}_0}^{\vec{x}} A_+)|+,\vec{x}\rangle$ where $\mathcal{C}$ is a path from an arbitrary point $\vec{x}_0$ to $\vec{x}$. Let U_S and U_N be the charts for which A_+^S and A_+^N, respectively, are well defined. Suppose that $\vec{x}_0 \in U_S$. Then

$$\tilde{\phi}(\vec{x},\mathcal{C}) = \begin{cases} \exp\left(- \int_{\vec{x}_0}^{\vec{x}} A_+^S \right) |+,\vec{x}\rangle^S \text{if } \vec{x} \in U_S \\ \exp\left(- \int_{\vec{x}_0}^{\vec{x}_1} A_+^S \right) \exp\left(- \int_{\vec{x}_1}^{\vec{x}} A^N \right) |+,\vec{x}\rangle^N \quad \text{if } \vec{x} \in U_N, \text{ with } \vec{x}_1 \in U_N \cap U_S. \end{cases} \tag{107}$$

We see that the formalism used by Ezawa to define a matter field in the presence of a magnetic monopole is similar to the adiabatic transport formula. Then we can say that the quantum system driven along a path $\mathcal{C}$ in the control parameter manifold $\mathcal{M}$ is similar to, for example, an electron which is forced to follow $\mathcal{C}$ in presence of a monopole magnetic field.

Now consider the case of a crossing of three nondegenerate states. The wave function is

$$\psi(t) = \sum_{b=1}^{3} \left[\mathbb{T} \exp\left(- i\hbar^{-1} \int_0^t E(\vec{R}(t'))\mathrm{d}t' - \int_{\vec{R}(0)}^{\vec{R}(t)} A(\vec{R}) \right) \right]_{ba} |b,\vec{R}(t)\rangle \tag{108}$$

and the gauge group is SU(3). SU(3) is represented on the space spanned by $\{|1,\vec{R}\rangle, |2,\vec{R}\rangle, |3,\vec{R}\rangle\}$ by the irreducible representation $D^{1,0}$ (see Refs. 32). The situation is completely analogous to that of a quark field ψ in the presence of a colored monopole, see Ref. 5, 6, and 31,

$\{|1,\vec{R}\rangle,|2,\vec{R}\rangle,|3,\vec{R}\rangle\}$ being a color triplet. As is the case in chromodynamics, *"since SU(3) is unbroken symmetry, (…) the specification of the colour of a quark field depends on an arbitray choice of basis for the three-dimensional space of colours at each point in space-time"* (see Ref. 33), the basis $\{|1,\vec{R}\rangle,|2,\vec{R}\rangle,|3,\vec{R}\rangle\}$ defined the colors at each point $\vec{R}$ of $\mathcal{M}$, the color operators being

$$J_3=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&0\end{pmatrix},\quad \sqrt{3}J_8=\begin{pmatrix}1&0&0\\0&1&0\\0&0&-2\end{pmatrix} \tag{109}$$

the matrices being written in the $\vec{R}$-dependent basis $\{|1,\vec{R}\rangle,|2,\vec{R}\rangle,|3,\vec{R}\rangle\}$. The initial point of the dynamics $\vec{R}(0)$ can be considered as being a privileged point and consitutes a symmetry breaking. For example, in the case of an atom or a molecule driven by a pulse chirped laser, the initial point is the position in $\mathcal{M}$ for which the laser is off. In this case the basis $\{|1,\vec{R}(0)\rangle,|2,\vec{R}(0)\rangle,|3,\vec{R}(0)\rangle\}$ is privileged as the basis for the bare atom or molecule unperturbed by the field. The two possible descriptions of the color using "the symmetry breaking basis" and using "the $\vec{R}$-dependent basis," are associated with the choice of the molecular time-dependent description of population transfers, using "the unperturbed basis" or using "the instantaneous dressed basis."

VII. FINAL REMARKS AND CONCLUSION

A. Global description versus local description

All of the previous discussion has concerned the neighborhood of a crossing, and has thus given a local analysis. If we consider $\mathcal{M}$ globally these might be several crossings (monopoles) on $\mathcal{M}$. Let n be the dimension of the original Hilbert space and m be the dimension of the adiabatic subspace. We know that the universal manifold of the gobal description is the Grassmanian manifold $G_m(\mathbb{C}^n)$. The relation between global and local description is the following. Let f be the global universal map from $\mathcal{M}$ to $G_m(\mathbb{C}^n)$. Let $\vec{R}_0$ be a point where there exists a level crossing. Let G/T be the flag manifold of this level crossing (the local universal manifold) and χ be the local universal map from $\mathcal{M}$ to G/T. $G_m(\mathbb{C}^n)=\mathrm{U}(n)/(\mathrm{U}(n-m)\times\mathrm{U}(m))$ where $\mathrm{U}(n)$ is the group of unitary tranformations of the original space, $\mathrm{U}(m)$ is the group of unitary transformations of the adiabatic space and $\mathrm{U}(n-m)$ characterizes the adiabatic independence of the quantum system from the exterior of the adiabatic space. It is clear that G is a subgroup of $\mathrm{U}(n)$ and T is a subgroup of $\mathrm{U}(m)$, and then G/T is a submanifold of $G_m(\mathbb{C}^n)$ which is localized with the point $f(\vec{R}_0)=\chi(\vec{R}_0)$.

The local description depends on the choice of the effective Hamiltonian technique. Indeed, H^{eff} does not have the same expression in the different partitioning methods.[20–22] The geometric local description will be relevant if and only if $H^{\mathrm{eff}}(\vec{R})$ is good approximation of $H(\vec{R})$ for the crossing, i.e., if the behaviors of the eigenvalues and of the overlaps of the eigenvectors of $H^{\mathrm{eff}}(\vec{R})$ (and their first derivatives) are close to the behaviors of the associated quantities of $H(\vec{R})$. In general the problem of finding an efficient effective Hamiltonian associated with a crossing is not a simple one.

B. The control manifold

All of the discussion can be generalized to a control manifold with dimension greater than two, exept for the links between $*_g f^* B$ and the monopole magnetic flux, which is the most interesting aspect of the monopole magnetic field in the two-dimensional case. Note that for a two-level crossing, the map $f:\mathcal{M}\to\mathbb{R}^3$ cannot be an immersion if $\dim\mathcal{M}>2$.

We can remark that in a theoretical study, the choice of the control manifold can be arbitrary; in order to have a physical meaning for $\mathcal{M}$ and its virtual magnetic monopoles, we can choose $\mathcal{M}$

to be closely appropriate to the experimental situation. The two parameters of $\mathcal{M}$ must be two "control levers" of the experimentalist, in order that the monopole effects can appear naturally in the experimental results

C. The charge of non-Abelian monopoles

The definition of the charge of a non-Abelian monopole, for example, for a three level crossing, is not clear. In the Abelian case the generalized universal space is $\mathbb{R}^3$ and we can apply the method followed in field theory. In the non-Abelian cases the generalized universal space is $\mathbb{R}^d$ with $d>3$, which cannot be identified with the usual physical space. The topological methods usually followed must be adapted and more subtle studies are needed to find a relevant definition of the charge of the non-Abelian adiabatic monopoles.

D. About nonadiabatic evolutions

The adiabatic assumption states that the quantum dynamical system can be described at each time by a little set of instantaneous eigenvectors. In the nonadiabatic cases, there exist some techniques to describe the quantum system with a time-dependent non-eigenbasis (see, for example, the time-dependent wave operator theory).[34] In this case, the dynamics can be represented by a finite dimensional effective Hamiltonian. We can suppose that these time-dependent vectors can be expressed as control parameter-dependent vectors (in fact this is a strong assumption because in general these vectors depend not only on the instantaneous time but also on the past evolution). In this case the wave function takes the form of Eq. (3) but where $|a,\vec{R}(t)\rangle$ is not an eigenvector and where $E(\vec{R}(t))_{ab}=\langle a,\vec{R}(t)|H^{\text{eff}}(\vec{R}(t))|b,\vec{R}(t)\rangle$ is not a diagonal matrix. Following the works of Mostafazadeh and Bohm[35,36] we can suppose that there exists a smooth map $\mathcal{F}:\mathcal{M}\to\mathcal{M}$ such that $\{|a,\vec{R}(t)\rangle\}_a$ are the eigenvectors of $\tilde{H}^{\text{eff}}(\vec{R})=H^{\text{eff}}(F(\vec{R}))$. Let f be the immersion map associated with $\tilde{H}^{\text{eff}}$, we can consider $f\circ F$ as the immersion map of H^{eff}, this map is well associated with the properties of magnetic monopoles since $\{|a,\vec{R}\rangle\}_a$ are the eigenvectors of $\tilde{H}^{\text{eff}}$. Nevertheless the physical significance of these monopoles is not clear because they are not associated with an eigenlevel crossing. Moreover the assumption of the existence of F and above all the assumption of the control parameters dependence of the basis are important limitations on the class of nonadiabatic quantum systems for which we can apply the theory presented in this paper.

E. Conclusion

The knowledge of the magnetic field in the control manifold can be very important for the numerical simulations of quantum adiabatic dynamics. By computing this field, which is equal to the monopole field density of $f(\mathcal{M})$, we can localize the level crossings. It is well known that the variations of the wave function are more important in the neighborhood of the level crossings. If we model the control manifold by using a discrete numerical lattice X, then we need more vertices in the neighborhood of the level crossings in order to have a minimal data storage requirement, together with a good description of the wave function. We must then employ a nonhomogeneous lattice with small cells in the neighborhood of the crossing and with larger cells elsewhere. We can use the field $*_g f^* B$ to obtain a criterion about the local choice of cell sizes.

(Received 31 May 2006; accepted 29 July 2006; published online 27 September 2006)

Conventional approach to quantum mechanics in phase space, (q,p), is to take the operator based quantum mechanics of Schrödinger, or an equivalent, and assign a c-number function in phase space to it. We propose to begin with a higher level of abstraction, in which the independence and the symmetric role of q and p is maintained throughout, and at once arrive at phase space state functions. Upon reduction to the q- or p-space the proposed formalism gives the conventional quantum mechanics, however, with a definite rule for ordering of factors of noncommuting observables. Further conceptual and practical merits of the formalism are demonstrated throughout the text. © *2006 American Institute of Physics.*

I. INTRODUCTION

Wigner's 1932 initiative[1] is a reformulation of the operator based quantum theory of Schrödinger in the language of c-number distribution functions in a phase space. His prescription, however, turns out to have a feature extra to what one finds in Schrödinger's theory. There is nothing in the founding principles of the operator based theory to prescribe a rule for ordering of the factors of noncommuting operators in a product. In contrast, Wigner's formalism, upon reduction from phase space to the configuration space, acquires Weyl's ordering,[2,3] How and at what stage, in going from Schrödinger's state functions in configuration space to those of Wigner in phase space and again coming back to the configuration space, acquires Weyl's ordering creep in? This feature is not unique to Wigner's functions. Other distributions exist in the literature, e.g., Kirkwood,[4] Husimi,[5] Margenau and Hill,[6] Torres-Vega and Frederick,[7–9] Li *et al.*,[10] de Gosson,[11,12] etc. Each of them carries its own ordering rule, with no precedence in the configuration space formalism. Can one conjecture that the phase space formulations of quantum mechanics are more complete than their configuration space counterpart, because of their built-in ordering rules? If so, there should be a way to arrive at phase space formulations without reference to the conventional operator based theory. Here we argue that in the classical dynamics and classical statistical dynamics (Liouville's equation) the generalized coordinates and momenta, q and p, respectively, play symmetric and more importantly, independent roles. In the operator based quantum theory one or the other loses its identity at the expense of the other and the formalism reduces to one in either q or p space. One could avoid this by carrying the q and p formalisms concomitantly and at once arrive at state functions in qp spaces. The so-obtained state functions are the qp representa-

[b)]Electronic mail: sobouti@iasbs.ac.ir
[c)]Electronic mail: htatti@iasbs.ac.ir

tion of the mixed states of quantum statistical mechanics. The operator based theory emerges as a special case of this general one, but this time with a definite ordering rule for noncommutative operators. The rule depends on the nature of the q and p variables, adopted initially.

II. EXTENSION OF THE CLASSICAL DYNAMICS

Let $q=\{q_i(t), i=1,\ldots,N\}$ be the collection of the generalized coordinates describing the state of motion of a dynamical system. It is customary to assign a Lagrangian, $L^q(q,\dot{q})$, to the system, define the conjugate momenta, $p=\partial L^q/\partial\dot{q}$, and construct the $H(q,p)=\dot{q}p-L^q$. One may do this the other way around. Begin with a given $H(q,p)$ and find $L^q(q,\dot{q})$ as a solution of the following differential equation;

$$H\left(q,\frac{\partial L^q}{\partial\dot{q}}\right)-\dot{q}\frac{\partial L^q}{\partial\dot{q}}+L^q=0. \tag{1}$$

One may, however, carry out the same procedure with q replaced by p and arrive at a $L^p(p,\dot{p})$ satisfying the differential equation

$$H\left(\frac{\partial L^p}{\partial\dot{p}},p\right)+\dot{p}\frac{\partial L^p}{\partial\dot{p}}-L^p=0. \tag{2}$$

The use of L^p to study the evolution of a dynamical system is not a common practice. But it is a possibility and has precedence.[13] There is no bar to employing the two alternatives simultaneously. We follow Sobouti and Nasiri[14] (hereafter, paper I) and define the "extended Lagrangian"

$$\mathcal{L}(q,\dot{q};p,\dot{p})=-\dot{q}p-q\dot{p}+L^q(q,\dot{q})+L^p(p,\dot{p}). \tag{3}$$

The first two terms on the right-hand side constitute a total time derivative and are introduced for later convenience. One may now write down the Euler-Lagrange equations for q and p,

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial\dot{q}}-\frac{\partial\mathcal{L}}{\partial q}=\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L^q}{\partial\dot{q}}-\frac{\partial L^q}{\partial q}=0, \tag{4a}$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial\mathcal{L}}{\partial\dot{p}}-\frac{\partial\mathcal{L}}{\partial p}=\frac{\mathrm{d}}{\mathrm{d}t}\frac{\partial L^p}{\partial\dot{p}}-\frac{\partial L^p}{\partial p}=0. \tag{4b}$$

Equation (4a) is the conventional equation of motion in q space. With preassigned initial values $q(t_0)$ and $\dot{q}(t_0)$ at t_0 it can be solved for the orbits $q(t)$ in q space. Similarly, with given initial values $p(t_0)$ and $\dot{p}(t_0)$, Eq. (4b) can be solved for the orbits $p(t)$ in the p space. The conditions for q and p orbits to represent the same state of motion of the system are $p(t_0)=\partial L^q/\partial\dot{q}|_{t_0}$ and $q(t_0)=\partial L^p/\partial\dot{p}|_{t_0}$. Such a state of motion will be referred to as a "pure state." Otherwise it will be called a "mixed state" of motion. The nomenclature is from the statistical quantum mechanics and it will be seen later that they imply the same notions as therein. On a pure state p and q are initially canonically conjugate pairs and it is shown in paper I that once they are canonically conjugate at one time they remain so for all times. On the other hand there are no restrictions on the initial values of q and p on mixed states. Therefore, $q(t)$ and $p(t)$ remain unrelated and evolve independently. The existence of the extended Lagrangian $\mathcal{L}(q,\dot{q};p,\dot{p})$, however, permits the following "extended momenta" to be defined:

$$\pi_q=\frac{\partial\mathcal{L}}{\partial\dot{q}}=\frac{\partial L^q}{\partial\dot{q}}-p, \tag{5a}$$

$$\pi_p = \frac{\partial \mathcal{L}}{\partial \dot{p}} = \frac{\partial L^p}{\partial \dot{p}} - q. \tag{5b}$$

These in turn allow an "extended Hamiltonian" to be defined through the following Legendre transformation;

$$\mathcal{H}(q,\pi_q;p,\pi_p) = \dot{q}\pi_q + \dot{p}\pi_p - \mathcal{L}(q,\dot{q};p,\dot{p}). \tag{6}$$

To eliminate $\dot{q}$ and $\dot{p}$ from $\mathcal{H}$ one substitutes (a) for $\mathcal{L}$ from Eq. (3), (b) for L^q and L^p from Eqs. (1) and (2), and (c) for $\partial L^q/\partial \dot{q}$ and $\partial L^p/\partial \dot{p}$ from Eqs. (5a) and (5b). One arrives at

$$\mathcal{H}(q,\pi_q;p,\pi_p) = H(q,p+\pi_q) - H(q+\pi_p,p) = \sum_{n=0} \frac{1}{n!}\left[\frac{\partial^n H}{\partial p^n}\pi_q^n - \frac{\partial^n H}{\partial q^n}\pi_p^n\right], \tag{7}$$

where the derivatives are to be evaluated at (q,p). We leave it to the reader to familiarize him/herself with $\mathcal{H}$ by writing down four Hamilton's equations for $\dot{q}, \dot{\pi}_q, \dot{p}$, and $\dot{\pi}_p$. Here, the condition for pure state motions is $\pi_q(t_0)=\pi_p(t_0)=0$, and once they are initially zero they remain so for all times. Then by Eqs. (5a) and (5b) q and p turn into canonically conjugate pairs for all times (paper I). To summarize, for any dynamical system we introduce an extended phase space, $(q,\pi_q;p,\pi_P)$, extended momenta, Lagrangians, and Hamiltonians. All concepts and procedures of the conventional dynamics are extendible to this extended dynamics. Of particular relevance to this paper, which will be referred to shortly, are: (1) canonical transformations from one set of variables $(q,\pi_q;p,\pi_p)$ to another, and (2) Poisson's brackets extended as

$$\{F,G\} = \frac{\partial F}{\partial q}\frac{\partial G}{\partial \pi_q} - \frac{\partial F}{\partial \pi_q}\frac{\partial G}{\partial q} + \frac{\partial F}{\partial p}\frac{\partial G}{\partial \pi_p} - \frac{\partial F}{\partial \pi_p}\frac{\partial G}{\partial p}. \tag{8}$$

III. QUANTUM DYNAMICS IN *qp* SPACE

Now that we have the extended the Hamiltonian of Eq. (7) we may construct a quantum mechanics in qp space. We do this on the following premises.

(1) Let $\mathcal{X}$ be the function space of all integrable complex functions $\chi(q,p)$. Let q,π_q,p, and, π_p be operators on $\mathcal{X}$, satisfying the commutation rules

$$[q,\pi_q] = [p,\pi_p] = i\hbar\,, \quad [q,p] = [\pi_q,\pi_p] = [q,\pi_p] = [p,\pi_q] = 0. \tag{9}$$

These are the fundamental Poisson brackets of Eq. (8), promoted to commutation brackets by Dirac's prescription. Note the manifest independence of q and p in the vanishing of their commutation brackets.

(2) By virtue of Eq. (9), $\mathcal{H}$ is now an operator on $\mathcal{X}$. Let $\chi(q,p,t) \in \mathcal{X}$ be a state function satisfying the Schrödinger-type equation

$$i\hbar\frac{\partial \chi}{\partial t} = \mathcal{H}\chi = \left[H\left(q,p - i\hbar\frac{\partial}{\partial q}\right) - H\left(q - i\hbar\frac{\partial}{\partial p},p\right)\right]\chi. \tag{10}$$

(3) Let the rule to evaluate the expectation values of an observable $O(q,p)$, a real c-number operator on $\mathcal{X}$, be

$$\langle O(q,p)\rangle = \int O(q,p)\mathrm{Re}\,\chi \mathrm{d}q\mathrm{d}p = \frac{1}{2}\int O(q,p)(\chi+\chi^*)\mathrm{d}q\mathrm{d}p. \tag{11}$$

We will return to this averaging rule shortly, and revise it. The logic behind it, however, is to be noted, the averages of observables should be real. In what follows we demonstrate that (1) the formalism so designed is a theory of quantum ensembles in phase space. Its pure state case is the conventional quantum mechanics, however, with a definite ordering rule accompanying it. (2) It

can be transformed to other phase space formalisms, including to that of Wigner, by suitable unitary or similarity transformations on $\mathcal{X}$. The latter in turn originates from suitable canonical transformations from one extended phase space coordinate to another.

A. Solutions of Eq. (10)

To begin with, χ is of the form

$$\chi(q,p) = F(q,p)e^{-ipq/\hbar}. \tag{12}$$

The exponential factor is a consequence of the total time derivative, $-\mathrm{d}(qp)/\mathrm{d}t$ in Eq. (3). It is easily verified that

$$\left(p - i\hbar\frac{\partial}{\partial q}\right)\chi = i\hbar\frac{\partial F}{\partial q}e^{-ipq/\hbar}, \tag{13a}$$

$$\left(q - i\hbar\frac{\partial}{\partial p}\right)\chi = i\hbar\frac{\partial F}{\partial p}e^{-ipq/\hbar}. \tag{13b}$$

Substitution of Eqs. (13) and (12) in Eq. (10) gives

$$i\hbar\frac{\partial F}{\partial t} = \left[H\left(q, -i\hbar\frac{\partial}{\partial q}\right) - H\left(-i\hbar\frac{\partial}{\partial p}, p\right)\right]F. \tag{14}$$

The operators on the right-hand side of Eq. (14) are recognized as the Hamiltonians of the conventional quantum mechanics, the first in q and the second in p representation. Thus, one obtains the superposition of the separable solutions

$$\chi(q,p,t) = \sum_{\alpha,\beta} A_{\alpha\beta}\psi_\alpha(q,t)\phi^*_\beta(p,t)e^{-ipq/\hbar}, \tag{15}$$

where

$$i\hbar\frac{\partial\psi_\alpha}{\partial t} = H\left(q, -i\hbar\frac{\partial}{\partial q}\right)\psi_\alpha, \tag{16a}$$

$$i\hbar\frac{\partial\phi_\beta}{\partial t} = H\left(i\hbar\frac{\partial}{\partial p}, p\right)\phi_\beta. \tag{16b}$$

To each $\psi_\alpha(q)$ there corresponds a $\phi_\alpha(p)$ that are Fourier transforms of each other,

$$\psi_\alpha(q) = \frac{1}{(2\pi\hbar)^{N/2}}\int \phi_\alpha(p)e^{ipq/\hbar}\mathrm{d}p, \tag{17}$$

where N is the number of degrees of freedom of the system.

B. The averaging rule revisited: Acceptable state functions

Let $Q(q)$ be an observable represented by a real polynomial or series in q. Its matrix representation, $\hat{Q}$, in either $\chi-$, $\psi-$, or ϕ-basis is Hermitian. Thus

$$Q_{\beta\alpha} = \int \psi_\alpha(q) Q(q) \psi^*_\beta(p) e^{-ipq/\hbar} \mathrm{d}p\mathrm{d}q$$

$$= \int \psi^*_\beta(q) Q(q) \psi_\alpha(q) \mathrm{d}q = \int \phi^*_\beta(p) Q\left(i\hbar \frac{\partial}{\partial p}\right) \phi_\alpha(p) \mathrm{d}p = Q^*_{\alpha\beta}, \tag{18}$$

where we have used the fact that ψ and ϕ bases are the Fourier transforms of each other. The coefficient $(2\pi\hbar)^{-N/2}$ is suppressed for brevity. The expectation value of Q, by Eq. (11), now becomes

$$\langle Q \rangle = \frac{1}{2} \int Q(\chi + \chi^*) \mathrm{d}p\mathrm{d}d = \frac{1}{2} \mathrm{tr}[\hat{\mathrm{Q}}(\hat{\mathrm{A}} + \hat{\mathrm{A}}^\dagger)], \tag{19}$$

where $\hat{A}$ is the matrix of $A_{\alpha\beta}$ of Eq. (15). This gives the freedom of choosing $\hat{A} = \hat{A}^\dagger$ and of simplifying Eq. (11) to read $\langle Q \rangle = \int Q\chi \mathrm{d}p\mathrm{d}q = \mathrm{tr}(\hat{Q}\hat{A})$. Choosing $Q(q) = 1$, imposes the further restriction $\mathrm{tr}\,\hat{A} = 1$. Requiring the averages of all positive definite functions of q to be positive still restricts $\hat{A}$ to be a positive definite matrix. Had one chosen a differentiable function $P(p)$ instead of $Q(q)$, one still would have arrived at the same requirements for $\hat{A}$.To summarize, χ of Eq. (15) is a physically acceptable solution if

$$\hat{A} = \hat{A}^\dagger, \text{ positive definite,} \quad \text{and} \quad \mathrm{tr}\hat{A} = 1. \tag{20}$$

With this provision the averaging rule of Eq. (11) for $Q(q) + P(p)$ reduces to

$$\langle Q(q) + P(p) \rangle = \int (Q + P) \chi \mathrm{d}p\mathrm{d}q. \tag{21}$$

For a product $Q(q)P(p)$, by the prescription of Eq. (11) and with the restrictions of Eq. (20) on $\hat{A}$, one has

$$\langle QP \rangle = \mathrm{Re}\ \mathrm{tr}(\hat{Q}\hat{P}\hat{A}) = \frac{1}{2}\ \mathrm{tr}(\hat{Q}\hat{P}\hat{A} + \hat{A}\hat{P}\hat{Q}) = \mathrm{tr}\left[\frac{1}{2}(\hat{Q}\hat{P} + \hat{P}\hat{Q})\hat{A}\right], \tag{22}$$

where $\hat{Q}$ and $\hat{P}$ are the matrix representations of $Q(q)$ and $P(p)$ as in Eq. (18). Translation of this to the q space language, say, is

$$\langle QP \rangle = \frac{1}{2} A_{\alpha\beta} \int \psi^*_\beta(q) \left[Q(q) P\left(-i\hbar \frac{\partial}{\partial q}\right) + P\left(-i\hbar \frac{\partial}{\partial q}\right) Q(q) \right] \psi_\alpha \mathrm{d}p. \tag{23}$$

Thus, upon reduction of the formalism of the present paper to that of the q-space, the ordering rule associated with a product $Q(q)P(p)$ is the symmetric ordering. It has emerged from the formalism itself, unlike the ad hoc ordering rules of the conventional quantum mechanics.

IV. MORE ABOUT EQ. (10)

It was stated earlier that the proposed dynamics is essentially that of the ensembles. Here we elaborate on this, and show that (1) the classical limit of the theory is Liouville's equation that governs the dynamics of classical ensembles. (2) Its pure state case is Schrödinger's operator based theory. (3) In its full generality the theory gives von Neumann's density matrix and the evolution equation associated with it.

A. Classical correspondence

In Eq. (10) expanding the Hamiltonian operators about (q,p), and retaining only the first terms in the expansion, gives

$$\frac{\partial \chi}{\partial t} + \frac{\partial H}{\partial p}\frac{\partial \chi}{\partial q} - \frac{\partial H}{\partial p}\frac{\partial \chi}{\partial p} = \frac{\mathrm{d}\chi}{\mathrm{d}t} = 0. \tag{24}$$

This is the Liouville equation for the distribution function of classical ensembles. Its most general solutions are $\chi[q(t),p(t)]$, where $q(t)$ and $p(t)$ are the classical trajectories in q and p spaces. The two trajectories may represent the same state of motion if they satisfy the conditions of initial canonical conjugacy narrated below Eq. (4). Otherwise, they remain independent and evolve independently. It is this classical notion of independence that we have carried through to the quantum formalism. Let us also note that the reduction of the phase space evolution equation to the classical Liouville's equation is a common feature of all such formalisms.

B. Schrödinger's case

Allowance for only one term in Eq. (15) reproduces the conventional quantum mechanics in all its details. Thus

$$\chi = \psi(q)\phi^*(p)e^{-ipq/\hbar}, \tag{25a}$$

$$i\hbar\frac{\partial \psi}{\partial t} = H\left(q, -i\hbar\frac{\partial}{\partial q}\right)\psi, \tag{25b}$$

$$\psi \text{ and } \phi \text{ Fourier transforms of each other}, \tag{25c}$$

$$\int \chi \mathrm{d}p\mathrm{d}q = \int \psi^*\psi \mathrm{d}q = \int \phi^*\phi \mathrm{d}p = 1, \tag{25d}$$

$$\langle Q(q)P(p)\rangle = \frac{1}{2}\int \psi^*\left[p\left(-i\hbar\frac{\partial}{\partial q}\right)Q(q) + Q(q)P\left(-i\hbar\frac{\partial}{\partial q}\right)\right]\psi \mathrm{d}q. \tag{25e}$$

Heisenberg's uncertainty principle follows immediately from Eq. (25) that one may find in standard texts in quantum mechanics. The ordering rule of Eq. (25e) is, however, the added feature of the theory.

C. Density matrix and von Neumann's equation

The state function of Eq. (15), as it stands represents the state of an ensemble in a mixed state. If the matrix $\hat{A}$ is diagonalized to $A_{\alpha\beta}=A_\alpha\delta_{\alpha\beta}$, χ reduces to $\chi=\Sigma A_\alpha\psi_\alpha\phi_\alpha^* e^{-ipq/\hbar}$. Upon integration over q or p one immediately recognizes A_α as the probability of the system to be in the state $\psi_\alpha(q,t)$ or $\phi_\alpha(p,t)$. One may, however, do better. Let $\{\phi_n(q)\}$ be a complete orthonormal time independent basis set, and $\{\phi_n(p)\}$ be its Fourier replica. These basis sets are not required to be the eigenstates of $H(q,p)$, though this is a possibility. Hereafter, to avoid the ambiguity, we use the Latin subscripts to denote the members of the basis set and reserve Greek subscripts to denote the solutions of Eqs. (16a) and (16b). Expansion of χ in these bases assumes the form $\chi(q,p,t)=A_{mn}(t)\psi_n(q)\phi_m^*(p)e^{-ipq/\hbar}$. Substituting this form in Eq. (10), multiplying the resulting equation by $\psi_n^*(q)\phi_m(p)e^{ipq/\hbar}$, and integrating over q and p gives

$$i\hbar\frac{d\hat{A}}{dt}=[\hat{A},\hat{H}],\quad \hat{A}=\hat{A}^{\dagger}\quad \text{positive definite and tr}\,\hat{A}=1, \tag{26}$$

where $\hat{A}$ is the matrix of the expansion coefficients and $\hat{H}$ that of the $H(q,p)$ in either $\chi-$, $\psi-$, or $\phi-$ basis. Equation (26) is von Neumann's equation for the evolution of the density matrix. As is known the case $\text{tr}(\hat{A}^2)=\text{tr}\,\hat{A}=1$ represents an ensemble in a pure state. If $\text{tr}(\hat{A}^2)<1$, the ensemble is in a mixed state.

V. CANONICAL TRANSFORMATIONS

All machinery of the canonical transformations from one extended coordinate system to another and their associated unitary or similarity transformations in the function space are available for a forage of deliberations. Except for a passing remark on the prospects of fuller uses of this approach at the end of this section, here we confine ourselves to one one-parameter family of transformations of which Wigner's state function emerges as a special case. Husimi's all positive distribution functions are also briefly mentioned.

Consider the infinitesimal transformations

$$q=Q-\delta\alpha\Pi_P,\quad \pi_q=\Pi_Q;\quad p=P-\delta\alpha\Pi_Q,\quad \pi_p=\Pi_P, \tag{27}$$

The generator of the transformation is $G=\pi_p\pi_q$. To this (and for a finite α) there corresponds the unitary operator

$$U_\alpha=e^{-i\alpha G/\hbar}=e^{i\hbar\alpha\partial^2/\partial_q\partial_p},\quad U_\alpha^{\dagger}U_\alpha=1, \tag{28}$$

in the function space. Operating by U_α on a pure state function $\chi(q,p,t)=\psi(q)\phi^*(p)\times\exp(-ipq/\hbar)$ generates another state function (let us call it α-representation)

$$\chi(q,p,t)=U_\alpha\chi=\left(\frac{1}{2\pi\hbar}\right)^N\int\psi(q-\alpha\tau)\psi^*(q+(1-\alpha)\tau)e^{ip\tau/\hbar}d\tau. \tag{29}$$

See the Appendix for proof of Eq. (29). For $\alpha=1/2$, Eq. (29) gives Wigner's standard function,[15,16] $\chi_{1/2}=W(q,p,t)$. The cases $\alpha=0$ and 1 simply give back χ and χ^* of this paper, respectively. Similarly, operation by U_α on Eq. (10) gives the evolution equation for χ_α,

$$\begin{aligned}
&i\hbar\frac{\partial\chi_\alpha(q,p,t)}{\partial t}=i\hbar\frac{\partial}{\partial t}(U_\alpha\chi)=(U_\alpha\mathcal{H}U_\alpha^{\dagger})U_\alpha\chi,\\
&i\hbar\frac{\partial\chi_\alpha(q,p,t)}{\partial t}=\mathcal{H}_\alpha\chi_\alpha=-\frac{\hbar^2(1-2\alpha)}{2m}\frac{\partial^2}{\partial q^2}\chi_\alpha-i\hbar\frac{p}{m}\frac{\partial}{\partial_q}\chi_\alpha\\
&\qquad+\sum_{n=0}\frac{(-\alpha)^n-(1-\alpha)^n}{n!}(-i\hbar)^n\frac{\partial^n V}{\partial q^n}\frac{\partial^n}{\partial p^n}\chi_\alpha.
\end{aligned} \tag{30}$$

See the Appendix for proof of Eq. (30). For $\alpha=1/2$, even n terms in Eq. (30) cancel out and one again recovers Wigner's evolution equation.[3] See Eq. (A7).

A. Assigning *q*-space operators to phase space functions: Ordering rule

The phase space state functions are devised to evaluate the expectation values of a c-number observable, $F(q,p)$, by integrations over the phase space. Upon reduction to the q space, say, $f(q,p)$ turns into a differential operator in terms of q and π_q. The questions are: (l) how are different factors of noncommuting q and π_q ordered in a given α-representation? (2) Averaging a given $F(q,p)$ with different χ_α's gives different values, how do such averages change from one

α-representation to another? Let $\hat{F}_\alpha(q,\pi_q)$ be the q space operator corresponding to the c-number monomial $q^n p^m$ in phase space when averaged by χ_α. The defining equation for$\hat{F}_\alpha(q,\pi_q)$ is

$$\langle q^n p^m\rangle_\alpha = \int q^n p^m \chi_\alpha \mathrm{d}p\mathrm{d}q = \int \psi^*(q)\hat{F}_\alpha(q,\pi_q)\psi(q)\mathrm{d}q. \tag{31}$$

For the combination of $\alpha=0$ and 1 corresponding to $(\chi+\chi^*)$ of Eq. (11) this is already worked out in Eq. (25e) and is the symmetric ordering

$$q^n p^m \to \tfrac{1}{2}(q^n \pi_q^m + \pi_q^m q^n). \tag{32}$$

For a general α, it is given in Eq. (A10),

$$q^n p^m \to \sum_{r=0}^{m} \binom{m}{r} ((1-\alpha)\pi_q)^r q^n (\alpha\pi_q)^{m-r}. \tag{33}$$

For $\alpha=1/2$ this reduces to Weyl's ordering,[2,3] which is known to go with Wigner's functions. To answer the second question we note the following:

$$\langle q^n p^m\rangle_{\alpha=0} = \int q^n p^m \chi \mathrm{d}q\mathrm{d}p = \int q^n p^m U_\alpha^\dagger \chi_\alpha \mathrm{d}q\mathrm{d}p = \int U_\alpha(q^n p^m)\chi_\alpha \mathrm{d}q\mathrm{d}p = \langle U_\alpha(q^n p^m)\rangle_\alpha, \tag{34}$$

where by Eq. (29) we have used $\chi=U^\dagger\chi_\alpha$. The conclusion is that $q^n p^m$ averaged by χ is the same as $U_\alpha(q^n p^m)$ averaged by χ_α. Upon adoption of

$$U_\alpha = \sum \frac{(-i\alpha\hbar)^k}{k!}\frac{\partial^k}{\partial q^k}\frac{\partial^k}{\partial p^k}$$

and operation by it on $q^n p^m$ one finds

$$\begin{aligned} U_\alpha(q^n p^m) &= \sum_{k=0}^{\text{smaller of } n \text{ or } m} (-i\hbar\alpha)^k k! \binom{n}{k}\binom{m}{k} q^{q^{n-k}} p^{m-k} \\ &= q^n p^m + (-i\hbar\alpha)mnq^{n-1}p^{m-1} + \frac{1}{2}(-i\hbar\alpha)^2 n(n-1)m(m-1)q^{n-2}p^{m-2} + \cdots . \end{aligned} \tag{35}$$

B. Assigning phase space functions to *q* space operators

To a given operator $\hat{F}(q,\pi_q)$, a Taylor-expanded series in whatever order of powers of q and π_q, we associate the following c-number function:

$$F(q,p) = \sum_{n,m} F_{mn}\chi_{nm} = \langle q|\hat{F}|p\rangle e^{-ipq/\hbar}, \tag{36}$$

where $F_{mn}=\langle n|\hat{F}|m\rangle$ is the matrix element of $\hat{F}$ in the basis of the eigenstates of $\hat{H}(q,\pi_g)$. This is actually the inverse of the procedure that we used in Eq. (31) to associate an operator with a c-number function (let $\alpha=0$ and replace $q^n p^m$ by $F(q,p)$ in Eq. (33) to see the analogy). The second equality in Eq. (36) expresses the same in the ket- and bra- notation of Dirac.

The corresponding function in α-representation is simply

$$F_\alpha(q,p) = U_\alpha F(q,p) = \sum_{n,m} F_{mn} U_\alpha \chi_{nm} = \int \langle q - \alpha\tau|\hat{F}|q + 1(1-\alpha)\tau\rangle e^{ip\tau/\hbar} \mathrm{d}\tau. \tag{37}$$

This is actually the generalization of Eq. (29) for a general operator $\hat{F}(q,\pi_q)$. The rule for the product $\hat{F}=\hat{A}\hat{B}$ is worked out in Eq. (A13):

$$F(q,p=)\langle q|\hat{A}(q,\pi_q)\hat{B}(q,\pi_q)|p\rangle e^{-ipq/\hbar} = \sum_{n=0}^{\infty} \frac{(-i\hbar)^n}{n!} \frac{\partial^n A(q,p)}{\partial p^n} \frac{\partial^n B(q,p)}{\partial q^n}. \tag{38}$$

One may also work out the α-representation of Eq. (38):

$$\begin{aligned} F_\alpha(q,p) = U_\alpha F(q,p) &= A_\alpha\left[q + i\hbar\,\alpha\frac{\partial}{\partial p}, p - i\hbar\,\alpha(1-\alpha)\frac{\partial}{\partial q}\right] B_\alpha(q,p) \\ &= \sum_{n=0}^{\infty} \frac{(i\hbar)^n}{n!}\left[\alpha\frac{\partial}{\partial_{qA}}\frac{\partial}{\partial_{pB}} - (1-\alpha)\frac{\partial}{\partial_{pA}}\frac{\partial}{\partial_{qB}}\right]^n A_\alpha(q,p)B_\alpha(q,p). \end{aligned} \tag{39}$$

See Eq. (A17) for details of the derivation. In Sec. VII, we analyze Bloch's problem as an illustration of the use of the developments of the last two subsections.

C. A remark on general transformations

An economical way of treating canonical transformations is the symplectic formalism. Let $\boldsymbol{\eta}$ be the column vector $(q,\ \pi_q;\ p,\ \pi_p)$. The equations of the classical dynamics assume the following form

$$\dot{\boldsymbol{\eta}} = \mathbf{J}\frac{\partial \mathcal{H}}{\partial \boldsymbol{\eta}}, \tag{40}$$

where $\mathcal{H}(\boldsymbol{\eta})$ is the extended Hamiltonian of Eq. (7) and $\mathbf{J}$ is the symplectic metric

$$\mathbf{J} = \begin{pmatrix} j & 0 \\ 0 & j \end{pmatrix}, \quad j = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{41}$$

An infinitesimal canonical transformation from $\boldsymbol{\eta}$ to $\boldsymbol{\eta}+\delta\boldsymbol{\eta}$ is of the form

$$\boldsymbol{\eta} + \delta\boldsymbol{\eta} = \boldsymbol{\eta} - \boldsymbol{\epsilon}\frac{\partial G(\boldsymbol{\eta})}{\partial \boldsymbol{\eta}}, \tag{42}$$

where G is the generator of the transformation and $\boldsymbol{\epsilon}$ indicates its infinitesimal character. The matrix of the transformation is

$$M_{ij} = \delta_{ij} - \boldsymbol{\epsilon}\frac{\partial^2 G}{\partial \eta_i \eta_j}. \tag{43}$$

The condition for canonicity is

$$\mathbf{M}\mathbf{J}\mathbf{M}^\dagger = \mathbf{J} + O(\boldsymbol{\epsilon}^2). \tag{44}$$

This imposes the condition on G to be either linear in η_j or quadratic and symmetric in η_i, η_j or both. For clarity, hereafter we confine our discussion to a system of one degree of freedom, $N=1$. The most general form of G with the restriction just mentioned is

$$G(\boldsymbol{\eta}) = a_i\eta_i + \alpha_{ij}\eta_i\eta_j, \quad i,j = 1,2,3,4 \text{ correspond to } q,\ \pi_q;\ p,\ \pi_p, \tag{45}$$

where the four parameters a_i initiate translations and the ten symmetric α_{ij} cause rotations, boosts, squeezes, scale changes, etc. The ten transformations α_{ij} constitute a symplectic group $SP(4)$, and

is locally isomorphic to the (3+2)-dimensional Lorentz group. This is the group that Kim and Noz[17] encounter in their study of four-dimensional phase space consisting of two oscillators representation of $O(3+2)$, and proves to be a useful mathematical tool in quantum optics. To each of the fourteen transformations of Eq. (45) there corresponds a unitary or similarity transformation in the function space. That of Eq. (27) it is unitary. An example of nonunitary operators is the following. To the canonical coordinate transformation

$$q = Q + \frac{i\epsilon}{2\hbar}\Pi_Q + \frac{1}{2}\Pi_P, \quad \pi_q = \Pi_Q,$$
$$p = P + \frac{i\hbar}{2\epsilon}\Pi_P + \frac{1}{2}\Pi_Q, \quad \pi_p = \Pi_P, \tag{46}$$

there corresponds the complex similarity operator

$$S_\varepsilon = \exp\left[\left(\frac{\varepsilon}{4}\frac{\partial^2}{\partial q^2} + \frac{\hbar^2}{4\varepsilon}\frac{\partial^2}{\partial p^2}\right) + \frac{i\hbar}{2}\frac{\partial^2}{\partial q\,\partial p}\right], \tag{47}$$

where ε is a finite parameter of the transformation. Husimi's[5] all positive distribution in terms of χ is

$$\chi_{\mathrm{Hus}}(q,p,\varepsilon) = S_\varepsilon \chi(q,p). \tag{48}$$

VI. BLOCK'S EQUATION IN PHASE SPACE

In this section we intend to illustrate some usage of the formalism developed so far. In any discussion of statistical mechanics, the partition function, $Z(\beta)=\mathrm{tr}\,\hat{\Omega}$, $\hat{\Omega}(q,\pi_q)=\exp(-\beta\hat{H})$, plays a pivotal role. Its calculation, however, is often cumbersome. One practice is to translate $\hat{\Omega}$ and the corresponding Bloch's differential equation[18] into a phase space language,[3,16] solve the equation for a c-number $\Omega(q,p,\beta)$ and calculate $Z(\beta)=\int\Omega(p,q,\beta)\mathrm{d}q\mathrm{d}p$. The ease of doing the job depends on the choice of the c-number assigned to $\hat{\Omega}$. Our suggestion is that of Eq. (36) Bloch's equation for $\hat{\Omega}$ is

$$\frac{\partial\hat{\Omega}}{\partial\beta} = -\hat{H}\hat{\Omega} = -\hat{\Omega}\hat{H}. \tag{49}$$

We apply the rule of Eq. (36) to Eq. (49). Noting that $\hat{H}(q,\pi_q)\rightarrow H(q,p)=p^2/2m+V(q)$ and using the product rule of Eq. (38) gives

$$-\frac{\partial\Omega(q,p;\beta)}{\partial\beta} = \left\{H(q,p) - \frac{ip\hbar}{m}\frac{\partial}{\partial q} - \frac{\hbar^2}{2m}\frac{\partial^2}{\partial q^2}\right\}\Omega(p,q). \tag{50}$$

This same result is obtained in Ref. 19, however, by a totally different approach and through much lengthier calculations using Moyal's characteristic technique. Equation (49) in Wigner's representation is obtained by replacing $\hat{\Omega}$ with $\Omega_W(q,p;\beta)$, $\hat{H}$ with $p^2/2m+V(q)$ and using Eq. (A17) with $\alpha=1/2$ to find the expression corresponding to $\hat{H}\hat{\Omega}$. In agreement with Refs. 3 and 16 one finds

$$-\frac{\partial\Omega_W(q,p;\beta)}{\partial\beta} = \left\{\frac{p^2}{2m} - \frac{\hbar^2}{8m}\frac{\partial^2}{\partial q^2} + \sum_{n=0}^{n=\infty}\frac{(i\hbar/2)^n}{n!}\frac{\partial^n}{\partial q^n}V(q)\frac{\partial^n}{\partial p^n}\right\}\Omega_W(q,p;\beta). \tag{51}$$

The contrast between the two, Eqs. (50) and (51), is striking. The former is a second-order differential equation in q and the exact quantum effects in it appear as $\hbar$ and $\hbar^2$ only, while the latter in addition to $\partial^2/\partial q^2$ is an nth-order differential equation in p and has all powers of $\hbar$ in it.

In the following we solve Eq. (50) and give the partition functions for the simple harmonic and linear potentials.

A. Simple harmonic potential

For $H(q,p)=l/2(p^2/m+m\omega^2q^2)$ the solution is of the form

$$\Omega = \exp\left[- A(\beta)H(q,p) - iB(\beta)\frac{pq}{\hbar} - C(\beta) \right]. \tag{52}$$

Substituting this in Eq. (50) and letting the coefficients of different powers of q and p vanish, gives

$$\frac{\mathrm{d}A}{\mathrm{d}\beta} = 1 - \hbar^2\omega^2A^2, \tag{53a}$$

$$\frac{\mathrm{d}B}{\mathrm{d}\beta} = \hbar^2\omega^2A(1-B), \tag{53b}$$

$$\frac{\mathrm{d}C}{\mathrm{d}\beta} = \frac{1}{2}\hbar^2\omega^2A. \tag{53c}$$

The condition $\Omega(q,p,0)=1$ imposes the boundary conditions $A(0)=B(0)=C(0)=0$. With these provisions one finds

$$A(\beta) = \frac{1}{\hbar\,\omega}\tanh\beta\hbar\,\omega, \tag{54a}$$

$$B(\beta) = \tanh\beta\hbar\,\omega\tanh\frac{\beta\hbar\,\omega}{2}, \tag{54b}$$

$$C(\beta) = -\frac{1}{2}\ln\cosh\beta\hbar\,\omega. \tag{54c}$$

The partition function is

$$Z(\beta) = \frac{1}{2\pi\hbar}\int_{-\infty}^{+\infty}\Omega(q,p,\beta)\mathrm{d}q\mathrm{d}p = \left[2\sinh\frac{\beta\hbar\,\omega}{2} \right]^{-1}. \tag{55}$$

The normalized density function is $\chi(q,p,\beta)=\Omega(q,p,\beta)/2\pi\hbar Z(\beta)$, with low and high temperature limits

$$\chi = \frac{\sqrt{2}}{\pi\hbar}\exp\left[- H(q,p) - \frac{ipq}{\hbar} \right], \quad \beta\hbar\,\omega \gg 1,$$

$$\chi = \frac{\beta\omega}{2\pi}\exp[-\beta H(q,p)], \quad \beta\hbar\,\omega \ll 1, \tag{56}$$

in agreement with the quantum and classical limits, respectively.

B. Linear potential

The case is of interest for quark model,[20] where a sea of semi-infinite matter creates a linear potential $V(q)=kq$, $0\leq q<\infty$, and $k>0$. By the same procedure above one obtains

$$\Omega(q,p,\beta) = \exp\left[-\beta H - \frac{i\beta^2 p\hbar k}{2m} + \frac{\beta^3\hbar^2 k^2}{6m}\right], \tag{57}$$

$$Z(\beta) = \sqrt{\frac{2\pi m}{\beta^3 k^2}}\exp\left[\frac{\beta^3\hbar^2 k^2}{24m}\right]. \tag{58}$$

$$\chi(q,p;\beta) = \sqrt{\frac{\beta^3 k^2}{2\pi m}}\exp\left[-\beta H - \frac{i\beta^2 p\hbar k}{2m} + \frac{\beta^3\hbar^2 k^2}{8m}\right]. \tag{59}$$

The corresponding Wigner's function[21] can be obtained by letting $U_{1/2}$ operate on Eq. (59).

VII. CONCLUSION

We have developed a quantum mechanics in phase space by carrying the independent and symmetric roles of q and p, so eminent in the Hamiltonian formulation of the classical mechanics, to quantum domain. This is done through the extension of the phase space by introducing the momenta π_q and π_p conjugate to q and p, respectively, and the subsequent extensions of the Lagrangians, Hamiltonians, Poisson's brackets, etc. In its full generality, the theory describes the dynamics of the quantum ensembles. Its pure state case is reducible to the conventional quantum mechanics in q- or p-spaces, however, with a definite rule for ordering of the factors of noncommuting operators. The latter feature is a direct consequence of the independence of q and p that is maintained at all stages of the formalism. Simple rules for assigning an operator $\hat{F}(q,\pi_q)$ in q-space to a function $F(q,p)$ in phase space and vice versa are prescribed. Extended canonical transformations enable one to go from one extended phase space to another. Correspondingly the associated unitary or similarity transformations in the function space enable one to generate further state functions from a given one. This unifying feature of the theory makes the comparison of the various functions existing in the literature possible and transparent.

To demonstrate the simplicity and the power of the formalism certain examples are worked out. Treatment of Bloch's equation, partition functions for simple harmonic and linear potentials, and the mathematical lemmas of the Appendix serve this end. Nasiri and Safari[22] and Razavi[23] have found the presented formalism of considerable assistance in their study of dissipative quantum systems.

ACKNOWLEDGMENTS

We thank M. R. H. Khajehpour for fruitful discussions on all aspects of the paper and R. F. O'Connell for valuable comments on our treatment of Bloch's equation.

APPENDIX

Evaluation of $\chi_\alpha = U_\alpha\chi$: By three Fourier and inverse Fourier transformations we convert $\chi = \psi(q)\phi^*(p)\exp(-ipq/\hbar)$ into the following forms;

$$\chi = \int \phi(p')\phi^*(p'')\exp\frac{iq(p'-p'')}{\hbar}\exp\frac{ip\tau}{\hbar}\exp\frac{-ip''}{\hbar}\mathrm{d}p'\mathrm{d}p''\mathrm{d}\tau. \tag{A1}$$

By this provision we have moved both q and p variables to the exponent. Next we expand U_α of Eq. (28) in power series, operate by it on the q and p exponents, and arrive at

$$\sum_{k=0}^{k=\infty}\frac{(i\alpha\hbar)^k}{k!}\frac{\partial^k}{\partial p^k}\frac{\partial^k}{\partial q^k}\exp\frac{iq(p'-p'')}{\hbar}\exp\frac{ip\tau}{\hbar} = \exp\frac{-i\alpha\tau(p'-p'')}{\hbar}\exp\frac{iq(p'-p'')}{\hbar}\exp\frac{ip\tau}{\hbar}. \tag{A2}$$

Using Eqs. (A1) and (A2) in the expression $\chi_\alpha = U_\alpha\chi$, and inverting ϕ's back to ψ's gives Eq. (29),

$$\chi_\alpha(p,q,t) = U_\alpha \chi = \left(\frac{1}{2\pi\hbar}\right)^N \int \psi(q-\alpha\tau)\psi^*(q+(1-\alpha)\tau)e^{ip\tau/\hbar}\mathrm{d}\tau. \tag{A3}$$

As mentioned earlier, for $\alpha=1/2$ one recovers Wigner's standard state functions.

Evolution equation for χ_α: To prove Eq. (30), it is sufficient to evaluate $\mathcal{H}_\alpha = U_\alpha \mathcal{H} U_\alpha^\dagger$, where $\mathcal{H}$ is the extended Hamiltonian of Eq. (10). It is easy to show that $Q = U_\alpha q U_\alpha^\dagger = q - \alpha\pi_P$ and $P = U_{\alpha p} U_\alpha^\dagger = p - \alpha\pi_q$, which is the essence of the transformations of Eq. (27). We also note that

$$U_\alpha q^n p^m U_\alpha^\dagger = (q-\alpha\pi_p)^n (p-\alpha\pi_q)^m = (p-\alpha\pi_q)^m (q-\alpha\pi_p)^n. \tag{A4}$$

We leave it to the reader to verify Eq. (A4) for him/herself for some small n and m. It is needless to say that $[Q,P]=0$, because the transformation is unitary. With these provisions one finds

$$\mathcal{H}_\alpha = H[q-\alpha\pi_p, p+(1-\alpha)\pi_q] - H[q-(1-\alpha)\pi_p, p-\alpha\pi_q). \tag{A5}$$

Expansion of the Hamiltonian about (q,p) gives

$$\mathcal{H}_\alpha = -\frac{\hbar^2(1-2\alpha)}{2m}\frac{\partial^2}{\partial q^2} - i\hbar\frac{p}{m}\frac{\partial}{\partial q} + \sum_{n=0}\frac{(-\alpha)^n - (1-\alpha)^n}{n!}(-i\hbar)^n \frac{\partial^n V}{\partial q^n}\frac{\partial^n}{\partial p^n}. \tag{A6}$$

The Wigner case is for $\alpha=1/2$,

$$\mathcal{H}_W = -i\hbar\frac{p}{m}\frac{\partial}{\partial q} + \sum_{n=0}\frac{1}{(2n+1)!}\left(\frac{\hbar}{2i}\right)^{2n+1}\frac{\partial^{2n+1}V}{\partial q^{2n+1}}\frac{\partial^{2n+1}}{\partial p^{2n+1}}. \tag{A7}$$

Ordering rule in α*-representation, proof of Eq.* (33): With Eqs. (31) and (A3) we have

$$\langle q^n p^m\rangle_\alpha = \int_{-\infty}^{+\infty} q^n \psi(q-\alpha\tau)\psi^*(q+(1-\alpha)\tau)p^m e^{ip\tau/\hbar}\mathrm{d}q\mathrm{d}p\mathrm{d}\tau. \tag{A8}$$

Writing p^m as $(i\hbar)^m\partial^m/\partial\tau^m$, integrating by parts m times with respect to τ frees the integrand from the p^m factor. Then integration with respect to p gives $\delta(\tau)$. Thus

$$\langle q^n p^m\rangle_\alpha = \int_{-\infty}^{+\infty} q^n(-i\hbar)^m\frac{\partial^m}{\partial\tau^m}[\psi(q-\alpha\tau)\psi^*(q+(1-\alpha)\tau)]\delta(\tau)\mathrm{d}q\mathrm{d}\tau. \tag{A9}$$

Next we substitute $\partial/\partial\tau$ by $\partial/\partial q$ with appropriate adjustments and carry out integrations by parts over q whereever necessary to free ψ^* and arrive at

$$\langle q^n p^m\rangle_\alpha = \int_{-\infty}^{+\infty}\psi^*(q)\left[\sum_{r=0}^{m}\binom{m}{r}((1-\alpha)\pi_q)^r q^n(\alpha\pi_q)^{m-r}\right]\psi(q)\mathrm{d}q. \tag{A10}$$

The expression in the integrand is the desired ordering of Eq. (33), corresponding to $q^n p^m$ in α-representation. For $\alpha=1/2$ one recovers Weyl's ordering

$$q^n p^m \to \left(\frac{1}{2}\right)^m \sum_{r=0}^{m}\binom{m}{r}\pi_q^r q^n \pi_q^{m-r}. \tag{A11}$$

The combination of $\alpha=0$ and 1, corresponding to averaging by $x+\chi^*$, is the symmetric ordering of Eq. (32). □

The product rule, proof of Eqs. (38) *and* (39): The phase space function corresponding to the product of two operators $\hat{F}=\hat{A}\hat{B}$, by the definition of Eq. (36), is

$$F(q,p)=\langle q|\hat{A}\hat{B}|p\rangle e^{-ipq/\hbar}=\int\langle q|\hat{A}|p'\rangle\langle p'|\hat{B}|p\rangle e^{-ipq/\hbar}\mathrm{d}q\mathrm{d}p$$

$$=\int A(q,p')B(q',p)\exp\frac{-i(q'-q)(p'-p)}{\hbar}\mathrm{d}q\mathrm{d}q, \tag{A12}$$

where by Eq. (36), we have substituted $\langle q|\hat{A}|p'\rangle=A(q,p')\exp(ip'q/\hbar)$ and similarly for $\langle q'|\hat{B}|p\rangle$. With further change of variables $q'-q=q''$ and $p'-p=p''$, we obtain

$$F(q,p)=\int A(q,p''+p)B(q''+q,p)e^{-iq''p''/\hbar}\mathrm{d}q''\mathrm{d}p''=\sum_{n=0}^{\infty}\frac{(-i\hbar)^n}{n!}\frac{\partial^n A(q,p)}{\partial p^n}\frac{\partial^n B(q,p)}{\partial q^n}, \tag{A13}$$

where we have Taylor-expanded $A(q,p+p'')$ and $B(q+q'',p)$ about (q,p) and carried out the required integration by parts.

To deduce Eq. (39), we first Fourier-transform $A(q,p)$ to $a(p',q')$ and $B(q,p)$ to $b(p'',q'')$ in Eq. (A13) and carry out the necessary differentiations:

$$F(q,p)=\sum_{n=0}^{\infty}\frac{(-i\hbar)^n}{n!}\frac{\partial^n}{\partial p^n}\int a(p',q')\exp\frac{-ip'q+iq'p}{\hbar}\mathrm{d}p'\mathrm{d}q'\frac{\partial^n}{\partial q^n}$$

$$\times\int b(p'',q'')\exp\frac{-ip''q+iq''p}{\hbar}\mathrm{d}q''\mathrm{d}p''$$

$$=\int a(p',q')\exp\frac{-ip'q+iq'p}{\hbar}b(p'',q'')\exp\frac{-ip'',q''p}{\hbar}e^{-iq'p''/\hbar}\mathrm{d}q'\mathrm{d}p'\mathrm{d}q''\mathrm{d}p''. \tag{A14}$$

Next we operate on Eq. (A14) by a Taylor-expanded form of U_α as in Eq. (A2) and perform the required differentiations:

$$F_\alpha(q,p)=U_\alpha F(q,p)=\int e^{i\alpha q'p'/\hbar}\exp\frac{-ip'q+iq'p-(1-\alpha)q'p''+\alpha q''p'}{\hbar}a(q',p')$$

$$\times e^{i\alpha q''p''/\hbar}\exp\frac{-ip''q+iq''p}{\hbar}b(p'',q'')\mathrm{d}q'\mathrm{d}p'\mathrm{d}q''\mathrm{d}p''. \tag{A15}$$

The exponentials preceding $a(p',q')$ can be written as

$$e^{i\hbar\alpha\partial^2/\partial p\partial q}\exp\frac{-ip'(q+\alpha q'')+iq'(p-(1-\alpha)p'')}{\hbar},$$

where the first factor is simply $U_\alpha(q,p)$ independent of the integration variables (q',p',q'',p''). With this provision integrations over q' and p' can now be carried out and $a(p',q')$ inverse-Fourier transformed. One finds

$$F_\alpha(q,p)=\int\{U_\alpha A[q+\alpha q'',p-(1-\alpha)p'']\}e^{i\alpha q''p''/\hbar}e^{(-ip''q+iq''p)/\hbar}b(p'',q'')\mathrm{d}q''\mathrm{d}p''. \tag{A16}$$

We again apply the same trick. To the left of the rightmost exponential we replace, everywhere, q'' by $(-i\hbar\partial/\partial p)$ and p'' by $(i\hbar\partial/\partial q)$, perform the inverse Fourier transform of $b(p'',q'')$ and find

$$F_\alpha(q,p) = U_\alpha F(q,p) = A_\alpha\left[q + i\hbar\,\alpha\frac{\partial}{\partial p}, p - i\hbar\,\alpha(1-\alpha)\frac{\partial}{\partial q}\right]B_\alpha(q,p)$$

$$= \sum_{n=0}^{\infty}\frac{(i\hbar)^n}{n!}\left[\alpha\frac{\partial}{\partial q_A}\frac{\partial}{\partial p_B} - (1-\alpha)\frac{\partial}{\partial p_A}\frac{\partial}{\partial q_B}\right]^n A_\alpha(q,p)B_\alpha(q,p). \tag{A17}$$

where $\partial/\partial p_A$ indicates a differentiation on $A(q,p)$ only, similarly the other differential operators.□

(Received 20 March 2006; accepted 15 August 2006; published online 28 September 2006)

We characterize the extremal points of the convex set of quantum measurements that are covariant under a finite-dimensional projective representation of a compact group, with action of the group on the measurement probability space which is generally nontransitive. In this case the POVM density is made of multiple orbits of positive operators, and, in the case of extremal measurements, we provide a bound for the number of orbits and for the rank of POVM elements. Two relevant applications are considered, concerning state discrimination with mutually unbiased bases and the maximization of the mutual information. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2349481]

I. INTRODUCTION

A fundamental issue in the theory of quantum information[1] is the investigation of the ultimate precision limits for extracting classical information from a quantum system. Indeed, when the information is encoded on quantum states, its read-out suffers the intrinsically quantum limitation of discriminating among nonorthogonal states. One then needs to optimize the discrimination with respect to a given optimality criterion, which is dictated by the particular task for which the measurement is designed, or by the particular way the information is encoded over states. The good news is that, although the position of the problem has a limited generality due to the specific form of the optimality criterion, nevertheless for a large class of criteria the optimization method is given by a standard procedure. In such approach all possible measurements form a convex set (the convex combination of two measurements corresponding to the random choice between their apparatuses), and the optimization consists in maximizing a convex functional, e.g., the mutual information,[2,3] or to minimizing a concave functional, e.g., a Bayes cost,[4,5] over the convex set of measurements. Since the global maximum of a convex functional (or the minimum of a concave functional) is achieved over extremal points, the optimization can be restricted to the extremal elements of the set only.

In most situations of interest, the set of signal states on which the information is encoded is invariant under the unitary action of some group of physical transformations. The symmetry of the set of signal states is then reflected in a symmetry of the optimal measurements, which without loss of generality can be assumed to be *covariant*[5] with respect to the same group of transformations.

The problem of charactering extremal covariant measurements has been addressed in Refs. 6 and 7, however restricting the analysis to the case of group-action that is *transitive* on the probability space of measurement outcomes, namely any two points in the probability space are connected by some group element. The present paper completes the investigation by generalizing all results to the case of nontransitive group actions. Indeed the discrimination of states belonging to disjoint group orbits occurs in actual applications, and this situation has received little attention in the literature. Moreover, when classical information is encoded on quantum states it can be

[a]Electronic mail: chiribella@unipv.it
[b]Electronic mail: dariano@unipv.it

convenient to decode it with a measurement having outcomes that are not in one-to-one correspondence with the encoding states. This typically happens when the optimality criterion is nonlinear in the probabilities of measurement outcomes, as in the case of the mutual information.[8] In the presence of group symmetry, as recently noted by Decker,[9] even if the encoding states form a single group orbit, the maximization of the mutual information often selects covariant measurements with probability space that splits into disjoint orbits. It is then interesting to quantify the number of orbits needed for the maximization of the mutual information, or at least to give an upper bound for it. Indeed, as we will see in the present paper, the characterization of extremal covariant measurements also provides as a by-product an alternative and simpler derivation of the bound given in Ref. 9.

II. STATEMENT OF THE PROBLEM

In the general framework of quantum mechanics the state of a system is represented by a density operator ρ on a given Hilbert space $\mathcal{H}$, whereas the statistics of a measurement is described by a positive operator valued measure (POVM), which associates a positive semidefinite operator $P(B) \in \mathcal{B}(\mathcal{H})$ to any subset $B \in \sigma(\mathfrak{X})$ of the σ-algebra of events in the probability space $\mathfrak{X}$. The defining properties for a POVM are

$$0 \leqslant P(B) \leqslant \mathbb{1}, \quad \forall\, B \in \sigma(\mathfrak{X}), \tag{1}$$

$$P(\cup_{k=1}^{\infty} B_k) = \sum_{k=1}^{\infty} P(B_k), \quad \forall\, \{B_k\} \text{ disjoint} \tag{2}$$

$$P(\mathfrak{X}) = \mathbb{1}. \tag{3}$$

The probability of the event $B \in \sigma(\mathfrak{X})$ is then given by the Born rule

$$p(B) = \mathrm{Tr}[\rho P(B)]. \tag{4}$$

In this paper we will consider the case where the probability space $\mathfrak{X}$ supports the action of a compact group $\mathbf{G}$, namely any group element $g \in \mathbf{G}$ acts as a measurable automorphism of the probability space $\mathfrak{X}$, which maps $x \in \mathfrak{X}$ to $gx \in \mathfrak{X}$. If any two points $x_1, x_2 \in \mathfrak{X}$ are connected by some group element, i.e., $x_2 = g x_1$ for some $g \in \mathbf{G}$, the group action is called *transitive*. In this case, which is the most studied in the literature,[4,5] the whole probability space is the group orbit of an arbitrary point $x_0 \in \mathfrak{X}$, namely $\mathfrak{X} = \{g x_0 \,|\, g \in \mathbf{G}\}$. In this paper we will study the more general case where the group action is not transitive, and, accordingly, the probability space is not a single group orbit, but the union of a set of disjoint orbits, each one being labeled by an index $i \in \mathcal{I}$ for some set $\mathcal{I}$. For simplicity, we will assume the index set $\mathcal{I}$ to be finite.

The simplest case of the nontransitive group action then arises when the probability space is the Cartesian product of the index set $\mathcal{I}$ with the compact group $\mathbf{G}$, i.e., $\mathfrak{X} = \mathcal{I} \times \mathbf{G}$. In this case, the action of a group element $h \in \mathbf{G}$ on a point $x = (i, g) \in \mathcal{I} \times \mathbf{G}$ is given by $hx = (i, hg)$. Measurements with outcomes in $\mathcal{I} \times \mathbf{G}$ naturally arise in the discrimination of a set of signal states which is the union of a certain number of disjoint group orbits, each orbit $\mathcal{O}_i$ being generated by the action of the group on a given initial state ρ_i, namely $\mathcal{O}_i = \{U_g \rho_i U_g^\dagger \,|\, g \in \mathbf{G}\}$ for some unitary representation $\mathsf{R}(\mathbf{G}) = \{U_g \,|\, g \in \mathbf{G}\}$. Precisely, if the *stability group* $\mathbf{G}_i = \{h \in \mathbf{G} \,|\, U_h \rho_i U_h^\dagger = \rho_i\}$ associated to any state ρ_i consists only of the identity element e, then there is a one-to-one correspondence between signal states and points of the probability space $\mathfrak{X} = \mathcal{I} \times \mathbf{G}$. In Sec. IV we will study in detail the case of POVMs with probability space $\mathfrak{X} = \mathcal{I} \times \mathbf{G}$.

If the stability groups associated to the initial states $\{\rho_i \,|\, i \in \mathcal{I}\}$ are nontrivial, namely $\mathbf{G}_i \neq \{e\}$ for some $i \in \mathcal{I}$, in order to have a one-to-one correspondence between signal states and measurement outcomes, one must consider the probability space $\mathfrak{X} = \cup_{i \in \mathcal{I}} \mathbf{G}/\mathbf{G}_i$, where $\mathbf{G}/\mathbf{G}_i$ denotes the quotient of $\mathbf{G}$ with respect to the equivalence relation "$g \sim g'$ if $g' = g \cdot h$ for some $h \in \mathbf{G}_i$." This more general case will be treated in Sec. V.

Definition 1 (*covariant POVMs*): *Let* $\mathfrak{X}$ *be a probability space supporting the group action* $g: x \in \mathfrak{X} \mapsto gx \in \mathfrak{X}$. *A POVM is covariant*[5] *if it satisfies the property*

$$P(B) = U_g^\dagger P(gB) U_g, \quad \forall\, B \in \sigma(\mathfrak{X}),\ \forall\, g \in \mathbf{G}, \tag{5}$$

where $gB \doteq \{gx | x \in B\}$.

In the case $\mathfrak{X} = \mathcal{I} \times \mathbf{G}$, it is simple to prove[10] that any covariant POVM admits an operator density $M(i,g)$ with respect to the (normalized) Haar measure $\mathrm{d}g$ on the group $\mathbf{G}$, namely, if $B = (i,A)$, where $A \subseteq \mathbf{G}$ is a measurable subset, then $P(B) = \int_A \mathrm{d}g M(i,g)$. Moreover, such an operator density has necessarily the form[10]

$$M(i,g) = U_g A_i U_g^\dagger, \tag{6}$$

where $A_i \in \mathcal{B}(\mathcal{H})$ are Hermitian operators satisfying the constraints

$$A_i \geqslant 0, \quad \forall\, i \in \mathcal{I}, \tag{7}$$

$$\sum_{i \in \mathcal{I}} \int_{\mathbf{G}} \mathrm{d}g\, U_g A_i U_g^\dagger = \mathbb{1}. \tag{8}$$

Here and throughout the paper we adopt for the Haar measure the normalization

$$\int_{\mathbf{G}} \mathrm{d}g = 1. \tag{9}$$

According to the above discussion, any covariant POVM with probability space $\mathfrak{X} = \mathcal{I} \times \mathbf{G}$ is completely specified by a set of operators $\{A_i | i \in \mathcal{I}\}$, such that both constraints in Eqs. (7) and (8) are satisfied. Moreover, it turns out that it is very useful to represent such a vector of operators as a single block operator $A = \oplus_{i \in I} A_i$, acting on an auxiliary Hilbert space $\mathcal{H}_{\mathrm{aux}} \doteq \oplus_{i \in I} W_i$, where $\mathcal{W}_i \simeq \mathcal{H}\, \forall\, i \in \mathcal{I}$. In terms of the block operator $A \in \oplus_{i \in I} B(W_i)$ the two constraints Eq. (7) and Eq. (8) become

$$A \geqslant 0, \tag{10}$$

and

$$\mathcal{L}(A) = \mathbb{1}, \tag{11}$$

where $\mathcal{L}: \oplus_{i \in I} B(W_i) \to B(H)$ is the linear map

$$\mathcal{L}(A) \doteq \sum_{i \in \mathcal{I}} \int_{\mathbf{G}} \mathrm{d}g\, U_g A_i U_g^\dagger. \tag{12}$$

The two constraints (10) and (11) define such a convex subset of the space of block operators $\oplus_{i \in I} B(W_i)$, which is in one-to-one affine correspondence with the convex set of covariant POVMs. In the following, the convex set of block operators will be denoted by C.

Proposition 1: *The convex set* C, *defined by the constraints* (10) and (11) *is compact in the operator norm.*

Proof: Since C is a subset of a finite dimensional vector space, it enough to show that C is bounded and closed. C is bounded, since for any $A \in \mathsf{C}$, one has $||A|| \leqslant \mathrm{Tr}[A] = \Sigma_{i \in \mathcal{I}} \mathrm{Tr}[A_i] = \mathrm{Tr}[\mathcal{L}(A)] = d$ (using Eqs. (10) and (11)). Moreover, C is closed. In fact, if $\{A_n\}$ is a Cauchy sequence of points in C, then A_n converges to some block operator $A \in \oplus_{i \in I} B(W_i)$. We claim that A belongs to C. Of course, A satisfies condition (10). As regards condition (11), just notice that the $\mathcal{L}$ is continuous, being linear. Therefore, we have $||\mathcal{L}(A) - \mathbb{1}|| = ||\mathcal{L}(A - A_n)|| \to 0$, namely A satisfies condition (11). ■

Observation 1: Since the convex set C is compact, it coincides with the convex hull of its extreme points, i.e., any element $A \in \mathsf{C}$ can be written as convex combination of extreme points. The classification of the extreme points of C will be given in Sec. IV.

Observation 2: In this section and all throughout the paper, $\mathbf{G}$ is assumed to be a compact Lie group. Nevertheless, all results clearly hold also if $\mathbf{G}$ is a finite group, with cardinality $|\mathbf{G}|$. In this case, one only has to make the substitution $\int_{\mathbf{G}} \mathrm{d}g \to (1/|\mathbf{G}|)\Sigma_{g\in\mathbf{G}}$. Moreover, since now the probability space $\mathfrak{X}=\mathcal{I}\times\mathbf{G}$ is discrete, there is no need of introducing any operator density, and we simply have

$$P(i,g) = \frac{1}{|\mathbf{G}|} U_g A_i U_g^\dagger. \tag{13}$$

An example of covariant POVM with a finite symmetry group will be given in Sec. VI.

III. SOME RESULTS OF ELEMENTARY GROUP THEORY

Let $\mathbf{G}$ be a compact Lie group and let $\mathrm{d}g$ be the invariant Haar measure on $\mathbf{G}$, normalized such that $\int_{\mathbf{G}} \mathrm{d}g = 1$. Consider a finite dimensional Hilbert space $\mathcal{H}$ and represent $\mathbf{G}$ on $\mathcal{H}$ by a unitary (generally projective) representation $\mathsf{R}(\mathbf{G})=\{U_g \,|\, g\in\mathbf{G}\}$. The collection of equivalence classes of irreducible representations which show up in the decomposition of $\mathsf{R}(\mathbf{G})$ will be denoted by S. Then $\mathcal{H}$ can be decomposed into the direct sum of orthogonal irreducible subspaces:

$$\mathcal{H} = \bigoplus_{\mu\in S} \bigoplus_{k=1}^{m_\mu} \mathcal{H}_k^\mu, \tag{14}$$

where the index μ labels equivalence classes of irreducible representations (irreps), while the index i is a degeneracy index labeling m_μ different equivalent representations in the class μ. Subspaces carrying equivalent irreps have all the same dimension d_μ and are connected by invariant isomorphisms, namely for any $k,l=1,\ldots,m_\mu$ there is an operator $T_{kl}^\mu \in \mathcal{B}(\mathcal{H})$ such that $\mathsf{Supp}(T_{kl}^\mu)=\mathcal{H}_l^\mu$, $\mathsf{Rng}(T_{kl}^\mu)=\mathcal{H}_k^\mu$, and $[T_{kl}^\mu, U_g]=0\ \forall g\in\mathbf{G}$. Due to Schur lemmas, any operator O in the commutant of the representation $\mathsf{R}(\mathbf{G})$ has the form:

$$O = \sum_\mu \sum_{k,l=1}^{m_\mu} \frac{\mathrm{Tr}[T_{lk}^\mu O]}{d_\mu} T_{kl}^\mu. \tag{15}$$

Using the above-presented formula, the normalization of a covariant POVM, given by Eq. (11), can be rewritten in a simple form. In fact, due to the invariance of the Haar measure $\mathrm{d}g$, we have $[\mathcal{L}(A), U_g]=0\ \forall g\in\mathbf{G}$, i.e., $\mathcal{L}(A)$ belongs to the commutant of $\mathsf{R}(\mathbf{G})$. Then, by exploiting Eq. (15), we rewrite the normalization constraint (11) as

$$\sum_{i\in\mathcal{I}} \mathrm{Tr}[T_{kl}^\mu A_i] = d_\mu \delta_{kl}, \quad \forall\, \mu\in S, \quad \forall\, k,l=1,\ldots,m_\mu, \tag{16}$$

δ_{kl} denoting the Kronecker delta.

Again, this condition can be recast into a compact form by introducing the auxiliary Hilbert space $\mathcal{H}_{\mathrm{aux}}=\oplus_{i\in I} W_i$, with $\mathcal{W}_i \simeq \mathcal{H}\ \forall i\in\mathcal{I}$, and constructing a block operator with a repeated direct sum of the same operator T_{kl}^μ, i.e.,

$$S_{kl}^\mu = \bigoplus_{i\in\mathcal{I}} S_{kli}^\mu, \quad S_{kli}^\mu = T_\mu^{kl}, \quad \forall\, i\in\mathcal{I}. \tag{17}$$

With this definition, Eq. (16) becomes

$$\mathrm{Tr}[S_{kl}^\mu A] = d_\mu \delta_{kl}, \quad \forall\, \mu\in S, \quad \forall\, k,l=1,\ldots,m_\mu, \tag{18}$$

where A is the block operator $A=\oplus_{i\in I} A_i$.

IV. EXTREMAL COVARIANT POVMs

This section contains the main result of the paper, namely the characterization of the extremal covariant POVMs with probability space $\mathcal{I}\otimes\mathbf{G}$. Such a characterization will be given by exploiting the one-to-one affine correspondence between the convex set of covariant POVMs and the convex set C of block operators defined by the constraints (10) and (11), or, equivalently, by (10) and (18).

Definition 2: *An Hermitian block operator* $P=\oplus_{i\in I}P_i$ *is a perturbation of* $A\in\mathsf{C}$ *if there exists an* $\epsilon>0$ *such that* $A+tP\in\mathsf{C}$ *for any* $t\in[-\epsilon,\epsilon]$.

Clearly, a point $A\in\mathsf{C}$ is extreme if and only if it admits only the trivial perturbation $P=0$.

Lemma 1: *A block operator* $P=\oplus_{i\in I}P_i$ *is a perturbation of* $A\in\mathsf{C}$ *if and only if*

$$\mathsf{Supp}(P)\subseteq\mathsf{Supp}(A), \tag{19}$$

$$\mathrm{Tr}[S_{kl}^{\mu}P]=0,\quad \forall\,\mu\in S,\quad \forall\,k,l=1,\ldots,m_{\mu}. \tag{20}$$

Proof: Condition (19) is equivalent to the existence of an $\epsilon>0$ such that $A+tP\geqslant 0$ for all $t\in[-\epsilon,\epsilon]$ (see Lemma 1 of Ref. 7). On the other hand, condition (20) is equivalent to require that $A+tP$ satisfies the normalization constraint (16) for all $t\in[-\epsilon,\epsilon]$. ■

Observation: Note that, due to the block form of both P and A, condition (19) is equivalent to

$$\mathsf{Supp}(P_i)\subseteq\mathsf{Supp}(A_i),\quad \forall\,i\in\mathcal{I}. \tag{21}$$

Using the previous lemma, we can obtain a first characterization of extremality:

Theorem 1 (Minimal support condition): *A point* $A\in\mathsf{C}$ *is extremal if and only if for any* $B\in\mathsf{C}$,

$$\mathsf{Supp}(B)\subseteq\mathsf{Supp}(A)=\Rightarrow A=B. \tag{22}$$

Proof: Suppose A extremal. Then, if $\mathsf{Supp}(B)\subseteq\mathsf{Supp}(A)$, according to Lemma 1, $P=A-B$ is a perturbation of $A\in\mathsf{C}$. Hence, P must be zero. Conversely, if P is a perturbation of A, then $B=A+tP$ is an element of C for some $t\neq 0$. Due to Lemma 1, we have $\mathsf{Supp}(B)\subseteq\mathsf{Supp}(A)$. Then, condition (22) implies $B=A+tP=A$, i.e., $P=0$. Therefore, A is extremal. ■

Corollary 1: *If* $A\in\mathsf{C}$ *and* $\mathrm{rank}(A)=1$, *then* A *is extremal*.

Proof: Since $\mathrm{rank}(A)=1$, then, for any $B\in\mathsf{C}$, the condition $\mathsf{Supp}(B)\subseteq\mathsf{Supp}(A)$ implies $B=\lambda A$ for some $\lambda>0$. Moreover, since both A and B are in C, from Eq. (18) we have $d_{\mu}=\mathrm{Tr}[S_{kk}^{\mu}B]=\lambda\,\mathrm{Tr}[S_{kk}^{\mu}A]=\lambda d_{\mu}$, whence necessarily $\lambda=1$. Condition (22) then ensures that A is extremal. ■

A deeper characterization of extremal covariant POVMs can be obtained by using the following lemma.

Lemma 2: *Let* A *be a point of* C, *represented as*

$$A=\bigoplus_{i\in\mathcal{I}}X_i^{\dagger}X_i, \tag{23}$$

and define $\mathcal{H}_i=\mathsf{Rng}(X_i)$ *the range of* X_i. *A block operator* $P=\oplus_{i\in I}P_i$ *is a perturbation of* A *if and only if*

$$P_i=X_i^{\dagger}Q_iX_i,\quad \forall\,i\in\mathcal{I}, \tag{24}$$

for some Hermitian $Q_i\in\mathcal{B}(\mathcal{H}_i)$, *and*

$$\sum_{i\in\mathcal{I}}\mathrm{Tr}[S_{kli}^{\mu}X_i^{\dagger}Q_iX_i]=0. \tag{25}$$

Proof: First of all, the form (24) is equivalent to condition (19). In fact, if P has the form (24), then clearly $\mathsf{Supp}(P)\subseteq\mathsf{Supp}(A)$. Conversely, if we assume condition (19) and write

$P=\oplus_{i\in I}P_i$, we have necessarily $\mathsf{Supp}(P_i)\subseteq\mathsf{Supp}(X_i^\dagger X_i)=\mathsf{Supp}(X_i)$. Exploiting the singular value decomposition $X_i=\Sigma_{n=1}^{r_i}\lambda_n^{(i)}|w_n^i\rangle\langle v_n^i|$, where $\{|v_n^i\rangle\}$ and $\{|w_n^i\rangle\}$ are orthonormal bases for $\mathsf{Supp}(X_i)$ and $\mathsf{Rng}(X_i)$ respectively, we have that any Hermitian operator P_i satisfying $\mathsf{Supp}(P_i)\subseteq\mathsf{Supp}(X_i)$ has the form $P_i=\Sigma_{m,n}p_{mn}^{(i)}|v_m\rangle\langle v_n|$, whence it can be written as $P_i=X_i^\dagger Q_i X_i$, for some suitable Hermitian operator $Q_i\in\mathcal{B}(\mathsf{Rng}(X))$. Once the equivalence between the form (24) and condition (19) is established, relation (25) follows directly from Eq. (20). ■

Observation: According to the previous lemma, a perturbation of A is completely specified by a set of Hermitian operators $\{Q_i\in\mathcal{B}(\mathcal{H}_i)|i\in\mathcal{I}\}$, where $\mathcal{H}_i=\mathsf{Rng}(X_i)$. Such operators can be cast into a single block operator $Q\in\oplus_{i\in I}\mathcal{B}(H_i)$ by defining

$$Q=\bigoplus_{i\in\mathcal{I}}Q_i. \tag{26}$$

In terms of the block operator Q we have the following:

Lemma 3: *Let* $A=\oplus_{i\in I}X_i^\dagger X_i$ *be a point of* C. *Define the block operators*

$$F_{kl}^\mu=\bigoplus_{i\in\mathcal{I}}X_i S_{kli}^\mu X_i^\dagger. \tag{27}$$

Then A admits a perturbation if and only if there exists an Hermitian block operator $Q\in\oplus_{i\in I}\mathcal{B}(H_i)$ *such that*

$$\mathrm{Tr}[F_{kl}^\mu Q]=0,\quad \forall\,\mu\in\mathsf{S},\quad \forall\,k,l=1,\ldots,m_\mu. \tag{28}$$

Proof: Using the definition of F_{kl}^μ and the cyclic property of the trace, it is immediate to see that Eq. (28) is equivalent to Eq. (25). ■

The previous lemma enables us to characterize the extremal points of C.

Theorem 2 (Spanning set condition): *Let* $A=\oplus_{i\in I}X_i^\dagger X_i$ *be a point of* C, *and* $\mathsf{F}=\{F_{kl}^\mu|\mu\in\mathsf{S},k,l=1,\ldots,m_\mu\}$ *be the set of block operators defined in Lemma 3*. *Then*, *A is extremal if and only if*

$$\mathsf{Span}(\mathsf{F})=\bigoplus_{i\in\mathcal{I}}\mathcal{B}(\mathcal{H}_i), \tag{29}$$

where $\mathcal{H}_i=\mathsf{Rng}(X_i)$.

Proof: A is extremal iff it admits only the trivial perturbation $P=0$. Equivalently, due to Lemma 3, A is extremal iff the only Hermitian operator $Q\in\oplus_{i\in I}\mathcal{B}(H_i)$ that satisfies Eq. (28) is the null operator $Q=0$. Let us decompose the Hilbert space $\mathcal{K}=\oplus_{i\in I}\mathcal{B}(H_i)$, as $\mathcal{K}=\mathsf{Span}(\mathsf{F})\oplus\mathsf{Span}(\mathsf{F})^\perp$, where $\perp$ denotes the orthogonal complement with respect to the Hilbert-Schmidt product $(A,B)=\mathrm{Tr}[A^\dagger B]$. Then, A is extremal iff the only Hermitian operator in $\mathsf{Span}(\mathsf{F})^\perp$ is the null operator. This is equivalent to the condition $\mathsf{Span}(\mathsf{F})^\perp=\{0\}$, i.e., $\mathcal{K}=\mathsf{Span}(\mathsf{F})$. ■

Corollary 2: *Let* $A=\oplus_{i\in I}X_i^\dagger X_i$ *be a point of* C, *and let define* $r_i=\mathrm{rank}(X_i)$. *If A is extremal*, *then the following relation holds*

$$\sum_{i\in\mathcal{I}}r_i^2\leqslant\sum_{\mu\in\mathsf{S}}m_\mu^2. \tag{30}$$

Proof: For an extreme point of C, relation (29) implies that the cardinality of the set F is greater than the dimension of $\mathcal{K}=\oplus_{i\in I}\mathcal{B}(H_i)$. Then, the upper bound (30) follows from $\dim\mathcal{K}=\Sigma_{i\in\mathcal{I}}r_i^2$ and from the fact that $|\mathsf{F}|=\Sigma_{\mu\in\mathsf{S}}m_\mu^2$. ■

Observation: If the group-representation $\mathsf{R}(\mathbf{G})$ is irreducible, then its Clebsch-Gordan decomposition contains only one term $\bar{\mu}$ with multiplicity $m_{\bar{\mu}}=1$. Then, bound (30) becomes $\Sigma_{i\in\mathcal{I}}r_i^2\leqslant 1$, namely for an extremal $A=\oplus_{i\in I}A_i$, one has necessarily $\mathrm{rank}(A_{i_0})=1$ for some $i_0\in\mathcal{I}$, and $A_i=0$ for any $i\neq i_0$ (this is also a sufficient condition, due to Corollary 1). In terms of the corresponding covariant POVM $M(i,g)=U_g A_i U_g^\dagger$, one has $M(i,g)=0$ for any $i\neq i_0$, i.e., corresponding to events in the probability space that never occur.

V. EXTREMAL COVARIANT POVMs IN THE PRESENCE OF NONTRIVIAL STABILITY GROUPS

In Sec. IV, we obtained a characterization of extremal covariant POVMs whose probability space is $\mathfrak{X}=\mathcal{I}\times\mathbf{G}$ for some finite index set $\mathcal{I}$. The framework we outlined is suitable for a straightforward generalization to the case $\mathfrak{X}=\cup_{i\in\mathcal{I}}\mathbf{G}/\mathbf{G}_i$, where $\mathbf{G}_i$ are compact subgroups of $\mathbf{G}$.

In this case, it is possible to show that a covariant POVM P admits a density $M(x_i)$ such that for any measurable subset $B\subseteq\mathbf{G}/\mathbf{G}_i$ one has $P(B)\equiv P_i(B)\doteq\int_{B_i}\mathrm{d}x_i M(x_i)$, where $\mathrm{d}x_i$ is the group invariant measure on $\mathbf{G}/\mathbf{G}_i$. The form of the operator density is now

$$M(x_i)=U_{g_i(x_i)}A_iU^\dagger_{g_i(x_i)}, \tag{31}$$

where $A_i\geqslant 0$, and $g_i(x_i)\in\mathbf{G}$ is any representative element of the equivalence class $x_i\in\mathbf{G}/\mathbf{G}_i$. The normalization of the POVM is still given by Eq. (16). In addition, in order to remove the dependence of $M(x_i)$ from the choice of the representative $g_i(x_i)$, each operator A_i must satisfy the relation

$$[A_i,U_h]=0,\quad \forall\, h\in\mathbf{G}_i. \tag{32}$$

The commutation constraint (32) can be simplified by decomposing each representation $\mathsf{R}(\mathbf{G}_i)=\{U_h|h\in\mathbf{G}_i\}$ into irreps

$$U_h=\bigoplus_{\nu\in\mathsf{S}_i}U_h^{\nu_i}\otimes\mathbb{1}_{m_{\nu_i}}, \tag{33}$$

where m_{ν_i} denotes the multiplicity of the irrep ν_i, and S_i denotes the collection of all irreps contained in the decomposition of $\mathsf{R}(\mathbf{G}_i)$. This corresponds to the decomposition of the Hilbert space $\mathcal{H}$ as

$$\mathcal{H}=\bigoplus_{\nu_i\in\mathsf{S}_i}\mathcal{H}_{\nu_i}\otimes\mathbb{C}^{m_{\nu_i}}, \tag{34}$$

where $\mathcal{H}_{\nu_i}$ is a representation space, supporting the irrep ν_i, and $\mathbb{C}^{m_{\nu_i}}$ is a multiplicity space. In this decomposition, the commutation relation (32) is equivalent to the block form

$$A_i=\bigoplus_{\nu_i\in\mathsf{S}_i}\mathbb{1}_{\nu_i}\otimes A_{i,\nu_i}, \tag{35}$$

where $A_{i,\nu_i}\geqslant 0$ are operators acting on the multiplicity space $\mathbb{C}^{m_{\nu_i}}$.

By defining $\omega=(i,\nu_i)$ and $\Omega=\cup_{i\in\mathcal{I}}S_i$, we can introduce an auxiliary Hilbert space, and associate to a covariant POVM the block operator

$$A=\bigoplus_{\omega\in\Omega}A_\omega, \tag{36}$$

where $A_\omega\doteq A_{i,\nu_i}$. Furthermore, we define the block operators

$$S^\mu_{kl}=\bigoplus_{\omega\in\Omega}S^\mu_{kl\omega}, \tag{37}$$

where now $S_{kl\omega}=\mathrm{Tr}_{\mathcal{H}_{\nu_i}}[\Pi_{\nu_i}T^\mu_{kl}]$. Here Π_{ν_i} denotes the projector onto $\mathcal{H}_{\nu_i}\otimes\mathbb{C}^{m_{\nu_i}}$, and $\mathrm{Tr}_{\mathcal{H}_{\nu_i}}$ denotes the partial trace over $\mathcal{H}_{\nu_i}$. With these definitions, the normalization of the POVM, given by Eq. (16), becomes equivalent to

$$\mathrm{Tr}[S^\mu_{kl}A]=\delta_{kl}d_\mu. \tag{38}$$

Now we call D the convex set of block operators $A=\oplus_{\omega\in\Omega}A_\omega$, defined by the two conditions $A\geqslant 0$ and Eq. (38). Such a convex set is in one-to-one affine correspondence with the convex set of covariant POVMs with probability space $\mathfrak{X}=\cup_{i\in\mathcal{I}}\mathbf{G}/\mathbf{G}_i$. Since the constraints defining D are formally the same defining the convex set C, we can exploit the characterization of extremal points of the previous section. In particular, Corollary 2 becomes

Corollary 3: *Let* $A=\oplus_{\omega\in\Omega}X_\omega^\dagger X_\omega$ *be a point of* D, *and define* $r_{i,\nu_i}\equiv r_\omega=\mathrm{rank}(X_\omega)$. *If* A *is extremal*, *then the following relation holds:*

$$\sum_{i\in\mathcal{I}}\sum_{\nu_i\in\mathsf{S}_i} r_{i,\nu_i}^2 \leqslant \sum_{\mu\in\mathsf{S}} m_\mu^2. \tag{39}$$

Observation: As in the case of Corollary 2, if the representation $\mathsf{R}(\mathbf{G})$ is irreducible, as a consequence of the bound about ranks, one obtains $\mathrm{rank}(A_{\omega_0})=1$ for some $\omega_0\in\Omega$, and $A_\omega=0$ for any $\omega\neq\omega_0$.

VI. APPLICATIONS

Here we give two examples of the use of the characterization of extremal POVMs in the solution of concrete optimization problems.

A. State discrimination with mutually unbiased bases

1. Two Fourier transformed bases

Here we consider a case of state discrimination where the set of signal states is the union of two mutually unbiased bases (MUBs),[11] related by Fourier transform. Precisely, let $\mathcal{H}$ be a d-dimensional Hilbert space, and consider the orthornormal bases $\mathcal{B}_1=\{|n\rangle\,|\,n=0,\ldots,d-1\}$ and $\mathcal{B}_2=\{|e_n\rangle\,|\,n=0,\ldots,d-1\}$, where $|e_n\rangle=(1/\sqrt{d})\Sigma_{m=0}^{d-1}\omega^{mn}|m\rangle$, $\omega=\exp(2\pi i/d)$. $\mathcal{B}_1$ and $\mathcal{B}_2$ are mutually unbiased, namely $|\langle m|e_n\rangle|^2=1/d$ for any m,n. Consider the two sets of states defined by $\mathcal{S}_1=\{\rho_{1n}=|n\rangle\langle n|\,|n=0,\ldots,d-1\}$ and $\mathcal{S}_2=\{\rho_{2n}=|e_n\rangle\langle e_n|\,|n=0,\ldots,d-1\}$. Now the problem is to determine with minimum error probability the state of the system, which is randomly prepared either in a state of $\mathcal{S}_1$ with probability p/d, or in a state of $\mathcal{S}_2$ with probability $(1-p)/d$.

Exploiting the results of the present paper it is immediate to find the measurement that minimizes the error probability. In fact, let us consider the irreducible representation of the group $\mathbf{G}=\mathbb{Z}_d\times\mathbb{Z}_d$ given by

$$\mathsf{R}(\mathbf{G})=\left\{U_{pq}=\sum_{n=0}^{d-1}\omega^{qn}|n\oplus p\rangle\langle n|,(p,q)\in\mathbb{Z}_d\times\mathbb{Z}_d\right\}, \tag{40}$$

where $\oplus$ denotes addition modulo d. Then, the sets $\mathcal{S}_1$ and $\mathcal{S}_2$ are the group orbits of the initial states ρ_{10} and ρ_{20}, respectively. Moreover, the states ρ_{10} and ρ_{20} have nontrivial stability groups $\mathbf{G}_1$ and $\mathbf{G}_2$, defined by the unitaries $\mathsf{R}(\mathbf{G}_1)=\{U_{0q}\,|\,q\in\mathbb{Z}_d\}$ and $\mathsf{R}(\mathbf{G}_2)=\{U_{p0}\,|\,p\in\mathbb{Z}_d\}$. Therefore, signal states are in one-to-one correspondence with points of the probability space $\mathcal{X}=\mathbf{G}/\mathbf{G}_1\cup\mathbf{G}/\mathbf{G}_2$, such points being denoted by couples (i,n) where $i\in\{1,2\}$ and $n\in\mathbb{Z}_d$. For the discrimination we can consider without loss of generality a covariant POVM, of the form of Eq. (31), where now the group element g is the couple $(p,q)\in\mathbb{Z}_d\times\mathbb{Z}_d$. Moreover, since the probabilities are linear in the POVM, in the minimization of the error probability we can restrict the attention to extremal covariant POVMs. Now, the representation $\mathsf{R}(\mathbf{G})$ is irreducible, whence Corollary 3 requires either $A_1=0$ or $A_2=0$ in Eq. (31). This means that either the states in $\mathcal{S}_1$ or the states in $\mathcal{S}_2$ are never detected. Moreover, since the states within a given set, either $\mathcal{S}_1$ or $\mathcal{S}_2$, are orthogonal, they can be perfectly distinguished among themselves. Therefore, the optimal POVM is $P^{(1)}(i,n)=\delta_{i1}|n\rangle\langle n|$ if $p\geqslant 1/2$, and $P^{(2)}(i,n)=\delta_{i2}|e_n\rangle\langle e_n|$ otherwise. In particular, if $p=1/2$, an experimenter who tries to discriminate states of two Fourier transformed bases cannot do anything better than randomly choosing one of the orthogonal measurements $P^{(1)}$ and $P^{(2)}$. This is the working principle of the BB84 crypthographic protocol.[13]

2. Mutually unbiased bases in prime dimension

If the dimension of the Hilbert space $\mathcal{H}$ is a prime number, then there are $d+1$ MUBs that are generated by the irreducible representation

$$\mathsf{R}(\mathbf{G}) = \left\{ U_{pq} = \sum_{n=0}^{d-1} \omega^{qn} |n \oplus p\rangle\langle n|, (p,q) \in \mathbb{Z}_d \times \mathbb{Z}_d \right\}$$

via the construction by Wootters and Fields[11] (see also Ref. 12).

In this case, the result of the previous paragraph can be immediately generalized to a case of state discrimination with more than two MUBs. Again, due to the irreducibility of the representation $\mathsf{R}(\mathbf{G})$, an extremal POVM is the group orbit of a single operator. Therefore, denoting by $\mathcal{S}_i$ the set of states associated to the basis $\mathcal{B}_i$, and by p_i/d the probability of extracting a state from $\mathcal{S}_i$ ($\Sigma_{i\in\mathcal{I}} p_i = 1$), we have that the covariant POVM which discriminates the signal states with minimum error probability is the orthogonal measurement onto the basis $\mathcal{B}_{\bar{l}}$ such that $p_{\bar{l}} = \max_{l\in\mathcal{I}}\{p_l\}$.

3. Mutually unbiased bases in dimension p^r

In the case of Hilbert space dimension $d = p^r$, where p is prime number, $d+1$ MUBs can be constructed by introducing a projective representation of the Abelian group $\tilde{\mathbf{G}} = \mathbb{F}_d \times \mathbb{F}_d$, where $\mathbb{F}_d$ is the finite field of cardinality d, considered here as an additive group. In order to apply the results of the paper to this case, we first outline the method for constructing MUBs presented in Ref. 12, to which we refer for details and for the explicit proofs.

Consider an orthonormal basis for $\mathcal{H}$, denoted as $\{|n\rangle \,|\, n \in \mathbb{F}_d\}$, in which basis elements are labeled by elements of the field. Then, introduce the projective representation

$$\mathsf{R}(\tilde{\mathbf{G}}) = \{U_p V_q | (p,q) \in \mathbb{F}_d \times \mathbb{F}_d\}, \tag{41}$$

where U_p, V_q are the unitary operators uniquely defined by the relations

$$U_p |n\rangle = |n+p\rangle,$$

$$V_q |n\rangle = \langle q,n\rangle |n\rangle. \tag{42}$$

Here, $\langle a,b\rangle \doteq \chi(a\cdot b)$, where $\chi(x)$ is any nontrivial character of the additive group $\mathbb{F}_d$, and $a+b$ ($a\cdot b$) denote the addition (product) in the finite field $\mathbb{F}_d$. With the above definition $\langle a,b\rangle$ is a symmetric bicharacter for the additive group $\mathbb{F}_d$, namely $|\langle a,b\rangle| = 1, \langle a,b\rangle = \langle b,a\rangle$, and $\langle a,b+c\rangle = \langle a,b\rangle\langle a,c\rangle$, for any $a,b,c \in \mathbb{F}_d$. By definition (42), the operators U_p, V_q commute up to a phase, namely

$$V_q U_p = \langle p,q\rangle U_p V_q. \tag{43}$$

To construct $d+1$ MUBs, it is useful to introduce $d+1$ sets of the unitary operators, each set being labeled by an index $i \in \mathbb{F}_d \cup \{\infty\}$ (∞ is just a label which denotes an additional value, not in $\mathbb{F}_d$, of the index i). The $d+1$ sets of unitary operators are defined by

$$W(i,j) \doteq \begin{cases} \alpha(i,j) U_j V_{i\cdot j}, & i \in \mathbb{F}_d \\ V_j, & i = \infty, \end{cases} \tag{44}$$

where $\alpha(i,j)$ are suitable phase factors (see Ref. 12), chosen in such a way that, for any fixed i, the operators $W(i,j)$ form a unitary representation of the additive group $\mathbb{F}_d$, namely

$$W(i,j)W(i,l) = W(i,j+l), \quad \forall\, j,l \in \mathbb{F}_d. \tag{45}$$

Since the group $\mathbb{F}_d$ is Abelian, for fixed i the operators $W(i,j)$ can be diagonalized on the same basis, denoted by $\mathcal{B}_i$. The above construction guarantees that the bases $\{\mathcal{B}_i | i \in \mathbb{F}_d \cup \{\infty\}\}$ are all mutually unbiased. Moreover, the one-dimensional projector $P(i,k)$ onto the kth element of the basis $\mathcal{B}_i$ can be written as[12]

$$P(i,k) = d^{-1} \sum_{j\in\mathbb{F}_d} \overline{\langle j,k\rangle} W(i,j). \tag{46}$$

Now we exploit the above-noted construction to show that, for any $i \in \mathbb{F}_d \cup \{\infty\}$, the set of states $\mathcal{S}_i = \{\rho_{ik} = P_{ik} | k \in \mathbb{F}_d\}$ is the orbit of the initial state $\rho_{i0} = P_{i0}$ under the action of the representation $\mathsf{R}(\tilde{G})$.

For $i \in \mathbb{F}_d$, we have indeed

$$\begin{aligned} U_p V_q P(i,k) V_q^\dagger U_p^\dagger &= d^{-1} \sum_{j \in \mathbb{F}_d} \overline{\langle j,k \rangle} \alpha(i,j) U_p V_q U_j V_{k \cdot j} V_{-q} U_{-p} \\ &= d^{-1} \sum_{j \in \mathbb{F}_d} \overline{\langle j,k \rangle} \langle j,q \rangle \langle i \cdot j, -p \rangle \alpha(i,j) U_j V_{i \cdot j} \\ &= d^{-1} \sum_{j \in \mathbb{F}_d} \overline{\langle j,k-q+i \cdot p \rangle} W(i,j) = P(i,k-q+i \cdot p), \end{aligned} \tag{47}$$

where we used Eqs. (46), (44), (43), and the properties $\langle a,-b \rangle = \overline{\langle a,b \rangle}$, $\langle a,b+c \rangle = \langle a,b \rangle \langle a,c \rangle$, and $\langle a,b \cdot c \rangle = \langle a \cdot b,c \rangle$. Similarly, for $i = \infty$ we obtain

$$U_p V_q P(\infty,k) V_q^\dagger U_p^\dagger = P(\infty,k+p). \tag{48}$$

Notice that from Eqs. (47), (48) it also follows that for any $i \in \mathbb{F}_d \cup \{\infty\}$, the stability group of $\rho_{i0} = P_{i0}$ is the additive group $\mathbb{F}_d$, which is projectively represented by the unitaries $\{U_p V_{i \cdot p} | p \in \mathbb{F}_d\}$ for $i \in \mathbb{F}_d$, and by the unitaries $\{V_q | q \in \mathbb{F}_d\}$ for $i = \infty$.

In the problem of state discrimination where the state ρ_{ik} is randomly drawn from the set $\mathcal{S}_i$ with probability p_i/d, we can then use the results about extremal covariant POVMs with nontrivial stability group to find the minimum error POVM. Again, since the representation $\mathsf{R}(\tilde{\mathbf{G}})$ is irreducible,[14] an extremal POVM must be the group orbit of a single operator. The optimal POVM for state discrimination is then the orthogonal measurement onto the basis $\mathcal{B}_{\bar{l}}$ which occurs with highest probability $p_{\bar{l}} = \max_i \{p_i\}$.

B. Maximization of the mutual information

A frequent problem in quantum communication is to find the POVM $P_i, i \in \mathcal{I}$, that maximizes the mutual information with a given set of signal states $\mathcal{S} = \{\rho_j | j \in \mathcal{J}\}$. Denoting by p_j the probability of the signal state ρ_j, by $q_i = \Sigma_{j \in \mathcal{J}} p_j \mathrm{Tr}[M_i \rho_j]$ the overall probability of the outcome i, and by $p_{ij} = p_j \mathrm{Tr}[M_i \rho_j]$ the joint probability of the outcome j with the state ρ_i, the mutual information is defined as

$$I = H(\{p_{ij}\}) - H(\{p_i\}) - H(\{q_j\}), \tag{49}$$

where $H(\{p_i\}) \doteq \Sigma_i - p_i \log(p_i)$ is the Shannon entropy. As in the minimization of a Bayes cost,[4,5] when the set of signal states is invariant under the action of some finite group $\mathbf{G}$ and all states in the same group orbit have the same probability, one can without loss of generality restrict the search for the optimal POVM among covariant POVMs with probability space $\mathcal{X} = \mathcal{I} \otimes \mathbf{G}$, for some finite index set $\mathcal{I}$.[15,9] However, differently from the case of state discrimination, the points of the probability space do not need to be in one-to-one correspondence with the signal states. Therefore, the set $\mathcal{I}$ is not specified *a priori*.

Combining our characterization of extremal covariant POVMs with the following basic properties of the mutual information (for the proofs, see Ref. 15), we can readily obtain a bound about the cardinality of the index set $\mathcal{I}$.

Property 1: *The mutual information is a convex functional of the POVM.*

Property 2: *In the maximization of the mutual information, one can consider without loss of generality POVMs made of rank-one operators.*

Consider a covariant POVM $P(i,g) = (1/(|\mathbf{G}|) U_g A_i U_g^\dagger$. Due to Property 1, in the maximization of the mutual information we can consider extremal covariant POVMs. Then, from Corollary 2,

we have the bound $\Sigma_{i\in\mathcal{I}}\mathrm{rank}(A_i)^2 \leqslant \Sigma_{\mu\in\mathsf{S}} m_\mu^2$. Due to Property 2, this also implies that the number of (rank-one) operators A_i must be smaller than $\Sigma_{\mu\in\mathsf{S}} m_\mu^2$. Therefore, we can assume without loss of generality

$$|\mathcal{I}| \leqslant \sum_{\mu\in\mathsf{S}} m_\mu^2. \tag{50}$$

This provides an alternative derivation of the bound given in Ref. 9. Finally, if the representation $\mathsf{R}(\mathbf{G})$ is irreducible, the bound gives $|\mathcal{I}|=1$, namely the probability space is $\mathcal{X}\simeq\mathbf{G}$, according to the classic result of Ref. 15.

ACKNOWLEDGMENTS

We acknowledge the referee for an observation that enriched the paper, by stimulating us to treat in detail the problem of state discrimination with $d+1$ MUBs in the general case of Hilbert space dimension p^r. [14] If an operator O commutes with all the unitaries U_pV_q in the representation $\mathsf{R}(\tilde{\mathbf{G}})$, then it must commute at least with U_p and V_q. In other words, O must be diagonal both on the eigenvectors of U_p and on the eigenvectors of V_q. But these two bases are mutually unbiased, whence the only possibility is O proportional to the identity, i.e., the representation $\mathsf{R}(\tilde{\mathbf{G}})$ is irreducible.

Pointwise analysis of scalar fields: A nonstandard approach

Hideyasu Yamashita[a)]
School of General Education, Aichi-Gakuin University, Nissin 470-0195, Japan

(Received 21 January 2006; accepted 31 July 2006; published online 8 September 2006)

A new nonstandard-analytical approach to quantum fields is presented, which gives a mathematical foundation for manipulating pointwise-defined quantum fields. In our approach, a field operator $\phi(x)$ is not a standard operator-valued distribution, but a nonstandard operator-valued function. Then formal expressions containing, e.g., $\phi(x)^2$ can be understood literally, and shown to be well defined. In the free field cases, we show that the Wightman functions are explicitly calculated with the pointwise field, without any regularization, e.g., Wick product. Our notion of pointwise fields is applied also to the path integral formalisms of scalar fields. We show that some of physicists' naive expressions of Lagrangian path integral formulas can be rigorously justified. © *2006 American Institute of Physics.*

I. INTRODUCTION

The main object of *nonstandard mathematics*,[1–3] originated by A. Robinson, is to give a rigorous foundation for the notions of infinities and infinitesimals, e.g., infinite real numbers and infinitesimal real numbers. *Nonstandard approaches to quantum physics*[4–12] are those which use nonstandard mathematics as a fundamental tool of quantum physics.

In this paper, we give a new nonstandard approach which gives a rigorous foundation for manipulating *pointwise-defined* quantum fields. For example, consider the physicist's naive expression of the Hamiltonian of a free scalar field with mass m:

$$H_m = \frac{1}{2}\int \left[\hat{\pi}(\boldsymbol{x})^2 + \sum_{k=1}^{\mathbf{d}} (\partial_k \hat{\phi}(\boldsymbol{x}))^2 + m^2 \hat{\phi}(\boldsymbol{x})^2 \right] \mathrm{d}\boldsymbol{x}.$$

In the standard approach, the field operators $\hat{\phi}$ and $\hat{\pi}$ are considered as operator-valued distributions, which are not pointwise-defined functions. So expressions like $\hat{\phi}(\boldsymbol{x})^2$ are mathematically meaningless, and hence the right-hand side must be regarded as nothing more than a formal expression. On the other hand, in our approach, the above-noted right-hand side can be understood *literally*, and shown to be well defined.

Our notion of pointwise fields is applicable also to the path integral formalisms. Standard justifications of path integrals for scalar fields are based on the theorems of Feynman–Kac–Nelson and Minlos, where the path space is taken to be the space $\mathcal{S}'$ of tempered distributions. Thus ϕ^2 and $(\partial_k \phi)^2$ are not always meaningful for a path $\phi \in \mathcal{S}'$. However, physicists use the path integral expression like

[a)]Electronic mail: yamasita@dpc.aichi-gakuin.ac.jp

$$\int e^{\alpha \int L(\phi, \partial_k \phi) \mathrm{d}x} \mathrm{d}\phi,$$

where L is the Lagrangian, and $\alpha \in \mathbf{C}$ is a constant. Usually L contains ϕ^2 and $(\partial_k \phi)^2$. Thus in the standard approach, the above-presented expression must be regarded as merely a formal one. On the other hand, our approach enables one to justify the expression *literally.*

Our approach is based on the notion of hyperfinite-dimensional Schrödinger representations of fields. A *Schrödinger representation of a quantum field* is a representation where the state space is a function space $\mathcal{H}$, typically $\mathcal{H}=L^2(M,\mu)$ with a measure space (M,μ), and the field operators at $t=0$, called *time zero field operators*, are represented as the multiplication operators on $\mathcal{H}$. A *hyperfinite-dimensional (or ⋆finite-dimensional) Schrödinger representation* is a Schrödinger representation where M is taken to be a hyperfinite-dimensional linear space, i.e., $M \cong {}^\star\mathbf{R}^\nu$ for a infinite ⋆natural number $\nu \in {}^\star\mathbf{N}$.

II. NONSTANDARD ANALYSIS

There are several different formulations of nonstandard analysis. This paper adopts the set-theoretical approach based on superstructures instituted by Robinson and Zakon[13] and follows the up-to-date description by Chang and Keisler.[14] For the introductory purpose, see Hurd and Loeb.[2]

In this paper, we always work with a nonstandard universe $\langle V(X), V(Y), \star \rangle$ which is κ-saturated with $\mathrm{card}(V(X)) < \kappa$; such a nonstandard universe is said to be *polysaturated*. We also assume that the base X includes the complex numbers $\mathbf{C}$ and any other structures under consideration such as given groups and Hilbert spaces.

For a set S, let ${}^\sigma S = \{{}^\star s \,|\, s \in S\}$. We identify ${}^\star z$ with z for all $z \in \mathbf{C}$. Hence, ${}^\sigma S = S$ if S is a subset of $\mathbf{C}$, e.g., ${}^\sigma\mathbf{C}=\mathbf{C}$, ${}^\sigma\mathbf{R}=\mathbf{R}$ (the real numbers), ${}^\sigma\mathbf{Z}=\mathbf{Z}$ (the integers), and ${}^\sigma\mathbf{N}=\mathbf{N}$. Let $\mathbf{R}^+$, ${}^\star\mathbf{R}_0$, ${}^\star\mathbf{R}_0^+$, ${}^\star\mathbf{R}_\infty^+$, and ${}^\star\mathbf{N}_\infty$ denote the sets of positive real numbers, infinitesimal hyper-real numbers, positive infinitesimal hyper-real numbers, positive infinite hyper-real numbers, and infinite hypernatural numbers, respectively. It is shown that ${}^\star\mathbf{N}_\infty = {}^\star\mathbf{N} \backslash \mathbf{N}$. We write $x \sim \infty$ if $x \in {}^\star\mathbf{R}_\infty^+$, and $0 < x < \infty$ if $x \in \mathrm{fin}\ {}^\star\mathbf{R}^+ = {}^\star\mathbf{R}^+ \backslash {}^\star\mathbf{R}_\infty^+$. If $r \in {}^\star\mathbf{R}$ and $|r| < \infty$, the standard part of r is denoted by ${}^\circ r$. If $r \sim \infty$, we write ${}^\circ r = \infty$. Let $x, y \in {}^\star\mathbf{R}^+$. We say that x is of the *order* of y, in symbols $x \asymp y$, iff $0 < x/y < \infty$ and $0 < y/x < \infty$. We write $x \ll y$ if $x/y \approx 0$. For a hyperfinite (⋆-finite) set F, let $|F|$ denote the internal cardinal number of F.

Let $(X, \mathcal{O})$ be a topological space. Let $\mathcal{O}_x$ denote the system of open neighborhoods of $x \in X$. The *monad* of $x \in X$ is the subset of ${}^\star X$ defined by $\mathrm{mon}_\mathcal{O}(x) = \cap \{{}^\star O \,|\, O \in \mathcal{O}_x\}$. The set of *near standard* points is the subset of ${}^\star X$ defined by $\mathrm{ns}({}^\star X) = \cup \{\mathrm{mon}_\mathcal{O}(x) \,|\, x \in X\}$. It is shown that $(X, \mathcal{O})$ is Hausdorff if and only if $x \neq y$ implies $\mathrm{mon}_\mathcal{O}(x) \cap \mathrm{mon}_\mathcal{O}(y) = \emptyset$. Thus for any Hausdorff space $(X, \mathcal{O})$, we can define the equivalence relation $\approx_\mathcal{O}$ on $\mathrm{ns}{}^\star X$ so that $a \approx_\mathcal{O} b$ iff $a \in \mathrm{mon}_\mathcal{O}(x)$ and $b \in \mathrm{mon}_\mathcal{O}(x)$ for some $x \in X$.

Let f and g be functions from ${}^\star\mathbf{R}^n$ to ${}^\star\mathbf{C}$. When we consider the approximation $f \approx g$, we must make clear what topology is considered. For example,

1. pointwise topology: $f \approx g \Leftrightarrow (\forall x \in \mathbf{R}) f(x) \approx g(x)$.
2. L^p topology: $f \approx g \Leftrightarrow \|f-g\|_p \approx 0$.
3. topology of Schwartz distributions:

$$f \approx g \Leftrightarrow (\forall h \in \mathcal{D}(\mathbf{R}^n))(f,h) \approx (g,h).$$

In this paper we frequently use the approximations with respect to L^2 topology and that of Schwartz distributions.

For further information on nonstandard real analysis, we refer to Stroyan and Luxemburg[3] and Hurd and Loeb.[2]

III. NONSTANDARD DISTRIBUTIONS

There are several approaches to nonstandard distribution theory. In this paper, we use the following framework.

Let $\mathbf{d} \in \mathbf{N}$. Let M be a $\mathbf{d}$-dimensional possibly noncompact Riemannian manifold. Let $\mathcal{D} = \mathcal{D}(M)$ be the space of smooth functions from M to $\mathbf{R}$ whose support is compact. $\mathcal{D}$ is furnished with the inner product

$$(f,g) = \int_M f(x)g(x)\mathrm{d}x.$$

The nonstandard extension ${}^\star\mathcal{D}$ has the transferred ${}^\star\mathbf{R}$-valued inner product

$${}^\star(f,g) = {}^\star\int_{{}^\star M} f(x)g(x)\mathrm{d}x.$$

We abbreviate ${}^\star(f,g)$ simply as (f,g).

Let $\mathcal{F}$ be a $\star$finite-dimensional subspace of ${}^\star\mathcal{D}$ such that

$${}^\sigma\mathcal{D} \subset \mathcal{F} \subset {}^\star\mathcal{D}.$$

The existence of such $\mathcal{F}$ is shown by the saturation principle in nonstandard analysis. Note that there is $\nu \in {}^\star\mathbf{N}$ satisfying $\mathcal{F} \cong {}^\star\mathbf{R}^\nu$ (isomorphism of *linear spaces).

Since $\mathcal{F}$ is $\star$finite-dimensional, its *internal* algebraic dual

$$\mathcal{F}_1^* = \{f | f:\mathcal{F} \to {}^\star\mathbf{R},\ {}^\star\text{linear}\}$$

is equal to its *internal* topological dual

$$\mathcal{F}_2^* = \{f | f:\mathcal{F} \to {}^\star\mathbf{R},\ {}^\star\text{continuous}\}.$$

Let $\mathcal{F}^*$ denote the internal dual space of $\mathcal{F}$, that is, $\mathcal{F}^* = \mathcal{F}_1^* = \mathcal{F}_2^*$. Note that the inner product $(\cdot,\cdot)$ naturally determines an isomorphism $e:\mathcal{F}^* \cong \mathcal{F}$. Since $\mathbf{R}$ is a subfield of ${}^\star\mathbf{R}$, the internal linear spaces $\mathcal{F}$ and $\mathcal{F}^*$ over ${}^\star\mathbf{R}$ can also be regarded as external linear spaces over $\mathbf{R}$, i.e., as real linear spaces in the usual (standard-mathematical) sense. Thus such a phrase as "linear map from $\mathcal{D}$ to $\mathcal{F}$" makes sense.

Let $\mathcal{D}^*$ denote the algebraic dual of $\mathcal{D}$ in the usual sense.

Lemma 3.1: *There is an injective linear map* $\pi:\mathcal{D}^* \to \mathcal{F}$ *such that*

$$(\forall f \in \mathcal{F})(\pi(F),f) = ({}^\star F)(f) \tag{1}$$

for all $F \in \mathcal{D}^*$.

Proof: Let $F \in \mathcal{D}^*$. The map $\alpha_F:\mathcal{F} \to {}^\star\mathbf{R}$ defined by $\alpha_F(f) = ({}^\star F)(f)$ is a *linear functional on $\mathcal{F}$, that is, $\alpha_F \in \mathcal{F}^*$. Define π by $\pi(F) = e(\alpha_F)$, where e denotes the natural isomorphism $e:\mathcal{F}^* \cong \mathcal{F}$. Then we can check that (1) holds. We will show that π is injective. Since π is linear, it suffices to show that

$$\pi(F) = 0 \Rightarrow F = 0 \text{ for any } F \in \mathcal{D}^*.$$

Suppose $\pi(F) = 0$. Then by (1), we have

$$(\forall f \in \mathcal{F})({}^\star F)(f) = 0.$$

Since ${}^\sigma\mathcal{D} \subset \mathcal{F}$, we have

$$(\forall f \in \mathcal{D})({}^\star F)({}^\star f) = 0.$$

By the transfer principle, this is equivalent to

$$(\forall f \in \mathcal{D})F(f) = 0.$$

This means $F=0$. *QED*

By the above Lemma, we have the relation

$$\mathcal{D} \overset{a}{\hookrightarrow} \mathcal{D}' \subset \mathcal{D}^* \overset{\pi}{\hookrightarrow} \mathcal{F} \subset {}^\star\mathcal{D} \subset {}^\star L^2(M),$$

where $\mathcal{D} \overset{a}{\hookrightarrow} \mathcal{D}'$ denotes the natural embedding $a: f \mapsto (\cdot, f)$. The embedding $\mathcal{D}' \subset \mathcal{D}^* \overset{\pi}{\hookrightarrow} \mathcal{F}$ permits us to consider a Schwartz distribution as an element of $\mathcal{F}$, a space of *pointwise-defined* functions on ${}^\star M$.

For $x \in {}^\star M$, define $\delta_x \in \mathcal{F}$ by

$$(\forall f \in \mathcal{F})(\delta_x, f) = f(x).$$

The nth derivatives of δ_x are already defined because $\delta_x \in {}^\star\mathcal{D}$. In the case where $M=\mathbf{R}^n$, clearly we have

$$((\partial/\partial x_k)\delta_x, f) = -(\delta_x, (\partial/\partial x_k)f).$$

But note that a derivative of δ_x may not be in $\mathcal{F}$. In the case where $M=\mathbf{R}^n$, $(\partial^l/\partial x_k^l)\delta_x (1 \leqslant k \leqslant n)$ is well-defined for any $l \in {}^\star\mathbf{N}$, but $(\partial^l/\partial x_k^l)\delta_x \notin \mathcal{F}$ can occur even if $l < \infty$. However we can define a "derivative" $\delta_x^k \in \mathcal{F}$ such that

$$(\delta_x^k, f) = -(\partial/\partial x_k)f(x), \quad f \in \mathcal{F}.$$

Clearly we see the relation $\delta_x^k = E_{\mathcal{F}}(\partial/\partial x_k)\delta_x$ where $E_{\mathcal{F}}$ is the orthogonal projection from ${}^\star L^2(\mathbf{R}^n)$ to $\mathcal{F}$. So δ_x^k is called a *projected derivative.*

Also note that the following relations do *not* hold:

$$x \neq y \Rightarrow \delta_x(y) = 0,$$

$$\delta_x(y) = \delta_0(y-x)(M = \mathbf{R}^n).$$

On the other hand, since our nonstandard delta functions are pointwise-defined, the product of delta functions such as $f(x) = \delta_a(x)^2$ are well defined. An inner product of delta functions such as (δ_x, δ_y) is also well defined. Thus we can directly justify the physicists' *trace formula* as follows.

Proposition 3.2: *The following properties hold.*

(*i*) $\delta_x(y) = \delta_y(x)$.

(*ii*) $\int_{{}^\star M} f(x)\delta_x \mathrm{d}x = f$ *for any* $f \in \mathcal{F}$.

(*iii*) (*Trace formula*) *Let* $A: \mathcal{F} \to \mathcal{F}$ *be an internal linear operator. Then*

$$\mathrm{Tr}\, A = \int_{{}^\star M} (\delta_x, A\delta_x)\mathrm{d}x. \tag{2}$$

(*iv*) *Let* $e_1, \ldots, e_\nu \in \mathcal{F}$ *be an orthonormal basis of* $\mathcal{F}$. *Then*

$$\delta_x(y) = \sum_{k=1}^{\nu} e_k(x)e_k(y). \tag{3}$$

Proof: (i) holds because $\delta_x(y) = (\delta_x, \delta_y) = \delta_y(x)$.

(ii) For any $g \in \mathcal{F}$,

$$\left(\int_{\star_M} f(x)\,\delta_x dx, g\right) = \int\int_{\star_M} f(x)\,\delta_x(y)\mathrm{d}x g(y)\mathrm{d}y = \int\int_{\star_M} \delta_x(y) g(y)\mathrm{d}y f(x)\mathrm{d}x = \int_{\star_M} (\delta_x, g) f(x)\mathrm{d}x$$

$$= \int_{\star_M} g(x) f(x)\mathrm{d}x = (f,g).$$

Thus (ii) holds.

(iii) Since (ii) and

$$(\delta_x, A\,\delta_y) = \int \delta_x(s)(A\,\delta_y)(s)\mathrm{d}s = (A\,\delta_y)(x),$$

we have

$$\mathrm{Tr}\,A = \sum_i (e_i, Ae_i) = \sum \left(\int_{\star_M} e_i(x)\,\delta_x \mathrm{d}x, A\int_{\star_M} e_i(x)\,\delta_x \mathrm{d}x\right) = \sum \int\int_{\star_M} e_i(x) e_i(y)(\delta_x, A\,\delta_y)\mathrm{d}x\mathrm{d}y$$

$$= \int\int_{\star_M} \delta_x(y)(\delta_x, A\,\delta_y)\mathrm{d}x\mathrm{d}y = \int\int_{\star_M} \delta_y(x)(\delta_x, A\,\delta_y)\mathrm{d}x\mathrm{d}y = \int\int_{\star_M} \delta_y(x)(A\,\delta_y)(x)\mathrm{d}x\mathrm{d}y$$

$$= \int_{\star_M} (\delta_y, A\,\delta_y)\mathrm{d}y.$$

(iv) For any $g \in \mathcal{F}$, we have

$$\left(\sum_{k=1}^{\nu} e_k(x) e_k(\cdot), g\right) = \sum_{k=1}^{\nu} e_k(x)(e_k, g) = g(x).$$

Thus Eq. (3) holds. *QED*

IV. HAMILTONIAN FORMALISM

Let $\mathbf{d} \in \mathbf{N}$, and M be a $\mathbf{d}$-dimensional Riemannian manifold. We work in $(\mathbf{d}+1)$-dimensional space-time ${}^\star M \times {}^\star\mathbf{R}$.

Since $\mathcal{F} \cong {}^\star\mathbf{R}^\nu$, $\mathcal{F}$ is equipped with the natural $\star$Lebesgue measure. Let $L^2(\mathcal{F})$ denote the $\star$Hilbert space of functions on $\mathcal{F}$ square integrable with respect to the $\star$Lebesgue measure:

$$L^2(\mathcal{F}) = \left\{ F | F: \mathcal{F} \to {}^\star\mathbf{C}, \text{internal}, \int_{\mathcal{F}} |F(f)|^2 \mathrm{d}f < {}^\star\infty \right\}.$$

The L^2 inner product is denoted by $\langle \cdot | \cdot \rangle$:

$$\langle F | G \rangle \equiv \int_{\mathcal{F}} \overline{F(f)} G(f)\mathrm{d}f.$$

On the other hand, the real inner product on $\mathcal{D}(M)$ is denoted by

$$(f,g) = \int_M f(\boldsymbol{x}) g(\boldsymbol{x})\mathrm{d}\boldsymbol{x}.$$

For $\boldsymbol{x} \in {}^\star M$, define the $\star$unbounded self-adjoint operator $\hat{\phi}(\boldsymbol{x})$ on $L^2(\mathcal{F})$ by

$$(\hat{\phi}(\boldsymbol{x}) F)(f) = f(\boldsymbol{x}) F(f).$$

For $f \in \mathcal{F}$, define the $\star$unbounded self-adjoint operator $\hat{\phi}(f)$ on $L^2(\mathcal{F})$ by

$$\hat{\phi}(f) = \int_{{}^\star M} f(\boldsymbol{x})\hat{\phi}(\boldsymbol{x})\mathrm{d}\boldsymbol{x}.$$

Evidently $\hat{\phi}(f)$ operates as follows:

$$(\hat{\phi}(f)F)(g) = (f,g)F(g).$$

Note that the relation $\hat{\phi}(\boldsymbol{x}) = \hat{\phi}(\delta_{\boldsymbol{x}})$ holds.

For $f \in \mathcal{F}$, define the $\star$unbounded self-adjoint operator $\hat{\pi}(f)$ on $L^2(\mathcal{F})$ by

$$(e^{it\hat{\pi}(f)}F)(g) = F(tf+g), \quad t \in {}^\star\mathbf{R}.$$

In other words, $i\hat{\pi}(f)$ is the internal differential operator in the direction of f. For $x \in {}^\star M$, define the $\star$unbounded self-adjoint operator $\hat{\pi}(\boldsymbol{x})$ on $L^2(\mathcal{F})$ by $\hat{\pi}(\boldsymbol{x}) = \hat{\pi}(\delta_{\boldsymbol{x}})$.

We can check the canonical commutation relations:

$$[\hat{\phi}(f),\hat{\phi}(g)] = [\hat{\pi}(f),\hat{\pi}(g)] = 0, \quad [\hat{\phi}(f),\hat{\pi}(g)] = i(f,g).$$

In other words,

$$[\hat{\phi}(\boldsymbol{x}),\hat{\phi}(\boldsymbol{y})] = [\hat{\pi}(\boldsymbol{x}),\hat{\pi}(\boldsymbol{y})] = 0, \quad [\hat{\phi}(\boldsymbol{x}),\hat{\pi}(\boldsymbol{y})] = i\delta_{\boldsymbol{x}}(\boldsymbol{y}).$$

But note that the following does *not* hold:

$$\boldsymbol{x} \neq \boldsymbol{y} \Rightarrow [\hat{\phi}(\boldsymbol{x}),\hat{\pi}(\boldsymbol{y})] = 0.$$

Let the *Hamiltonian H* be an internal positive operator on $L^2(\mathcal{F})$ with a nondegenerate ground state $\Omega \in L^2(\mathcal{F})$, called the *vacuum*. For $x \in {}^\star\mathbf{R} \times {}^\star M$, the field operator $\hat{\phi}(x)$ is determined by H:

$$\hat{\phi}(x) = \hat{\phi}(x_0,\boldsymbol{x}) \equiv e^{-ix_0H}\hat{\phi}(\boldsymbol{x})e^{ix_0H}, \quad \boldsymbol{x} \in {}^\star M.$$

For $f \in {}^\star\mathcal{D}(\mathbf{R}\times M)$, define $\hat{\phi}(f)$ by

$$\hat{\phi}(f) = \int_{{}^\star\mathbf{R}\times{}^\star M} f(x)\hat{\phi}(x)\mathrm{d}x.$$

For $f_1,\ldots,f_n \in \mathcal{D}(\mathbf{R}\times M)$, define $w_n(f_1,\ldots,f_n) \in \mathbf{C}\cup\{\infty\}$ by

$$w_n(f_1,\ldots,f_n) = {}^\circ\langle\Omega|\hat{\phi}({}^\star f_1)\cdots\hat{\phi}({}^\star f_n)\Omega\rangle.$$

If $\{w_n\}_{n\in\mathbf{N}}$ are Schwartz distributions, the Hamiltonian H is called *Schwartz*. If $M=\mathbf{R}^{\mathbf{d}}$ and if $\{w_n\}_{n\in\mathbf{N}}$ satisfy the Wightman axioms for scalar fields, H is called *Wightman.*

If the vacuum expectations $\{w_n\}_{n\in\mathbf{N}}$ characterize a (standard) quantum field theory $\mathcal{A}$, the triple $(L^2(\mathcal{F}),\hat{\phi},H)$ is called a *hyperfinite(-dimensional) Schrödinger representation* of $\mathcal{A}$.

The following problem is still open:

Question: Does every scalar field theory satisfying the Wightman axioms have a hyperfinite Schrödinger representation?

Let $e_1,\ldots,e_\nu$ be an orthonormal basis of $\mathcal{F}$. Define the $\star$unbounded self-adjoint operator $\Delta_{\mathcal{F}}$ on $L^2(\mathcal{F})$ to be the ν-dimensional Laplacian, that is,

$$\Delta_{\mathcal{F}} = -\sum_{k=1}^{\nu}\hat{\pi}(e_k)^2,$$

which is determined independent from the basis $\{e_k\}$.

Let $\Xi_{\mathcal{F}}$ be the positive operator on $L^2(\mathcal{F})$ defined by

$$(\Xi_{\mathcal{F}}F)(f) = (f,f)F(f), \quad f \in \mathcal{F}.$$

We see the following relation:

$$\Xi_{\mathcal{F}} = \sum_{k=1}^{\nu} \hat{\phi}(e_k)^2.$$

Proposition 4.1: *The following equations hold*:

$$\Delta_{\mathcal{F}} = -\int_{^\star\mathbf{R}^{\mathbf{d}}} \hat{\pi}(\boldsymbol{x})^2 \mathrm{d}\boldsymbol{x}, \tag{4}$$

$$\Xi_{\mathcal{F}} = \int_{^\star\mathbf{R}^{\mathbf{d}}} \hat{\phi}(\boldsymbol{x})^2 \mathrm{d}\boldsymbol{x}. \tag{5}$$

Proof: The first equation is shown as follows:

$$\begin{aligned}
\Delta_{\mathcal{F}} &= -\sum_{k=1}^{\nu} \hat{\pi}(e_k)^2 = -\sum_{k=1}^{\nu} \left[\int_{^\star\mathbf{R}^{\mathbf{d}}} e_k(\boldsymbol{x}) \hat{\pi}(\boldsymbol{x}) \mathrm{d}\boldsymbol{x} \right]^2 = -\sum_{k=1}^{\nu} \int_{^\star\mathbf{R}^{\mathbf{d}}} \int_{^\star\mathbf{R}^{\mathbf{d}}} e_k(\boldsymbol{x}) \hat{\pi}(\boldsymbol{x}) e_k(\boldsymbol{y}) \hat{\pi}(\boldsymbol{y}) \mathrm{d}\boldsymbol{x}\mathrm{d}\boldsymbol{y} \\
&= -\int_{^\star\mathbf{R}^{\mathbf{d}}} \int_{^\star\mathbf{R}^{\mathbf{d}}} \sum_{k=1}^{\nu} e_k(\boldsymbol{x}) e_k(\boldsymbol{y}) \hat{\pi}(\boldsymbol{x}) \hat{\pi}(\boldsymbol{y}) \mathrm{d}\boldsymbol{x}\mathrm{d}\boldsymbol{y} \\
&= -\int_{^\star\mathbf{R}^{\mathbf{d}}} \int_{^\star\mathbf{R}^{\mathbf{d}}} \delta_{\boldsymbol{x}}(\boldsymbol{y}) \hat{\pi}(\boldsymbol{x}) \hat{\pi}(\boldsymbol{y}) \mathrm{d}\boldsymbol{x}\mathrm{d}\boldsymbol{y} = -\int_{^\star\mathbf{R}^{\mathbf{d}}} \hat{\pi}(\boldsymbol{x})^2 \mathrm{d}\boldsymbol{x}.
\end{aligned}$$

The second is shown similarly. *QED*

Let $A : \mathcal{F} \to \mathcal{F}$ be invertible internal linear operators. Define the operator T_A on $L^2(\mathcal{F})$ by

$$(T_A F)(f) = F(A^{-1}f).$$

Clearly, T_A is unitary if $A \in SL(\mathcal{F})$.

The most general form of the free Hamiltonian will be

$$H = -\alpha T_A \Delta_{\mathcal{F}} T_A^{-1} + \beta T_B \Xi_{\mathcal{F}} T_B^{-1},$$

where A and B are invertible internal linear operators on $\mathcal{F}$.

We assume that A and B are positive without loss of generality. Let $F \in L^2(\mathcal{F})$. Then we have

$$(T_A^{-1} H T_A F)(f) = -\alpha(\Delta_{\mathcal{F}} F)(f) + \beta(f, B^{-1}A^2B^{-1}f)F(f).$$

Since $B^{-1}A^2B^{-1}$ is a ν-dimensional positive matrix, it has positive eigenvalues $\lambda_1, \ldots, \lambda_\nu \in {}^\star\mathbf{R}$ and corresponding eigenvectors $v_1, \ldots, v_\nu \in \mathcal{F}$:

$$B^{-1}A^2B^{-1}v_k = \lambda_k v_k, \quad (v_k, v_l) = \delta_{kl}, \quad k,l = 1, \ldots, \nu.$$

Thus we have

$$T_A^{-1} H T_A = \sum_{k=1}^{\nu} \alpha \hat{\pi}(v_k)^2 + \beta \lambda_k \hat{\phi}(v_k)^2,$$

and hence

$$H=\sum_{k=1}^{\nu}\left[\alpha T_A\hat{\pi}(v_k)^2T_A^{-1}+\beta\lambda_k T_A\hat{\phi}(v_k)^2T_A^{-1}\right]=\sum_{k=1}^{\nu}\left[\alpha\hat{\pi}(Av_k)^2+\beta\lambda_k\hat{\phi}(A^{-1}v_k)^2\right].$$

This is the decomposition of H into independent harmonic oscillators, because the following canonical commutation relations hold:

$$[\hat{\phi}(A^{-1}v_k),\hat{\pi}(Av_l)]=i(A^{-1}v_k,Av_l)=i\delta_{kl}.$$

V. FREE MASSIVE SCALAR FIELDS

The Hamiltonian of a free scalar field (Klein-Gordon field) with mass m is given by

$$H_m=\frac{1}{2}\int_{{}^\star\mathbf{R}^{\mathbf{d}}}\left[\hat{\pi}(\boldsymbol{x})^2+\sum_{k=1}^{\mathbf{d}}(\partial_k\hat{\phi}(\boldsymbol{x}))^2+m^2\hat{\phi}(\boldsymbol{x})^2\right]\mathrm{d}\boldsymbol{x}.$$

In this section, we show that the right-hand side can be interpreted *literally*, and is well-defined, and that it has the following property.

Theorem 5.1: *H_m is Wightman. The vacuum expectation values $\{w_n\}$ characterize the free scalar field of mass m.*

Let $E_{\mathcal{F}}$ denote the internal orthogonal projection from ${}^\star L^2(M)$ to $\mathcal{F}$. For an internal operator X on ${}^\star L^2(M)$, define the operator $(X)_{\mathcal{F}}:\mathcal{F}\to\mathcal{F}$ by

$$(X)_{\mathcal{F}}=E_{\mathcal{F}}X\restriction\mathcal{F}.$$

Set

$$H_m=-\alpha T_A\Delta_{\mathcal{F}}T_A^{-1}+\beta T_B\Xi_{\mathcal{F}}T_B^{-1},$$

and we find

$$\alpha=\beta=\tfrac{1}{2},\quad A=I.$$

To give the explicit form of the positive operator B, we must solve

$$T_B\Xi_{\mathcal{F}}T_B^{-1}=\int_{{}^\star\mathbf{R}^{\mathbf{d}}}\left[\sum_{k=1}^{\mathbf{d}}(\partial_k\hat{\phi}(\boldsymbol{x}))^2+m^2\hat{\phi}(\boldsymbol{x})^2\right]\mathrm{d}\boldsymbol{x}.$$

Let $F\in L^2(\mathcal{F})$. Then for any $f\in\mathcal{F}$,

$$\left(\int_{{}^\star\mathbf{R}^{\mathbf{d}}}\left[\sum_{k=1}^{\mathbf{d}}(\partial_k\hat{\phi}(\boldsymbol{x}))^2+m^2\hat{\phi}(\boldsymbol{x})^2\right]\mathrm{d}\boldsymbol{x}F\right)(f)$$

$$=\int_{{}^\star\mathbf{R}^{\mathbf{d}}}\left[\sum_{k=1}^{\mathbf{d}}(\partial_k f(\boldsymbol{x}))^2+m^2f(\boldsymbol{x})^2\right]\mathrm{d}\boldsymbol{x}F(f)$$

$$=(f,(-\Delta+m^2)f)F(f)=(f,(-\Delta+m^2)_{\mathcal{F}}f)F(f),$$

where Δ is the Laplacian on ${}^\star\mathbf{R}^{\mathbf{d}}$.

On the other hand,

$$(T_B\Xi_{\mathcal{F}}T_B^{-1}F)(f)=(\Xi_{\mathcal{F}}T_B^{-1}F)(B^{-1}f)=(B^{-1}f,B^{-1}f)F(f)=(f,B^{-2}f)F(f).$$

Thus we have

$$B^{-2}=(-\Delta+m^2)_{\mathcal{F}},$$

$$H = (-1/2)\Delta_{\mathcal{F}} + (1/2)T_B \Xi_{\mathcal{F}} T_B^{-1}.$$

Let $e_k \in \mathcal{F}$ be an orthonormal basis of $\mathcal{F}$ such that

$$B^{-2} e_k = \lambda_k e_k, \quad \lambda_k \in {}^{\star}\mathbf{C}.$$

Then

$$H_k = (1/2)[\hat{\pi}(e_k)^2 + \lambda_k \hat{\phi}(e_k)^2] = \lambda_k^{1/2}(a^+(e_k)a(e_k) + (1/2))$$

where

$$a(e_k) \equiv 2^{-1/2}\lambda_k^{1/4}(\hat{\phi}(e_k) + \lambda_k^{-1/2} i\hat{\pi}(e_k)),$$

$$a^+(e_k) \equiv 2^{-1/2}\lambda_k^{1/4}(\hat{\phi}(e_k) - \lambda_k^{-1/2} i\hat{\pi}(e_k)).$$

Thus their time evolutions are given by

$$a_t(e_k) \equiv e^{itH} a(e_k) e^{-itH} = e^{itH_k} a(e_k) e^{-itH_k} = a(e_k) e^{-i\lambda_k^{1/2} t},$$

$$a_t^+(e_k) \equiv e^{itH} a^+(e_k) e^{-itH} = e^{itH_k} a^+(e_k) e^{-itH_k} = a^+(e_k) e^{i\lambda_k^{1/2} t}.$$

Since we have

$$\hat{\phi}(e_k) = 2^{-1/2}\lambda_k^{-1/4}[a(e_k) + a^+(e_k)], \quad \hat{\pi}(e_k) = -i2^{-1/2}\lambda_k^{1/4}[a(e_k) - a^+(e_k)],$$

the time evolutions of field operators are given by

$$\hat{\phi}_t(e_k) \equiv e^{itH_k}\hat{\phi}(e_k)e^{-itH_k} = 2^{-1/2}\lambda_k^{-1/4}[e^{-i\lambda_k^{1/2}t}a(e_k) + e^{i\lambda_k^{1/2}t}a^+(e_k)],$$

$$\hat{\pi}_t(e_k) \equiv e^{itH_k}\hat{\pi}(e_k)e^{-itH_k} = -i2^{-1/2}\lambda_k^{1/4}[e^{-i\lambda_k^{1/2}t}a(e_k) - e^{i\lambda_k^{1/2}t}a^+(e_k)].$$

For $x=(x_0,\boldsymbol{x}) \in {}^{\star}\mathbf{R}^{\mathbf{d}+1}$, let $\hat{\phi}(x) \equiv e^{ix_0 H_k}\hat{\phi}(\boldsymbol{x})e^{-ix_0 H_k}$. Then we have the following representation of $\hat{\phi}(x)$:

$$\hat{\phi}(x) = \sum_k e_k(\boldsymbol{x})\hat{\phi}(x_0, e_k) = 2^{-1/2}\sum_k e_k(x)\lambda_k^{-1/4}[e^{-i\lambda_k^{1/2}x_0}a(e_k) + e^{i\lambda_k^{1/2}x_0}a^+(e_k)].$$

Thus the two-point Wightman function is calculated as follows:

$$\begin{aligned}
\langle\Omega|\hat{\phi}(x)\hat{\phi}(y)\Omega\rangle &= \langle\Omega|2^{-1}\sum_{jk}[e_k(\boldsymbol{x})e_j(\boldsymbol{y})\lambda_k^{-1/2}e^{-i\lambda_k^{1/2}x_0}a(e_k)e^{i\lambda_j^{1/2}y_0}a^+(e_j)]\Omega\rangle \\
&= \langle\Omega|2^{-1}\sum_{jk}[e_k(\boldsymbol{x})e_j(\boldsymbol{y})\lambda_k^{-1/2}e^{-i\lambda_k^{1/2}(x_0-y_0)}a(e_k)a^+(e_j)]\Omega\rangle \\
&= \langle\Omega|2^{-1}\sum_{k}[e_k(\boldsymbol{x})e_k(\boldsymbol{y})\lambda_k^{-1/2}e^{-i\lambda_k^{1/2}(x_0-y_0)}a(e_k)a^+(e_k)]\Omega\rangle \\
&= 2^{-1}\sum_k [e_k(\boldsymbol{x})e_k(\boldsymbol{y})\lambda_k^{-1/2}e^{-i\lambda_k^{1/2}(x_0-y_0)}].
\end{aligned}$$

Let $\Lambda = -\Delta + m^2$ and $\Lambda_{\mathcal{F}} = (\Lambda)_{\mathcal{F}}$. Then by the relation

$$\delta_{\boldsymbol{x}} = \sum_k e_k(\boldsymbol{x})e_k,$$

we find

$$\langle\Omega|\hat{\phi}(x)\hat{\phi}(y)\Omega\rangle = (1/2)(\delta_x, \Lambda_{\mathcal{F}}^{-1/2} e^{-i\Lambda_{\mathcal{F}}^{1/2}(x_0-y_0)}\delta_y).$$

To show that H is Wightman, we evaluate the smeared two-point function $\langle\Omega|\hat{\phi}(x_0,f)\hat{\phi}(y_0,g)\Omega\rangle$ for $f,g\in\mathcal{D}(\mathbf{R}^{\mathbf{d}})$.

Notice that the following relations hold for Λ and $\Lambda_{\mathcal{F}}$:

$$(\forall r\in\mathbf{R})\Lambda^r({}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}})) = {}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}}), \tag{6}$$

$$(\forall n\in\mathbf{Z})(\Lambda_{\mathcal{F}})^n({}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}})) = {}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}}), \tag{7}$$

$$(\forall n\in\mathbf{Z})(\forall f\in {}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}}))\Lambda^n f = (\Lambda_{\mathcal{F}})^n f. \tag{8}$$

These imply that

$$(\forall r\in\mathbf{R})(\forall f\in {}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}}))e^{ir\Lambda}f \approx e^{ir\Lambda_{\mathcal{F}}}f, \tag{9}$$

$$(\forall r\in\mathbf{R})(\forall f\in {}^{\sigma}\mathcal{D}(\mathcal{R}^{\mathbf{d}}))\Lambda^r f \approx (\Lambda_{\mathcal{F}})^r f. \tag{10}$$

Therefore we conclude that for $f,g\in\mathcal{D}(\mathcal{R}^{\mathbf{d}})$,

$$\begin{aligned}\langle\Omega|\hat{\phi}(x_0,f)\hat{\phi}(y_0,g)\Omega\rangle &= (f,\Lambda_{\mathcal{F}}^{-1/2}e^{-i\Lambda_{\mathcal{F}}^{1/2}(x_0-y_0)}g) \approx (f,\Lambda^{-1/2}e^{-i\Lambda^{1/2}(x_0-y_0)}g)\\ &= \left(\hat{f},\left(\sum p_i^2+m^2\right)^{-1/2}e^{-i(\Sigma\, p_i^2+m^2)^{1/2}(x_0-y_0)}\hat{g}\right) = (\hat{f},\omega_{\boldsymbol{p}}^{-1}e^{-i\omega_{\boldsymbol{p}}(x_0-y_0)}\hat{g})\\ &= \int_{{}^{\star}\mathbf{R}^{\mathbf{d}}}\overline{\widetilde{f}(\boldsymbol{p})}\frac{e^{-i\omega_{\boldsymbol{p}}(x_0-y_0)}}{\omega_{\boldsymbol{p}}}\widetilde{g}(\boldsymbol{p})\mathrm{d}\boldsymbol{p},\end{aligned} \tag{11}$$

where $\widetilde{f}$ is the Fourier transform of f, and

$$\omega_{\boldsymbol{p}} = \left(\sum_{k=1}^{\mathbf{d}} p_k^2 + m^2\right)^{1/2}.$$

The last formula (11) is the same as the standard two-point function of a free scalar field. This means that all the vacuum expectations of our nonstandard field operators $\hat{\phi}(f_1)\cdots\hat{\phi}(f_n)$ are infinitesimally near to the standard ones, and hence H is Wightman.

VI. LAGRANGIAN PATH INTEGRAL

Consider the Hamiltonian

$$H = -\Delta_{\mathcal{F}} + V,$$

where the potential $V:\mathcal{F}\to{}^{\star}\mathbf{R}$ is such that H is self-adjoint. We examine a nonstandard path integral representation of the time evolution with respect to H.

Let $0\leqslant\theta<\pi/2$, $t\geqslant 0$ and $\tau=e^{i\theta}t$. For $f_0,\ldots,f_n\in\mathcal{F}$, define $R_n(f_0,\ldots,f_n,\tau)\in{}^{\star}\mathbf{C}$ by

$$R_n(f_0,\ldots,f_n,\tau) = \sum_{j=1}^{n}\frac{\tau}{n}\left[\frac{1}{2}\left(\frac{|f_j-f_{j-1}|}{\tau/n}\right)^2 + V(f_j)\right].$$

For $f_{\mathrm{ini}},f_{\mathrm{fin}}\in\mathcal{F}$, define $K_n(f_{\mathrm{ini}},f_{\mathrm{fin}};\tau)\in{}^{\star}\mathbf{C}$ by

$$K_n(f_{\mathrm{ini}},f_{\mathrm{fin}};\tau) \equiv (2\pi\tau/n)^{-\nu n/2}\int_{\mathcal{F}}\cdots\int_{\mathcal{F}} e^{-R_n(f_0,\ldots,f_n,\tau)}\mathrm{d}f_{n-1}\cdots df_1,$$

where $f_0=f_{\mathrm{ini}}$, $f_n=f_{\mathrm{fin}}$. For $F\in L^2(\mathcal{F})$, define $\hat{K}_n(\tau)F\in L^2(\mathcal{F})$ by

$$(\hat{K}_n(\tau)F)(f) \equiv \int_{\mathcal{F}} K_n(g,f;\tau)F(g)\mathrm{d}g.$$

By transferring the standard Trotter formula, we find

$$e^{-\tau(-\Delta_{\mathcal{F}}+V)}F = \lim_{n\to{}^\star\infty} \hat{K}_n(\tau)F.$$

The exact expression of this equation is the following:

$$(\forall \epsilon \in {}^\star\mathbf{R}^+)(\exists k \in {}^\star\mathbf{N})(\forall n \in {}^\star\mathbf{N})(n > k \Rightarrow \|\hat{K}_n(\tau)F - e^{-\tau(-\Delta_{\mathcal{F}}+V)}F\| < \epsilon),$$

where $\|\cdot\|$ denotes the ${}^\star\mathbf{R}$-valued norm on $L^2(\mathcal{F})$.

By the saturation principle, we find the following.

Theorem 6.1: *Let* $S \subset L^2(\mathcal{F})$ *satisfy* $\mathrm{card}(S) < \kappa$. *Then there exists* $n \sim \infty$ *such that for any* $F \in S$,

$$e^{-\tau(-\Delta_{\mathcal{F}}+V)}F \approx \hat{K}_n(\tau)F.$$

Let $\epsilon = t/n$ $(=|\tau|/n)$. For $\Phi = (f_0, \ldots, f_n) \in \mathcal{F}^{n+1}$, define the $\mathcal{F}$-valued path $\tilde{\Phi}:[0,t]\to\mathcal{F}$ by

$$\tilde{\Phi}(t) = (((k+1)\epsilon - t)f_k + (t - k\epsilon)f_{k+1})/\epsilon$$

if $k\epsilon \leqslant t \leqslant (k+1)\epsilon$ $(k=0,\ldots,n)$. That is, $\tilde{\Phi}$ is the piecewise linear path such that $\tilde{\Phi}(k\epsilon) = f_k$ for $k = 0, \ldots, n$.

Define the set of paths $\mathcal{L}_n$ by

$$\mathcal{L}_n = \{\tilde{\Phi} | \Phi \in \mathcal{F}^{n+1}\}.$$

For $f, g \in \mathcal{F}$, define $\mathcal{L}_n[f,g] \subset \mathcal{L}_n$ by

$$\mathcal{L}_n[f,g] = \{\phi \in \mathcal{L}_n | \phi(0) = f, \phi(t) = g\}.$$

The $\star$Lebesgue measures on $\mathcal{L}_n$ and $\mathcal{L}_n[f,g]$ are naturally defined by those of $\mathcal{F}^{n+1}$ and $\mathcal{F}^{n-1}$, respectively, i.e., for any function $h:\mathcal{L}_n \to {}^\star\mathbf{C}$,

$$\int_{\mathcal{L}_n} F(\phi)\mathrm{d}\phi \equiv \int_{\mathcal{F}^{n+1}} h(\tilde{\Phi})\mathrm{d}\Phi = \int_{\mathcal{F}} \cdots \int_{\mathcal{F}} h(\tilde{\Phi})\mathrm{d}\phi_0 \cdots \mathrm{d}\phi_n.$$

$$\int_{\mathcal{L}_n[f,g]} h(\phi)\mathrm{d}\phi \equiv \int_{\mathcal{F}} \cdots \int_{\mathcal{F}} h((f,\phi_1,\ldots,\phi_{n-1},g)^\sim)\mathrm{d}\phi_1 \cdots \mathrm{d}\phi_{n-1}.$$

For a path $\phi:[0,t]\to\mathcal{F}$, define the generalized action integral $S(\phi,\tau)$ by

$$S(\phi,\tau) \equiv \int_0^t \left[\frac{e^{-i\theta}}{2}\|\dot{\phi}(s)\|^2 + e^{i\theta}V(\phi(s))\right]\mathrm{d}s.$$

Of course, if $\tau > 0$ (equivalently $\theta = 0$) then $S(\phi,\tau)$ is the Euclidean action of the path ϕ, and if τ is pure imaginary (equivalently $\theta = \pi/2$) then $-iS(\phi,\tau)$ is the Minkowskian action of the path ϕ.

For $f_{\mathrm{ini}}, f_{\mathrm{fin}} \in \mathcal{F}$, let

$$K'_n(\tau; f_{\mathrm{ini}}, f_{\mathrm{fin}}) \equiv (2\pi\tau/n)^{-\nu n/2} \int_{\mathcal{L}_n[f_{\mathrm{ini}},f_{\mathrm{fin}}]} e^{-S(\phi,t,\theta)}\mathrm{d}\phi.$$

For $F \in L^2(\mathbf{R}^N)$, define $\hat{K}'_n(\tau)F \in L^2(\mathcal{F})$ by

$$(\hat{K}'_n(\tau)F)(f) \equiv \int_{\mathcal{F}} K'_n(\tau;g,f)F(g)\mathrm{d}g.$$

Note that

$$\left|\exp\left(-\frac{\tau}{2n}\sum_{j=1}^{n}\left(\frac{\|\phi_j-\phi_{j-1}\|}{\tau/n}\right)^2\right)\right| = \left|\exp\left(-\frac{e^{-i\theta}t}{2n}\sum_{j=1}^{n}\left(\frac{\|\phi_j-\phi_{j-1}\|}{t/n}\right)^2\right)\right|$$
$$= \exp\left(-\frac{n\cos\theta}{2t}\sum_{j=1}^{n}\|\phi_j-\phi_{j-1}\|^2\right).$$

This implies that the paths which effectively contribute to the path integral satisfy

$$\|\phi_{k+1}-\phi_k\|^2 \leqslant O\left(\frac{t}{n\cos\theta}\right) = O\left(\frac{t}{n(\pi/2-\theta)}\right)$$

as $n \to {}^\star\infty$ when $0 \leqslant \theta < \pi/2$. Therefore it follows that

$$R_n(\Phi,\tau) - S(\tilde{\Phi}) \to 0 \quad \text{as } n \to {}^\star\infty$$

and

$$(\hat{K}_n(\tau) - \hat{K}'_n(\tau))F \to 0 \quad \text{as } n \to {}^\star\infty$$

when $0 \leqslant \theta < \pi/2$. Thus

$$e^{-\tau(-\Delta_{\mathcal{F}}+V)}F = \lim_{n\to{}^\star\infty} \hat{K}'_n(\tau)F.$$

By the saturation principle, we have

Theorem 6.2 (Lagrangian path integral): *Let* $S \subset L^2(\mathcal{F})$ *and* $\mathrm{card}S < \kappa$. *Suppose* $0 \leqslant \theta < \pi/2$. *Then there exists* $n \in {}^\star\mathbf{N}$ *such that for any* $F \in S$,

$$(e^{-\tau(-\Delta_{\mathcal{F}}+V)}F)(f) \approx (\hat{K}'_n(\tau)F)(f) = (2\pi\tau/n)^{-\nu n/2}\int_{\mathcal{F}}\int_{\mathcal{L}_n[g,f]} e^{-S(\phi,\tau)}F(g)\mathrm{d}\phi\mathrm{d}g.$$

where $\tau = e^{i\theta}t$, $t \in {}^\star\mathbf{R}$. *The above approximation "*$\approx$*" is with respect to the* $\star$ *norm of* $L^2(\mathcal{F})$.

Next we consider the case of free scalar field Hamiltonian:

$$H_m = \frac{1}{2}\int_{{}^\star\mathbf{R}^{\mathbf{d}}}\left[\hat{\pi}(\boldsymbol{x})^2 + \sum_{k=1}^{\mathbf{d}}(\partial_k\hat{\phi}(\boldsymbol{x}))^2 + m^2\hat{\phi}(\boldsymbol{x})^2\right]\mathrm{d}\boldsymbol{x}.$$

The infinite energy of vacuum is not regularized on H_m:

$$H_m\Omega = E_0\Omega, \quad E_0 = \nu/2 \sim \infty.$$

Let H'_m be the vacuum-energy regularization of H_m, i.e.,

$$H'_m = H_m - E_0.$$

Set

$$H'_m = \tfrac{1}{2}\Delta_{\mathcal{F}} + V,$$

then as shown in Sec. V, we have for $f \in \mathcal{F}$,

$$V(f) = (1/2)(f,(-\Delta + m^2)f) - E_0 = \frac{1}{2}\int_{{}^\star\mathbf{R}^\mathbf{d}} \left[\sum_{k=1}^{\mathbf{d}} (\partial_k f(\boldsymbol{x}))^2 + m^2 f(\boldsymbol{x})^2 \right] \mathrm{d}\boldsymbol{x} - E_0.$$

Hence we have

$$\begin{aligned} S(\phi,\tau) &\equiv \int_0^t \left[\frac{e^{-i\theta}}{2} \|\dot{\phi}(s)\|^2 + \int_{{}^\star\mathbf{R}^\mathbf{d}} \frac{e^{i\theta}}{2} \left[\sum_{k=1}^{\mathbf{d}} (\partial_k \phi(s)(\boldsymbol{x}))^2 + m^2 \phi(s)(\boldsymbol{x})^2 \right] \mathrm{d}\boldsymbol{x} - E_0 \right] \mathrm{d}s \\ &= \int_0^t \left[\int_{{}^\star\mathbf{R}^\mathbf{d}} \frac{e^{-i\theta}}{2} \dot{\phi}(s)(\boldsymbol{x})^2 + \frac{e^{i\theta}}{2} \left[\sum_{k=1}^{\mathbf{d}} (\partial_k \phi(s)(\boldsymbol{x}))^2 + m^2 \phi(s)(\boldsymbol{x})^2 \right] \mathrm{d}\boldsymbol{x} - E_0 \right] \mathrm{d}s \\ &= \int_0^t \int_{{}^\star\mathbf{R}^\mathbf{d}} \frac{e^{-i\theta}}{2} \dot{\phi}(s)(\boldsymbol{x})^2 + \frac{e^{i\theta}}{2} \sum_{k=1}^{\mathbf{d}} (\partial_k \phi(s)(\boldsymbol{x}))^2 + \frac{e^{i\theta}}{2} m^2 \phi(s)(\boldsymbol{x})^2 \mathrm{d}\boldsymbol{x}\mathrm{d}s - tE_0 \\ &= \frac{e^{i\theta}}{2} \int_{[0,t]\times{}^\star\mathbf{R}^\mathbf{d}} \left(\mathcal{E}_\theta \partial^k \phi \partial_k \phi + m^2 \phi^2 \right) \mathrm{d}x - tE_0, \end{aligned}$$

where $\mathcal{E}_\theta$ denotes the θ-parametrized Einstein convention:

$$\mathcal{E}_\theta A^k B_k = e^{-2i\theta} A_0 B_0 + \sum_{k=1}^{\mathbf{d}} A_k B_k,$$

which is the Euclidean inner product if $\theta=0$, and is the Minkowskian inner product if $\theta=\pi/2$. Evidently

$$L = \tfrac{1}{2}(\mathcal{E}_\theta \partial^k \phi \partial_k \phi + m^2 \phi^2)$$

is the θ-parametrized Lagrangian for a free scalar field. Thus we can write

$$S(\phi,\tau) = e^{i\theta} \int_{[0,t]\times{}^\star\mathbf{R}^\mathbf{d}} L\mathrm{d}x - tE_0.$$

Then we have the following theorem:

Theorem 6.3 (Lagrangian path integral for free scalar fields): *Let* $S \subset L^2(\mathcal{F})$ *and* $\mathrm{card}S < \kappa$. *Suppose* $0 \leqslant \theta < \pi/2$. *Then there exists* $n \in {}^\star\mathbf{N}$ *such that for any* $F \in S$,

$$(e^{-\tau H'_m} F)(f) \approx (2\pi\tau/n)^{-\nu n/2} e^{tE_0} \int_{\mathcal{F}} \int_{\mathcal{L}_n[g,f]} e^{-e^{i\theta}\int_{[0,t]\times{}^\star\mathbf{R}^\mathbf{d}} L\mathrm{d}x} F(g)\mathrm{d}\phi\mathrm{d}g,$$

where $\tau = e^{i\theta}t$, $t \in {}^\star\mathbf{R}$. *The above approximation* "$\approx$" *is with respect to the* $\star$*norm of* $L^2(\mathcal{F})$.

VII. GENERATING FUNCTIONAL

In the physical literature, the *generating functional* of a scalar field $\hat{\phi}$ is "defined" by

$$Z[J] = \langle \Omega | \mathrm{T} \exp\left[i \int J(x)\hat{\phi}(x)\mathrm{d}x \right] \Omega \rangle, \tag{12}$$

where T denotes the time-ordered product (T-product).

However, if $\hat{\phi}$ is regarded as a standard operator-valued distribution, the T-product is not well-defined. On the other hand, if $\hat{\phi}$ is regarded as a nonstandard pointwise field operator instead of a standard operator-valued distribution, the T-product can be defined rigorously. Let us call it a *nonstandard T-product.* However the problem of uniqueness of the nonstandard T-product still remains unsolved; we supposed $\mathcal{F}$ to be an *arbitrary* hyperfinite-dimensional subspace such that

$\mathcal{D}\subset\mathcal{F}\subset{}^{\star}\mathcal{D}$. The definition of the T-product can be sensitive to the selection of $\mathcal{F}$. This problem is open:

Question: Does a nonstandard T-product depend on $\mathcal{F}$? If so, what selection of $\mathcal{F}$ defines physically meaningful T-products?

In this paper, we do not examine this problem further. Instead we consider the path integral representation of a generating functional. In the physical literature, the following formula is given:

$$Z[J]=\frac{\int \exp i\int_{\mathbf{R}^{\mathbf{d}+1}}[L(\phi,\partial\phi)+J(x)\phi(x)]\mathrm{d}x\mathrm{d}\phi}{\int \exp i\int_{\mathbf{R}^{\mathbf{d}+1}}[L(\phi,\partial\phi)]\mathrm{d}x\mathrm{d}\phi}. \tag{13}$$

In our approach, to examine the right-hand side of this formula seems easier than to examine T-products.

In Sec. VI, the path space $\mathcal{L}$ was defined to be a set of paths $\phi:[0,t]\to\mathcal{F}$. Let $T\in{}^{\star}\mathbf{R}_{\infty}^{+}$. In this section, we consider the path space $\mathcal{L}_T$ is a set of the paths $\phi:{}^{\star}R\to\mathcal{F}$, where $\phi(t)=0$ if $|t|>T$. For $\phi_1,\phi_2\in\mathcal{L}_T$, the inner product (ϕ_1,ϕ_2) is given by

$$(\phi_1,\phi_2)=\int_{{}^{\star}\mathbf{R}}(\phi_1(x_0),\phi_2(x_0))\mathrm{d}x_0=\int_{{}^{\star}\mathbf{R}^{\mathbf{d}+1}}\phi_1(x)\phi_2(x)\mathrm{d}x,$$

where $\phi_j(x)\equiv\phi_j(x_0)(x_1,\ldots,x_{\mathbf{d}})$. Thus $\mathcal{L}_T$ is naturally embedded into ${}^{\star}L(\mathbf{R}^{\mathbf{d}+1})$. We can suppose ${}^{\sigma}\mathcal{D}(\mathbf{R}^{\mathbf{d}+1})\subset\mathcal{L}_T$ by the saturation principle.

Equation (13) is rewritten in our notations parallel to Theorem 6.3 as

$$Z[J]=\frac{\int_{\mathcal{L}_T}\exp-\int_{{}^{\star}\mathbf{R}^{\mathbf{d}+1}}[e^{i\theta}L(\phi,\partial\phi)+J(x)\phi(x)]\mathrm{d}x\mathrm{d}\phi}{\int_{\mathcal{L}_T}\exp-\int_{{}^{\star}\mathbf{R}^{\mathbf{d}+1}}e^{i\theta}L(\phi,\partial\phi)\mathrm{d}x\mathrm{d}\phi}. \tag{14}$$

Here we confine ourselves to the case of free massive scalar fields:

$$L=\tfrac{1}{2}(\mathcal{E}_{\theta}\partial^{k}\phi\partial_{k}\phi+m^{2}\phi^{2}).$$

Thus for any $\phi\in\mathcal{L}_T$ we have

$$\begin{aligned}\int_{\mathbf{R}^{\mathbf{d}+1}}[L(\phi,\partial\phi)+J(x)\phi(x)]\mathrm{d}x\mathrm{d}\phi&=\int_{\mathbf{R}^{\mathbf{d}+1}}\left[\frac{1}{2}(-\mathcal{E}_{\theta}\phi\partial^{k}\partial_{k}\phi+m^{2}\phi^{2})+J(x)\phi(x)\right]\mathrm{d}x\mathrm{d}\phi\\&=\frac{1}{2}(\phi,(-\mathcal{E}_{\theta}\partial^{k}\partial_{k}+m^{2})\phi)+(J,\phi).\end{aligned}$$

Note that

$$\begin{aligned}\mathrm{Re}\left[e^{i\theta}\int_{{}^{\star}\mathbf{R}^{\mathbf{d}+1}}L(\phi,\partial\phi)\mathrm{d}x\mathrm{d}\phi\right]&=\mathrm{Re}\left[e^{i\theta}\frac{1}{2}(\phi,(-\mathcal{E}_{\theta}\partial^{k}\partial_{k}+m^{2})\phi)\right]\\&=\mathrm{Re}\left[e^{i\theta}\frac{1}{2}\left(\phi,\left(-e^{-2i\theta}\partial_{0}^{2}-\sum_{k=1}^{\mathbf{d}}\partial_{k}^{2}+m^{2}\right)\phi\right)\right]\\&=\cos\theta\frac{1}{2}\left(\phi,\left(-\sum_{k=0}^{\mathbf{d}}\partial_{k}^{2}+m^{2}\right)\phi\right)\geqslant 0.\end{aligned}$$

Therefore if $0\leqslant\theta<\pi/2$ then the real part of the exponent is strictly negative, and hence the

above-mentioned path integral is well-defined. (In the purely Minkowskian case $\theta=\pi/2$, it is unclear whether it can be well-defined.) Since $\mathcal{L}$ is hyperfinite-dimensional, the integral can be calculated by transferring the finite-dimensional standard Gaussian integral formula:

Proposition 7.1: *Let $\tilde{\mathcal{L}}_T=\mathcal{L}_T+i\mathcal{L}_T$ be the internal complexification of $\mathcal{L}_T$. Let $A:\tilde{\mathcal{L}}_T\to\tilde{\mathcal{L}}_T$ be an internal linear operator such that*

1. *A is symmetric in the sense of*

$$(\forall\phi,\psi\in\mathcal{L}_T)\quad(\phi,A\psi)=(\psi,A\phi), \tag{15}$$

2. $(\forall\phi\in\mathcal{L}_T)\quad\phi\neq 0\Rightarrow \mathrm{Re}(\phi,A\phi)>0.$

Then the following holds:

$$\int_{\mathcal{L}_T}\exp\left[-\frac{1}{2}(\phi,A\phi)+(\phi,\psi)\right]d\phi=\left(\det\frac{A}{2\pi}\right)^{-1/2}\exp\frac{1}{2}(\psi,A^{-1}\psi). \tag{16}$$

Let $\Lambda_\theta=e^{i\theta}(-\mathcal{E}_\theta\partial^k\partial_k+m^2)$ be an ($\star$unbounded) operator on $L^2(\mathbf{R}^{\mathbf{d}+1})$, and E be the orthogonal projection from $L^2(\mathbf{R}^{\mathbf{d}+1})$ to $\tilde{\mathcal{L}}_T$. Let $\Lambda_\theta^E=E\Lambda_\theta\restriction\tilde{\mathcal{L}}_T$. We can check that Λ_θ^E is symmetric in the sense of (15).

Applying the above-mentioned formula, we find for any $J\in{}^\star L^2(\mathbf{R}^{\mathbf{d}+1})$,

$$Z[J]=\frac{\displaystyle\int_{\mathcal{L}_T}\exp-\left[e^{i\theta}\frac{1}{2}(\phi,(-\mathcal{E}_\theta\partial^k\partial_k+m^2)\phi)+(J,\phi)\right]\mathrm{d}\phi}{\displaystyle\int_{\mathcal{L}_T}\exp-e^{i\theta}\frac{1}{2}(\phi,(-\mathcal{E}_\theta\partial^k\partial_k+m^2)\phi)\mathrm{d}\phi}=\frac{\displaystyle\int_{\mathcal{L}_T}\exp\left[-\tfrac{1}{2}(\phi,\Lambda_\theta^E\phi)-(J,\phi)\right]\mathrm{d}\phi}{\displaystyle\int_{\mathcal{L}_T}\exp-\tfrac{1}{2}(\phi,\Lambda_\theta^E\phi)\mathrm{d}\phi}$$

$$=\exp\frac{1}{2}(J,(\Lambda_\theta^E)^{-1}J).$$

In the case where $0\leqq\theta<\pi/2$, and $\theta\in\mathbf{R}$ (and hence $\theta\neq\pi/2$), the properties parallel to Eqs. (6)–(10) hold for Λ_θ; especially we see

$$(\forall n\in\mathbf{Z})(\forall f\in{}^\sigma\mathcal{D}(\mathcal{R}^{\mathbf{d}}))\quad\Lambda_\theta^n f=(\Lambda_\theta^E)^n f. \tag{17}$$

Thus we have for any $f\in{}^\sigma\mathcal{D}(\mathcal{R}^{\mathbf{d}})$,

$$Z[J]=\exp\tfrac{1}{2}(J,(\Lambda_\theta^E)^{-1}J)=\exp\tfrac{1}{2}(J,\Lambda_\theta^{-1}J). \tag{18}$$

By the principle of eternity in nonstandard analysis, there exists $\epsilon\approx 0$, $\epsilon>0$ such that

$$Z[J]=\exp\tfrac{1}{2}(J,\Lambda_{(\pi/2)-\epsilon}^{-1}J). \tag{19}$$

This means that our nonstandard method permits us to consider some "almost Minkowskian" cases in manipulating path integrals. Purely Minkowskian path integrals seem difficult to be justified even if we use nonstandard methods, but the "almost Minkowskian" path integrals can be used as a substitute for them.

By the Fourier transformation, Λ_θ^{-1} is represented as the multiplication operator

$$\tilde{\Lambda}_\theta^{-1}(p)=\frac{e^{i\theta}}{p_0^2+e^{2i\theta}\sum_k p_k^2+e^{2i\theta}m^2}.$$

In the "almost Minkowskian" case $\theta=(\pi/2)-\epsilon$, we find

$$\tilde{\Lambda}_{\theta}^{-1}(p) \approx \frac{i}{p_0^2 - \sum_k p_k^2 - m^2 + i\epsilon},$$

where the approximation is in the sense of Schwartz distribution. Since the right-hand side is the Fourier transform of the Feynman Green function $\Delta_F(x)$, we have

$$Z[J] \approx \exp \tfrac{1}{2}(J, \Delta_F J),$$

for any $J \in \mathcal{D}(\mathbf{R}^{\mathbf{d}+1})$. Thus a rigorous justification of physicists' path-integral calculation of the generating functional has been given.

(Received 17 November 2005; accepted 29 July 2006; published online 12 September 2006)

In the framework of quantum field theory on noncommutative space–time with the symmetry group $O(1,1)\times SO(2)$, we prove that the Jost-Lehmann-Dyson representation, based on the causality condition taken in connection with this symmetry, leads to the mere impossibility of drawing any conclusion on the analyticity of the $2\rightarrow 2$-scattering amplitude in $\cos\Theta$, Θ being the scattering angle. Discussions on the possible ways of obtaining high-energy bounds analogous to the Froissart-Martin bound on the total cross section are also presented. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2338761]

I. INTRODUCTION

The development of quantum field theory (QFT) on noncommutative (NC) space–time, especially after the seminal work of Seiberg and Witten,[1] which showed that the NC QFT arises from string theory, has lately triggered interest also towards the formulation of an axiomatic approach to the subject. The power of the axiomatic approach is that that the results are rigorously derived, with no reference to the specific form of interaction or to perturbation theory. Consequently, in the framework of noncommutative spaces, the analytical properties of scattering amplitude in energy E and forward dispersion relations have been considered,[2,3] Wightman functions have been introduced and the CPT theorem has been proven,[4,5] and as well attempts towards a proof of the spin-statistics theorem have been made.[5] [In the context of the Lagrangian approach to NC QFT, the CPT and spin-statistics theorems have been proven in general in Ref. 6; for CPT invariance in NC QED, see Refs. 7 and 8, and in NC standard model.[9]]

In the axiomatic approach to commutative QFT, one of the fundamental results consisted of the rigorous proof of the Froissart bound on the high-energy behavior of the scattering amplitude, based on its analyticity properties.[10,11] In this paper we aim at obtaining the analog of this bound when the space–time is noncommutative. Such an undertaking, besides being topical in itself, would also prove fruitful in the conceptual understanding of subtle issues, such as causality, in nonlocal theories to which the NC QFTs belong.

In the following, we shall consider NC QFT on a space–time with the commutation relation

$$[x_\mu, x_\nu] = i\theta_{\mu\nu}, \tag{1.1}$$

where $\theta_{\mu\nu}$ is an antisymmetric constant matrix (for a review, see, e.g., Refs. 12 and 13). Such NC theories violate Lorentz invariance, while translational invariance still holds. We can always choose the system of coordinates such that $\theta_{13}=\theta_{23}=0$ and $\theta_{12}=-\theta_{21}\equiv\theta$. Then, for the particular case of space–space noncommutativity, i.e., $\theta_{0i}=0$, the theory is invariant under the subgroup $O(1,1)\times SO(2)$ of the Lorentz group. The requirement that time be commutative ($\theta_{0i}=0$) discards the well-known problems with the unitarity[14] of the NC theories and with causality[15,16] (see also Ref. 6). As well, the $\theta_{0i}=0$ case allows a proper definition of the S-matrix.[3]

In the conventional (commutative) QFT, the Froissart bound was first obtained[10] using the conjectured Mandelstam representation (double dispersion relation),[17] which assumes analyticity in the entire E and $\cos\Theta$ complex planes. The Froissart bound,

$$\sigma_{\text{tot}}(E) \leqslant c \ln^2 \frac{E}{E_0}, \tag{1.2}$$

expresses the upper limit of the total cross section σ_{tot} as a function of the center-of-mass system (CMS) energy E, when $E \to \infty$. However, such an analyticity or equivalently the double dispersion relation has not been proven, while smaller domains of analyticity in $\cos\Theta$ were already known.[18]

One of the main ingredients in rigorously obtaining the Froissart bound is the Jost-Lehmann-Dyson representation[19,20] of the Fourier transform of the matrix element of the commutator of currents, which is based on the causality as well as the spectral conditions (for an overall review, see Ref. 21). Based on this integral representation, one obtains the domain of analyticity of the scattering amplitude in $\cos\Theta$. This domain proves to be an ellipse—the so-called Lehmann's ellipse.[18]

However, this domain of analyticity in $\cos\Theta$ can be enlarged to the so-called Martin's ellipse by using the dispersion relations satisfied by the scattering amplitude and the unitarity constraint on the partial-wave amplitudes. Using this larger domain of analyticity, the Froissart bound (1.2) was rigorously proven in QFT (Ref. 11) (for a review, see Ref. 22).

Further on, the analog of the Froissart-Martin bound was rigorously obtained for the $2 \to 2$-particle scattering in a space–time of arbitrary dimension D.[23,24]

In NC QFT with $\theta_{0i}=0$, we shall follow the same path for the derivation of the high-energy bound on the scattering amplitude, starting from the Jost-Lehmann-Dyson representation and adapting the derivation to the new symmetry $O(1,1)\times SO(2)$ and to the nonlocality of the NC theory. [A preliminary work along this line with stronger claims, based on a conjecture, has been previously reported in Ref. 25.] In Sec. II we derive the Jost-Lehmann-Dyson representation satisfying the light-wedge (instead of light-cone) causality condition, inspired by the above symmetry. We show that no analyticity of the scattering amplitude in $\cos\Theta$ can be obtained in such a case. Since the causality condition is the key ingredient for the analyticity of the scattering amplitude, in Sec. III we discuss possible causality postulates in the noncommutative case, in relation both with the maximal symmetry of the theory (twisted Poincaré[26]) and with the scale of nonlocality as obtained so far in perturbative calculations. It turns out that by postulating a *finite range of nonlocality*, compatible with the twisted Poincaré symmetry, and by using the global nature of local commutativity, we can obtain from the Jost-Lehmann-Dyson representation a domain of analyticity in $\cos\Theta$, which coincides with the Lehmann ellipse. Further, the extension of this analyticity domain to Martin's ellipse is possible in the case of the incoming particles' momenta orthogonal to the NC plane (x_1, x_2), which eventually enables us to derive the analog of the Froissart-Martin bound (1.2) for the total cross section. The general configuration of incoming particles' momenta is also discussed, together with the problems which arise in such a case. However, the perturbative calculations performed so far seem to indicate an *infinite range of nonlocality*, in which case the initial causality condition involving the light wedge should be postulated, leading to the lack of analyticity of the scattering amplitude. The situation is discussed in connection with the perturbative problem of UV/IR mixing in NC QFT. Section 6 is devoted to conclusion and discussions.

II. JOST-LEHMANN-DYSON REPRESENTATION

The Jost-Lehmann-Dyson representation[19,20] is the integral representation for the Fourier transform of the matrix elements of causal commutators, satisfying the causality and spectral conditions. For definiteness and simplicity, we shall obtain it below for a particular matrix element of the commutator of currents

$$f(q) = \int d^4x e^{iqx} f(x), \tag{2.1}$$

where

$$f(x) = \left\langle p' \left| \left[j\left(\frac{x}{2}\right), j'\left(-\frac{x}{2}\right) \right] \right| p \right\rangle. \tag{2.2}$$

The process considered is the $2 \to 2$ scalar particles scattering, $k+p \to k'+p'$, and j and j' are the scalar currents corresponding to the incoming and outgoing particles with momenta k and k' (see also Refs. 21 and 27). We emphasize that the (form of the) integral representation eventually obtained is, however, valid for *any* other matrix element of any commutator of currents.

For NC QFT with $O(1,1) \times SO(2)$ symmetry, in Ref. 28 a new causality condition was proposed, involving (instead of the light cone) the light wedge corresponding to the coordinates x_0 and x_3, which form a two-dimensional space with the $O(1,1)$ symmetry. Accordingly, we shall require the vanishing of the commutator of two currents (in general, observables) at spacelike separations in the sense of $O(1,1)$ as

$$\left[j\left(\frac{x}{2}\right), j'\left(-\frac{x}{2}\right) \right] = 0, \quad \text{for } \tilde{x}^2 \equiv x_0^2 - x_3^2 < 0. \tag{2.3}$$

The spectral condition compatible with (2.3) would require now that the physical momenta be in the forward light wedge,

$$\tilde{p}^2 \equiv p_0^2 - p_3^2 > 0 \quad \text{and} \quad p_0 > 0. \tag{2.4}$$

The standard spectral condition

$$p_0^2 - p_1^2 - p_2^2 - p_3^2 \geqslant 0, \quad p_0 > 0,$$

based on Poincaré symmetry or twisted Poincaré symmetry,[26] implies the forward light-wedge condition (2.4) as well.

The spectral condition (2.4) will impose restrictions on $f(q)$. Using the translational invariance in (2.2), one can express the matrix element of the commutator of currents, $f(x)$, in the form

$$\begin{aligned} f(x) &= \int dq e^{-iqx + i(p+p')(x/2)} G_1(q) - \int dq e^{iqx - i(p+p')(x/2)} G_2(q) \\ &= \int dq e^{-iqx} \left[G_1\left(q + \frac{1}{2}(p+p')\right) - G_2\left(-q + \frac{1}{2}(p+p')\right) \right], \end{aligned} \tag{2.5}$$

where

$$\begin{aligned} G_1(q) &= \langle p' | j(0) | q \rangle \langle q | j'(0) | p \rangle, \\ G_2(q) &= \langle p' | j'(0) | q \rangle \langle q | j(0) | p \rangle. \end{aligned} \tag{2.6}$$

Comparing (2.5) with the inverse Fourier transformation, $f(x) = \int dq e^{-iqx} f(q)$, it follows that

$$f(q) = f_1(q) - f_2(q) = G_1\left(q + \frac{1}{2}(p+p')\right) - G_2\left(-q + \frac{1}{2}(p+p')\right). \tag{2.7}$$

[Throughout the paper we omit all the inessential factors of $(2\pi)^n$, which are irrelevant for the analyticity considerations.] Given the way the functions G_1 and G_2 are defined in (2.6), one finds that $f(q)=0$ in the region where the momenta $q+1/2(p+p')$ and $-q+1/2(p+p')$ are simultaneously nonphysical, i.e., when they are out of the future light wedge (2.4).

In order to express the condition for $f(q)=0$, we shall define the $O(1,1)$-invariant $\tilde{m}^2=k_0^2-k_3^2=f(m^2,k_1^2+k_2^2)$, where k is the momentum of an arbitrary state and m is its mass. However, we have to point out that $\tilde{m}$ is only a kinematical variable, invariant with respect to $O(1,1)$ (but not the mass).

For the *physical* states with momentum $q+1/2(p+p')$, we take $\tilde{m}_1$ to be the minimal value of the $O(1,1)$-invariant quantity above. Then, in the Breit frame, where $1/2(p+p')=(p_0,0,0,0)$, one finds that $f_1(q)\neq 0$ for all the q values, satisfying the spectral condition $q_0+p_0\geqslant 0$ and $(q_0-p_0)^2-q_3^2\geqslant 0$. In other words, $f_1(q)=0$ for $q_0<-p_0+\sqrt{q_3^2+\tilde{m}_1^2}$. Similarly, one finds that $f_2(q)=0$ for $p_0-\sqrt{q_3^2+\tilde{m}_2^2}<q_0$ [where $\tilde{m}_2$ has a meaning analogous to that of $\tilde{m}_1$, but for the states with the momentum $-q+1/2(p+p')$].

As a result, due to the spectral condition (2.4), $f(q)=0$ in the region outside the hyperbola

$$p_0-\sqrt{q_3^2+\tilde{m}_2^2}<q_0<-p_0+\sqrt{q_3^2+\tilde{m}_1^2}. \tag{2.8}$$

To derive the Jost-Lehmann-Dyson representation, further we consider the six-dimensional space–time with the Minkowskian metric $(+,-,-,-,-,-)$. On this space, we define the vector $z=(x_0,x_1,x_2,x_3,y_1,y_2)$. For practical purposes we introduce also the notations for the two-dimensional vector $\tilde{x}=(x_0,x_3)$ and the four-dimensional vector $\tilde{z}=(z_0,z_3,z_4,z_5)\equiv(x_0,x_3,y_1,y_2)$. On the six-dimensional space we define the function

$$F(z)=f(x)\delta(\tilde{x}^2-y^2)=f(x)\delta(\tilde{z}^2), \tag{2.9}$$

depending on all six coordinates.

When the causality condition (2.3) is fulfilled, i.e., for the physical region, $f(x)$ and $F(z)$ determine each other, since

$$\int dy_1dy_2F(z)=f(x)\theta(\tilde{x}^2)=\begin{cases}f(x) & \text{for} \quad \tilde{x}^2>0,\\ 0 & \text{for} \quad \tilde{x}^2<0.\end{cases} \tag{2.10}$$

The Fourier transform of $F(z)$,

$$F(r)=\int d^6z e^{izr}F(z), \tag{2.11}$$

can be expressed, using (2.9) and (2.10), as

$$F(r)=\int d^4qD_1(r-\hat{q})f(q). \tag{2.12}$$

Denoting the remaining four-dimensional vector $\tilde{r}=(r_0,r_3,r_4,r_5)$, we have

$$D_1(r)=\int d^6z e^{izr}\delta(\tilde{z}^2)=\frac{\delta(r_1)\delta(r_2)}{\tilde{r}^2}=\delta(r_1)\delta(r_2)D_1(\tilde{r}), \tag{2.13}$$

with $D_1(\tilde{r})=1/\tilde{r}^2$.

We define now the "subvector" of a six-dimensional vector as $\hat{q}=(q_0,q_1,q_2,q_3,0,0)$ and we find the relation between $F(\hat{q})$ and $f(q)$ in view of the causality condition (2.3),

$$F(\hat{q})=\int d^4xf(x)\theta(\tilde{x}^2)e^{iqx}=f(q). \tag{2.14}$$

$D_1(\tilde{r})$ satisfies the four-dimensional wave equation,

$$\Box_4D_1(\tilde{r})=0, \tag{2.15}$$

where the d'Alembertian is defined with respect to the coordinates r_0,r_3,r_4,r_5. Then, due to (2.12), it follows that $F(r)$ satisfies the same equation,

$$\Box_4 F(r) = 0. \tag{2.16}$$

It is crucial to note that $F(r)$ depends on all six variables $r_0, \ldots, r_5$

$$F(r) = \int d^4q f(q) D_1(\tilde{r} - \tilde{q}) \delta(r_1 - q_1) \delta(r_2 - q_2),$$

where $\tilde{q} = (q_0, q_3, 0, 0)$.

The solution of (2.16) can be written in the form:[31]

$$F(r') = \int d^3\Sigma_\alpha \int\int dr_1 dr_2 \left[F(r) \frac{\partial D(\tilde{r} - \tilde{r}')}{\partial \tilde{r}_\alpha} - D(\tilde{r} - \tilde{r}') \frac{\partial F(r)}{\partial \tilde{r}_\alpha} \right] \delta(r_1) \delta(r_2),$$

where $D(\tilde{r})$ satisfies the homogeneous differential equation $\Box_4 D(\tilde{r}) = 0$, with the initial conditions

$$D(\vec{r}) \Big|_{r_0=0} = 0 \quad \text{and} \quad \frac{\partial D}{\partial r_0}(\vec{r}) \Big|_{r_0=0} = \prod_{i=1}^{3} \delta(r_i).$$

The first condition implies that $D(\tilde{r})$ is an odd function, with the result that

$$D(\tilde{r}) = \int d^4z e^{-i\tilde{z}\tilde{r}} \epsilon(z_0) \delta(\tilde{z}^2) = \epsilon(r_0) \delta(\tilde{r}^2). \tag{2.17}$$

We note here that the surface Σ is three-dimensional and not five-dimensional as it is in the commutative case with light-cone causality condition. Now we can express $f(q)$ using (2.14) as

$$f(q) = F(\hat{q}) = \int dr_1 dr_2 \delta(r_1 - q_1) \delta(r_2 - q_2) \int d^3\Sigma_\alpha \left[F(r) \frac{\partial D(\tilde{r} - \tilde{q})}{\partial \tilde{r}_\alpha} - D(\tilde{r} - \tilde{q}) \frac{\partial F(r)}{\partial \tilde{r}_\alpha} \right]. \tag{2.18}$$

Due to the arbitrariness of the surface Σ, one can reduce the integration over r_4 and r_5, using the cylindrical symmetry, to the integral over $\kappa^2 = r_4^2 + r_5^2$. Subsequently, we change the notation of variables r_i to u_i and use the explicit form of $D(\tilde{r})$ from (2.17) to obtain

$$\begin{aligned} f(q) = & \int du_1 du_2 \delta(u_1 - q_1) \delta(u_2 - q_2) \int d^1\Sigma_j d\kappa^2 \\ & \times \left\{ F(u, \kappa^2) \frac{\partial}{\partial \tilde{u}_j} [\epsilon(u_0 - q_0) \delta((\tilde{u} - \tilde{q})^2 - \kappa^2)] - \epsilon(u_0 - q_0) \delta((\tilde{u} - \tilde{q})^2 - \kappa^2) \frac{\partial F(u, \kappa^2)}{\partial \tilde{u}_j} \right\}. \end{aligned} \tag{2.19}$$

Using the standard mathematical procedure[31] for performing the integration in (2.19), we obtain the Jost-Lehmann-Dyson representation in NC QFT, satisfying the light-wedge causality condition (2.3),

$$f(q) = \int d^4u d\kappa^2 \epsilon(q_0 - u_0) \delta[(q_0 - u_0)^2 - (q_3 - u_3)^2 - \kappa^2] \times \delta(q_1 - u_1) \delta(q_2 - u_2) \phi(u, \kappa^2), \tag{2.20}$$

where $\phi(u, \kappa^2) = -[\partial F(u, \kappa^2)] / \partial \tilde{u}_0$.

Equivalently, denoting $\tilde{u} = (u_0, u_3)$, (2.20) can be written as

$$f(q) = \int d^2\tilde{u} d\kappa^2 \epsilon(q_0 - u_0) \delta[(\tilde{q} - \tilde{u})^2 - \kappa^2] \phi(\tilde{u}, q_1, q_2, \kappa^2). \tag{2.21}$$

The function $\phi(\tilde{u},q_1,q_2,\kappa^2)$ is an arbitrary function, except that the requirement of spectral condition determines a domain in which $\phi(\tilde{u},q_1,q_2,\kappa^2)=0$. This domain is outside the region where the δ function in (2.21) vanishes, i.e.,

$$(\tilde{q}-\tilde{u})^2-\kappa^2=0, \tag{2.22}$$

but with $\tilde{q}$ in the region given by (2.8), where $f(q)=0$. Putting together (2.22) and (2.8), we obtain the domain out of which $\phi(\tilde{u},q_1,q_2,\kappa^2)=0$,

$$\begin{aligned} &\text{a)} \quad \tfrac{1}{2}(\tilde{p}+\tilde{p}')\pm\tilde{u} \text{ are in the forward lightwedge (cf. (2.4));} \\ &\text{b)} \quad \kappa \geqslant \max\left\{0,\tilde{m}_1-\sqrt{\left(\frac{\tilde{p}+\tilde{p}'}{2}+\tilde{u}\right)^2},\tilde{m}_2-\sqrt{\left(\frac{\tilde{p}+\tilde{p}'}{2}-\tilde{u}\right)^2}\right\}. \end{aligned} \tag{2.23}$$

For the purpose of expressing the scattering amplitude, we actually need the Fourier transform $f_R(q)$ of the retarded commutator,

$$f_R(x)=\theta(x_0)f(x)=\left\langle p'\left|\,\theta(x_0)\left[j\left(\frac{x}{2}\right),j'\left(-\frac{x}{2}\right)\right]\right|p\right\rangle. \tag{2.24}$$

Using (2.24) and the Fourier transformation $f(x)=\int dq' e^{-iq'x}f(q')$, we can express $f_R(q)$ as follows:

$$f_R(q)=\int dx e^{iqx}f_R(x)=\int dx e^{iqx}\theta(x_0)f(x)=\int dq' f(q')\int dx e^{i(q-q')x}\theta(x_0). \tag{2.25}$$

Taking into account that

$$\int dx_0 e^{i(q-q')x}\theta(x_0)=-i\frac{e^{i(\vec{q}-\vec{q}')\vec{x}}}{q_0-q_0'},$$

Eq. (2.25) becomes

$$f_R(q)=i\int dq_0'\frac{f(q_0',\vec{q})}{q_0'-q_0}.$$

Now, in the above formula we introduce the Jost-Lehmann-Dyson representation (2.21), with the result

$$f_R(q)=i\int\frac{dq_0'}{q_0'-q_0}\int d^2\tilde{u}d\kappa^2\epsilon(q_0'-u_0)\delta[(q_0'-u_0)^2-(q_3-u_3)-\kappa^2]\phi(\tilde{u},q_1,q_2,\kappa^2). \tag{2.26}$$

In (2.26) one can integrate over q_0', using the known formula of integration with a δ-function, $\int G(x)\delta(g(x))dx=\Sigma_i G(x_{0i})/\partial g/\partial x|_{x=x_{0i}}$, where x_{0i} are the simple roots of the function $g(x)$. We identify in (2.26) $G(q_0')=[\epsilon(q'0-u_0)]/(q_0'-q_0)$ and $g(q_0')=(q_0'-u_0)^2-(q_3-u_3)-\kappa^2$ (with the roots $q_0'=u_0\pm[(q_3-u_3)^2+\kappa^2]^{1/2}$).

With these considerations, from (2.26) we obtain the NC version of the Jost-Lehmann-Dyson representation for the retarded commutator,

$$f_R(q)=\int d^2\tilde{u}d\kappa^2\frac{\phi(\tilde{u},q_1,q_2,\kappa^2)}{(q_0-u_0)^2-(q_3-u_3)^2-\kappa^2}. \tag{2.27}$$

Compared to the usual Jost-Lehmann-Dyson representation,

$$f_R^{\text{comm}}(q) = \int d^4u d\kappa^2 \frac{\phi(u,\kappa^2)}{(q_0-u_0)^2-(\vec{q}-\vec{u})^2-\kappa^2}, \tag{2.28}$$

the expression (2.27) is essentially different in the sense that the arbitrary function ϕ now depends on q_1 and q_2. This feature will have further crucial implications in the discussion of analyticity of the scattering amplitude in $\cos\Theta$.

A. (Non-)Analyticity of the scattering amplitude in $\cos\Theta$

In the center-of-mass system (CMS) and in a set in which the incoming particles are along the vector $\vec{\beta}=(0,0,\theta)$, the scattering amplitude in NC QFT depends still on only two variables, the CM energy E and the cosine of the scattering angle, $\cos\Theta$ (for a discussion about the number of variables in the scattering amplitude for a general type of noncommutativity, see Ref. 29). [The 'magnetic' vector $\vec{\beta}$ is defined as $\beta_i = 1/2\,\epsilon_{ijk}\theta_{jk}$. The terminology stems from the antisymmetric background field $B_{\mu\nu}$ (analogous to $F_{\mu\nu}$ in QED), which gives rise to noncommutativity in string theory, with $\theta_{\mu\nu}$ essentially proportional to $B_{\mu\nu}$ (see, e.g., Ref. 1).]

Depending on the variable in which the analyticity is considered, one chooses an appropriate reduction formula for the scattering amplitude, such that in a given frame all the dependence on the considered variable is contained only in the exponent. Since we are interested in the analyticity in $\cos\Theta$, it is natural to take the reduction

$$M(E,\cos\Theta) = i\int d^4x e^{i(k'-p')\cdot(x/2)}\theta(x)\left\langle 0\left|\left[j_1\left(\frac{x}{2}\right),j_2\left(-\frac{x}{2}\right)\right]\right|p,k\right\rangle,$$

where $-1/2(k'-p')=q$, such that in the center-of-mass frame the whole dependence on $\cos\Theta$ is contained in q (j_1 and j_2 are the appropriate currents, corresponding to the outgoing particles of momenta p' and k'). The previous expression of the scattering amplitude $M(E,\cos\Theta)$ considered as a function of the complex vector $q=-1/2(k'-p')$ can be treated along the same lines as the retarded matrix element $f_R(q)$ between one-particle states introduced above in Eq. (2.25). This treatment results in a Jost-Lehmann-Dyson representation similar to (2.27), which therefore allows one to write the scattering amplitude as follows (compare with the expression given in Ref. 21 for the commutative case):

$$M(E,\cos\Theta) = i\int d^2\tilde{u} d\kappa^2 \frac{\phi(\tilde{u},\kappa^2,k+p,(k'-p')_{1,2})}{\left[\frac{1}{2}(\tilde{k}'-\tilde{p}')+\tilde{u}\right]^2-\kappa^2}, \tag{2.29}$$

where $\phi(\tilde{u},\kappa^2,\ldots)$ is a function of its $O(1,1)$- and $SO(2)$-invariant variables: $u_0^2-u_3^2$, $(k_0+p_0)^2-(k_3-p_3)^2$, $(k_1+p_1)^2+(k_2+p_2)^2$, $(k_1'-p_1')^2+(k_2'-p_2')^2,\ldots$. The function ϕ is zero in a certain domain, determined by the causal and spectral conditions, but otherwise arbitrary.

For the discussion of analyticity of $M(E,\cos\Theta)$ in $\cos\Theta$, it is of crucial importance that all dependence on $\cos\Theta$ be contained in the denominator of (2.29). But, since the *arbitrary* function ϕ depends now on $(k'-p')_{1,2}$, it also depends on $\cos\Theta$. This makes impossible the mere consideration of any analyticity property of the scattering amplitude in $\cos\Theta$.

Since the Jost-Lehmann-Dyson representation reflects the effect of the causal and spectral axioms, we notice that the hypotheses (2.3) and (2.4) used for the present derivation allow for a much larger physical region, by not taking into account at all the effect of the NC coordinates x_1 and x_2. One might wonder now whether in the above derivation there is any condition which could be subject to challenge. In that case there might also appear the possibility that an analyticity domain can be obtained, leading to some high-energy upper bound on the scattering amplitude.

III. CAUSALITY IN NC QFT

A. Causality and symmetry in NC QFT

In the following, we shall challenge the causality condition (2.3):

$$f(x)=0, \quad \text{for } \tilde{x}^2 \equiv x_0^2 - x_3^2 < 0, \tag{3.1}$$

which takes into account *only* the variables connected with the $O(1,1)$ symmetry.

This causality condition is suitable in the case when the nonlocality in the NC variables x_1 and x_2 is *infinite*. The fact that in the causality condition (3.1) the coordinates x_1 and x_2 do not enter means that the propagation of a signal in this plane is instantaneous: *no matter how far apart in the noncommutative coordinates two events are*, the allowed region for correlation is given by only the condition $x_0^2 - x_3^2 > 0$, which involves the propagation of a signal only in the x_3-direction, while the time for the propagation along x_1- and x_2-directions is totally ignored.

Recall that we are using an axiomatic approach, in whose commutative counterpart the assumption of locality was a postulate. In our noncommutative case, the postulate of locality has to be replaced by a postulate prescribing the scale of nonlocality. Postulating that the scale of nonlocality in x_1 and x_2 is $l \sim \sqrt{\theta}$, then the propagation of the interaction in the noncommutative coordinates is instantaneous *only within this distance l*. It follows then that two events are correlated, i.e., $f(x) \neq 0$, when $x_1^2 + x_2^2 \leqslant l^2$ (where $x_1^2 + x_2^2$ is the distance in the NC plane with $SO(2)$ symmetry), provided also that $x_0^2 - x_3^2 \geqslant 0$ (the events are timelike separated in the sense of $O(1,1)$). Adding the two conditions, we obtain that

$$f(x) \neq 0, \quad \text{for } x_0^2 - x_3^2 - (x_1^2 + x_2^2 - l^2) \geqslant 0. \tag{3.2}$$

The negation of condition (3.2) leads to the conclusion that the locality condition should indeed be given by

$$f(x)=0, \quad \text{for } \tilde{x}^2 - (x_1^2 + x_2^2 - l^2) \equiv x_0^2 - x_3^2 - (x_1^2 + x_2^2 - l^2) < 0,$$

or, equivalently,

$$f(x)=0, \quad \text{for } x_0^2 - x_3^2 - (x_1^2 + x_2^2) < -l^2, \tag{3.3}$$

where l^2 is a constant proportional to the NC parameter θ. When $l^2 \to 0$ (3.3) becomes the usual locality condition.

When $x_1^2 + x_2^2 > l^2$, for the propagation of a signal only the difference $x_1^2 + x_2^2 - l^2$ is time-consuming and thus in the locality condition it is the quantity $x_0^2 - x_3^2 - (x_1^2 + x_2^2 - l^2)$ which will occur. Therefore, we shall have again the locality condition of the form (3.3).

Since there is no noncommutativity in the momentum space, the spectral condition will read now as

$$p_0^2 - p_1^2 - p_2^2 - p_3^2 \geqslant 0, \quad p_0 > 0. \tag{3.4}$$

At this point we recall that the maximal symmetry of a NC QFT with $\theta_{\mu\nu}$ a constant matrix is not the classical $O(1,1) \times SO(2)$ symmetry, but a quantum symmetry, namely the twisted Poincaré symmetry,[26] whose representation content is identical to the usual Poincaré symmetry. Moreover, the usual space–time interval $x^2 = x_0^2 - x_1^2 - x_2^2 - x_3^2$ is invariant under the twisted Poincaré algebra, as well as the scale of nonlocality l, since the latter is expressed in terms of the twisted Poincaré-invariant θ. Consequently (3.3) and (3.4) are compatible with the twisted Poincaré algebra.

In fact, the consideration of nonlocal theories of the type (3.3) and (3.4) was initiated by Wightman.[30] It was proven later[31–33] (see also Ref. 34) that, indeed, in a quantum field theory which satisfies the translational invariance and the spectral axiom (3.4), the nonlocal commutativity

$$\left[j_1\left(\frac{x}{2}\right), j_2\left(-\frac{x}{2}\right)\right] = 0, \quad \text{for } x_0^2 - x_1^2 - x_2^2 - x_3^2 < -l^2$$

implies the local commutativity

$$\left[j_1\left(\frac{x}{2}\right), j_2\left(-\frac{x}{2}\right)\right] = 0, \quad \text{for } x_0^2 - x_1^2 - x_2^2 - x_3^2 < 0. \tag{3.5}$$

This powerful theorem (stating the "global nature of local commutativity"), which does not require standard Lorentz invariance, but only translational invariance, can be applied in the noncommutative case with postulated finite nonlocality, with the conclusion that the causality properties of a QFT with space–space noncommutativity are physically identical to those of the corresponding commutative QFT.

It is then obvious that the Jost-Lehmann-Dyson representation (2.28) obtained in the commutative case holds also on the NC space for any orientation of the vector $\vec{\beta}$. Consequently, the NC two-particle→two-particle scattering amplitude will have the same form as in the commutative case,

$$M(E, \cos\Theta) = i \int d^4u d\kappa^2 \frac{\phi(u, \kappa^2, k+p)}{\left[\frac{1}{2}(k'-p') + u\right]^2 - \kappa^2}. \tag{3.6}$$

This leads to the analyticity of the NC scattering amplitude in $\cos\Theta$ in the analog of the Lehmann ellipse, which behaves at high energies E the same way as in the commutative case, i.e., with the semimajor axis as

$$y_L = (\cos\Theta)_{\max} = 1 + \frac{\text{const}}{E^4}. \tag{3.7}$$

1. Enlargement of the domain of analyticity in $\cos\Theta$ *and use of unitarity. Martin's ellipse*

Two more ingredients are needed in order to enlarge the domain of analyticity in $\cos\Theta$ to the Martin's ellipse and to obtain the Froissart-Martin bound: the dispersion relations and the unitarity constraint on the partial-wave amplitudes.[22]

When using the causality condition (2.3), the forward dispersion relation cannot be obtained in NC theory with general direction of the $\vec{\beta}$-vector.[2] However, the conclusion at which we arrived by imposing the nonlocal commutativity condition (3.3) and reducing it to the local commutativity (3.5) leads straightforwardly to the usual forward dispersion relation also in the NC case with a general $\vec{\beta}$ direction.

As for the unitarity constraint on the partial wave amplitudes, the problem has been investigated in Ref. 29, for a general case of noncommutativity $\theta_{\mu\nu}$, $\theta_{0i} \neq 0$. For space–space noncommutativity ($\theta_{0i}=0$), the scattering amplitude depends, besides the center-of-mass energy, E, on three angular variables. In a system where we take the incoming momentum $\vec{p}$ in the z-direction, these variables are the polar angles of the outgoing particle momentum, Θ and ϕ, and the angle α between the vector $\vec{\beta}$ and the incoming momentum. The partial-wave expansion in this case reads

$$A(E, \Theta, \phi, \alpha) = \sum_{l,l',m} (2l'+1) a_{ll'm}(E) Y_{lm}(\Theta, \phi) P_{l'}(\cos\alpha), \tag{3.8}$$

where Y_{lm} are the spherical harmonics and $P_{l'}$ are the Legendre polynomials.

Imposing the unitarity condition directly on (3.8) or using the general formulas given in Ref. 29, it can be shown that a simple unitarity constraint which involves single partial-wave amplitudes one at a time can be obtained only in a setting where the incoming momentum is orthogonal

to the NC plane (equivalently, it is parallel to the vector $\vec{\beta}$). In this case the amplitude depends only on one angle, Θ, and the unitarity constraint is reduced to the well-known one of the commutative case, i.e.,

$$\mathrm{Im}\, a_l(E) \geqslant |a_l(E)|^2. \tag{3.9}$$

For this particular setting, $\vec{p} \| \vec{\beta}$, it is then straightforward, following the prescription developed for commutative QFT, to enlarge the analyticity domain of scattering amplitude to Martin's ellipse with the semimajor axis at high energies as

$$y_M = 1 + \frac{\mathrm{const}}{E^2}, \tag{3.10}$$

and subsequently obtain the NC analog of the Froissart-Martin bound on the total cross section, in the CMS and for $\vec{p} \| \vec{\beta}$,

$$\sigma_{\mathrm{tot}}(E) \leqslant c \ln^2 \frac{E}{E_0}. \tag{3.11}$$

Thus, the unitarity constraint on the partial-wave amplitudes distinguishes a particular setting ($\vec{p} \| \vec{\beta}$) in which the Lehmann's ellipse can be enlarged to the Martin's ellipse and the Froissart-Martin bound can be obtained, with the assumption of finite nonlocality. Nevertheless, this does not necessarily exclude the possibility of obtaining a rigorous high-energy bound on the cross section for $\vec{p}$ not parallel to $\vec{\beta}$, and the issue deserves further investigation.

B. Causality and nonlocality in NC QFT

It was shown in the previous subsection that the violation of Lorentz invariance in itself does not forbid the existence of an analyticity domain of the scattering amplitude in $\cos\Theta$ and the derivation of a high-energy bound, compatible with the twisted Poincaré symmetry.

However, for the derivation of the analog of the Froissart-Martin bound the key ingredient was the assumption of finite nonlocality. This issue deserves a more thorough investigation, in the light of the Lagrangian models studied so far. We have to point out from the very beginning that the Lagrangian models have been studied up to at most two loops, and that no definite statement about the renormalizability of NC quantum field theories in general has been made so far.

It is well known that in NC QFT treated with the Weyl-Moyal correspondence (i.e., with the usual product of fields replaced by Moyal $\star$-product in the Lagrangian) the short distance (UV) effects are related to the long-distance (topological) features of the space–time. This fact was first noticed in Ref. 35, where it was shown that noncommutativity leads to UV-regular theories when at most one dimension of the space–time is noncompact. For the NC flat space–time UV-regularity is not achieved, but instead the exotic phenomenon of UV/IR mixing appears.[36] The physical meaning of this mixing is that at quantum level, even very low-energy processes receive contributions from high-energy virtual particles. The nonlocality is energy dependent, and for virtual particles of arbitrarily high energy, the nonlocality is arbitrarily large.

Another investigation leading to the same conclusion was performed in the first paper dealing with the causality in NC QFT in the Lagrangian approach.[15] There it was shown, through the study of a scattering process, that space–space NC ϕ^4 in $2+1$ dimensions is causal at macroscopical level. However the incident particles should be viewed as extended rigid rods, of the size θp, perpendicular to their momentum. In other words, the noncommutativity introduces an energy-dependent scale of spatial nonlocality θp.

Judging by the above-mentioned results obtained in specific NC models up to one-loop level, the previous analysis of analyticity and high-energy bounds in axiomatic NC QFT becomes inconclusive. It appears that the finite nonlocality condition (3.3) is solely a conjecture, but only based on this conjecture one can derive rigorously the analyticity properties and high-energy

bounds on the scattering amplitude (see Sec. III). We should recall, however, that the infinite nonlocality in NC QFT has been found up to one-loop level and there is no indication that the infinite nonlocality is not an artifact of perturbation theory.

Nevertheless, in the case of a *compact* noncommutative space–time, the NC QFT is finite, i.e., there are no UV divergences,[35] consequently no UV/IR mixing, and the range of nonlocality is finite. For such NC QFT the finite nonlocality is no longer a conjecture and one may reconsider the rigorous axiomatic derivation of the analyticity and high-energy bounds along the lines of Sec. III A.

IV. CONCLUSION AND DISCUSSIONS

In this paper we have tackled the problem of high-energy bounds on the two-particle $\rightarrow$two-particle scattering amplitude in NC QFT. The key issue in the analysis proved to be the scale of nonlocality of the quantum field theory on NC space–time.

We have found that, assuming infinite nonlocality and using the causal and spectral conditions (2.3) and (2.4) proposed in Ref. 28 for NC theories with $O(1,1)\times SO(2)$ symmetry, a new form of the Jost-Lehmann-Dyson representation (2.27) is obtained, which does not permit us to draw any conclusion about the analyticity of the scattering amplitude (2.29) in $\cos\Theta$. Therefore, the derivation of high-energy bounds on the scattering amplitude is impossible.

However, by postulating that the nonlocality in the noncommuting coordinates is finite, we were led to impose a new causality condition (3.3), which accounts for the finitness of the range of nonlocality and prevents the *instantaneous propagation of signals* in the *entire* noncommutative plane (x_1,x_2). We proved that the new causality condition, compatible also with the twisted Poincaré symmetry, is formally identical to the one corresponding to the commutative case (3.5), using the Wightman-Vladimirov-Petrina theorem.

Thus, with the assumption of finite nonlocality, the scattering amplitude in NC QFT is proved to be analytical in $\cos\Theta$ in the Lehmann ellipse, just as in the commutative case; moreover, dispersion relations can be written on the same basis as in commutative QFT. Finally, based on the unitarity constraint on the partial-wave amplitudes in NC QFT, we can conclude that, for theories with space–space noncommutativity ($\theta_{0i}=0$), the total cross section is subject to an upper bound (3.11) identical to the Froissart-Martin bound in its high-energy behavior, when the incoming particle momentum $\vec{p}$ is orthogonal to the NC plane.

Though the perturbative studies performed so far (up to one loop) indicate an infinite range of nonlocality as more plausible, it is not yet clear whether this is a mere artifact of the perturbation theory or not. Therefore, a clear-cut conclusion about the existence of high-energy bounds in NC QFT cannot be drawn, unless the question of the scale of nonlocality is elucidated. In perturbative terms, this is equivalent to the standing problem of UV/IR mixing. However, for compact noncommutative spaces, where the range of nonlocality is finite and the NC QFT models do not exhibit UV divergences, we trust that an analog of the Froissart-Martin bound holds.

Note added: Recently, the validity of the Froissart-Martin bound in NC QFT has been studied based on the AdS/CFT correspondence.[37] The original idea appeared in Ref. 38, where the AdS/CFT correspondence was used to infer the Froissart-Martin bound in high-energy QCD scattering. According to Ref. 37, the Froissart-Martin bound holds as well in NC QFT. This might appear to contradict the results of the present paper. However, in Ref. 37 the Froissart-Martin bound was derived in a specific scalar field model, perturbatively and essentially by using an IR cutoff brane. It turns out that in the considered toy model the Froissart-Martin bound is saturated in both the commutative and noncommutative directions; however, the size of the cross section is smaller in the commutative directions than in the noncommutative ones, with a ratio which depends only on the noncommutative parameter and the IR cutoff. This strongly suggests that the IR cutoff actually acts as a restriction on the range of nonlocality to a finite region in the noncommutative plane.

(Received 25 November 2005; accepted 29 July 2006; published online 13 September 2006)

We present the novel topological tensor currents to describe the infinitesimal thin higher-dimensional topological defects in the local $SO(n)$ gauge theory. The topological quantization of defects and the inner structure of the currents are obtained. As the generalization of Nielsen-Olesen local $U(1)$ field theory for Nambu string, the local $SO(n)$ gauge-invariant Lagrangian and the motion equation of the higher-dimensional topological defects are derived. Moreover, for closed defects, we study their important topological configuration, i.e., the higher-dimensional knotlike structures. Using the topological tensor currents and their preimages, we construct a series of metric independent integrals and prove their gauge independence. Similar to the helicity integral characterizing one-dimensional knotlike vortex filament, these topological invariants are evaluated to the generalized linking numbers of higher-dimensional knotlike defects. © *2006 American Institute of Physics.*

I. INTRODUCTION

Topological defects play an important role in many areas of physics. Generally speaking, in condensed matter systems they determine such phenomena as response to external stresses,[1,2] the nature of phase transitions,[3,4] or the approach to equilibrium after a quench into an ordered phase.[5] In particle physics, defects, sometimes called as solitons, act as either stable or long-lived elementary particles.[6,7] In quantum field theory, their existence means that the full nonperturbative theory may have a much richer structure than is apparent in perturbation theory.[8,9] As evidence of cosmological phase transitions in the early universe, topological defects remain somewhere in our universe, and can help to resolve the origin of large-scale structure formation and the anisotropies of the cosmic microwave background, as well as in various high-energy phenomena.[10–13] Various defects can be classified by their topological property and independent of concrete physical models. A systematic topological theory of defects has been extensively summarized by Mermin,[14] Anderson,[15] and Vilenkin.[11] Roughly speaking, topological defects represent regions in space–time where the order parameter (order parameter in condensed matter physics or Higgs field in particle physics) is frustrated. It cannot relax into the vacuum state by topological obstructions. The order parameter space may be identical with coset space G/H if the system has undergone a symmetry breaking $G \to H$. Correspondingly, the homotopy groups of coset space detect and classify the topological defects that can arise in this theory. A more detailed inner structure of defects and their evolution and correlation, which play a special role in certain cosmological[13] and phase ordering

[a)]Electronic mail: wsf0103@st.lzu.edu.cn

problems,[5] needs to study the topological density of defects. This has been carried out by Halperin[16] and exploited by Liu and Mazenko[17] in the case of point defects. Duan *et al.* have obtained the complete expression of the topological current of point defects (its time component is the density)[18] and generalized the case to line defects,[19] then to arbitrary dimensional defects.[20] The corresponding generalized topological tensor currents are defined in terms of direction field of the n-component order parameter $n^a=\phi^a/|\phi|(a=1,\ldots,n)$

$$J_0 = *\,(c_0\epsilon_{a_1a_2\cdots a_n}dn^{a_1}\wedge dn^{a_2}\wedge\cdots\wedge dn^{a_n}), \tag{1}$$

where * denote the Hodge star on $D+1$-dimensional (dim) Euclidean space–time R^{D+1} and c_0 is the normalized coefficient. These currents J_0 are natural conversed $*d*J_0=0$, whose Hodge star carry integer topological charges

$$\int_{R^{D+1}} *J_0 = \text{winding number } W,$$

where the coefficient c_0 is normalized as $1/[A(S^{n-1})(n-1)!]$ up to the sign **. Using ϕ-mapping theory,[21] the inner structure of topological currents can be demonstrated

$$J_0^{\mu_1\cdots\mu_{D+1-n}}(x)=\sum_{i=1}^{l}\beta_i\eta_i\int_{N_i}\delta^{D+1}(x-z_i(u))dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_{D+1-n}}, W=\sum_{i=1}^{l}\beta_i\eta_i, \tag{2}$$

where the Hopf index β_i and Brower degree η_i of zero points of order parameter ϕ^a characterize the topological charges of l $D-n$-dim defects which localized on their $D+1-n$-dim world volume N_i. The topological evolution of defects involving generating, annihilating, colliding, splitting, and merging can be described explicitly.[20] Obviously, these topological currents provide a unified framework for various defects in 3+1-dim space–time and the higher-dim extended objects, e.g., p–branes[22,23] which originate from M–theory[24,25] and the brane worlds[26–28] which have been the focus of a lot of attention recently, which may actually just represent topological defects in a higher-dimensional space.[29–34]

However, the topological currents made of order parameter ϕ have not obvious local gauge symmetry. This is a deficiency in this framework which seems to exclude the extensive local defects. Moreover, for the closed defects with dimension $\geqslant 1$, their nontrivial geometric configuration, namely, the (one-dim) knot and higher-dim knotlike structures should be demonstrated in a sound framework. Especially, the knotlike structure recently has attracted intense interest in disparate fields[35–38] since Faddev and Niemi[39] in a realistic 3+1-dim model found the knotlike structure appears as stable, finite energy solitons.

In this paper, we will present novel topological tensor currents with local SO(n) gauge symmetry in arbitrary $D+1$ dimensional Euclidean space–time. The desired local defects in these currents are explored as the higher-dim generalization of classical Abrikosov–Nielsen-Olesen (ANO) vortex[40,41] or instantons[42] for even-n case and of the 't Hooft–Polyakov magnetic monopole[43] for odd-n case. The quantized topological charges of these currents can be obtained under corresponding lower energy boundary conditions. For the topological defects with infinitesimal core size, these boundary conditions are naively extended to whole space except the locations of the defects. We hence obtain an essential result that the local topological currents act as above global topological currents. In other words, the local topological currents may actually describe the infinitesimal thin higher-dimensional local defects in terms of the inner structure of the global topological currents. As the generalization of Nielson-Olesien local $U(1)$ field theory[44] for Nambu string,[45] the local $SO(n)$ fields theory for higher-dimensional infinitesimal thin defects are also obtained. Moreover, using the local topological currents and their preimages, we construct a series of metric independent integrals and prove their gauge independence. Similar to the helicity integral characterizing one-dimensional knotlike vortex filament,[46] these topological invariants are

evaluated to the generalized linking numbers of higher-dimensional knotlike, infinitesimal thin defects. Thus, we perfect the unified framework for higher-dim topological defects in the context of topological currents.

II. TOPOLOGICAL TENSOR CURRENTS OF LOCAL HIGHER-DIM DEFECTS

In this paper, the desired local defects are restricted in $SO(n)$ gauge theory. We select this group because it is enough to accommodate various defects and it makes the framework compact and simple. Also, due to the latter reason, we express the $SO(n)$ group and Higgs fields configuration in the notation of Clifford algebra valued differential form.[47] Consider an $SO(n)$ group, and define connection $\omega=\frac{1}{2}\omega_{\mu}^{ab}I_{ab}dx^{\mu}$, where $I_{ab}=\frac{1}{4}[\gamma_a,\gamma_b]$ is the generator of $SO(n)$ group, γ_a $(a=1,\ldots,n)$ and $\gamma=\gamma_1\gamma_2\cdots\gamma_n$ are the bases of Clifford algebra satisfied $\gamma_a\gamma_b+\gamma_b\gamma_a=2\delta_{ab}I$.[48] The curvature $F=d\omega-\omega\wedge\omega$. The n vector multiplet Higgs field $\phi=\phi^a\gamma_a$ with covariant derivative $D\phi=d\phi-[\omega,\phi]$.

On $D+1$-dim Euclidean space–time R^{D+1} we present two kinds of topological tensor currents with local $SO(n)$ gauge symmetry for even-$n=2r$ and odd-$n=2r+1$ cases, respectively,

$$J=\begin{cases} *a\ \mathrm{Tr}(\gamma F^r)=\ *a\ \mathrm{Tr}(\gamma F\wedge F\cdots\wedge F) & \text{for } n=2r \\ *b\ \mathrm{Tr}(\gamma D\phi F^r)=\ *b\ \mathrm{Tr}(\gamma D\phi F\wedge F\cdots\wedge F) & \text{for } n=2r+1, \end{cases}$$

where a,b are the normalized coefficients which will be given later. These currents J are natural conversed $*d*J=0$, i.e., $*J$ are the closed differential forms due to their invariant symmetries and the Bianchi identity $DF=0$. The topological charges of currents are defined as the integrals of the Hodge star of currents on a subspace R^n of total space–time R^{D+1},

$$Q=\int_{R^n} *J. \tag{3}$$

In $3+1$-dim space-time, they are proportional to the topological charges of ANO vortex for $n=2$ and 't Hooft–Polyakov magnetic monopole for $n=3$, respectively. The similar topological charge of general n cases has been discussed by Tchrakian[49] for generalized monopole on $n+1$-dim space-time $(D-n=0)$ and instantons on n-dim space-time $(D-n=-1)$. But we focus on imbedding the topological charge, exactly, the $*J$ to higher-dim $D+1$-dim space-time $(D-n>0)$. In other words, we explore the desired local defects as the higher-dim generalization (i.e., the extended objects, string, membrane, 3-brane,…) of classical ANO vortex for even-n case and of the 't Hooft–Polyakov magnetic monopole for odd-n case. It is well known that the finite energy conditions for these two classical defects need a converged field configuration at space infinity,[41,43] which may be generalized to higher-dim space R^D (Ref. 50)

$$F\to 0,\ \text{i.e.},\ \omega\to\text{pure gauge}; \tag{4}$$

$$D\phi\to 0,\quad \text{and}\quad |\phi|\to\text{vacuum value}. \tag{5}$$

Under these finite energy conditions, we can quantize topological charges of the topological tensor currents.

For even-$n=2r$ case we have

$$
\begin{aligned}
Q = a\int_{R^n} \mathrm{Tr}(\gamma F^r) &= ar\int_{R^n} d\int_0^1 dt\ \mathrm{Tr}(\gamma\omega F_t^{r-1}) \\
&= ar\int_{\partial R^n = S^{n-1}} \int_0^1 dt\ \mathrm{Tr}(\gamma\omega F_t^{r-1}) \\
&= \sum_{k=0}^{r-1}\left[(-1)^{r-k}\binom{r-1}{k}\frac{ar}{r+k}\right]\int_{S^{n-1}} \mathrm{Tr}[\gamma n(dn)^{n-1}] \\
&= \int_{S^{n-1}} \frac{1}{A(S^{n-1})(n-1)!}\epsilon_{a_1 a_2,\ldots,a_n} n^{a_1}\wedge dn^{a_2}\wedge\cdots\wedge dn^{a_n} = W. \qquad (6)
\end{aligned}
$$

In the above first equation, sign ** has been absorbed in normalized coefficient a; in the second equation, the Chern-Weil homomorphism[51] is used as $\omega_t = t\omega, F_t = td\omega - t^2\omega^2$; in the third equation, the Stokes theorem is used and the boundary of R^n at infinity is compact as $n-1$-dim sphere; in the fourth equation, we use the boundary condition (4) and set the pure gauge as dnn without losing the generalization, where unit vector n is well defined as the direction of Higgs field ϕ at infinity if the singularity of n, i.e., zero of ϕ has been localized inside the sphere. Noticing the trace formula about even-dim Clifford base $\mathrm{Tr}(\gamma\gamma_{a_1}\gamma_{a_2,\ldots,}\gamma_{a_n}) = \epsilon_{a_1 a_2\cdots a_n}(-1)^{n/2}2^{n/2}$, the normalized coefficient can be obtained in the fifth equation $a = 1/[A(S^{n-1})(n-1)!]/\Sigma_{k=0}^{r-1}\left[(-1)^k\binom{r-1}{k}\right][(r2^r)/(r+k)]$; the last equation is just the definition of winding number W.

For odd-$n = 2r+1$ case we have

$$
\begin{aligned}
Q = b\int_{R^n} \mathrm{Tr}(\gamma D\phi F^r) &= b\int_{R^n} d\ \mathrm{Tr}(\gamma\phi F^r) \\
&= b\int_{\partial R^n = S^{n-1}} \mathrm{Tr}(\gamma\phi F^r) \\
&= b(-4)^{-r}|\phi|_{\mathrm{vacuum}}\int_{S^{n-1}} \mathrm{Tr}[\gamma n(dn)^{n-1}] \\
&= \int_{S^{n-1}} \frac{1}{A(S^{n-1})(n-1)!}\epsilon_{a_1 a_2,\ldots,a_n} n^{a_1}\wedge dn^{a_2}\wedge\cdots\wedge dn^{a_n} = W. \qquad (7)
\end{aligned}
$$

The first, third, and last equations have similar derivation of the even-dim case. In the second equation, the invariant symmetries $\mathrm{Tr}(\gamma[\omega, n]F^r) + r\ \mathrm{Tr}(\gamma n[\omega, F]F^{r-1}) = 0$[51] and Bianchi identity $DF = 0$ have been used; in the fourth equation, we use the boundary condition (5), which may solve the connection as $\frac{1}{2}dnn$ without losing the generalization and replace the Higgs field as $\phi = |\phi|_{\mathrm{vacuum}} n$ at infinity. The unit vector n is well defined as even-dim cases. By another trace formula about odd-dim Clifford base $\mathrm{Tr}(\gamma\gamma_{a_1}\gamma_{a_2},\ldots,\gamma_{a_n}) = \epsilon_{a_1 a_2,\ldots,a_n}(-1)^{(n-1)/2}2^{(n-1)/2}$, the normalized coefficient can be obtained $b = 1/[A(S^{n-1})(n-1)!]/2^{-r}|\phi|_{\mathrm{vacuum}}$.

Hereto, the topological charges of tensor currents have been topologically quantized as $Q = W$. In $n = 2$ and 3, the topological charges degenerate as quantized magnetic flux of ANO vortex and quantized magnetic charge of 't Hooft–Polyakov magnetic monopole, respectively.

In the following, we progress to explore the inner structure of topological tensor currents and expect that they indeed describe the desired higher-dim defects. It is known that the framework for higher-dim defects in terms of topological tensor currents must be independent of concrete dynamic models, so we need to find the defects only involving topological information. It sounds difficult but in fact Nielsen and Olesen have pointed out[41] that the Ginzburg-Landau Lagrangian may only leave the δ-function-like vortex contribution if the vortex core is infinitesimally thin. And, this kind of vortex may be described by a Nielsen-Olesen Lagrangian[44] as the Nambu string which only carries the topological information of the world sheet of free string.[45] This argument

does not even rely on the detail of the Ginzburg-Landau Lagrangian. Here, we will generalize this idea to higher-dim defects. We notice an important result that the infinitesimal thin defects indeed mean that the boundary conditions (4) and (5) should be naively extended to whole space except for the location of defects.[52] Thus, without solving the concrete dynamic soliton solution, we still can discuss the behavior of topological currents. One can find F, $D\phi$, then both currents J are nonzero only on the location of infinitesimal thin defects. Since the extended boundary conditions are well defined except on the singularity of n, the infinitesimal thin defects should be localized on the zero points of Higgs fields ϕ for consistency. Moreover, observing the formulas (3), (6), and (7)

$$Q=\int_{R^n} {}^*J=\int_{S^{n-1}} \frac{1}{A(S^{n-1})(n-1)!}\epsilon_{a_1a_2,\ldots,a_n}n^{a_1}\wedge dn^{a_2}\wedge\cdots\wedge dn^{a_n},$$

and using the Stokes theorem, we have

$$\int_{R^n} {}^*J=\int_{R^n} \frac{1}{A(S^{n-1})(n-1)!}\epsilon_{a_1a_2,\ldots,a_n}dn^{a_1}\wedge dn^{a_2}\wedge\cdots\wedge dn^{a_n}=\int_{R^n} {}^*J_0,$$

where J_0 are just the global currents (1). Using the known ϕ-mapping theory,[21] we can prove the ${}^*J_0$ have the following structure:

$$\frac{1}{A(S^{n-1})(n-1)!}\epsilon_{a_1a_2,\ldots,a_n}dn^{a_1}\wedge dn^{a_2}\wedge\cdots\wedge dn^{a_n}=\delta(\vec{\phi})J\left(\frac{\phi}{x}\right), \tag{8}$$

where $J(\phi/x)$ is the Jacobian determinant $J(\phi/x)=1/n!\,\epsilon_{a_1,\ldots,a_n}\epsilon^{\mu_1\mu_2,\ldots,\mu_n}\partial_{\mu_1}\phi^{a_1}\cdots\partial_{\mu_n}\phi^{a_n}$. One can find that J_0 is nonzero only when $\vec{\phi}=0$, which is identical to the behavior of local currents J under extended boundary conditions. Hereto, we obtain an important result under extended boundary conditions

$$J=J_0.$$

This means the local currents J have the identical inner structure (2)

$$J^{\mu_1\cdots\mu_{D+1-n}}(x)=\sum_{i=1}^{l}\beta_i\eta_i\int_{N_i}\delta^{D+1}(x-z_i(u))dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_{D+1-n}}. \tag{9}$$

From this expression, we conclude that the constructed topological tensor currents J with local gauge symmetry may actually describe the l infinitesimal thin $D-n$-dim defects spanning the $D+1-n$-dim world volume N_i, which carry the quantized topological charges $\beta_i\eta_i$. It is one of the essential results of this paper. Moreover, as the generalization of Nielsen-Olesen $U(1)$ local field theory for Nambu string, we construct local $SO(n)$ gauge-invariant Lagrangian in $D+1$-dim Euclidean space–time,

$$L=\frac{1}{(D+1-n)!}\sqrt{J^{\mu_1\cdots\mu_{D+1-n}}J_{\mu_1\cdots\mu_{D+1-n}}}.$$

Substituting the inner structure of J (9) into the action of L, we obtain

$$S=\int_{R^{D+1}}Ld^{D+1}x=\sum_{i=1}^{l}\beta_i\eta_i\int_{N_i}\sqrt{g_u}d^{(D+1-n)}u=\sum_{i=1}^{l}\beta_i\eta_iS_i,$$

where S_i is the area of singular world volume N_i. This action is just the generalized Nambu action for multi $D-n$-dim local defects, which is the straightforward generalization of Nambu action for the string of $D-n=1$. From the principle of least action, we obtain the evolution equation of these higher-dim topological defects,

$$\frac{1}{\sqrt{g_u}}\frac{\partial}{\partial u^A}\left(\sqrt{g_u}g^{AB}\frac{\partial x^\mu}{\partial u^B}\right)=0,$$

where $A,B=1,\ldots,D+1-n$, $\mu=1,\ldots,D+1$ and g_u is the determinant of induced metric g^{AB} of world volume N_i. As a matter of fact, this is just the equation of harmonic map.[53]

III. HIGHER-DIM KNOTLIKE LOCAL DEFECTS

The knotlike structures should be characterized by knot or link invariants. At the classical level, a knot is characterized by helicity[46] or Hopf invariants.[54,55] The generalization of helicity based on the so-called Novikov invariants[56] recently have been proposed.[57] But they maintain Abelian gauge symmetry and describe the linking of the higher-dim knots with only codimension two. There are no non-Abelian higher-dim link invariants, at least to our knowledge. At the quantum level, the knot invariants include the linking number and its generalization have been rigorously considered in the known topological quantum field theory[58] as the vacuum expectation values of constructed Wilson line or surface operators. There are various methods[59–61] to evaluate the quantum operators. The simplest[59] is to compute their Gaussian integral directly, where an integral expression of the generalized linking number of p-dim knot N^p and $D-p-1$-dim knot N^{D-p-1} in D-dim spacelike manifold X is obtained,

$$Lk(N^p,N^{D-p-1})=\int_X d^{-1}j_{p+1}\wedge j_{D-p}, \tag{10}$$

where $j_{n=p+1,D-p}$ are the n-rank closed differential-form deRham currents satisfying

$$\int_X f_{D-n}(x)\wedge j_n(x)=\int_{N^{D-n}} f_{D-n}(y)$$

for any $D-n$-form f on the $D-n$-dim closed submanifold N^{D-n} of X.

Based on this expression of the generalized linking number, in this section we will construct the classical-level non-Abelian higher-dim link invariants to describe the infinitesimal thin local higher-dim knotlike defects in the topological tensor currents.

Observing the time component of topological currents in R^{D+1} space–time, one can easily find their Hodge star in D-dim space R^D

$$*J=*J_0=\left[\sum_{i=1}^{l}\beta_i\eta_i\int_{N_i}\delta^D(x-z_i(u))d^Dx\right],$$

where N_i represent infinitesimal thin $D-n$-dim defects (not world volume hereafter). If these defects N_i are *closed*, this Hodge star is just proportional to the deRham current, which can be formulated as

$$*J=\sum_{i=1}^{l}\beta_i\eta_i j_{D-n,i}, \tag{11}$$

where $j_{D-n,i}$ represents the ith $D-n$-rank deRham current in R^D. We have known that $*J$ have well-defined preimages on flat space R^D up to coefficients

$$(d^{-1} * J_n) = \begin{cases} \int_0^1 dt\, \mathrm{Tr}(\gamma\omega F_t^{r-1}) & \text{for } n = 2r \\ \mathrm{Tr}(\gamma\phi F^r) & \text{for } n = 2r+1, \end{cases} \tag{12}$$

where the subscript n on J denotes the rank of differential form $*J$. Using two kinds of $*J$ and their two kinds of preimages, we may construct the following four kinds of metric-independent integrals in a D-dim space R^D:

$$H = c\int_{R^D} (d^{-1} * J_{p+1}) \wedge * J_{D-p}, \tag{13}$$

where c are the normalized coefficients. Obviously, when $p+1$ is odd, these integrals H have local non-Abelian product gauge symmetry $SO(p+1)\times SO(D-p)$. Below, we will discuss the cases of even $p+1$. Consider the infinitesimal gauge transformation $\delta_v\omega = Dv$, $\delta_v F = [v, F]$. We know that $*J_{p+1}$ is gauge invariant and use its preimage (12)

$$\delta_v(*J_{p+1}) = \delta_v\left[d\int_0^1 dt\, \mathrm{Tr}(\gamma\omega F_t^{(p+1)/2-1}) \right] = d\,\delta_v\left[\int_0^1 dt\, \mathrm{Tr}(\gamma\omega F_t^{(p+1)/2-1}) \right] = 0.$$

According to Poincare's lemma,[51] the last equation implies $\delta_v[\int_0^1 dt\, \mathrm{Tr}(\gamma\omega F_t^{(p+1)/2-1})]$ can be written as an exact form on flat R^D

$$\delta_v\left[\int_0^1 dt\, \mathrm{Tr}(\gamma\omega F_t^{(p+1)/2-1}) \right] = dA.$$

We do not need to know the explicit expression of A, which can be determined similar to the well-known work of Zumino *et al.* for generalized chiral anomaly.[62] Now, we consider the infinitesimal gauge transformation of the integral for the even $p+1$ cases (13)

$$\delta_v H = c\int_{R^D} \delta_v\left[\int_0^1 dt\, \mathrm{Tr}(\gamma\omega F_t^{(p+1)/2-1}) \right] \wedge * J_{D-p} = c\int_{R^D} dA \wedge * J_{D-p} = c\int_{\partial R^D = S^{D-1}} A \wedge * J_{D-p} = 0,$$

where the third equation has used Stokes theorem and the last equation has used the boundary conditions (4) and (5). Hereto we have proved the gauge independence of the metric independent integrals, namely, which also have local non-Abelian product gauge symmetry $SO(p+1)\times SO(D-p)$. Thus, we indeed obtain four kinds of classical local non-Abelian topological invariants. Furthermore, substitute the relation between the topological currents and deRham currents (11) into the topological invariants (13) with respect to the integral expression of the generalized linking number (10), then we have

$$\begin{aligned} H = c\int_{R^D} (d^{-1} * J_{p+1}) \wedge * J_{D-p} &= \sum_{i=1}^{l} \beta_i\eta_i \sum_{j=1}^{k} \beta_j\eta_j \int_{R^D} (d^{-1} j_{p+1,i}) \wedge j_{D-p,j} \\ &= \sum_{i=1}^{l} \beta_i\eta_i \sum_{j=1}^{k} \beta_j\eta_j Lk(N_i^p, N_j^{D-p-1}). \end{aligned}$$

The topological invariants are evaluated as generalized linking numbers of l p-dim knots N_i^p and k $D-p-1$-dim knots N_j^{D-p-1} with quantized topological charges $\beta_i\eta_i$ and $\beta_j\eta_j$. In a given D-dim space, one can find that four kinds of topological invariants exactly describe the four types of generalized linking numbers of two odd-dim knots; two even-dim knots; one odd p-dim knot and one even $D-p-1$-dim knot; and one even p-dim knot and one odd $D-p-1$-dim knot. Correspondingly, the normalized coefficients are $-1, 1, 1, -1$, respectively. Especially, when $D=3$, the topological invariant degenerates as the helicity integral $H=\int_{R^3} A\wedge F$, which normally characterizes the linking number of one-dim knotlike vortex filament.[46]

IV. CONCLUSION

This paper describes a unified framework for higher-dim knotlike and local topological defects in terms of topological currents. We propose the novel topological tensor currents with local SO(n) gauge symmetry in arbitrary-dim Euclidean space–time. These topological currents have quantized topological charges and may actually describe the infinitesimal thin multi-higher-dim defects. As the generalization of Nielsen-Olesen local $U(1)$ field theory for Nambu string, the local $SO(n)$ gauge-invariant Lagrangian and the motion equation of the higher-dim topological defects are derived. In the theory of extra dimensions,[63] it is best to think of the brane world as the topological defect of almost-zero width, so we suggest that our theory for $D-N=4$ case can be applied to describe its topological structure. Moreover, we construct the classical-level non-Abelian higher-dim link invariants to characterize the higher-dim knotlike infinitesimal thin defects in the topological currents. This theory can be treated as the higher-dim generalization of well-known helicity theory.

(Received 19 December 2005; accepted 4 July 2006; published online 29 September 2006)

We construct Gepner models in terms of coset conformal field theories and compute their twisted equivariant K-theories. These classify the *D*-brane charges on the associated geometric backgrounds and therefore agree with the topological K-theories. We show this agreement for various cases, in particular, the Fermat quintic.
 [DOI: 10.1063/1.2245211]

I. INTRODUCTION

It is by now firmly established[1,2] that the K-theory groups of space-time are the *D*-brane charge groups. More precisely, the claim is that the isomorphism classes of *D*-brane boundary states modulo boundary renormalization group (RG) flow are in one to one correspondence[3] with suitable K-theory classes of the string theory background in question. For geometrical backgrounds such as Calabi-Yau manifolds, one can construct a variety of *D*-branes by applying methods from boundary CFT, matrix factorizations, and geometry.[4–11] However, determining the endpoint of the RG flow[12] is unfortunately not easy.

Most well understood in this context are purely geometrical backgrounds of string theory, such as tori, orbifolds, and Calabi-Yau manifolds. In these instances, the K-theories were either already available in the mathematics literature or are easily computed by standard techniques and the complementary string theory computation of D-brane charges is relatively straightforward.

Less trivial is the situation of string theory backgrounds with nontrivial NSNS three-form flux H, where it is believed that twisted K-theory is the correct structure to classify D-brane charges.[2,13,14] Explicit checks of this claim have so far been restricted to backgrounds with large symmetries, namely supersymmetric WZW and coset conformal field theories (CFT)s.[15–26] The computation of twisted K-theories for compact Lie groups and coset models thereof were greatly simplified by the theorem of Freed, Hopkins, and Teleman.[27–29]

Our objective in this paper is to test the twisted K-theory proposal beyond standard CFT backgrounds by extending it to Gepner models. These are essentially orbifolds of tensor products of $\mathcal{N}=2$ minimal models, realized for our purposes in terms of $SU(2)/U(1)$ supersymmetric coset models. They are known to describe certain tori and Calabi-Yau spaces at particular points in their moduli space. Because the K-groups are a topological quantity, the *D*-brane charge group should be independent of the moduli. Therefore the twisted equivariant K-theory of the Gepner models has to agree with the topological K-theory of the corresponding Calabi-Yau manifold. This provides a non-trivial check of the brane charge classification.

[a)]Electronic mail: vbraun@physics.upenn.edu

Technically, we are going to make use of the twisted equivariant Chern character. Consequently, we are going to compute the complexified K-groups,

$$K^*(X;\mathbb{C}) := K^*(X)\otimes_{\mathbb{Z}}\mathbb{C} \tag{1}$$

only. The downside is that one looses interesting torsion[30–32] information, since

$$K^*(X) = \mathbb{Z}^r \oplus \mathbb{Z}_{n_1} \oplus \cdots \oplus \mathbb{Z}_{n_k} \Rightarrow K^*(X;\mathbb{C}) = \mathbb{C}^r. \tag{2}$$

However, since none of the Calabi-Yau threefolds with Gepner points actually have torsion in their K group, we do not expect to find any in the Gepner models either.

During the final stage of this work, we received a preprint[11] that constructs a basis of *D*-branes for the *D*-brane charge group. We will discuss a few details of their approach in Sec. VI.

II. THE QUINTIC

As an hors d'œuvre to our work, let us discuss[4,33] the $(k=3)^5$ Gepner model. It is known to correspond to the Fermat quintic

$$Q = \left\{ [x_0{:}x_1{:}x_2{:}x_3{:}x_4] \,\middle|\, \sum_{i=0}^{4} x_i^5 = 0 \,\right\} \subset \mathbb{P}^4 \Bigg\}. \tag{3}$$

The Hodge diamond of the quintic is by now quite familiar to all string theorists, and reads

$$h^{pq}(Q) = \begin{array}{ccccccccc} & & & & 1 & & & & \\ & & & 0 & & 0 & & & \\ & & 0 & & 1 & & 0 & & \\ & 1 & & 101 & & 101 & & 1 & \\ & & 0 & & 1 & & 0 & & \\ & & & 0 & & 0 & & & \\ & & & & 1 & & & & \end{array} . \tag{4}$$

We also know that there is no torsion in its cohomology, which then determines its K-theory to be

$$K^0(Q) = H^{\text{even}}(Q;\mathbb{C}) = \mathbb{Z}^4 \Rightarrow K^0(Q;\mathbb{C}) = \mathbb{C}^4,$$

$$K^1(Q) = H^{\text{odd}}(Q;\mathbb{Z}) = \mathbb{Z}^{204} \Rightarrow K^1(Q;\mathbb{C}) = \mathbb{C}^{204}. \tag{5}$$

We are going to arrive at the same answer for the complexified K-groups directly from the Gepner model, without making any reference to the quintic hypersurface.

The Gepner model corresponding to the quintic is a $\mathbb{Z}_5$ orbifold of 5 copies of the level $k=3$ minimal model; see Secs. III B and III F for more details. Moreover, the minimal model can be realized as an $\mathfrak{su}(2)_k/\mathfrak{u}(1)$ coset CFT. The coset CFT has a nice sigma model interpretation; it is an $SU(2)$ WZW model with a gauged $U(1)$ action. More precisely, the $U(1)$ acts as

$$U(1)\times SU(2) \to SU(2), \quad \left[e^{i\theta}, \begin{pmatrix} a & b \\ c & d \end{pmatrix} \right] \mapsto \begin{pmatrix} \cos\frac{\theta}{2} & \sin\frac{\theta}{2} \\ -\sin\frac{\theta}{2} & \cos\frac{\theta}{2} \end{pmatrix} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \cos\frac{\theta}{2} & \sin\frac{\theta}{2} \\ -\sin\frac{\theta}{2} & \cos\frac{\theta}{2} \end{pmatrix}^{-1} . \tag{6}$$

[The cognoscente of course realize that our choice of maximal torus $U(1)\subset SU(2)$ is random. Since all maximal tori are conjugate, we just picked this one for explicitness.] Also see Fig. 1 for a picture of the orbits. The fixed point set of the $U(1)$ action is a circle inside $SU(2)\simeq S^3$, which we denote by

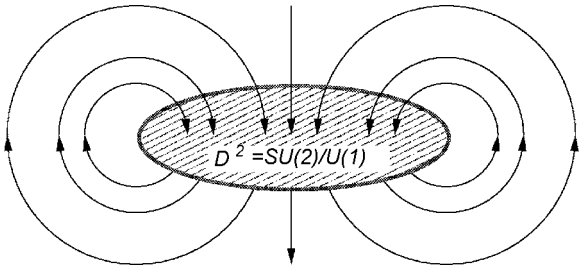

FIG. 1. $U(1)$ action on $SU(2)$.

$$S_A^1 \overset{\text{def}}{=} [SU(2)]^{U(1)} = \left\{ \begin{pmatrix} \cos\varphi & \sin\varphi \\ -\sin\varphi & \cos\varphi \end{pmatrix} \middle| \varphi \in [0, \ldots, 2\pi) \right\}. \tag{7}$$

(For any space X with action of a group G, we write X^G for the G-fixed points. If $g \in G$, then we write X^g for the points fixed by the subgroup $\langle g \rangle \subset G$.) The space of orbits $SU(2)/U(1)$ is a disk, bounded by the fixed points S_A^1. Rotating this disk is another symmetry of the geometry, but arbitrary rotations are not a symmetry of the theory. The reason is that the H field is not symmetric under arbitrary rotations of the disk. Rather, the rotation group is broken to rotations by $2\pi/5$. This $\mathbb{Z}_5$ group action lifts to an action on the $SU(2)$ with fixed point set S_B^1; see Fig. 2. The fixed point sets S_A^1 and S_B^1 form a Hopf link inside $SU(2) \simeq S^3$.

By now it is firmly established that the charge group is given by the K-theory of space-time. More precisely, one has to pick the right "flavor" of K-theory depending on which $\mathcal{N}=1$ supersymmetric theory one formulates on the background.[19,22,26,34] For the coset model, the background is $SU(2)$ with an H flux. The latter implies that the correct K-theory is the so-called twisted K-theory, which we denote by ${}^tK$. Moreover, we want to gauge a $U(1)$ symmetry. As is familiar to all string theorists, this does *not* mean that we work on the set theoretic quotient $SU(2)/U(1)$. Instead, we have to correctly incorporate the twisted sectors, which on the level of cohomology means that we have to compute the $U(1)$ equivariant cohomology groups. Therefore, the correct K-theory for the minimal model is

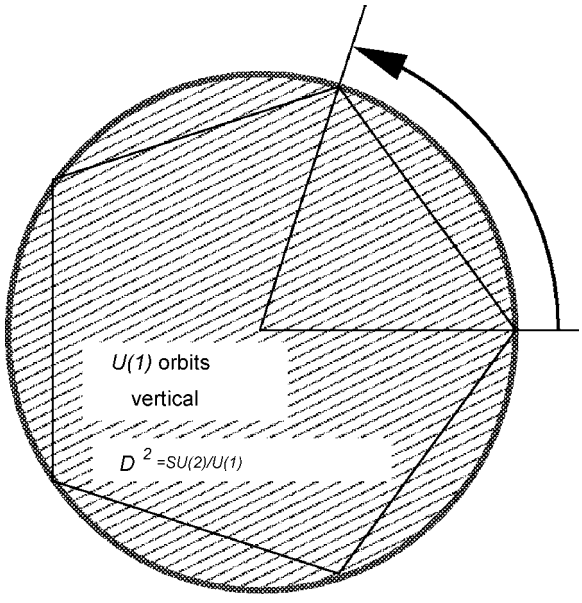

FIG. 2. $\mathbb{Z}_5$ action on $SU(2)$.

$$D\text{-brane charges in } \mathfrak{su}(2)_k/\mathrm{u}(1) \text{ coset} = {}^tK_{U(1)}(SU(2)), \tag{8}$$

with the twist class

$$t = k+2 \in \mathbb{Z} = H^3_{U(1)}(SU(2);\mathbb{Z}). \tag{9}$$

Hence, the D-brane charges in the tensor product of five minimal models are

$${}^tK_{U(1)\times U(1)\times U(1)\times U(1)\times U(1)}(SU(2)\times SU(2)\times SU(2)\times SU(2)\times SU(2)), \tag{10}$$

where each $U(1)$ acts on just one of the $SU(2)$ factors. Finally, the Gepner model is the $\mathbb{Z}_5$ orbifold by the diagonal $\mathbb{Z}_5$ action. Therefore

$$D\text{-brane charges in the } (k=3)^5 \text{ Gepner model} = {}^tK_{U(1)^5\times\mathbb{Z}_5}(SU(2)^5) \tag{11}$$

To compute these K-groups, we are using a twisted version of the equivariant Chern isomorphism,

$$\mathrm{ch}: K^{0,1}_G(X;\mathbb{C}) \xrightarrow{\sim} \bigoplus_{g\in G} H^{\mathrm{even,odd}}_G(X^g;\mathbb{C}). \tag{12}$$

(In this paper, we are only concerned with Abelian groups G. In general the sum is over conjugacy classes.) Adding an additional twist to the equivariant Chern character has two consequences. First, one is lead to twisted cohomology, which is roughly the cohomology of $d+[H]$ instead of d on differential forms. Second, the cohomology is with local coefficients, that is, with coefficients in a flat line bundle ${}^t\mathcal{L}$ instead of the trivial flat line bundle $\mathbb{C}$. The ensuing twisted equivariant Chern character (see Sec. III C)

$$\mathrm{ch}: {}^tK^*_G(X;\mathbb{C}) \to \bigoplus_{g\in G} {}^tH^*_G(X^g;{}^t\mathcal{L}(g)) \tag{13}$$

is an isomorphism, provided that only finitely many summands on the right are nonvanishing. This turns out to be the case here, and

$$\begin{aligned} {}^tK^*_{U(1)^5\times\mathbb{Z}_5}(SU(2)^5;\mathbb{C}) &\simeq \bigoplus_{g\in U(1)^5\times\mathbb{Z}_5} {}^tH^*_{U(1)^5\times\mathbb{Z}_5}([SU(2)^5]^g;{}^t\mathcal{L}(g)) \\ &= \bigoplus_{g\in U(1)^5\times\mathbb{Z}_5} [{}^tH^*_{U(1)^5}([SU(2)^5]^g;{}^t\mathcal{L}(g))]^{\mathbb{Z}_5} \end{aligned} \tag{14}$$

is indeed an isomorphism. More specifically, as we are going to show in Sec. III C the only contributions are from the 4^5+4 group elements

$$g = (\omega^{m_1},\omega^{m_2},\omega^{m_3},\omega^{m_4},\omega^{m_5},1), \quad m_i \in \{1,\ldots,4\}, \tag{15a}$$

$$g = (1,1,1,1,1,n), \quad n \in \{1,\ldots,4\}, \tag{15b}$$

in $U(1)^5\times\mathbb{Z}_5$, where we write $\omega \overset{\text{def}}{=} \exp(2\pi i/5)$. The corresponding fixed point sets are of the form

$$g = (\omega^{m_1},\omega^{m_2},\omega^{m_3},\omega^{m_4},\omega^{m_5},1) \Rightarrow [SU(2)^5]^g = (S^1_A)^5, \tag{16a}$$

$$g = (1,1,1,1,1,n) \Rightarrow [SU(2)^5]g = (S^1_B)^5. \tag{16b}$$

As we are going to discuss in more detail in the next section, the twisted equivariant cohomology for a single factor ${}^tH_{U(1)}(SU(2)^g;{}^t\mathcal{L}(g))$ for $g\in U(1)\times\mathbb{Z}_5$ is

$$g = (\omega^m,1) \Rightarrow {}^tH^0_{U(1)}(S^1_A;{}^t\mathcal{L}(g)) = 0, \quad {}^tH^1_{U(1)}(S^1_A;{}^t\mathcal{L}(g)) = \omega^m, \tag{17a}$$

$$g=(1,n)\Rightarrow {}^tH^0_{U(1)}(S^1_B;{}^t\mathcal{L}(g))=1,\quad {}^tH^1_{U(1)}(S^1_B;{}^t\mathcal{L}(g))=0, \tag{17b}$$

where we write the cohomology groups as $\mathbb{Z}_5$ characters. [By abuse of notation, we denote the generator for the character ring again ω. In other words, $m\in\mathbb{Z}_5=\{0,\ldots,4\}$ acts by multiplication with $\omega^m=\exp(2\pi im/5)$.] The cohomology groups for the tensor product of 5 such factors is readily determined from the Künneth formula, and one obtains

$$\bigoplus_{g=(\omega^{m_1},\ldots,\omega^{m_5},1)} {}^tH^*_{U(1)^5}((S^1_A)^5;{}^t\mathcal{L}(g))=\begin{cases}0, & *=0;\\ (\omega+\omega^2+\omega^3+\omega^4)^5, & *=5\equiv 1 \bmod 2;\end{cases} \tag{18a}$$

$$\bigoplus_{g=(1,\ldots,1,\omega^n)} {}^tH^*_{U(1)^5}((S^1_B)^5;{}^t\mathcal{L}(g))=\begin{cases}4, & *=0;\\ 0, & *=1.\end{cases} \tag{18b}$$

It is now easy to determine the $\mathbb{Z}_5$-invariant part. Using the twisted equivariant Chern character, Eq. (14), we obtain

$${}^tK^*_{U(1)^5\times\mathbb{Z}_5}(SU(2)^5;\mathbb{C})=\begin{cases}\mathbb{C}^4, & *=0;\\ [(\omega+\omega^2+\omega^3+\omega^4)^5]^{\mathbb{Z}_5}=\mathbb{C}^{204}, & *=1\end{cases} \tag{19}$$

which precisely equals the K-theory of the quintic hypersurface. (Perhaps not surprisingly, formally the same computation arises when one tries[35] to construct Gepner models using matrix factorizations. However, the authors of Ref. 35 fail to address the twisted sector branes that arise when the Gepner model contains minimal models of different levels.)

III. K-theory OF GEPNER MODELS

A. Group theory

As we saw in the quintic example discussed in Sec. II, one has to determine cohomology groups that form representations under a discrete group G_{GSO} ($=\mathbb{Z}_5$ for the quintic) that implements the GSO (After Gliozzi, Scherk, and Olive[36]) projection. Now we could always work with polynomials of characters as in Eq. (19), but this becomes cumbersome if one has to deal with tensor products of different minimal models.

For cyclic groups $\mathbb{Z}_\kappa$, the following representations will appear again and again. (In this paper, we are only going to consider complex representations.)

- The trivial representation $\mathbb{C}$.
- The regular representation $R\mathbb{Z}_\kappa$, which is defined as follows: Take the vector space $\mathbb{C}^\kappa$. The group acts by cyclically permuting the κ basis vectors. The regular representation can be diagonalized to the sum of all one-dimensional representations. Explicitly, if $\chi:\mathbb{Z}_\kappa\to\mathbb{C}$, $\chi(1)=\exp(2\pi i/\kappa)$ is the generating character, then

$$R\mathbb{Z}_\kappa=\bigoplus_{i=0}^{\kappa-1}\chi^i. \tag{20}$$

- The representation $\widetilde{R\mathbb{Z}_\kappa}$, which is the regular representation without its trivial subrepresentation,

$$\widetilde{R\mathbb{Z}_\kappa}=\bigoplus_{i=1}^{\kappa-1}\chi^i. \tag{21}$$

More formally, it is the cokernel

$$0 \to \mathbb{C} \to R\mathbb{Z}_\kappa \to \widetilde{R\mathbb{Z}}_\kappa \to 0. \tag{22}$$

Moreover, since we are actually computing cohomology groups, everything has a cohomological $\mathbb{Z}_2$ grade. By definition, we assign

$$\deg(\mathbb{C}) = 0, \tag{23a}$$

$$\deg(R\mathbb{Z}_\kappa) = \deg(\widetilde{R\mathbb{Z}}_\kappa) = 1. \tag{23b}$$

Of course, we have the usual operations of restriction and induction (transfer) to relate G_{GSO} representations and representations of subgroups of G_{GSO}. However, G_{GSO} is always a cyclic group and we have yet another operation that will occur frequently. This works as follows. Given any subgroup $\mathbb{Z}_\kappa \subset G_{\mathrm{GSO}}$, we have in addition to the inclusion i also a projection π,

$$\mathbb{Z}_\kappa \underset{\pi:\, n \mapsto n \bmod \kappa}{\overset{i:\, n \mapsto \frac{|G_{\mathrm{GSO}}|}{\kappa} n}{\rightleftarrows}} G_{\mathrm{GSO}} \simeq \mathbb{Z}_{|G_{\mathrm{GSO}}|} \tag{24}$$

by modding out by κ. Given a representation $\rho: \mathbb{Z}_\kappa \to \mathbb{C}^n$, we can then define a representation $p^{G_{\mathrm{GSO}}}_{\mathbb{Z}_\kappa}(\rho)$ of G_{GSO} on the same vector space $\mathbb{C}^n$ by composing

$$p^{G_{\mathrm{GSO}}}_{\mathbb{Z}_\kappa}(\rho) \overset{\mathrm{def}}{=} \rho \circ \pi : G_{\mathrm{GSO}} \to \mathbb{C}^n, (n,v) \mapsto \rho(n \bmod \kappa, v). \tag{25}$$

Now, in general, the projection π depends on which generators you chose for G_{GSO}, a random choice. However, for the identity, the regular, and the reduced regular representation of $\mathbb{Z}_\kappa$ the resulting G_{GSO} representation does *not* depend on that choice. We are only going to use the $p^{G_{\mathrm{GSO}}}_{\mathbb{Z}_\kappa}$ operation in these cases.

For example, consider the group $\mathbb{Z}_{12} = \{0, 1, \ldots, 11\}$ with the character $\chi(1) = e^{2\pi i/12}$. Then the representation

$$p^{\mathbb{Z}_{12}}_{\mathbb{Z}_3}(\widetilde{R\mathbb{Z}_3}) \otimes_{\mathbb{C}} p^{\mathbb{Z}_{12}}_{\mathbb{Z}_4}(\widetilde{R\mathbb{Z}_4}) = (\chi^4 + \chi^8)(\chi^3 + \chi^6 + \chi^9) = \chi + \chi^2 + \chi^5 + \chi^7 + \chi^{10} + \chi^{11}, \tag{26}$$

is the six-dimensional representation of $\mathbb{Z}_{12}$ of cohomology degree $2 \equiv 0 \bmod 2$ generated by

$$\mathrm{diag}(e^{2\pi i/12}, e^{4\pi i/12}, e^{10\pi i/12}, e^{14\pi i/12}, e^{20\pi i/12}, e^{22\pi i/12}). \tag{27}$$

In the future, we are just going to write $\otimes$, and it will be understood that we are tensoring over $\mathbb{C}$.

B. Minimal model as coset

The minimal models for the $\mathcal{N}=2$ superconformal algebra have equivalent realizations in terms of super-GKO coset models,

$$\frac{\mathfrak{su}(2)_k \oplus \mathfrak{u}(1)_2}{\mathfrak{u}(1)_{k+2}}, \tag{28}$$

as well as Landau-Ginzburg models. The modular invariant partition functions fall into an ADE classification.[37–39] From the coset CFT point of view these are obtained from the ADE modular invariants of the $\mathfrak{su}(2)_k$ WZW model. We shall focus on the A series minimal models. There are various subtleties concerning that modular invariant corresponds to the A-type superpotential, and it will turn out that there are essentially four distinct models that will be of interest. The fields of the coset CFT are labeled by (j,n,s), where $j = 0, \ldots, k/2$ is the $\mathfrak{su}(2)_k$ highest weight, $n \in \mathbb{Z}_{2(k+2)}$ labels the representations of the denominator $\mathfrak{u}(1)_{k+2}$ and $s \in \mathbb{Z}_4$ labels the free fermion representations in $\mathfrak{u}(1)_2$. There is a $\mathbb{Z}_{k+2} \times \mathbb{Z}_2$ discrete group acting on the fields in the following fashion:

$$\alpha:\Phi_{(j,n,s)} \mapsto (-1)^{2n/k+2}\Phi_{(j,n,s)},$$

$$\beta:\Phi_{(j,n,s)} \mapsto (-1)^{s}\Phi_{(j,n,s)}. \tag{29}$$

The $\mathbb{Z}_{k+2}$ action is realized geometrically in the gauged WZW model by the rotation of the disk target space. Orbifolding the A-type theory with respect to these symmetries yields new modular invariants, as was first observed in Ref. 15. Note that a related issue arose in the context of WZW models for nonsimply laced groups in Ref. 22, where nontrivial automorphisms acting on the fermions gave rise to new modular invariants for the supersymmetric WZW models.

Since $s=1,3$ corresponds to the Ramond sector, the orbifold by $\mathbb{Z}_2=\langle\beta\rangle$ is from a space-time point of view the same as modding out $(-1)^F$. The state space of the (charge conjugate) diagonal modular invariant is

$$\mathcal{H}_{MM_k} = \bigoplus_{(j,n,s)} \mathcal{H}_{(j,n,s)} \otimes \overline{\mathcal{H}}_{(j,n,s)}, \tag{30}$$

where the direct sum is over the standard range of super-parafermion representations, including the selection and identification rules

$$(j,n,s) \equiv (k/2-j,n+k+2,s+2), \quad 2j+n+s \in 2\mathbb{Z}. \tag{31}$$

The state space of the $\mathbb{Z}_2$ orbifold is then obtained as

$$\mathcal{H}_{MM_k/\mathbb{Z}_2} = \bigoplus_{(j,n,s)} \mathcal{H}_{(j,n,s)} \otimes \overline{\mathcal{H}}_{(j,n,-s)}. \tag{32}$$

Orbifolding MM_k by $\mathbb{Z}_{k+2}\times\mathbb{Z}_2$, it was observed in Ref. 15 that the partition function is the same as in MM_k, and that this model is, in fact, dual to MM_k. Likewise, $MM_k/\mathbb{Z}_{k+2}$ is T-dual to $MM_k/\mathbb{Z}_2$.

Gepner models are orbifolds of tensor products of minimal models with not necessarily equal level, which give rise to consistent GSO-projected string theory backgrounds. Consider a tensor product of r minimal models, of level $(k_1,\ldots,k_r)$, and define

$$\lambda = (j_1,\ldots,j_r), \quad \mu = (n_1,\ldots,n_r;s_1\ldots,s_r), \tag{33}$$

and $\beta_j=(0,\ldots,0,2,0,\ldots,0)$, with the nonzero entry at slot s_j and $\beta_0=(1,\ldots,1)$. Further define $K=lcm(2,k_j+2)$. Then the partition function for the Gepner model is given by

$$Z_{(k_1,\ldots,k_r)} = \sum_{\lambda,\mu}\sum_{b_0=0}^{2K-1}\sum_{b_j=0,1}\delta_\beta(-1)^{b_0}\chi_{\lambda,\mu}\overline{\chi}_{\lambda,\mu+b_0\beta_0+\Sigma b_j\beta_j}. \tag{34}$$

The characters of the tensor product of the minimal models are denoted by χ. In principle, one can define the conserved *D*-brane charges using RG flow,[3,40] but in practice this is not feasible.

C. Chern character of the minimal model

Now that we have defined all the ingredients, we can start to compute the relevant *K*-groups. Our main tool is going to be the twisted equivariant Chern character.[28,41] For explicitness, let us consider a single minimal model whose complexified *D*-brane charge group is

$${}^{\kappa}K_{U(1)}(SU(2))\otimes_{\mathbb{Z}}\mathbb{C} \overset{\text{def}}{=} {}^{\kappa}K_{U(1)}(SU(2);\mathbb{C}), \tag{35}$$

where $\kappa=k+2$ is going to be the twist class for the remainder of this section. [That is, the twist class is κ times the generator of $H^3_{U(1)}(SU(2);\mathbb{Z})$.] Now, given a twisted equivariant vector bundle, we can tensor it with any group representation, and get another equivariant vector bundle with the same twist. In other words, there is an action of $K_{U(1)}(\{\text{pt.}\};\mathbb{C})=RU(1)=\mathbb{C}[z,z^{-1}]$ on the twisted equivariant K-theory.

In geometrical terms, $\mathbb{C}[z,z^{-1}]$ is the ring of functions on $\mathbb{C}^\times \overset{\text{def}}{=} \mathbb{C}\backslash\{0\}$. And the twisted equivariant K-theory ${}^\kappa K_{U(1)}(SU(2);\mathbb{C})$ is a module over this function algebra, that is a sheaf over the base space $\mathbb{C}^\times$. The twisted equivariant Chern character identifies the stalks (fibers) of this sheaf over a point in $\mathbb{C}^\times$ with a certain cohomology group. More precisely, Freed-Hopkins-Teleman[28] identify the stalk over $\zeta \in \mathbb{C}^\times$ with

$$ {}^\kappa K^*_{U(1)}(SU(2);\mathbb{C})\big|_\zeta \simeq {}^\kappa H^*_{U(1)}(SU(2)^\zeta; {}^\kappa\mathcal{L}(\zeta)), \tag{36}$$

where ${}^\kappa\mathcal{L}(\zeta)$ is a certain flat line bundle. Note that when we say that ζ acts on $SU(2)$, we really mean that $\zeta/|\zeta| \in U(1)$ acts on $SU(2)$.

In general, the knowledge of the stalks is not enough to reconstruct the sheaf, for example, every fiber of a line bundle is just isomorphic to $\mathbb{C}$. However, in the case of a single minimal model, the sheaf turns out to be a skyscraper sheaf, and can indeed be reconstructed.

D. Twisted equivariant cohomology of the minimal model

In this section, we are going to determine the twisted equivariant cohomology groups that appear in the Chern character formula, Eq. (36). We advise the reader who is not interested in all the details to note the result, Eqs. (45a) and (45b), and then proceed with the next section.

In fact, the problem is very similar to ${}^\kappa K_{SU(2)}(SU(2);\mathbb{C})$ that is explicitly worked out as an example in Ref. 28. Depending on ζ, there are two different fixed point sets. One possibility is $\zeta \in \mathbb{R}_{>0}$, which acts trivially on the whole $SU(2)$. It turns out[28] that the line bundle ${}^\kappa\mathcal{L}(\zeta)$ is trivial in that case. Therefore, the *untwisted* equivariant cohomology is

$$ H^*_{U(1)}(SU(2)^\zeta; {}^\kappa\mathcal{L}(\zeta)) = H^*_{U(1)}(SU(2);\mathbb{C}) = \mathbb{C}[u,t]/u^2, \tag{37}$$

where we used the Leray spectral sequence

$$ H^p(BU(1); H^q(SU(2);\mathbb{C})) \Rightarrow H^{p+q}_{U(1)}(SU(2);\mathbb{C}) \tag{38}$$

with $t \in H^2(BU(1);\mathbb{C})$ of degree 2 and $u \in H^3(SU(2);\mathbb{C})$ of degree 3. To determine the twisted equivariant cohomology ${}^\kappa H^*_{U(1)}(SU(2);\mathbb{C})$ from the untwisted one, we have to mode out by the additional differential $d_3 = \kappa u$. (More formally, we are using the untwisted to twisted cohomology spectral sequence. Note that $(d_3)^2 \sim u^2 = 0$ in $\mathbb{C}[u,t]/u^2$.) An easy computation shows that

$$ {}^\kappa H^*_{U(1)}(SU(2)^\zeta; {}^\kappa\mathcal{L}(\zeta)) = {}^\kappa H^*_{U(1)}(SU(2);\mathbb{C}) = \frac{\ker(d_3)}{\mathrm{img}(d_3)} = 0. \tag{39}$$

This settles the case where the whole $SU(2)$ is fixed under the ζ action. The other possibility is the generic case where $SU(2)^\zeta = S^1_A$. In that case, the flat line bundle ${}^\kappa\mathcal{L}(\zeta)$ over S^1_A has[28] holonomy ζ^κ, so all cohomology groups vanish unless $\zeta^\kappa = 1$. In that case, that is over the $\kappa - 1$ points,

$$ \zeta_m \overset{\text{def}}{=} e^{2\pi i m/\kappa}, \quad m = 1, \ldots, \kappa - 1, \tag{40}$$

the untwisted cohomology is

$$ H^*_{U(1)}(S^1_A; {}^\kappa\mathcal{L}(\zeta_m)) = H^*(BU(1);\mathbb{C}) \otimes H^*(S^1_A; {}^\kappa\mathcal{L}(\zeta_m)) = \mathbb{C}[t] \otimes \mathbb{C}[v]/v^2 = \mathbb{C}[v,t]/v^2, \tag{41}$$

where $\deg(v) = 1$ and $\deg(t) = 2$. The twist class is in $H^3_{U(1)}(S^1_A; {}^\kappa\mathcal{L}(\zeta_m)) = \mathbb{C}\cdot tv$. Hence, if one normalizes the tv properly, then $d_3 = \kappa tv$. The d_3 cohomology is

$$ {}^{\kappa}H^{*}_{U(1)}(S^1_A;{}^{\kappa}\mathcal{L}(\zeta_m)) = \frac{\ker(d_3)}{\mathrm{img}(d_3)} = \mathbb{C}v = \begin{cases} \mathbb{C}, & *=1; \\ 0, & \text{otherwise}. \end{cases} \tag{42} $$

In addition to the $U(1)$ action on $SU(2)$, we can also act with $\mathbb{Z}_\kappa$. We find two more cases: the fixed point set can be either S^1_B or empty. The cohomology of the empty set, of course, vanishes. In the former case, note that $U(1)$ acts simply transitive on S^1_B, so the equivariant cohomology is just the cohomology of a point. To summarize, there are four different cases corresponding to different $g \in U(1)\times\mathbb{Z}_\kappa$. The twisted cohomology groups are (ignoring the $\mathbb{Z}_\kappa$ action on the cohomology and the precise degrees for now)

$$ g=(1,0) \Rightarrow {}^{\kappa}H^{*}_{U(1)}(SU(2)^g;{}^{\kappa}\mathcal{L}(g)) = {}^{\kappa}H^{*}_{U(1)}(SU(2);\mathbb{C}) = 0, \tag{43a} $$

$$ g=(\zeta,0) \Rightarrow {}^{\kappa}H^{*}_{U(1)}(SU(2)^g;{}^{\kappa}\mathcal{L}(g)) = {}^{\kappa}H^{*}_{U(1)}(S^1_A;{}^{\kappa}\mathcal{L}(g)) = \delta_{\zeta^\kappa,1}\mathbb{C}, \tag{43b} $$

$$ g=(1,n) \Rightarrow {}^{\kappa}H^{*}_{U(1)}(SU(2)^g;{}^{\kappa}\mathcal{L}(g)) = H^{*}_{U(1)}(S^1_B;\mathbb{C}) = H^{*}(\{\mathrm{pt}\,.\,\}) = \mathbb{C}, \tag{43c} $$

$$ g=(\zeta,n) \Rightarrow {}^{\kappa}H^{*}_{U(1)}(SU(2)^g;{}^{\kappa}\mathcal{L}(g)) = H^{*}_{U(1)}(\varnothing;\mathbb{C}) = 0, \tag{43d} $$

where we took $n \in \mathbb{Z}_\kappa\backslash\{0\}$ and $\zeta \in \mathbb{C}^\times\backslash\{1\}$.

All that remains is to determine the precise action of $\mathbb{Z}_\kappa$ on the cohomology group, Eq. (43b). For that, note that even though the line bundle ${}^{\kappa}\mathcal{L}(\zeta_m)$ in Eq. (41) is trivial, the trivializing section winds m times around the S^1_A relative to *the* trivial line bundle. Therefore rotating S^1_A by $2\pi/\kappa$ multiplies v with the phase $\exp(2\pi i m/\kappa)$. In terms of the character $\chi:\mathbb{Z}_\kappa\to U(1)$, $m\mapsto\exp(2\pi i m/\kappa)$, this means that

$$ \bigoplus_{\zeta\in\mathbb{C}^\times} {}^{\kappa}H^{*}_{U(1)}(SU(2)^\zeta;{}^{\kappa}\mathcal{L}(\zeta)) = \begin{Bmatrix} 0, & *=0 \\ \chi+\chi^2+\cdots+\chi^{\kappa-1}, & *=1 \end{Bmatrix} = \widetilde{R\mathbb{Z}}_\kappa, \tag{44} $$

as the $\mathbb{Z}_\kappa$ representation. In other words, we can write the twisted equivariant cohomology groups as

$$ n=0\in\mathbb{Z}_\kappa \Rightarrow \bigoplus_{\zeta\in\mathbb{C}^\times} {}^{\kappa}H^{*}_{U(1)}(SU(2)^{(\zeta,n)};{}^{\kappa}\mathcal{L}(\zeta,n)) = \widetilde{R\mathbb{Z}}_\kappa, \tag{45a} $$

$$ n\neq 0\in\mathbb{Z}_\kappa \Rightarrow \bigoplus_{\zeta\in\mathbb{C}^\times} {}^{\kappa}H^{*}_{U(1)}(SU(2)^{(\zeta,n)};{}^{\kappa}\mathcal{L}(\zeta,n)) = \mathbb{C}, \tag{45b} $$

using the conventions for cohomology degrees in Eqs. (23a), (23b).

E. Mirror symmetry for minimal models

As a quick application, let us compute the K-groups of the minimal model and its $\mathbb{Z}_\kappa$ orbifold. According to the twisted equivariant Chern character, the K-groups of the minimal model are

$$ {}^{\kappa}K^{*}_{U(1)}(SU(2);\mathbb{C}) = \bigoplus_{\zeta\in\mathbb{C}^\times} {}^{\kappa}H^{*}_{U(1)}(SU(2)^\zeta;{}^{\kappa}\mathcal{L}(\zeta)) = \widetilde{R\mathbb{Z}}_\kappa \simeq \begin{cases} 0, & *=0; \\ \mathbb{C}^{\kappa-1}, & *=1, \end{cases} \tag{46} $$

using the cohomology groups computed in Eq. (45a). We recover the known[19] *D*-brane charge groups for the coset minimal model.

Similarly, we can compute the *D*-brane charge group in the $\mathbb{Z}_\kappa$ orbifold, which is known to be the mirror of the minimal model. One obtains

$$\begin{aligned}
{}^{\kappa}K^{*}_{U(1)\times\mathbb{Z}_\kappa}\left(SU(2);\mathbb{C}\right) &= \bigoplus_{(\zeta,n)\in\mathbb{C}^\times\times\mathbb{Z}_\kappa} {}^{\kappa}H^{*}_{U(1)\times\mathbb{Z}_\kappa}\left(SU(2)^{(\zeta,n)};{}^{\kappa}\mathcal{L}(\zeta,n)\right)\\
&= \bigoplus_{n\in\mathbb{Z}_\kappa}\bigoplus_{\zeta\in\mathbb{C}^\times} {}^{\kappa}H^{*}_{U(1)\times\mathbb{Z}_\kappa}\left(SU(2)^{(\zeta,n)};{}^{\kappa}\mathcal{L}(\zeta,n)\right)\\
&= \bigoplus_{n\in\mathbb{Z}_\kappa}\left[\bigoplus_{\zeta\in\mathbb{C}^\times} {}^{\kappa}H^{*}_{U(1)}\left(SU(2)^{(\zeta,n)};{}^{\kappa}\mathcal{L}(\zeta,n)\right)\right]^{\mathbb{Z}_\kappa}\\
&= \left[\underbrace{\widetilde{R\mathbb{Z}}_\kappa}_{n=0}\oplus\underbrace{\mathbb{C}}_{n=1}\ominus\cdots\oplus\underbrace{\mathbb{C}}_{n=\kappa-1}\right]^{\mathbb{Z}_\kappa}\\
&= \mathbb{C}^{\kappa-1}\simeq\begin{cases}\mathbb{C}^{\kappa-1}, & *=0;\\ 0, & *=1.\end{cases}
\end{aligned}\tag{47}$$

Note that the $\mathbb{Z}_\kappa$ equivariant cohomology is simply the $\mathbb{Z}_\kappa$ invariant subspace of the cohomology group. For that, it is important to work with complex coefficients, because it would generate torsion contributions over the integers. Also note that the $\mathbb{Z}_\kappa$ equivariant K-theory is in general *not* the same as the $\mathbb{Z}_\kappa$ invariant K-groups.

To summarize, we observe that the $\mathbb{Z}_\kappa$ orbifold indeed exchanges $K^0\leftrightarrow K^1$, as we expect from the mirror involution. Furthermore, recall the distinction between *A*- and *B*-type branes.[15] The *A*-branes carry the charges in Eq. (45a), contributing to K^1 of the minimal model. On the other hand, the *B*-branes Eq. (45b), are only stable in the $\mathbb{Z}_\kappa$ orbifold of the minimal model where they contribute to K^0.

F. K-groups for Gepner models

Having tackled a single minimal model, we now proceed to Gepner models.[4,37–39] For that we take *d* copies of the $SU(2)$ with the action of *d* copies of $U(1)$ factor by factor. That is,

$$U(1)^d\times SU(2)^d\to SU(2)^d,\tag{48}$$

with a choice of twist

$$\overline{\kappa}=(\kappa_1,\kappa_2,\ldots,\kappa_d),\tag{49}$$

where $k_i=\kappa_i-2$ is the level in the CFT of the *i*th factor. The overall central charge is

$$c=\sum_{i=1}^{d}\frac{3k_i}{k_i+2}=\sum_{i=1}^{d}\frac{3(\kappa_i-2)}{\kappa_i}.\tag{50}$$

Whenever $c/3$ is integer, this could be the central charge of a geometric compactification of that dimension. However, a mere tensor product of minimal models is never geometric because of noninteger charges. In other words, it does not have space-times supersymmetry. The solution to this problem[37] is to orbifold by a certain discrete symmetry group G_{GSO}.

As we have seen, each of the minimal models has a discrete symmetry group $\mathbb{Z}_{\kappa_i}=\{0,1,\ldots,\kappa_i-1\}$. The GSO projection is the group generated by

$$(1,1,\ldots,1)\in\prod_{i=1}^{d}\mathbb{Z}_{\kappa_i}.\tag{51}$$

It follows that

$$G_{\mathrm{GSO}} = \mathbb{Z}_{\mathrm{lcm}(\kappa_1,\kappa_2,\ldots,\kappa_d)}. \tag{52}$$

According to the general dictionary between *D*-brane charge groups and K-theory group, the *D*-brane charges in the Gepner model are

$$\overline{{}^{\kappa}K}_{U(1)^d\times G_{\mathrm{GSO}}}(SU(2)^d). \tag{53}$$

We can again compute (the complexification) through the twisted equivariant Chern character. Once we translate the K-groups into cohomology, we can use the following:

- the G_{GSO} equivariant cohomology is the G_{GSO} invariant cohomology and
- the Künneth theorem for cohomology,

neither of which hold in general for twisted equivariant K-theory. Again, we have to complexify

$$U(1)^d \times G_{\mathrm{GSO}} \rightsquigarrow (\mathbb{C}^\times)^d \times G_{\mathrm{GSO}} \tag{54}$$

and think of the cohomology and K-groups as sheaves over this space. According to Sec. III D, the only potentially nonvanishing cohomology groups for the ith minimal model sit over the κ_ith roots of unity,

$$\mathcal{Z}_i \overset{\mathrm{def}}{=} \{e^{2\pi i m/\kappa_i} | m \in \mathbb{Z}_{\kappa_i} = \{0,\ldots,\kappa_i - 1\}\} \subset \mathbb{C}^\times, \tag{55}$$

therefore the only nonvanishing cohomology groups of the product are over the points

$$\mathcal{Z} \overset{\mathrm{def}}{=} \prod_{i=1}^{d} \mathcal{Z}_i = \{(e^{2\pi i m_1/\kappa_1},\ldots,e^{2\pi i m_d/\kappa_d} | m_i \in \mathbb{Z}_{\kappa_i}\} \subset (\mathbb{C}^\times)^d. \tag{56}$$

Using all that, we obtain

$$\begin{aligned}
\overline{{}^{\kappa}K}^{*}_{U(1)^d}(SU(2)^d;\mathbb{C}) &= \bigoplus_{g\in G_{\mathrm{GSO}}}\left[\bigoplus_{\overline{z}\in(\mathbb{C}^\times)^d} \overline{{}^{\kappa}H}^{*}_{U(1)^d}\left(\bigtimes_{i=1}^{d} SU(2)^{(z_i,g)}; \bigotimes_{i=1}^{d} {}^{\kappa_i}\mathcal{L}(z_i,g)\right)\right]^{G_{\mathrm{GSO}}} \\
&= \bigoplus_{g\in G_{\mathrm{GSO}}}\left[\bigoplus_{\overline{z}\in\mathcal{Z}} \overline{{}^{\kappa}H}^{*}_{U(1)^d}\left(\bigtimes_{i=1}^{d} SU(2)^{(z_i,g)}; \bigotimes_{i=1}^{d} {}^{\kappa_i}\mathcal{L}(z_i,g)\right)\right]^{G_{\mathrm{GSO}}} \\
&= \bigoplus_{g\in G_{\mathrm{GSO}}}\left[\bigotimes_{i=1}^{d}\left\{\bigoplus_{z_i\in\mathcal{Z}_i} {}^{\kappa_i}H^{*}_{U(1)}(SU(2)^{(z_i,g)}; {}^{\kappa_i}\mathcal{L}(z_i,g))\right\}\right]^{G_{\mathrm{GSO}}}.
\end{aligned} \tag{57}$$

Note that according to Eqs. (45a) and (45b),

$$\bigoplus_{z_i\in\mathcal{Z}_i} {}^{\kappa_i}H^{*}_{U(1)}(SU(2)^{(z_i,g)}; {}^{\kappa_i}\mathcal{L}(z_i,g)) = \begin{cases} \widetilde{R\mathbb{Z}}_{\kappa_i}, & g \equiv 0 \bmod \kappa_i \Leftrightarrow \kappa_i | g; \\ \mathbb{C}, & \kappa_i \nmid g. \end{cases} \tag{58}$$

Moreover, G_{GSO} obviously acts on $\widetilde{R\mathbb{Z}}_{\kappa_i}$ as $p^{G_{\mathrm{GSO}}}_{\mathbb{Z}_{\kappa_i}}(\widetilde{R\mathbb{Z}}_{\kappa_i})$, see Eq. (25). Therefore, we can simplify Eq. (57) to

TABLE I. Elliptic curves with enhanced automorphism groups.

Complex structure	Symmetry	Gepner model	Hypersurface
$\tau=i$	$\mathbb{Z}_4$	$k=(0,2,2)$	$\{x_0^2+x_1^4+x_2^4=0\}\subset \mathbb{WP}_{2,1,1}$
$\tau=e^{2\pi i/3}$	$\mathbb{Z}_6$	$k=(1,1,1)$	$\{x_0^3+x_1^3+x_2^3=0\}\subset \mathbb{WP}_{1,1,1}$
$\tau=e^{2\pi i/3}$	$\mathbb{Z}_6$	$k=(0,1,4)$	$\{x_0^2+x_1^3+x_2^6=0\}\subset \mathbb{WP}_{3,2,1}$

$$ {}^{\bar{\kappa}}K^*_{U(1)^d}(SU(2)^d;\mathbb{C}) = \bigoplus_{g\in G_{\mathrm{GSO}}}\left[\bigotimes_{\kappa_i|g} p^{G_{\mathrm{GSO}}}_{\mathbb{Z}_{\kappa_i}}(\widetilde{R\mathbb{Z}}_{\kappa_i})\right]^{G_{\mathrm{GSO}}}, \tag{59}$$

where we would like to remind the reader that $n|0$ for all n, that $\otimes_{i\in\emptyset}=\mathbb{C}$, and that we defined $\widetilde{R\mathbb{Z}}_{\kappa_i}$ to have cohomological degree 1.

IV. EXAMPLES

A. Toroidal theories

There are three Gepner models[42] that describe an elliptic curve. Two of them, $k=(1,1,1)$ and $k=(0,1,4)$, turn out to be the same CFT (for example, have identical partition functions). Hence, we obtain two different CFTs corresponding to the two orbifold singularities in the complex structure moduli space of the torus; see Table I. Recall that each elliptic curve $\mathbb{C}/(\mathbb{Z}\oplus\tau\mathbb{Z})$ has a $\mathbb{Z}_2$ symmetry, but at $\tau=i$ and $\tau=\exp(2\pi i/3)$ the symmetry is enhanced to $\mathbb{Z}_4$ and $\mathbb{Z}_6$, respectively. We easily compute using Eq. (59) that in all three cases,

$$ {}^{\bar{\kappa}}K^*_{U(1)^3\times G_{\mathrm{GSO}}}(SU(2)^3;\mathbb{C}) = \left\{\begin{matrix}\mathbb{C}^2, & *=0\\ \mathbb{C}^2, & *=1\end{matrix}\right\} = K^*(T^2;\mathbb{C}), \tag{60}$$

as expected, since we are dealing with a topological invariant of the torus. Note that the toroidal Gepner models always have three factors, even if that forces one of the levels to be zero. It is important to realize[43,44] that adding one factor with $c=0$ in the Gepner model does indeed have a physical effect. For example, we can easily compute the D-brane charges in the $k=(2,2)\Leftrightarrow\kappa=(4,4)$ model and obtain

$$ {}^{(4,4)}K^*_{U(1)^2\times G_{\mathrm{GSO}}}(SU(2)^2;\mathbb{C}) = \begin{cases}\mathbb{C}^6, & *=0;\\ 0, & *=1.\end{cases} \tag{61}$$

This is not the D-brane charge group of any geometric $c=3$ CFT. Note that the usual argument why $k=0$ factors do not matter is wrong: in the corresponding Landau-Ginzburg model, the $k=0$ factor corresponds to a field Φ that appears in the superpotential as

$$W_{\mathrm{LG}} = \cdots + \Phi^2. \tag{62}$$

Folklore says that one can integrate out Φ at no cost. But that is only true if one restricts to the closed string sector, if one considers D-branes and open strings,[43] then one must include a boundary action that will contain Φ as well.

B. Twisted sectors

Let us have a closer look at the formula for the K-groups of a Gepner model, Eq. (59). First, let us rewrite it as

$$ {}^{\bar{\kappa}}K^*_{U(1)^d}(SU(2)^d;\mathbb{C}) = \bigoplus_{g\in G_{\mathrm{GSO}}}(\mathcal{K}_g)^{G_{\mathrm{GSO}}}, \tag{63}$$

with

$$\mathcal{K}_g \overset{\text{def}}{=} \bigotimes_{\kappa_i | g} p_{\mathbb{Z}_{\kappa_i}}^{G_{\text{GSO}}}(\widetilde{R\mathbb{Z}}_{\kappa_i}). \tag{64}$$

Obviously, this has an interpretation of $\mathcal{K}_g^{G_{\text{GSO}}}$ being the contribution of the g-twisted sector in the G_{GSO} orbifold. Note that a single tensor factor $p_{\mathbb{Z}_{\kappa_i}}^{G_{\text{GSO}}}(\widetilde{R\mathbb{Z}}_{\kappa_i})$ does not have any G_{GSO}-invariant subspace, so the only way to obtain something invariant is to either have zero factors (which yields a *B*-type brane), or ≥ 2 factors. This is very familiar from the geometric interpretation as hypersurfaces in weighted projective spaces. If two or more weights $|G_{\text{GSO}}|/\kappa_i$ have a common factor, then the Calabi-Yau hypersurface inherits an orbifold singularity from the ambient space. The exceptional divisor from the resolution of the singularity increases the rank of the K-groups.

Specifically, in complex dimension ≥ 2 one can have genuine singularities that require resolutions and contribute twisted sector *D*-brane charges. To see that explicitly within the Gepner model context, let us consider the following two *K*3 Gepner models. First consider the $(k=2)^4$ Gepner model, corresponding to the Fermat quartic,

$$\{x_0^4 + x_1^4 + x_2^4 + x_3^4 = 0\} \subset \mathbb{P}^3. \tag{65}$$

In this case, the ambient space and the hypersurface are nonsingular. The contribution of the untwisted and the three g-twisted sectors is

$$\begin{array}{l|cccc} g \in G_{\text{GSO}} & 0 & 1 & 2 & 3 \\ \mathcal{K}_g & (\widetilde{R\mathbb{Z}}_4)^4 & \mathbb{C} & \mathbb{C} & \mathbb{C} \\ \dim_{\mathbb{C}} \mathcal{K}_g^{G_{\text{GSO}}} & 21 & 1 & 1 & 1 \\ \text{Type: Even/Odd} & O^4 & E^4 & E^4 & E^4 \end{array} \Rightarrow {}^{(4,4,4,4)}K^*_{U(1)^4}\left(SU(2)^4;\mathbb{C}\right) = \begin{cases} \mathbb{C}^{24}, & *=0; \\ 0, & *=1. \end{cases} \tag{66}$$

We can do the same for the $k=(1,2,2,4) \Leftrightarrow \kappa=(3,4,4,6)$ Gepner model. It corresponds to the singular *K*3 hypersurface,

$$X \overset{\text{def}}{=} \{x_0^3 + x_1^4 + x_2^4 + x_3^6 = 0\} \subset \mathbb{WP}_{4,3,3,2}. \tag{67}$$

The weighted projective space has a rational curve C_2 of $\mathbb{C}^2/\mathbb{Z}_2$ singularities and another rational curve C_3 of $\mathbb{C}^2/\mathbb{Z}_3$ singularities embedded as

$$C_2 \hookrightarrow \mathbb{WP}_{4,3,3,2}, \quad [s_0,s_1] \mapsto [s_0,0,0,s_1],$$

$$C_3 \hookrightarrow \mathbb{WP}_{4,3,3,2}, \quad [s_0,s_1] \mapsto [0,s_0,s_1,0]. \tag{68}$$

The surface inherits $4A_1$ and $6A_2$ orbifold singularities from

$$C_2 \cap X = 4, \quad C_3 \cap X = 6. \tag{69}$$

The resolution $\widetilde{X}$ is then a smooth *K*3 surface. This concludes the geometric point of view, now let us analyze the K-theory computation from the Gepner model side. Using Eq. (63), we find

$$\begin{array}{l|cccccccccccc} g \in G_{\text{GSO}} & 0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\ \mathcal{K}_g & \widetilde{R\mathbb{Z}}_{3,4,4,6} & \mathbb{C} & \mathbb{C} & \widetilde{R\mathbb{Z}}_3 & \widetilde{R\mathbb{Z}}_{4,4} & \mathbb{C} & \widetilde{R\mathbb{Z}}_{3,6} & \mathbb{C} & \widetilde{R\mathbb{Z}}_{4,4} & \widetilde{R\mathbb{Z}}_3 & \mathbb{C} & \mathbb{C} \\ \dim_{\mathbb{C}} \mathcal{K}_g^{G_{\text{GSO}}} & 10 & 1 & 1 & 0 & 3 & 1 & 2 & 1 & 3 & 0 & 1 & 1 \\ \text{Type: Even/Odd} & O^4 & E^4 & E^4 & - & EO^2E & E^4 & OE^2O & E^4 & EO^2E & - & E^4 & E^4 \end{array} \tag{70}$$

where we abbreviated

$$\widetilde{R\mathbb{Z}}_{\kappa_1,\kappa_2,\ldots} \overset{\text{def}}{=} \bigotimes_{i=1,2,\ldots} p^{G_{\text{GSO}}}_{\mathbb{Z}_{\kappa_i}}(\widetilde{R\mathbb{Z}}_{\kappa_i}). \tag{71}$$

Of course, in the end we obtain again the K-groups of the $K3$ manifold. However, this times some of the charge groups involve mixtures of even- and odd-dimensional branes. In the same way one can analyze all $K3$ Gepner models; see Appendix A.

V. KNÖRRER PERIODICITY

If one adds two variables with a quadratic superpotential to the Landau-Ginzburg theory[45–47] with fields $\Phi=(\phi_1,\ldots)$,

$$W_{\text{LG}}(\Phi) \to \widehat{W}_{\text{LG}} = W_{\text{LG}}(\Phi) + x^2 + y^2, \tag{72}$$

then one obtains the same theory again. This is quite nontrivial, because adding a single variable with a quadratic superpotential certainly does yield an inequivalent theory as discussed in Sec. IV A.

The evidence for periodicity is that the topological B-branes, that is the category of matrix factorizations, are equivalent. This fact is known as Knörrer periodicity,[48]

$$\mathbf{MF}(\mathbb{C}[\Phi]/W_{\text{LG}}(\Phi)) \simeq \mathbf{MF}(\mathbb{C}[\Phi,x,y]/\widehat{W}_{\text{LG}}(\Phi,x,y)). \tag{73}$$

This periodicity manifests itself in our formula Eq. (59), as follows. Adding two factors with $k=0 \Leftrightarrow \kappa=2$ amounts to inserting

$$p^{G_{\text{GSO}}}_{\mathbb{Z}_2}(\widetilde{R\mathbb{Z}}_2) \otimes p^{G_{\text{GSO}}}_{\mathbb{Z}_2}(\widetilde{R\mathbb{Z}}_2) = \mathbb{C} \tag{74}$$

whenever $2|g$. But

$$(\cdots) \otimes \mathbb{C} = (\cdots) \tag{75}$$

is the identity, so we obtain again the same K-groups.

Note that the above argument is flawed since adding the $\kappa=2$ factors might change the G_{GSO} group Eq. (52). If the initial order $|G_{\text{GSO}}|$ was odd, that is,

$$\text{lcm}(\kappa_1,\ldots,\kappa_d) \in 2\mathbb{Z}+1, \tag{76}$$

then

$$\text{lcm}(\kappa_1,\ldots,\kappa_d,2,2) = 2\text{lcm}(\kappa_1,\ldots,\kappa_d). \tag{77}$$

Therefore, periodicity only holds if one had already an even κ_i. In general, Knörrer periodicity need not hold for the first time one adds two $k=0$ factors, but it always holds from the second time onward,

$${}^{(\kappa_1,\ldots,\kappa_d,2)}K_{U(1)^{d+1}\times G_{\text{GSO}}}(SU(2)^{d+1};\mathbb{C}) = {}^{(\kappa_1,\ldots,\kappa_d,2,2,2)}K_{U(1)^{d+3}\times G_{\text{GSO}}}(SU(2)^{d+3};\mathbb{C}). \tag{78}$$

This is somewhat reminiscent of stabilization in K-theory.

VI. GENERALIZED PERMUTATION BRANES

In this section, we are going to focus on the Calabi-Yau ($c=9$) Gepner models. It is clear from Sec. III E that all D-brane charges can be found as suitable combinations of the D-branes in the coset or its mirror ($\mathbb{Z}_\kappa$ orbifold). In particular, the usual tensor product and permutation branes give

TABLE II. Gepner models associated to $K3$.

all the *D*-brane charges in the untwisted sector, corresponding to $g=0$ in Eq. (59). Similarly, one obtains zero or one brane in the twisted ($g=1,\ldots,|G_{\mathrm{GSO}}|$) sectors. But the latter is not enough to fill out the *D*-brane charge lattice, in general, since sometimes there are two or more independent charges coming from a twisted sector. Of course, all that means is that the boundary state construction is incomplete. Using Landau-Ginzburg models and matrix factorizations one obtains[11,49] all brane charges.

Inspection of the formula for the K-groups, Eq. (59), shows that two or more brane charges can only come from a $g\in G_{\mathrm{GSO}}$ sector where some κ_i divides g. Moreover, if only a single κ_i divides g, then there is no contribution because

$$[p^{G_{\mathrm{GSO}}}_{\mathbb{Z}_{\kappa_i}}(\widetilde{R\mathbb{Z}}_{\kappa_i})]^{G_{\mathrm{GSO}}}=0 \tag{79}$$

has no invariant subspace. Hence, the interesting case is if two or more κ_i have a common factor. Following Ref. 11, let us consider the case where r of the shifted levels $\overline{\kappa}=(\kappa_1,\ldots)$ have the same divisor $d>2$. (If the common divisor $d=2$, then there is again only a one-dimensional contribution to the K group in the $g\in d\mathbb{Z}$ twisted sectors, which is not so interesting. Of course, our arguments hold in that case as well).

First, note that r odd contributes to K^1 only, as is evident from our degree convention, Eqs. (23a) and (23b). Not so surprisingly, if one[11] restricts oneself to K^0 then there are no *D*-brane charges for $r=1,3,5$. This leaves the cases $r=2$ and $r=4$. Looking at the list of Gepner models, $r=4$ can only occur if the Gepner model has more than five minimal model factors. There is nothing wrong with that, and our formula, Eq. (59), gives the correct answer for the K-groups. However, if one[11] were to restrict oneself to 5 minimal model factors, then $r=4$ cannot occur either.

VII. CONCLUSIONS

There is a very simple formula, Eq. (59), for the rank of the K-groups of Gepner models. The summands in the formula have a natural interpretation as the contributions from twisted sectors. We checked the computation in $c=3,6,9$ Gepner models and find agreement with the topology of the associated Calabi-Yau manifolds.

APPENDIX A: K3 GEPNER MODELS

There are 16 Gepner models that are associated to $K3$ surfaces[50–52] listed in Table II. We checked that we obtain

$$\overline{\kappa}K^*_{U(1)^d\times G_{\mathrm{GSO}}}(SU(2)^d;\mathbb{C}) = \left\{\begin{matrix}\mathbb{C}^{24}, & *=0\\ 0, & *=1\end{matrix}\right\} = K^*(K3;\mathbb{C}) \tag{A1}$$

in all 16 cases. It is important that the right number of $k=0$ factors appears so that there are four minimal models altogether (exceptionally, six in the first two Gepner models).

In addition to the 16 known $K3$ Gepner models, we found that

$$^{(2,3,3,3,3,3,3)}K^*_{U(1)^7\times G_{\mathrm{GSO}}}(SU(2)^7;\mathbb{C}) = K^*(K3;\mathbb{C}), \tag{A2}$$

as well. Although it has not the conventional number of factors, this $\overline{k}=(0,1,1,1,1,1,1)$ Gepner model seems to yield yet another $K3$ CFT.

There is yet another combination of levels such that the total central charge $c=6$, which is $\overline{k}=(0,1,1,1,2,2)$. One can easily compute that

$$^{(2,3,3,3,4,4)}K^*_{U(1)^6\times G_{\mathrm{GSO}}}(SU(2)^6;\mathbb{C}) = \left\{\begin{matrix}\mathbb{C}^8, & *=0\\ \mathbb{C}^8, & *=1\end{matrix}\right\} = K^*(T^4;\mathbb{C}).$$

Clearly, this Gepner model describes a T^4 compactification with (accidentally) enhanced $\mathcal{N}=8$ space-time supersymmetry.

APPENDIX B: CALABI-YAU THREEFOLD GEPNER MODELS

First, note that a proper Calabi-Yau threefold X, that is a compact Kähler manifold of holonomy $SU(3)$ satisfies

$$\operatorname{rank} K^0(X) = 2h^{11}(X)+2, \quad \operatorname{rank} K^1(X) = 2h^{21}(X)+2. \tag{B1}$$

We can check this formula against the known list[53] of 168 Gepner models with central charge $c=9$, which are associated to Calabi-Yau threefolds. The list of all Gepner models is reproduced in Table III. If one uses these $N=(2,2)$ SCFTs as the compactification of the $E_8\times E_8$ heterotic string, then their low-energy spectrum consists of a number $n_{\overline{\mathbf{27}}}=h^{11}(X)$ of matter fields transforming in the $\overline{\mathbf{27}}$ and $n_{\overline{\mathbf{27}}}=h^{21}(X)$ of field in the $\mathbf{27}$ representation of E_6.

One can check that the formula, Eq. (B1), is obeyed for each Gepner model except for the seven cases with $n_{\overline{\mathbf{27}}}=n_{\mathbf{27}}=21$. The obvious explanation is that this misfit is associated $K3\times T^2$, which has Hodge numbers

$$h^{pq}(K3\times T^2) = \begin{array}{ccccccc} & & & 1 & & & \\ & & 1 & & 1 & & \\ & 1 & & 21 & & 1 & \\ 1 & & 21 & & 21 & & 1 \\ & 1 & & 21 & & 1 & \\ & & 1 & & 1 & & \\ & & & 1 & & & \end{array}. \tag{B2}$$

Since $K3\times T^2$ has only $SU(2)$ holonomy, that is, it is not a proper Calabi-Yau manifold, it does not have to obey Eq. (B1). Adding up the even and odd cohomology groups, we find that

$$K^0(K3\times T^2) = \mathbb{Z}^{48}, \quad K^1(K3\times T^2) = \mathbb{Z}^{48}. \tag{B3}$$

These topological K-groups are in precise agreement with what we computed using the coset, Eq. (59).

Electromagnetic and gravitational interactions of the spinning particle

Nuri Ünal[a)]
Department of Physics, Akdeniz University, PK. 510 Antalya, 07058 Turkey

(Received 14 February 2006; accepted 18 July 2006; published online 1 September 2006)

We consider the invariance of the spinning free particle Lagrangian under the global coordinate transformations for the classical model of the electron with internal degrees of freedom and obtain the conservation of the energy-momentum, total angular momentum, and electric charge. The local gauge transformations give the electromagnetic and gravitational interactions of the spinning particle in the Riemann-Cartan space from the generalized spin connections. We show that the covariant constancy of the Dirac matrices gives; (i) the form invariance of the classical equations of motion, except the gravitational force terms in nongeodesic equation, (ii) the conservation of the electromagnetic current, (iii) the quantum Hamiltonian and equations of motion from the classical ones without the quantum ordering corrections, and (iv) the minimal coupling of the gravitation with the spinning particle in the Hamiltonian and in wave equations in the Riemann-Cartan space–time. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2337847]

I. INTRODUCTION

Soon after Einstein proposed his gravitational theory, Weyl extended it to include electromagnetism and later revitalized his gauge idea, U(1) gauge invariance. In 1954, Yang and Mills generalized U(1) into SU(2). In 1956, Utiyama gauged the Lorentz group, SO(1,3),[1] and later Kibble extended it into Poincare group, **P**.[2]

In the field theory, the matter fields are the definite eigenstates of the mass, the electric (intrinsic) charge and the spin. In this connection, the minimal couplings of the matter field with the gravitation and the electromagnetism are discussed separately. The space–time symmetries are built by the requirement that the Lagrangian density for the free matter fields be invariant under the action of the corresponding symmetry group. Here, **P**, consisting of translations and the Lorentz rotations, is an important example. On the other hand, the inner symmetries require the invariance of the Lagrangian density for the matter fields under the action of some Lie group which is only represented in the space of fields and does not act on space–time. Here the example is the invariance under U(1) for electromagnetism.

In most of the gauge theories of gravitation, **P** is considered partly as a space–time symmetry group and partly as an inner symmetry group. They generate the translations and Lorentz rotations, and SO(1, 3) frame rotations of matter fields, respectively.[3–9] The global covariance of the matter field under the translation and rotation subgroups of **P** yields the conservation of the energy-momentum and the total angular momentum, respectively. In the local extension of the gauge group **P**, its space–time part becomes the diffeomorphism group, the gauged theory is invariant under the general coordinate transformations and the local SO(1, 3) frame rotations. In another approach, **P** is considered as the internal symmetry group of matter fields in Minkowski space–time to obtain a complementary gauge formulation of gravitation and to discuss the renormalization procedure.[10]

[a)]Electronic mail: nuriunal@akdeniz.edu.tr

From the matter fields, the Klein-Gordon equation is generalized into a curved space–time without SO(1, 3) frame rotations. However, the Dirac equation is generalized into the curved space–time by introducing the Fock-Ivananko two-vector or the spin connection as the contribution of SO(1, 3) frame rotations.[11] The Dirac algebra relates the metric tensor of the space–time to the anti-commutator of the space–time dependent Dirac matrices. In this generalization, the electromagnetic potential and spin connection appear together. In their pioneering investigations, Schrödinger[12] and Bargmann[13] discussed the generalization of the spin connection and showed that it gives the space–time curvature, the spin-2 gravitational field, and an Abelian spin-1 curvature. Since the spin-1 part of the connection is coupled to all spinors with the identical charge, this part is not identified with the electromagnetism. Recently, Crawford also discussed the generalization of the spin connection.[14] He investigated the coupling of the torsion with the spinning particle by evaluating the commutators of the covariant derivatives for the Dirac matrices, $[\nabla_\mu, \nabla_\nu]\gamma^\alpha$, and showed that it is possible only by relaxing the constraint about the covariant constancy of the Dirac matrices. He obtained the same conclusion for the spin-1 curvature as in Ref. 12.

Kibble and later Barducci *et al.* investigated the coupling of the spinning particle directly to the torsion[2,15] and obtained that there is no coupling between the spinning particle and the torsion. However, Hehl derived the equations of motion for a spinning object with independent velocity and momentum, and obtained the coupling of the spinning particle directly to the torsion.[16]

In the classical and quantum field theories, the scalar product is defined by the local **P** invariant determinant of the tetrads, $\det e^{-1}$, for the Riemann-Cartan space–time, but there is an ambiguity about the covariant constancy of $\det e^{-1}$ and the minimal coupling of the fields to the gravitation in the Riemann-Cartan space–time.[17] If $\det e^{-1}$ is not covariantly constant then, there is not the minimal coupling of the gravitation in the Lagrangian density.

The aim of this study is to derive the minimal coupling of the electromagnetism and the gravitation for the spinning particle in the Riemann-Cartan space–time by deriving a unified spin connection in a complementary approach. For this aim, our motivation is the spinning particle model presented as the classical model of the zitterbewegung.[18] In this model, the spinning particle does not correspond to definite mass, charge, and the spin eigenstates contrary to the field theories. The quantities, the mass and spin, are identified by using the conserved dynamical variables of the particle without discussing the corresponding global gauge transformations, but the electric charge is introduced manually into the interaction Lagrangian,[19] where the coupling of the gravitation and electromagnetism are discussed separately in the Riemann space–time without any discussion on the generalization of the spin connection.

In the spinning particle model, the phase space of the particle consists of two sets of coordinates and momenta: The space–time coordinates and the complex, four internal coordinates and conjugate external and internal momenta, respectively. In usual approaches, the gauge transformations are performed in fields, which have infinite degrees of freedom. In this approach, the space–time and internal Lorentz transformations of the fields are considered together and the electromagnetic phase transformations are considered separately. Thus the spin connection and electromagnetic field are considered as separate gauge fields. In this study, we perform the space–time and internal gauge transformations in a unified way in the particle system with finite degrees of freedom. Since the phase space of the particle is divided into two separate parts, we perform the space–time transformations as the gauge transformations of the **P** and the internal coordinate transformations as the gauge transformations of the group U(2,2), which leaves the bilinear of the complex four internal coordinates and momenta. It includes the gauge transformations corresponding to the internal Lorentz transformations and the electromagnetic phase transformations. Due to the gauge group U(2,2), we realize the non-Abelian phase transformations represented by the generalized spin connection which corresponds to the gauge fields of $\mathrm{U}(1) \times \mathrm{SU}(2,\mathrm{C})$ subgroup of U(2,2).

First, we formulate the global Poincare transformations for the external space–time coordinates, and the rotations and phase transformations between the holomorphic, internal coordinates

of the spinning particle. The gauge groups of these transformations are **P** and U(2,2), respectively. The invariance of the free particle Lagrangian under the following subgroups of **P** and U(2,2) gives the conservation of the following physical quantities:

(1) The translation subgroup of **P** gives the conservation of the energy-momentum one-vector.
(2) The space–time rotation subgroup of **P** with the internal rotation group SU(2, C) together gives the conservation of the angular momentum two-vector.
(3) The internal U(1) phase transformation subgroup of U(2,2) gives the conservation of a scalar and real quantity, which will be identified as the electric charge of the particle.
The free particle Lagrangian is also invariant under the global proper time translations and another real, non-negative scalar quantity is conserved, and this quantity will be identified as the mass of the particle.

Second, we derive the gravitational and electromagnetic interactions of the spinning particle as the local gauge transformations for the gauge groups, **P**, and $\mathrm{SU}(2,\mathrm{C})\times\mathrm{U}(1)$ subgroup of U(2,2).

In Sec. I, we review the classical model of the zitterbewegung, in Sec. II, we discuss the invariance of the free particle Lagrangian under the global gauge transformations and derive the interaction Lagrangian by applying the local gauge transformations to the free particle Lagrangian. In Sec. III, we derive the classical equations of motion and compare them with the flat space–time equations except for the electromagnetic and gravitational force terms in nongeodesic equations. In Sec. IV we show that covariant constancy of the Dirac matrices gives the conservation of the electromagnetic current. Section V presents conclusions.

Classical spinning particle model. We use the classical spinning particle model developed to represent the classical analogue of the zitterbewegung motion of the electron. In this model, the particle has both usual space–time degrees of freedom and four additional internal degrees of freedom. These additional degrees of freedom correspond to the zitterbewegung oscillations and the spin of the particle. They are represented by the four complex internal holomorphic coordinates. In this model, the conjugate momenta of the space–time coordinates and velocity are linearly independent. Then, the Lagrangian of the free particle is defined by a constraint between the space–time four velocity and one-vector part of the Dirac algebra denoted by the bilinear of the complex four internal coordinates and momenta. Since external and internal coordinates are dynamically independent, the gauge transformations are Poincare transformations of the space–time coordinates of the particle with gauge group **P** and the internal coordinate transformations between the holomorphic coordinates of the four harmonic oscillators with the gauge group U(2,2). The generators of U(2,2) are the elements of the Dirac algebra. The gauge group $\mathrm{U}(1)\times\mathrm{SU}(2,\mathrm{C})$ includes the electromagnetism and gravitational interactions of the particle with the gauge potential represented by the generalized spin connection in Refs. 12–14.

To discuss the classical analogous of the zitterbewegung it is assumed that the internal configuration space of the particle consists from the four complex coordinates, z^i with $i=1,..,4$. We denote z^i by the complex four component spinor, z. In the Minkowski space–time, M_4 the Hermitian conjugate of z is $\bar{z}=(z_1^*,z_2^*,-z_3^*,-z_4^*)$ and we denote internal momenta of the particle as the complex spinors $\bar{z}$. Then, the Lagrangian for the free spinning particle, L is

$$L=\frac{1}{2i}\left(\frac{\mathrm{d}\bar{z}}{\mathrm{d}s}z-\bar{z}\frac{\mathrm{d}z}{\mathrm{d}s}\right)+p_a\left(\frac{\mathrm{d}x^a}{\mathrm{d}s}-\bar{z}\gamma^a z\right), \tag{1}$$

where x^a and p_a are the space–time coordinates and the momenta of the particle in the Minkowski space–time, M_4, with the metric $\eta_{ab}=(1,-1,-1,-1)$, s is the proper time of the particle and γ^a are constant Dirac matrices. The dynamical variables z_i are four complex coordinates and configuration space is C^4. The signatures of the bilinear in the quadratic form $\bar{z}z$ are $(+,+,-,-)$ and the transformations between the holomorphic coordinates conserve these signatures. We use the Latin indices for local Lorentz frames and the Greek indices for noncoordinate frames..

The classical spinning particle, represented by Eq. (1), has continuous values for spin. The quantization of this system corresponds to the coherent eigenstates of the internal, four complex

operators $\hat{z}$. In general, the harmonic oscillator coherent states are the continuous eigenstates with complex eigenvalues of the lowering operator $\hat{a}$. In this model the lowering operators of the internal oscillators are $\hat{z}^i$. The expectation values of the spin operators, $\hat{S}^{ab}$ between these coherent states also have continuous values. In quantum mechanics the physical particles correspond to the eigenstates of the spin operator, $\hat{S}^{ab}$, with discrete eigenvalues and they correspond to definite and discrete energy or internal angular momentum eigenstates of the four harmonic oscillators. The coherent spinning particle states represent the unphysical particle states, which are the coherent superposition of the physical spinning particle states. Thus, the dynamical variables of the classical zitterbewegung system correspond to the expectation of the corresponding operators between the minimum uncertain quantum spinning particle system.

In Eq. (1), p_a may be considered as the four Lagrange multipliers with the constraints

$$\dot{x}^a - \bar{z}\gamma^a z = 0, \tag{2}$$

where the overdot means the derivative with respect to s. This constraint relates the external and internal dynamics of the particle. Since the Lagrangian in Eq. (1) is defined in the phase space, the Hamiltonian structure of the system is known or chosen at the beginning.

II. GAUGE TRANSFORMATIONS

A. Global coordinate and phase transformations

In M_4, there are two kinds of coordinate transformations. These are the space–time translations and external Lorentz rotations:

$$x^a \to x'^a = x^a - i\xi^c P_c x^a - \frac{i}{2}\epsilon^{cd} L_{cd} x^a, \tag{3}$$

where P_c and L_{cd} are the generators of the translations and rotations, respectively. The Lagrangian in Eq. (1) is invariant under the translations. The Noether current is the energy momentum current

$$T^{ab}(u) = \int ds \bar{z}\gamma^a z p^b \delta^4[u - x(s)]$$

and the conserved charge of the translations is

$$p^a = \int T^{ab}(u) \mathrm{d}\sigma_b = p^a \int \mathrm{d}s \mathrm{d}\sigma_b \frac{du^b}{\mathrm{d}s} \delta^4[u - x(s)], \tag{4}$$

where σ_b is the three-dimensional hypersurface along the direction n_b.

In C^4, there are two kinds of internal transformations. These are the phase transformations generated by the SU(2, C) and U(1) subgroups of U(2,2) and they conserve the signatures of the frequencies of the zitterbewegung oscillations $(+,+,-,-)$:

$$z_i \to z_i' = \exp\left(-i\phi 1 - \frac{i}{2}\epsilon^{cd}\Sigma_{cd}\right)_i^j z_j, \tag{5}$$

$$\bar{z}^i \to \bar{z}'^i = \bar{z}^j \exp\left(+i\phi 1 + \frac{i}{2}\epsilon^{cd}\Sigma_{cd}\right)_j^i, \tag{6}$$

where Σ_{cd} is

$$\Sigma_{cd} = \frac{1}{2i}[\gamma_c, \gamma_d].$$

In Eqs. (5) and (6), there are two kinds of phase transformations: The first part, U(1) transformations, corresponds to the multiplication of all the complex spinor, z_i with $\exp(-i\phi 1_i^j)$ and the second part, SU(2, C) transformations, corresponds to the multiplication of the complex spinors, z_i with $\exp[(-(i/2)\epsilon^{cd}(\Sigma_{cd})_i^j)]$ term. The second part corresponds to the internal Lorentz rotations between the complex spinor, z_i.

The Lagrangian (1) is invariant under the external and internal Lorentz rotations and phase transformations and the Noether currents are

$$J^a(u) = \int \bar{z}\gamma^a z\bar{z}z\delta^4[u - x(s)]\mathrm{d}s, \tag{7}$$

and

$$M^{abc}(u) = \int \mathrm{d}s\left(x^a p^b - x^b p^a + \frac{1}{2}\bar{z}\Sigma^{ab}z\right)\bar{z}\gamma^c z\delta^4[u - x(s)].$$

The corresponding conserved charges are defined as

$$Q = \int \mathrm{d}\sigma_b J^b(u) = \bar{z}z \int \mathrm{d}s\mathrm{d}\sigma_b \frac{\mathrm{d}u^b}{\mathrm{d}s}\delta^4[u - x(s)] = \bar{z}z, \tag{8}$$

and

$$J^{ab} = \int M^{abc}(u)\mathrm{d}\sigma_c = (x^a p^b - x^b p^a + S^{ab}), \tag{9}$$

where the spin tensor, S^{ab} is

$$S^{ab} = \frac{1}{2}\bar{z}\Sigma^{ab}z. \tag{10}$$

There are no translation terms like $\exp(-i\zeta^c\gamma_c)$ in U(2,2) because they do not conserve the constraint in the Lagrangian. The generators of the $\mathrm{U}(1)\times\mathrm{SU}(2,\mathrm{C})$ are 1 and Σ_{cd} and correspond to the zero-vector and two-vectors of the four-dimensional Clifford or Dirac algebra.

The Lagrangian (1) is also invariant under the translation of the proper time s:

$$s \to s' = s - i\tau H s,$$

where H is the generator of the proper time translations, the Hamiltonian and the conserved quantity is the energy of the particle in proper time:

$$H = p_a\bar{z}\gamma^a z. \tag{11}$$

B. Local coordinate and phase transformations

Here, we consider the local coordinate and phase transformations as gauge transformations. The external translations and Lorentz rotations are expressed by the nonholonomic transformations

$$\mathrm{d}x^a \to \mathrm{d}x^\mu = (\delta^\mu{}_b + \zeta^\mu{}_{,b} + \epsilon^\mu{}_{c,b}x^c)\mathrm{d}x^b. \tag{12}$$

The internal transformations are

$$z_i \to z_i' = U_i^j z_j, \tag{13}$$

$$\bar{z}^i \to \bar{z}'^i = \bar{z}^j (U^{-1})_j^{\ i}, \tag{14}$$

where U is

$$U[x(s)] = \exp\left[- i\phi(x) 1 - \frac{i}{4} \epsilon^{cd}(x) \Sigma_{cd} \right]. \tag{15}$$

Under these transformations

$$\dot{x}^a \to \dot{x}^\mu = (\delta^\mu_{\ b} + \zeta^\mu_{\ ,b} + \epsilon^\mu_{\ c,b} x^c) \dot{x}^b, \tag{16}$$

and

$$\bar{z} \gamma^a z \to (\bar{z} \gamma^a z)' = \bar{z} \gamma^a z. \tag{17}$$

Then the Lagrange multiplier term in the Lagrangian becomes

$$p_a (\dot{x}^a - \bar{z} \gamma^a z) \to p_a e^a_{\ \mu} (\dot{x}^\mu - \bar{z} e^\mu_{\ b} \gamma^b z),$$

where the tetrads $e^\mu_{\ b}$ are defined as

$$e^\mu_{\ b}(x) = (\delta^\mu_{\ b'} + \zeta^\mu_{\ ,b'} + \epsilon^\mu_{\ c,b'} x^c),$$

and $e^a_{\ \mu}$ are the inverse of the tetrads, $e^\mu_{\ a}$. In the same way, space dependent Dirac matrices $\gamma^\mu(x)$ are defined as

$$\gamma^\mu(x) = e^\mu_{\ a}(x) \gamma^a. \tag{18}$$

These coordinates define the metric, $g_{\mu\nu}$:

$$g_{\mu\nu}(x) = e^a_{\ \mu}(x) e^b_{\ \nu}(x) \eta_{ab}.$$

The momentum, p_μ, is defined in global coordinates as

$$p_\mu = e^a_{\ \mu}(x) p_a.$$

Then the Lagrange multiplier term is rewritten as

$$p_\mu (\dot{x}^\mu - \bar{z} \gamma^\mu z), \tag{19}$$

and it is form invariant under the transformations (12).

The kinetic part of the Lagrangian is transformed as

$$\frac{1}{2i}(\dot{\bar{z}} z - \bar{z} \dot{z}) \to \frac{1}{2i}(\dot{\bar{z}} z - \bar{z} \dot{z})' = \frac{1}{2i}(\dot{\bar{z}} z - \bar{z} \dot{z}) + \frac{1}{2i}\left(\bar{z} \frac{\mathrm{d}U^{-1}}{\mathrm{d}s} U z - \bar{z} U^{-1} \frac{\mathrm{d}U}{\mathrm{d}s} z \right). \tag{20}$$

By evaluating the derivatives and considering the Lagrange multiplier, Eq. (20) gives

$$\frac{1}{2i}\left(\bar{z} \frac{\mathrm{d}U^{-1}}{\mathrm{d}s} U z - \bar{z} U^{-1} \frac{\mathrm{d}U}{\mathrm{d}s} z \right) = \bar{z} B_\mu(x) z \bar{z} \gamma^\mu z.$$

The $\bar{z} B_\mu(x) z \bar{z} \gamma^\mu z$ is the additional gauge interaction term and B_μ is

$$B_\mu(x) = e^a_{\ \mu}(x) \left[\phi_{,a}(x) + \tfrac{1}{4} \epsilon^{cd}_{\ \ ,a}(x) \Sigma_{cd} \right], \tag{21}$$

where $\frac{1}{4} e^a_{\ \mu}(x) \epsilon^{cd}_{\ \ ,a}(x)$ is the nonholonomic connection, $\Gamma_\mu^{\ cd}(x)$. To compensate for the effects of the local transformations, we introduce $B_\mu(x)$ as the gauge potentials that $e^a_{\ \mu}(x) \phi_{,a}(x)$ and $\frac{1}{4} \Gamma_\mu^{\ cd}(x) \Sigma_{cd}$ are introduced as the gauge potential of the U(1) and SU(2, C) phase transformations, respectively. They are the electromagnetic potential, $A_\mu(x)$, and the Fock-Ivanenko two-vectors, Γ_μ:

$$A_\mu(x) = e^a{}_\mu(x)\phi_{,a}(x),$$

$$\Gamma_\mu(x) = \tfrac{1}{4}\Gamma_\mu{}^{cd}(x)\Sigma_{cd}.$$

We rewrite the additional interaction terms as

$$\bar{z}B_\mu(x)z = \bar{z}[A_\mu(x) + \Gamma_\mu(x)]z. \tag{22}$$

Then, Lagrangian of the spinning particle, interacting with electromagnetic and gravitational fields, is

$$L = \frac{1}{2i}(\dot{\bar{z}}z - \bar{z}\dot{z}) + p_\mu\dot{x}^\mu - H, \tag{23}$$

where H is the Hamiltonian:

$$H = (p_\mu - \bar{z}B_\mu z)\bar{z}\gamma^\mu z = \Pi_\mu\bar{z}\gamma^\mu z. \tag{24}$$

The H in Eq. (24) looks like the Dirac or spin-1/2 particle Hamiltonian, but it, in fact, corresponds to the classical Hamiltonian of the zitterbewegung system with internal degrees of freedom and so the dynamical variables of the system have continuous values.

III. EQUATIONS OF MOTION

In this section, we derive the classical equations of motion. They are

$$\frac{\mathrm{d}}{\mathrm{d}s}x^\mu = \dot{x}^\mu = e^\mu{}_b\bar{z}\gamma^b z, \tag{25}$$

$$\frac{\mathrm{d}}{\mathrm{d}s}\bar{z} = -i\bar{z}B_\mu\dot{x}^\mu + i\bar{z}\gamma^\alpha\Pi_\alpha, \tag{26}$$

$$\frac{\mathrm{d}}{\mathrm{d}s}z = iB_\mu z\dot{x}^\mu - i\gamma^\alpha z\Pi_\alpha. \tag{27}$$

We define the covariant time derivatives of the spinors $\bar{z}$ and z and rewrite Eqs. (26) and (27) as

$$\frac{D\bar{z}}{Ds} = \frac{\mathrm{d}}{\mathrm{d}s}\bar{z} + i\bar{z}\Gamma_\alpha\dot{x}^\alpha = i\bar{z}\gamma^\alpha\Pi_\alpha - i\bar{z}A_\alpha\dot{x}^\alpha, \tag{28}$$

$$\frac{Dz}{Ds} = \frac{\mathrm{d}}{\mathrm{d}s}z - i\Gamma_\alpha z\dot{x}^\alpha = -i\gamma^\alpha z\Pi_\alpha + i\bar{z}\Gamma_\alpha\dot{x}^\alpha. \tag{29}$$

To define the covariant derivatives we evaluate the derivatives of $\dot{x}^\mu$:

$$\frac{D\dot{x}^\mu}{Ds} = \bar{z}\frac{D\gamma^\mu}{Ds}z + \frac{D\bar{z}}{Ds}\gamma^\mu z + \bar{z}\gamma^\mu\frac{Dz}{Ds} = \bar{z}\gamma^\mu{}_{;\alpha}z\dot{x}^\alpha + i\bar{z}[\gamma^\alpha, \gamma^\mu]z\Pi_\alpha.$$

The covariant derivative of γ^μ is

$$\gamma^\mu{}_{;\alpha} = \nabla_\alpha\gamma^\mu + \gamma^\lambda\Gamma_{\alpha\lambda}{}^\mu.$$

Since

$$\nabla_\alpha \gamma^\mu = -\gamma^\lambda \Gamma_{\alpha\lambda}{}^{\mu},$$

the covariant derivative of γ^μ vanishes. Then

$$\frac{D\dot{x}^\mu}{Ds} = 4S^{\mu\nu}\Pi_\nu. \tag{30}$$

In a similar way, the covariant derivative of $S^{\mu\nu}$ is

$$\frac{DS^{\mu\nu}}{Ds} = \frac{1}{4i}\frac{D\bar{z}}{Ds}[\gamma^\mu,\gamma^\nu]z + \frac{1}{4i}\bar{z}[\gamma^\mu,\gamma^\nu]\frac{Dz}{Ds} + \frac{1}{4i}\bar{z}[\gamma^\mu{}_{;\alpha},\gamma^\nu]z\dot{x}^\alpha + \frac{1}{4i}\bar{z}[\gamma^\mu,\gamma^\nu{}_{;\alpha},]z\dot{x}^\alpha,$$

or

$$\frac{DS^{\mu\nu}}{Ds} = \dot{x}^\nu\Pi^\mu - \dot{x}^\mu\Pi^\nu. \tag{31}$$

Here the equations of motion for $\dot{x}^\mu$ and $S^{\mu\nu}$ are derived for completeness and they are equivalent to Eqs. (28) and (29).

To derive $D\Pi_\mu/Ds$ we first evaluate $\mathrm{d}p_\mu/\mathrm{d}s$:

$$\frac{\mathrm{d}p_\mu}{\mathrm{d}s} = \frac{\mathrm{d}(e^a_\mu p_a)}{\mathrm{d}s} = p_a\frac{\mathrm{d}e^a_\mu}{\mathrm{d}s} + e^a_\mu\frac{\mathrm{d}p_a}{\mathrm{d}s} = p_a\frac{\mathrm{d}e^a_\mu}{\mathrm{d}s} + e^a_\mu\frac{\partial L}{\partial x^a} = p_c\frac{\mathrm{d}e^c_\mu}{\mathrm{d}s} - e^c_\mu\frac{\partial H}{\partial x^c}.$$

Then

$$\frac{\mathrm{d}\Pi_\mu}{\mathrm{d}s} = \frac{\mathrm{d}p_\mu}{\mathrm{d}s} - \frac{\mathrm{d}(\bar{z}B_\mu z)}{\mathrm{d}s} = \dot{x}^\alpha e^c_\alpha\frac{\partial e^b_\mu}{\partial x^c}p_b - e^c_\mu\frac{\partial H}{\partial x^c} - \frac{d(\bar{z}B_\mu z)}{ds}.$$

We evaluate the second and third terms by using Eqs. (24)–(26):

$$e^c_\mu\frac{\partial H}{\partial x^c} = \bar{z}\gamma^\alpha z\left[\frac{\partial p_\alpha}{\partial x^\mu} - \frac{\partial(\bar{z}B_\alpha z)}{\partial x^\mu}\right] + \bar{z}\frac{\partial\gamma^\alpha}{\partial x^\mu}z\Pi_\alpha = \dot{x}^\alpha(p_b e^b_{\alpha,\mu} - \bar{z}B_{\alpha,\mu}z) + \bar{z}\gamma^\alpha{}_{,\mu}z\Pi_\alpha,$$

$$\frac{\mathrm{d}(\bar{z}B_\mu z)}{\mathrm{d}s} = \dot{x}^\alpha\bar{z}\frac{\partial B_\mu}{\partial x^\alpha}z + \frac{\mathrm{d}\bar{z}}{\mathrm{d}s}B_\mu z + \bar{z}B_\mu\frac{\mathrm{d}z}{\mathrm{d}s} = \dot{x}^\alpha\bar{z}B_{\mu,\alpha}z - i\bar{z}[B_\alpha,B_\mu]z\dot{x}^\alpha + i\bar{z}[\gamma^\alpha,B_\mu]z\Pi_\alpha.$$

Then $\mathrm{d}\Pi_\mu/\mathrm{d}s$ becomes

$$\frac{\mathrm{d}\Pi_\mu}{\mathrm{d}s} = \dot{x}^\alpha c_{\alpha\mu}{}^c p_c - \bar{z}e^c_\mu(\gamma^\alpha{}_{,c} + i[\gamma^\alpha,B_c])z\Pi_\alpha + \dot{x}^b e^c_\mu\bar{z}(B_{b,c} - B_{c,b} + i[B_b,B_c])z, \tag{32}$$

where the commutator coefficients, $c_{\mu\nu}{}^c$ are

$$\frac{\partial p_\mu}{\partial x^\nu} - \frac{\partial p_\nu}{\partial x^\mu} = \left(e^c_\nu\frac{\partial e^b_\mu}{\partial x^c} - e^c_\mu\frac{\partial e^b_\nu}{\partial x^c}\right)p_b = c_{\mu\nu}{}^c p_c = (\Gamma_{\mu\nu}{}^c - \Gamma_{\nu\mu}{}^c - T_{\mu\nu}{}^c)p_c.$$

We define the covariant derivative of Π_μ by considering its covariant vector character:

$$\frac{D\Pi_\mu}{Ds} = \frac{d\Pi_\mu}{ds} - \Gamma_{\mu\nu}{}^c\dot{x}^\nu e^\beta_c\Pi_\beta = -\dot{x}^\nu[(\Gamma_{\mu\nu}{}^c - \Gamma_{\nu\mu}{}^c - c_{\mu\nu}{}^c)e^\beta_c\Pi_\beta - \bar{z}(B_{\nu,\mu} - B_{\mu,\nu} + i[B_\nu,B_\mu] - c_{\mu\nu}{}^c e^\beta_c B_\beta)z].$$

The first term in square brackets is proportional to the energy-momentum tensor, $\dot{x}^\alpha\Pi_\beta$, and the proportionality factor is the gauge field of the translations, the torsion tensor, $T_{\mu\nu}{}^c$:

$$T_{\mu\nu}{}^{c} = (\Gamma_{\mu\nu}{}^{c} - \Gamma_{\nu\mu}{}^{c} - c_{\mu\nu}{}^{c}).$$

We define the curvature two-form for the generalized spin connection $B_{\mu\nu}$ as

$$B_{\mu\nu} = \bar{z}(B_{\nu,\mu} - B_{\mu,\nu} + i[B_{\nu}, B_{\mu}] - c_{\mu\nu}{}^{c} B_{c})z.$$

The second term is the product of the velocity of the particle and the curvature two-form, $B_{\mu\nu}$, and it can be decomposed as

$$B_{\mu\nu} = e_{\mu}^{m} e_{\nu}^{n} \left[\bar{z} z F_{mn} + \frac{1}{2} R_{mnab} \frac{1}{2} \bar{z} \Sigma^{ab} z \right],$$

where F_{mn} is the field strength tensor of the electromagnetic interactions, R_{mnab} is the generalized Riemann tensor for the noncoordinate frames. These are the gauge fields of the U(1) phase transformations and SO(3,1) Lorentz rotations and SU(2, C) subgroup of U(2,2). Then the expression of the Lorentz force for the spinning particle in the electromagnetic and gravitational interactions becomes

$$\frac{D\Pi_{\mu}}{Ds} = -\dot{x}^{\alpha} \Pi^{\beta} T_{\mu\alpha\beta} + \bar{z} z F_{\mu\nu} \dot{x}^{\nu} + \frac{1}{2} R_{\alpha\beta\mu\nu} \frac{1}{2} \bar{z} \Sigma^{\alpha\beta} z \dot{x}^{\nu}. \tag{33}$$

The equations of motion can also be derived by using the Hamiltonion, H and the following generalized Poisson parentheses:

$$\{f, g\} = \left(\frac{\partial f}{\partial x^{\alpha}} \frac{\partial g}{\partial p_{\alpha}} - \frac{\partial g}{\partial x^{\alpha}} \frac{\partial f}{\partial p_{\alpha}} \right) + \frac{1}{i} \left(\frac{\partial f}{\partial z} \frac{\partial g}{\partial \bar{z}} - \frac{\partial g}{\partial z} \frac{\partial f}{\partial \bar{z}} \right).$$

Then the equations of motion become

$$\frac{\mathrm{d}}{\mathrm{d}s} x^{a} = \{x^{a}, H\}, \quad \frac{\mathrm{d}p_{a}}{\mathrm{d}s} = \{p_{a}, H\},$$

$$\frac{\mathrm{d}}{\mathrm{d}s} \bar{z} = \{\bar{z}, H\}, \quad \frac{\mathrm{d}}{\mathrm{d}s} z = \{z, H\}.$$

IV. CONSERVATION OF THE CURRENTS

To derive the form of the energy-momentum current, $T^{\mu\nu}$, we rewrite the Hamiltonian as

$$H = g_{\mu\nu} T^{\mu\nu},$$

where $T^{\mu\nu}$ is

$$T^{\mu\nu} = \Pi^{\mu} \bar{z} \gamma^{\nu} z.$$

In Eq. (33), the Lorentz force can be written as the covariant derivative of $T^{\mu\nu}$:

$$T^{\mu\nu}{}_{;\nu} = \bar{z} \gamma^{\nu} z \Pi^{\mu}{}_{;\nu} = \frac{D}{Ds} \Pi^{\mu}. \tag{34}$$

Equation (34) shows that the energy-momentum current is not conserved for the spinning particle in the presence of the electromagnetic gauge field, $F_{\mu\nu}$, the torsion gauge field $T_{\mu\alpha}{}^{\beta}$, and the gauge field of the Lorentz rotations $R_{\alpha\beta\mu\nu}$.

The electromagnetic current, j^{μ} is defined as

$$j^{\mu} = \bar{z} z \bar{z} \gamma^{\mu} z. \tag{35}$$

The covariant derivative of j^{μ} is

$$j^{\mu}{}_{;\mu} = \bar{z} z \bar{z} \gamma^{\mu}{}_{;\mu} z = 0. \tag{36}$$

V. CONCLUSION

In Sec. III we show that Eqs. (30) and (31) are in the *same form* with the corresponding equations of motion in flat space–time. Equation (33) is the nongeodesic generalization of the corresponding flat space–time equation of motion. In Sec. IV we show that the covariant constancy of the Dirac matrices gives the conservation of the electric current.

To derive the quantum equations of motion we choose x^a and $\bar{z}_i$ as the variables in the configuration space of the particle and represent them by c-number variables. Then we represent the canonical conjugate variables p_a, and $\bar{z}_i$ as derivatives with $\hbar = 1$:

$$\hat{p}_a = i \frac{\partial}{\partial x^a},$$

$$\hat{z} = - \frac{\partial}{\partial \bar{z}}.$$

Since γ^{μ} is covariant constant then the quantum Hamiltonian is obtained from the classical one in Eq. (24) by replacing the classical dynamical variables with the corresponding quantum operators for $\hat{x}^a$, $\hat{z}^i$, $\hat{p}_a$, and $\hat{\bar{z}}_i$ without any ordering corrections:

$$\hat{H} = (\hat{p}_{\mu} - \hat{\bar{z}} \hat{B}_{\mu} \hat{z}) \hat{\bar{z}} \gamma^{\mu} \hat{z}.$$

The quantum equations of motion are derived by evaluating the following commutators:

$$\frac{\mathrm{d}}{\mathrm{d}s} x^a = i[x^a, \hat{H}], \quad \frac{\mathrm{d}p_a}{\mathrm{d}s} = i[p_a, \hat{H}],$$

$$\frac{\mathrm{d}}{\mathrm{d}s} \bar{z} = i[\bar{z}, \hat{H}], \quad \frac{\mathrm{d}}{\mathrm{d}s} z = i[z, \hat{H}].$$

Since there is no ordering corrections in the quantum Hamiltonian, the quantum equations of motion will be in the same form with the classical equations of motion in the Riemann-Cartan space–time.

The Hamiltonian in Eq. (24) corresponds to the classical Hamiltonian of the zitterbewegung system with the continuous, complex internal degrees of freedom and the continuous spin values. The corresponding quantum Hamiltonian, $\hat{H}$, gives the evolution of the continuous coherent eigenstates of $\hat{z}$, in proper time. To derive the Hamiltonians for the discrete spin eigenstates we evaluate the evolution operators for each spin eigenstate separately and this gives the Dirac Hamiltonian $\hat{H}_{\mathrm{D}} = \hat{\Pi}_{\mu} \gamma^{\mu}$ for spin $1/2$ eigenstates.[23]

In this space–time the scalar product is defined as

$$(\chi, \varphi) = \int \mathrm{d}^4 x \det e^{-1} \bar{\chi} \varphi,$$

and the minimal coupling of the Dirac field with gravitation is described by

$$(\Psi,\hat{H}_{\mathrm{D}}\Psi)=i\int \mathrm{d}^4x\ \det e^{-1}\bar{\Psi}\gamma^{\mu}\nabla_{\mu}\Psi.$$

Since γ^{μ} is covariant constant, then $(\det e^{-1})$ is also covariant constant and the scalar product and the interaction Hamiltonian is Hermitian:

$$(\Psi,\hat{H}_{\mathrm{D}}\Psi)=\frac{1}{2}\int \mathrm{d}^4x\ \det e^{-1}[\bar{\Psi}\gamma^{\mu}i\nabla_{\mu}\Psi+\overline{(i\nabla_{\mu}\Psi)}\gamma^{\mu}\Psi].$$

Thus we see that the ambiguity about the minimal coupling of matter with gravitation is solved by the covariant constancy of the Dirac matrices.

We see from Eqs. (26) and (27) that $\bar{z}z$ term is a constant of motion. Since it may be negative, zero, or positive we identify it as the charge of the particle, e.

In Eq. (33) the electromagnetic field is coupled with the electric current, $\bar{z}z\dot{x}^{\nu}$ and it is the source of the electromagnetic interactions. In a similar way, the Riemann tensor and the torsion tensor are coupled with the spin angular momentum current and the energy-momentum (current) tensor of the spinning particle, respectively, and they are the sources of the internal and the space–time rotations and space–time translations.

In Eq. (31), $DS_{\mu\nu}/Ds$ is proportional to the normal components of Π^{μ} with respect to velocity, $\dot{x}^{\nu}$. To derive the other form of the equation of motions for Π_{μ}, we decompose it into the parallel and normal components with respect to the velocity, $\dot{x}^{\nu}$:

$$\Pi_{\mu}=\frac{1}{(\dot{x})^2}\left(Hg_{\mu\nu}\dot{x}^{\nu}+\dot{x}^{\nu}\frac{DS_{\mu\nu}}{Ds}\right). \tag{37}$$

In Eq. (37), the first term of Π_{μ} is proportional to $\dot{x}_{\mu}$ and the proportionality constant is the Hamiltonian, H and we identify it as the mass of the particle, m. Then Eqs. (31), (30), and (33) become

$$\frac{DS^{\mu\nu}}{Ds}=\frac{1}{(\dot{x})^2}\left[\dot{x}^{\mu}\dot{x}_{\alpha}\frac{DS^{\nu\alpha}}{Ds}-\dot{x}^{\nu}\dot{x}_{\alpha}\frac{DS^{\mu\alpha}}{Ds}\right], \tag{38}$$

$$\frac{D\dot{x}^{\mu}}{Ds}=4S^{\mu\nu}\frac{1}{\sqrt{(\dot{x})^2}}\left(Hg_{\nu\alpha}\frac{\dot{x}^{\alpha}}{\sqrt{(\dot{x})^2}}+\frac{\dot{x}^{\alpha}}{\sqrt{(\dot{x})^2}}\frac{DS_{\nu\alpha}}{Ds}\right), \tag{39}$$

$$\frac{D}{Ds}\left[\left(mg_{\mu\nu}\dot{x}^{\nu}+\dot{x}^{\nu}\frac{DS_{\mu\nu}}{Ds}\right)\right]=-\dot{x}^{\alpha}T_{\mu\alpha}{}^{\beta}\left(mg_{\beta\nu}\dot{x}^{\nu}+\dot{x}^{\nu}\frac{DS_{\beta\nu}}{Ds}\right)+eF_{\mu\nu}\dot{x}^{\nu}+\frac{1}{2}R_{\alpha\beta\mu\nu}\frac{1}{2}\bar{z}\Sigma^{\alpha\beta}z\dot{x}^{\nu}. \tag{40}$$

Since the existence of the zitterbewegung oscillations, Eq. (39) shows that $(\dot{x})^2$ is not constant:

$$\dot{x}_{\mu}\frac{D\dot{x}^{\mu}}{Ds}=\frac{4\dot{x}_{\mu}S^{\mu\nu}}{\sqrt{(\dot{x})^2}}\frac{\dot{x}^{\alpha}}{\sqrt{(\dot{x})^2}}\frac{DS_{\nu\alpha}}{Ds}\neq 0.$$

In the phenomenological spin models, $(\dot{x})^2$ is taken as a constant and then $p_{\mu}S^{\mu\nu}/\sqrt{(\dot{x})^2}=0$.

Audretsch showed the vanishing of the covariant derivative of the spin polarization pseudovector, $S^{5\mu}$, by using only the positive energy solutions of the Dirac equation.[20] In our case the corresponding spin polarization pseudovector is

$$S^{5\mu}=\frac{1}{4i}\bar{z}[i\gamma^5,\gamma^{\mu}]z, \tag{41}$$

and the covariant proper time dependence is given as

$$\frac{DS^{5\mu}}{Ds} = \dot{x}^5 \Pi^\mu, \tag{42}$$

where $\dot{x}^5$ is $\bar{z} i\gamma^5 z$. In a separate study we will show that the correct spin polarization pseudovector is defined as

$$S_\perp^{5\mu} = \frac{1}{4i}\bar{z}[i\gamma^5, \gamma^\mu - \gamma\cdot\pi\pi^\mu/\pi^2]z.$$

In the Minkowski space–time, $S_\perp^{5\mu}$ is a constant of motion. In the presence of the electromagnetic interactions it satisfies the Bargmann-Michel-Teledgi equation with zitterbewegung corrections.[21] In the Riemann-Cartan space–time, the covariant derivative of spin polarization pseudovector is also proportional to the generalized Lorentz force in Eq. (33).

The right-hand side of Eq. (33) is the generalization of the electromagnetic Lorentz force to the Riemann-Cartan space, U_4. Except for the electromagnetic force the other terms are derived also by Hehl[16] in the nongeodesic equation for p_μ. For the Riemann space, V_4, the torsion tensor is zero and we obtain the classical Papapetrou equation.[19] For the Weitzenbock space, W_4, the curvature is zero and we obtain the nongeodesic equation for spinning particle with the Cartan connection.

For the spinless particle $S^{\alpha\beta}$ vanishes, $(\dot{x})^2$ becomes 1, and $\Pi_\mu = m g_{\mu\nu}\dot{x}^\nu$. Then the Lorentz force becomes

$$\frac{D}{Ds}(g_{\mu\nu}\dot{x}^\nu) = -T_{\mu\alpha\beta}\dot{x}^\alpha\dot{x}^\beta + \frac{e}{m}F_{\mu\nu}\dot{x}^\nu$$

for the Riemann-Cartan space, U_4. For the Riemann space, V_4, the torsion tensor is zero and we obtain the geodesic equation with the electromagnetic force. For the Weitzenbock space, W_4, the curvature is zero and we obtain the nongeodesic equation with Cartan connection and it coincides with the previous expression,[22] and is also equivalent to the geodesic equation.

We show in Eq. (33) that the spin-1 part of the generalized spin connection can be identified as the electromagnetism and the torsion is coupled with the spinning particle in the presence of the condition about the covariant constancy of the Dirac matrices.[12–14]

The other interactions can be formulated in a similar way by considering the groups larger than U(2,2). The invariant properties of the spinning particles under the conformal transformations can be discussed also by using the group U(2,2). The quantization of the spinning particle in the Riemann-Cartan Maxwell space will be studied later. The Lagrangian in Eq. (4) gives the Dirac equation for spin-1/2 case, spin-1 (symmetric) part of the DKP equation, and the higher spin wave equations.[23,24]

On the essential constants in Riemannian geometries

G. O. Papadopoulos[a),b)]

(Received 21 October 2005; accepted 29 July 2006; published online 6 September 2006)

In the present work the problem of distinguishing between essential and spurious (i.e., absorbable) constants contained in a metric tensor field in a Riemannian geometry is considered. The contribution of the study is the presentation of a sufficient and necessary criterion, in terms of a covariant statement, which enables one to determine whether a constant is essential or not. It turns out that the problem of characterization is reduced to that of solving a system of partial differential equations of the first order. In any case, the metric tensor field is assumed to be smooth with respect to the constant to be tested. It should be stressed that the entire analysis is purely of local character. © *2006 American Institute of Physics.*

I. INTRODUCTION

When dealing with Riemannian spaces, especially in a local description and in a coordinate approach, one frequently encounters the problem of attributing a character to a constant (or a parameter) which may appear in the metric tensor field. Generally, there are two possibilities: this constant is either essential (i.e., a true degree of freedom) or spurious (i.e., absorbable with the help of a change in the coordinates).

The issue is of great interest in the context of general relativity, where the metric tensor field is the solution to the Einstein equations, and the constants emerge from the integration procedure. But, this observation will not limit the spirit of the present work.

There is a variety of ways to attack the problem under discussion. In the relevant literature, one can find two main approaches:

A_1 The first main approach consists simply of trying to find that particular change in the coordinates which can serve to eliminate the "suspect" constant. When this is possible, the constant is incorporated in the very definition of the new coordinate system, being thus absorbed. The difficulty here is that, in general, there is no systematic way to find the desired transformation. Obviously, failure to find such a transformation does not necessarily imply the essentiality of the constant.

A_1 The second main approach, which is more elaborate and sophisticated, can be divided into two subcategories: one can either use the invariant classification methods for a single Riemannian space, or implement the methods of the *equivalence problem* (Ref. 1). The second way (which may be more laborious than the first) consists of the following steps: one considers twice the metric tensor field, once for a given value of the constant and once for another value of it. The final step is to compare these two metrics and to check whether they are equivalent or not. A positive answer dictates that the constant is spurious (and a negative, that it is essential) (see also Ref. 2 for a connection between limits of space–time and the problem of essentiality).

The nonequivalence between two given Riemannian spaces can easily be checked using the

[a)]Electronic mail: gopapado@phys.uoa.gr

notion of *curvature invariant relations*, functionally independent relations among scalars. These scalars are constructed either from the Riemann tensor and its covariant derivatives up to a given order by contracting all the indices, or as "ratios" between two tensors (obtained from the Riemann tensor) which differ only by a factor. The first case gives scalars entering *syzygies, polynomial invariants, mixed invariants*, and the *Cartan invariants*—see Ref. 1 and the references therein for details. The second case is described in Ref. 3 (especially the last two references therein). It is sufficient for the two given spaces to differ in only one such relation in order to be inequivalent.

Curvature-invariant relations have one very important property: they do not depend on points of the Riemannian space; thus, their functional forms are invariant statements (i.e., they retain the same functional form in all coordinate systems). Consequently, if these functional forms depend on some constants, that means these constants, which clearly are some from those in the metric tensor field, are not affected by a change in the coordinates. If a constant of the metric tensor field could be eliminated by such a change, then the metric tensor field in the new coordinate system as well as all the curvature invariant relations based on it, would lack this particular constant, an invariant statement, since the curvature invariant relations are invariant in form. Therefore, only essential constants will appear in the curvature-invariant relations.

An example will elucidate the above arguments: consider the well-known Schwarzschild metric in the usual local coordinate system $\{t,r,\theta,\phi\}$ and e.g., the two curvature scalars,

$$S_1 \equiv R_{\alpha\beta\mu\nu}R^{\alpha\beta\mu\nu} = 48M^2/r^6, \tag{1.1}$$

$$S_2 \equiv S_{1;\mu}^{;\mu} = -3456M^3/r^9 + 1440M^2/r^8, \tag{1.2}$$

which are, of course, r-dependent. However, if r is eliminated between them, one arrives at the relation

$$R(S_1,S_2,M) \equiv S_2 + 6\sqrt{3}S_1^{3/2} - 5M^{-2/3}\sqrt[3]{9/2}S_1^{4/3} = 0. \tag{1.3}$$

This relation is not only independent of the space–time points, i.e., it can be evaluated everywhere in the Schwarzschild space–time (except, of course, the true singularity at $r=0$), but also invariant under any change in the local coordinate system; although the functional form (in terms of the coordinates) of the two curvature scalars S_1, S_2 will change, the relation $R(S_1,S_2,M)$ will retain its form (as a function of its arguments S_1, S_2, and M) and thus constitutes a curvature invariant relation. Indeed, consider for example the change $r\to\tilde{r}: r=M^{1/3}\tilde{r}$, which eliminates the parameter M from S_1 and alters the form of S_2, yet keeps the relation $R(S_1,S_2,M)$ unchanged. To use the above considerations in order to deduce equivalence between two Riemannian spaces is problematic, since it would require the existence of a countable basis for an arbitrary functional space.

The following section presents a sufficient and necessary criterion, in a covariant language which offers one the ability to check whether a constant, appearing in a metric tensor field, is essential or not. In the second case, the criterion also provides a way to find the desired local finite transformation of the change in the coordinates.

II. CRITERION

Before presenting the criterion, a word must be said for the existence of yet another kind of constant, namely the global (topological) constants: indeed, there are cases where a constant can be removed from local coordinate patches but it does appear in the transforms between them (e.g., in the appropriate range of the coordinates).

From the previous section, it is clear that *essential* and *spurious* are mutually complementary notions. It will turn out more practical, though equivalent, to deal with spurious. Indeed, if the constant is spurious one can, in the coordinates in which the constant is removed, take a product metric tensor field on $\mathcal{S}\times I$ (where $\mathcal{S}$ is the initial n-dimensional manifold and I the domain of definition of the spurious constant), and then deduce that the only nonzero components of curvature in $n+1$ dimensions are those which correspond to the curvature tensor of the n-dimensional metric tensor field. In these coordinates the normals to $\mathcal{S}$ form a symmetry. Alternatively, one can

also consider the $(n+1)$-dimensional manifold using the original coordinates, with the spurious constant as the extra coordinate, and use the constant to label the n-dimensional slices.

The above arguments can be made more precise as follows: Let $\mathcal{S}$ be a Riemannian space which is described by the pair $(\mathcal{M},g)$ (this definition is influenced by the definition of space–time, but C^∞-instead of simply C^r, connectedness as well as the Hausdorff condition seem to be minimal extensions), where $\mathcal{M}$ is an n-dimensional, connected, Hausdorff, and (C^∞) manifold and g is a (C^r) metric tensor field on it; (the value of r depends on the applications. In the context e.g., of general relativity, it is assumed that $r\geq 2$—see Ref. 4, pp. 55–59 for a relevant discussion) a nondegenerate, covariant tensor field of order 2, with the property that at each point of $\mathcal{M}$ one can choose a frame of n vectors $\{z_0,\ldots,z_{n-1}\}$, such that: $g(z_\alpha,z_\beta)=\eta_{\alpha\beta}$, where η is a diagonal matrix with entries $\{\varepsilon_0,\ldots,\varepsilon_{n-1}\}$, and $\varepsilon_\alpha=\pm 1$. [Small Greek indices take the values $\{0,\ldots,n-1\}$.]

Let also this metric tensor field depend on a constant λ; so, in a local coordinate system $\{x^\mu\}$, it is

$$g_{\alpha\beta}=g_{\alpha\beta}(x^\gamma;\lambda). \tag{2.1}$$

It is also supposed that the metric tensor field g is a (C^∞) function (i.e., smooth) with respect to λ—a basic assumption which is also encountered in Ref. 2, where limits of space–time are considered [which of course have to be defined in terms of essential constant(s)].

Let $I\subseteq\mathbb{R}$ be the domain of definition (i.e., the range of possible values) of the constant λ. Another Riemannian space $\widetilde{\mathcal{S}}$ can, naturally, emerge; the product: $\widetilde{\mathcal{S}}=\mathcal{S}\times I$. By this it is meant that the initial Riemannian space is nothing but the hypersurface $\lambda=$const. in $\widetilde{\mathcal{S}}$; a local isometric embedding. If $p\in\widetilde{\mathcal{S}}$, then the tangent space $T_p\mathcal{S}$ of $\mathcal{S}$ is a subspace of $T_p\widetilde{\mathcal{S}}$. Since $\mathcal{S}$ is a regular submanifold of $\widetilde{\mathcal{S}}$, there exists a basis $\{\mathbf{e}_0,\mathbf{e}_\mu\}\equiv\mathbf{e}_N$ of $T_p\widetilde{\mathcal{S}}$ such that its "spatial" part $\{\mathbf{e}_\mu\}$ is the basis of $T_p\mathcal{S}$. [Capital Latin indices take the values $\{0,\ldots,n\}$.] Since the difference of dimensions is 1, the subspace has no torsion. Consequently there is only one normal to it, vector $\mathbf{n}$. Without loss of generality it is taken to be of unit length. Then, one assigns

$$\mathbf{n}=n^A\mathbf{e}_A=\frac{1}{N}\mathbf{e}_0-\frac{N^\alpha}{N}\mathbf{e}_\alpha\Rightarrow n^A=\frac{1}{N}\{1,-N^\alpha\}, \tag{2.2}$$

with

$$\widetilde{g}(\mathbf{n},\mathbf{n})=\varepsilon=\pm 1 \tag{2.3}$$

(the sign is rather irrelevant), so

$$\mathbf{e}_0=N\mathbf{n}+N^\alpha\mathbf{e}_\alpha. \tag{2.4}$$

The quantity N is the *lapse function* and the object N^α is the *shift vector*. By definition,

$$\widetilde{g}_{00}=\widetilde{g}(\mathbf{e}_0,\mathbf{e}_0)=N^2\widetilde{g}(\mathbf{n},\mathbf{n})+N^\alpha N^\beta\widetilde{g}(\mathbf{e}_\alpha,\mathbf{e}_\beta), \tag{2.5}$$

$$\widetilde{g}_{0\alpha}=\widetilde{g}(\mathbf{e}_0,\mathbf{e}_\alpha)=N_\alpha\equiv N^\beta g_{\alpha\beta}, \tag{2.6}$$

$$\widetilde{g}_{\alpha\beta}=\widetilde{g}(\mathbf{e}_\alpha,\mathbf{e}_\beta)=g_{\alpha\beta}. \tag{2.7}$$

Thus, the Greek indices change position with the initial metric $g_{\alpha\beta}$, while the capital Latin indices change position with the new metric $\widetilde{g}_{AB}$. Finally,

$$\widetilde{g}_{AB}=\begin{pmatrix} N_\rho N^\rho+\varepsilon N^2 & N_\beta \\ N_\alpha & g_{\alpha\beta}\end{pmatrix}. \tag{2.8}$$

A straightforward calculation results in

$$\widetilde{\Gamma}^0_{00} = \frac{\dot{N}}{N} + \varepsilon \frac{N^\mu N^\nu}{N} K_{\mu\nu} + \frac{N^\mu}{N} N_{|\mu}, \tag{2.9a}$$

$$\widetilde{\Gamma}^0_{0\nu} = \varepsilon \frac{N^\mu}{N} K_{\mu\nu} + \frac{N_{|\nu}}{N}, \tag{2.9b}$$

$$\widetilde{\Gamma}^0_{\mu\nu} = \varepsilon \frac{K_{\mu\nu}}{N}, \tag{2.9c}$$

$$\widetilde{\Gamma}^\kappa_{00} = -\frac{\dot{N}}{N} N^\kappa - \varepsilon \frac{N^\mu N^\nu N^\kappa}{N} K_{\mu\nu} - \frac{N^\mu N_{|\mu}}{N} N^\kappa + \dot{N}^\kappa - \varepsilon N N^{|\kappa} + N^\kappa_{|\nu} N^\nu - 2N K^\kappa_\nu N^\nu, \tag{2.9d}$$

$$\widetilde{\Gamma}^\kappa_{0\nu} = -\frac{N^\kappa}{N} N_{|\nu} - \varepsilon \frac{N^\kappa N^\mu}{N} K_{\mu\nu} + N^\kappa_{|\nu} - N K^\kappa_\nu, \tag{2.9e}$$

$$\widetilde{\Gamma}^\kappa_{\mu\nu} = \Gamma^\kappa_{\mu\nu} - \varepsilon \frac{N^\kappa}{N} K_{\mu\nu}, \tag{2.9f}$$

where

$$K_{\mu\nu} = \frac{1}{2N}(N_{\mu|\nu} + N_{\nu|\mu} - \dot{g}_{\mu\nu}) \tag{2.10}$$

is the *extrinsic curvature* (in the literature of the theory of surfaces, it is also known as *second fundamental form*, of *shape tensor*) and describes the embedding curvature.

The bar (|) denotes covariant derivative with respect to the initial metric g of the subspace, while the dot $(\cdot)$ denotes differentiation with respect to the extra coordinate, i.e., λ.

The general theory of embedding can be found in any book on differential geometry, e.g., Ref. 5 are some classical references. There, one can see that the present case, where the difference in the dimensions is 1 (resulting in zero torsion for the subspace) is very simple. In fact, the Mainardi-Codazzi conditions are identically satisfied, while the Weingarten-Gauss conditions assume the form

$$\widetilde{R}_{\alpha\beta\mu\nu} = R_{\alpha\beta\mu\nu} - \varepsilon(K_{\alpha\mu}K_{\beta\nu} - K_{\alpha\nu}K_{\beta\mu}), \tag{2.11a}$$

$$\widetilde{R}_{\perp\beta\mu\nu} = K_{\beta\nu|\mu} - K_{\beta\mu|\nu}, \tag{2.11b}$$

of course, after the use of the projections

$$T^{A\ldots}_{B\ldots} n^B \equiv T^{A\ldots}_{\perp\ldots}, \quad T^{A\ldots}_{B\ldots} n_A \equiv T^{\perp\ldots}_{B\ldots}, \quad T^{A\ldots}_{B\ldots} y^B_{,\alpha} \equiv T^{A\ldots}_{\alpha\ldots}, \tag{2.12}$$

$y^B_{,\alpha}$ being the Jacobian $\partial y^A / \partial x^\alpha$ between a set of local coordinates in $\widetilde{\mathcal{S}}$, say $\{y^A\}$, and the set of the corresponding local coordinates in $\mathcal{S}$, say $\{x^\alpha\}$.

For the chosen embedding it is $\{y^A\}=\{\lambda, x^\alpha\}$

If one defines the tensor on $\widetilde{\mathcal{S}}$

$$C_{AB} \doteq -\frac{1}{2}\mathcal{L}_{\mathbf{n}} \widetilde{g}_{AB} \equiv -\frac{1}{2}(\mathbf{n}_{A;B} + \mathbf{n}_{B;A}), \tag{2.13}$$

where the semicolon (;) denotes covariant differentiation with respect to the new metric $\widetilde{g}$, one will have

$$C_{AB} = \begin{pmatrix} N^\mu N^\nu K_{\mu\nu} + \varepsilon N^\mu N_{|\mu} & \varepsilon \frac{1}{2} N_{|\beta} + K_{\beta\mu} N^\mu \\ \varepsilon \frac{1}{2} N_{|\alpha} + K_{\alpha\mu} N^\mu & K_{\alpha\beta} \end{pmatrix}. \tag{2.14}$$

In order for the two spaces, i.e., the embedding and the embedded, to have exactly the same geometrical information (in other words, exactly the same curvature properties), something which happens when and only when the constant (i.e., the extra coordinate) λ is absorbable, the Weingarten-Gauss conditions (2.11) suggest that the extrinsic curvature must vanish—for any embedding

$$K_{\alpha\beta} = 0. \tag{2.15}$$

Condition (2.15) as well as the demand for its validity for any embedding, and thus for the particular embedding in a Gaussian system of coordinates $N=1$ or $N=N(\lambda)$ and $N^\alpha=0$, result in the vanishing of the tensor C_{AB}; an invariant statement. Hence, follows the:

Criterion. The constant λ contained in the metric tensor field g of the Riemannian space $\mathcal{S}$ is spurious, if and only if the Lie derivative of the metric tensor field $\tilde{g}$ of the embedding space $\tilde{\mathcal{S}}$ with respect to the normal (to the subspace) vector $\mathbf{n}$, $\mathcal{L}_{\mathbf{n}}\tilde{g}$, vanishes.

Proof. First, one observes that the vanishing of the tensor field C_{AB} results in the following set of partial differential equations (PDEs):

$$C_{00} = 0 \Rightarrow N^\mu N_{|\mu} = 0, \tag{2.16a}$$

$$C_{0\alpha} = 0 \Rightarrow N_{|\alpha} = 0, \tag{2.16b}$$

$$C_{\alpha\beta} = 0 \Rightarrow K_{\alpha\beta} = 0, \tag{2.16c}$$

or

$$N = N(\lambda) \quad \text{(though an arbitrary function)}, \tag{2.17a}$$

$$N_{\alpha|\beta} + N_{\beta|\alpha} = \dot{g}_{\alpha\beta}. \tag{2.17b}$$

The lines preceding the criterion prove its necessity. In order to prove its sufficiency, let $n^A = 1/[N(\lambda)]\{1, -N^\alpha(\lambda, x^\beta)\}$ a normal vector whose components satisfy (2.17b). The set of its integral curves, parametrized by a parameter s, has the form

$$\frac{dy^A}{ds} = n^A(y^B(s)), \tag{2.18}$$

and, from the theory of ordinary differential equations, it is known that this problem is well posed and it always has a solution. Written out in detail,

$$\frac{dy^0}{ds} = \frac{1}{N(y^0)}, \tag{2.19a}$$

$$\frac{dy^\alpha}{ds} = -\frac{N^\alpha(y^0, y^\beta)}{N(y^0)}, \tag{2.19b}$$

As usual, this set defines a one-parametric (s being the parameter) family of transformations from the set $\{y^A\}$ to the set $\{\overline{y}^A\}$, the latter being the constants of integration of the flow lines of the vector $\mathbf{n}$. It is very easy to see that the emerging transformation has the general functional form

$$y^0 \to \overline{y}^0 : \overline{y}^0 = f(y^0), \tag{2.20a}$$

$$y^\alpha \to \overline{y}^\alpha : \overline{y}^\alpha = f^\alpha(y^0, y^\gamma), \tag{2.20b}$$

while the vector **n** undergoes a change,

$$\mathbf{n} \to \overline{\mathbf{n}} : \overline{n}^A = \frac{\partial \overline{y}^A}{\partial y^B} n^B, \tag{2.21}$$

with the help of the transformation (2.20),

$$\overline{n}^A = \frac{1}{N(y^0)} \left\{ \frac{\partial f(y^0)}{\partial y^0}, \frac{\partial f^\alpha(y^0, y^\gamma)}{\partial y^0} - \frac{\partial f^\alpha(y^0, y^\gamma)}{\partial y^\beta} N^\beta(y^E) \right\}. \tag{2.22}$$

But,

$$\frac{d\overline{y}^\alpha}{ds} = 0 \Rightarrow \frac{\partial f^\alpha(y^0, y^\gamma)}{\partial y^0} - \frac{\partial f^\alpha(y^0, y^\gamma)}{\partial y^\beta} N^\beta(y^E) = 0 \tag{2.23}$$

by virtue of the flow lines equations (2.19). Thus,

$$\mathbf{n} \to \overline{\mathbf{n}} : \overline{n}^A = \frac{1}{N(y^0)} \left\{ \frac{\partial f(y^0)}{\partial y^0}, 0 \right\}, \tag{2.24}$$

i.e., a Gaussian system of coordinates. Hence, in the new coordinate system, the vanishing of the tensor $\overline{C}_{AB}$, obviously, is tantamount to

$$\frac{\partial \overline{g}_{\alpha\beta}}{\partial \overline{y}^0} = 0, \tag{2.25}$$

i.e., the transformed metric tensor field of the subspace does not contain the corresponding extra coordinate $\overline{y}^0$, which is a function of the constant under discussion. Q.E.D.

III. AN APPLICATION AND A PEDAGOGICAL EXAMPLE

One immediate and simple application of the criterion is achieved when the latter is applied to the case where the "suspect" constant is an overall factor; i.e., in a local system of coordinates $\{x^\mu\}$,

$$g_{\alpha\beta} = g_{\alpha\beta}(x^\gamma; \lambda) \equiv \lambda G_{\alpha\beta}(x^\gamma). \tag{3.1}$$

Then, the criterion, in its "solved form" (2.17b), results in

$$N_{\alpha|\beta} + N_{\beta|\alpha} = \dot{g}_{\alpha\beta} = G_{\alpha\beta} \Rightarrow N_{\alpha|\beta} + N_{\beta|\alpha} = \frac{1}{\lambda} g_{\alpha\beta}, \tag{3.2}$$

which is nothing but the homothety equations for the subspace—a well-known result.

For the sake of simplicity and brevity, the paper concludes with a pedagogical example.

Let a two-dimensional metric tensor field, which in a local coordinate system $\{x^\mu\} \equiv \{u, v\}$, has the form

$$g_{\alpha\beta}(u, v; \lambda) = (1 + \lambda^2) \begin{pmatrix} 0 & 1 + u^2 + (1 + \lambda^2)^2 v^2 \\ 1 + u^2 + (1 + \lambda^2)^2 v^2 & 0 \end{pmatrix}. \tag{3.3}$$

Solution to

$$N_{\alpha|\beta} + N_{\beta|\alpha} = \dot{g}_{\alpha\beta} \tag{3.4}$$

results in

$$N^{\alpha} = \left\{0, \frac{2\lambda v}{1+\lambda^2}\right\} \equiv \left\{0, \frac{2y^0 y^2}{1+(y^0)^2}\right\}, \tag{3.5}$$

and hence

$$n^A = \frac{1}{N(y^0)}\left\{1,0,-\frac{2y^0 y^2}{1+(y^0)^2}\right\}. \tag{3.6}$$

The corresponding flow lines are described by

$$\frac{dy^0}{ds} = \frac{1}{N(y^0)}, \tag{3.7a}$$

$$\frac{dy^1}{ds} = 0, \tag{3.7b}$$

$$\frac{dy^2}{ds} = -\frac{1}{N(y^0)}\frac{2y^0 y^2}{(1+(y^0)^2)}, \tag{3.7c}$$

and the integral curves

$$\int N(y^0)dy^0 = s + \bar{y}^0, \tag{3.8a}$$

$$y^1 = \bar{y}^1, \tag{3.8b}$$

$$y^2 = \bar{y}^2(1+(y^0)^2)^{-1}. \tag{3.8c}$$

Then, as expected, it is

$$\bar{n}^A = \{1,0,0\}, \tag{3.9}$$

leading to the transformed embedding metric,

$$\bar{\bar{g}}_{AB} = \begin{pmatrix} \varepsilon & 0 \\ 0 & \bar{g}_{\alpha\beta} \end{pmatrix}, \tag{3.10}$$

with

$$\bar{g}_{\alpha\beta} = \begin{pmatrix} 0 & 1+\bar{u}^2+\bar{v}^2 \\ 1+\bar{u}^2+\bar{v}^2 & 0 \end{pmatrix}. \tag{3.11}$$

Though the example may seem simple and trivial, its purpose is to exhibit not only the implementation of the criterion but also all the details connected to it.

Colliding and intersecting hypersurfaces filled with matter (membranes) are studied in the Lovelock higher order curvature theory of gravity. Lovelock terms couple hypersurfaces of different dimensionalities, extending the range of possible intersection configurations. We restrict the study to constant curvature membranes in constant curvature anti-de Sitter (AdS) and dS background and consider their general intersections. This illustrates some key features which make the theory different from the Einstein gravity. Higher co-dimension membranes may lie at the intersection of co-dimension one hypersurfaces in Lovelock gravity; the hypersurfaces are located at the discontinuities of the first derivative of the metric, and they need not carry matter. The example of colliding membranes shows that general solutions can only be supported by (spacelike) matter at the collision surface, thus naturally conflicting with the dominant energy condition (DEC). The imposition of the DEC gives selection rules on the types of collision allowed. When the hypersurfaces do not carry matter, one gets a solitonlike configuration. Then, at the intersection one has a co-dimension two or higher membrane standing alone in AdS-vacuum space–time *without conical singularities*. Another result is that if the number of intersecting hypersurfaces goes to infinity the limiting space–time is free of curvature singularities if the intersection is put at the boundary of each AdS bulk. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2338143]

I. INTRODUCTION

Lately, a strange idea has become popular in cosmology. It has been suggested[1] that we live on a $(3+1)$-dimensional membrane, called a brane world, living in a higher dimensional space–time. Many general relativity models have been invented to describe the gravitational behavior of such a brane world. Although there is a clear conceptual link with string theory, i.e., the extra dimensions and the existence of membranes with matter and gauge fields confined to their world-sheets, it is also clear that this is a highly speculative idea.

This idea motivates a general study of hypersurfaces in d-dimensional curved space–time. Co-dimension one hypersurfaces are understood as co-dimension one submanifolds which are the locus of the discontinuities of the first derivative of the metric. To draw specific conclusions we need a theory of gravity, determining the metric of the d-dimensional space–time locally. Lovelock gravity is a natural choice in d dimensions in place of Einstein gravity in four dimensions; it is the only theory (action functional) for the metric which gives second-order field equations when torsion is zero, that is, when the covariant derivative is given by the usual formula.[2,3] One can get

[a)]Electronic mail: eliasgravanis@netscape.net
[b)]Electronic mail: steve-at-cecs.cl

a relation between the discontinuity of the first derivative of the metric to the energy tensor of matter on the hypersurface. Hypersurfaces of any co-dimensionality which (potentially) carry matter will be called membranes.

The more complicated, compared to Einstein's theory, structure of derivatives in Lovelock gravity makes it possible to have membranes of co-dimensionality higher than one, via intersections of co-dimension one hypersurfaces, without any space–time singularities. Put slightly differently, high co-dimension membranes can be embedded in space–time without causing conical or more pathological curvature singularities if they are embedded at the intersection of co-dimension one hypersurfaces. In fact, in d dimensions there exist membranes of co-dimensionality up to the integer part of $(d-1)/2$, such that the metric is everywhere continuous, its first derivative has (bounded) discontinuities at the hypersurfaces and space–time is everywhere, and especially at the membranes, a manifold.[4,5]

The higher dimensional gravity theory of Lovelock[3] is an interesting generalization of general relativity. In $d \geqslant 5$ the Einstein–Hilbert is not the most general Lagrangian that produces second-order field equations and it was extended by Lovelock to a more general theory with this property. The latter gives the theory familiar features, in accordance with our experience from classical mechanics and field theory. It allows for a Hamiltonian formulation[6] and the possibility of a well-posed initial value problem.[7] The Lagrangian which possesses this property was found by Lovelock[3] and it is a linear combination of terms corresponding to the Euler densities in all lower even dimensions,[2]

$$\mathcal{L} = \sum_{n=0}^{[(d-1)/2]} \frac{1}{2^n} \beta_n \delta^{\mu_1 \cdots \mu_{2n}}_{\nu_1 \cdots \nu_{2n}} R^{\nu_1 \nu_2}_{\mu_1 \mu_2} \cdots R^{\nu_{2n-1} \nu_{2n}}_{\mu_{2n-1} \mu_{2n}} \sqrt{g} d^d x, \tag{1}$$

where $[x]$ is the integer part x. The generalization of the Einstein tensor is the Lovelock tensor:

$$H^{\mu}_{\nu} = - \sum_{n=0}^{[(d-1)/2]} \frac{1}{2^{n+1}} \beta_n \delta^{\mu \mu_1 \cdots \mu_{2n}}_{\nu \nu_1 \cdots \nu_{2n}} R^{\nu_1 \nu_2}_{\mu_1 \mu_2} \cdots R^{\nu_{2n-1} \nu_{2n}}_{\mu_{2n-1} \mu_{2n}}. \tag{2}$$

The delta is the generalized totally antisymmetrized Kronecker delta. It is the determinant of a matrix with elements δ^M_N,

$$\delta^{\mu_1 \cdots \mu_p}_{\nu_1 \cdots \nu_p} = \det \begin{pmatrix} \delta^{\mu_1}_{\nu_1} & \delta^{\mu_2}_{\nu_1} & \cdots & \delta^{\mu_p}_{\nu_1} \\ \delta^{\mu_1}_{\nu_2} & \delta^{\mu_2}_{\nu_2} & \cdots & \delta^{\mu_p}_{\nu_2} \\ \vdots & \vdots & \ddots & \vdots \\ \delta^{\mu_1}_{\nu_p} & \delta^{\mu_2}_{\nu_p} & \cdots & \delta^{\mu_p}_{\nu_p} \end{pmatrix} = p! \delta^{\mu_1}_{[\nu_1} \cdots \delta^{\mu_p}_{\nu_p]}. \tag{3}$$

The Lovelock theories have been studied extensively. Higher dimensional black hole solutions have been found.[8–10] This has shed some interesting light on questions of black hole entropy. Some cosmological metrics have been studied.[11]

The $n_{\max}=2$ Lovelock theory, which we call the Gauss–Bonnet theory, has a special physical significance. This is because the $n=2$ term is the only quadratic term which has a ghost free perturbation theory about flat space–time. It has been conjectured that the Gauss–Bonnet term is the leading order, purely geometric, correction to the effective action of an underlying unitary fundamental theory.[12] In particular, the Lovelock contributions, motivated by string theory, have played a role in brane-world cosmology.[13,14]

It was Zumino[2] who formulated the theory in the way we prefer, as an elegant way to prove suggestions by Zwiebach related to low energy string theory.[12] We use the vielbein formulation: E^a is the vielbein frame, ω^{ab} the spin connection, and Ω^{ab} is the curvature two-form,

$$\Omega^{ab} = \tfrac{1}{2} R^{cd}{}_{ab} E^c \wedge E^d,$$

$$R^{cd}{}_{ab} = E^a_\mu E^b_\nu R^{\mu\nu}_{\kappa\lambda} E^\kappa_c E^\lambda_d.$$

In this language, the Lovelock Lagrangian is

$$\mathcal{L} = \sum_{n=0}^{[(d-1)/2]} \beta_n \Omega^{a_1 a_2} \wedge \cdots \Omega^{a_{2n-1} a_{2n}} \wedge e_{a_1 \cdots a_{2n}}, \tag{4}$$

where

$$e_{a_1 \cdots a_p} = \frac{1}{(d-p)!} \epsilon_{a_1 \ldots a_d} E^{a_{p+1}} \wedge \cdots \wedge E^{a_d} \tag{5}$$

and we have defined the totally antisymmetric tensor such that $\epsilon_{(1)\ldots(d)} = 1$. The Latin letters from the beginning of the alphabet are used for the local Lorentz indices (d-dimensional). Greek letters from the middle of the alphabet are used for space–time coordinate indices (d-dimensional).

In the Lovelock theory, singular hypersurfaces of co-dimension one can be meaningfully defined in terms of distributions,[14,15] due to the property of quasilinearity in second derivatives.[16] Brane worlds of co-dimension one have thus been the most well studied and understood. They can also be formulated by means of boundary terms in the action. The correct boundary term is most elegantly derived by a dimensional continuation of the Gauss–Bonnet theorem for a manifold with boundary.[17] The latter approach is the one we have adopted.

The possibility of colliding shells or branes of matter has been studied in the context of GR.[18] In Lovelock gravity, there has been some study of intersecting brane worlds, see, e.g., Ref. 19 and more recently, Refs. 20 and 21, but so far there has been no study of collisions in this context except for our comments in our recent work.[4,5] In that work, we restricted the smoothness of the metric so that there were well-defined orthonormal vectors at the intersection/collision. The most striking fact, physically, about intersections or collisions is that they could carry their own singular stress-energy tensor. This is a phenomenon that does not occur in the Einstein theory. That difference and related properties of the Gauss–Bonnet term were used in Ref. 19 to address the cosmological constant problem and formulate higher co-dimension brane worlds via intersections, continuing on previous work in GR context, see, e.g., Ref. 22. Our aim here will be to discuss general properties of the intersections and collisions of hypersurfaces in Lovelock gravity, mostly via the example of anti-de Sitter (AdS) and dS background, which may be useful also outside the brane-world context.

In the Einstein theory, singular matter can only be accommodated at an intersection of co-dimension two if there is a conical singularity, with a deficit angle. Then, it is impossible to define two orthonormal vectors normal to the intersection. Although Lovelock gravity with a conical singularity can be described in terms of distributions,[23–25] there is a certain ambiguity about the solutions—in general, we would not expect the thin brane to be the unique limit of a thick brane solution.[26,27] We shall not consider this kind of singularity in the present work.

There is, however, an interesting possibility. We consider intersections of hypersurfaces, non-null as well as null, which carry zero energy tensor. At their intersections there appear higher co-dimension membranes. For non-null co-dimension one hypersurfaces we have an intersection of solitonlike configurations, pure (cosmological constant-) vacuum gravitational field self-supported and with a nonzero jump in the extrinsic curvature; for null hypersurfaces we have intersection/collision of gravitational shock waves. In both cases one has at their intersections membranes of co-dimension $\geqslant 2$ surrounded by pure AdS background on a nonsingular space–time. This is a phenomenon not possible in Einstein gravity.[26]

Previous works on related problems in the brane world were in the context of: Einstein gravity, e.g., Ref. 22; in supergravity, where intersection rules for branes carrying form field charges were derived in Refs. 28–30; and in various formulations when Gauss–Bonnet or higher Euler densities are included, e.g., Refs. 31 and 19, 20, 21, and 24. An important difference in this work and our previous ones[4,5] is that one may have a high co-dimension membrane without the

cost of making space–time singular.[31,24,21] Our primary intention really is to point out properties of Lovelock gravity which are interesting on their own, but our results may be useful to other endeavors.

In Secs. II–IV we present the example of intersecting hypersurfaces in an AdS background. In Sec. V we discuss colliding hypersurfaces in dS background and point out the spontaneous dominant energy condition violation in collisions. In Sec. VI, we discuss the dimensionalities of the intersection in relation to a four-dimensional universe. In Sec. VII we discuss higher co-dimension membranes using intersections of solitonic configurations and shock waves.

The intersection junction conditions. For our purposes, hypersurfaces are $(d-1)$-dimensional surfaces which divide the space–time up into d-dimensional bulk regions. We shall assume that they are space–time like (i.e., with space-like normal vector). If there is a nonzero singular component to the stress-energy tensor with its support on the hypersurface, we shall also call it a brane.

The mathematics of the intersections becomes simple if we consider a kind of minimal intersection, which involves the minimum number of hypersurfaces needed to build the intersection of a given co-dimensionality (dimensionality of its normal space). Put differently, in such an intersection any bulk region has (a co-dimension one) common boundary with *any other* bulk region. Not without a reason we call them simplicial intersections: if abstractly we assign a point to every bulk region in which the connection is continuous, then a co-dimension p intersection corresponds to a p-dimensional simplex, that is, the p-dimensional polyhedron with the minimum number of vertices. This abstraction turns into a practical method of calculating the Lagrangian densities integrated over the intersections.[4,5]

One of the simplifications related to the simplicial intersection is that if we label the bulk regions with i (and designate $\{i\}$) then the co-dimension p intersection can be labeled by an antisymmetric symbol involving the labels of the $p+1$ bulk regions meeting there; the simplest example are the co-dimension one hypersurfaces designated in general as $\{i_0 i_1\}=-\{i_1 i_0\}$. So we introduce the following.[4,5]

Definition 1.1: (simplicial intersection) Let $\{i\}$ be a bulk region. $\{i_0 \ldots i_p\}$ is a simplicial intersection where bulk regions $i_0, \ldots, i_p$ meet, if it is a $(d-p)$-dimensional submanifold. The connections in the bulk regions are $\omega_0, \ldots, \omega_p$, respectively. $\{i_0 \ldots i_p\}$ is a part of the boundary of the $(p-1)$-intersection $\{i_0 \ldots i_{p-1}\}$. The orientation is $\partial\{i_0 \ldots i_{p-1}\}=+\{i_0 \ldots i_p\}+\cdots$. Swapping any pair of indices reverses the orientation.

Note that intersections may be spacelike, timelike, or null (or vary between them).

There are junction conditions relating the singular stress-energy to the geometry.[4,5] Let ω_i be the connection in region $\{i\}$. At a hypersurface $\{ij\}$ there can be a discontinuity $\omega_i \neq \omega_j$. The junction conditions at a p-intersection are obtained from the intersection Lagrangian:

$$\sum_{n=1}^{[(d-1)/2]} \beta_n \mathcal{L}^n_{(p)},$$

$$\mathcal{L}^n_{(p)}(E, \omega_0, \ldots, \omega_p) = A_p \int_{s_{0\ldots p}} d^p t (\omega_1 - \omega_0)^{a_1 b_1} \cdots (\omega_p - \omega_0)^{a_p b_p} \Omega(t)^{a_{p+1} b_{p+1} \ldots a_n b_n} e_{a_1 \ldots b_n}, \qquad (6)$$

$$A_p = (-1)^{p(p-1)/2} \frac{n!}{(n-p)!}.$$

$\Omega(t)$ is the curvature of the interpolating connection $\omega(t)$:

$$\omega(t) := \sum_{i=0}^{p} t^i \omega_i, \quad \Omega(t) = d\omega(t) + \omega(t) \wedge \omega(t). \tag{7}$$

The $\Omega(t)^{a_{p+1}\ldots b_n}$ is short for the $(n-p)$-fold product: $\Omega(t)\wedge\cdots\wedge\Omega(t)$. The integral is over the p-dimensional simplex

$$s_{0\ldots p} = \left\{ t \in \mathbf{R}^{p+1} \,\middle|\, \sum_{i=0}^{p} t_i = 1, \text{ all } t_i \geqslant 0 \right\}. \tag{8}$$

The junction conditions come from explicit Euler variation with respect to the vielbein: $\delta_{E^c}\mathcal{L}_{(p)} = -2(T_{(d,d-p)})^b_c \tilde{e}_b$, where $T_{(d,d-p)}$ is the part of the singular stress-energy tensor with support on the intersection. The factor of -2 is explained in the Appendix. So the junction conditions can be written as

$$(T_{(d,d-p)})^b_c \tilde{e}_b = \frac{1}{2}(-1)^{(p-1)(p-2)/2} \sum_{n=p}^{[(d-1)/2]} \frac{n!}{(n-p)!} (\mathcal{E}^n_{(p)})_c, \tag{9}$$

$$(\mathcal{E}^n_{(p)})_c \equiv \int_{s_{1\ldots p+1}} d^p t (\omega_2 - \omega_1)^{a_1 b_1} \cdots (\omega_{p+1} - \omega_1)^{a_p b_p} \Omega(t)^{a_{p+1} b_{p+1} \ldots a_n b_n} e_{a_1 \ldots b_n c}. \tag{10}$$

$\tilde{e}$ is the natural volume element on the intersection. We note that $\mathcal{E}^n_{(p)}$ is zero if $p > n$. (In Einstein theory the only junction condition is that of the hypersurface, where if the energy tensor carried by it vanishes then so does the discontinuity of the connection, in the non-null case. For a general intersection in Lovelock gravity the energy tensor may vanish without implying vanishing of the connection discontinuities. Even for the single hypersurface case, $\mathcal{E}_{(1)} = \Sigma_n \beta_n \mathcal{E}^n_{(1)} = 0$ does not imply that the connection becomes continuous. Simple solutions where this happens can easily be found and such space–times have been called solitons.[31] If such a hypersurface is spacelike, there is a breakdown of causality. Another important case of vanishing energy tensor is that of the null hypersurface, that is, of the shock wave. Shock waves exist in GR[32] as well as in higher order Lovelock theory.)

Also there is another implicit junction condition: there is a well-defined (pseudo-) orthonormal frame everywhere. If this condition is not obeyed, then the above-presented formula is not valid. In the case of a hypersurface junction condition, it is equivalent to a well-defined induced geometry on the hypersurface. For higher co-dimension intersections it is a quite stringent condition. For example, for a co-dimension two intersection, there can be no deficit angle.

II. INTERSECTIONS IN AdS AND GAUSS-BONNET TERM

We have seen that there is a possibility to localize matter on an intersection in the Gauss–Bonnet theory. We now proceed to a specific example.

A. The bulk vacuum solution

We shall take the simplest kind of bulk solution. Each bulk region is a constant curvature region of space–time. Such a space–time satisfies $R_{\mu\nu\rho\sigma} = 1/[d(d-1)]R(g_{\mu\rho}g_{\nu\sigma} - g_{\mu\sigma}g_{\nu\rho})$, R being a constant.[33] There are three possibilities:

(i) de Sitter space ($R > 0$),
(ii) anti-de Sitter space ($R < 0$),
(iii) flat space ($R = 0$).

In the Einstein theory, constant curvature empty space will be one of the above three, depending on whether the cosmological constant is positive, negative, or zero. In the higher order Lovelock theory, it is possible that more than one type of constant curvature space–time will

satisfy the vacuum field equations. The different possibilities arise because the field equations are polynomial in the curvature. For a constant curvature, this just reduces to a polynomial equation in the curvature scalar.

A more general space–time would be made up of regions of less symmetric vacuum space–time. We will not attempt this here, but leave it as a project for the future.

We take the example of AdS bulk space–time, motivated by: (1) the Randall–Sundrum idea of the nonfactorizable metric[1] which allows gravitons to be approximately localized in a large extra dimension; (2) the special role of AdS space in recent advances;[35] (3) the simplicity of the problem from a mathematical point of view. AdS space has constant negative curvature:

$$\Omega^{ab} = -\frac{1}{l^2} E^a \wedge E^b. \tag{11}$$

The constant l has dimensions of length. It is easy to check that if we write

$$\omega^{ab} = \frac{1}{l}(u^a E^b - u^b E^a), \tag{12}$$

where u^a is a constant vector, we have, assuming zero torsion $dE^a = -\omega^a{}_b \wedge E^b$,

$$\Omega^{ab} = -\frac{u^2}{l^2} E^a \wedge E^b. \tag{13}$$

Above $u^2 = \eta_{ab} u^a u^b$. For an AdS solution, we take u to be space-like $u^2 = +1$. The opposite sign choice gives dS space–time. AdS, dS, or flat space is a vacuum solution of the general Lovelock theory (4) provided that the following relation is satisfied:

$$\sum_{n=0}^{[(d-1)/2]} \frac{(-u^2)^n (d-1)!}{(d-1-2n)!} \frac{\beta_n}{l^{2n}} = 0. \tag{14}$$

Now let us write the solution in terms of coordinates. We will write the AdS metric in conformally flat form. Define $u \cdot x \equiv \eta_{\mu\nu} u^{(\mu)} x^\nu$,

$$ds^2 = \frac{1}{((u \cdot x)/l + C)^2} \eta_{\mu\nu} dx^\mu dx^\nu, \quad (u \cdot x)/l + C > 0, \tag{15}$$

with C an arbitrary constant. Contact between (15) and (12) is made by the choice for the vielbein:

$$E^a = \frac{1}{(u \cdot x)/l + C} \delta^a_{(\mu)} dx^\mu.$$

We will only be interested in the vicinity of the intersection and will not worry here about the global details of joining together regions of AdS.

B. Three-way intersection

We will consider the simplest three-way vertex. There is a plane covered by coordinates $(x, y) \equiv (x^{d-2}, x^{d-1})$. It will also be convenient to use cylindrical coordinates: $x = \rho \cos\theta$, $y = \rho \sin\theta$. There are three bulk regions, $i = 1, 2, 3$, broken up by three hypersurfaces, $\{ij\}$, at $\theta = \text{const}$. The hypersurfaces meet at the intersection, $\{123\}$, at $\rho = 0$. The space–time is divided into regions:

region 1: $0 < \theta < \theta_1$,

region 2: $\theta_1 < \theta < \theta_2$,

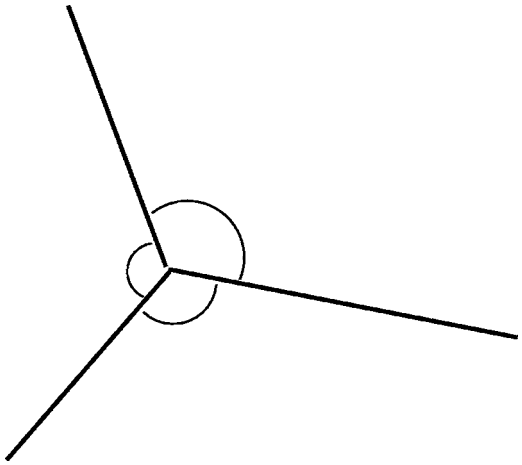

FIG. 1. The intersection of three hypersurfaces. Each bulk region, denoted by $\{i\}$, is a piece of constant curvature space–time. If there is no deficit angle we have $\theta_3=2\pi$. The three angles shown are θ_1, $\theta_2-\theta_1$, and $\theta_3-\theta_2$.

region 3: $\theta_2<\theta<\theta_3$, with the identification $\theta_3\equiv 0$. One can have a conical singularity at the intersection with deficit angle $2\pi-\theta_3$ but we will not do so for reasons we will mention. So we take $\theta_3=2\pi$ (Fig. 1). In each region i let $u_i=(0,\ldots,0,\cos\phi_i,\sin\phi_i)$ such that $u_i\cdot x=\rho\cos(\theta-\phi_i)$. The metric in each region takes the following form:

$$ds_i^2=\frac{1}{(\rho\cos(\theta-\phi_i)/l+1)^2}\eta_{\mu\nu}dx^\mu dx^\nu. \tag{16}$$

We have chosen $C=1$ here for convenience. We insist that the metric is continuous, so the factor $(u\cdot x)/l+1$ should be continuous across the walls:

$$\cos(\theta_1-\phi_1)=\cos(\theta_1-\phi_2), \tag{17}$$

$$\cos(\theta_2-\phi_2)=\cos(\theta_2-\phi_3), \tag{18}$$

$$\cos(\phi_3)=\cos(\phi_1). \tag{19}$$

There is the trivial solution $\phi_i=\phi_{i+1}$, which is smooth across the hypersurface. If we are to have any matter on the hypersurfaces (a brane) we must choose the nonsmooth solutions:

$$\begin{aligned}\phi_1&=-\phi_3=\theta_1-\theta_2,\\ \phi_2&=\theta_1+\theta_2.\end{aligned} \tag{20}$$

This allows for u to be different in each region. The spin-connection (12) is not single-valued at the walls.

At the intersection, we need more than just continuity of the metric. We must have a well-defined orthonormal basis

$$E_\mu^a E_\nu^b g^{\mu\nu}=\eta^{ab}$$

everywhere, including at $\rho=0$. Now, since the metric is conformally flat, the angle between two vectors is

$$v \angle w = \frac{v^\mu w^\nu g_{\mu\nu}}{(v^\mu v^\nu g_{\mu\nu})^{1/2}(w^\mu w^\nu g_{\mu\nu})^{1/2}} = \frac{v^\mu w^\nu \eta_{\mu\nu}}{(v^\mu v^\nu \eta_{\mu\nu})^{1/2}(w^\mu w^\nu \eta_{\mu\nu})^{1/2}}.$$

This is well known—a conformal transformation preserves angle. So theta is indeed a measure of the angle between vectors. At $\rho=0$, we have $E^a=(\ldots,\cos\theta_a,\sin\theta_a)$, but with the identification $\theta\equiv\theta+\theta_3$. Since $\eta^{ab}=E^a\angle E^b=\cos(\theta_b-\theta_a)$, for a well-defined orthonormal frame we require $\cos(\theta_b-\theta_a+r\theta_3)=1$ *or* 0 for arbitrary integer r, so we should set $\theta_3=2\pi$. Thus we insist upon having no deficit angle at the intersection.

C. The junction conditions

Recall that the junction condition at each p-intersection is (9). In the next section we shall evaluate the general form of $\mathcal{E}^n$ for the intersections in AdS. Here we shall stick to the codimension two intersection in the Einstein–Gauss–Bonnet theory. Furthermore, we shall not calculate the energy-momentum tensor on the branes but proceed to find what is at the intersection.

There is no contribution from the Einstein term: $\mathcal{E}^1_{(2)}=0$. Only the Gauss–Bonnet contributes. $\mathcal{E}^2_{(2)}$ is

$$(\mathcal{E}^2_{(2)})_f = (\omega_2-\omega_1)^{ab}\wedge(\omega_3-\omega_1)^{cd}\wedge e_{abcdf}\int_{s_{123}} d^2t.$$

The volume of the two-simplex is 1/2,

$$\begin{aligned}(\mathcal{E}^2_{(2)})_f &= \tfrac{1}{2}(\omega_2-\omega_1)^{ab}\wedge(\omega_3-\omega_1)^{cd}\wedge e_{fabcd}\\ &= -2(u_2-u_1)^a(u_3-u_1)^b E^c\wedge E^d\wedge e_{fabcd}\\ &= -2(d-4)(d-3)[(u_2-u_1)^{(1)}(u_3-u_1)^{(2)}-(u_2-u_1)^{(2)}(u_3-u_1)^{(1)}]e_{f(1)(2)}.\end{aligned}$$

The factor in square brackets is

$$\begin{aligned}&(\cos\phi_2-\cos\phi_1)(\sin\phi_3-\sin\phi_1)-(\cos\phi_3-\cos\phi_1)(\sin\phi_2-\sin\phi_1)\\ &\quad=\sin(\phi_3-\phi_2)+\sin(\phi_2-\phi_1)+\sin(\phi_1-\phi_3)\\ &\quad=\sin(2\theta_2)+\sin(2\theta_1-2\theta_2)-\sin(2\theta_1).\end{aligned}$$

Note $e_{(1)(2)}=\tilde{e}$ is the natural volume element on the intersection. Putting this into (9), we get the following result:

Proposition 2.1: The junction condition for the intersection is

$$(T_{123})^a_b = -2(d-4)(d-3)\beta_2[\sin(2\theta_2)+\sin(2\theta_1-2\theta_2)-\sin(2\theta_1)]\delta^a_b. \tag{21}$$

The singular matter on the intersection is a $(d-2)$-dimensional cosmological constant or tension. (If the energy tensor T^a_b on a hypersurface takes the form $-V\delta^a_b$, we will call the constant V the cosmological constant or tension of the membrane, which in some cases might be negative where it amounts to pressure. In this paper we are mainly interested in whether the value of the energy tensor is zero or not and we will be writing the tensor as $T^a_b=\Lambda\delta^a_b$ so one should bear in mind that $V=-\Lambda$.)

Using the double angle formulas, we can prove that this tension vanishes in $d\geqslant 5$ if and only if: either $\cos(2\theta_1)=1$, $\cos(2\theta_2)=1$, or $\cos(2\theta_1)=\cos(2\theta_2)$ and $\sin(2\theta_1)=\sin(2\theta_2)$. These solutions are not really intersections at all:

(i) $\theta_1=\theta_2\Rightarrow\phi_1=\phi_3=0$, region 2 is shrunk to zero; $\theta_1=0\Rightarrow\phi_2=\phi_3$, region 1 is shrunk to zero; or $\theta_2=2\pi\Rightarrow\phi_2=\phi_1$, region 3 is shrunk to zero. In these cases there is just a smooth AdS bulk.

(ii) $\theta_1=\pi\Rightarrow\phi_2=\phi_3$, $\theta_2=\pi\Rightarrow\phi_2=\phi_1$ or $\theta_1-\theta_2=\pi\Rightarrow\phi_3=\phi_1=\pi$ In these cases there is just a single hypersurface.

III. HIGHER CO-DIMENSION INTERSECTIONS IN AdS

So far we have dealt with co-dimension two intersections. We now proceed to look at the higher co-dimension simplicial intersection in AdS background. There are $p+1$ bulk regions, $\{i\}$, separated by $p+1$ hypersurfaces, $\{ij\}$, intersecting at the simplicial intersection $\{i_0 \ldots i_p\}$. The metric in each bulk region is, cf. (15):

$$ds^2 = \frac{1}{(u_i \cdot x + 1)^2}(\delta_{\alpha\beta} dx^\alpha dx^\beta + dx^2_{(d-p)}). \tag{22}$$

The branes intersect at $x^\alpha = (0, \ldots, 0)$. Each brane is paramterized generally by $f(x^\alpha) = 0$, and is assumed to be maximally symmetric in the other $d-p$ dimensions.

The continuity of the metric at each hypersurface $\{ij\}$: $(u_i - u_j) \cdot x = 0$, implies that $(u_i - u_j)$ is proportional to the normal vector to $\{ij\}$. Each AdS region is characterized by a unit spacelike vector $u_i^a, i = 0, \ldots, p$ and the same AdS scale l which we set to 1. Define

$$u_{ij} = u_i - u_j \tag{23}$$

and

$$u(t) = \sum_{i=0}^{p} t^i u_i \tag{24}$$

with $\Sigma_{i=0}^p t^i = 1$, and

$$R(t)^a_b = u(t)^2 \delta^a_b + N^a_b, \quad N^{ab} = \sum_{i=0}^{p} \sum_{j=0}^{p} t^i t^j u^a_{ij} u^b_{ij}. \tag{25}$$

Proposition 3.1: The curvature of the interpolating connection is

$$\Omega^{ab}(t) = - R(t)^{c[a} E_c \wedge E^{b]}, \tag{26}$$

where the symmetric matrix $R(t)$ is defined in (25).

Note: We will *not* need to take the u_i all of the same causal nature in this proof; each u_i may be time- or spacelike, or null.

Proof: By (12) the connection on each region i is assumed to be given by

$$\omega_i^{ab} = u_i^a E_i^b - u_i^b E_i^a. \tag{27}$$

The curvature of the interpolating connection $\omega(t) = \Sigma_{i=0}^p t^i \omega_i$ then is

$$\Omega(t)^{ab} = d\omega(t)^{ab} + \omega(t)^a_c \wedge \omega(t)^{cb} = - u(t)^2 E^a \wedge E^b + \sum_{i=0}^{p} t^i u_i^a u_{ic} E^b \wedge E_c + \sum_{ij} u_i^a u_{jc} E^c \wedge E^b - (a \leftrightarrow b) \tag{28}$$

where we have used zero torsion and metric continuity to calculate

$$d\omega(t)^{ab} = \sum_i t^i d\omega_i^{ab} = \sum_i t^i (u_i^a dE_i^b - u_i^b dE_i^a) = \sum_i t^i (- u_i^a \omega_{ic}^b \wedge E^c + u_i^b \omega_{ic}^a \wedge E^c), \tag{29}$$

where we drop the region index from the frame E after the derivative is taken as the metric itself is continuous, all E_i agree at the hypersurface, only its derivative jumps.

Now, by using $\Sigma_{i=0}^p t^i = 1$, we have

$$\sum_{ij} t^i t^j (u_i - u_j)^a (u_i - u_j)_c = 2\sum_i t^i u_i^a u_{ic} - 2\sum_{ij} t^i t^j u_i^a u_{jc} \tag{30}$$

so by (25) and (23) we get (26). □

The intersection junction conditions are (9) with

$$\mathcal{E}^n_{(p)} = 2^p(-1)^{n-p}\int_{s_{01\ldots p}} d^p t u^{a_1}_{10}\ldots u^{a_p}_{p0} E^{b_1\ldots b_p} R(t)^{a_{p+1}}_{c_{p+1}}\ldots R(t)^{a_n}_{c_n} E^{c_{p+1}b_{p+1}\ldots c_n b_n} e_{a_1\ldots b_n c}. \tag{31}$$

Note first that by $u_{ij}=u_{i0}-u_{j0}$ all terms involving N^a_b defined by (25) and (23) drop out in the previous equation by the presence of the factors $u_{10}\ldots u_{p0}$ (involving all vectors which span the normal space) and the antisymmetry of the volume form $e_{a1\ldots b_n c}$. Note that this also true if some u_{i0}'s are null. Now applying the identity

$$E^{c_1\ldots c_n}\wedge e_{d_1\ldots d_m} = \frac{m!}{(m-n)!}\delta^{c_1}_{[d_{m-n+1}}\ldots\delta^{c_n}_{d_m} e_{\ d_1\ldots d_{m-n}]}, \tag{32}$$

we can then write

$$\mathcal{E}^n_{(p)} = (-1)^{n-p}(-1)^{p(p-1)/2}2^p\int_{s_{01\ldots p}} d^p t u^{a_1}_{10}\ldots u^{a_p}_{p0}(u(t)^2)^{n-p}$$
$$\times\frac{(2n+1)!}{(p+1)!}\delta^{b_1}_{[b_1}\ldots\delta^{b_p}_{b_p}\delta^{a_{p+1}}_{a_{p+1}}\delta^{b_{p+1}}_{b_{p+1}}\ldots\delta^{a_n}_{a_n}\delta^{b_n}_{b_n} e_{\ ca_1\ldots a_p]}. \tag{33}$$

The factor of $(-1)^{p(p-1)/2}$ comes from the rearrangement of the indices. The quantity after the symbol $\times$ equals

$$\frac{(d-p-1)!}{(d-2n-1)!} e_{ca_1\ldots a_p} \tag{34}$$

and is calculated in the Appendix.

Let $n^1,\ldots,n^p$ be orthonormal vectors that span the normal space. The one free index intersection volume form is defined by

$$\tilde{e}_c = \prod_{i=1}^{p}(n^i\cdot n^i)(n^1)^{a_1}\ldots(n^p)^{a_p} e_{a_1\ldots a_p c}. \tag{35}$$

Note the difference in the position of the free index c from the previous formula.

If we define the matrix of components

$$u^j_i := u^a_{i0} n^j_a, \tag{36}$$

expanding the vectors u_{i0} in (33) in the orthonormal basis we have

$$u^{a_1}_{10}\ldots u^{a_p}_{p0} e_{a_1\ldots a_p c} = \det(u^j_i)\tilde{e}_c, \tag{37}$$

so finally

$$(\mathcal{E}^n_{(p)})_c = \frac{n!}{(n-p)!}\frac{(d-p-1)!}{(d-2n-1)!}(-1)^{n-p}(-1)^{p(p-1)/2}2^p\det(u^j_i)\int_{s_{01\ldots p}} d^p t(u(t)^2)^{n-p}\tilde{e}_c. \tag{38}$$

Substituting this in (9) and reinstating l, we get:

Proposition3.2: The junction condition for the simplicial p-intersection is

$$(T_{d,01\ldots p})^a_b = \Lambda_{d,01\ldots p}\delta^a_b,$$
$$\Lambda_{d,01\ldots p} = \sum_{n=p}^{[(d-1)/2]} \frac{\beta_n}{l^{2n-p}}(-1)^{n-p+1}\frac{n!}{(n-p)!}\frac{(d-p-1)!}{(d-2n-1)!}2^{p-1}\det(u_i^j)\int_{s_{01\ldots p}} d^p t(u(t)^2)^{n-p}, \tag{39}$$

where $T_{d,01\ldots p}$ is the energy-momentum tensor on the intersection.

Before proceeding let us first look at the Einstein case where only β_1 is nonzero. AdS and dS space–times correspond to the vector u being spacelike and timelike, respectively, so we find that the bulk cosmological constant is

$$V_d = -\Lambda_d = \mp \beta_1 \frac{(d-1)(d-2)}{2l^2}, \tag{40}$$

which is the standard formula with beta related to the Newton's constant G by $\beta_1 = (8\pi G)^{-1}$. The tension of a hypersurface in Einstein gravity reads

$$V_{d,10} = -\Lambda_{d,10} = (d-2)\frac{\beta_1}{l}(u_1 - u_0)^a n_a, \tag{41}$$

where n^a is the normal vector on the hypersurface $\{10\}$. Applying this to the geometry of the three-way intersection discussed in Sec. II B we find

$$V_{d,10} = (d-2)\frac{\beta_1}{l}(\sin(\phi_1 - \theta_0) - \sin(\phi_0 - \theta_0)) = (d-2)\frac{\beta_1}{l}2\sin(\phi_1 - \theta_0), \tag{42}$$

where $u_i = (\cos\phi_i, \sin\phi_i)$ and $n_i = (-\sin\theta_i, \cos\theta_i)$, and the positions of the hypersurfaces $\{10\}$,$\{21\}$,$\{02\}$ are $\theta_0, \theta_1, \theta_2$, respectively. We have labeled the regions by 0,1,2 instead of 1,2,3 as in Sec. II B. We have applied the continuity conditions (17) to get the left-hand side of (42). Then the tension is positive if $\phi_1 - \theta_0$ is greater than zero and smaller than π. In a similar fashion it is possible for all three to have positive tensions. In particular, the tensions become equal (and positive) in the symmetric case where the vectors u are symmetrically arranged and so are the hypersurfaces, with the directions of the u's lying in between the hypersurfaces at $\pi/3$ angle from them.[37] This setup on AdS background has been studied in the past, see, e.g., Ref. 39. In the following we will use the symmetrically arranged vectors u in the case of general co-dimension to show that $\det(u_i^j)$ in (39) is always positive. For special Lovelock gravities we will see that the tensions of the intersections are all positive.

Something interesting about the contributions of the individual Euler terms, that is, about the value of $\Lambda_{d,01\ldots p}$ when a single such term is considered or contributes, is that it never vanishes.

Proposition 3.3: Each term in (39) cannot vanish unless β_n is zero. (The terms can possibly cancel among themselves).

Proof: First recall:

$$u_i^j = \begin{pmatrix} u_{10}^{(1)} & \cdots & u_{10}^{(p)} \\ \vdots & \ddots & \vdots \\ u_{p0}^{(p)} & \cdots & u_{p0}^{(p)} \end{pmatrix}$$

and each vector u_{i0} is proportional to the normal vector of the hypersurface $\{0i\}$. If the determinant of u_i^j is zero then the vectors u_{i0} are not linearly independent. That is, they cannot span the p-dimensional normal space of the codimension p simplicial intersection so the configuration degenerates to a lower co-dimension intersection.

Also since

$$u(t) = \sum_{i=0}^{p} t^i u_i = u_0 + \sum_{i=1}^{p} t^i u_{i0}$$

and u_i's are spacelike vectors then $u(t)^2 \geqslant 0$. But u_{i0} are linearly independent space-like vectors which span the normal space and u_0 a spacelike vector on it, that is, $u(t)$ cannot be zero everywhere on the p-simplex. So the integral in (39) does not vanish. □

Now define

$$P_{d,p}(x) := 2^{p-1} \sum_{n=p}^{[(d-1)/2]} \frac{\beta_n}{l^{2n-p}} (-1)^{n-p+1} \frac{n!}{(n-p)!} \frac{(d-p-1)!}{(d-2n-1)!} x^{n-p}, \tag{43}$$

where the dependence of $P_{d,p}$ on β's and l is suppressed. $\Lambda_{d,01\ldots p}$ then reads

$$\Lambda_{d,01\ldots p} = \det(u_i^j) \int_{s_{01\ldots p}} d^p t P_{d,p}(u(t)^2). \tag{44}$$

We have the following

Proposition 3.4: A sufficient condition for $\Lambda_{d,01\ldots p} \neq 0$ is $P_{d,p}(x) > 0$ (or <0) for $0 < x < 1$.

Proof: Since, $|u(t)| \leqslant \Sigma_{i=0}^{p} t^i |u_i| = \Sigma_{i=0}^{p} t^i = 1$, by $|u_i| = 1$ with $|u| = \sqrt{u^2}$, the proposition is clear for $x = u(t)^2$ and $0 \leqslant x \leqslant 1$. Also if $u(t)^2 = 0$ then $0 = u(t) = \Sigma_{i=0}^{p} t^i u_i$, so by linear independence of the t^i we get that all $u_i = 0$; this happens only at one point on the simplex. On a similar basis, if $u(t)^2 = 1$ then all vectors u_i must be equal; $u(t)^2 = 1$ happens only at the $p+1$ points, the zero-dimensional faces of the simplex. So for the integral (44) one may take $0 < x < 1$ and if $P_{d,p} > 0$ (or <0) in this region the integral does not vanish. □

An interesting case we can study is Chamseddine's Chern–Simons theory with AdS gauge group, in d=odd.[40,9] It is a Chern-Simons theory from an Euler density in $d+1$=even dimensions with tangent space being AdS instead of Minkowski. This Chern-Simons theory is classically equivalent to a Lovelock gravity, existing in d=odd, with coefficients

$$\beta_n^C = \kappa (d-2n)! \frac{(\pm 1)^{n+1} \lambda^{2n-d}}{d-2n} \binom{k}{n} = \kappa (\pm 1)^{n+1} \lambda^{2n-d} (d-2n-1)! \binom{k}{n}, \tag{45}$$

where $n = 0, \ldots, k$ with $k = (d-1)/2 = [(d-1)/2]$ and the minus (plus) sign corresponds to the dS (AdS) group case and λ is the dS (AdS) gauge group length parameter and κ a dimensionless constant. [By considering intersections in Chamseddine's theory we go through a curious kind of cycle- Chern–Simons (gauge theory) → Lovelock Gravity → Chern–Simons (intersection terms). Whether there is anything deep behind this or just coincidence, we do not know.] The factor $(d-2n)!$ comes from our definition of the Euler terms in (4) compared to the definition in the references.

It is easy to see that the bulk equations of motion for our AdS background (11) implies $l^2 = \lambda^2$. This is the vacuum solution of the theory. As both variables are assumed positive we have $\lambda = l$. Using the formula for β_n^C above in (43) and redefining the summed index as $n-p=m$ we see that

$$\begin{aligned} P_{d,p}(x) &= -\kappa 2^{p-1} l^{p-d} \frac{k!(2k-p)!}{(k-p)!} \sum_{m=0}^{k-p} (\pm x)^m \frac{(k-p)!}{m!(k-p-m)!} \\ &= -\kappa 2^{p-1} l^{p-d} \frac{k!(2k-p)!}{(k-p)!} (1-x)^{k-p}, \quad k := \frac{d-1}{2}. \end{aligned} \tag{46}$$

So we obtain the following formula for the co-dimension p membrane embedded at the intersection of the regions labeled by $0, 1, \ldots, p$ in Chamseddine's theory

$$\Lambda_{d,01\ldots p} = -\kappa 2^{p-1} l^{p-d} \frac{k!(2k-p)!}{(k-p)!} \det(u_i^j) \int_{s_{01\ldots p}} d^p t (1-u(t)^2)^{k-p}. \tag{47}$$

All these Λ's are nonzero: as the polynomial does not change sign for $0<x<1$ so we see from Proposition 3.4 that (for Chamseddine's theory with AdS group) $\Lambda_{d,01\ldots p} \neq 0$.

Let the vectors $u_0, \ldots, u_p$ be symmetrically arranged in the normal space forming a symmetric hedgehog. This is discussed in Appendix D where formulas for $\det(u_i^j)$ and $u(t)^2$ are obtained. One finds

$$\Lambda_{d,p} = -\kappa l^{p-d} \sqrt{2} (2\sqrt{6})^{p-1} \frac{k!(2k-p)!}{(k-p)!} \left(1+\frac{1}{k}\right)^{k-p/2} \int_{s_p} d^p t \left\{1 - \sum_{i=0}^{p} t_i^2\right\}^{k-p}, \tag{48}$$

where s_p is any p-simplex, as by symmetry the tensions of all $(d-p)$-dimensional membranes in the configuration are the same. One could say that $V_{d,p} = -\Lambda_{d,p}$ is the tension of *the* (maximally symmetric) co-dimension p membrane in the vacuum of Chamseddine's gravity; it has been emphasized at the introduction that these membranes are embedded in space–time without causing singularities or changing its topology, for $p=1, \ldots, k$. The tensions in this formula depend only on the dimensionless κ, the length l, and the dimensions d and p and they are all positive.

Let us now turn to d=even. Consider the following Lagrangian in $d=2k+2$ dimensions defined as

$$\kappa f\left(\left(\Omega \pm \frac{1}{\lambda^2} E \wedge E\right)^{k+1}\right) = \kappa \sum_{n=0}^{k} \frac{(k+1)!}{n!(k+1-n)!} (\pm 1)^{k+1-n} \lambda^{2n-2k-2} f(\Omega^n E^{2k+2-2n}) + \kappa f(\Omega^{k+1}). \tag{49}$$

For the $+$ $(-)$ sign choice the constant curvature vacuum solution is an AdS (dS) space–time with curvature proportional to λ^{-2} where λ is a length parameter; we will call (49) the AdS and dS Born–Infeld theories, respectively.[41,9] κ is again a dimensionless parameter.

The last term is topological (exact form locally) and drops out of the equations of motion. So using (5) and the general definition of the Lovelock Lagrangian (4) we find

$$\beta_n^{\mathrm{BI}} = \kappa (\pm 1)^{k+1-n} \lambda^{2n-d} d(d-2n-1)! \binom{k}{n}, \tag{50}$$

where again $k=d/2-1=[(d-1)/2]$, $n=0, \ldots, k$. These coefficients are similar to β_n^C's so one may say that Born–Infeld theory is the analogue to Chamseddine theory in d=even.

Again the bulk equations of motion for our AdS background (11) give that $\lambda^2 = l^2$ for the AdS Born–Infeld theory. Putting the AdS β_n^{BI}'s into (43) we have

$$P_{d,p}(x) = -\kappa 2^{p-1} d \frac{k!(d-p-1)!}{(k-p)!} l^{p-d} (1-x)^{k-p}. \tag{51}$$

From this we obtain formulas similar to (47) and (48), and from Proposition 4 we have that for (AdS Born–Infeld theory) all $\Lambda_{d,01\ldots p}$ are nonzero.

Note that the results for nonvanishing simplicial intersection's energy tensors are due to the high symmetry of the system: the bulk regions are portions of the same, highly symmetric space–time, AdS, and the gravity theories have an AdS with a given radius as the single vacuum solution. In general, vanishing (simplicial) intersection's tensor does *not* imply degeneration of the intersection, that is, the connection can be discontinuous at the hypersurfaces. On the other hand, it is an interesting fact that the high symmetry of the background and of the theory makes all these intersection energy tensors (tensions of the embedded membranes) strictly nonzero.

In d=even it is easy to see why the polynomials get these summed expressions (49) and in turn by the similarity of the coefficients, to see why in Chamseddine's Lagrangian expressions get

simplified too. In fact the simplicity has nothing to do with the AdS background we mainly use in this work: according to our discussion in Ref. 5 the simplicial intersection Lagrangians are generated by expanding the polynomial

$$\eta_{\mathrm{BI}} = \kappa f((\Omega_F \pm \lambda^{-2} E(t) \wedge E(t))^{k+1}) = \kappa f((d_t \omega + \Omega(t) \pm \lambda^{-2} E(t) \wedge E(t))^{k+1}). \tag{52}$$

The intersection Lagrangians read[5]

$$\int_{s_{01\ldots p}} \eta_{\mathrm{BI}} = \kappa(-1)^{p(p-1)/2} \frac{(k+1)!}{(k+1-p)!} \int_{s_{01\ldots p}} d^p t f((\omega_1 - \omega_0) \ldots (\omega_p - \omega_0)[\Omega(t) \pm \lambda^{-2} E \wedge E]^{k+1-p}) \tag{53}$$

from which the equations of motion (junction conditions) are obtained by merely varying with respect to the frame E, as the variation with respect to the connection vanishes under the zero torsion condition for the frame on each bulk region.[5] For AdS backgrounds and going through the steps that lead to (39) we can show that (53) leads to (51). (53) can be applied to more general backgrounds such as the asymptotically AdS black holes of these theories, see, e.g., Refs. 41, 9, and 10 which will support less trivial energy tensors and time evolution at the intersection hypersurfaces.

IV. NONSIMPLICIAL INTERSECTIONS AND AdS BOUNDARY

We now return to a co-dimension two intersection. Let us now see what happens if there are four or more hypersurfaces intersecting. We have bulk regions $i=1,\ldots,m$ with hypersurfaces given by the configuration of angles: $\theta_1,\ldots,\theta_m$. We label the intersection as I.

The metric continuity condition $(u_i - u_{i+1}) \cdot x_i = 0$ for the ith hypersurface gives

$$\cos(\theta_i - \phi_i) = \cos(\theta_i - \phi_{i+1}) \tag{54}$$

writing $x_i = \rho_i(\cos\theta_i, \sin\theta_i)$ where (ρ_i, θ_i) is the position of the ith hypersurface on plane. One solution of this equation says that $\phi_i - \phi_{i+1}$ is integer multiple of 2π which is rejected as implying that $u_i = u_{i+1}$ which would make the connection continuous there by (12). The other is $\theta_i - \phi_{i+1} = -(\theta_i - \phi_i) + 2\pi\nu_i$ or

$$\theta_i = \tfrac{1}{2}(\phi_i + \phi_{i+1}) + \nu_i \pi. \tag{55}$$

$i=1,\ldots,m$ with the convention $\phi_{m+1} = \phi_1$. ν_i's are integers. There is a discontinuity $u_i \neq u_{i+1}$ which implies also the discontinuity $\omega_i \neq \omega_{i+1}$ of the connection, from the formula (12).

Now one finds

$$\sum_{j=1}^{i-1} (-1)^j \theta_j + \sum_{j=i}^{m} (-1)^{m-j} \theta_j = (-1)^i \frac{(-1)^m - 1}{2} \phi_i + \bar{\nu}_i \pi, \tag{56}$$

where $\bar{\nu}_i = \Sigma_{j=1}^{i-1}(-1)^j \nu_j + \Sigma_{j=i}^{m}(-1)^{m-j}\nu_j$.

For $m=$even one finds for all i the single expression

$$\theta_1 - \theta_2 + \theta_3 - \theta_4 + \cdots + \theta_{m-1} - \theta_m = -\bar{\nu}\pi, \tag{57}$$

where all $\bar{\nu}_i$'s are equal and denoted $\bar{\nu}$. The angles ϕ_i drop out. We have chosen $0 \leqslant \theta_1 < \theta_2 < \ldots < \theta_m < 2\pi$. It is not hard to see that the above-presented equation makes sense only for $\bar{\nu} = 1$. So in this case we cannot put the discontinuity hypersurfaces anywhere we like, without making the metric discontinuous. So ϕ_i's cannot be expressed in terms of the positions of the hypersurfaces. The tension in I is only a function of the bulk regions data ϕ_i. The intersection behaves rather as part of the background. The same happens to the analogous situation when we study collisions.

For an $m=$odd number of hypersurfaces we have from the above-presented formula

$$\sum_{j=1}^{i-1}(-1)^j\theta_j-\sum_{j=i}^{m}(-1)^j\theta_j=(-1)^{i-1}\phi_i+\bar{\nu}_i\pi. \tag{58}$$

We then derive:

$$(-1)^i(\phi_{i+1}-\phi_i)=2\sum_{j=1}^{i-1}(-1)^j\theta_j-2\sum_{j=i+1}^{m}(-1)^j\theta_j-(\bar{\nu}_{i+1}+\bar{\nu}_i)\pi. \tag{59}$$

We need the junction conditions for a nonsimplicial intersection. It is worthwhile digressing to explain a bit the abstract approach of Ref. 5, which allows us at once to write down the answer. In the following we give only a sketch of the method. For a full account the reader should consult Ref. 5.

The intersection Lagrangians are obtained by expanding a polynomial

$$\eta=(d_t\omega(t)+\Omega(t))^{a_1\ldots a_{2n}}\wedge e_{a_1\ldots a_{2n}}. \tag{60}$$

The structure of the Lagrangian at the intersection {123} of the hypersurfaces {12}, {23}, {31}, separating three bulk regions, given by

$$\mathcal{L}_{123}=\int_{s_{123}}\eta \tag{61}$$

is a result of the simplex boundary rule

$$\partial s_{123}=s_{23}-s_{13}+s_{12}. \tag{62}$$

See Appendix C for the general definition of the simplex and the associated boundary operator. The form η is a generalized Lagrangian, an example of which we used in (52). η generates the intersection Lagrangians according to a rule like (61) by integrating over t. Here t is the coordinate on the simplex. More generally t is the coordinate on a chain which is dual to the intersection in the following sense.

Consider a nonsimplicial intersection, for example of four hypersurfaces {12}, {23}, {34}, {41}, separating four bulk regions. We consider a three-dimensional simplex with vertices labeled by 1,…,4. The Lagrangian at the intersection is constructed by finding a chain (a chain or p-chain is, for our purposes, a linear combination of p-dimensional simplices with integer or rational coefficients.) c on that simplex such that

$$\partial c=s_{12}+s_{23}+s_{34}+s_{41}, \tag{63}$$

where the right-hand side reflects the arrangement of the hypersurfaces on the normal plane of their intersection.

By (62) it is easy to see that such a chain is

$$c=s_{123}+s_{134}, \tag{64}$$

where the boundary operator acts linearly; c is not unique, different c's obeying (63) differ by a chain which is itself a boundary. Then the Lagrangian, given by

$$\int_c\eta \tag{65}$$

is

$$\mathcal{L}_{123}+\mathcal{L}_{134}. \tag{66}$$

As c is not unique, this Lagrangian is not unique either. If c' is another chain satisfying (63) then $c'=c+\partial\sigma$ for some chain σ, so by Stokes theorem the Lagrangians corresponding to them are

related by $\int_{c'}\eta=\int_c\eta+\int_\sigma d_t\eta$. It is a special property of the polynomials (60) that the pull back of $d_t\eta+d_x\eta$ onto the $d+1$ dimensional space $\sigma\times$ (intersection) vanishes. So Lagrangians constructed by different chains c differ only by exact forms

$$\int_c \eta=\int_{c'} \eta+d\int_\sigma \eta.$$

It easy to construct now the Lagrangian for the nonsimplicial intersection of m hypersurfaces which reads $\mathcal{L}_I=\mathcal{L}_{123}+\mathcal{L}_{134}+\cdots+\mathcal{L}_{1,m-1,m}$. This gives

$$\begin{aligned}(T_I)^a_b&=-2(d-4)(d-3)\beta_2\Delta\,\delta^a_b,\\ \Delta&=\sum_{i=1}^{m}\sin(\phi_{i+1}-\phi_i)\end{aligned}\tag{67}$$

with $\phi_{m+1}\equiv\phi_1$. Using (59), we can express Δ purely in terms of the configuration:

$$\Delta=\sum_i \sin\left(2\sum_{j=1}^{i-1}(-1)^{i-j}\theta_j-2\sum_{j=i+1}^{m}(-1)^{i-j}\theta_j-(-1)^i(\bar{\nu}_{i+1}+\bar{\nu}_i)\pi\right).\tag{68}$$

The solution $\phi_i=\phi_{i+1}$ is trivial so the terms in brackets cannot vanish individually. However, there are more degrees of freedom than for the three-way intersection. There should be nontrivial zeroes of Δ. The simplest three-way planar intersection (Sec. II) in AdS background will have singular matter at the intersection. The intersection of a higher odd number of branes may or may not, depending on the geometry.

We now point out an interesting relation between the limit $m\to\infty$ of the number of intersecting hypersurfaces and the boundary of AdS. In the example of a nonsimplicial co-dimension two intersection of m hypersurfaces let the vectors u_i be arranged symmetrically by

$$\phi_i=(i-1)\frac{2\pi}{m},\quad i=1,2,\ldots,m.\tag{69}$$

From (55) and taking $\nu_1=\ldots\nu_{m-1}=0$ and $\nu_m=1$, which is also consistent with the constraint $\bar{\nu}=1$ in (57) for $m=$even, we find

$$\begin{aligned}\theta_{i|i\neq m}&=\left(i-\frac{1}{2}\right)\frac{2\pi}{m},\\ \theta_m&=\frac{(m-1)}{m}\pi+\pi=\left(m-\frac{1}{2}\right)\frac{2\pi}{m}.\end{aligned}\tag{70}$$

So the direction of the u vector of every bulk region is in between the directions of the hypersurfaces bounding that region.

From the ϕ_i's and θ_i's we find that the metric is given by $g_{\mu\nu}=\eta_{\mu\nu}(C+(1/l)\rho g_m(\theta))^{-2}$ where ρ is the radial variable on the normal plane, $C>0$ is a constant we usually set to 1, and

$$g_m(\theta)=\left\{\cos\left(\theta-i\frac{2\pi}{m}\right)\quad,\quad -\frac{\pi}{m}+i\frac{2\pi}{m}\leqslant\theta\leqslant\frac{\pi}{m}+i\frac{2\pi}{m},\quad i=0,1,\ldots,m-1.\right.\tag{71}$$

It is continuous and 2π-periodic in the 2π-periodic variable θ. In fact the function repeats the same values in every region: at all hypersurfaces it has the value $\cos(\pi/m)$ and approaches the value 1 in the middle of the interval; it is a copy of

$$\cos\theta, \quad \theta \in \left[-\frac{\pi}{m}, \frac{\pi}{m}\right] \tag{72}$$

for m times. So the interior of the bulk regions is a copy of that piece of the AdS space–time with radius l, a $1/m$ of the whole. In particular we have that

$$\cos\left(\frac{\pi}{m}\right) \leqslant g_m(\theta) \leqslant 1, \quad \forall\ \theta \in [0, 2\pi]. \tag{73}$$

If we take the limit $m \to \infty$ the function $g_m(\theta)$ approaches the constant value 1. In this limit the metric of the space–time becomes

$$ds^2_{m\to\infty} = \left(C + \frac{1}{l}\rho\right)^{-2} (d\rho^2 + \rho^2 d\theta^2 + \eta_{\alpha\beta} dx^\alpha dx^\beta), \tag{74}$$

where x^α are the coordinates parallel to the co-dimension two intersection. The curvature two-form is calculated to be

$$\Omega^{ab} = \delta^a_i \frac{1}{l^2}\left(1 + C\frac{l}{\rho}\right) Q^i_j E^j \wedge E^b - \delta^b_i \frac{1}{l^2}\left(1 + C\frac{l}{\rho}\right) Q^i_j E^j \wedge E^a - \frac{1}{l^2} E^a \wedge E^b, \tag{75}$$

where $i, j = 1, 2$ are indices of the Cartesian coordinates on (ρ, θ) plane and $Q^i_j = \delta^{ij} - x^i x^j/\rho^2$ projection operator on it, and the Ricci scalar is

$$R = 2(d-1)\frac{1}{l^2}\left(1 + C\frac{l}{\rho}\right) - d(d-1)\frac{1}{l^2}. \tag{76}$$

For $C \neq 0$ the space develops a curvature singularity.

The curvature singularity can actually be removed if the intersection is located within the boundary of each AdS bulk region. The constant C, taken to be the same for all regions, restricts the coordinates via $C + u_i \cdot x/l > 0$ for the ith region. Call A_i the space defined by this inequality. If we set $(C=0)$ we have that the metric in A_i is

$$ds^2_i = \frac{l^2}{(u_i \cdot x)^2} \eta_{\mu\nu} dx^\mu dx^\nu \tag{77}$$

with $u_i \cdot x > 0$. We want to include the space $u_i \cdot x = 0$ in A_i i.e., to consider the closure $\bar{A}_i$ of the open A_i. The metric (77) does not extend over the boundary of this space and it is given a meaning along the lines of Penrose's conformal compactification. One may multiply this metric with a function f with a first-order zero at the points x with $u_i \cdot x = 0$, to get a metric $d\tilde{s}^2_i = f^2 ds^2_i$ which extends to the boundary $u_i \cdot x = 0$ of A_i and defines a metric $d\tilde{s}^2_{ib}$ in it; the function f is arbitrarily chosen in $\bar{A}_i$, as long as it has a first-order zero at the boundary. As there is no natural choice of f, the coefficient of the zero is arbitrary and the metric $d\tilde{s}^2_{ib}$ is only well-defined up to conformal transformations. A_i is a part of the AdS space–time, the patch covered in Poincare coordinates which we have used to write the AdS metric in (77) and $u_i \cdot x = 0$ is a part of the AdS boundary. The boundary has the topology of sphere times the real line: $\mathbf{S}^{d-1} \times \mathbf{R}$.[33,34]

So let $C=0$ in the bulk regions so that the ith region is a subspace of A_i. The intersection is located at a common co-dimension two subset of the boundary of all A_i's; it is given by $\rho = 0$ in each one of them. When this is the case the infinite m metric reads

$$ds^2_{m\to\infty} = \frac{l^2}{\rho^2}(d\rho^2 + \rho^2 d\theta^2 + \eta_{\alpha\beta} dx^\alpha dx^\beta) = \frac{l^2}{\rho^2}(d\rho^2 + \eta_{\alpha\beta} dx^\alpha dx^\beta) + l^2 d\theta^2, \tag{78}$$

which is nothing but a $(d-1)$-dimensional AdS times a circle with radius l: $\mathrm{AdS}_{d-1} \times \mathbf{S}^1$. That is, a dimension gets compactified and $\rho = 0$ becomes the boundary of an AdS (a single Poincare patch of an AdS_{d-1}). The AdS_{d-1} metric is conformal (with a constant factor) to that of the $\mathrm{AdS}_{d|\theta=\mathrm{const.}}$

and it is the AdS living at each hypersurface, ending at $\rho=0$. The boundary of the limiting space–time has topology $\mathbf{S}^{d-2}\times\mathbf{S}^1\times\mathbf{R}$.

We have mentioned that because the metric at the boundary of the AdS is defined up to conformal transformations the energy tensor there has to be traceless. In our case it is diagonal so it should vanish identically. Now for finite m the tension at the intersection (67) via (69) reads

$$2(d-3)(d-4)\beta_2 l^{-2}\cdot m\sin\frac{2\pi}{m}. \tag{79}$$

Absence of a curvature singularity in the limit $m\to\infty$ is consistent only with $\beta_2=0$ (or $d\leqslant 4$) i.e., only Einstein gravity. This is for the symmetric configuration (69). On the other hand take m =even and consider the configuration

$$\phi_i=(i-1)\frac{2\pi}{m}+(-1)^i\epsilon,\quad i=1,\ldots,m=\text{even}, \tag{80}$$

where ϵ is a constant so that by the metric continuity condition (55) the positions (70) remain unchanged, employing the fact that for m=even the positions θ_i do not fix completely the ϕ_i's. The limiting metric in this case is

$$ds^2_{m\to\infty}=\frac{l^2}{\cos^2\epsilon}\frac{1}{\rho^2}(d\rho^2+\eta_{\alpha\beta}dx^\alpha dx^\beta)+\frac{l^2}{\cos^2\epsilon}d\theta^2, \tag{81}$$

namely just the radii l of (78) are rescaled. From (67) and finite m one finds for the tension on the intersection

$$2(d-3)(d-4)\beta_2 l^{-2}\cdot m\sin\frac{2\pi}{m}\cdot\cos(2\epsilon). \tag{82}$$

For conformal matter on the intersection this should vanish, which happens in Einstein–Gauss–Bonnet theory if and only if

$$\cos^2\epsilon=\tfrac{1}{2} \tag{83}$$

determining completely the limiting metric (81).

Conversely, note that in $d\geqslant 5$ Einstein gravity alone could not completely fix the metric (81). It is the higher Lovelock term which can reach the co-dimension two submanifold $\rho=0$ and fix the metric. In fact one can prove the following

Proposition 4.1: Any configuration converges in the limit $m\to\infty$ to the family of metrics (81). In Einstein gravity the whole family is allowed and the limit is ambiguous. When the Gauss–Bonnet term is included a single element is picked by (83).

Proof: From (55) we have

$$\theta_{i+1}-\theta_i=\tfrac{1}{2}(\phi_{i+2}-\phi_i)+(\nu_{i+1}-\nu_i)\pi. \tag{84}$$

In the $i+1$th region the argument of the cosine in the intersections metric (77) ranges according to

$$\tfrac{1}{2}(\phi_i-\phi_{i+1})+\nu_i\pi\leqslant\theta-\phi_{i+1}\leqslant\tfrac{1}{2}(\phi_{i+2}-\phi_{i+1})+\nu_{i+1}\pi. \tag{85}$$

In the limit $m\to\infty$, $(\theta_{i+1}-\theta_i)\to 0$ (or to 2π when $i=m$ with $\theta_{m+1}\equiv\theta_1+2\pi$.) From the first formula we see that the argument of the cosine goes to the fixed value

$$\tfrac{1}{2}(\phi_i-\phi_{i+1})+\nu_i\pi=\tfrac{1}{2}(\phi_{i+2}-\phi_{i+1})+\nu_{i+1}\pi \tag{86}$$

up to a possible 2π. From this equality we see that in the limit $m\to\infty$,

$$\tfrac{1}{2}(\phi_{i+1}-\phi_i)=(-1)^i\epsilon+\nu\pi \tag{87}$$

for some constant ϵ for an integer ν. (Comparing with (55), this implies $\phi_i\to\theta_i+(-1)^{i-1}\epsilon$ plus integer multiples of $\pi/2$.) That is, the limiting metric is given by the one-parameter family of metrics (81).

Now the quantity Δ in (67) reads for large m,

$$\Delta=\frac{1}{2}\sum_{i=1}^{m}\cos(\phi_{i+1}-\phi_i)\sin 2(\theta_i-\theta_{i-1}), \tag{88}$$

neglecting terms of order $(\theta_i-\theta_{i+1})^2\sim 1/m^2$ in the sum. As the sines in (88) are of order $1/m$ only the order one part of the cosine's argument matters for large m. This has been identified as $(-1)^i 2\epsilon$. Δ converges to $2\pi\cos(2\epsilon)$ and the tension on the intersection vanishes under (83). Put differently, one sets this tension to zero for any m obtaining relations among ϕ whose limit constrained by (84) is given by (83) with (87). □

Summarizing, if the number m of intersecting hypersurfaces separated by AdS backgrounds goes to infinity, the limiting space–time does not have $1/\rho$ curvature singularities if the intersection is put at the boundary of each AdS region. The constraint for a traceless energy tensor at the intersection can be satisfied, as described in Proposition (4.1).

V. COLLIDING SHELLS AND DOMINANT ENERGY CONDITION

A collision is described by an intersection with the timelike coordinate being on the plane of intersection. We take the vectors u to be timelike, that is, we consider dS space–time. The three normal vectors u_i-u_j are spacelike; let $u_i=(\cosh\zeta_i,\sinh\zeta_i)$ so $(u_i-u_j)^2=2(\cosh(\zeta_i-\zeta_j)-1)>0$, so the hypersurfaces are actually timelike. Let the positions of the hypersurfaces be given by the configuration of rapidities: ψ_1, ψ_2 ψ_3. A general point on a hypersurface is labeled $\tau(\cosh\psi_i,\sinh\psi_i)$, suppressing the other dimensions. (It is clear that the description of collisions in dS is an analytic continuation of that of intersections in AdS, so some aspects of intersections can be translated to the collisions. Consider then a nonsimplicial collision, of m hypersurfaces. When $m=\text{even}>4$ without much thought we get the constraint

$$\psi_1-\psi_2+\cdots+\psi_{m-1}-\psi_m=0 \tag{89}$$

with the right-hand side being zero as there is no 2π periodicity here. An explicit calculation confirms this. In this case the pressure p at the intersection is not completely determined by the rapidities ψ_i. One of the ζ_i must also be specified.)

From the calculation of Sec. IV we have that the pressure p in the spacelike collision surface is

$$\mathsf{p}=2\sum_{n=2}(-1)^n\frac{\beta_n}{l^{2n-2}}n(n-1)\frac{(d-3)!}{(d-2n-1)!}\det(u_j^i)\int_{s_{012}}d^2t(u(t)^2)^{n-2}. \tag{90}$$

[Calculating the energy tensor on a spacelike hypersurface one should keep in mind that we define the volume element (35) to be negative for such hypersurfaces so the energy tensor is minus the value given at (39).] One can prove an analogous situation to Proposition 3.3. The reasoning is similar, only now $u(t)^2\leqslant 0$, or more specifically $u(t)^2\leqslant -1$. None of the terms in the sum vanishes alone. So in general, and in particular for the special Lovelock gravities described by the above-discussed Chamseddine and Born-Infeld Lagrangians, the pressure p does not vanish. That is in general intersecting inflationary space–times with different timelike coordinate lead to matter with pressure at their spacelike intersection in Lovelock gravity.

This explicit example gives us the chance to point out the following, already clear from the general formulas: in a collision, i.e., intersection of *timelike* hypersurfaces, there is in general matter appearing at the spacelike collision surface. Viewed on the normal space, this looks like a collision of particles such that an instanton may appear at the collision event. Now, the dominant

energy condition[33] is that for all timelike ξ^a, $T_{ab}\xi^a\xi^b \geqslant 0$ and $T^{ab}\xi_a$ is a nonspacelike vector, where T^{ab} is the energy tensor. This is clearly violated by the above-noted energy tensor. Thus the dominant energy condition (DEC) can be violated at collisions in Lovelock gravity.

In Einstein's theory, the gravitational field equations themselves cannot impose the dominant energy condition. One must also specify the matter equations of motion or, equivalently, the stress-energy tensor. For example, the junction conditions allow a spacelike hypersurface with spacelike matter.

However as we discussed in Ref. 4, for colliding shells, the dominant energy condition at the collision is obeyed if and only if there is no conical defect. So the dominant energy condition arises naturally *at the collision* from a condition on the regularity of the metric. Suppose that we have some matter action to describe the free shells which respects the dominant energy condition. When the shells collide, perhaps there could also be some contact interaction at the collision surface, so in principle, we could add an interaction term to the matter action. The regularity of the metric imposes that this interaction term must vanish.

For the higher order Lovelock theories, this condition does not arise naturally. The junction conditions for the collision surface are nontrivial. They allow for pressure and momentum localized at the collision. This pressure and momentum is purely tangential to the surface. So the collision process will involve something flowing along the space-like collision surface in violation of the dominant energy condition. So the higher order Lovelock theories impose no energy condition on the type of interaction allowed. In general, we could have a collision where all of the shells are ingoing and annihilate each other, with the energy flowing away to spatial infinity along the collision surface. These novelties arise from the peculiar fact that in the energy exchange relations[4] for the collision of shells the purely stress tensor at the spacelike collision surface contributes with components normal on the surface.

On the other hand, when we consider the matter component of the theory it is very natural to impose the DEC, which is interpreted as that the energy cannot flow faster than the speed of light. If the matter part of the theory is such that the DEC is respected, then this places a strong restriction on the kinds of geometry which are allowed. For example, if two maximally symmetric shells collide in dS, it is impossible to have a single outgoing maximally symmetric brane in dS bulk. There must be more than one outgoing brane and/or some disturbance of the bulk. So we have a constraint which is a kind of selection rule for the allowed collisions due to the higher order Lovelock terms.

As a last comment, we should note that the other energy conditions are also violated in general. The dominant condition for a perfect fluid with energy density ϱ and pressure p reads $\varrho \geqslant |\mathsf{p}|$. As discussed this is not satisfied in an arbitrary collision of shells in Lovelock gravity because $\varrho = 0$ and p is in general nonzero. The weak energy condition reads $\varrho \geqslant 0$ and $\varrho + \mathsf{p} \geqslant 0$. This is satisfied in the above-discussed examples if $\mathsf{p} \geqslant 0$. [Note that (regarding the bulk cosmological constant as matter) the dS background itself satisfies the dominant and weak energy conditions, and also the null energy condition which simply reads $\varrho + \mathsf{p} \geqslant 0$. It does not satisfy the strong energy condition: $\varrho + \mathsf{p} \geqslant 0$ and $\varrho + 3\mathsf{p} \geqslant 0$ as $\mathsf{p} = -\varrho \leqslant 0$. The AdS background satisfies the null and strong energy condition but it does not agree with the weak and the dominant energy conditions.] This is certainly not the case in general: for example if we calculate (90) for the case of Chamseddine gravity we get

$$\mathsf{p} = (-1)^{k+1} \cdot \frac{1}{2}\kappa l^{2-d}(d-1)(d-3)(d-3)!\det(u^i_j)\int_{s_{012}} d^2t(-1-u(t)^2)^{k-2}, \tag{91}$$

where $k=(d-1)/2$. This is positive if $d=4m-1$, for some integer m, and violates the weak energy condition by being negative in $d=4m+1$ dimensions.

VI. DIMENSIONALITIES OF INTERSECTIONS AND FOUR-DIMENSIONAL BRANE UNIVERSE

In d bulk dimensions Lovelock Lagrangian contains terms of nth power of the curvature, with $d>2n$, or $n_{\max}=[(d-1)/2]$, [] the integer part. The lowest dimensional intersection is $d-n_{\max}$ or

$$d-\left[\frac{d-1}{2}\right]. \tag{92}$$

That is, one cannot have an intersection of dimension lower than roughly half the bulk dimensionality, or, for a given intersection dimensionality the maximum possible bulk dimensions are roughly twice that. In particular if we are interested in four-dimensional submanifolds it is easy to see that the available bulk dimensionalities are $d=5,6,7$.

Consider a space–time without boundary or with boundary that is smooth, i.e., the normal direction changes continuously along it. Let us also insist that space–time is a (differentiable) manifold. The metric is assumed nonsingular in the sense of being C^{1-},[33] which in particular means that the first derivative of the metric may have only finite discontinuities and remains bounded in general. This excludes conical singularities. Also, it excludes the general case of orbifolds.

We want to restrict matter in submanifolds under these conditions. Consider a manifold and let finite discontinuities of the first derivative of the metric occur at hypersurfaces, which in general intersect. This respects the above-presented conditions. Also, in Lovelock gravity matter does get localized at (restricted on) the discontinuities and their intersections. One may say that this is the only way to get matter restricted in submanifolds under the conditions set in the previous paragraph as an alternative is not known.

So intersections provide the means to restrict matter in submanifolds of co-dimension two or higher in a nonsingular space–time. Lovelock gravity is in a certain sense a natural generalization of Einstein theory in $d\geqslant 5$ dimensions: (1) it is the most general action for the metric field which produces at most second-order field equations under the condition of zero torsion.[3,2] Under these conditions and the above-discussed conditions, one may say that the four-dimensional intersections in $d\leqslant 7$ dimensions exhaust the list of possibilities in the spirit of the idea to think of our universe as a subspace of higher dimensional space–time; one of course may consider theories of fourth or higher order field equations, hypersurfaces of arbitrary thickness, conical or other singularities in the bulk geometry, etc., but all these add a very large number of model-dependent possibilities in the already not entirely economical RS-scenario. Another possibility is to assume that subspaces have their own intrinsic gravity terms, apart from the ones induced by the bulk. Then one has to invent mechanisms of how they arise.

Let now the boundary of the space–time be not smooth, the direction of its normal vector changes discontinuously crossing hypersurfaces embedded in the boundary. Then new surface terms should be added in action involving various angles. In Einstein gravity this has been analyzed in the past,[42] and has also been used in the intersecting brane world literature.[43] This kind of action could also be constructed for the general Lovelock gravity.

VII. VACUUM SOLUTIONS AND HIGHER CO-DIMENSION MEMBRANES

The higher order derivative structure of Lovelock gravity allows for vacuum solutions when the connection is discontinuous at non-null as well as null hypersurfaces. As in general there are nontrivial junction conditions at the intersections, higher co-dimension membranes are allowed to exist in vacuum without deficit angle or more pathological curvature singularities.

A. Solitonic configurations

Consider a single hypersurface between the regions labeled by 0 and 1 and a case where

$$\Lambda_{d,01} = 0. \tag{93}$$

This is to be satisfied for β_n's, l, and the u's, along with the bulk equation of motion (14). Solving (93) for l, when it is possible, we obtain an $l=l(\beta_{n\geqslant 1}, u_i)$. This put in (14) gives the bulk cosmological constant $\Lambda_{\text{bulk}}=-\frac{1}{2}\beta_0=-\frac{1}{2}\beta_0(\beta_{n\geqslant 1}, u_i)$.

This is a solitonic configuration in the sense that via a discontinuity in the connection at a hypersurface there exists in space–time a self-supported vacuum gravitational field (modulo the bulk cosmological constant). For Einstein–Gauss–Bonnet theory such a space–time was considered, in relation to brane-world problems, in Ref. 31.

These kinds of solutions (stable or not) existing for some Lovelock gravities are not related to topological numbers and one obvious statement is that they are due to the appearance of more than one delta function (or, to delta function $\times$ zero) in the field equations in Lovelock gravity in the presence of a hypersurface. A different way to put it is that they are possible because Lovelock gravity is on the verge of not having a well-defined initial value problem:[7] as a spacelike hypersurface evolves it is possible to pass through a stage where its extrinsic curvature jumps without matter being responsible for that. This is of course not a problem in the solitonic configurations, as they *are* solutions over the whole of time.

Now, when hypersurfaces intersect, in general matter will be localized at the intersection and so the same can happen when solitons intersect. Consider first a co-dimension two intersection. When the energy tensor at the co-dimension two hypersurface does not vanish we have a case where a co-dimension two matter is standing alone in space–time without the appearance of a conical singularity. By (39), define coefficients $c^n_{01\ldots p}$ via

$$\Lambda_{d,01\ldots p} = \sum_{n=p}^{k} c^n_{01\ldots p}\beta_n \tag{94}$$

with $k=[(d-1)/2]$. The dependence of the c's on d is understood. Let $d\geqslant 5$ and consider Einstein–Gauss–Bonnet theory. Three intersecting solitonic configurations of the above-discussed kind means that $\Lambda_{d,01}=\Lambda_{d,12}=\Lambda_{d,20}=0$ so

$$\begin{aligned} c^1_{01}\beta_1 + c^2_{01}\beta_2 &= 0, \\ c^1_{12}\beta_1 + c^2_{12}\beta_2 &= 0, \\ c^1_{20}\beta_1 + c^2_{20}\beta_2 &= 0. \end{aligned} \tag{95}$$

For β's not to be zero the relations have to be linearly dependent. This is possible: it is adequate to take all three angles between u_0, u_1, u_2 equal, as then $u(t)^2$ will give the same integral over all one-simplices. One then obtains a relation for the couplings constants, that is, is specified a class of the Lovelock gravities that accommodates such a configuration. Let $u_0=(1,0)$, $u_1=(-1/2,\sqrt{3}/2)$, $u_2=(-1/2,-\sqrt{3}/2)$. We find

$$-l^{-1}(d-2)\det(u)\beta_1 + l^{-3}(d-2)(d-3)(d-4)\det(u)\beta_2 = 0. \tag{96}$$

So for $d\geqslant 5$ solving for β_2 we have by (94)

$$\Lambda_{d,012} = c^2_{012}\beta_2 = -3\sqrt{3}\beta_1, \tag{97}$$

where we used also the volume of the two-simplex $\int_{s_{012}} d^2t=\frac{1}{2}$. As the geometry does not contain a deficit angle (which is not hard to see employing the metric continuity conditions) we have a co-dimension two surface filled with matter in space–time without conical singularities. Moreover the energy density is positive, the tension on the co-dimension two intersection is $V_{d,012}=-\Lambda_{d,012}=3\sqrt{3}\beta_1>0$. We discuss higher than two co-dimension membranes in AdS and the associated Lovelock gravities in Appendix D. In general backgrounds, solitonic solutions are possible

with no relations among the beta couplings. This interesting implication of Lovelock gravity is discussed in future work.

B. Shock waves

We turn now to the case of shock waves.[32] Let a hypersurface separating a dS region with vector u_0, $u_0^2=-1$, and an AdS region with vector u_1, $u_1^2=1$. The hypersurface is given by the continuity condition $(u_0-u_1)\cdot x=0$. Let the vector u_0-u_1 be null. Then also $u_0\cdot u_1=0$.

Proposition 7.1: Consider pure Gauss–Bonnet gravity with cosmological constant. Then a null hypersurface separating a dS and an AdS with the same length scale l is a shock wave.

Proof: First, by the bulk equations (14) we see that if β_n is not zero for $n=0,2=$even, the same l can be a solution for both dS and AdS. Now, let us repeat Eq. (33),

$$\mathcal{E}^n_{(p)}=(-1)^{n-p}(-1)^{p(p-1)/2}2^p\int_{s_{01\ldots p}} d^p t u^{a_1}_{10}\ldots u^{a_p}_{p0}(u(t)^2)^{n-p}\frac{(d-p-1)!}{(d-2n-1)!}e_{ca_1\ldots a_p}. \tag{98}$$

This is still valid even if one (or more) of the u_{i0}'s is null. It is important that we nowhere refer to the intrinsic geometry of the null hypersurface. If this quantity vanishes there cannot be a nonzero energy tensor in the null hypersurface.

For Gauss–Bonnet gravity and a null hypersurface discontinuity the single contribution is β_2 times (putting the common length l back)

$$-2l^{-3}(d-3)(d-4)\int_0^1 dtu(t)^2u^a_{10}e_{ca}. \tag{99}$$

But

$$u(t)^2=-t_0^2+t_1^2=-(1-t)^2+t^2 \tag{100}$$

taking $t_1=t$, that is

$$\int_0^1 dtu(t)^2=0 \tag{101}$$

so the energy tensor at the null discontinuity vanishes identically. □

Also we have

Proposition 7.2: Let Lovelock gravity be given by a sum of even order Euler terms. Then a null hypersurface separating a dS and an AdS with the same length scale l is a shock wave.

Proof: By the bulk equations (14) we see that if β_n is not zero for $n=$even, the same l can be a solution for both dS and AdS. For the null hypersurface between dS and AdS with the same scale we have from before that $u(t)^2=-(1-t)^2+t^2=2t-1$ so

$$\int_0^1 dt(u(t)^2)^{n-1}=\int_0^1 dt(2t-1)^{n-1}=\frac{(-1)^{n-1}+1}{2}\frac{1}{n} \tag{102}$$

so from (98) for $p=1$ we have that the energy tensor at the null hypersurface vanishes for all $n=$even. □

Consider now the nonsimplicial intersection such that four dS and AdS regions are put alternatively: $u_0=(1,0)$, $u_1=(0,1)$, $u_2=(-1,0)$, $u_3=(0,-1)$. Let the gravity be pure Gauss–Bonnet. Then all four hypersurfaces are null and shocks.

The co-dimension two hypersurface is spacelike. Its Lagrangian is

$$\mathcal{L}_{012}+\mathcal{L}_{023}. \tag{103}$$

The intersection is non-null so by (39) we get the energy tensor on it is pure pressure equal to

$$8\beta_2 l^{-2}(d-3)(d-4). \tag{104}$$

This is calculated via the determinants of $\binom{u_{10}}{u_{20}}$ and $\binom{u_{20}}{u_{30}}$ which both equal to 2.

In general, consider the same configuration for a Lovelock gravity involving all possible even order Euler terms. The Lagrangian is still given by (103). Over the simplex s_{012} we have

$$u(t)^2 = -t_0^2 + t_1^2 - t_2^2 + 2t_0t_2 = t_1^2 - (t_0 - t_2)^2 = (1-2t_0)(1-2t_2) \tag{105}$$

using the u's above and that $t_0+t_1+t_2=1$ over this simplex. There is a similar expression over s_{023}. So we have

$$\int_{s_{012}} d^2t(u(t)^2)^{n-2} = \int_0^1 dt_0 \int_0^{1-t_0} dt_2((1-2t_0)(1-2t_2))^{n-2} = \frac{1}{2(n-1)^2}, \tag{106}$$

where we used formula (102) and that n=even. The same quantity is obtained from the simplex s_{023}. Having calculated the above-noted determinants (equal to 2) we use these results in formula (39) to get for the pressure at the intersection

$$\sum_{n=\text{even}\geqslant 2} \frac{4n}{n-1}\frac{\beta_n}{l^{2n-2}}\frac{(d-3)!}{(d-2n-1)!}. \tag{107}$$

We see then that in a collision of shocks a co-dimension two matter is required to exist at the collision event surface. As noted earlier this spacelike matter violates the dominant energy condition, as a general feature of collisions in Lovelock gravity, here seen in the case of shock waves.

APPENDIX A: SOME MANIPULATIONS WITH KRONECKER DELTA

In this appendix, we derive the quantity given in Eq. (34). We would like to determine the constants $A(d)_{mn}$ in

$$\frac{(m+n+1)!}{(n+1)!}\delta^{a_1}_{[a_1}\ \dots\ \delta^{a_m}_{a_m}e_{\ cb_1\dots b_m]} = A(d)_{mn}e_{cb_1\dots b_m}. \tag{A1}$$

In components this means

$$\frac{(m+n+1)!}{(n+1)!}\delta^{a_1}_{[a_1}\ \dots\ \delta^{a_m}_{a_m}\epsilon_{\ cb_1\dots b_m]c_{n+2}\dots c_d} = A(d)_{mn}\epsilon_{cb_1\dots b_mc_{n+2}\dots c_d}. \tag{A2}$$

Contracting with the same epsilon symbol with indices upstairs we have, using standard formulas (see, e.g., the Appendix of Ref. 36),

$$-d!A(d)_{mn} = -(d-n-1)!(m+n+1)!\delta^{a_1}_{[a_1}\ \dots\ \delta^{a_m}_{a_m}\delta^c_c\delta^{b_1}_{b_1}\dots\ \delta^{b_n}_{b_n]}. \tag{A3}$$

It is easy to show that the contracted delta's times $(m+n+1)!$ give

$$\frac{d!}{(d-m-n-1)!} \tag{A4}$$

so

$$A(d)_{mn} = \frac{(d-n-1)!}{(d-m-n-1)!}. \tag{A5}$$

APPENDIX B: VARIATIONAL PRINCIPLE FOR METRIC AND VIELBEIN

The action for Lovelock theory with matter is

$$\mathcal{S} = \int_M \mathcal{L}_{\text{Lovelock}} + \int_M \mathcal{L}_{\text{mat}}.$$

The Euler variation with respect to $g^{\mu\nu}$ (neglecting boundary terms) leads to

$$\delta S = \int_M (H_{\mu\nu} - T_{\mu\nu})\delta g^{\mu\nu} e,$$

where $H_{\mu\nu}$ is the Lovelock tensor, $T^{\mu\nu}$ the stress-energy tensor. The volume element e is

$$e = \sqrt{-g}dx^1 \wedge \cdots \wedge dx^d.$$

These more familiar expressions for the gravitational action principle are in terms of variation with respect to the metric. Since we have used the vielbein language,[37] it is useful to be able to translate between the two. The volume element is, in terms of vielbeins:

$$e = \frac{1}{d!}\epsilon_{a_1\ldots a_d}E^{a_1} \wedge \cdots \wedge E^{a_d} = E^{(1)} \wedge \cdots \wedge E^{(d)}. \tag{B1}$$

We also define

$$e_{a_1\ldots a_p} := \frac{1}{(d-p)!}\epsilon_{a_1\ldots a_d}E^{a_{p+1}} \wedge \cdots \wedge E^{a_d} \tag{B2}$$

We shall need these identities:

$$E^{c_1\ldots c_n} \wedge e_{d_1\ldots d_m} = \frac{m!}{(m-n)!}\delta^{c_1}_{[d_{m-n+1}} \ldots \delta^{c_n}_{d_m} e_{\ d_1\ldots d_{m-n}]}, \tag{B3}$$

$$\delta E^b = \delta E^b_\mu E^\mu_c E^c, \tag{B4}$$

$$\delta E^b_\mu E^\mu_a = -E^b_\mu \delta E^\mu_a, \tag{B5}$$

$$\delta g^{\mu\nu} = 2\eta^{ab}\delta E^\mu_a E^\nu_b. \tag{B6}$$

The point is that because the ω equation of motion vanishes identically, we can use (B6) to replace metric variations directly for vielbein variations, $\delta_g\mathcal{L} = \delta_{g(E)}\mathcal{L}$. First, we define

$$T_{ab} := E^\mu_a T_{\mu\nu}E^\nu_b, \tag{B7}$$

Using (B3)–(B6) and noting that

$$\delta E^b \wedge E_a = -E^b_\mu \delta E^\mu_a e,$$

we find that

$$T_{\mu\nu}\delta g^{\mu\nu} e = -2T^c_b \delta E^b \wedge e_c.$$

The field equations in terms of the vielbeins are

$$\delta_{E^c}\mathcal{L}_{\text{Lovelock}} = -2T^b_c e_b. \tag{B8}$$

If there is singular matter with support on some intersection I, we have a term in the action:

$$\int_I \tilde{\mathcal{L}}_{\text{mat}}. \tag{B9}$$

The variation gives the stress-energy tensor on I:

$$\delta\tilde{\mathcal{L}}_{\text{mat}} \equiv -\tilde{T}_{\mu\nu}\delta h^{\mu\nu}\tilde{e} \tag{B10}$$

is the energy-momentum tensor on I. On the intersection we have an induced metric h and the corresponding volume element

$$\tilde{e} = \sqrt{|h|}d^{d-p}x. \tag{B11}$$

The stress-energy tensor will be related to the variation of the appropriate boundary term in the Lovelock action:

$$\sum_n \beta_n \int_I \mathcal{L}^n_{(p)}.$$

Let $n^1,\ldots,n^p$ be an ordered set of orthonormal vectors which spans the space of vectors normal to I. In terms of the vielbeins, the volume element is

$$\tilde{e} = \prod_{i=1}^{p} (n^i \cdot n^i)(n^1)^{a_1}\cdots(n^p)^{a_p} e_{a_1\ldots a_p}. \tag{B12}$$

The order of the normal vectors gives the orientation on I. The factor $\Pi(n^i\cdot n^i)$ is ± 1 depending on whether I is timelike or spacelike.

If we vary the frames tangential to I such that they remain tangent to I, there is a simple relation:

$$\delta E^a \wedge \tilde{e}_b = E^\mu_b \delta E^a_\mu \tilde{e} \quad (\delta E^a \text{ tangential}). \tag{B13}$$

(This is sufficient if we vary $\tilde{\mathcal{L}}_{\text{mat}}$ only with respect to the induced metric h and not the position of the intersection. In this paper, we consider only dS/AdS bulk solutions, where the terms involving δE^0 not tangential always vanish anyway.) Following the same procedure as above, we then derive

$$\sum_n \beta_n \delta_{E^c}\mathcal{L}^n_{(p)} = -2\tilde{T}^b_c e_b. \tag{B14}$$

It is important to remember this factor of $-1/2$ when relating the stress-energy tensor to the Euler variation with respect to the vielbein. This has been used in Eq. (9).

APPENDIX C: A WORD ON THE SIMPLEX

A (Euclidean) p-dimensional simplex or p-simplex s_p is defined as $\{t \in \mathbf{R}^{p+1} \,|\, \Sigma_{i=0}^p t^i = 1, \text{ all } t^i \geqslant 0\}$. A bit more generally is defined as the set of points $\Sigma_{i=0}^p t^i a_i$ with the same conditions for the t_i's as above, for $a_0,\ldots,a_p$ points in the Euclidean space $\mathbf{R}^{p+1}$ such that $a_1-a_0,\ldots,a_p-a_0$ are linearly independent.[38] This reflects nicely the properties of the vector $u(t)$ encountered in this paper.

A zero-simplex is a point, a one-simplex is an interval, a two-simplex is a triangle, a three-simplex is a tetrahedron, etc. A k-dimensional face of the simplex, designated $s_{i_0}\ldots i_k$, is the subset of s_p such that

$$s_{i_0\ldots i_k} = \{t \in s_p | t^j = 0,\ \forall\, j \neq i_0, \ldots, i_k\}. \tag{C1}$$

Of course by definition a k-dimensional face is itself a k-simplex. It is easy to see that there are $\binom{p+1}{k+1}$ k-dimensional faces on the p-simplex.

Clearly $(k-1)$-simplices are parts of the boundary of the k-simplices. The rule which takes into account orientations is

$$\partial s_{i_0\ldots i_k} = \sum_{r=0}^{k} (-1)^r s_{i_0\ldots \hat{i_r}\ldots i_k}, \tag{C2}$$

where the caret means that this is index is absent. The symbols $s_{i_0}\ldots i_k$ are completely antisymmetric.

APPENDIX D: MEMBRANES OF CO-DIMENSION HIGHER THAN TWO IN AdS BULK

1. The symmetric hedgehog

Let the vectors u be symmetrically arranged in the k-dimensional normal space, forming a symmetric hedgehog. In particular the average position defined by their ends (the barycenter) coincides with the origin

$$u_0 + \cdots + u_k = 0. \tag{D1}$$

Also by symmetry all inner products are equal. Call this cosine $\cos\phi_k$. Taking the square of the above we have

$$(1 + k\cos\phi_k)(k+1) = 0. \tag{D2}$$

So

$$\cos\phi_k = -\frac{1}{k}. \tag{D3}$$

Then

$$u(t)^2 = \left(\sum_{i=0}^{p} u_i t_i\right)^2 = \sum_{i=0}^{p} t_i^2 + \cos\phi_k \sum_{i\neq j} t_i t_j = \left(1 + \frac{1}{k}\right)\sum_{i=0}^{p} t_i^2 - \frac{1}{k}, \tag{D4}$$

where in the last equality we used (D3) and that $(\Sigma_i t_i)^2 = 1$.

The other bit we need is the determinants made out of the vectors u_{i0}. It equals the volume of a p dimensional parallelepiped made out of vectors with length

$$|u_i - u_0| = \sqrt{2 - 2\cos\phi_k} = \sqrt{2 + \frac{2}{k}} \tag{D5}$$

and angle between any two vectors u_{i0} and u_{j0} given by the cosine

$$\frac{(u_i - u_0)\cdot(u_j - u_0)}{|u_i - u_0||u_j - u_0|} = \frac{1 - \cos\phi_k}{2(1 - \cos\phi_k)} = \frac{1}{2} = \cos 60^\circ. \tag{D6}$$

So all "heights" of the parallelepiped are given by the length in (D5) times $\sin 60^\circ = \sqrt{3}/2$. The determinant related to a p-simplex face of the k-simplex is

$$\det(u_i^j) = \left(\frac{\sqrt{3}}{2}\right)^{p-1}\left(2 + \frac{2}{k}\right)^{p/2}. \tag{D7}$$

2. Gravity

In the case of Chamseddine and Born-Infeld type of Lovelock gravity we considered (AdS) vacuum and intersections such that the u vectors are symmetrically arranged. Here we find the Lovelock gravity such that the tension of all membranes with co-dimension $p \neq k=[(d-1)/2]$ is zero.

So $\Lambda_{d,01\ldots p}=\Lambda_{d,p}$ here and for each p we consider one expression and call the coefficients in (94) simply c_p^n. If all except the co-dimension k intersection Λ's vanish, we have

$$\begin{aligned} c_1^1\beta_1 + c_1^2\beta_2 + \cdots + c_1^{k-1}\beta_{k-1} &= -c_1^k\beta_k, \\ c_2^2\beta_2 + \cdots + c_2^{k-1}\beta_{k-1} &= -c_2^k\beta_k, \\ &\vdots \\ c_{k-1}^{k-1}\beta_{k-1} &= -c_{k-1}^k\beta_k, \end{aligned} \tag{D8}$$

where we put the last term in the sums on the right-hand side to give it the form of an upper triangular $(k-1)\times(k-1)$ linear system.

The inverse of the matrix $\mu=(c_p^n)$ of the coefficients is rather easily calculated by the method of forming a $(k-1)\times 2(k-1)$ matrix by putting a unit matrix on the side of μ and adding appropriate multiples of lines to other lines of this big matrix until in the place of μ the unit matrix appears; then in place the unit matrix μ^{-1} appears. Then we find that the inverse μ^{-1} is an upper triangular matrix. The diagonal terms are $1/c_p^p$ and the upper triangular part is

$$(\mu^{-1})_p^n = -\frac{c_p^n}{c_n^n c_p^p} \tag{D9}$$

$n=p+1,\ldots,k-1$. So

$$\beta_p = -\frac{c_p^k}{c_p^p}\beta_k + \sum_{n=p+1}^{k-1}\frac{c_p^n}{c_n^n c_p^p}c_n^k\beta_k = \left(-\tilde{c}_p^k + \sum_{n=p+1}^{k-1}\tilde{c}_p^n\tilde{c}_n^k\right)\beta_k, \tag{D10}$$

$p=1,\ldots,k-1$, where

$$\tilde{c}_p^n := \frac{c_p^n}{c_p^p} = l^{2p-2n}(-1)^{n-p}\frac{n!}{(n-p)!}\frac{(d-2p-1)!}{(d-2n-1)!}\int_{s_p} d^p t(u(t)^2)^{n-p} \tag{D11}$$

These coefficients depend on d and the AdS radius l but also on a coupling beta which is left arbitrary. In detail, β_0 is fixed in terms of a given bulk cosmological constant $\Lambda_{\text{bulk}}=-\frac{1}{2}\beta_0$, and by the bulk equations of motion (14) the coupling β_k is fixed in terms of l and Λ_{bulk}. Einstein gravity with arbitrary cosmological constant is the trivial case of these.

Meromorphic Lax representations of (1+1)-dimensional multi-Hamiltonian dispersionless systems

Błażej M. Szablikowski[a] and Maciej Błaszak[b]
Institute of Physics, A. Mickiewicz University, Umultowska 85, 61-614 Poznań, Poland

(Received 21 April 2006; accepted 31 July 2006; published online 19 September 2006)

Rational Lax hierarchies introduced by Krichever are generalized. A systematic construction of infinite multi-Hamiltonian hierarchies and related conserved quantities is presented. The method is based on the classical R-matrix approach applied to Poisson algebras. A proof that Poisson operators constructed near different points of Laurent expansion of Lax functions are equal is given. All results are illustrated by several examples. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2344853]

I. INTRODUCTION

In Refs. 1 and 2 I. M. Krichever introduced the so-called universal Whitham hierarchies by means of moduli spaces of Riemann surfaces of all genera. There is an important class of finite-field reductions of the zero-genus case, being the so-called algebraic orbits, given by rational Lax functions on $\mathbb{C}P^1$ of the form

$$L = p^N + \sum_{k=0}^{N-1} a_k p^k + \sum_{l=1}^{\alpha} \sum_{i=1}^{i_l} \frac{a_{l,i}}{(p-p_l)^i}, \quad n \geqslant 0, \quad i_l \geqslant 0, \tag{1.1}$$

where a's and the poles p_l are smooth dynamical fields. These reductions permit the construction of integrable (1+1)-dimensional dispersionless system. Around all poles of (1.1), i.e., ∞ and p_l, the powers of Laurent expansions of L generate infinite Lax hierarchies of commuting vector fields with Lie bracket being the canonical Poisson bracket (3.1) with $r=0$. Moreover, near these poles one can construct infinite hierarchies of constants of motion. Rational Lax functions (1.1) with related Lax hierarchies have been introduced in Ref. 2 in the context of topological field theories. From this point of view they have been considered also in Refs. 3 and 4. The bi-Hamiltonian structures of Benney and Toda like Lax hierarchies, but with Poisson bracket (3.1) with $r=1$, and rational Lax functions was developed in Ref. 5. Their various reductions were also studied. They also have been investigated in the context of degenerate Frobenius manifolds.[6] In Ref. 7, it was shown how to construct recursion operators for some classes of such rational Lax representations.

(1+1)-dimensional dispersionless (or hydrodynamic) systems are first-order PDEs of the form

$$(u_i)_t = \sum_j A_i^j(u)(u_j)_x, \quad i,j = 1, \ldots, n.$$

An important subclass of such systems are these which have multi-Hamiltonian structure, infinite hierarchy of symmetries, and conservation laws. Differential Poisson structures for hydrodynamic systems were introduced for the first time by Dubrovin and Novikov[8] in the form (1.2) with $c=0$, where g^{ij} is a contravariant nondegenerate flat metric and Γ_k^{ij} are related coefficients of the

[a]Electronic mail: bszablik@amu.edu.pl
[b]Electronic mail: blaszakm@amu.edu.pl

contravariant Levi-Civita connection. Then, they were generalized by Mokhov and Ferapontov[9] to the nonlocal form

$$\pi_{ij} = g^{ij}(u)\partial_x - \sum_k \Gamma^{ij}_k(u)(u_k)_x + c\ (u_i)_x \partial_x^{-1} (u_j)_x \tag{1.2}$$

in the case when g^{ij} is of constant curvature c. The natural geometric setting of related bi-Hamiltonian structures (Poisson pencils) is the theory of Frobenious manifolds based on the geometry of pencils of contravariant metrics.[10] Nevertheless, the condition of nondegeneracy of g^{ij} for the above-mentioned Poisson tensors is not necessary. The degenerate hydrodynamic Poisson tensors were considered by Grinberg[11] and Dorfmann.[12]

In the theory of nonlinear evolutionary PDEs (dynamical systems) one of the most important problems is a systematic construction of integrable systems. By integrable systems we understand those which have infinite hierarchy of commuting symmetries. It is well known that a very powerful tool, called the classical R-matrix formalism, can be used for systematic construction of $(1+1)$-dimensional field and lattice integrable dispersive systems (soliton systems)[13–17] as well as dispersionless integrable field systems.[18–20] Moreover, the R-matrix approach allows a construction of Hamiltonian structures and conserved quantities.

In this paper the systematic approach of classical R-matrices to $(1+1)$-integrable dispersionless multi-Hamiltonian systems with meromorphic Lax hierarchies is presented. In the frames of that formalism we generalize the rational Lax functions defined by Krichever onto a wider class of Lax hierarchies considered in Refs. 19 and 20. However, these articles only presented theory of polynomial Lax functions with Lax hierarchies generated only by powers constructed at ∞. In the following article it is shown that, in applicable cases, for a given appropriate meromorphic Lax function one can construct Lax hierarchies not only related to poles of Lax function, as in the case considered by Krichever, but also to its roots. These Lax hierarchies mutually commute. As well, it is shown how to construct Poisson tensors and infinite hierarchies of constants of motion. It is proved that Poisson tensors, from the original function space, reconstructed for different poles and roots are equal. Also, we have examined systematically the forms of appropriate meromorphic Lax functions, with finite number of dynamical fields, allowing construction of consistent dispersionless systems. We illustrate results by a large number of examples. Let us notice that symmetries generated by logarithmic functions are not considered in this article, see the related comment in Sec. V.

II. CLASSICAL *R*-MATRIX THEORY ON POISSON ALGEBRAS

Let $\mathcal{A}$ be a commutative associative algebra with unit. If there is a Lie bracket on $\mathcal{A}$ such that for each element $a \in \mathcal{A}$, the operator $\mathrm{ad}_a : b \mapsto \{a,b\}$ is a derivation of the multiplication, i.e., $\{a,bc\}=\{a,b\}c+b\{a,c\}$, then $(\mathcal{A},\{\cdot,\cdot\})$ is called a Poisson algebra and bracket $\{\cdot,\cdot\}$ is a Poisson bracket. Thus, the Poisson algebras are Lie algebras with an additional structure. We assume the existence of a nondegenerate ad-invariant scalar product $(\cdot,\cdot)$ on $\mathcal{A}$ with respect to which the operation of multiplication is symmetric, i.e., $(ab,c)=(a,bc)$, $\forall a,b,c \in \mathcal{A}$.

A linear map $R:\mathcal{A}\to\mathcal{A}$ being an R-matrix defines a second Lie product on $\mathcal{A}$ given by

$$\{a,b\}_R := \{Ra,b\} + \{a,Rb\}. \tag{2.1}$$

We will additionally assume that R commutes with derivatives with respect to evolution parameters, i.e.,

$$(RL)_t = RL_t. \tag{2.2}$$

This property is equivalent to the assumption that R commutes with differentials of smooth maps from $\mathcal{A}$ to $\mathcal{A}$. This property is used in the proof of Theorem 4.2 in Ref. 18, although not explicitly stressed there. The equality (2.2) will be used in Sec. III E to show a commutation between particular Lax hierarchies. Then, for each integer $n \geqslant 0$, the formula

$$\{H,F\}_n = (L,\{R(L^n dF),dH\} + \{dF,R(L^n dH)\}) \tag{2.3}$$

defines a Poisson structure on algebra of smooth functions $\mathcal{C}^\infty\mathcal{A}$, where differentials $dF, dH \in \mathcal{A}$.[18] Moreover, all $\{\cdot,\cdot\}_n$ are compatible. The related Poisson bivectors π_n, such that $\{H,F\}_n = (dF, \pi_n dH)$, are given by the following Poisson maps:

$$\pi_n: dH \mapsto \{R(L^n dH),L\} + L^n R^*(\{dH,L\}), \quad n \geqslant 0, \tag{2.4}$$

where the adjoint of R is defined by the relation $(R^*a,b)=(a,Rb)$. Notice that the bracket (2.3) with $n=0$ is just a Lie-Poisson bracket with respect to the Lie bracket (2.1). Referring to the dependence on L, Poisson maps (2.4) are called linear for $n=0$, quadratic for $n=1$, and cubic for $n=2$, respectively.

We will look for a natural set of functions in involution with respect to the Poisson brackets (2.3). Such functions are Casimirs of the natural Lie-Poisson bracket $\{H,F\}=(L,\{dF,dH\})$. A sufficient condition for smooth function $C(L)$ to be a Casimir function is that its differential $dC \in \ker \mathrm{ad}_L$, i.e. $[dC,L]=0$. Let us assume that an appropriate scalar product on Poisson algebra $\mathcal{A}$ is given by the trace form $\mathrm{Tr}: \mathcal{A} \to \mathbb{R}$ or $\mathbb{C}$, such that $(a,b)=\mathrm{Tr}(ab)$. Then, the most natural Casimirs are functionals given by the trace of powers of L, i.e.,

$$dC_q(L) = L^q \Leftrightarrow \begin{cases} C_q(L) = \dfrac{1}{q+1}\,\mathrm{Tr}(L^{q+1}) & \text{for } q \neq -1 \\ C_{-1}(L) = \mathrm{Tr}(\ln L) & \text{for } q = -1. \end{cases} \tag{2.5}$$

Hence, taking these $C_q(L)$ as Hamiltonian functionals, one finds a Lax hierarchy of evolution equations which are multi-Hamiltonian dynamical systems

$$L_{t_q} = \{R(dC_q),L\} = \pi_0(dC_q) = \pi_1(dC_{q-1}) = \ldots = \pi_l(dC_{q-l}) = \ldots . \tag{2.6}$$

For any R-matrix each two evolution equations in the hierarchy (2.6) commute due to the involutivity of the Casimirs C_q. Each equation admits all the Casimir functionals as a set of conserved quantities in involution. In this sense we will regard (2.6) as a hierarchy of integrable evolution equations.

One can construct the simplest R-structures decomposing the Poisson algebra $\mathcal{A}$ into a direct sum of Lie subalgebras $\mathcal{A}_+$ and $\mathcal{A}_-$, i.e., $\mathcal{A}=\mathcal{A}_+ \oplus \mathcal{A}_-$, $[\mathcal{A}_\pm,\mathcal{A}_\pm] \subset \mathcal{A}_\pm$. Denoting the projections onto these subalgebras by $P_\pm$, the classical R-matrix is well defined as

$$R = \tfrac{1}{2}(P_+ - P_-) = P_+ - \tfrac{1}{2} = \tfrac{1}{2} - P_-. \tag{2.7}$$

Following the above-mentioned scheme, we are able to construct in a systematic way integrable multi-Hamiltonian dispersionless systems, with infinite hierarchy of involutive constants of motion and infinite hierarchy of related commuting symmetries, on appropriate Poisson algebras. Finally, in the last step, we reconstruct our multi-Hamiltonian hierarchies in the original function space of related dispersionless systems.

III. LAX HIERARCHIES FOR DISPERSIONLESS SYSTEMS

A. Poisson algebras of meromorphic functions

Let $\mathcal{F}$ be the algebra of meromorphic functions with a finite number of poles, i.e., these analytic functions which have no essential singularities, on a Riemann sphere $\mathbb{C}P^1$ (i.e., complex plane with point at ∞). Let p be a point in $\mathbb{C}P^1$. Assume now that this algebra depends effectively on an additional spatial variable $x \in \Omega$. Denote by $\mathcal{A}$ the algebra of all smooth functions: $f: \Omega \to \mathcal{F}$, i.e., $\mathcal{A}=\mathcal{C}^\infty(\Omega,\mathcal{F})$. Let $\Omega=\mathbb{S}^1$ if we assume these functions to be periodic in x or $\Omega=\mathbb{R}$ if these functions are supposed to belong to the Schwartz space for a fixed parameter p. The Poisson bracket on $\mathcal{A}$ can be introduced in infinitely many ways as

$$\{f,g\}_r := p^r(\partial_p f \partial_x g - \partial_x f \partial_p g), \quad r \in \mathbb{Z}, \quad f,g \in \mathcal{A}. \tag{3.1}$$

Then, fixing r, $\mathcal{A}$ is the Poisson algebra with an appropriate bracket (3.1). Poisson brackets (3.1) are generalizations of canonical Poisson bracket ($r=0$) through the addition of p^r factor.

To construct classical R-matrices we have to decompose $\mathcal{A}$ into a direct sum of Lie subalgebras. It can be done by expanding functions belonging to $\mathcal{A}$ in an appropriate annulus near a given point λ. Three kinds of points on $\mathbb{C}P^1$, parameterized by p, will be important. Two fixed points: ∞ and 0, as well as points being smooth fields $v(x)$ from Ω to $\mathbb{C}P^1$.

B. Classical *R*-matrices

Once we fixed Poisson algebra we are able to construct R-matrices and related Lax vector fields for which the algebra $\mathcal{A}$ constitutes the phase space.

Expanding meromorphic functions from $\mathcal{A}$ into Laurent series at λ we decompose the algebra $\mathcal{A}$ in the following way:

$$\mathcal{A} = \mathcal{A}^{\infty}_{\geqslant k-r} \oplus \mathcal{A}^{\infty}_{<k-r} := \left\{ \sum_{i=k-r}^{N} a_i(x)p^i \right\} \oplus \left\{ \sum_{i<k-r} a_i(x)p^i \right\}, \quad \lambda = \infty, \tag{3.2}$$

$$\mathcal{A} = \mathcal{A}^{\lambda}_{\geqslant k-r} \oplus \mathcal{A}^{\lambda}_{<k-r} := \left\{ \sum_{i\geqslant k-r} a_i(p-\lambda)^i \right\} \oplus \left\{ \sum_{i=-m_\lambda}^{k-r-1} a_i(p-\lambda)^i \right\}, \quad \lambda = 0 \text{ or } v(x), \tag{3.3}$$

where $a_i(x)$ and $v(x)$ are dynamical fields. Let ap^m and bp^n be elements from (3.2) or (3.3) for $\lambda=0$ of order m and n, respectively. Poisson bracket (3.1) between these elements has the order $m+n+r-1$ as

$$\{ap^m, bp^n\}_r = (mab_x - na_x b)p^{m+n+r-1}.$$

For $\lambda=v(x)$ the situation is a bit more complicated as one has to expand p^r in (3.1) at $v(x)$, i.e.,

$$p^r = \sum_{s=0}^{\infty} \binom{r}{s} v(x)^{r-s}(p-v(x))^s,$$

where $\binom{r}{s} = (-1)^s \binom{-r+s-1}{s}$ for $r<0$. Hence, p^r as the element of $\mathcal{A}$ has the lowest order equal zero, the highest order equal r for $r\geqslant 0$, and infinity for $r<0$. Therefore

$$\{a(p-v)^m, b(p-v)^n\}_r = ((p-v)^{\alpha} + \cdots + v^r) \times (mab_x - na_x b)(p-v)^{m+n-1},$$

where $\alpha=r$ for $r\geqslant 0$ and α goes to ∞ for $r<0$. Now, simple inspection shows that $\mathcal{A}^{\lambda}_{\geqslant k-r}, \mathcal{A}^{\lambda}_{<k-r}$ are Lie subalgebras of $\mathcal{A}$ in the following cases:

$$\text{for } \lambda = \infty, 0 \text{ if } \begin{cases} r=0,\ k=0 \\ r\in\mathbb{Z},\ k=1,2 \\ r=2,\ k=3 \end{cases}$$

$$\text{for } \lambda = v(x) \text{ if } \begin{cases} r=0,\ k=0,1,2 \\ r=1,\ k=1,2 \\ r=2,\ k=2,3. \end{cases}$$

So, fixing r we fix the Lie algebra structure with k numbering the R-matrices given in the following form:

$$R = P^{\lambda}_{\geqslant k-r} - \tfrac{1}{2} = \tfrac{1}{2} - P^{\lambda}_{<k-r}, \tag{3.4}$$

where $P^{\lambda}_{\cdot}$ are appropriate projections onto respective Lie subalgebras. All R-matrices for $\lambda = \infty, 0$ commute with derivatives with respect to evolution parameters. Let $L=\Sigma_i a_i(p-v)^i$, then

$$(RL)_t - RL_t = P^{v}_{<k-r}L_t - (P^{v}_{<k-r}L)_t = (k-r)a_{k-r-1}v_t(p-v)^{k-r-1}$$

and equality (2.2) holds for $\lambda=v(x)$ when $k-r=0$. Hence, in the case $\lambda=v(x)$ further on we will consider only R-matrices (3.4) for $k=r=0,1,2$. Henceforth, calling for appropriate r and k we will refer to these for which R-matrices (3.4), with respect to λ, are well defined and satisfy (2.2).

Let $L \in \mathcal{A}$ be a meromorphic function with pole or root at λ. Then, the Lax hierarchy assigned by (3.4) has the form

$$\frac{\partial L}{\partial t_{\lambda,q}} = \{\Omega^{\lambda}_q, L\}_r, \quad q \in \mathbb{Z}_+, \tag{3.5}$$

for appropriate r and k. The functions $\Omega_{\lambda,q}$ coupled with evolution parameters $t_{\lambda,q}$ are defined by

$$\Omega^{\infty}_q := \left(L^{q/N}\right)^{\infty}_{\geqslant k-r} \quad \text{for } \lambda = \infty, \quad \Omega^{\lambda}_q := -\left(L^{q/m_\lambda}\right)^{\lambda}_{<k-r} \quad \text{for } \lambda = 0 \text{ or } v(x), \tag{3.6}$$

where $(A)^{\lambda}_{\geqslant k-r} \equiv P^{\lambda}_{\geqslant k-r}(A)$. If L has pole at λ the powers in (3.6) are positive as $N, m_\lambda > 0$ for $\lambda = \infty$ or $\lambda = 0, v(x)$, respectively. In this case N, m_λ are orders of respective poles. If L has root at λ the powers in (3.6) are negative as $N, m_\lambda < 0$ and $-N, -m_\lambda$ are orders of respective roots.

Now, we will show that schemes for Lax hierarchies defined for ∞ and 0 are interrelated.

Proposition 3.1: Under the transformation: $x'=x$, $p'=p^{-1}$, $t'=t$; *the Lax hierarchy* (3.5) *for* $\lambda=\infty$ *and appropriate* r,k *with Lax function* L *transforms into* (3.5) *for* $\lambda=0$ *and* $k'=3-k, r'=2-r$ *where Lax function is given by* $L'(p')=L(p)$.

Proof: It follows from the observation that $\{\cdot,\cdot\}_r = p^r\partial_p \wedge \partial_x = -p'^{2-r}\partial_{p'} \wedge \partial_{x'} = -\{\cdot,\cdot\}'_{r'}$ and $(L^n)^{\infty}_{\geqslant k-r} = (L'^n)^{0}_{\leqslant r-k} = (L'^n)^{0}_{<k'-r'}$. □

C. Scalar products

To construct Poisson structures one has to define an appropriate scalar product on $\mathcal{A}$. We will define it near a given point λ by means of the trace form in the algebra $\mathcal{A}$ with the Poisson structure (3.1) for fixed r by

$$\mathrm{Tr}_\infty f := -\int_\Omega \mathrm{res}_\infty(p^{-r}f)\mathrm{d}x \quad \text{for } \lambda = \infty, \quad \mathrm{Tr}_\lambda f := \int_\Omega \mathrm{res}_\lambda(p^{-r}f)\mathrm{d}x \quad \text{for } \lambda = 0, v(x),$$

where $f \in \mathcal{A}$ and res is the standard residue. In further considerations the residue theorem will be very useful. Let Γ be a set of all finite poles of f. Then, according to the residue theorem

$$\sum_{\lambda\in\Gamma,\ \lambda\neq\infty} \mathrm{res}_\lambda f = \frac{1}{2\pi i}\oint_{\gamma_\Gamma} f\,\mathrm{d}p \equiv -\mathrm{res}_\infty f, \tag{3.7}$$

where γ_Γ is a closed curve encircling all finite poles of f. So, residue at ∞ may be different than zero even if f does not have singularity at this point.

Lemma 3.2: For two arbitrary functions $f,g \in \mathcal{A}$ *the scalar product:*

$$(f,g)_\lambda := \mathrm{Tr}_\lambda(fg), \quad \lambda = \infty, 0, v(x) \tag{3.8}$$

is symmetric, *nondegenerate*, *and* ad-*invariant*.

Proof: The nondegeneracy and symmetry of (3.8) are obvious. Let γ_λ be a closed curve circling once a finite pole λ, then

$$\mathrm{Tr}_\lambda\{f,g\}_r = \int_\Omega \mathrm{res}_\lambda(\partial_p f \partial_x g)\,\mathrm{d}x - \int_\Omega \mathrm{res}_\lambda(\partial_x f \partial_p g)\,\mathrm{d}x = \frac{1}{2\pi i}\int_\Omega \oint_{\gamma_\lambda} (\partial_p f \partial_x g)\,\mathrm{d}p\,\mathrm{d}x$$
$$- \frac{1}{2\pi i}\int_\Omega \oint_{\gamma_\lambda} (\partial_x f \partial_p g)\,\mathrm{d}p\,\mathrm{d}x = 0,$$

where the last equality follows by integrating by parts with respect to p and x. Similar proof is for $\lambda=\infty$. Therefore

$$(\{f,g\}_r,h)_\lambda - (\{g,h\}_r,f)_\lambda = \mathrm{Tr}_\lambda(\{f,g\}_r h) - \mathrm{Tr}_\lambda(\{g,h\}_r f) = \mathrm{Tr}_\lambda(\{fh,g\}_r - f\{h,g\}_r) + \mathrm{Tr}_\lambda(f\{h,g\}_r)$$
$$= \mathrm{Tr}_\lambda\{fh,g\}_r = 0,$$

i.e., ad-invariance is proved. □

For functional $H=\int_\Omega h(u_i)\,\mathrm{d}x$, where u_i are dynamical coefficients of $L\in\mathcal{A}$, we have to show how to construct its differential near a given point λ denoted by $d_\lambda H\in\mathcal{A}$. Coefficients of $d_\lambda H$ depend on dynamical fields and usual variational derivatives $\delta H/\delta u_i$ in such a way that the trace duality assumes the usual Euclidean form, i.e.,

$$(d_\lambda H, L_t)_\lambda = \mathrm{Tr}_\lambda(d_\lambda H L_t) = \sum_i \int_\Omega \frac{\delta H}{\delta u_i}(u_i)_t\,\mathrm{d}x. \tag{3.9}$$

Notice that from (3.9) it follows that at different points λ and μ the following equality holds:

$$(d_\lambda H, K)_\lambda = (d_\mu H, K)_\mu, \tag{3.10}$$

where K is vector field on $\mathcal{A}$ such that it spans exactly the same subspace of $\mathcal{A}$ as L_t.

To find R^* needed in (2.4), i.e., the adjoints of R-matrices (3.4), one has to determine the adjoint projections related to given point λ from the following relation $((P^\lambda)^* f,g)_\lambda=(f,P^\lambda g)_\lambda$, where $f,g\in\mathcal{A}$. So, for 0 and ∞ we have that

$$(P^0_{<k-r})^* = 1 - P^0_{<2r-k}, \quad (P^\infty_{\geqslant k-r})^* = 1 - P^\infty_{\geqslant 2r-k}.$$

The case of $\lambda=v(x)$ is more delicate. Let $A=\Sigma_m a_m(p-v)^m$ and $B=\Sigma_n b_n(p-v)^n$, then for $r\geqslant 0$:

$$(A,P^v_{<0}B)_v = \int_\Omega \mathrm{res}_v\left(\sum_{s\geqslant 0}\sum_m\sum_{n<0}\binom{-r}{s} v^{-r-s} a_m b_n (p-v)^{m+n+s}\right)\mathrm{d}x$$

$$= \int_\Omega \sum_{s\geqslant 0}\sum_{n<0}\binom{-r}{s} v^{-r-s} a_{-n-s-1} b_n\,\mathrm{d}x = \int_\Omega \sum_{s\geqslant 0}\sum_{m\geqslant -s}\binom{-r}{s} v^{-r-s} a_m b_{-m-s-1}\,\mathrm{d}x$$

$$= \int_\Omega \mathrm{res}_v\left(\sum_{s\geqslant 0}\sum_{m\geqslant -s}\sum_n \binom{-r}{s} v^{-r-s} a_m b_n (p-v)^{m+n+s}\right)\mathrm{d}x$$

$$= \left(p^r \sum_{s\geqslant 0}\binom{-r}{s} v^{-r-s}(p-v)^s P^v_{\geqslant -s} A, B\right)_v,$$

where we used an appropriate expansion of p^{-r} at v. Hence

$$(P^v_{<0})^* = 1 - p^r \sum_{s=0}^{\infty}\binom{-r}{s} v^{-r-s}(p-v)^s P^v_{<-s}, \quad r\geqslant 0,$$

when $r=0$ it reduces to $(P^v_{<0})^*=1-P^v_{<0}$. We will use simplified notation

$$P'_v = \sum_{s=0}^{\infty} \binom{-r}{s} v^{-r-s}(p-v)^s P^v_{<-s}$$

as then $(P^v_{<0})^* = 1 - p^r P'_v$.

D. Poisson structures

The Poisson structures (2.3) at respective points, related to respective R-matrices, are

$$\{H,F\}^n_\lambda = (d_\lambda F, \pi^\lambda_n d_\lambda H)_\lambda, \quad \lambda = \infty, 0, v(x), \quad n \geqslant 0 \tag{3.11}$$

for which Poisson operators (2.4) are given by the following forms:

$$\pi^\infty_n d_\infty H = \{(L^n d_\infty H)^\infty_{\geqslant k-r}, L\}_r - L^n(\{d_\infty H, L\}_r)^\infty_{\geqslant 2r-k},$$

$$\pi^0_n d_0 H = \{L, (L^n d_0 H)^0_{<k-r}\}_r - L^n(\{L, d_0 H\}_r)^0_{<2r-k}, \tag{3.12}$$

$$\pi^v_n d_v H = \{L, (L^n d_v H)^v_{<0}\}_r - L^n p^r P'_v(\{L, d_v H\}_r).$$

It is important here to mention that for a given Lax operator L it may happen that L_t does not span a proper subspace of the full Poisson algebra $\mathcal{A}$, i.e., the image of the Poisson operator $\pi_n dH$ does not coincide with this subspace. Then, in general, the Dirac reduction can be invoked for restriction of a given Poisson tensor to a suitable subspace.

Lemma 3.3: The following relations will be needed to prove the forthcoming theorem:

$$(d_\infty F, \{L, (L^n d_0 H)^0_{<k-r}\}_r)_\infty = (d_0 H, L^n(\{d_\infty F, L\}_r)^\infty_{\geqslant 2r-k})_0,$$

$$(d_\infty F, L^n(\{L, d_0 H\}_r)^0_{<2r-k})_\infty = (d_0 H, \{(L^n d_\infty F)^\infty_{\geqslant k-r}, L\}_r)_0,$$

for arbitrary k and r, and

$$(d_\infty F, \{L, (L^n d_v H)^v_{<0}\}_r)_\infty = (d_v H, L^n(\{d_\infty F, L\}_r)^\infty_{\geqslant r})_v, \tag{3.13}$$

$$(d_\infty F, L^n p^r P'_v(\{L, d_v H\}_r))_\infty = (d_v H, \{(L^n d_\infty F)^\infty_{\geqslant 0}, L\}_r)_v, \tag{3.14}$$

where $r \geqslant 0$.

Proof: We will prove only the first and last relations as for the two remaining ones the proof is similar. We use property of ad-invariance and we omit (or add) these elements which do not contribute in calculations of residues:

$$(d_\infty F, \{L, (L^n d_0 H)^0_{<k-r}\}_r)_\infty = ((L^n d_0 H)^0_{<k-r}, \{d_\infty F, L\}_r)_\infty$$

$$= \int_\Omega \operatorname{res}_\infty (p^{-r}(L^n d_0 H)^0_{<k-r}\{L, d_\infty F\}_r)\, \mathrm{d}x = \int_\Omega \operatorname{res}_\infty (p^{-r}(L^n d_0 H)^0_{<k-r}(\{L, d_\infty F\}_r)^\infty_{\geqslant 2r-k})\, \mathrm{d}x$$

$$\overset{\text{by (3.7)}}{=} \int_\Omega \operatorname{res}_0 (p^{-r}(L^n d_0 H)^0_{<k-r}(\{d_\infty F, L\}_r)^\infty_{\geqslant 2r-k})\, \mathrm{d}x$$

$$= \int_\Omega \operatorname{res}_0 (p^{-r} L^n d_0 H(\{d_\infty F, L\}_r)^\infty_{\geqslant 2r-k})\, \mathrm{d}x = (d_0 H, L^n(\{d_\infty F, L\}_r)^\infty_{\geqslant 2r-k})_0.$$

Let $r \geqslant 0$. Using proper expansion of p^{-r} at v we have

$$(d_\infty F, L^n p^r P_v'(\{L, d_v H\}_r))_\infty = -\int_\Omega \operatorname{res}_\infty (d_\infty F L^n P_v'(\{L, d_v H\}_r))\, \mathrm{d}x$$

$$= \int_\Omega \operatorname{res}_\infty ((L^n d_\infty F)^\infty_{\geqslant 0} P_v'(\{d_v H, L\}_r))\, \mathrm{d}x \overset{\text{by (3.7)}}{=} \int_\Omega \operatorname{res}_v ((L^n d_\infty F)^\infty_{\geqslant 0} P_v'(\{L, d_v H\}_r))\, \mathrm{d}x$$

$$= \int_\Omega \operatorname{res}_v ((L^n d_\infty F)^\infty_{\geqslant 0} \{L, d_v H\}_r)\, \mathrm{d}x = ((L^n d_\infty F)^\infty_{\geqslant 0}, \{L, d_v H\}_r)_v$$

$$= (d_v H, \{(L^n d_\infty F)^\infty_{\geqslant 0}, L\}_r)_v.$$

Thus all relations are valid. □

Theorem 3.4: *Let $H(L)$ and $F(L)$ be smooth functions of $L \in \mathcal{A}$. Then for all appropriate k and r*

$$\forall_\lambda \{H, F\}^n_\lambda = \{H, F\}^n_\infty \quad \textit{and} \quad \pi^\lambda_n d_\lambda H = \pi^\infty_n d_\infty H.$$

Therefore, Poisson structures, from the original function space of related dispersionless systems, calculated for appropriate fixed r and k at different points are equal.

Proof: We will prove only the case for $\lambda = v(x)$ as for other cases the proof is similar. Thus,

$$\{H, F\}^n_v = (d_v F, \pi^v_n d_v H)_v \overset{\text{by (3.10)}}{=} (d_\infty F, \pi^v_n d_v H)_\infty$$

$$= (d_\infty F, \{L, (L^n d_v H)^v_{<0}\}_r - L^n p^r P_v'(\{L, d_v H\}_r))_\infty$$

$$\overset{\text{by (3.13-3.14)}}{=} (d_v H, L^n (\{d_\infty F, L\}_r)^\infty_{\geqslant r} - \{(L^n d_\infty F)^\infty_{\geqslant 0}, L\}_r)_v$$

$$= -(d_v H, \pi^\infty_n d_\infty F)_{v,r} \overset{\text{by (3.10)}}{=} -(d_\infty H, \pi^\infty_n d_\infty F)_\infty = \{H, F\}^n_\infty.$$

Now, from the equality of the above-noted Poisson brackets it follows that

$$(d_\infty F, \pi^\infty_n d_\infty H)_\infty = (d_\lambda F, \pi^\lambda_n d_\lambda H)_\lambda \overset{\text{by (3.10)}}{=} (d_\infty F, \pi^\lambda_n d_\lambda H)_\infty \Leftrightarrow \pi^\lambda_n d_\lambda H = \pi^\infty_n d_\infty H.$$

Hence the theorem is proved. □

E. Commuting multi-Hamiltonian Lax hierarchies

Let $L \in \mathcal{A}$ be a Lax function and Γ be a set of all poles and roots of L. Then, one can construct the following multi-Hamiltonian Lax hierarchies (2.6) for appropriate r and k,

$$\frac{\partial L}{\partial t_{\lambda,q}} = \{\Omega^\lambda_q, L\}_r = \pi^\lambda_0 d_\lambda H^\lambda_{q/n} = \pi^\lambda_1 d_\lambda H^\lambda_{q/n-1} = \cdots \quad \lambda \in \Gamma,\ q > 0, \tag{3.15}$$

where $n = N$ for $\lambda = \infty$ and $n = m_\lambda$ for $\lambda \neq \infty$. The Hamiltonians are then defined through trace forms near these poles and are given by (2.5) for $q \geqslant 0$ as

$$H^\lambda_{q/n}(L) = \frac{\epsilon}{\dfrac{q}{n} + 1} \int_\Omega \operatorname{res}_\lambda (p^{-r} L^{q/n+1})\, \mathrm{d}x \quad \text{for } q \neq -n \tag{3.16}$$

$$H^{\lambda}_{-1}(L) = \epsilon \int_{\Omega} \mathrm{res}_{\lambda}(p^{-r} \ln L)\, \mathrm{d}x \quad \text{for } q = -n,$$

where $\epsilon = -1$ for $\lambda = \infty$ and $\epsilon = 1$ for $\lambda \neq \infty$. Calculations of H^{λ}_{-n} from (3.16) for λ being the root of L may cause difficulties as then $\ln L$ has at λ logarithmic singularity. However, due to Poincare lemma, as $\mathcal{A}$ is convex, all one-forms $d_{\lambda} H^{\lambda}_{-1}$ are exact and we are able to find H^{λ}_{-1} in an alternative approach. For example, we first look for coefficients of dH^{λ}_{-1} which can be simply obtained from

$$\mathrm{Tr}_{\lambda}(L^{-1} L_t) = \sum\nolimits_i \int_{\Omega} \frac{\delta H^{\lambda}_{-1}}{\delta u_i} (u_i)_t \, \mathrm{d}x,$$

since $d_{\lambda} H^{\lambda}_{-1} = L^{-1}$. Then, we calculate the functional H^{λ}_{-1} integrating a respective system of equations.

Let us show that Lax hierarchies (3.15) related to different $\lambda \in \Gamma$ for fixed r and k mutually commute. Hamiltonians (3.16), as Casimirs of the natural Lie-Poisson bracket, are in involution with respect to Poisson brackets (3.11) related to all applicable $\lambda \in \Gamma$. From Theorem 3.4 it follows that $\pi^{\lambda}_n d_{\lambda} = \pi^{\mu}_n d_{\mu}$ for $\lambda, \mu \in \Gamma$. Now, hence πd is the Lie algebra homomorphism, from the algebra of smooth functions to the Lie algebra of vector fields, the commutation between Lax hierarchies (3.15) is immediate. Hence, the following corollary is valid.

Corollary 3.5: Let L be a Lax function from algebra $\mathcal{A}$ with fixed Poisson bracket given by r and let us fix an appropriate k. Then, around each applicable point being pole or root of L one finds infinite hierarchy of commuting multi-Hamiltonian symmetries and infinite hierarchy of constants of motion. Moreover, vector fields from these different hierarchies mutually commute.

In further considerations we are interested in extracting closed systems with finite number of dynamical functions. Therefore, we will look for meromorphic Lax functions, with finite number of dynamical coefficients, which allow a construction of consistent evolution Lax hierarchies. So, in the following section we will select appropriate meromorphic Lax functions.

IV. MEROMORPHIC LAX FUNCTIONS

We would like to investigate the general form of meromorphic Lax functions being appropriate ones, i.e., such which allow a construction of integrable dispersionless equations. The meromorphic Lax function L is an appropriate one if the right-hand sides of Lax hierarchies (3.15) can be written in the form of evolutions L_t, i.e., left-hand sides. We will distinguish among three cases: the first one when L is a finite formal Laurent series at 0, the second one when L is a finite formal Laurent series at pole $v(x)$, and finally more general case of meromorphic functions.

A. Polynomial Lax functions in p and p^{-1}

Let us consider Lax functions of the form

$$L = u_N p^N + u_{N-1} p^{N-1} + \cdots + u_{1-m} p^{1-m} + u_{-m} p^{-m}, \tag{4.1}$$

i.e., formal finite Laurent series at 0. The coefficients u_i are dynamical fields. For Lax functions (4.1), in general, we can construct powers near ∞ and 0 which will generate related Lax hierarchies (3.15). If $k = r$ negative powers calculated around roots of L generate additional Lax hierarchies.

From now on, without loss of generality, we will choose all appearing constants in the form that will simplify all formulas.

Proposition 4.1: Lax function of the form (4.1) *is an appropriate one in the following cases:*

1. $k=0$, $r=0$: $N \geqslant 2$, $u_N = 1$, $u_{N-1} = 0$, $m = 0$;
2. $k=1$, $r \in \mathbb{Z}$: $N \neq 0$, $u_N = 1$, $m \neq 0$ *for* $r=1$;
3. $k=2$, $r \in \mathbb{Z}$: $N \neq 0$ for $r=1$, $m \neq 0$, $u_{-m} = 1$;

4. $k=3$, $r=2$: $N=0$, $m\geqslant 2$, $u_{1-m}=0$, $u_{-m}=1$.

We will not prove this proposition as it is the standard case considered in Ref. 20.

Proposition 4.2: Under the transformation $p'=p^{-1}$ Lax hierarchies, from Proposition 4.1, *generated by powers calculated at ∞ and* 0 *for appropriate r and k transforms into Lax hierarchies for* 0 *and ∞ with $r'=2-r$ and $k'=3-k$, respectively.*

The proof immediately follows from Proposition 3.1. Notice that by transformation $p'=p^{-1}$ for $r=k=0,1,2$ Lax hierarchies (3.15) defined at roots of L being dynamical fields fall out from the scheme presented in this article. On the other hand, for: $k=1,r=0$; $k=2,r=1$; $k=3,r=2$; according to Proposition 4.1 one can construct Lax hierarchies only at ∞ and 0. However, by $p'=p^{-1}$ they transform into cases: $k=2,r=2$; $k=1,r=1$; $k=0,r=0$; respectively, for which one is able to construct Lax hierarchies related to all poles (including poles being dynamical fields) of L' and L'^{-1}. Hence, the relevant cases from Proposition 4.1 are:

- $k=0$, $r=0$;
- $k=1$, $r\in\mathbb{Z}\backslash\{0\}$;
- $k=2$, $r=2$.

The remaining cases can be obtained by transformation $p'=p^{-1}$ according to Proposition 4.2.

To construct Poisson operators we have to choose a point near which we will perform the calculations. Nevertheless, as follows from Theorem 3.4, the explicit form of Poisson operators in the original function space is the same for all points. Thus, we choose the ∞ as it is the standard case. Then, as we assumed the usual Euclidean form (3.9), differentials of functional H are given by

$$dH \equiv d_\infty H = \sum_{i=-m}^{N+k-2} \frac{\delta H}{\delta u_i} p^{r-1-i},$$

where $m=0$ for $k=0$. Still we have to check whether the above-mentioned Lax functions span proper subspaces, with respect to Poisson operators (3.12), of the full Poisson algebras. We will limit ourselves to linear ($n=0$) and quadratic ($n=1$) Poisson tensors, as obviously it is enough to define bi-Hamiltonian structures. Besides, in the all nontrivial cases Lax functions do not span proper subspaces with respect to Poisson tensors for $n\geqslant 2$.

Poisson tensors restricted to finite number of fields are properly defined if the highest and lowest orders of $\pi_n^\infty dH$ and L_t will coincide. Simple inspection shows that the highest order of $\pi_n^\infty dH$ is equal to $\max\{N+k-2, nN+2r-k-1\}$ and the lowest is 0 for $k=0$ and $\min\{k-1-m, -nm+2r-k\}$ for $k=1,2$. Hence, in the case $k=0$ the Lax function always span the proper subspace with respect to the linear Poisson tensor, but for $k=1,2$ only in case when $N\geqslant 2r-2k+1\geqslant -m$, otherwise the Dirac reduction is required. The linear Poisson tensor is of the form

$$\pi_0^\infty dH = \{(dH)_{\geqslant k-r}^\infty, L\}_r - (\{dH, L\}_r)_{\geqslant 2r-k}^\infty. \tag{4.2}$$

The reduced linear tensor for $N=-1$ and $k=r=1,2$ is given by (4.12). For the quadratic Poisson tensors the Dirac reduction is always necessary. The calculation procedure of Dirac reduction is explained in Ref. 20 (in a bit different notation). The reduced quadratic Poisson tensor for $k=r=0,1,2$ is given by

$$(\pi_1^\infty)^{\mathrm{red}} dH = \{(LdH)_{\geqslant 0}^\infty, L\}_r - L(\{dH, L\}_r)_{\geqslant r}^\infty + \frac{1}{N}\{L, \partial_x^{-1}\mathrm{res}_\infty\{dH, L\}_0\}_r, \tag{4.3}$$

and for $k=1,r=0$ and $k=2,r=1$ takes the form

$$(\pi_1^\infty)^{\mathrm{red}} dH = \{(LdH)_{\geqslant 1}^\infty, L\}_r - L(\{dH, L\}_r)_{\geqslant r-1}^\infty + \frac{1}{m}\{L, \partial_x^{-1}\mathrm{res}_\infty\{dH, L\}_0\}_r. \tag{4.4}$$

Both reduced Poisson tensors are always local as $\mathrm{res}_\infty\{\cdot,\cdot\}_0=(\cdots)_x$.

In the article, in general, we present examples for the simplest Lax functions, where calculations are not very complicated. From the Lax hierarchies considered we exhibit only the first nontrivial systems.

Example 4.3: Two field system: $k=1$, $r\in\mathbb{Z}$.

Let us consider the Lax function of the form

$$L=p+u+vp^{-1}. \tag{4.5}$$

It has poles at ∞ *and* 0. *Then, for* ∞ *we have*

$$L_{t_{2-r}}=\{\Omega^{\infty}_{2-r},L\}_r\Leftrightarrow\begin{pmatrix}u\\v\end{pmatrix}_{t_{2-r}}=(2-r)\begin{pmatrix}(1-r)uu_x-v_x\\-u_xv-(1-r)uv_x\end{pmatrix}=\pi_0 dH^{\infty}_{2-r}=\pi_1^{\mathrm{red}}dH^{\infty}_{1-r}, \tag{4.6}$$

where $\Omega^{\infty}_{2-r}=(L^{2-r})^{\infty}_{\geqslant 1-r}=p^{2-r}+(2-r)up^{1-r}$. *When* $r=2$ *the next equation from the hierarchy is the first nontrivial one. For* $r=1$ *this is the well-known dispersionless Toda system. The hierarchy for* 0 *is the same as L has only two poles of the same order and* $(L^q)^{\infty}_{\geqslant 1-r}=L-(L^q)^{0}_{<1-r}$. *The roots of L are* $\lambda_{\pm}=\frac{1}{2}(-u\pm\sqrt{u^2-4v})$. *Thus, for* $r=1$,

$$\Omega_1^{\lambda_{\pm}}=-(L^{-1})^{\lambda_{\pm}}_{<0}=-\frac{1}{1-\dfrac{4v}{\lambda_{\pm}}}(p-\lambda_{\pm})^{-1}$$

and one finds the following:

$$L_{\tau_1^{\pm}}=\{\Omega^{\lambda_{\pm}}_{-1},L\}_1\Leftrightarrow\begin{pmatrix}u\\v\end{pmatrix}_{\tau_1^{\pm}}=\frac{\pm 1}{(u^2-4v)^{\frac{3}{2}}}\begin{pmatrix}2u_xv-uv_x\\v(2v_x-uu_x)\end{pmatrix}=\pi_0 dH^{\lambda_{\pm}}_{-1}=\pi_1^{\mathrm{red}}dH^{\lambda_{\pm}}_{-2}.$$

Of course, for $k=r=1$ *all equations mutually commute.*

The Lax function (4.5) *defines proper subspace with respect to the linear Poisson tensor* (4.2) *only for* $r=0,1$. *In the cases, the reduced quadratic Poisson tensors are given by* (4.4) and (4.3), *respectively. Hence, for* $r=0$,

$$\pi_0=\begin{pmatrix}0&\partial\\\partial&0\end{pmatrix},\quad \pi_1^{\mathrm{red}}=\begin{pmatrix}2\partial&\partial u\\u\partial&\partial v+v\partial\end{pmatrix}, \tag{4.7}$$

and related Hamiltonians are $H_1^{\infty}=\int_{\Omega}uv\ \mathrm{d}x$, $H_2^{\infty}=\int_{\Omega}(u^2v+v^2)\ \mathrm{d}x$. *For* $r=1$,

$$\pi_0=\begin{pmatrix}0&\partial v\\v\partial&0\end{pmatrix},\quad \pi_1^{\mathrm{red}}=\begin{pmatrix}\partial v+v\partial&u\,\partial v\\v\,\partial u&2v\,\partial v\end{pmatrix}$$

and

$$H_0^{\infty}=\int_{\Omega}uv\ \mathrm{d}x,\quad H_1^{\infty}=\int_{\Omega}(u^2v+v^2)\ \mathrm{d}x,$$

$$H^{\lambda_{\pm}}_{-2}=\int_{\Omega}\frac{\mp 1}{\sqrt{u^2-4v}}\ \mathrm{d}x,\quad H^{\lambda_{\pm}}_{-1}=\pm\int_{\Omega}\ln\frac{u+\sqrt{u^2-4v}}{v}\ \mathrm{d}x.$$

Example 4.4: Two field system: $k=2$, $r=2$.

We will consider Lax function of the form

$$L=vp+u+p^{-1}$$

i.e., function (4.5) *transformed by* $p\mapsto p^{-1}$. *By Proposition 4.2 the hierarchy for* ∞ *is given by hierarchy* (4.6) *for* $k=1$, $r=0$ *from the above-presented example. The roots of L are* $\alpha_{\pm}$

$=(-u\pm\sqrt{u^2-4v})/2v$. *Thus, for*

$$\Omega_1^{\alpha_\pm}=-(L^{-1})_{<0}^{\alpha_\pm}=-\frac{1}{v-\frac{4v^2}{\alpha_\pm^2}}(p-\alpha_\pm)^{-1}$$

one finds

$$L_{\xi_1^\pm}=\{\Omega_{-1}^{\alpha_\pm},L\}_2\Leftrightarrow\begin{pmatrix}u\\v\end{pmatrix}_{\xi_1^\pm}=\frac{\pm1}{(u^2-4v)^{3/2}}\begin{pmatrix}-uu_x+2v_x\\2u_xv-uv_x\end{pmatrix}=\pi_0 dH_{-1}^{\alpha_\pm}=\pi_1^{\mathrm{red}}dH_{-2}^{\alpha_\pm}.$$

This system by Proposition 4.2 commutes with (4.6) *for* $r=0$. *Thus, the Poisson tensors are given by* (4.7) *with Hamiltonians*

$$H_{-2}^{\alpha_\pm}=\int_\Omega\frac{\pm u}{2\sqrt{u^2-4v}}\mathrm{d}x,\quad H_{-1}^{\alpha_\pm}=\mp\int_\Omega\frac{1}{2}(u+\sqrt{u^2-4v})\mathrm{d}x.$$

B. Polynomial Lax functions in $(p-v)$ and $(p-v)^{-1}$

Let us consider Lax functions which are formal Laurent series around v, with a finite number of dynamical coefficients, of the form

$$L=u_N(p-v)^N+u_{N-1}(p-v)^{N-1}+\cdots+u_{1-m}(p-v)^{1-m}+u_{-m}(p-v)^{-m},\quad m\neq0.\tag{4.8}$$

Lax functions (4.8) have poles at ∞ and v, near which calculated powers generate, if allowed by k and r, respective Lax hierarchies. Additional powers with related hierarchies can be constructed around the roots of L.

Proposition 4.5: Lax function of the form (4.8) *is an appropriate one in the following cases:*

1. $k=r=0$: $u_N=1$, $u_{N-1}=Nv$;
2. $k=1$, $r\in\mathbb{Z}$: $N\neq0$, $u_N=1$, $L|_{p=0}=0$ *for* $r=1$;
3. $k=2$, $r\in\mathbb{Z}$: $N\neq0$ *when* $r=1$, $L|_{p=0}=0$, $\frac{d}{dp}L|_{p=0}=1$;
4. $k=3$, $r=2$: $N=0$, $L|_{p=0}=0$, $\frac{d}{dp}L|_{p=0}=1$, $\frac{d^2}{dp^2}L|_{p=0}=0$.

Moreover, for fixed r and k, the respective Lax hierarchies commute.

Proof: It is enough to consider the Lax hierarchy related to ∞. Function (4.8) will be appropriate Lax function if the left- and right-hand sides of Lax hierarchy (3.15) for $\lambda=\infty$ will coincide and the number of independent equations will be the same as the number of dynamical coefficients in L. This Lax hierarchy can be written in two equivalent representations

$$L_t=\{A_{\geqslant k-r}^\infty,L\}_r=-\{A_{<k-r}^\infty,L\}_r.$$

So, we have to examine expansions of this hierarchy near ∞ and v as well as at 0, since the factor p^r occurs in Poisson bracket. It turns out that the first representation yields direct access to terms with lowest orders, whereas the second representation yields information about terms with highest orders. Near ∞ we have

$$L_t=(u_N)_tp^N+(u_{N-1}-Nv)_tp^{N-1}+\textit{lower terms},$$

$$L_t=-\{A_{<k-r}^\infty,L\}_r=-\{\alpha p^{k-r-1}+l.t.,u_Np^N+l.t.\}_r=(\ldots)p^\alpha+l.t.,$$

where $\alpha=N+k-2$ for $N\neq0$ or $r\neq k-1$; and $\alpha=0$ for $N=0$ and $r=k-1$. This imposes the constraints on fields u_N and u_{N-1} given in the Proposition. The expansion of $A_{\geqslant k-r}^\infty$ near v is of the form $A_{\geqslant k-r}^\infty=$*higher terms*$+\gamma_1(p-v)+\gamma_0$ as $A_{\geqslant k-r}^\infty$ does not have singularity at v. So, near v we have

$$L_t = higher\ terms + (u_{-m} + (m-1)v)_t (p-v)^{-m} + mv_t (p-v)^{-m-1},$$

$$L_t = \{A^{\infty}_{\geqslant k-r}, L\}_r = \{h\,.\,t\,.\, + \gamma_0, h\,.\,t\,.\, + u_{-m}(p-v)^{-m}\}_r = h\,.\,t\,.\, + (\ldots)(p-v)^{-m-1}$$

and the lowest order of the left- and right-hand side are always the same. The expansion of $A^{\infty}_{\geqslant k-r}$ near 0 is of the form $A^{\infty}_{\geqslant k-r} = higher\ terms + \gamma p^{k-r}$. So we have

$$L_t = higher\ terms + \tfrac{1}{2}\left(\tfrac{d^2}{dp^2}L\big|_{p=0}\right)_t p^2 + \left(\tfrac{d}{dp}L\big|_{p=0}\right)_t p + (L|_{p=0})_t,$$

$$L_t = \{A^{\infty}_{\geqslant k-r}, L\}_r = \left\{h\,.\,t\,.\, + \gamma p^{k-r}, h\,.\,t\,.\, + \tfrac{d}{dp}L\big|_{p=0} p + L|_{p=0}\right\}_r = h\,.\,t\,.\, + (\ldots)p^{\alpha}.$$

For $k=r=0$ we have $\alpha=0$ and there is no need for additional constraints. For $k=1$ if $r\neq 1$: $\alpha=0$ and both sides have the same order in expansion at 0. But for $k=r=1$ we have $\alpha=1$. Hence, $(L|_{p=0})_t=0$ and we have to impose the constraint $L|_{p=0}=0$. Then, both sides have the same form. For $k=2$ and arbitrary r: $\alpha>0$ and the first constraint of the form $L|_{p=0}=0$ is needed. Taking into consideration this constraint: $\alpha=2$ and it follows that $((d/dp)L|_{p=0})_t=0$. Hence, both sides will agree if we impose an additional constraint $(d/dp)L|_{p=0}=1$. For $k=3$ the reasoning is similar to the case $k=2$, but there will be one more constraint of the form $(d^2/dp^2)L|_{p=0}=0$ needed. Commutation of Lax hierarchies follows from Corollary 3.5. □

Proposition 4.6: Lax hierarchies defined at ∞ and v for the case k=r=0 of Proposition 4.5 by the transformation p↦p−v turns to Lax hierarchies related to ∞ and 0, *respectively, for the case k=1, r=0 of Proposition 4.1.*

Proof: Consider the transformation $p'=p-v$, $x'=x$, $t'=t$. Then, $\partial_p=\partial_{p'}$, $\partial_x=\partial_{x'}-v_x\partial_{p'}$ and $\partial_t=\partial_{t'}-v_t\partial_{p'}$. The points at ∞ and v transform into points at ∞ and 0, respectively, and the Poisson bracket (3.1) for $r=0$ is preserved:

$$\{\cdot,\cdot\}_0 = \partial_p \wedge \partial_x = \partial_{p'} \wedge (\partial_{x'} + v_{x'}\partial_{p'}) = \partial_{p'} \wedge \partial_{x'} = \{\cdot,\cdot\}'_0.$$

Let L be the Lax function of the form (4.8) from Proposition 4.5 for $r=k=0$. Then, by the above-noted transformation $L'=L$ is a Lax function of the form (4.1) from Proposition 4.5 for $r=0$, $k=1$. For meromorphic function $A\in\mathcal{A}$, let $[A]_\lambda$ mean the zero-order term of Laurent series at λ. From (3.15) for $\lambda=\infty$ and v it follows that $v_{t_{\infty,q}}=([L^{q/N}]_\infty)_x$ and $v_{t_{v,q}}=([L^{q/m}]_v)_x$, respectively. Thus the left- and right-hand sides of (3.15) for $\lambda=v$ are equal

$$L_\tau = L'_{\tau'} - v_\tau L'_{p'} = L'_{\tau'} - ([L'^{\frac{q}{m}}]^v)_x L'_{p'} = L'_{\tau'} + \{[L'^{\frac{q}{m}}]^0, L'\}'_0,$$

$$L_\tau = -\{(L'^{\frac{q}{m}})^v_{<0}, L\}_0 = -\{(L'^{\frac{q}{m}})^0_{<0}, L'\}'_0,$$

where $\tau=t_{v,q}$ and $\tau'=t'_{v,q}$. Hence,

$$L'_{\tau'} = -\{(L'^{\frac{q}{m}})^0_{<1}, L'\}'_0.$$

Similar calculations are valid at ∞. □

A similar observation as in the above-noted Proposition has been made earlier in Ref. 4.

Notice that for the case $k=r=0$ of Proposition 4.5 one is able to construct Lax hierarchies related to the roots of L, which is not possible for the case $k=1, r=0$ of Proposition 4.1. In this sense, the first case is more general.

Proposition 4.7: Under the transformation $p'=p^{-1}$, the following equalities between some cases from Proposition 4.5 hold:

- *the Lax hierarchy related to* 0 *for $k=3, r=2$ is equivalent to the Lax hierarchy related to ∞ for $k=r=0$ with $N=-1$;*
- *the Lax hierarchy related to* 0 *for $k=2, r\neq 1$ with $N=0$ is equivalent to the Lax hierarchy related to ∞ for $k=1, r\neq 1$ with $N=-1$;*

- *Lax hierarchies related to* ∞ *and* 0 *for* $k=2, r=1$ *with* $N=-1$ *are equivalent to Lax hierarchies related to* 0 *and* ∞ *for* $k=1, r=1$ *with* $N=-1$, $L|_{p=0}=0$, *respectively*.

Proof: The appropriate Lax function from Proposition 4.5 for $k=3$, $r=2$ has the form

$$L = u_0 + u_{-1}(p-v)^{-1} + \cdots + u_{-m}(p-v)^{-m},$$

where $L|_{p=0}=0$, $(d/dp)L|_{p=0}=1$ and $(d^2/dp^2)L|_{p=0}=0$. Taking into consideration the above-noted constraints, expansion of L around 0 is $L=\cdots+(\cdots)p^2+p$. By transformation $p'=p^{-1}$ we have that

$$(p-v)^{-1} = (p'^{-1}-v)^{-1} = -v' - v'^2(p'-v')^{-1}$$

where $v'=v^{-1}$. Thus L transforms into

$$L' = u'_0 + u'_{-1}(p'-v')^{-1} + \cdots + u'_{-m}(p'-v')^{-m}.$$

From the expansion around 0 of L it follows that expansion of L' near ∞ is $L'=p'^{-1}+(\cdots)p'^{-2}+\cdots$. Hence, $u'_0=0$, $u'_{-1}=1$ and the Lax function L' is an appropriate one for $k=r=0$. An analogues approach must be taken for the next two relations. The rest holds by Proposition 3.1. □

Now, let us pass to the Hamiltonian formulation of Lax hierarchies related to the appropriate Lax functions from Proposition 4.5. In general, the relevant cases are for $k=0,1,2$. Further we will consider only them. The differential at ∞ of functional H for the Lax function of the general form (4.8) is given by

$$dH \equiv d_\infty H = p^r\left(\frac{1}{mu_{-m}}\left(\frac{\delta H}{\delta v} + \sum_{i=1-m}^{N} iu_i\frac{\delta H}{\delta u_{i-1}}\right)(p-v)^m + \sum_{i=1-m}^{N+1}\frac{\delta H}{\delta u_{i-1}}(p-v)^{-i}\right) \tag{4.9}$$

as

$$\mathrm{Tr}_\infty(L_t dH) = -\int_\Omega \mathrm{res}_\infty(p^{-r}L_t dH)\,\mathrm{d}x \overset{\text{by (3.7)}}{=} \int_\Omega \mathrm{res}_v(p^{-r}L_t dH)\,\mathrm{d}x = \int_\Omega\left(\sum_{i=-m}^{N}(u_i)_t\frac{\delta H}{\delta u_i} + v_t\frac{\delta H}{\delta v}\right)\mathrm{d}x.$$

For the Lax functions with constraints from Proposition 4.5 one has to modify differentials (4.9) in an appropriate way or construct them by (4.11), i.e., in the same way as in the next section. One has to examine when a given Lax function from Proposition spans the proper subspace with respect to Poisson tensors. The procedure is rather technical and similar to the proof of this proposition. Thus, we omit it and we will present only the final results. The Lax functions from Proposition 4.5 for $k=0,1,2$ span proper subspace with respect to linear Poisson tensor $n=0$ if $N\geqslant 2r-2k+1$, $m\geqslant -1$ and $r\geqslant k$. Then, it is given by (4.2). If it is not the case, Dirac reduction is required. The reduced linear Poisson tensor for $N=-1$, $m\geqslant 1$ and $k=r=0,1,2$ is given by (4.12). These Lax functions do not form a proper subspace with respect to quadratic Poisson tensor $n=1$ and always the Dirac reduction procedure is needed. For $k=r=0,1,2$ reduced quadratic Poisson tensors have the form (4.3).

Example 4.8: Two-field system: $k=r=1$.

The Lax function, taking into consideration appropriate constraints, is given by the form

$$L = (p-v) + u + v(u-v)(p-v)^{-1} = \frac{p(p+u-2v)}{p-v}.$$

For ∞ *one finds* $\Omega_1^\infty=(L)^\infty_{\geqslant 0}=p+u-v$ *and*

$$L_{t_1} = \{\Omega_1^\infty, L\}_1 \Leftrightarrow \begin{pmatrix} u \\ v \end{pmatrix}_{t_1} = \begin{pmatrix} 2u_x v + uv_x - 2vv_x \\ u_x v \end{pmatrix} = \pi_0 dH_1^\infty = \pi_1^{\mathrm{red}} dH_0^\infty.$$

The Lax hierarchy related to v *is the same as* $L=(L)^\infty_{\geqslant 0}+(L)^v_{<0}$. *The Lax function has two roots* 0 *and* $2v-u$. *Then, for* $\Omega_1^0=-(L^{-1})^0_{<0}=-[v/(2v-u)]p^{-1}$ *we have*

$$L_{\tau_1} = \{\Omega_1^0, L\}_1 \Leftrightarrow \begin{pmatrix} u \\ v \end{pmatrix}_{\tau_1} = \begin{pmatrix} \dfrac{v_x}{2v-u} \\ \dfrac{2vv_x - u_x v}{(u-2v)^2} \end{pmatrix} = \pi_0 dH_{-1}^0 = \pi_1^{\mathrm{red}} dH_{-2}^0.$$

The Lax hierarchy related to the root $2v-u$ *is up to the sign the same as above since* $L^{-1} = (L^{-1})_{\geqslant 0}^0 + (L^{-1})_{<0}^{2v-u}$.

The general form for a differential of a given functional H according to (4.9) *is*

$$dH = \frac{(2-u)\dfrac{\delta H}{\delta u} + v\dfrac{\delta H}{\delta v}}{(u-v)v^2} p(p-v) + \frac{1}{v}\frac{\delta H}{\delta v} p.$$

The Lax function defines the proper subspace with respect to the linear Poisson tensor (4.2). *The reduced quadratic Poisson tensors are given by* (4.4). *Then*,

$$\pi_0 = \begin{pmatrix} \partial v + v\,\partial & \partial v \\ v\,\partial & 0 \end{pmatrix} \quad \pi_1^{\mathrm{red}} = \begin{pmatrix} 2\,\partial uv + 2uv\,\partial & u\,\partial v + 2v\,\partial v \\ v\,\partial u + 2v\,\partial v & 2v\,\partial v \end{pmatrix}.$$

The respective Hamiltonians are

$$H_0^\infty = \int_\Omega (u-v)\,\mathrm{d}x, \quad H_1^\infty = \frac{1}{2}\int_\Omega (u^2 - v^2)\,\mathrm{d}x,$$

$$H_{-2}^0 = \int_\Omega \frac{v-u}{(u-2v)^2}\,\mathrm{d}x, \quad H_{-1}^0 = \int_\Omega \ln\left(\frac{u}{v} - 2\right)\mathrm{d}x.$$

C. Rational Lax functions

Let us consider the general form of meromorphic Lax function given by

$$L = \sum_{k=-m_0}^{N} u_k p^k + \sum_{i=1}^{\alpha} \sum_{k_i=1}^{m_i} a_{i,k_i} (p - v_i)^{-k_i}, \tag{4.10}$$

where u_k, a_{i,k_i}, and v_i are dynamical fields. From this class of functions considered in the following section we exclude those which have been examined earlier, i.e., (4.1) and (4.8). Any function (4.10) in general has a pole at ∞ of order N, at 0 of order m_0 and α evolution poles at v_j of order m_j. Then, one can construct positive powers of Laurent series at poles of L. Additional Lax hierarchies are generated by negative powers constructed near to the roots of L.

Proposition 4.9: Function of the form (4.10) *is an appropriate one in the following cases:*

1. $k=r=0$:
   - $N \geqslant 1$, $u_N=1$, $u_{N-1}=0$, $m_0=0$,
   - $\forall_k\ u_k=0$, $\Sigma_{i=1}^{\alpha} a_{i,1}=1$, $\Sigma_{i=1}^{\alpha}(a_{i,1}v_i + a_{i,2})=0$;
2. $k=1$, $r \in \mathbb{Z}$:
   - $N \geqslant 1$, $u_N=1$, $m_0 \geqslant 1$,
   - $N=-1$, $u_{-1} + \Sigma_{i=1}^{\alpha} a_{i,1}=1$, $m_0 \geqslant 1$,
   - $N \geqslant 1$, $u_N=1$, $m_0=0$, $L|_{p=0}=0$ *for* $r=1$,
   - $\forall_k\ u_k=0$, $\Sigma_{i=1}^{\alpha} a_{i,1}=1$, $L|_{p=0}=0$ *for* $r=1$;
3. $k=2$, $r \in \mathbb{Z}$:

- $N \geqslant 1$, $m_0 \geqslant 1$, $u_{-m_0}=1$,
- $N \geqslant 1$, $m_0=0$, $L|_{p=0}=0$, $\frac{d}{dp}L|_{p=0}=1$,
- $N=0$, $u_0=0$ for $r=1$, $m_0 \geqslant 1$, $u_{-m_0}=1$,
- $\forall_{k\neq 0}\ u_k=0$, $u_0=0$ *for* $r=1$, $L|_{p=0}=0$, $\frac{d}{dp}L|_{p=0}=1$;

4. $k=3$ and $r=2$

- $N=0$, $m_0 \geqslant 1$, $u_{1-m_0}=0$, $u_{-m_0}=1$,
- $\forall_{k\neq 0}\ u_k=0$, $L|_{p=0}=0$, $\frac{d}{dp}L|_{p=0}=1$, $\frac{d^2}{dp^2}L|_{p=0}=0$.

Moreover Lax hierarchies calculated at different points for fixed r and k mutually commute. We excluded here the Lax functions of the form (4.1) and (4.8).

The proof is similar to the one of Proposition 4.5. So, the meromorphic function of the form (4.10) will be an appropriate Lax function with respect to Lax hierarchies (3.15) defined at poles and roots of L if:

- the right-hand sides of the Lax hierarchy considered and the time derivatives L_t will have the same order at all above poles,
- the number of independent equations, resulting from Lax hierarchies, will be the same as that of dynamical coefficients included in L.

The first condition implies all constraints considered in Proposition 4.9. To see that, an analysis like that in the proof of Proposition 4.5 is needed. So, by the first condition the right-hand sides of considered Lax hierarchies for appropriate r and k can be uniquely presented in the form of L_t, i.e., the left-hand sides. So, the second condition immediately follows from the first one.

The simplest way of deriving dispersionless systems related to given meromorphic Lax functions is to transform Lax hierarchies into purely polynomial form in p through removal of finite singularities. It can be done by multiplication of both sides of Lax hierarchies by a proper factor.

Proposition 4.10: Under transformation $p'=p^{-1}$ *Lax hierarchies*, *from Proposition* 4.9, *defined at* ∞ *and* 0 *for appropriate r and k transforms into Lax hierarchies defined at* 0 *and* ∞ *for* $r'=2-r$ *and* $k'=3-k$, *respectively*.

See proof of Proposition 4.7 and the comment after Proposition 4.2. Hence, the relevant cases from Proposition 4.9 are exactly the same as in Sec. IV A for Proposition 4.1.

Once again we will consider Poisson tensors defined at ∞. This time we are not going to present the explicit form of differentials $d_\infty H$ for the general meromorphic Lax function, but we will explain how to construct them. We postulate that

$$dH \equiv d_\infty H = \sum_{i=N_\infty-\beta+1}^{N_\infty} \gamma_i p^{r-i-1}, \tag{4.11}$$

where β is a number of dynamical coefficients in L and N_∞ is the highest order of Laurent series of L_t at ∞. The form (4.11) allows us to solve (3.9) ($\lambda=\infty$) to obtain functions γ_i in terms of dynamical coefficients of L and its variational derivatives such that we obtain the required Euclidean form. We will consider only relevant cases of meromorphic Lax functions from Proposition 4.9. Verification that they span the proper subspace with respect to Poisson tensors is similar to the proof of this proposition. These Lax functions span the proper subspace with respect to the linear Poisson tensor (4.2) for $k=0$ if $N \geqslant 1$ and for $k=1,2$ if $N \geqslant 2r-2k+1 \geqslant -m_0$. If not the case, the Dirac reduction is required. The reduced linear tensors for $k=r=0,1,2$ and $N=-1$ (N is the highest order of Laurent series of$L$ at ∞) are given by

$$\pi_0^\infty dH = \{(dH)_{\geqslant 0}^\infty, L\}_r - (\{dH, L)_r\}_{\geqslant r}^\infty + \{\gamma_1 p + \gamma_0, L\}_r,$$

$$\gamma_1 = \partial_x^{-1}\mathrm{res}_\infty\{dH, L\}_0, \tag{4.12}$$

$$\gamma_0 = \partial_x^{-1}\mathrm{res}_\infty\{dH,L\}_1 - \partial_x^{-1}(\gamma_1((L)_{-2}^\infty)_x + 2(\gamma_1)_x(L)_{-2}^\infty),$$

where $(L)_{-2}^\infty$ is the coefficient staying at the term of order -2 in Laurent series at ∞. For $k=r=0$ we have $(L)_{-2}^\infty=0$ and (4.12) simplified. Notice that for $k=r=0$ the reduced Poisson tensor (4.12) is always local, but for the remaining cases it is in general not. In the case of quadratic Poisson tensors, considered Lax functions do not span proper subspaces and the Dirac reduction is needed. The reduced quadratic Poisson tensor for $k=r=0,1,2$ are given by (4.3), and for $k=1,r=0$ and $k=2,r=1$ by (4.4) where $m=m_0$.

Example 4.11: The two-field system: $k=r=0$.

The Lax function has the form

$$L = u(p-v)^{-1} + (1-u)\left(p - \frac{uv}{u-1}\right)^{-1},$$

where constraints from Proposition 4.9 *are properly taken into consideration. The roots of L are* ∞ *and* $\alpha=(2uv-v)/(u-1)$. *Then, for* ∞ *we have*

$$L_{t_2} = \{\Omega_2^\infty, L\}_0 \Leftrightarrow \begin{pmatrix} u \\ v \end{pmatrix}_{t_2} = \begin{pmatrix} 2uv \\ \dfrac{(3u-1)v^2}{u-1} \end{pmatrix}_x = \pi_0^{\mathrm{red}} dH_{-2}^\infty = \pi_1^{\mathrm{red}} dH_{-3}^\infty,$$

where $\Omega_2^\infty=(L^{-2})_{\geqslant 0}^\infty=p^2+2uv^2/(u-1)$. *The hierarchy for* α *is the same as* $(L^q)_{\geqslant 0}^\infty=L-(L^q)_{<0}^\alpha$. *The function L has poles at v and* $\lambda=uv/(u-1)$. *At the point v one finds the following system:*

$$L_{\tau_1} = \{\Omega_1^v, L\}_0 \Leftrightarrow \begin{pmatrix} u \\ v \end{pmatrix}_{\tau_1} = \begin{pmatrix} \dfrac{u(u-1)^3}{v^2} \\ \dfrac{(u-1)^2}{v} \end{pmatrix}_x = \pi_0^{\mathrm{red}} dH_1^v = \pi_1^{\mathrm{red}} dH_0^v,$$

where $\Omega_1^v=-(L)_{<0}^v=-u(p-v)^{-1}$. *The Lax function is invariant with respect to the transformation* $u\mapsto 1-u$, $v\mapsto uv/(u-1)$. *Therefore, the Lax hierarchy related to* λ *can be obtained through this transformation.*

In this case the differential of a given functional calculated by (4.11) *is*

$$dH = \left(\frac{2(u-1)^3}{v^3}\frac{\delta H}{\delta u} + \frac{(u-1)^2}{uv^2}\frac{\delta H}{\delta v}\right)p^3 + \left(\frac{3(u-1)^2(2u-1)}{v^2}\frac{\delta H}{\delta u} + \frac{(u-1)(3u-1)}{uv}\frac{\delta H}{\delta v}\right)p^2.$$

Then, from (4.12) and (4.3) *we find the following Poisson tensors:*

$$\pi_0^{\mathrm{red}} = \begin{pmatrix} 0 & \partial(1-u) \\ (1-u)\partial & -\partial v - v\partial \end{pmatrix}, \quad \pi_1^{\mathrm{red}} = \begin{pmatrix} \partial\dfrac{u}{v^2}(u-1)^3 + \dfrac{u}{v^2}(u-1)^3\partial & \dfrac{(u-1)^2}{v}\partial \\ \partial\dfrac{(u-1)^2}{v} & 0 \end{pmatrix},$$

respectively. The Hamiltonians are

$$H_{-3}^\infty = \int_\Omega \frac{uv}{1-u}\,\mathrm{d}x, \quad H_{-2}^\infty = \int_\Omega \frac{uv^2}{1-u}\,\mathrm{d}x, \quad H_0^v = \int_\Omega v\,\mathrm{d}x, \quad H_1^v = \int_\Omega \frac{u(u-1)^2}{v}\,\mathrm{d}x.$$

Example 4.12: The four-field dispersionless system: $k=r=0$.

For the Lax function of the form

$$L = p + a(p-v)^{-1} + b(p-w)^{-1} \tag{4.13}$$

near ∞ *one finds*

$$L_{t_2}=\{\Omega_2^\infty,L\}_0\Leftrightarrow\begin{pmatrix}a\\b\\v\\w\end{pmatrix}_{t_2}=\begin{pmatrix}2av\\2bw\\2a+2b+v^2\\2a+2b+w^2\end{pmatrix}_x=\pi_0 dH_2^\infty=\pi_1^{\mathrm{red}}dH_1^\infty,$$

where $\Omega_2^\infty=(L^2)_{\geqslant 0}^\infty=p^2+2a+2b$. *Near the* v *we have*

$$L_{\tau_1}=\{\Omega_1^v,L\}_0\Leftrightarrow\begin{pmatrix}a\\b\\v\\w\end{pmatrix}_{\tau_1}=\begin{pmatrix}a-\dfrac{ab}{(v-w)^2}\\[2mm]\dfrac{ab}{(v-w)^2}\\[2mm]v+\dfrac{b}{v-w}\\[2mm]\dfrac{a}{v-w}\end{pmatrix}_x=\pi_0 dH_1^v=\pi_1^{\mathrm{red}}dH_0^v,$$

where $\Omega_1^v=-(L)_{<0}^v=-a(p-v)^{-1}$. *There are three, very complicated, roots of L. Thus, we are not going to calculate the respective equations.*

The differential of a functional H is

$$dH=\left(\frac{2}{v-w}\frac{\delta H}{\delta b}+\frac{1}{b}\frac{\delta H}{\delta w}\right)\frac{(p-v)^2(p-w)}{(v-w)^2}+\left(\frac{2}{w-v}\frac{\delta H}{\delta a}+\frac{1}{a}\frac{\delta H}{\delta v}\right)\frac{(p-v)(p-w)^2}{(w-v)^2}$$
$$+\frac{1}{(v-w)^2}\frac{\delta H}{\delta b}(p-v)^2+\frac{1}{(w-v)^2}\frac{\delta H}{\delta a}(p-w)^2.$$

Then, from (4.2) and (4.3) *one finds the linear*

$$\pi_0=\begin{pmatrix}0&0&\partial&0\\0&0&0&\partial\\\partial&0&0&0\\0&\partial&0&0\end{pmatrix}$$

and quadratic Poisson tensors

$$\pi_1^{\mathrm{red}}=\begin{pmatrix}\partial a+a\,\partial-\partial\dfrac{ab}{(v-w)^2}-\dfrac{ab}{(v-w)^2}\partial & \partial\dfrac{ab}{(v-w)^2}+\dfrac{ab}{(v-w)^2}\partial & \left(v+\dfrac{b}{v-w}\right)\partial & \dfrac{a}{v-w}\partial\\[2mm]\partial\dfrac{ab}{(v-w)^2}+\dfrac{ab}{(v-w)^2}\partial & \partial b+b\,\partial-\partial\dfrac{ab}{(v-w)^2}-\dfrac{ab}{(v-w)^2}\partial & -\dfrac{b}{v-w}\partial & \left(w-\dfrac{a}{v-w}\right)\partial\\[2mm]\partial\left(v+\dfrac{b}{v-w}\right) & -\partial\dfrac{b}{v-w} & 2\partial & \partial\\[2mm]\partial\dfrac{a}{v-w} & \partial\left(w-\dfrac{a}{v-w}\right) & \partial & 2\partial\end{pmatrix},$$

respectively. The Hamiltonians are

$$H_1^\infty=\int_\Omega(av+bw)\,\mathrm{d}x,\quad H_2^\infty=\int_\Omega((a+b)^2+av^2+bw^2)\,\mathrm{d}x,$$

$$H_0^v=\int_\Omega a\,\mathrm{d}x,\quad H_1^v=\int_\Omega\left(av+\frac{ab}{v-w}\right)\mathrm{d}x.$$

Example 4.13: Four-field system: $k=1$, $r\in\mathbb{Z}$.

Let us consider a Lax function of the form

$$L = p + u + vp^{-1} + w(p-s)^{-1}. \tag{4.14}$$

It has poles at ∞, 0, *and* w. *Related equations to* ∞ *for* $\Omega^{\infty}_{2-r}=(L^{2-r})^{\infty}_{\geqslant 1-r}=p^{2-r}+(2-r)up^{1-r}$ *are*

$$L_{t_{2-r}} = \{\Omega^{\infty}_{2-r}, L\}_r \Leftrightarrow \begin{pmatrix} u \\ v \\ w \\ s \end{pmatrix}_{t_{2-r}} = (2-r)\begin{pmatrix} (1-r)uu_x + v_x + w_x \\ u_x v + (1-r)uv_x \\ u_x w + (1-r)uw_x + (ws)_x \\ u_x s + (1-r)us_x + ss_x \end{pmatrix} = \pi_0 dH^{\infty}_{2-r} = \pi_1^{\mathrm{red}} dH^{\infty}_{1-r}.$$

The first equations from Lax hierarchies related to 0 *for* $r\neq 0$ *are*

$$L_{\tau_r} = \{\Omega^0_r, L\}_r \Leftrightarrow \begin{pmatrix} u \\ v \\ w \\ s \end{pmatrix}_{\tau_r} = rv^r \begin{pmatrix} \ln v \\ u - \dfrac{w}{s} \\ \dfrac{w}{s} \\ \ln \dfrac{s}{v} \end{pmatrix}_x = \pi_0 dH^0_r = \pi_1^{\mathrm{red}} dH^0_{r-1},$$

where $\Omega^0_r=-(L^r)^0_{<1-r}=-v^r p^{-r}$. *But for* $r=0$ *we have*

$$L_{\tau_1'} = \{\Omega^0_1, L\}_0 \Leftrightarrow \begin{pmatrix} u \\ v \\ w \\ s \end{pmatrix}_{\tau_1'} = \begin{pmatrix} u - \dfrac{w}{s} \\ v - \dfrac{vw}{s^2} \\ \dfrac{vw}{s^2} \\ \dfrac{w-v}{s} - u \end{pmatrix}_x = \pi_0 dH^0_1 = \pi_1^{\mathrm{red}} dH^0_0,$$

where $\Omega^0_1=-(L)^0_{<1}=w/s-u-vp^{-1}$. *For* $r=1$ *and* $\Omega^s_1=-(L)^s_{<0}=-w(p-s)^{-1}$ *one finds*

$$L_{\xi_1} = \{\Omega^s_1, L\}_1 \Leftrightarrow \begin{pmatrix} u \\ v \\ w \\ s \end{pmatrix}_{\xi_1} = \begin{pmatrix} w_x \\ v\left(\dfrac{w}{s}\right)_x \\ u_x w + (ws)_x - v\left(\dfrac{w}{s}\right)_x \\ u_x s + ss_x + s\left(\dfrac{v}{s}\right)_x \end{pmatrix} = \pi_0 dH^s_1 = \pi_1^{\mathrm{red}} dH^s_0.$$

Once again we are not going to consider Lax hierarchies related to roots of L.

The differential of a functional H *is*

$$dH = \left(\frac{\delta H}{\delta s} + \frac{1}{s^2}\left(\frac{\delta H}{\delta v} - \frac{\delta H}{\delta w}\right)\right)p^{r+2} - \left(\frac{2}{s}\left(\frac{\delta H}{\delta v} - \frac{\delta H}{\delta w}\right) + \frac{1}{w}\frac{\delta H}{\delta s}\right)p^{r+1} + \frac{\delta H}{\delta v}p^r + \frac{\delta H}{\delta u}p^{r-1}.$$

The Lax function (4.14) *span the proper subspace with respect to linear Poisson tensor* (4.2) *only for* $r=0,1$. *The reduced quadratic tensors are for* $r=0,1$ *given by* (4.4) and (4.3), *respectively*. *Thus, for* $r=0$:

$$\pi_0 = \begin{pmatrix} 0 & \partial & 0 & 0 \\ \partial & 0 & 0 & -\partial \\ 0 & 0 & 0 & \partial \\ 0 & -\partial & \partial & 0 \end{pmatrix} \tag{4.15}$$

and

$$\pi_1^{red} = \begin{pmatrix} 2\partial & \partial\left(u - \frac{w}{s}\right) & \partial\frac{w}{s} & -\partial \\ \left(u - \frac{w}{s}\right)\partial & \partial v\left(1 - \frac{w}{s^2}\right) - v\left(1 - \frac{w}{s^2}\right)\partial & \partial\frac{vw}{s^2} + \frac{vw}{s^2}\partial & \left(\frac{w-v}{s} - u\right)\partial \\ \frac{w}{s}\partial & \partial\frac{vw}{s^2} + \frac{vw}{s^2}\partial & \partial w\left(1 - \frac{v}{s^2}\right) - w\left(1 - \frac{v}{s^2}\right)\partial & \left(u + s + \frac{v-w}{s}\right)\partial \\ -\partial & \partial\left(\frac{w-v}{s} - u\right) & \partial\left(u + s + \frac{v-w}{s}\right) & 2\partial \end{pmatrix}. \tag{4.16}$$

The related Hamiltonians are

$$H_1^\infty = \int_\Omega \left(uv + uw + ws\right)\,\mathrm{d}x, \quad H_2^\infty = \int_\Omega \left(u^2v + v^2 + ws^2 + 2uws + u^2w + 2vw + w^2\right)\,\mathrm{d}x,$$

$$H_0^0 = \int_\Omega v\mathrm{d}x, \quad H_1^0 = \int_\Omega v\left(u - \frac{w}{s}\right)\,\mathrm{d}x.$$

For $r=1$ *we have*

$$\pi_0 = \begin{pmatrix} 0 & \partial v & \partial w & \partial s \\ v\partial & 0 & 0 & 0 \\ w\partial & 0 & s\,\partial w + w\,\partial s & s\,\partial s \\ s\partial & 0 & s\,\partial s & 0 \end{pmatrix}$$

and

$$\pi_1^{\mathrm{red}} = \begin{pmatrix} \partial(v+w) + (v+w)\partial & u\,\partial v & 2\,\partial ws + ws\,\partial + u\,\partial w & (u+s)\,\partial s \\ v\,\partial u & 2v\,\partial v & 2v\,\partial w & v\,\partial s \\ \partial ws + 2ws\,\partial + w\,\partial u & 2w\,\partial v & \pi_{ww} & (s^2 + us + v + 2w)\,\partial s \\ s\,\partial(u+s) & s\,\partial v & s\,\partial(s^2 + us + v + 2w) & 2s\,\partial s \end{pmatrix},$$

where $\pi_{ww} = \partial uws + uws\,\partial + w\,\partial(2s^2+w) + (2s^2+w)\,\partial w$. *The related Hamiltonians are*

$$H_0^\infty = \int_\Omega u\mathrm{d}x, \quad H_1^\infty = \int_\Omega \left(\frac{1}{2}u^2 + v + w\right)\mathrm{d}x,$$

$$H_0^0 = \int_\Omega \left(u - \frac{w}{s}\right)\mathrm{d}x, \quad H_1^0 = \int_\Omega \left(\frac{1}{2}u^2 + v - \frac{uw}{s} - \frac{vw}{s^2} + \frac{w^2}{2s^2}\right)\mathrm{d}x,$$

$$H_0^s = \int_\Omega \frac{w}{s}\mathrm{d}x, \quad H_1^s = \int_\Omega \left(w + \frac{uw}{s} + \frac{vw}{s^2} - \frac{w^2}{2s^2}\right)\mathrm{d}x.$$

Example 4.14: Four-field system: $k=r=2$.
Lax function (4.14) *transformed by* $p\mapsto p^{-1}$ *has the form*

$$L=vp+u-\frac{w}{s}+p^{-1}-\frac{w}{s^2}(p-s^{-1})^{-1}.$$

For $\Omega_1^{s^{-1}}=-(L)_{<0}^{s^{-1}}=-(w/s^2)(p-s^{-1})^{-1}$ *one finds the system*

$$L_{\xi_1'}=\{\Omega_1^{s^{-1}},L\}_1\Leftrightarrow\begin{pmatrix}u\\v\\w\\s\end{pmatrix}_{\xi_1'}=\begin{pmatrix}-\frac{w}{s}\\-\frac{vw}{s^2}\\w\left(\frac{v}{s^2}-1\right)\\-u-s+\frac{v-w}{s}\end{pmatrix}_x=\pi_0 dH_1^{s^{-1}}=\pi_1^{\mathrm{red}}dH_0^{s^{-1}}$$

commuting, *by Proposition* (4.10), *with equations from Example* 4.13 *for* $r=0$. *The linear and quadratic Poisson tensors are given by* (4.15) and (4.16), *respectively*. *Hamiltonian functionals are given by*

$$H_0^{s^{-1}}=-\int_\Omega w\,\mathrm{d}x,\quad H_1^{s^{-1}}=\int_\Omega w\left(u+\frac{v-1}{s}\right)\mathrm{d}x.$$

V. COMMENTS

The case $r=k=0$ of meromorphic Lax hierarchies considered in this article are finite-field reductions to zero-genus Whitham hierarchy.[2]. Originally in Ref. 2 each Lax hierarchy defined at pole v of Lax function, being dynamical field, is extended over additional symmetry related to the generating function $\Omega_0^v=\ln(p-v)$. For example, for Lax function (4.13) the additional symmetry at v is

$$L_s=\{\Omega_0^v,L\}_0\Leftrightarrow\begin{pmatrix}a\\b\\v\\w\end{pmatrix}_s=\begin{pmatrix}v+\frac{b}{v-w}\\-\frac{b}{v-w}\\\ln a\\\ln(v-w)\end{pmatrix}_x.$$

The calculus including ln-terms is discussed in Ref. 4. In Ref. 22 it is shown how the Toda hierarchy from Example 4.3 can be extended over a whole family of symmetries generated by functions containing beside powers logarithms of Lax function $\ln L$. However, $\ln L$ at poles and roots of L has singularities of logarithmic type. So, such additional symmetries fall out from the scheme of meromorphic functions considered in this article. In Ref. 22 they manage with this problem representing $\ln L$ as a sum of two infinite series convergent near ∞ and 0, respectively. Following this idea, one is able to directly generalize this result from Ref. 22 only onto Lax functions from Secs. IV A and IV B. However, the general theory of such symmetries seems to be problematic. This problem is under investigation.

All the Poisson tensors constructed in the following article are nondegenerate. References 5 and 6 deal with rational Lax functions from the algebra with fixed Poisson bracket for $r=1$. However, only the Lax hierarchies generated by powers constructed near ∞ have been considered there. For the class of rational Lax functions used in these papers the bi-Hamiltonian structures are

degenerate, i.e., the determinants of the related metrics vanish. The reason is that the constraint of the form $L|_{p=0}=0$ is not taken into consideration. So, one dynamical field always can be represented as a function of all others. This fact entails the degeneracy of Poisson tensors.

There is a different approach to meromorphic Lax functions. From the complex analysis it is well known that meromorphic function can be uniquely presented in the factorized form. Because of such a factorization there is no problem in finding poles and roots of L near which one constructs powers and related Lax hierarchies. Another advantage is that the dispersionless systems obtained have very symmetrical form. However, the disadvantage is that Poisson tensors are significantly more complicated. Such factorized form of Lax functions as well allows for finding new reductions which are not obvious when we have Lax function in the standard form, see Refs. 5 and 6.

In this paper we have considered dispersionless systems with a finite number of dynamical fields. However, Lax function being infinite formal Laurent series leads to the construction of dispersionless infinite-field Benney moment like equations. Such systems for Laurent series at ∞ have been considered earlier in Ref. 19. The original Benney moment equation can be obtained for $k=r=0$. If we consider formal Laurent series at a pole being a dynamical field $v(x)$ we will construct new classes of infinite-field dispersionless systems. They, together with bi-Hamiltonian structures, will be studied in a forthcoming article. Furthermore, all finite-field dispersionless systems, with meromorphic Lax functions, considered in this paper may be considered as reductions of these infinite-field systems.

All Lax functions used in the article belong to the algebras of meromorphic functions. However, there are known the so-called waterbag hydrodynamic type systems with Lax functions, containing logarithmic terms, that are not meromorphic functions.[23,24] Similar systems are also considered in Ref. 25, but by means of the Riemann surfaces rather than Lax functions.

Another issue is the extension of the theory of meromorphic Lax representations presented for dispersionless systems in order to construct integrable dispersive soliton systems for rational Lax operators. The first approach toward this was made in Ref. 21. However, the authors constructed soliton systems related only to the case $k=r=0$ from our article. A more general theory of dispersive deformations of formal Lax functions being polynomials in p and p^{-1} is presented in Ref. 17. This approach is based on the Weyl-Moyal-like quantization procedure. The idea relies on the deformation of the usual multiplication in the algebra $\mathcal{A}$ to the new associative but noncommutative $\star$-product. However, this theory works only for $r=0,1,2$. Deformations of Poisson algebras for $r=0,2$ are equivalent and lead to the construction of field soliton systems, but for $r=1$ they lead to the construction of lattice soliton systems. So, in a forthcoming article we are going to study the field and lattice soliton systems for rational Lax operators.

Map of discrete system into continuous

Vasily E. Tarasov[a)]
Skobeltsyn Institute of Nuclear Physics, Moscow State University, Moscow 119992, Russia

(Received 29 April 2006; accepted 18 July 2006; published online 7 September 2006)

Continuous limits of discrete systems with long-range interactions are considered. The map of discrete models into continuous medium models is defined. A wide class of long-range interactions that give the fractional equations in the continuous limit is discussed. The one-dimensional systems of coupled oscillators for this type of long-range interactions are considered. The discrete equations of motion are mapped into the continuum equation with the Riesz fractional derivative. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2337852]

I. INTRODUCTION

Equations which involve derivatives or integrals of noninteger order[1–5] have found many applications in recent studies in mechanics and physics.[6–11] Usually the fractional equations for dynamics or kinetics appear as some phenomenological models. Recently, the method to obtain fractional analogues of equations of motion was considered for sets of coupled particles with a long-range interaction.[12–14] Examples of systems with interacting oscillators, spins, or waves are used for numerous applications in physics, chemistry, biology.[15–26] Transfer from the equations of motion for discrete systems to the continuous media equation with fractional derivatives is an approximate procedure. Different applications of the procedure have already been used to derive fractional sine-Gordon and fractional wave Hilbert equation,[12,14] to study synchronization of coupled oscillators,[13] and for fractional Ginzburg-Landau equation.[13]

Long-range interaction has been the subject of great interest for a long time. Thermodynamics of the model of classical spins with long-range interactions has been studied in Refs. 15–17 and 19. An infinite one-dimensional Ising model with long-range interactions was considered by Dyson.[15] The d-dimensional classical Heisenberg model with long-range interaction is described in Refs. 16 and 19, and their quantum generalization can be found in Ref. 17. The long-range interactions have been widely studied in discrete systems on lattices as well as in their continuous analogues. Solitons in a one-dimensional lattice with the long-range Lennard-Jones-type interaction were considered in Ref 27. Kinks in the Frenkel-Kontorova model with long-range interparticle interactions were studied in Ref. 28. The properties of time periodic spatially localized solutions (breathers) on discrete chains in the presence of algebraically decaying interactions were considered in Refs. 24 and 25. Energy and decay properties of discrete breathers in systems with long-range interactions have also been studied in the framework of the Klein-Gordon,[22] and discrete nonlinear Schrödinger equations.[29] A remarkable property of the dynamics described by the equation with fractional space derivatives is that the solutions have power-like tails. Similar features were observed in the lattice models with power-like long-range interactions.[23–25,30–32,14] As it was shown in Refs. 13 and 14, analysis of the equations with fractional derivatives can provide results for the space asymptotics of their solutions.

The goal of this paper is to study a connection between the dynamics of system of particles with long-range interactions and the fractional continuous medium equations by using the transform operation. Here, we consider the one-dimensional lattice of coupled nonlinear oscillators. We make the transform to the continuous limit and derive the fractional equation which describes the

[a)]Electronic mail: tarasov@theory.sinp.msu.ru

dynamics of the oscillatory medium. We show how the continuous limit for the systems of oscillators with long-range interaction can be described by the corresponding fractional equation.

In Sec. II, the equations of motion for the system of oscillators with long-range interaction are considered. In Sec. III, the transform operation that maps the discrete equations into continuous medium equation is defined. In Sec. IV, the Fourier series transform of the equations of a system with long-range interaction is realized. In Sec. V, we consider a wide class of long-range interactions that can give the fractional equations in the continuous limit. In Sec. VI, the simple example of nearest-neighbor interaction is considered to demonstrate the application of the transform operation to the well-known case. In Sec. VII, the power-law long-range interactions with positive integer powers are considered. In Sec. VIII, the power-law long-range interactions with noninteger powers and the correspondent continuous medium equations are discussed. In Sec. IX, the nonlinear long-range interactions for the discrete systems are used to derive the Burgers, Korteweg-de Vries, and Boussinesq equations and their fractional generalizations in the continuous limit. In Sec. X, the fractional equations are obtained from the dispersion law for three-dimensional discrete system. The conclusion is given in Sec. XI.

II. EQUATIONS OF MOTION FOR INTERACTING OSCILLATORS

Consider a one-dimensional system of interacting oscillators that are described by the equations of motion,

$$\frac{\partial^2 u_n}{\partial t^2} = g\hat{\mathcal{I}}_n(u) + F(u_n), \tag{1}$$

where u_n are displacements from the equilibrium. The terms $F(u_n)$ characterize an interaction of the oscillators with the external on-site force. The term $\hat{\mathcal{I}}_n(u)$ is defined by

$$\hat{\mathcal{I}}_n(u) \equiv \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)E(u_n,u_m), \tag{2}$$

and it takes into account the interaction of the oscillators in the system.

Examples:

1) If $J(n,m)=\delta_{n+1,m}-\delta_{n,m}$, and $E(u_n,u_m)=u_m$, then $\hat{\mathcal{I}}_n(u)=u_{n+1}-u_n=\Delta u_n$.

2) For $J(n,m)=\delta_{n+1,m}-2\delta_{n,m}+\delta_{n-1,m}$, and $E(u_n,u_m)=u_m$, we get

$$\hat{\mathcal{I}}_n(u) = u_{n+1} - 2u_n + u_{n-1} = \Delta^2 u_n.$$

3) We can consider the long-range interaction that is given by $J(n)=|n|^{-(1+\alpha)}$, where α is a positive real number. In this case, we have nonlocal coupling given by the power-law function. Constant α is a physical relevant parameter. Some integer values of α correspond to the well-known physical situations: Coulomb potential corresponds to $\alpha=0$, dipole-dipole interaction corresponds to $\alpha=2$, and the limit $\alpha\to\infty$ is for the case of nearest-neighbor interaction.

For the term (2) with $E(u_n,u_m)=u_m$, the translation invariance condition is

$$\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m) = 0 \tag{3}$$

for all n. If (3) cannot be satisfied, we must define $E(u_n,u_m)=u_n-u_m$, and the interaction term (2) is

$$\hat{\mathcal{I}}_n(u) \equiv \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)[u_n - u_m]. \tag{4}$$

This interaction term is translation invariant. Note that the noninvariant terms lead to the divergences in the continuous limit (see the Appendix).

In this paper, we consider the wide class of interactions (4) that create a possibility to present the continuous medium equations with fractional derivatives. We also discuss the term (2) with $E(u_n,u_m)=f(u_n)-f(u_m)$ as nonlinear long-range interaction. As the examples, we consider $f(u)=u^2$ and $f(u)=u-gu^2$ that gives the Burgers, Korteweg-de Vries, and Boussinesq equations and their fractional generalizations in the continuous limit.

III. TRANSFORM OPERATION

In this section, we define the operation that transforms the system of equations for $u_n(t)$ into continuous medium equation for $u(x,t)$.

To derive a continuous medium equation, we suppose that $u_n(t)$ are Fourier coefficients of some function $\hat{u}(k,t)$. We define the field $\hat{u}(k,t)$ on $[-K/2,K/2]$ as

$$\hat{u}(k,t) = \sum_{n=-\infty}^{+\infty} u_n(t)e^{-ikx_n} = \mathcal{F}_\Delta\{u_n(t)\}, \tag{5}$$

where $x_n=n\Delta x$, $\Delta x=2\pi/K$ is distance between oscillators, and

$$u_n(t) = \frac{1}{K}\int_{-K/2}^{+K/2} \mathrm{d}k\hat{u}(k,t)e^{ikx_n} = \mathcal{F}_\Delta^{-1}\{\hat{u}(k,t)\}. \tag{6}$$

These equations are the basis for the Fourier transform, which is obtained by transforming $u_n(t)$ from discrete variable to a continuous one in the limit $\Delta x\to 0$ $(K\to\infty)$. The Fourier transform can be derived from (5), (6) in the limit as $\Delta x\to 0$. Replace the discrete $u_n(t)$ with continuous $u(x,t)$ while letting $x_n=n\Delta x=2\pi n/K\to x$. Then change the sum to an integral, and Eqs. (5) and (6) become

$$\tilde{u}(k,t) = \int_{-\infty}^{+\infty} \mathrm{d}x e^{-ikx}u(x,t) = \mathcal{F}\{u(x,t)\}, \tag{7}$$

$$u(x,t) = \frac{1}{2\pi}\int_{-\infty}^{+\infty} \mathrm{d}k e^{ikx}\tilde{u}(k,t) = \mathcal{F}^{-1}\{\tilde{u}(k,t)\}, \tag{8}$$

where

$$\tilde{u}(k,t) = \mathcal{L}\hat{u}(k,t), \tag{9}$$

and $\mathcal{L}$ denotes the passage to the limit $\Delta x\to 0$ $(K\to\infty)$. Note that $\tilde{u}(k,t)$ is a Fourier transform of the field $u(x,t)$, and $\hat{u}(k,t)$ is a Fourier series transform of $u_n(t)$. The function $\tilde{u}(k,t)$ can be derived from $\hat{u}(k,t)$ in the limit $\Delta x\to 0$.

The procedure of the replacement of a discrete model by the continuous one is defined by the transform operation.

Definition 1: Transform operation $\hat{T}$ is a combination $\hat{T}=\mathcal{F}^{-1}\mathcal{L}\mathcal{F}_\Delta$ of the operations:

1) The Fourier series transform:

$$\mathcal{F}_\Delta: \quad u_n(t) \to \mathcal{F}_\Delta\{u_n(t)\} = \hat{u}(k,t). \tag{10}$$

2) The passage to the limit $\Delta x\to 0$:

$$\mathcal{L}: \quad \hat{u}(k,t) \to \mathcal{L}\{\hat{u}(k,t)\} = \tilde{u}(k,t). \tag{11}$$

3) The inverse Fourier transform:

$$\mathcal{F}^{-1}: \quad \tilde{u}(k,t) \to \mathcal{F}^{-1}\{\tilde{u}(k,t)\} = u(x,t). \tag{12}$$

The operation $\hat{T}=\mathcal{F}^{-1}\mathcal{L}\mathcal{F}_{\Delta}$ is called a transform operation, since it performs a transform of a discrete model of coupled oscillators into the continuous medium model.

Proposition 1: The transform operation $\hat{T}$ maps the function $F(u_n)$ into the function $F(u(x,t))$, i.e.,

$$\hat{T}F(u_n(t)) = F(u(x,t)), \tag{13}$$

where $u(x,t)=\hat{T}u_n(t)$, if the function F satisfies $\mathcal{L}F(u_n)=F(\mathcal{L}u_n)$.

Proof: The Fourier series transform leads to

$$\mathcal{F}_{\Delta}: \quad F(u_n) \to \mathcal{F}_{\Delta}F(u_n). \tag{14}$$

Note that $\mathcal{F}_{\Delta}F(u_n) \neq F(\mathcal{F}_{\Delta}u_n)=F(\hat{u}(k,t))$. The passage to the limit $\Delta x \to 0$ gives

$$\mathcal{L}: \quad \mathcal{F}_{\Delta}F(u_n) \to \mathcal{L}\mathcal{F}_{\Delta}F(u_n). \tag{15}$$

Then

$$\mathcal{L}\mathcal{F}_{\Delta}\{F(u_n)\} = \mathcal{F}\{\mathcal{L}F(u_n)\} = \mathcal{F}\{F(\mathcal{L}u_n)\} = \mathcal{F}\{F(u(x,t))\}, \tag{16}$$

where we use $\mathcal{L}\mathcal{F}_{\Delta}=\mathcal{F}\mathcal{L}$. The inverse Fourier transform get

$$\mathcal{F}^{-1}: \quad \mathcal{F}\{F(u(x,t))\} \to \mathcal{F}^{-1}\{\mathcal{F}\{F(u(x,t))\}\} = F(u(x,t)). \tag{17}$$

As the result, we prove (13).

IV. EQUATIONS FOR MOMENTUM SPACE

Let us consider a system of infinite numbers of oscillators with interparticle interaction that is described by (4). We suppose that $J(n,m)$ satisfies the condition

$$J(n,m) = J(n-m), \quad \sum_{n=1}^{\infty} |J(n)|^2 < \infty, \tag{18}$$

where $J(-n)=J(n)$.

Proposition 2: The Fourier series transform $\mathcal{F}_{\Delta}$ maps the equations of motion

$$\frac{\partial^2 u_n(t)}{\partial t^2} = g \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)[u_n - u_m] + F(u_n), \tag{19}$$

where u_n is the position of the nth oscillator, and F is an external on-site force, into

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} = g[\hat{J}_{\alpha}(0) - \hat{J}_{\alpha}(k\Delta x)]\hat{u}(k,t) + \mathcal{F}_{\Delta}\{F(u_n)\}, \tag{20}$$

where

$$\hat{u}(k,t) = \mathcal{F}_{\Delta}\{u_n(t)\}, \quad \hat{J}_{\alpha}(k\Delta x) = \mathcal{F}_{\Delta}\{J(n)\},$$

and $\mathcal{F}_{\Delta}\{F(u_n)\}$ is an operator notation for the Fourier series transform of $F(u_n)$.

Proof: To derive the equation for the field $\hat{u}(k,t)$, we multiply Eq. (19) by $\exp(-ikn\Delta x)$, and summing over n from $-\infty$ to $+\infty$. Then

$$\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}\frac{\partial^2}{\partial t^2}u_n(t) = g\sum_{n=-\infty}^{+\infty}\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x}J(n,m)[u_n - u_m] + \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}F(u_n). \tag{21}$$

From

$$\hat{u}(k,t) = \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}u_n(t), \tag{22}$$

the left-hand side of (21) gives

$$\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}\frac{\partial^2 u_n(t)}{\partial t^2} = \frac{\partial^2}{\partial t^2}\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}u_n(t) = \frac{\partial^2\hat{u}(k,t)}{\partial t^2}. \tag{23}$$

The second term of the right-hand side of (21) is

$$\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}F(u_n) = \mathcal{F}_\Delta\{F(u_n)\}. \tag{24}$$

The first term of the right-hand side (r.h.s) of (21) is defined by the function $J(n,m)$. Let us introduce the notation

$$\hat{J}_\alpha(k\Delta x) = \sum_{\substack{n=-\infty \\ n\neq 0}}^{+\infty} e^{-ikn\Delta x}J(n). \tag{25}$$

Using $J(-n)=J(n)$, the function (25) can be presented by

$$\hat{J}_\alpha(k\Delta x) = \sum_{n=1}^{+\infty} J(n)(e^{-ikn\Delta x} + e^{ikn\Delta x}) = 2\sum_{n=1}^{+\infty} J(n)\cos(k\Delta x). \tag{26}$$

From (26) it follows that

$$\hat{J}_\alpha(k\Delta x + 2\pi m) = \hat{J}_\alpha(k\Delta x), \tag{27}$$

where m is an integer.

The interaction term in (21) is

$$\sum_{n=-\infty}^{+\infty}\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x}J(n,m)[u_n - u_m] = \sum_{n=-\infty}^{+\infty}\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x}J(n,m)u_n - \sum_{n=-\infty}^{+\infty}\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x}J(n,m)u_m. \tag{28}$$

Using (22) and (25), the first term on the r.h.s. of (28) gives

$$\sum_{n=-\infty}^{+\infty}\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x}J(n,m)u_n = \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}u_n\sum_{\substack{m'=-\infty \\ m'\neq 0}}^{+\infty} J(m') = \hat{u}(k,t)\hat{J}_\alpha(0), \tag{29}$$

where we use (18) and $J(m'+n,n)=J(m')$, and

$$\hat{J}_\alpha(0) = \sum_{\substack{n=-\infty \\ n\neq 0}}^{+\infty} J(n) = 2\sum_{n=1}^{\infty} J(n). \tag{30}$$

For the second term on the r.h.s. of (28):

$$\sum_{n=-\infty}^{+\infty} \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x} J(n,m) u_m = \sum_{m=-\infty}^{+\infty} u_m \sum_{\substack{n=-\infty \\ n\neq m}}^{+\infty} e^{-ikn\Delta x} J(n,m)$$

$$= \sum_{m=-\infty}^{+\infty} u_m e^{-ikm\Delta x} \sum_{\substack{n'=-\infty \\ n'\neq 0}}^{+\infty} e^{-ikn'\Delta x} J(n') = \hat{u}(k,t)\hat{J}_\alpha(k\Delta x), \tag{31}$$

where we use $J(m,n'+m)=J(n')$.

As a result, Eq. (21) has the form

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} = g[\hat{J}_\alpha(0) - \hat{J}_\alpha(k\Delta x)]\hat{u}(k,t) + \mathcal{F}_\Delta\{F(u_n)\}, \tag{32}$$

where $\mathcal{F}_\Delta\{F(u_n)\}$ is an operator notation for the Fourier series transform of $F(u_n)$.

V. ALPHA-INTERACTION

Let us consider the interaction term

$$\hat{\mathcal{I}}_n(u) \equiv \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)[u_n - u_m], \tag{33}$$

where

$$J(n,m) = J(n-m) = J(m-n), \quad \sum_{n=1}^{\infty} |J(n)|^2 < \infty. \tag{34}$$

In Sec. IV, we prove that the Fourier series transform $\mathcal{F}_\Delta$ of (33) gives

$$\mathcal{F}_\Delta\{\hat{\mathcal{I}}_n(u)\} = g[\hat{J}_\alpha(0) - \hat{J}_\alpha(k\Delta x)]\hat{u}(k,t), \tag{35}$$

where $\hat{u}(k,t)=\mathcal{F}_\Delta\{u_n(t)\}$, and

$$\hat{J}_\alpha(k) = \sum_{\substack{n=-\infty \\ n\neq 0}}^{+\infty} e^{-ikn} J(n) = 2\sum_{n=1}^{\infty} J(n)\cos(kn). \tag{36}$$

Definition 2: The interaction term (33) in the equation of motion (1) is called α-interaction if the function (36) satisfies the condition

$$\lim_{k\to 0} \frac{[\hat{J}_\alpha(k) - \hat{J}_\alpha(0)]}{|k|^\alpha} = A_\alpha, \tag{37}$$

where $\alpha>0$ *and* $0<|A_\alpha|<\infty$.

If the function $\hat{J}_\alpha(k)$ is given, then $J(n)$ can be defined by

$$J(n) = \frac{1}{\pi}\int_0^{\pi} \hat{J}_\alpha(k)\cos(nk)\mathrm{d}k. \tag{38}$$

The condition (37) means that $\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = O(|k|^\alpha)$, i.e.,

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = A_\alpha|k|^\alpha + R_\alpha(k), \tag{39}$$

for $k \to 0$, where

$$\lim_{k\to 0} R_\alpha(k)/|k|^\alpha = 0. \tag{40}$$

Examples:

1) The first example of the α-interaction is

$$\hat{J}_\alpha(k) = A_\alpha|k|^\alpha.$$

Using (38), we obtain

$$J(n) = A_\alpha\left(\frac{(-1)^n\pi^{\alpha+1}}{\alpha+1} - \frac{(-1)^n\pi^{1/2}}{(\alpha+1)|n|^{\alpha+1/2}}L_1(\alpha+3/2,1/2,\pi n)\right), \tag{41}$$

where $L_1(\mu,\nu,z)$ is the Lommel function.[33]

2) The second example of the α-interaction is

$$J(n) = \frac{(-1)^n}{n^2}. \tag{42}$$

Using (Ref. 34, Sec. 5.4.2.12)

$$\sum_{n=1}^{\infty}\frac{(-1)^n}{n^2}\cos(nk) = \frac{1}{4}\left(k^2 - \frac{\pi^2}{3}\right), \quad |k| \leqslant \pi,$$

we get

$$\hat{J}_\alpha(k) = 2\sum_{n=1}^{+\infty}\frac{(-1)^n}{n^2}\cos(kn) = \frac{1}{2}k^2 - \frac{\pi^2}{6}, \quad |k| \leqslant \pi. \tag{43}$$

Then we have $\alpha=2$, and

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = (1/2)k^2. \tag{44}$$

The inverse Fourier transform of this expression gives the coordinate derivatives of second order

$$\mathcal{F}^{-1}\{\hat{J}_\alpha(k) - \hat{J}_\alpha(0)\} = -\frac{1}{2}\frac{\partial^2}{\partial x^2}.$$

3) For the interaction (42), we have $\alpha=2$ and the inverse Fourier transform of (44) gives the second-order derivative. At the same time, the interaction

$$J(n) = \frac{1}{n^2}$$

gives $\alpha=1$ and then the first-order coordinate derivative. It can be proved by using (Ref. 34, Sec. 5.4.2.12)

$$\hat{J}_\alpha(k) = 2\sum_{n=1}^{+\infty} \frac{\cos(kn)}{n^2} = \frac{1}{6}[3k^2 - 6\pi k + 2\pi^2], \quad (0 \leqslant k \leqslant 2\pi), \tag{45}$$

and $\hat{J}_\alpha(k) - \hat{J}_\alpha(0) \approx -\pi k$ for $k \to 0$. Therefore, the inverse Fourier transform leads to the derivative of first order.

4) For noninteger and odd numbers s,

$$J(n) = |n|^{-(s+1)}, \quad s > 0 \tag{46}$$

is an α-interaction.

For $0 < s < 2 (s \neq 1)$, we get

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = 2\Gamma(-s)\cos(\pi s/2)|k|^s. \tag{47}$$

For $s = 1$,

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = -(\pi/2)k. \tag{48}$$

For noninteger $s > 2$,

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = -\zeta(\alpha - 1)k^2, \tag{49}$$

where $\zeta(z)$ is the Riemann zeta-function, The interaction (46) is considered in Sec. VII.

5) The other example is

$$J(n) = \frac{(-1)^n}{\Gamma(1 + \alpha/2 + n)\Gamma(1 + \alpha/2 - n)}. \tag{50}$$

Using the series (Ref. 34, Sec. 5.4.8.12)

$$\sum_{n=1}^{\infty} \frac{(-1)^n}{\Gamma(\beta + 1 + n)\Gamma(\beta + 1 - n)} \cos(nk) = \frac{2^{2\beta-1}}{\Gamma(2\beta + 1)} \sin^{2\beta}\left(\frac{k}{2}\right) - \frac{1}{2\Gamma^2(\beta + 1)}, \tag{51}$$

where $\beta > -1/2$ and $0 < k < 2\pi$, we get

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = \frac{2^\alpha}{\Gamma(\alpha + 1)} \sin^\alpha\left(\frac{k}{2}\right). \tag{52}$$

In the limit $k \to 0$, we obtain

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) \approx \frac{1}{\Gamma(\alpha + 1)}|k|^\alpha. \tag{53}$$

For noninteger α, the inverse Fourier transform of (53) gives the fractional Riesz derivative[1] of order α.

6) The α-interaction

$$J(n) = \frac{(-1)^n}{a^2 - n^2},$$

gives

$$\hat{J}(k) = \frac{\pi}{a \sin(\pi a)} \cos(ak) - \frac{1}{a^2}. \tag{54}$$

For $k \to 0$, we obtain

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) \approx \frac{a\pi}{2\sin(a\pi)} k^2. \tag{55}$$

The inverse Fourier transform of (55) leads to the coordinate derivative of second order.

7) For $J(n)=1/n!$, we use

$$\sum_{n=1}^{\infty} \frac{\cos(kn)}{n!} = e^{\cos k} \cos(\sin k), \quad |k| < \infty. \tag{56}$$

The passage to the limit $k \to 0$ gives

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) \approx -4ek. \tag{57}$$

Then $\alpha=1$, and we get the derivative of first order.

Proposition 3: The transform operation $\hat{T}$ maps the discrete equations of motion

$$\frac{\partial^2 u_n}{\partial t^2} = g \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)[u_n - u_m] + F(u_n) \tag{58}$$

with noninteger α-interaction into the fractional continuous medium equations:

$$\frac{\partial^2}{\partial t^2} u(x,t) - G_\alpha A_\alpha \frac{\partial^\alpha}{\partial |x|^\alpha} u(x,t) - F(u(x,t)) = 0, \tag{59}$$

where $\partial^\alpha / \partial |x|^\alpha$ is the Riesz fractional derivative, and

$$G_\alpha = g|\Delta x|^\alpha \tag{60}$$

is a finite parameter.

Proof: The Fourier series transform $\mathcal{F}_\Delta$ of (58) gives (20). We will be interested in the limit $\Delta x \to 0$. Then Eq. (20) can be written as

$$\frac{\partial^2}{\partial t^2} \hat{u}(k,t) - G_\alpha \hat{\mathcal{T}}_{\alpha,\Delta}(k) \hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{61}$$

where we use finite parameter (60), and

$$\hat{\mathcal{T}}_{\alpha,\Delta}(k) = -A_\alpha |k|^\alpha - R_\alpha(k\Delta x)|\Delta x|^{-\alpha}. \tag{62}$$

Note that R_α satisfies the condition

$$\lim_{\Delta x \to 0} \frac{R_\alpha(k\Delta x)}{|\Delta x|^\alpha} = 0.$$

The expression for $\hat{\mathcal{T}}_{\alpha,\Delta}(k)$ can be considered as a Fourier transform of the operator (4). Note that $g \to \infty$ for the limit $\Delta x \to 0$, if G_α is a finite parameter.

In the limit $\Delta x \to 0$, Eq. (61) gets

$$\frac{\partial^2}{\partial t^2} \tilde{u}(k,t) - G_\alpha \hat{\mathcal{T}}_\alpha(k) \tilde{u}(k,t) - \mathcal{F}^{-1}\{F(u(x,t))\} = 0, \tag{63}$$

where

$$\tilde{u}(k,t) = \mathcal{L}\hat{u}(k,t), \quad \hat{\mathcal{T}}_\alpha(k) = \mathcal{L}\hat{\mathcal{T}}_{\alpha,\Delta}(k) = -A_\alpha |k|^\alpha.$$

The inverse Fourier transform of (63) gives

$$\frac{\partial^2}{\partial t^2}u(x,t) - G_\alpha \mathcal{T}_\alpha(x)u(x,t) - F(u(x,t)) = 0, \tag{64}$$

where $\mathcal{T}_\alpha(x)$ is an operator

$$\mathcal{T}_\alpha(x) = \mathcal{F}^{-1}\{\hat{\mathcal{T}}_\alpha(k)\} = A_\alpha \frac{\partial^\alpha}{\partial |x|^\alpha}. \tag{65}$$

Here, we have used the connection between the Riesz fractional derivative and its Fourier transform:[1]

$$|k|^\alpha \leftrightarrow -\frac{\partial^\alpha}{\partial |x|^\alpha}. \tag{66}$$

The properties of the Riesz derivative can be found in Refs. 1–4. Note that the Riesz derivative could be represented as

$$\frac{\partial^\alpha}{\partial |x|^\alpha}u(x,t) = -\frac{1}{2\cos(\pi\alpha/2)}(\mathcal{D}^\alpha_+ u(x,t) + \mathcal{D}^\alpha_- u(x,t)), \tag{67}$$

where $\alpha \neq 0,1,3,5,\ldots$, and $\mathcal{D}^\alpha_\pm$ are Riemann-Liouville left and right fractional derivatives defined by[1–4]

$$\begin{aligned} \mathcal{D}^\alpha_+ u(x,t) &= \frac{1}{\Gamma(m-\alpha)}\frac{\partial^m}{\partial x^m}\int_{-\infty}^{x}\frac{u(\xi,t)\mathrm{d}\xi}{(x-\xi)^{\alpha-m+1}}, \\ \mathcal{D}^\alpha_- u(x,t) &= \frac{(-1)^m}{\Gamma(m-\alpha)}\frac{\partial^m}{\partial x^m}\int_{x}^{\infty}\frac{u(\xi,t)\mathrm{d}\xi}{(\xi-x)^{\alpha-m+1}}, \end{aligned} \tag{68}$$

where $m-1<\alpha<m$.

As the result, we obtain continuous medium equations (59) from (64) and (65).

VI. SIMPLE EXAMPLE OF NEAREST-NEIGHBOR INTERACTION

In this section, we demonstrate the application of transform operation to the well-known case:

$$J(n,m) = \delta_{n+1,m} - 2\delta_{n,m} + \delta_{n-1,m}, \tag{69}$$

where $\delta_{n,m}$ is the Kronecker symbol. Then the interaction term (2) has the form

$$\hat{\mathcal{I}}_n(u) = (u_{n+1} - u_n) - (u_n - u_{n-1}), \tag{70}$$

and describes the nearest-neighbor interaction. As the result, equations of motion (19) have the form

$$\frac{\partial^2 u_n}{\partial t^2} = g[u_{n+1} - 2u_n + u_{n-1}] + F(u_n). \tag{71}$$

The well-known result is the following.

Proposition 4: The transform operation $\hat{T}$ maps the equation of motion (71) into the continuous medium equation

$$\frac{\partial^2 u(x,t)}{\partial t^2} = G_2\frac{\partial^2}{\partial x^2}u(x,t) + F(u), \tag{72}$$

where

$$G_2 = g(\Delta x)^2 \tag{73}$$

is a finite parameter.

Proof: To derive the equation for the field $\hat{u}(k,t)$, we multiply Eq. (71) by $\exp(-ikn\Delta x)$, and summing over n from $-\infty$ to $+\infty$. Then

$$\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}\frac{\partial^2}{\partial t^2}u_n(t) = g\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}[u_{n+1} - 2u_n + u_{n-1}] + \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}F(u_n). \tag{74}$$

The first term on the r.h.s. of (74) is

$$\begin{aligned}
\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}J(n,m)u_m &= \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}[u_{n+1} - 2u_n + u_{n-1}] \\
&= \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}u_{n+1} - 2\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}u_n + \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}u_{n-1} \\
&= \sum_{m'=-\infty}^{+\infty} e^{-ik(m-1)\Delta x}u_m - 2\hat{u}(k,t) + \sum_{s=-\infty}^{+\infty} e^{-ik(s+1)\Delta x}u_s \\
&= e^{ik\Delta x}\sum_{m'=-\infty}^{+\infty} e^{-ikm\Delta x}u_m - 2\hat{u}(k,t) + e^{-ik\Delta x}\sum_{s=-\infty}^{+\infty} e^{-iks\Delta x}u_s \\
&= e^{ik\Delta x}\hat{u}(k,t) - 2\hat{u}(k,t) + e^{-ik\Delta x}\hat{u}(k,t) = [e^{ik\Delta x} + e^{-ik\Delta x} - 2]\hat{u}(k,t) \\
&= 2[\cos(k\Delta x) - 1]\hat{u}(k,t) = -4\sin^2(k\Delta x)\hat{u}(k,t).
\end{aligned} \tag{75}$$

As the result, we obtain

$$\frac{\partial^2\hat{u}(k,t)}{\partial t^2} = g\hat{J}_\alpha(k\Delta x)\hat{u}(k,t) + \mathcal{F}_\Delta\{F(u_n(t))\}, \tag{76}$$

where

$$\hat{J}_\alpha(k\Delta x) = -4\sin^2(k\Delta x). \tag{77}$$

For $\Delta x \to 0$, the asymptotics of the sine is

$$\sin(z) = \sum_{m=0}^{\infty}\frac{(-1)^{m+1}}{(2m+1)!}z^{2m+1} \approx z - \frac{1}{6}z^3,$$

and (77) can be presented by

$$\hat{J}_\alpha(k\Delta x) \approx -(k\Delta x)^2 + \tfrac{1}{12}(k\Delta x)^4. \tag{78}$$

Using the finite parameter (73), the transition to the limit $\Delta x \to 0$ in Eq. (76) gives

$$\frac{\partial^2\tilde{u}(k,t)}{\partial t^2} = -G_2k^2\tilde{u}(k,t) + \mathcal{F}^{-1}\{F(u)\}, \tag{79}$$

where we use $0 < |G_2| < \infty$. As the result, the inverse Fourier transform of (79) leads to the continuous medium equation (72).

VII. INTEGER POWER-LAW INTERACTION

Let us consider the power-law interaction (4) with

$$J(n) = |n|^{-(s+1)} \tag{80}$$

with positive integer number s.

Proposition 5: The power-law interaction (80) for the odd number s is α-interaction with α =1 for s=1, and α=2 for s=3,5,7,…. For even numbers s, (80) is not α-interaction. For odd number s, the transform operation $\hat{T}$ maps the equations of motion with the interaction (80) into the continuous medium equation with derivatives of first order for s=1, and the second order for other odd s.

Proof: From (20), we get the equation for $\hat{u}(k,t)$ in the form

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} + g[\hat{J}_\alpha(k\Delta x) - \hat{J}_\alpha(0)]\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{81}$$

where

$$\hat{J}_\alpha(k\Delta x) = \sum_{\substack{n=-\infty \\ n\neq 0}}^{+\infty} e^{-ikn\Delta x}|n|^{-(1+s)}. \tag{82}$$

The function (82) can be presented by

$$\hat{J}_\alpha(k\Delta x) = \sum_{n=1}^{+\infty} \frac{1}{n^{1+s}}(e^{-ikn\Delta x} + e^{ikn\Delta x}) = 2\sum_{n=1}^{+\infty} \frac{1}{n^{1+s}} \cos(kn\Delta x). \tag{83}$$

Then we can use (Ref. 46, Sec. 5.4.2.12 and 5.4.2.7) the relations

$$\sum_{n=1}^{\infty} \frac{\cos(nk)}{n^2} = \frac{1}{12}(3k^2 - 6\pi k + 2\pi^2), \quad (0 \leqslant k \leqslant 2\pi), \tag{84}$$

$$\sum_{n=1}^{\infty} \frac{\cos(nk)}{n^{2m}} = \frac{(-1)^{m-1}(2\pi)^{2m}}{2(2m)!} B_{2m}\left(\frac{k}{2\pi}\right), \quad (0 \leqslant k \leqslant 2\pi), \tag{85}$$

where $m=1,2,3,\ldots$, and $B_{2m}(z)$ are the Bernulli polynomials.[35] These polynomials are defined by

$$B_n(k) = \sum_{s=0}^{n} C_n^s B_s k^{n-s}, \tag{86}$$

where B_s are the Bernoulli numbers from

$$\frac{z}{e^z - 1} = \sum_{s=0}^{\infty} B_s \frac{z^s}{s!}, \quad (|z| < 2\pi). \tag{87}$$

For example,

$$B_2(k) = k^2 - k + 1/6, \quad B_4(k) = k^4 - 2k^3 + k^2 - 1/30. \tag{88}$$

Note $B_{2m-1}=0$ for $m=2,3,4,\ldots$.[35]

For $s=1$, we have

$$\hat{J}_\alpha(k\Delta x) - \hat{J}_\alpha(0) = \tfrac{1}{2}(k\Delta x)^2 - \pi k\Delta x \approx -\pi k\Delta x. \tag{89}$$

For $s=2m-1$ $(m=2,3,\ldots)$, we have

$$\hat{J}_\alpha(k) = \frac{(-1)^{m-1}}{(2m)!}(2\pi)^{2m}B_{2m}\left(\frac{k}{2\pi}\right) \quad (0 \leqslant k \leqslant 2\pi). \tag{90}$$

Then

$$\hat{J}_\alpha(k\Delta x) - \hat{J}_\alpha(0) \approx \frac{(-1)^{m-1}(2\pi)^{2m-2}}{4(2m-2)!}B_{2m-2}(k\Delta x)^2. \tag{91}$$

For example, the interaction (80) with $s=3$ gives

$$\hat{J}_\alpha(k) - \hat{J}_\alpha(0) = -\frac{1}{48}[k^4 - 4\pi k^3 + 4\pi^2 k^2] \approx -\frac{\pi^2}{12}k^2. \tag{92}$$

For $s=0$, we have (Ref. 34, Sec. 5.4.2.9) the relation

$$\sum_{n=1}^{\infty}\frac{\cos(nk)}{n} = -\ln[2\sin(k/2)]. \tag{93}$$

Then, the limit $\Delta x \to 0$ gives

$$\hat{J}_\alpha(k\Delta x) \approx -\ln(k\Delta x) \to \infty. \tag{94}$$

For even numbers s,

$$|\hat{J}_\alpha(k\Delta x) - \hat{J}_\alpha(0)|/|k\Delta x|^s \to \infty \tag{95}$$

since the expression has the logarithmic poles.

The transition to the limit $\Delta x \to 0$ in Eq. (81) with $s=1$ gives

$$\frac{\partial^2 \tilde{u}(k,t)}{\partial t^2} - G_1 k\tilde{u}(k,t) - \mathcal{F}^{-1}\{F(u(x,t))\} = 0, \tag{96}$$

where $G_1 = \pi g\Delta x$ is a finite parameter. The inverse Fourier transform of (96) leads to the continuous medium equation with coordinate derivative of first order:

$$\frac{\partial^2}{\partial t^2}u(x,t) - iG_1\frac{\partial}{\partial x}u(x,t) - F(u(x,t)) = 0. \tag{97}$$

This equation can be considered as the nonlinear Schrödinger equation.

The limit $\Delta x \to 0$ in Eq. (81) with $s=2m-1$ $(m=2,3,\ldots)$ gives

$$\frac{\partial^2 \tilde{u}(k,t)}{\partial t^2} + G_2 k^2\tilde{u}(k,t) - \mathcal{F}^{-1}\{F(u(x,t))\} = 0, \tag{98}$$

where

$$G_2 = \frac{(-1)^{m-1}(2\pi)^{2m-2}}{4(2m-2)!}B_{2m-2}g(\Delta x)^2$$

is a finite parameter. The inverse Fourier transform of (98) leads to the partial differential equation of second order:

$$\frac{\partial^2}{\partial t^2}u(x,t) - G_2\frac{\partial^2}{\partial x^2}u(x,t) - F(u(x,t)) = 0. \tag{99}$$

This equation can be considered as a nonlinear wave equation.

VIII. NONINTEGER POWER-LAW INTERACTION

Let us consider the power-law interaction with

$$J(n) = |n|^{-(s+1)}, \tag{100}$$

where s is a positive noninteger number.

Proposition 6: The power-law interaction (100) with noninteger s is α-interaction with $\alpha=s$ for $0<s<2$, and $\alpha=2$ for $s>2$. For $0<s<2$ $(s\neq 1)$, the transform operation $\hat{T}$ maps the discrete equations with the interaction (100) into the continuous medium equation with fractional Riesz derivatives of order α. For $\alpha>2$ $(\alpha\neq 3,4,5,\ldots)$, the continuous medium equation has the coordinate derivatives of second order.

Proof: From (20), we obtain the equation for $\hat{u}(k,t)$ in the form

$$\frac{\partial^2\hat{u}(k,t)}{\partial t^2} + g[\hat{J}_\alpha(k\Delta x) - \hat{J}_\alpha(0)]\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{101}$$

where

$$\hat{J}_\alpha(k\Delta x) = \sum_{\substack{n=-\infty \\ n\neq 0}}^{+\infty} e^{-ikn\Delta x}\frac{1}{|n|^{1+\alpha}}. \tag{102}$$

For fractional positive α, the function (102) can be presented by

$$\hat{J}_\alpha(k\Delta x) = \sum_{n=1}^{+\infty}\frac{1}{n^{1+\alpha}}(e^{-ikn\Delta x} + e^{ikn\Delta x}) = Li_{1+\alpha}(e^{ik\Delta x}) + Li_{1+\alpha}(e^{-ik\Delta x}), \tag{103}$$

where $Li_\beta(z)$ is a polylogarithm function. Using the series representation of the polylogarithm:[36]

$$Li_\beta(e^z) = \Gamma(1-\beta)(-z)^{\beta-1} + \sum_{n=0}^{\infty}\frac{\zeta(\beta-n)}{n!}z^n, \quad |z|<2\pi, \quad \beta\neq 1,2,3,\ldots, \tag{104}$$

we obtain

$$\hat{J}_\alpha(k\Delta x) = A_\alpha|\Delta x|^\alpha|k|^\alpha + 2\sum_{n=0}^{\infty}\frac{\zeta(1+\alpha-2n)}{(2n)!}(\Delta x)^{2n}(-k^2)^n, \quad \alpha\neq 0,1,2,3,\ldots, \tag{105}$$

where $\zeta(z)$ is the Riemann zeta-function, $|k\Delta x|<2\pi$, and

$$A_\alpha = 2\Gamma(-\alpha)\cos\left(\frac{\pi\alpha}{2}\right). \tag{106}$$

From (105), we have

$$J_\alpha(0) = 2\zeta(1+\alpha).$$

Then

$$\hat{J}_\alpha(k\Delta x) - \hat{J}_\alpha(0) = A_\alpha|\Delta x|^\alpha|k|^\alpha + 2\sum_{n=1}^{\infty} \frac{\zeta(1+\alpha-2n)}{(2n)!}(\Delta x)^{2n}(-k^2)^n, \tag{107}$$

where $\alpha \neq 0,1,2,3,\ldots$, and $|k\Delta x| < 2\pi$.

Substitution of (107) into Eq. (101) gives

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} + gA_\alpha|\Delta x|^\alpha|k|^\alpha\hat{u}(k,t) + 2g\sum_{n=1}^{\infty} \frac{\zeta(\alpha+1-2n)}{(2n)!}(\Delta x)^{2n}(-k^2)^n\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0. \tag{108}$$

We will be interested in the limit $\Delta x \to 0$. Then Eq. (108) can be written in a simple form

$$\frac{\partial^2}{\partial t^2}\hat{u}(k,t) + G_\alpha\hat{\mathcal{T}}_{\alpha,\Delta}(k)\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \quad \alpha \neq 0,1,2,\ldots, \tag{109}$$

where we use the finite parameter

$$G_\alpha = g|\Delta x|^{\min\{\alpha;2\}}, \tag{110}$$

and

$$\hat{\mathcal{T}}_{\alpha,\Delta}(k) = \begin{cases} A_\alpha|k|^\alpha - |\Delta x|^{2-\alpha}\zeta(\alpha-1)k^2, & 0 < \alpha < 2 \quad (\alpha \neq 1) \\ |\Delta x|^{\alpha-2}A_\alpha|k|^\alpha - \zeta(\alpha-1)k^2, & \alpha > 2 \quad (\alpha \neq 3,4,\ldots). \end{cases} \tag{111}$$

The expression for $\hat{\mathcal{T}}_{\alpha,\Delta}(k)$ can be considered as a Fourier transform of the interaction operator (2). From (110), we see that $g \to \infty$ for the limit $\Delta x \to 0$, and finite value of G_α.

Note that (111) has a scale k_0:

$$k_0 = |A_\alpha/\zeta(\alpha-1)|^{1/(2-\alpha)}|\Delta x|^{-1} \tag{112}$$

such that the nontrivial expression $\hat{\mathcal{T}}_{\alpha,\Delta}(k) \sim |k|^\alpha$ appears only for $0 < \alpha < 2$, $(\alpha \neq 1)$, $k \ll k_0$.

The transition to the limit $\Delta x \to 0$ in Eq. (109) gives

$$\frac{\partial^2}{\partial t^2}\tilde{u}(k,t) + G_\alpha\hat{\mathcal{T}}_\alpha(k)\tilde{u}(k,t) - \mathcal{F}^{-1}\{F(u(x,t))\} = 0 \quad (\alpha \neq 0,1,2,\ldots), \tag{113}$$

where

$$\hat{\mathcal{T}}_\alpha(k) = \begin{cases} A_\alpha|k|^\alpha, & 0 < \alpha < 2, \quad \alpha \neq 1 \\ -\zeta(\alpha-1)k^2, & 2 < \alpha, \quad \alpha \neq 3,4,\ldots. \end{cases} \tag{114}$$

The inverse Fourier transform to (113) is

$$\frac{\partial^2}{\partial t^2}u(x,t) + G_\alpha\mathcal{T}_\alpha(x)u(x,t) - F(u(x,t)) = 0 \quad \alpha \neq 0,1,2,\ldots, \tag{115}$$

where

$$\mathcal{T}_\alpha(x) = \mathcal{F}^{-1}\{\hat{\mathcal{T}}_\alpha(k)\} = \begin{cases} -A_\alpha\partial^\alpha/\partial|x|^\alpha & (0 < \alpha < 2, \quad \alpha \neq 1) \\ \zeta(\alpha-1)\partial^2/\partial|x|^2 & (\alpha > 2, \quad \alpha \neq 3,4,\ldots). \end{cases}$$

Here, we have used the connection between the Riesz fractional derivative and its Fourier transform:[1]

$$|k|^{\alpha} \leftrightarrow -\frac{\partial^{\alpha}}{\partial|x|^{\alpha}}, \quad k^2 \leftrightarrow -\frac{\partial^2}{\partial|x|^2}. \tag{116}$$

The properties of the Riesz derivative can be found in Refs. 1–4.

As the result, we obtain the continuous medium equations

$$\frac{\partial^2}{\partial t^2}u(x,t) - G_{\alpha}A_{\alpha}\frac{\partial^{\alpha}}{\partial|x|^{\alpha}}u(x,t) = F(u(x,t)), \quad 0 < \alpha < 2 \quad (\alpha \neq 1), \tag{117}$$

and

$$\frac{\partial^2}{\partial t^2}u(x,t) + G_{\alpha}\zeta(\alpha-1)\frac{\partial^2}{\partial|x|^2}u(x,t) = F(u(x,t)), \quad \alpha > 2 \quad (\alpha \neq 3,4,\ldots). \tag{118}$$

Analogously, the continuous limit for the system

$$\frac{\partial u_n}{\partial t} = g\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} |n-m|^{-\alpha-1}[u_n - u_m] + F(u_n) \tag{119}$$

gives the partial differential equations

$$\frac{\partial}{\partial t}u(x,t) - G_{\alpha}A_{\alpha}\frac{\partial^{\alpha}}{\partial|x|^{\alpha}}u(x,t) = F(u(x,t)), \quad 0 < \alpha < 2 \quad (\alpha \neq 1), \tag{120}$$

and

$$\frac{\partial}{\partial t}u(x,t) + G_{\alpha}\zeta(\alpha-1)\frac{\partial^2}{\partial|x|^2}u(x,t) = F(u(x,t)), \quad \alpha > 2 \quad (\alpha \neq 3,4,\ldots). \tag{121}$$

For $F(u)=0$, Eq. (120) is the fractional kinetic equation that describes the fractional superdiffusion.[37–39] If $F(u)$ is a sum of linear and cubic terms, then Eq. (120) has the form of the fractional Ginzburg-Landau equation.[40–44] A remarkable property of the dynamics described by the equation with fractional space derivatives is that the solutions have power-like tails.

IX. NONLINEAR LONG-RANGE INTERACTION

In this section, we consider the discrete equations with nonlinear long-range interaction:

$$\hat{\mathcal{I}}_n(u) = \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_{\alpha}(n,m)[f(u_n) - f(u_m)], \tag{122}$$

where $f(u)$ is a nonlinear function of $u_n(t)$, and $J_{\alpha}(n,m)$ defines the α-interaction. As the example of $J_{\alpha}(n,m)=J_{\alpha}(n-m)$, we can use the functions

$$J_{\alpha}(n) = \frac{(-1)^n}{\Gamma(1+\alpha/2+n)\Gamma(1+\alpha/2-n)}. \tag{123}$$

We consider the interaction with $f(u)=u^2$ and $f(u)=u-gu^2$ that gives the Burgers, Korteweg-de Vries, and Boussinesq equations in the continuous limit for $\alpha=1,2,3,4$. If we use the fractional α in Eq. (123), we can obtain the fractional generalization of these equations.

Proposition 7: The Fourier series transform $\mathcal{F}_{\Delta}$ maps the equations of motion

$$\frac{\partial^2 u_n(t)}{\partial t^2} = g \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_\alpha(n-m)[f(u_n) - f(u_m)] + F(u_n), \tag{124}$$

where F is an external on-site force, into

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} = g[\hat{J}_\alpha(0) - \hat{J}_\alpha(k\Delta x)]\mathcal{F}_\Delta\{f(u_n)\} + \mathcal{F}_\Delta\{F(u_n)\}, \tag{125}$$

where $\hat{u}(k,t) = \mathcal{F}_\Delta\{u_n(t)\}$, *and* $\hat{J}_\alpha(k\Delta x) = \mathcal{F}_\Delta\{J(n)\}$.

If $J_\alpha(n)$ *defines the* α*-interaction, then the continuous limit* $\Delta x \to 0$ *and the inverse Fourier transform give*

$$\frac{\partial^2 u(x,t)}{\partial t^2} = G_\alpha A_\alpha \frac{\partial^\alpha}{\partial |x|^\alpha} f(u(x,t)) + F(u(x,t)), \tag{126}$$

where $G_\alpha = g|\Delta x|^\alpha$ *is a finite parameter.*

Proof: The Fourier series transform of the interaction term (122) can be presented as

$$\begin{aligned}\sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x}\hat{\mathcal{I}}_n(u) &= \sum_{n=-\infty}^{+\infty} \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x} J(n,m)[f(u_n) - f(u_m)] \\ &= \sum_{n=-\infty}^{+\infty} \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x} J(n,m) f(u_n) - \sum_{n=-\infty}^{+\infty} \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x} J(n,m) f(u_m). \end{aligned} \tag{127}$$

For the first term on the r.h.s. of (127):

$$\sum_{n=-\infty}^{+\infty} \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x} J(n,m) f(u_n) = \sum_{n=-\infty}^{+\infty} e^{-ikn\Delta x} f(u_n) \sum_{\substack{m'=-\infty \\ m'\neq 0}}^{+\infty} J(m') = \mathcal{F}_\Delta\{f(u_n)\}\hat{J}_\alpha(0), \tag{128}$$

where we use $J(m'+n,n) = J(m')$. For the second term on the r.h.s. of (127):

$$\begin{aligned}\sum_{n=-\infty}^{+\infty} \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} e^{-ikn\Delta x} J(n,m) f(u_m) &= \sum_{m=-\infty}^{+\infty} f(u_m) \sum_{\substack{n=-\infty \\ n\neq m}}^{+\infty} e^{-ikn\Delta x} J(n,m) \\ &= \sum_{m=-\infty}^{+\infty} f(u_m) e^{-ikm\Delta x} \sum_{\substack{n'=-\infty \\ n'\neq 0}}^{+\infty} e^{-ikn'\Delta x} J(n') = \mathcal{F}_\Delta\{f(u_n)\}\hat{J}_\alpha(k\Delta x), \end{aligned} \tag{129}$$

where we use $J(m,n'+m) = J(n')$.

As the result, we obtain Eq. (125).

For the limit $\Delta x \to 0$, Eq. (125) can be written as

$$\frac{\partial^2}{\partial t^2}\hat{u}(k,t) - G_\alpha \hat{\mathcal{I}}_{\alpha,\Delta}(k)\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{130}$$

where we use finite parameter $G_\alpha = g|\Delta x|^\alpha$, and

$$\hat{\mathcal{T}}_{\alpha,\Delta}(k) = -A_\alpha |k|^\alpha - R_\alpha(k\Delta x)|\Delta x|^{-\alpha}. \tag{131}$$

Here, the function R_α satisfies the condition

$$\lim_{\Delta x \to 0} \frac{R_\alpha(k\Delta x)}{|\Delta x|^\alpha} = 0.$$

In the limit $\Delta x \to 0$, we get

$$\frac{\partial^2}{\partial t^2}\tilde{u}(k,t) - G_\alpha \hat{\mathcal{T}}_\alpha(k)\mathcal{F}^{-1}\{f(u(x,t))\} - \mathcal{F}^{-1}\{F(u(x,t))\} = 0, \tag{132}$$

where

$$\tilde{u}(k,t) = \mathcal{L}\hat{u}(k,t), \quad \hat{\mathcal{T}}_\alpha(k) = \mathcal{L}\hat{\mathcal{T}}_{\alpha,\Delta}(k) = -A_\alpha |k|^\alpha.$$

The inverse Fourier transform of (132) gives

$$\frac{\partial^2}{\partial t^2}u(x,t) - G_\alpha \mathcal{T}_\alpha(x) f(u(x,t)) - F(u(x,t)) = 0, \tag{133}$$

where $\mathcal{T}_\alpha(x)$ is an operator

$$\mathcal{T}_\alpha(x) = \mathcal{F}^{-1}\{\hat{\mathcal{T}}_\alpha(k)\} = A_\alpha \frac{\partial^\alpha}{\partial |x|^\alpha}. \tag{134}$$

As the result, we obtain the continuous medium equation (126).

Let us consider examples of quadratic-nonlinear long-range interactions.

1) The continuous limit of the lattice equations

$$\frac{\partial u_n(t)}{\partial t} = g_1 \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_1(n,m)[u_n^2 - u_m^2] + g_2 \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_2(n,m)[u_n - u_m], \tag{135}$$

where $J_i(n)$ $(i=1,2)$ define the α_i-interactions with $\alpha_1=1$ and $\alpha_2=2$, gives the Burgers equation[45] that is a nonlinear partial differential equation of second order:

$$\frac{\partial}{\partial t}u(x,t) + G_1 u(x,t)\frac{\partial}{\partial x}u(x,t) - G_2 \frac{\partial^2}{\partial x^2}u(x,t) = 0. \tag{136}$$

It is used in fluid dynamics as a simplified model for turbulence, boundary layer behavior, shock wave formation, and mass transport. If we consider $J_2(n,m)$ with fractional $\alpha_2=\alpha$, then we get the fractional Burgers equation that is suggested in Ref. 46.

2) The continuous limit of the system of equations

$$\frac{\partial u_n(t)}{\partial t} = g_1 \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_1(n,m)[u_n^2 - u_m^2] + g_3 \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_3(n,m)[u_n - u_m], \tag{137}$$

where $J_i(n)$ $(i=1,3)$ define the α_i-interactions with $\alpha_1=1$ and $\alpha_3=3$, gives Korteweg-de Vries (KdV) equation

$$\frac{\partial}{\partial t}u(x,t) - G_1 u(x,t)\frac{\partial}{\partial x}u(x,t) + G_3 \frac{\partial^3}{\partial x^3}u(x,t) = 0. \tag{138}$$

First formulated as part of an analysis of shallow-water waves in canals, it has subsequently been found to be involved in a wide range of physics phenomena, especially those exhibiting shock

waves, traveling waves, and solitons. Certain theoretical physics phenomena in the quantum mechanics domain are explained by means of a KdV model. It is used in fluid dynamics, aerodynamics, and continuum mechanics as a model for shock wave formation, solitons, turbulence, boundary layer behavior, and mass transport.

If we use noninteger α_i-interactions for $J_i(n)$, then we get the fractional generalization of the KdV equation.[47,48]

3) The continuous limit of

$$\frac{\partial^2 u_n(t)}{\partial t^2} = g_2 \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_2(n,m)[f(u_n) - f(u_m)] + g_4 \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J_4(n,m)[u_n - u_m], \tag{139}$$

where

$$f(u) = u - gu^2,$$

and $J_i(n)$ define the α_i-interactions with $\alpha_2=2$ and $\alpha_4=4$, gives the Boussinesq equation that is a nonlinear partial differential equation of fourth order

$$\frac{\partial^2}{\partial t^2}u(x,t) - G_2\frac{\partial^2}{\partial x^2}u(x,t) + gG_2\frac{\partial^2}{\partial x^2}u^2(x,t) + G_4\frac{\partial^4}{\partial x^4}u(x,t) = 0. \tag{140}$$

This equation was formulated as part of an analysis of long waves in shallow water. It was subsequently applied to problems in the percolation of water in porous subsurface strata. It also crops up in the analysis of many other physical processes.

X. FRACTIONAL DERIVATIVES FROM DISPERSION LAW

Let us consider the three-dimensional lattice that is described by the equations of motion

$$\frac{\partial u_{\mathbf{n}}}{\partial t} = g \sum_{\substack{\mathbf{m}=-\infty \\ \mathbf{m}\neq \mathbf{n}}}^{+\infty} J(\mathbf{n},\mathbf{m})[u_{\mathbf{n}} - u_{\mathbf{m}}] + F(u_{\mathbf{n}}), \tag{141}$$

where $\mathbf{n}=(n_1,n_2,n_3)$, and $J(\mathbf{n},\mathbf{m})=J(\mathbf{n}-\mathbf{m})=J(\mathbf{m}-\mathbf{n})$. We suppose that $u_{\mathbf{n}}(t)$ are Fourier coefficients of the function $\hat{u}(\mathbf{k},t)$:

$$\hat{u}(\mathbf{k},t) = \sum_{\mathbf{n}=-\infty}^{+\infty} u_{\mathbf{n}}(t)e^{-i\mathbf{k}\mathbf{r}_{\mathbf{n}}} = \mathcal{F}_\Delta\{u_{\mathbf{n}}(t)\}, \tag{142}$$

where $\mathbf{k}=(k_1,k_2,k_3)$, and

$$\mathbf{r}_{\mathbf{n}} = \sum_{i=1}^{3} n_i \mathbf{a}_i.$$

Here, $\mathbf{a}_i$ are translational vectors of the lattice. The continuous medium model can be derived in the limit $|\mathbf{a}_i| \to 0$.

To derive the equation for $\hat{u}(\mathbf{k},t)$, we multiply (141) by $\exp(-i\mathbf{k}\mathbf{r}_{\mathbf{n}})$, and summing over $\mathbf{n}$. Then, we obtain

$$\frac{\partial \hat{u}(\mathbf{k},t)}{\partial t} = g[\hat{J}_\alpha(0) - \hat{J}_\alpha(\mathbf{k}\mathbf{a})]\hat{u}(\mathbf{k},t) + \mathcal{F}_\Delta\{F(u_{\mathbf{n}})\}, \tag{143}$$

where $\mathcal{F}_\Delta\{F(u_{\mathbf{n}})\}$ is an operator notation for the Fourier series transform of $F(u_{\mathbf{n}})$, and

$$\hat{J}_\alpha(\mathbf{ka}) = \sum_{\mathbf{n}=-\infty}^{+\infty} e^{-i\mathbf{k}\mathbf{r}_\mathbf{n}} J(\mathbf{n}). \tag{144}$$

For the three-dimensional lattice, we define the α-interaction with $\alpha=(\alpha_1,\alpha_2,\alpha_3)$, as an interaction that satisfies the conditions:

$$\lim_{k\to 0} \frac{[\hat{J}_\alpha(\mathbf{k}) - \hat{J}_\alpha(0)]}{|k_i|^{\alpha_i}} = A_{\alpha_i} \quad (i=1,2,3), \tag{145}$$

where $0<|A_{\alpha_i}|<\infty$. The conditions (145) mean that

$$\hat{J}_\alpha(0) - \hat{J}_\alpha(\mathbf{k}) = \sum_{i=1}^{3} A_{\alpha_1} |k_i|^{\alpha_i} + \sum_{i=1}^{3} R_{\alpha_i}(\mathbf{k}), \tag{146}$$

where

$$\lim_{k_i\to 0} R_{\alpha_i}(\mathbf{k})/|k_i|^{\alpha_i} = 0. \tag{147}$$

In the continuous limit ($|\mathbf{a}_i|\to 0$), the α-interaction in the three-dimensional lattice gives the continuous medium equations with the derivatives $\partial^{\alpha_1}/\partial x^{\alpha_1}$, $\partial^{\alpha_2}/\partial y^{\alpha_2}$, and $\partial^{\alpha_3}/\partial z^{\alpha_3}$.

Let us recall the appearance of the nonlinear parabolic equation.[49–52] Consider wave propagation in some media and present the wave vector $\mathbf{k}$ in the form

$$\mathbf{k} = \mathbf{k}_0 + \boldsymbol{\kappa} = \mathbf{k}_0 + \boldsymbol{\kappa}_\parallel + \boldsymbol{\kappa}_\perp, \tag{148}$$

where $\mathbf{k}_0$ is the unperturbed wave vector and subscripts ($\parallel$, $\perp$) are taken, respectively, to the direction of $\mathbf{k}_0$. A symmetric dispersion law

$$\omega(k) = \omega(\mathbf{k}) = \hat{J}_\alpha(\mathbf{ka}) - \hat{J}_\alpha(0) \tag{149}$$

for $\kappa=|\mathbf{k}-\mathbf{k}_0| \ll k_0=|\mathbf{k}_0|$ can be written as

$$\omega(k) = \omega(|\mathbf{k}|) = \omega(k_0 + [|\mathbf{k}| - k_0]) \approx \omega(k_0) + v_g(|\mathbf{k}| - k_0) + \tfrac{1}{2} v_g'(|\mathbf{k}| - k_0)^2, \tag{150}$$

where

$$v_g = \left(\frac{\partial\omega}{\partial k}\right)_{k=k_0}, \quad v_g' = \left(\frac{\partial^2\omega}{\partial k^2}\right)_{k=k_0}, \tag{151}$$

and

$$|\mathbf{k}| = |\mathbf{k}_0 + \boldsymbol{\kappa}| = \sqrt{(\mathbf{k}_0 + \kappa_\parallel)^2 + \kappa_\perp^2} \approx k_0 + \kappa_\parallel + \frac{1}{2k_0}\kappa_\perp^2. \tag{152}$$

Substitution of (152) into (150) gives

$$\omega(k) \approx \omega_0 + v_g\kappa_\parallel + \frac{v_g}{2k_0}\kappa_\perp^2 + \frac{v_g'}{2}\kappa_\parallel^2, \tag{153}$$

where $\omega_0=\omega(k_0)$. Expressions (143) and (153) in the dual space ("momentum representation") correspond to the following equation for $u=u(\mathbf{r},t)$ in the coordinate space:

$$i\frac{\partial u}{\partial t} = \omega_0 u - iv_g\frac{\partial u}{\partial x} - \frac{v_g}{2k_0}\Delta_\perp u - \frac{v_g'}{2}\Delta_\parallel u + F(u) \tag{154}$$

with respect to the field $u=u(t,x,y,z)$, where x is along $\mathbf{k}_0$, and we use the operator correspondence between the dual space and usual space-time:

$$\omega(k) \leftrightarrow i\frac{\partial}{\partial t}, \quad \boldsymbol{\kappa}_\parallel \leftrightarrow -i\frac{\partial}{\partial x},$$
$$(\boldsymbol{\kappa}_\perp)^2 \leftrightarrow -\Delta_\perp = -\frac{\partial^2}{\partial y^2} - \frac{\partial^2}{\partial z^2}, \quad (\boldsymbol{\kappa}_\parallel)^2 \leftrightarrow -\Delta_\parallel = -\frac{\partial^2}{\partial x^2}. \tag{155}$$

Equation (154) is known as the nonlinear parabolic equation.[49–52] The change of variables from (t,x,y,z) to $(t,x-v_g t,y,z)$ gives

$$-i\frac{\partial u}{\partial t} = \frac{v_g}{2k_0}\Delta_\perp u + \frac{v_g'}{2}\Delta_\parallel u - \omega_0 u - F(u), \tag{156}$$

which is also known as the nonlinear Schrödinger equation.

Wave propagation in oscillatory medium with long-range interaction of oscillators can be easily generalized by rewriting the dispersion law (153), in the following way:

$$\omega(k) = \omega_0 + v_g\kappa_\parallel + G_\alpha(\boldsymbol{\kappa}_\perp^2)^{\alpha/2} + G_\beta(\boldsymbol{\kappa}_\parallel^2)^{\beta/2} \quad (1<\alpha,\beta<2) \tag{157}$$

with new finite constants G_α and G_β.

Using the connection between Riesz fractional derivative and its Fourier transform[1]

$$(-\Delta_\perp)^{\alpha/2} \leftrightarrow (\boldsymbol{\kappa}_\perp^2)^{\alpha/2} \quad (-\Delta_\parallel)^{\beta/2} \leftrightarrow (\boldsymbol{\kappa}_\parallel^2)^{\beta/2}, \tag{158}$$

we obtain from (157)

$$i\frac{\partial u}{\partial t} = -iv_g\frac{\partial u}{\partial x} + G_\alpha(-\Delta_\perp)^{\alpha/2}u + G_\beta(-\Delta_\parallel)^{\beta/2}u + \omega_0 u + F(u), \tag{159}$$

where $u=u(t,x,y,z)$. By changing the variables from (t,x,y,z) to (t,ξ,y,z), $\xi=x-v_g t$, and using

$$(-\Delta_\parallel)^{\beta/2} = \frac{\partial^\beta}{\partial|x|^\beta} = \frac{\partial^\beta}{\partial|\xi|^\beta}, \tag{160}$$

we obtain from (159)

$$i\frac{\partial u}{\partial t} = G_\alpha(-\Delta_\perp)^{\alpha/2}u + G_\beta(-\Delta_\parallel)^{\beta/2}u + \omega_0 u + F(u), \tag{161}$$

which can be called the fractional nonlinear parabolic equation. For $G_\beta=0$ and $F(u)=b|u|^2u$, we get the fractional Ginzburg-Landau equation.[40–44]

We may consider one-dimensional simplifications of Eq. (161), i.e.,

$$i\frac{\partial u}{\partial t} = G_\beta\frac{\partial^\beta u}{\partial|\xi|^\beta} + \omega_0 u + F(u), \tag{162}$$

where $u=u(t,\xi)$, $\xi=x-v_g t$, or

$$i\frac{\partial u}{\partial t} = G_\alpha\frac{\partial^\alpha u}{\partial|z|^\alpha} + \omega_0 u + F(u), \tag{163}$$

where $u=u(t,z)$.

Let us comment on the physical structure of (161). The first and second terms on the right-hand side are related to wave propagation in oscillatory medium with long-range interaction of oscillators. The term with $F(u)$ on the right-hand side of Eqs. (159) and (161) correspond to wave interaction due to the nonlinear properties of the media. Thus, Eq. (161) can describe fractal processes of self-focusing and related issues.

XI. CONCLUSION

One-dimensional system of long-range interacting oscillators serves as a model for numerous applications in physics, chemistry, biology, etc. Long-range interactions are important types of interactions for complex media. An interesting situation arises when we consider the wide class of α-interactions, where α is noninteger. A remarkable feature of these interactions is the existence of a transform operation that replaces the set of coupled individual oscillator equations by the continuous medium equation with the space derivative of noninteger order α. Such transform operation is an approximation that appears in the continuous limit. This limit allows us to consider different models in a unified way by applying tools of fractional calculus.[53,54]

Periodic space-localized oscillations, which arise in discrete systems, have been widely studied for short-range interactions. In the paper, the systems with long-range interactions were considered. The method to map the discrete equations of motion into the continuous fractional order differential equation is developed by the transform operation. It is known that the properties of a system with long-range interaction are very different from short-range one. The method of fractional calculus can be a new tool for the analysis of different lattice systems.

APPENDIX: DIVERGENCE OF NONINVARIANT INTERACTION TERM

Noninvariant interaction term leads to the infinity in the continuous medium equation. To demonstrate this property, we prove the following proposition.

Proposition 8. The α-interaction term

$$g \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)u_m, \tag{A1}$$

where $J(n,m)=|n-m|^{-(\alpha+1)}$ is not translation-invariant. The transform operation $\hat{T}$ of the term (A1) leads to the divergence of order $|\Delta x|^{-\alpha}$ in the continuous medium equations.

Let us prove this proposition for $0<\alpha<2$ ($\alpha\neq 1$), and the following equations of motion

$$\frac{\partial^2 u_n}{\partial t^2} + g \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m)u_m - F(u_n) = 0. \tag{A2}$$

Since

$$\sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} J(n,m) = \sum_{\substack{m=-\infty \\ m\neq n}}^{+\infty} |n-m|^{-(\alpha+1)} \neq 0,$$

then the interparticle interaction term in (A2) is noninvariant with respect to translations. To derive the equation for $\hat{u}(k,t)$, we multiply Eq. (A2) by $\exp(-ikn\Delta x)$, and summing over n. Then, we obtain

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} + g\hat{J}_\alpha(k\Delta x)\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{A3}$$

where $\hat{J}_\alpha(k)$ is defined by (102). Using (105), we present Eq. (A3) in the form

$$\frac{\partial^2 \hat{u}(k,t)}{\partial t^2} + gA_\alpha |\Delta x|^\alpha |k|^\alpha \hat{u}(k,t) + 2g\zeta(\alpha+1)\hat{u}(k,t) + 2g\sum_{n=1}^{\infty} \frac{\zeta(\alpha+1-2n)}{(2n)!}(\Delta x)^{2n}(-k^2)^n \hat{u}(k,t)$$
$$- \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{A4}$$

where ζ is the Riemann zeta-function and A_α is defined by (106). For the limit $\Delta x \to 0$ and $0 < \alpha < 2$ $(\alpha \neq 1)$, Eq. (A4) can be written as

$$\frac{\partial^2}{\partial t^2}\hat{u}(k,t) + G_\alpha A_\alpha |k|^\alpha \hat{u}(k,t) + 2g\zeta(\alpha+1)\hat{u}(k,t) - \mathcal{F}_\Delta\{F(u_n(t))\} = 0, \tag{A5}$$

where $0 < \alpha < 2$, $\alpha \neq 1$, and $G_\alpha = g|\Delta x|^\alpha$ is a finite parameter. Note that $g \to \infty$ for $\Delta x \to 0$, if G_α is a finite. Therefore, the transition to the limit $\Delta x \to 0$ in Eq. (A5) gives the divergence term

$$\lim_{\Delta x \to 0} g\zeta(\alpha+1)\hat{u}(k,t) = \zeta(\alpha+1)G_\alpha \tilde{u}(k,t) \lim_{\Delta x \to 0} |\Delta x|^{-\alpha} \to \infty. \tag{A6}$$

To have the continuous model equations without divergences, we must consider $[u_m(t) - u_n(t)]$ instead of $u_m(t)$ in the interaction terms (A1).

Coupled double well (ϕ^4) one-dimensional potentials abound in both condensed matter physics and field theory. Here we provide an exhaustive set of exact periodic solutions of a coupled ϕ^4 model in an external field in terms of elliptic functions (domain wall arrays) and obtain single domain wall solutions in specific limits. We also calculate the energy and interaction between solitons for various solutions. Both topological and nontopological (e.g., some pulse-like solutions in the presence of a conjugate field) domain walls are obtained. We relate some of these solutions to the recently observed magnetic domain walls in certain multiferroic materials and also in the field theory context wherever possible. Discrete analogs of these coupled models, relevant for structural transitions on a lattice, are also considered. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2345110]

I. INTRODUCTION

There are many physical situations, both in condensed matter and field theory, where two double well potentials model the phenomena of interest with a specific coupling between the two fields. One such phenomenon of current intense interest is the coexistence of magnetism and ferroelectricity (i.e., magnetoelectricity) in a given material. This is a highly desired functionality in technological applications involving cross-field response, switching, and actuation. In general, this phenomenon is referred to as multiferroic behavior.[1] Recently, two different classes of (single phase) multiferroics, namely the orthorhombically distorted perovskites[2] and rare earth hexagonal structures,[3] have emerged. The latter show magnetic domain walls in the basal planes which can be modeled by a coupled ϕ^4 model[4] in the presence of a magnetic field. Coupled ϕ^4 models[5–7] also arise in the context of many ferroelectric and other second-order phase transitions. The coupled ϕ^4 model for multiferroics[4] has a biquadratic coupling whereas the coupled ϕ^4 model for a surface phase transition with hydration forces,[7] relevant in biophysics context, has a bilinear coupling. Other types of couplings are also known for structural phase transitions with strain.[8]

Similarly, there are analogous coupled models in field theory.[9,10] Several related models have been discussed in the literature and their soliton solutions have been found[11–18] including periodic ones.[19–21] Here our motivation is to obtain various possible domain wall solutions of these models with either a bilinear or a biquadratic coupling and then connect to experimental observations wherever possible.

The paper is organized as follows. In Sec. II we provide the solutions for the coupled ϕ^4 model with an explicit biquadratic coupling in the presence of an external field (with an additional linear-quadratic coupling) and calculate their energy as well as interaction between the solitons. We also obtain solutions in the limit of no field. In Sec. III we consider a coupled ϕ^4 model with

[a)]Electronic mail: khare@iopb.res.in
[b)]Electronic mail: avadh@lanl.gov

a bilinear coupling. In Sec. IV we obtain several solutions of a coupled discrete ϕ^4 model with biquadratic coupling (but without an external field). In Sec. V we obtain a solution of the coupled discrete ϕ^4 model with bilinear coupling. To the best of our knowledge, no solution of the coupled ϕ^4 model in an external field is known. Similarly, no solutions of either the coupled continuum ϕ^4 model with a bilinear coupling or the discrete case are known. Even for the continuum coupled case with a biquadratic coupling and zero external field, out of the six possible solutions only three were known previously[20] but the other three are new. Finally, we conclude in Sec. VI with remarks on related models.

II. COUPLED ϕ^4 SOLUTIONS IN AN EXTERNAL FIELD

We consider several exact solutions of the coupled ϕ^4 system in a magnetic field (H_z) as given in Ref. 4 for hexagonal multiferroics. In particular, there are nine periodic solutions (valid for arbitrary m, the modulus of elliptic functions), which at $m=1$ reduce to just four solutions. In particular, there is one "bright-bright," one "dark-dark," and one each of bright-dark and dark-bright solutions. Notice that the equations of motion are asymmetric in the two scalar fields (ϕ and ψ) due to different coupling of the scalar fields to the magnetic field. Thus, the dark-bright and the bright-dark solutions are distinct.

The potential, with a *biquadratic* coupling between the two fields and in an external magnetic field (H_z), is given by

$$V = \alpha_1\phi^2 + \beta_1\phi^4 + \alpha_2\psi^2 + \beta_2\psi^4 + \gamma\phi^2\psi^2 - H_z[\rho_1\phi + \rho_2\phi^3 + \rho_3\phi\psi^2], \tag{1}$$

where α_i, β_i, γ, and ρ_i are material (or system) dependent parameters. Hence the (static) equations of motion are

$$\frac{d^2\phi}{dx^2} = 2\alpha_1\phi + 4\beta_1\phi^3 + 2\gamma\phi\psi^2 - H_z[\rho_1 + 3\rho_2\phi^2 + \rho_3\psi^2], \tag{2}$$

$$\frac{d^2\psi}{dx^2} = 2\alpha_2\psi + 4\beta_2\psi^3 + 2\gamma\phi^2\psi - 2H_z\rho_3\phi\psi. \tag{3}$$

These coupled set of equations admit several periodic solutions which we now discuss one by one systematically.

For static solutions the energy is given by

$$E = \int \left[\frac{1}{2}\left(\frac{d\phi}{dx}\right)^2 + \frac{1}{2}\left(\frac{d\psi}{dx}\right)^2 + V(\phi,\psi)\right]dx, \tag{4}$$

where the limits of integration are from $-\infty$ to ∞ in the case of hyperbolic solutions (i.e., single solitons) on the full line. On the other hand, in the case of periodic solutions (i.e., soliton lattices), the limits are from $-K(m)$ to $+K(m)$. Here $K(m)$ [and $E(m)$ below] denote the complete elliptic integral of the first (and second) kind.[22] Using equations of motion, one can show that for all of our solutions

$$V(\phi,\psi) = \left[\frac{1}{2}\left(\frac{d\phi}{dx}\right)^2 + \frac{1}{2}\left(\frac{d\psi}{dx}\right)^2\right] + C, \tag{5}$$

where the constant C in general varies from solution to solution. Hence the energy $\hat{E}=E-\int C dx$ is given by

$$\hat{E} \equiv E - \int C\mathrm{d}x = \int \left[\left(\frac{\mathrm{d}\phi}{\mathrm{d}x} \right)^2 + \left(\frac{\mathrm{d}\psi}{\mathrm{d}x} \right)^2 \right] \mathrm{d}x. \tag{6}$$

In the following we will give explicit expressions for energy in the case of all nine periodic solutions (and hence the corresponding four hyperbolic solutions). In each case we also provide an expression for the constant C.

A. Solution I

We look for the most general periodic solutions in terms of the Jacobi elliptic functions $\mathrm{sn}(x,m)$, $\mathrm{cn}(x,m)$, and $\mathrm{dn}(x,m)$.[22] It is not difficult to show that

$$\phi = F + A\mathrm{sn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{sn}[D(x+x_0),m], \tag{7}$$

is an exact solution provided the following eight coupled equations are satisfied:

$$2\alpha_1 F + 4\beta_1 F^3 + 2\gamma FG^2 - H_z\rho_1 - 3H_z\rho_2 F^2 - H_z\rho_3 G^2 = 0, \tag{8}$$

$$2\alpha_1 A + 12\beta_1 F^2 A + 4\gamma BFG + 2\gamma AG^2 - 6H_z\rho_2 AF - 2H_z\rho_3 BG = -(1+m)AD^2, \tag{9}$$

$$12\beta_1 FA^2 + 2\gamma FB^2 + 4\gamma ABG - 3H_z\rho_2 A^2 - H_z\rho_3 B^2 = 0, \tag{10}$$

$$2\beta_1 A^2 + \gamma B^2 = mD^2, \tag{11}$$

$$2\alpha_2 G + 4\beta_2 G^3 + 2\gamma GF^2 - 2H_z\rho_3 GF = 0, \tag{12}$$

$$2\alpha_2 B + 12\beta_2 G^2 B + 4\gamma AFG + 2\gamma BF^2 - 2H_z\rho_3(BF+AG) = -(1+m)BD^2, \tag{13}$$

$$12\beta_2 GB^2 + 2\gamma GA^2 + 4\gamma ABF - 2H_z\rho_3 AB = 0, \tag{14}$$

$$2\beta_2 B^2 + \gamma A^2 = mD^2. \tag{15}$$

Here A and B denote the amplitudes of the "kink lattice," F and G are constants, D is an inverse characteristic length, and x_0 is the (arbitrary) location of the kink. Five of these equations determine the five unknowns A,B,D,F,G while the other three equations give three constraints between the nine parameters $\alpha_{1,2},\beta_{1,2},\gamma,H_z,\rho_1,\rho_2,\rho_3$. In particular, A and B are given by

$$A^2 = \frac{mD^2[2\beta_2 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}, \quad B^2 = \frac{mD^2[2\beta_1 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}. \tag{16}$$

Thus this solution exists provided $2\beta_1 > \gamma$ and $2\beta_2 > \gamma$.

It may be noted here that in case both $F,G=0$ then no solution exists so long as $H_z \neq 0$. In fact this is true for all nine solutions that we discuss in the following. There are two special cases (i.e., when either $F=0$ or $G=0$) when the analysis becomes somewhat simpler.

$G=0$, $F\neq 0$: In this case A,B are again given by Eq. (16) while

$$(1+m)D^2 = \frac{\rho_2\rho_3 H_z^2}{2\gamma} - \frac{2\rho_1\gamma}{\rho_3}, \quad F = \frac{\rho_3 H_z}{2\gamma}. \tag{17}$$

The three (and not four, since one of the equations is identically satisfied) constraints are

$$\beta_1 = \frac{\rho_2\gamma}{2\rho_3}, \quad \alpha_1 = \frac{\rho_2\rho_3 H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3}, \quad \alpha_2 = \frac{\rho_3^2 H_z^2}{4\gamma} - \frac{\rho_2\rho_3 H_z^2}{4\gamma} + \frac{\rho_1\gamma}{\rho_3}. \tag{18}$$

m=1: In this limiting case we have a bright-bright soliton solution given by

$$\phi = F + A\tanh[D(x+x_0)], \quad \psi = B\tanh[D(x+x_0)], \tag{19}$$

with A, B, and D determined by

$$A^2 = \frac{D^2[2\beta_2 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}, \quad B^2 = \frac{D^2[2\beta_1 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}, \quad 2D^2 = \frac{\rho_2\rho_3 H_z^2}{2\gamma} - \frac{2\rho_1\gamma}{\rho_3}, \tag{20}$$

while the other relations remain unchanged and are again given by Eqs. (17) and (18).

F=0, *G≠0*: In this case A, B are again given by Eq. (16) with

$$(1+m)D^2 = 4\alpha_2 + \frac{2\rho_3 H_z AG}{B}, \quad G^2 = -\frac{\alpha_2}{2\beta_2}, \tag{21}$$

and the corresponding four constraints are

$$\beta_2 = \frac{\rho_3\alpha_2}{2\rho_1}, \quad (1+m)D^2 = -2\alpha_1 - 2\gamma G^2 + \frac{2\rho_3 H_z BG}{A},$$
$$4\gamma ABG = 3H_z\rho_2 A^2 + H_z\rho_3 B^2, \quad \rho_3 H_z AB = \gamma GA^2 + 6\beta_2 GB^2. \tag{22}$$

The solution at $m=1$ can be easily written down as above.

Special case of $H_z=0$: In this case the field equations are completely symmetric in the two fields ϕ, ψ and solution exists even if both $F, G=0$. In particular, with $H_z=0$, the solution is as given by Eq. (7) but with $F=0=G$[20] where A, B are again as given by Eq. (16) and further both α_1, α_2 turn out to be negative, i.e.,

$$\alpha_1 = \alpha_2 = -\frac{(1+m)D^2}{2}. \tag{23}$$

Special case of $\gamma^2=4\beta_1\beta_2$: One can show that the solution (7) exists even in case $\gamma^2 = 4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{24}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$A^2 + B^2 = \frac{mD^2}{\gamma}. \tag{25}$$

Other relations can be easily worked out depending on if F or G (or neither) is zero. For example, in case $G=0$, $F\neq 0$, one has

$$\rho_2 = \rho_3, \quad \alpha_2 = \frac{\rho_1\gamma}{\rho_3}, \quad \alpha_1 - \alpha_2 = \frac{\rho_3^2 H_z^2}{2\gamma}. \tag{26}$$

Energy: Corresponding to the periodic solution [Eq. (7) with $G=0$] the energy $\hat{E}$ and the constant C are given by

$$\hat{E} = \frac{2(A^2+B^2)D}{3m}[(1+m)E(m) - (1-m)K(m)],$$
$$C = -\tfrac{1}{2}(A^2+B^2)D^2 - F^2[\alpha_1 + 3\beta_1 F^2 - 2H_z\rho_2 F]. \tag{27}$$

It is worth pointing out that even in the case of the solution (7) with either $F=0$, $G\neq 0$ or both F,G nonzero, the energy $\hat{E}$ is the same. Only the value of C is different. For example, in the case of $F=0$, $G\neq 0$, C is given by

$$C=-\frac{1}{2}(A^2+B^2)D^2-\frac{\alpha_2^2}{4\beta_2}, \tag{28}$$

while in the case of both F, G being nonzero, C is

$$C=-\tfrac{1}{2}(A^2+B^2)D^2-F^2[\alpha_1+3\beta_1F^2-2H_z\rho_2F]-G^2[\alpha_2+3\beta_2G^2+3\gamma F^2-2H_z\rho_3F]. \tag{29}$$

On using the expansion formulas for $E(m)$ and $K(m)$ around $m=1$ as given in[22]

$$K(m)=\ln\left(\frac{4}{\sqrt{1-m}}\right)+\frac{(1-m)}{4}\left[\ln\left(\frac{4}{\sqrt{1-m}}\right)-1\right]+\cdots, \tag{30}$$

$$E(m)=1+\frac{(1-m)}{2}\left[\ln\left(\frac{4}{\sqrt{1-m}}\right)-\frac{1}{2}\right]+\cdots, \tag{31}$$

for m near one, the energy of the periodic solution can be rewritten as the energy of the corresponding hyperbolic (bright-bright) soliton solution [Eq. (19)] plus the interaction energy. We find

$$\hat{E}=E_{\text{kink}}+E_{\text{int}}=(A^2+B^2)D\left[\frac{4}{3}+\frac{(1-m)}{3}\right]. \tag{32}$$

Note that this solution exists only when $2\beta_1\geqslant\gamma$, $2\beta_2\geqslant\gamma$ and $4\beta_1\beta_2\geqslant\gamma^2$. The interaction energy vanishes at exactly $m=1$, as it should.

B. Solution II

A different type of solution ("pulse lattice") is given by

$$\phi=F+A\,\text{cn}[D(x+x_0),m],\quad \psi=G+B\,\text{cn}[D(x+x_0),m], \tag{33}$$

provided the following eight coupled equations are satisfied:

$$2\alpha_1F+4\beta_1F^3+2\gamma FG^2-H_z\rho_1-3H_z\rho_2F^2-H_z\rho_3G^2=0, \tag{34}$$

$$2\alpha_1A+12\beta_1F^2A+4\gamma BFG+2\gamma AG^2-6H_z\rho_2AF-2H_z\rho_3BG=(2m-1)AD^2, \tag{35}$$

$$12\beta_1FA^2+2\gamma FB^2+4\gamma ABG-3H_z\rho_2A^2-H_z\rho_3B^2=0, \tag{36}$$

$$2\beta_1A^2+\gamma B^2=-mD^2, \tag{37}$$

$$2\alpha_2G+4\beta_2G^3+2\gamma GF^2-2H_z\rho_3GF=0, \tag{38}$$

$$2\alpha_2B+12\beta_2G^2B+4\gamma AFG+2\gamma BF^2-2H_z\rho_3(BF+AG)=(2m-1)BD^2, \tag{39}$$

$$12\beta_2GB^2+2\gamma GA^2+4\gamma ABF-2H_z\rho_3AB=0, \tag{40}$$

$$2\beta_2B^2+\gamma A^2=-mD^2. \tag{41}$$

Notice that two of these equations are meaningful only if $\gamma<0$ since $\beta_1,\beta_2>0$ from stability considerations. Thus, we write $\gamma=-|\gamma|$. Five of these equations determine the five unknowns

A,B,D,F,G while the other three equations give three constraints between the nine parameters $\alpha_{1,2},\beta_{1,2},\gamma,H_z,\rho_1,\rho_2,\rho_3$. In particular, A and B are given by

$$A^2=\frac{mD^2[2\beta_2+|\gamma|]}{[\gamma^2-4\beta_1\beta_2]},\quad B^2=\frac{mD^2[2\beta_1+|\gamma|]}{[\gamma^2-4\beta_1\beta_2]}. \tag{42}$$

Thus this solution exists provided $\gamma^2>4\beta_1\beta_2$.

There are two special cases when the analysis becomes somewhat simpler and we consider both cases one by one.

$G=0$, $F\neq 0$: In this case A,B are again given by Eq. (42) while

$$(2m-1)D^2=\frac{\rho_2\rho_3H_z^2}{2|\gamma|}-\frac{2\rho_1|\gamma|}{\rho_3},\quad F=-\frac{\rho_3H_z}{2|\gamma|}, \tag{43}$$

and the corresponding three constraints are

$$\beta_1=-\frac{\rho_2|\gamma|}{2\rho_3},\quad \alpha_1=-\frac{\rho_2\rho_3H_z^2}{2|\gamma|}-\frac{\rho_1|\gamma|}{\rho_3},\quad \alpha_2=-\frac{\rho_3^2H_z^2}{4|\gamma|}+\frac{\rho_2\rho_3H_z^2}{4|\gamma|}-\frac{\rho_1|\gamma|}{\rho_3}. \tag{44}$$

$F=0$, $G\neq 0$: In this case A,B are again given by Eq. (42) with

$$(2m-1)D^2=2\alpha_1-\frac{2\rho_3H_zBG}{A}-2|\gamma|G^2,\quad G^2=-\frac{\alpha_2}{2\beta_2}, \tag{45}$$

and the corresponding four constraints are

$$\begin{gathered}\beta_2=\frac{\rho_3\alpha_2}{2\rho_1},\quad (2m-1)D^2=-4\alpha_2-\frac{2\rho_3H_zAG}{B},\\ -4|\gamma|ABG=3H_z\rho_2A^2+H_z\rho_3B^2,\quad \rho_3H_zAB=-|\gamma|GA^2+6\beta_2GB^2.\end{gathered} \tag{46}$$

Special case of $H_z=0$: In this case the field equations are completely symmetric in the two fields ϕ,ψ and a solution exists even when both $F,G=0$. In particular, with $H_z=0$, the solution is as given by Eq. (33) but with $F=0=G$[20] where A,B are again as given by Eq. (42) and furthermore, α_1,α_2 are positive (negative) so long as $m>(<)1/2$, i.e.,

$$\alpha_1=\alpha_2=\frac{(2m-1)D^2}{2}. \tag{47}$$

Energy: Corresponding to the "pulse lattice" solution [Eq. (33) with $G=0$] the energy is given by

$$\begin{gathered}\hat{E}=\frac{2(A^2+B^2)D}{3m}[(2m-1)E(m)+(1-m)K(m)],\\ C=-\tfrac{1}{2}(1-m)(A^2+B^2)D^2-F^2[\alpha_1+3\beta_1F^2-2H_z\rho_2F].\end{gathered} \tag{48}$$

It is worth pointing out that even in the case of the solution (33) with either $F=0$, $G\neq 0$ or both F, G nonzero, the energy $\hat{E}$ is the same. Only the value of C is different. For example, in the case of $F=0$, $G\neq 0$, C is given by

$$C=-\frac{1}{2}(1-m)(A^2+B^2)D^2-\frac{\alpha_2^2}{4\beta_2}, \tag{49}$$

while in the case of both F, G being nonzero, C is

$$C = -\tfrac{1}{2}(1-m)(A^2+B^2)D^2 - F^2[\alpha_1 + 3\beta_1 F^2 - 2H_z\rho_2 F] - G^2[\alpha_2 + 3\beta_2 G^2 + 3\gamma F^2 - 2H_z\rho_3 F]. \tag{50}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (dark-dark) soliton solution

$$\phi = F + A\,\mathrm{sech}[D(x+x_0)], \quad \psi = B\,\mathrm{sech}[D(x+x_0)], \tag{51}$$

plus the interaction energy. We find

$$\hat{E} = E_{\mathrm{pulse}} + E_{\mathrm{int}} = (A^2+B^2)D\left[\frac{2}{3} - \frac{5(1-m)}{6} + (1-m)\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{52}$$

Note that this solution exists only when $\gamma<0$, $4\beta_1\beta_2<\gamma^2$. Again, the interaction energy vanishes at $m=1$.

C. Solution III

In this case, there is another "pulse lattice" solution which is given by

$$\phi = F + A\,\mathrm{dn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{dn}[D(x+x_0),m], \tag{53}$$

provided the following eight coupled equations are satisfied

$$2\alpha_1 F + 4\beta_1 F^3 + 2\gamma F G^2 - H_z\rho_1 - 3H_z\rho_2 F^2 - H_z\rho_3 G^2 = 0, \tag{54}$$

$$2\alpha_1 A + 12\beta_1 F^2 A + 4\gamma BFG + 2\gamma AG^2 - 6H_z\rho_2 AF - 2H_z\rho_3 BG = (2-m)AD^2, \tag{55}$$

$$12\beta_1 FA^2 + 2\gamma FB^2 + 4\gamma ABG - 3H_z\rho_2 A^2 - H_z\rho_3 B^2 = 0, \tag{56}$$

$$2\beta_1 A^2 + \gamma B^2 = -D^2, \tag{57}$$

$$2\alpha_2 G + 4\beta_2 G^3 + 2\gamma GF^2 - 2H_z\rho_3 GF = 0, \tag{58}$$

$$2\alpha_2 B + 12\beta_2 G^2 B + 4\gamma AFG + 2\gamma BF^2 - 2H_z\rho_3(BF+AG) = (2-m)BD^2, \tag{59}$$

$$12\beta_2 GB^2 + 2\gamma GA^2 + 4\gamma ABF - 2H_z\rho_3 AB = 0, \tag{60}$$

$$2\beta_2 B^2 + \gamma A^2 = -D^2. \tag{61}$$

Notice that (as in the cn–cn case) two of these equations are meaningful only if $\gamma<0$ since $\beta_1,\beta_2>0$ from stability considerations. We therefore write $\gamma=-|\gamma|$. Five of these equations determine the five unknowns A,B,D,F,G while the other three equations give three constraints between the nine parameters $\alpha_{1,2},\beta_{1,2},|\gamma|,H_z,\rho_1,\rho_2,\rho_3$. In particular, A and B are given by

$$A^2 = \frac{D^2[2\beta_2+|\gamma|]}{[\gamma^2-4\beta_1\beta_2]}, \quad B^2 = \frac{D^2[2\beta_1+|\gamma|]}{[\gamma^2-4\beta_1\beta_2]}. \tag{62}$$

There are two special cases when the analysis becomes somewhat simpler and we consider both the cases one by one.

$G=0$, $F\neq 0$: In this case A,B are again given by Eq. (62) while

$$(2-m)D^2 = \frac{\rho_2\rho_3 H_z^2}{2|\gamma|} - \frac{2\rho_1|\gamma|}{\rho_3}, \quad F = -\frac{\rho_3 H_z}{2|\gamma|}, \tag{63}$$

and the three constraints are

$$\beta_1 = -\frac{\rho_2|\gamma|}{2\rho_3}, \quad \alpha_1 = -\frac{\rho_2\rho_3 H_z^2}{2|\gamma|} - \frac{\rho_1|\gamma|}{\rho_3}, \quad \alpha_2 = -\frac{\rho_3^2 H_z^2}{4|\gamma|} + \frac{\rho_2\rho_3 H_z^2}{4|\gamma|} - \frac{\rho_1|\gamma|}{\rho_3}. \tag{64}$$

$F=0$, $G\neq 0$: In this case A, B are again given by Eq. (62) with

$$(2-m)D^2 = 2\alpha_1 - \frac{2\rho_3 H_z BG}{A} - 2|\gamma|G^2, \quad G^2 = -\frac{\alpha_2}{2\beta_2}, \tag{65}$$

and the corresponding four constraints are

$$\begin{gathered}\beta_2 = \frac{\rho_3\alpha_2}{2\rho_1}, \quad (2-m)D^2 = -4\alpha_2 - \frac{2\rho_3 H_z AG}{B}, \\ -4|\gamma|ABG = 3H_z\rho_2 A^2 + H_z\rho_3 B^2, \quad \rho_3 H_z AB = -|\gamma|GA^2 + 6\beta_2 GB^2.\end{gathered} \tag{66}$$

Special case of $H_z=0$: With $H_z=0$, the solution is as given by Eq. (53) but with $F=0=G$[20] where A, B are again as given by Eq. (62) and furthermore, both α_1, α_2 are positive definite:

$$\alpha_1 = \alpha_2 = \frac{(2-m)D^2}{2}. \tag{67}$$

Energy: Corresponding to the "pulse lattice" solution [Eq. (53) with $G=0$] the energy is given by

$$\begin{gathered}\hat{E} = \frac{2(A^2+B^2)D}{3}[(2-m)E(m) - (1-m)K(m)], \\ C = \tfrac{1}{2}(1-m)(A^2+B^2)D^2 - F^2[\alpha_1 + 3\beta_1 F^2 - 2H_z\rho_2 F].\end{gathered} \tag{68}$$

It is worth pointing out that even in the case of the solution (53) with either $F=0$, $G\neq 0$ or both F, G nonzero, the energy $\hat{E}$ is the same. Only the value of C is different. For example, in the case of $F=0$, $G\neq 0$, C is given by

$$C = \frac{1}{2}(1-m)(A^2+B^2)D^2 - \frac{\alpha_2^2}{4\beta_2}, \tag{69}$$

while in the case of both F, G being nonzero, C is

$$C = \tfrac{1}{2}(1-m)(A^2+B^2)D^2 - F^2[\alpha_1 + 3\beta_1 F^2 - 2H_z\rho_2 F] - G^2[\alpha_2 + 3\beta_2 G^2 + 3\gamma F^2 - 2H_z\rho_3 F]. \tag{70}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (dark-dark) soliton solution as given by Eq. (51) plus the interaction energy. We find

$$\hat{E} = E_{\text{pulse}} + E_{\text{int}} = (A^2+B^2)D\left[\frac{2}{3} - \frac{(1-m)}{2} - (1-m)\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{71}$$

Note that this solution also exists only when $\gamma<0$, $4\beta_1\beta_2<\gamma^2$. Again, the interaction energy vanishes at $m=1$.

D. Solution IV

In addition to the cn–cn and dn–dn solutions discussed earlier, there are two novel (mixed) soliton solutions of dn–cn and cn–dn type. Let us discuss them one by one. We shall see that for these two solutions (in fact it is true for all six solutions that we discuss in the following) G is necessarily zero while F is necessarily nonzero (unless $H_z=0$), otherwise the solution does not exist. In particular, it is easily shown that

$$\phi = F + A\,\mathrm{dn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{cn}[D(x+x_0),m], \tag{72}$$

is a solution provided $G=0$ and further, the following seven coupled equations are satisfied:

$$2\alpha_1 F + 4\beta_1 F^3 + (2/m)\gamma(m-1)FB^2 - H_z\rho_1 - 3H_z\rho_2 F^2 + (1/m)(1-m)H_z\rho_3 B^2 = 0, \tag{73}$$

$$2\alpha_1 A + 12\beta_1 F^2 A + (2/m)(m-1)\gamma AB^2 - 6H_z\rho_2 AF = (2-m)AD^2, \tag{74}$$

$$12\beta_1 FA^2 + (2/m)\gamma FB^2 - 3H_z\rho_2 A^2 - (1/m)H_z\rho_3 B^2 = 0, \tag{75}$$

$$\gamma B^2 + 2m\beta_1 A^2 = -mD^2, \tag{76}$$

$$2\alpha_2 B + 2(1-m)\gamma A^2 B + 2\gamma BF^2 - 2H_z\rho_3 BF = (2m-1)BD^2, \tag{77}$$

$$2\beta_2 B^2 + m\gamma A^2 = -mD^2, \tag{78}$$

$$4\gamma FAB - 2H_z\rho_3 AB = 0. \tag{79}$$

Again a solution exists only if $\gamma<0$ and thus we write $\gamma=-|\gamma|$. The solution (72) exists provided

$$A^2 = \frac{D^2[|\gamma| + 2\beta_2]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad B^2 = \frac{mD^2[2\beta_1 + |\gamma|]}{[\gamma^2 - 4\beta_1\beta_2]}, \tag{80}$$

where

$$(2-m)D^2 = \frac{2}{m}(1-m)|\gamma|B^2 - \frac{2\rho_1|\gamma|}{\rho_3} + \frac{\rho_2\rho_3 H_z^2}{2|\gamma|}, \quad F = -\frac{\rho_3 H_z}{2|\gamma|}, \tag{81}$$

and the three constraints are

$$\begin{aligned} \beta_1 &= -\frac{\rho_2|\gamma|}{2\rho_3}, \quad \alpha_2 = -\frac{\rho_2\rho_3 H_z^2}{2|\gamma|} - \frac{\rho_1|\gamma|}{\rho_3}, \\ (2m-1)D^2 &= 2\alpha_2 - 2(1-m)|\gamma|A^2 + \frac{H_z^2\rho_3^2}{2|\gamma|}. \end{aligned} \tag{82}$$

Special case of $H_z=0$: With $H_z=0$, the solution is as given by Eq. (72) but with $F=0=G$ where A and B are again as given by Eq. (80) and furthermore, α_2 is positive, i.e.,

$$\alpha_1 = \frac{mD^2}{2} - 2(1-m)\beta_1 A^2, \quad m\alpha_2 = m\frac{D^2}{2} + 2(1-m)\beta_2 B^2 > 0. \tag{83}$$

Energy: Corresponding to the "pulse lattice" solution [Eq. (72) with $G=0$] the energy $\hat{E}$ and C are given by

$$\hat{E} = \frac{2D}{3m}\left([(2-m)mA^2 + (2m-1)B^2]E(m) + (1-m)(B^2 - 2mA^2)K(m)\right),$$

$$C = \frac{1}{2}A^2D^2(1-m) - F^2[\alpha_1 + 3\beta_1F^2 - 2H_z\rho_2F] + \frac{(1-m)}{m^2}[m\gamma F^2 - \alpha_2 m + \beta_2(1-m)B^2]B^2. \tag{84}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (dark-dark) soliton solution (51) plus the interaction energy. We find

$$\hat{E} = E_{\text{pulse}} + E_{\text{int}} = D\left[\frac{2}{3}(A^2+B^2) + \frac{(1-m)}{6}(3A^2 - 5B^2) + (1-m)(B^2 - A^2)\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{85}$$

Note that this solution also exists only when $\gamma < 0$, $4\beta_1\beta_2 < \gamma^2$. The interaction energy vanishes for $m=1$, as it should.

E. Solution V

It is easily shown that there is also a cn–dn solution which is distinct from the above-noted dn–cn solution. This solution is given by

$$\phi = F + A\,\text{cn}[D(x+x_0), m], \quad \psi = G + B\,\text{dn}[D(x+x_0), m], \tag{86}$$

provided $G=0$ and the following seven coupled equations are satisfied:

$$2\alpha_1F + 4\beta_1F^3 + 2\gamma(1-m)FB^2 - H_z\rho_1 - 3H_z\rho_2F^2 - (1-m)H_z\rho_3B^2 = 0, \tag{87}$$

$$2\alpha_1A + 12\beta_1F^2A + 2(1-m)\gamma AB^2 - 6H_z\rho_2AF = -(1-2m)AD^2, \tag{88}$$

$$12\beta_1FA^2 + 2m\gamma FB^2 - 3H_z\rho_2A^2 - mH_z\rho_3B^2 = 0, \tag{89}$$

$$m\gamma B^2 + 2\beta_1A^2 = -mD^2, \tag{90}$$

$$2\alpha_2B - (2/m)(1-m)\gamma A^2B + 2\gamma BF^2 - 2H_z\rho_3BF = (2-m)BD^2, \tag{91}$$

$$2m\beta_2B^2 + \gamma A^2 = -mD^2, \tag{92}$$

$$4\gamma FAB - 2H_z\rho_3AB = 0. \tag{93}$$

Again a solution exists only if $\gamma < 0$ and hence we put $\gamma = -|\gamma|$. The solution turns out to be

$$A^2 = \frac{mD^2[|\gamma| + 2\beta_2]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad B^2 = \frac{D^2[2\beta_1 + |\gamma|]}{[\gamma^2 - 4\beta_1\beta_2]}, \tag{94}$$

where

$$(2m-1)D^2 = -2(1-m)|\gamma|B^2 - \frac{2\rho_1|\gamma|}{\rho_3} + \frac{\rho_2\rho_3H_z^2}{2|\gamma|}, \quad F = -\frac{\rho_3H_z}{2|\gamma|}, \tag{95}$$

and the three constraints are

$$\beta_1 = -\frac{\rho_2|\gamma|}{2\rho_3}, \quad \alpha_1 = -\frac{\rho_2\rho_3 H_z^2}{2|\gamma|} - \frac{\rho_1|\gamma|}{\rho_3},$$
$$(2-m)D^2 = 2\alpha_2 + (2/m)(1-m)|\gamma|A^2 + \frac{H_z^2\rho_3^2}{2|\gamma|}. \tag{96}$$

Special case of $H_z=0$: With $H_z=0$, the solution is as given by Eq. (86) but with $F=0=G$ where A and B are again as given by Eq. (94) and furthermore, α_1 is positive, i.e.,

$$m\alpha_1 = m\frac{D^2}{2} + 2(1-m)\beta_1 A^2 > 0, \quad \alpha_2 = \frac{mD^2}{2} - 2(1-m)\beta_2 B^2. \tag{97}$$

It is worth pointing out that with $H_z=0$, the field equations are completely symmetric between the two fields ϕ and ψ and hence solutions IV and V are identical in the limit $H_z=0$.

$m=1$: In the special case of $m=1$ and $G=0$, $F\neq 0$, all four solutions II to V reduce to a dark-dark type soliton solution (51), i.e.,

$$\phi = F + A\,\mathrm{sech}[D(x+x_0)], \quad \psi = B\,\mathrm{sech}[D(x+x_0)], \tag{98}$$

with A, B, and D given by

$$A^2 = \frac{D^2[|\gamma| + 2\beta_2]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad B^2 = \frac{D^2[2\beta_1 + |\gamma|]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad D^2 = -\frac{2\rho_1|\gamma|}{\rho_3} + \frac{\rho_2\rho_3 H_z^2}{2|\gamma|}, \tag{99}$$

while the other relations remain unchanged and are again given by Eqs. (43) and (44).

Similarly, in the special case of $m=1$ and $F=0$, $G\neq 0$, both solutions II and III reduce to a dark-dark type soliton solution

$$\phi = A\,\mathrm{sech}[D(x+x_0)], \quad \psi = G + B\,\mathrm{sech}[D(x+x_0)], \tag{100}$$

with A and B again given by Eq. (99) while

$$D^2 = 2\alpha_1 - \frac{2\rho_3 H_z BG}{A} - 2|\gamma|G^2, \quad D^2 = -4\alpha_2 - \frac{2\rho_3 H_z AG}{B}. \tag{101}$$

Other relations remain unchanged and are again given by Eqs. (45) and (46).

Energy: Corresponding to the "pulse lattice" solution [Eq. (86) with $G=0$] the energy is given by

$$\hat{E} = \frac{2D}{3m}\big([(2-m)mB^2 + (2m-1)A^2]E(m) + (1-m)(A^2 - 2mB^2)K(m)\big),$$
$$C = -\tfrac{1}{2}A^2D^2(1-m) - F^2[\alpha_1 + 3\beta_1F^2 - 2H_z\rho_2F] + [-\gamma F^2 + \alpha_2 + \beta_2(1-m)B^2]B^2. \tag{102}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (dark-dark) soliton solution [Eq. (51)] plus the interaction energy. We find

$$\hat{E} = E_{\mathrm{pulse}} + E_{\mathrm{int}} = D\left[\frac{2}{3}(A^2+B^2) + \frac{(1-m)}{6}(3B^2 - 5A^2) + (1-m)(A^2-B^2)\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{103}$$

Note that this solution also exists only when $\gamma<0$, $4\beta_1\beta_2<\gamma^2$. Again, the interaction energy vanishes at $m=1$. It is amusing to note that the energy of solution V is easily obtained from that of solution IV by simply interchanging A and B.

F. Solution VI

Apart from the solutions which at $m=1$ reduce to the bright-bright and dark-dark solutions, there are four solutions which at $m=1$ go over to either bright-dark or dark-bright solutions, which we now discuss one by one.

One such solution, kink-like in ϕ and pulse-like in ψ, is

$$\phi = F + A\,\mathrm{sn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{cn}[D(x+x_0),m], \tag{104}$$

provided $G=0$ and the following seven coupled equations are satisfied:

$$2\alpha_1 F + 4\beta_1 F^3 + 2\gamma F B^2 - H_z\rho_1 - 3H_z\rho_2 F^2 - H_z\rho_3 B^2 = 0, \tag{105}$$

$$2\alpha_1 A + 12\beta_1 F^2 A + 2\gamma A B^2 - 6H_z\rho_2 AF = -(1+m)AD^2, \tag{106}$$

$$12\beta_1 F A^2 - 2\gamma F B^2 - 3H_z\rho_2 A^2 + H_z\rho_3 B^2 = 0, \tag{107}$$

$$2\beta_1 A^2 - \gamma B^2 = mD^2, \tag{108}$$

$$2\alpha_2 B + 2\gamma A^2 B + 2\gamma B F^2 - 2H_z\rho_3 BF = (2m-1)BD^2, \tag{109}$$

$$2\beta_2 B^2 - \gamma A^2 = -mD^2, \tag{110}$$

$$(4\gamma F - 2H_z\rho_3)AB = 0. \tag{111}$$

In this case it turns out that the solution exists only if either $2\beta_1 > \gamma > 2\beta_2$, $\gamma^2 > 4\beta_1\beta_2$ or $2\beta_2 > \gamma > 2\beta_1$, $\gamma^2 < 4\beta_1\beta_2$. We find that

$$A^2 = \frac{mD^2[\gamma - 2\beta_2]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad B^2 = \frac{mD^2[2\beta_1 - \gamma]}{[\gamma^2 - 4\beta_1\beta_2]}, \tag{112}$$

where

$$-(1+m)D^2 = 2\gamma B^2 + \frac{2\rho_1\gamma}{\rho_3} - \frac{\rho_2\rho_3 H_z^2}{2\gamma}, \quad F = \frac{\rho_3 H_z}{2\gamma}, \tag{113}$$

and the three constraints are

$$\beta_1 = \frac{\rho_2\gamma}{2\rho_3}, \quad \alpha_1 = \frac{\rho_2\rho_3 H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3},$$
$$(2m-1)D^2 = 2\alpha_2 + 2\gamma A^2 - \frac{H_z^2\rho_3^2}{2\gamma}. \tag{114}$$

Special case of $H_z=0$*:* With $H_z=0$, the solution is again given by Eq. (104) but with $F=0=G$ where A and B are again as given by Eq. (112) and furthermore, α_1, α_2 turn out to be negative, i.e.,

$$\alpha_1 = -\frac{(1+m)D^2}{2} - \gamma B^2, \quad \alpha_2 = -\frac{D^2}{2} - 2\beta_2 B^2. \tag{115}$$

Special case of $\gamma^2=4\beta_1\beta_2$*:* One can show that the solution (104) exists even in case $\gamma^2=4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{116}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$A^2 - B^2 = \frac{mD^2}{\gamma}. \tag{117}$$

Further, one has

$$\rho_2 = \rho_3, \quad \alpha_1 = \frac{\rho_3^2 H_z^2}{2\gamma} + \frac{\rho_1 \gamma}{\rho_3}, \quad \alpha_2 - \alpha_1 = \frac{mD^2}{2} - \frac{\rho_3^2 H_z^2}{2\gamma}. \tag{118}$$

Energy: Corresponding to the mixed "kink-pulse lattice" solution [Eq. (104)] the energy is given by

$$\hat{E} = \frac{2D}{3m}\big([(2-m)mB^2 + (1+m)A^2]E(m) - (1-m)(A^2+2B^2)K(m)\big),$$
$$C = -\tfrac{1}{2}A^2D^2 - F^2[\alpha_1 + 3\beta_1 F^2 - 2H_z\rho_2 F] + [-\gamma F^2 + \alpha_2 + \beta_2 B^2]B^2. \tag{119}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (bright-dark) soliton solution

$$\phi = F + A\tanh[D(x+x_0)], \quad \psi = B\,\mathrm{sech}[D(x+x_0)], \tag{120}$$

plus the interaction energy. We find

$$\hat{E} = E_{\mathrm{soliton}} + E_{\mathrm{int}} = D\left[\frac{2}{3}(2A^2+B^2) + \frac{(1-m)}{6}(2A^2+3B^2) - (1-m)B^2\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{121}$$

Note that this solution also exists only when either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \geqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $\gamma^2 \leqslant 4\beta_1\beta_2$. The interaction energy vanishes at $m=1$.

G. Solution VII

It is easy to show that another such (kink- and pulse-like) solution is

$$\phi = F + A\,\mathrm{sn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{dn}[D(x+x_0),m], \tag{122}$$

provided $G=0$ and the following seven coupled equations are satisfied:

$$2\alpha_1 F + 4\beta_1 F^3 + 2\gamma F B^2 - H_z\rho_1 - 3H_z\rho_2 F^2 - H_z\rho_3 B^2 = 0, \tag{123}$$

$$2\alpha_1 A + 12\beta_1 F^2 A + 2\gamma A B^2 - 6H_z\rho_2 AF = -(1+m)AD^2, \tag{124}$$

$$12\beta_1 FA^2 - 2m\gamma FB^2 - 3H_z\rho_2 A^2 + mH_z\rho_3 B^2 = 0, \tag{125}$$

$$2\beta_1 A^2 - m\gamma B^2 = mD^2, \tag{126}$$

$$2\alpha_2 B + (2/m)\gamma A^2 B + 2\gamma BF^2 - 2H_z\rho_3 BF = (2-m)BD^2, \tag{127}$$

$$2m\beta_2 B^2 - \gamma A^2 = -mD^2, \tag{128}$$

$$4\gamma FAB - 2H_z\rho_3 AB = 0. \tag{129}$$

In this case also it turns out that the solution exists only if either $2\beta_1 > \gamma > 2\beta_2$ and $\gamma^2 > 4\beta_1\beta_2$ or $2\beta_2 > \gamma > 2\beta_1$ and $\gamma^2 < 4\beta_1\beta_2$. We find that

$$A^2 = \frac{mD^2[\gamma - 2\beta_2]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad B^2 = \frac{D^2[2\beta_1 - \gamma]}{[\gamma^2 - 4\beta_1\beta_2]}, \tag{130}$$

where

$$-(1+m)D^2 = 2\gamma B^2 + \frac{2\rho_1\gamma}{\rho_3} - \frac{\rho_2\rho_3 H_z^2}{2\gamma}, \quad F = \frac{\rho_3 H_z}{2\gamma}, \tag{131}$$

and the three constraints are

$$\beta_1 = \frac{\rho_2\gamma}{2\rho_3}, \quad \alpha_1 = \frac{\rho_2\rho_3 H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3},$$
$$(2-m)D^2 = 2\alpha_2 + (2/m)\gamma A^2 - \frac{H_z^2\rho_3^2}{2\gamma}. \tag{132}$$

Special case of $H_z=0$: With $H_z=0$, the solution is again given by Eq. (122) but with $F=0=G$ where A and B are again as given by Eq. (130) and furthermore, α_1, α_2 turn out to be negative, i.e.,

$$\alpha_1 = -\frac{(1+m)D^2}{2} - \gamma B^2, \quad \alpha_2 = -\frac{mD^2}{2} - 2\beta_2 B^2. \tag{133}$$

$m=1$: In the special case of $m=1$ and $G=0$, $F\neq 0$, both solutions VI and VII reduce to a bright-dark type of solution as given by Eq. (120), i.e.,

$$\phi = F + A\tanh[D(x+x_0)], \quad \psi = B\,\mathrm{sech}[D(x+x_0)], \tag{134}$$

with A, B, and D given by

$$A^2 = \frac{D^2[\gamma - 2\beta_2]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad B^2 = \frac{D^2[2\beta_1 - \gamma]}{[\gamma^2 - 4\beta_1\beta_2]}, \quad D^2 = -\gamma B^2 - \frac{\rho_1\gamma}{\rho_3} + \frac{\rho_2\rho_3 H_z^2}{4\gamma}, \tag{135}$$

while the other relations remain unchanged and are again given by Eqs. (131) and (132).

Special case of $\gamma^2=4\beta_1\beta_2$: One can show that the solution (122) exists even in case $\gamma^2=4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{136}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$A^2 - mB^2 = \frac{mD^2}{\gamma}. \tag{137}$$

Further, one has

$$\rho_2 = \rho_3, \quad \alpha_1 = \frac{\rho_3^2 H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3}, \quad \alpha_2 - \alpha_1 = \frac{D^2}{2} - \frac{\rho_3^2 H_z^2}{2\gamma}. \tag{138}$$

Energy: Corresponding to the mixed "kink-pulse lattice" solution [Eq. (122)] the energy and the constant C are given by

$$\hat{E} = \frac{2D}{3m}\big([(2m-1)B^2 + (1+m)A^2]E(m) - (1-m)(A^2 - B^2)K(m)\big), \tag{139}$$

$$C = -\tfrac{1}{2}A^2D^2 - F^2[\alpha_1 + 3\beta_1F^2 - 2H_z\rho_2F] + [-\gamma F^2 + \alpha_2 + \beta_2B^2]B^2. \tag{140}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (bright-dark) soliton solution [Eq. (120)] plus the interaction energy. We find

$$\hat{E} = E_{\text{soliton}} + E_{\text{int}} = D\left[\frac{2}{3}(2A^2 + B^2) + \frac{(1-m)}{6}(2A^2 - 5B^2) + (1-m)B^2\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{141}$$

Note that this solution also exists only when either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \geqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $\gamma^2 \leqslant 4\beta_1\beta_2$. The interaction energy vanishes for $m=1$.

H. Solution VIII

Finally, we discuss two periodic solutions both of which at $m=1$ reduce to a dark-bright type of solution. The first such (pulse-like in ϕ and kink-like in ψ) solution is given by

$$\phi = F + A\,\mathrm{cn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{sn}[D(x+x_0),m], \tag{142}$$

provided $G=0$ and the following seven coupled equations are satisfied:

$$2\alpha_1F + 4\beta_1F^3 + 2\gamma FB^2 - H_z\rho_1 - 3H_z\rho_2F^2 - H_z\rho_3B^2 = 0, \tag{143}$$

$$2\alpha_1A + 12\beta_1F^2A + 2\gamma AB^2 - 6H_z\rho_2AF = (2m-1)AD^2, \tag{144}$$

$$12\beta_1FA^2 - 2\gamma FB^2 - 3H_z\rho_2A^2 + H_z\rho_3B^2 = 0, \tag{145}$$

$$2\beta_1A^2 - \gamma B^2 = -mD^2, \tag{146}$$

$$2\alpha_2B + 2\gamma A^2B + 2\gamma BF^2 - 2H_z\rho_3BF = -(1+m)BD^2, \tag{147}$$

$$2\beta_2B^2 - \gamma A^2 = mD^2, \tag{148}$$

$$4\gamma FAB - 2H_z\rho_3AB = 0. \tag{149}$$

In this case it turns out that the solution exists only if either $2\beta_1 > \gamma > 2\beta_2$ and $\gamma^2 < 4\beta_1\beta_2$ or $2\beta_2 > \gamma > 2\beta_1$ and $\gamma^2 > 4\beta_1\beta_2$. We find that

$$A^2 = \frac{mD^2[\gamma - 2\beta_2]}{[4\beta_1\beta_2 - \gamma^2]}, \quad B^2 = \frac{mD^2[2\beta_1 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}, \tag{150}$$

where

$$(2m-1)D^2 = 2\gamma B^2 + \frac{2\rho_1\gamma}{\rho_3} - \frac{\rho_2\rho_3H_z^2}{2\gamma}, \quad F = \frac{\rho_3H_z}{2\gamma}, \tag{151}$$

and the three constraints are

$$\beta_1 = \frac{\rho_2\gamma}{2\rho_3}, \quad \alpha_1 = \frac{\rho_2\rho_3H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3},$$
$$-(1+m)D^2 = 2\alpha_2 + 2\gamma A^2 - \frac{H_z^2\rho_3^2}{2\gamma}. \tag{152}$$

Special case of $H_z=0$: When $H_z=0$, the solution is again given by Eq. (142) but with $F=0=G$ where A and B are again as given by Eq. (150) and furthermore, α_1, α_2 turn out to be negative, i.e.,

$$\alpha_1 = -\frac{D^2}{2} - 2\beta_1 A^2, \quad \alpha_2 = -\frac{(1+m)D^2}{2} - \gamma A^2. \tag{153}$$

It is worth pointing out that with $H_z=0$, the field equations are completely symmetric between the two fields ϕ and ψ and hence the solutions VI and VIII are identical in the limit $H_z=0$.

Special case of $\gamma^2=4\beta_1\beta_2$: One can show that the solution (142) exists even in case $\gamma^2=4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{154}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$B^2 - A^2 = \frac{mD^2}{\gamma}. \tag{155}$$

Further, one has

$$\rho_2 = \rho_3, \quad \alpha_1 = \frac{\rho_3^2 H_z^2}{2\gamma} + \frac{\rho_1 \gamma}{\rho_3}, \quad \alpha_1 - \alpha_2 = \frac{mD^2}{2} + \frac{\rho_3^2 H_z^2}{2\gamma}. \tag{156}$$

Energy: Corresponding to the mixed "kink-pulse lattice" solution [Eq. (142)] the energy and the constant C are given by

$$\hat{E} = \frac{2D}{3m}\big([(2m-1)A^2 + (1+m)B^2]E(m) - (1-m)(B^2-A^2)K(m)\big), \tag{157}$$

$$C = -\tfrac{1}{2}(1-m)A^2D^2 - F^2[\alpha_1 + 3\beta_1 F^2 - 2H_z\rho_2 F] + [-\gamma F^2 + \alpha_2 + \beta_2 B^2]B^2. \tag{158}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (dark-bright) soliton solution

$$\phi = F + A\,\mathrm{sech}[D(x+x_0)], \quad \psi = B\tanh[D(x+x_0)], \tag{159}$$

plus the interaction energy. We find

$$\hat{E} = E_{\mathrm{soliton}} + E_{\mathrm{int}} = D\left[\frac{2}{3}(2B^2+A^2) + \frac{(1-m)}{6}(2B^2-5A^2) + (1-m)A^2\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{160}$$

Note that this solution also exists only when either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \leqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $\gamma^2 \geqslant 4\beta_1\beta_2$. Again, the interaction energy vanishes at $m=1$. It is amusing to note that the energy of the solution VIII is easily obtained from that of solution VI by simply interchanging A and B.

I. Solution IX

Another solution which at $m=1$ reduces to a dark-bright type of soliton solution is given by

$$\phi = F + A\,\mathrm{dn}[D(x+x_0),m], \quad \psi = G + B\,\mathrm{sn}[D(x+x_0),m], \tag{161}$$

provided $G=0$ and the following seven coupled equations are satisfied:

$$2\alpha_1 F + 4\beta_1 F^3 + (2/m)\gamma F B^2 - H_z\rho_1 - 3H_z\rho_2 F^2 - \frac{H_z\rho_3 B^2}{m} = 0, \tag{162}$$

$$2\alpha_1 A + 12\beta_1 F^2 A + (2/m)\gamma A B^2 - 6H_z\rho_2 AF = (2-m)AD^2, \tag{163}$$

$$12\beta_1 F A^2 - (2/m)\gamma F B^2 - 3H_z\rho_2 A^2 + \frac{H_z\rho_3 B^2}{m} = 0, \tag{164}$$

$$2m\beta_1 A^2 - \gamma B^2 = -mD^2, \tag{165}$$

$$2\alpha_2 B + 2\gamma A^2 B + 2\gamma B F^2 - 2H_z\rho_3 BF = -(1+m)BD^2, \tag{166}$$

$$2\beta_2 B^2 - m\gamma A^2 = mD^2, \tag{167}$$

$$4\gamma FAB - 2H_z\rho_3 AB = 0. \tag{168}$$

In this case it turns out that the solution exists only if either $2\beta_1 > \gamma > 2\beta_2$ and $\gamma^2 < 4\beta_1\beta_2$ or $2\beta_2 > \gamma > 2\beta_1$ and $\gamma^2 > 4\beta_1\beta_2$. We find that

$$A^2 = \frac{D^2[\gamma - 2\beta_2]}{[4\beta_1\beta_2 - \gamma^2]}, \quad B^2 = \frac{mD^2[2\beta_1 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}, \tag{169}$$

where

$$(2-m)D^2 = (2/m)\gamma B^2 + \frac{2\rho_1\gamma}{\rho_3} - \frac{\rho_2\rho_3 H_z^2}{2\gamma}, \quad F = \frac{\rho_3 H_z}{2\gamma}, \tag{170}$$

and the three constraints are

$$\begin{aligned} \beta_1 &= \frac{\rho_2\gamma}{2\rho_3}, \quad \alpha_1 = \frac{\rho_2\rho_3 H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3}, \\ -(1+m)D^2 &= 2\alpha_2 + 2\gamma A^2 - \frac{H_z^2\rho_3^2}{2\gamma}. \end{aligned} \tag{171}$$

Special case of $H_z=0$: When $H_z=0$, the solution is again given by Eq. (161) but with $F=0=G$ where A and B are again as given by Eq. (169) and furthermore, α_1, α_2 turn out to be negative, i.e.,

$$\alpha_1 = -\frac{mD^2}{2} - 2\beta_1 A^2, \quad \alpha_2 = -\frac{(1+m)D^2}{2} - \gamma A^2. \tag{172}$$

It is worth pointing out that with $H_z=0$, the field equations are completely symmetric between the two fields ϕ and ψ and hence the solutions VII and IX are identical in the limit $H_z=0$.

$m=1$: In the special case of $m=1$ and $G=0$, $F\neq 0$, both solutions VIII and IX reduce to a dark-bright type of solution (159), i.e.,

$$\phi = F + A\,\mathrm{sech}[D(x+x_0)], \quad \psi = B\tanh[D(x+x_0)], \tag{173}$$

with A, B, and D given by

$$A^2 = \frac{D^2[\gamma - 2\beta_2]}{[4\beta_1\beta_2 - \gamma^2]}, \quad B^2 = \frac{D^2[2\beta_1 - \gamma]}{[4\beta_1\beta_2 - \gamma^2]}, \quad D^2 = 2\gamma B^2 + \frac{2\rho_1\gamma}{\rho_3} - \frac{\rho_2\rho_3 H_z^2}{2\gamma}, \tag{174}$$

while the other relations remain unchanged and are given by Eqs. (151) and (152).

Special case of $\gamma^2 = 4\beta_1\beta_2$*:* One can show that the solution (161) exists even in case $\gamma^2 = 4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{175}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$B^2 - mA^2 = \frac{mD^2}{\gamma}. \tag{176}$$

Further, one has

$$\rho_2 = \rho_3, \quad \alpha_1 = \frac{\rho_3^2 H_z^2}{2\gamma} + \frac{\rho_1\gamma}{\rho_3}, \quad \alpha_1 - \alpha_2 = \frac{D^2}{2} + \frac{\rho_3^2 H_z^2}{2\gamma}. \tag{177}$$

Energy: Corresponding to the mixed "pulse-kink lattice" solution [Eq. (161)] the energy and the constant C are given by

$$\hat{E} = \frac{2D}{3m}\big([(2-m)mA^2 + (1+m)B^2]E(m) - (1-m)(B^2 + 2A^2)K(m)\big), \tag{178}$$

$$C = \tfrac{1}{2}(1-m)A^2D^2 - F^2[\alpha_1 + 3\beta_1F^2 - 2H_z\rho_2F] + [-m\gamma F^2 + m\alpha_2 + \beta_2B^2]\frac{B^2}{m^2}. \tag{179}$$

For m near one, the energy of this periodic solution can be rewritten as the energy of the corresponding hyperbolic (dark-bright) soliton solution [Eq. (159)] plus the interaction energy. We find

$$\hat{E} = E_{\text{soliton}} + E_{\text{int}} = D\left[\frac{2}{3}(2B^2 + A^2) + \frac{(1-m)}{6}(2B^2 + 3A^2) - (1-m)A^2\ln\left(\frac{4}{\sqrt{1-m}}\right)\right]. \tag{180}$$

Note that this solution also exists only when either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \leqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $\gamma^2 \geqslant 4\beta_1\beta_2$. The interaction energy vanishes at $m=1$. It is amusing to note that the energy of solution IX is easily obtained from that of solution VII by simply interchanging A and B.

Summarizing, we have obtained nine periodic solutions in terms of Jacobi elliptic functions, in the case of a coupled ϕ^4 field theory with biquadratic coupling and an external magnetic field. This was possible because the magnetic field interaction is not symmetric between the two fields ϕ and ψ. In the special case when the modulus parameter m of the Jacobi elliptic function is one, these nine solutions reduce to four different soliton solutions valid on the full line and expressed in terms of hyperbolic functions. Note, however, that in case the external field $H_z=0$, instead of nine, we only obtain six distinct periodic solutions (of which three are previously known[20]), which in the limit $m=1$ give three distinct soliton solutions.

It is worth emphasizing the restrictions on the various parameters in the case of the nine solutions. For example, in the case of sn–sn solution (with $G=0$), $2\beta_1 \geqslant \gamma$, $2\beta_2 \geqslant \gamma$. Further, in the special case of $H_z=0=F=G$, one can show that $\alpha_1 < 0$, $\alpha_2 < 0$. On the other hand, in the case of cn–cn, dn–dn, cn–dn, and dn–cn solutions (with $G=0$), $\gamma < 0$ and further $\gamma^2 > 4\beta_1\beta_2$. In the special case of $H_z=0=F=G$, in addition one finds that (i) for the cn–cn case α_1, $\alpha_2 > (<) 0$ provided $m > (<) 1/2$, (ii) $\alpha_1 > 0$, $\alpha_2 > 0$ for the dn–dn solution, (iii) for the dn–cn solution, $\alpha_2 > 0$, (iv) $\alpha_1 < 0$ for the cn–dn solution. Instead, for the sn–cn as well as sn–dn solutions, either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \geqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $\gamma^2 \leqslant 4\beta_2\beta_4$. Finally, in the cn–sn and dn–sn

cases, either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \leqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $\gamma^2 \geqslant 4\beta_1\beta_2$. If in addition $H_z = 0 = F = G$, then for all four solutions (i.e., sn–cn, cn–sn, sn–dn, dn–sn), $\alpha_1 < 0$ and $\alpha_2 < 0$.

III. SOLUTIONS WITH BILINEAR COUPLING

Several years ago, a coupled ϕ^4 model was considered in the context of a surface phase transition with hydration forces[7] which is similar to the one considered in the last section except that there was no external magnetic field H_z and instead of a biquadratic coupling there was a bilinear coupling between the two fields. The purpose of this section is to obtain a bright-bright soliton solution of that model.

The potential (i.e., free energy) is given by

$$V = \alpha_1\phi^2 + \beta_1\phi^4 + \alpha_2\psi^2 + \beta_2\psi^4 + \delta_1(\phi - \psi)^2 + \delta_2(\phi + \psi)^2, \tag{181}$$

with δ_1, δ_2 being the coupling parameters between the two fields. The (static) equations of motion which follow from here are

$$\frac{\mathrm{d}^2\phi}{\mathrm{d}x^2} = 2\alpha_1\phi + 4\beta_1\phi^3 + 2\delta_1(\phi - \psi) + 2\delta_2(\phi + \psi), \tag{182}$$

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}x^2} = 2\alpha_2\psi + 4\beta_2\psi^3 - 2\delta_1(\phi - \psi) + 2\delta_2(\phi + \psi). \tag{183}$$

It is not difficult to show that this pair of coupled field equations admits the "kink-kink" type periodic solution

$$\phi = A\,\mathrm{sn}[D(x + x_0), m], \quad \psi = B\,\mathrm{sn}[D(x + x_0), m], \tag{184}$$

provided

$$\begin{gathered} mD^2 = 2\beta_1A^2 = 2\beta_2B^2, \\ A^2 = \frac{-m}{(1+m)\beta_1}\left[\alpha_1 + \delta_1 + \delta_2 + (\delta_2 - \delta_1)\sqrt{\frac{\beta_1}{\beta_2}}\right], \end{gathered} \tag{185}$$

and furthermore the parameters $\alpha_1, \alpha_2, \beta_1, \beta_2, \delta_1, \delta_2$ satisfy the constraint

$$\alpha_2 - \alpha_1 = (\delta_1 - \delta_2)\left[\sqrt{\frac{\beta_2}{\beta_1}} - \sqrt{\frac{\beta_1}{\beta_2}}\right]. \tag{186}$$

Since $A^2 > 0$, the relation (185) gives us a strong constraint on some of the parameters. The energy $\hat{E}$ and the constant C corresponding to the periodic solution [Eq. (184)] are

$$\begin{gathered} \hat{E} = \frac{2(A^2 + B^2)D}{3m}[(1+m)E(m) - (1-m)K(m)], \\ C = -\tfrac{1}{2}(A^2 + B^2)D^2. \end{gathered} \tag{187}$$

In the limit $m = 1$, this solution reduces to the bright-bright soliton solution

$$\phi = A\tanh[D(x + x_0)], \quad \psi = B\tanh[D(x + x_0)], \tag{188}$$

provided

$$D^2 = 2\beta_1 A^2 = 2\beta_2 B^2,$$
$$A^2 = \frac{-1}{2\beta_1}\left[\alpha_1 + \delta_1 + \delta_2 + (\delta_2 - \delta_1)\sqrt{\frac{\beta_1}{\beta_2}}\right], \tag{189}$$

while relation (186) remains unchanged. For m near one, the energy of the periodic solution can be rewritten as the energy of the corresponding hyperbolic (bright-bright) soliton solution [Eq. (188)] plus the interaction energy. We find

$$\hat{E} = E_{\text{kink}} + E_{\text{int}} = (A^2 + B^2)D\left[\frac{4}{3} + \frac{(1-m)}{3}\right]. \tag{190}$$

The interaction energy vanishes at $m=1$. In view of the requirement $\beta_1, \beta_2 > 0$ arising from stability, we are unable to find any other solution to this coupled set of equations with a bilinear coupling.

IV. SOLUTIONS OF DISCRETE COUPLED ϕ^4-TYPE EQUATIONS WITH BIQUADRATIC COUPLING

Discrete coupled ϕ^4 models arise in the context of structural transitions on a lattice, collective proton dynamics in ice,[23] etc. The purpose of this section is to give an exhaustive list of solutions to the discrete coupled ϕ^4-type equations with biquadratic coupling (but in the absence of an external magnetic field H_z). In the next section, we shall obtain a solution of the discrete coupled ϕ^4-type equations with bilinear coupling.

We start from the coupled static field equations (2) and (3). The discrete analog of these field equations, for $H_z=0$, has the form

$$\frac{1}{h^2}(\phi_{n+1} + \phi_{n-1} - 2\phi_n) - 2\alpha_1\phi_n - 2[2\beta_1\phi_n^2 + \gamma\psi_n^2]\phi_n = 0, \tag{191}$$

$$\frac{1}{h^2}(\psi_{n+1} + \psi_{n-1} - 2\psi_n) - 2\alpha_2\psi_n - 2[2\beta_2\psi_n^2 + \gamma\phi_n^2]\psi_n = 0, \tag{192}$$

where h is the lattice spacing. We are unable to find any solution to this coupled set of field equations. However, as in the Ablowitz-Ladik discretization of the discrete nonlinear Schrödinger equation,[24] if we replace ϕ_n and ψ_n in the last term in Eqs. (191) and (192) by their average, then we can find exact solutions to this coupled system. In particular, instead of Eqs. (191) and (192), we consider the discretized equations

$$\frac{1}{h^2}(\phi_{n+1} + \phi_{n-1} - 2\phi_n) - 2\alpha_1\phi_n - [2\beta_1\phi_n^2 + \gamma\psi_n^2][\phi_{n+1} + \phi_{n-1}] = 0, \tag{193}$$

$$\frac{1}{h^2}(\psi_{n+1} + \psi_{n-1} - 2\psi_n) - 2\alpha_2\psi_n - [2\beta_2\psi_n^2 + \gamma\phi_n^2][\psi_{n+1} + \psi_{n-1}] = 0. \tag{194}$$

Note that single solitons and their stability in coupled Ablowitz-Ladik chains have been studied previously.[25] We now show that this modified set of coupled discrete equations has six different periodic solutions which in the limit $m=1$ reduce to the bright-bright, bright-dark, and dark-dark soliton solutions. In all the solutions, we shall see that the static kink can be placed anywhere with respect to the lattice. Hence we suspect that in all these cases, there may be an absence of the Peierls-Nabarro barrier,[26–28] which is the energy cost associated with moving a localized solution such as a soliton by a half lattice constant on a discrete lattice. It would be nice if one can demonstrate this explicitly.

A. Solution I

It is easy to show that the field Eqs. (193) and (194) admit the kink-kink type solution

$$\phi_n = A\,\mathrm{sn}[hD(n+x_0),m], \quad \psi_n = B\,\mathrm{sn}[hD(n+x_0),m], \tag{195}$$

provided

$$A^2 = \frac{m(2\beta_2-\gamma)\mathrm{sn}^2(hD,m)}{h^2(4\beta_1\beta_2-\gamma^2)}, \quad B^2 = \frac{m(2\beta_1-\gamma)\mathrm{sn}^2(hD,m)}{h^2(4\beta_1\beta_2-\gamma^2)},$$
$$\alpha_1 = \alpha_2 = -\frac{1}{h^2}[1-\mathrm{cn}(hD,m)\mathrm{dn}(hD,m)], \tag{196}$$

where h is the lattice spacing. Thus, note that as in the continuum case, this solution exists provided $2\beta_1>\gamma$, $2\beta_2>\gamma$, $\alpha_1<0$, $\alpha_2<0$. It is interesting to note that the solutions to both the discrete and the continuum model exist under the same set of conditions.

Continuum limit: It is instructive to consider the continuum limit $h\to 0$ and show that the above-noted solution smoothly goes over to the corresponding continuum solution. In particular, on using the fact that as $h\to 0$,

$$\mathrm{sn}(hD,m)\to hD, \quad \mathrm{cn}^2(hD,m)\to 1-h^2D^2, \quad \mathrm{dn}^2(hD,m)\to 1-mh^2D^2, \tag{197}$$

it readily follows that the above-noted solution indeed reduces to the corresponding continuum solution [Eq. (7)] obtained in Sec. II (when $H_z=F=G=0$), i.e.,

$$A^2 = \frac{m(2\beta_2-\gamma)D^2}{(4\beta_1\beta_2-\gamma^2)}, \quad B^2 = \frac{m(2\beta_1-\gamma)D^2}{(4\beta_1\beta_2-\gamma^2)}, \quad \alpha_1=\alpha_2=-\frac{(1+m)D^2}{2}. \tag{198}$$

In fact we shall see that all six solutions of this coupled discrete model smoothly go over to the corresponding continuum solutions obtained in Sec. II in the limit $h\to 0$.

In the limit $m=1$, the periodic solution (195) reduces to the bright-bright soliton solution

$$\phi_n = A\tanh[hD(n+x_0)], \quad \psi_n = B\tanh[hD(n+x_0)]. \tag{199}$$

Special case of $\gamma^2=4\beta_1\beta_2$: One can show that the solution (195) exists even in case $\gamma^2=4\beta_1\beta_2$. It turns out that such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{200}$$

and that in this case one cannot determine A,B. However, they must satisfy the constraint

$$A^2+B^2 = \frac{m\,\mathrm{sn}^2(hD,m)}{h^2\gamma}. \tag{201}$$

In the continuum limit $h\to 0$, as expected, this reduces to the constraint equation (25) obtained in Sec. II.

B. Solution II

It is easily shown that a kink-pulse type solution

$$\phi_n = A\,\mathrm{sn}[hD(n+x_0),m], \quad \psi_n = B\,\mathrm{cn}[hD(n+x_0),m], \tag{202}$$

is an exact solution to the field Eqs. (193) and (194) provided

$$A^2 = \frac{m(\gamma - 2\beta_2)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2 - 4\beta_1\beta_2)}, \quad B^2 = \frac{m(2\beta_1 - \gamma)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2 - 4\beta_1\beta_2)}. \tag{203}$$

Furthermore,

$$-\alpha_1 = \frac{1}{h^2} + \frac{\mathrm{cn}(hD,m)[2m\beta_1(\gamma - 2\beta_2)\mathrm{sn}^2(hD,m) - (\gamma^2 - 4\beta_1\beta_2)]}{h^2(\gamma^2 - 4\beta_1\beta_2)\mathrm{dn}(hD,m)}, \tag{204}$$

$$-\alpha_2 = \frac{1}{h^2} + \frac{\mathrm{cn}(hD,m)[m\gamma(\gamma - 2\beta_2)\mathrm{sn}^2(hD,m) - (\gamma^2 - 4\beta_1\beta_2)]}{h^2(\gamma^2 - 4\beta_1\beta_2)\mathrm{dn}^2(hD,m)}. \tag{205}$$

Again, as in the continuum case either $2\beta_1 > \gamma > 2\beta_2$ and $\gamma^2 > 4\beta_1\beta_2$ or $2\beta_2 > \gamma > 2\beta_1$ and $4\beta_1\beta_2 > \gamma^2$. It is, however, not clear here if α_1 and α_2 have a definite sign. However, in the limit $m=1$, as in the continuum case, one finds that $\alpha_1 < 0$, $\alpha_2 < 0$.

It is readily checked that in the continuum limit this solution smoothly goes over to the corresponding continuum solution, Eqs. (104) and (112). Furthermore, the corresponding bright-dark solution is easily obtained in the limit $m=1$.

Special case of $\gamma^2 = 4\beta_1\beta_2$*:* One can show that the solution (202) exists even in case $\gamma^2 = 4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{206}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$A^2 - B^2\mathrm{dn}^2(hD,m) = \frac{m\,\mathrm{sn}^2(hD,m)}{h^2\gamma}. \tag{207}$$

In the continuum limit $h \to 0$, as expected, this reduces to the constraint equation (117) obtained in Sec. II.

C. Solution III

Yet another kink-pulse type solution is given by

$$\phi_n = A\,\mathrm{sn}[hD(n + x_0), m], \quad \psi_n = B\,\mathrm{dn}[hD(n + x_0), m], \tag{208}$$

provided

$$A^2 = \frac{m(\gamma - 2\beta_2)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2 - 4\beta_1\beta_2)}, \quad B^2 = \frac{(2\beta_1 - \gamma)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2 - 4\beta_1\beta_2)}. \tag{209}$$

Furthermore,

$$-\alpha_1 = \frac{1}{h^2} + \frac{\mathrm{dn}(hD,m)[2\beta_1(\gamma - 2\beta_2)\mathrm{sn}^2(hD,m) - (\gamma^2 - 4\beta_1\beta_2)]}{h^2(\gamma^2 - 4\beta_1\beta_2)\mathrm{cn}(hD,m)}, \tag{210}$$

$$-\alpha_2 = \frac{1}{h^2} + \frac{\mathrm{dn}(hD,m)[\gamma(\gamma - 2\beta_2)\mathrm{sn}^2(hD,m) - (\gamma^2 - 4\beta_1\beta_2)]}{h^2(\gamma^2 - 4\beta_1\beta_2)\mathrm{cn}^2(hD,m)}. \tag{211}$$

Special case of $\gamma^2 = 4\beta_1\beta_2$*:* One can show that the solution (208) exists even in case $\gamma^2 = 4\beta_1\beta_2$. It turns out such a solution exists only if

$$2\beta_1 = 2\beta_2 = \gamma, \tag{212}$$

and that in this case one cannot determine A, B. However, they must satisfy the constraint

$$A^2 - mB^2\,\mathrm{cn}^2(hD,m) = \frac{m\,\mathrm{sn}^2(hD,m)}{h^2\gamma}. \tag{213}$$

In the continuum limit $h\to 0$, as expected, this reduces to the constraint equation (137) obtained in Sec. II.

Note that in the $m=1$ limit the solutions II and III reduce to the same bright-dark soliton solution. In addition, as in the continuum case, this solution exists if either $2\beta_1 \geqslant \gamma \geqslant 2\beta_2$ and $\gamma^2 \geqslant 4\beta_1\beta_2$ or $2\beta_2 \geqslant \gamma \geqslant 2\beta_1$ and $4\beta_1\beta_2 \geqslant \gamma^2$. It is, however, not clear here if α_1 and α_2 have a definite sign. However, in the limit $m=1$, as in the continuum case, one finds that $\alpha_1<0$ and $\alpha_2<0$.

D. Solution IV

Finally, we present three periodic solutions, all of which in the limit $m=1$ reduce to the dark-dark soliton solution. One of the pulse-pulse type periodic solutions is given by

$$\phi_n = A\,\mathrm{cn}[hD(n+x_0),m], \quad \psi_n = B\,\mathrm{cn}[hD(n+x_0),m], \tag{214}$$

provided as in the continuum case, $\gamma<0$ and $\gamma^2>4\beta_1\beta_2$. We find

$$A^2 = \frac{2m(\beta_2+|\gamma|)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2-4\beta_1 4\beta_2)\mathrm{dn}^2(hD,m)}, \quad B^2 = \frac{2m(\beta_1+|\gamma|)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2-4\beta_1 4\beta_2)\mathrm{dn}^2(hD,m)},$$
$$\alpha_1 = \alpha_2 = -\frac{1}{h^2}\left[1-\frac{\mathrm{cn}(hD,m)}{\mathrm{dn}^2(hD,m)}\right]. \tag{215}$$

Using Eq. (197) it is easily shown that as in the continuum case, α_1, $\alpha_2>(<)\ 0$ provided $m>(<)\ 1/2$. This solution is equivalent to the continuum solution, Eqs. (33) and (42).

E. Solution V

Another pulse-pulse type solution is given by

$$\phi_n = A\,\mathrm{dn}[hD(n+x_0),m], \quad \psi_n = B\,\mathrm{dn}[hD(n+x_0),m], \tag{216}$$

provided as in the continuum case, $\gamma<0$ and $\gamma^2>4\beta_1\beta_2$. We find

$$A^2 = \frac{2(\beta_2+|\gamma|)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2-4\beta_1\beta_2)\mathrm{cn}^2(hD,m)}, \quad B^2 = \frac{2(\beta_1+|\gamma|)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2-\beta_1 4\beta_2)\mathrm{cn}^2(hD,m)},$$
$$\alpha_1 = \alpha_2 = -\frac{1}{h^2}\left[1-\frac{\mathrm{dn}(hD,m)}{\mathrm{cn}^2(hD,m)}\right]. \tag{217}$$

Using Eq. (197) it is easily shown that as in the continuum case, α_1, $\alpha_2>0$. This solution is equivalent to the continuum solution, Eqs. (53) and (62).

F. Solution VI

Yet another pulse-pulse type solution is

$$\phi_n = A\,\mathrm{dn}[hD(n+x_0),m], \quad \psi_n = B\,\mathrm{cn}[hD(n+x_0),m], \tag{218}$$

provided as in the continuum case, $\gamma<0$ and $\gamma^2>4\beta_1\beta_2$. We find

$$A^2 = \frac{(2\beta_2+|\gamma|)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2-4\beta_1\beta_2)\mathrm{cn}^2(hD,m)}, \quad B^2 = \frac{m(2\beta_1+|\gamma|)\mathrm{sn}^2(hD,m)}{h^2(\gamma^2-4\beta_1\beta_2)\mathrm{dn}^2(hD,m)}. \tag{219}$$

Furthermore,

$$-\alpha_1 = \frac{1}{h^2} + \frac{[2\beta_1(2\beta_2 + |\gamma|)\mathrm{dn}^2(hD,m) - \gamma(2\beta_1 + |\gamma|)\ \mathrm{cn}^2(hD,m))]}{h^2(\gamma^2 - 4\beta_1\beta_2)\mathrm{dn}(hD,m)\mathrm{cn}^2(hD,m)}, \tag{220}$$

$$-\alpha_2 = \frac{1}{h^2} + \frac{[2\beta_2(2\beta_1 + |\gamma|)\mathrm{cn}^2(hD,m) - |\gamma|(|\gamma| + 2\beta_2)\mathrm{dn}^2(hD,m)]}{h^2(\gamma^2 - 4\beta_1\beta_2)\mathrm{dn}^2(hD,m)\mathrm{cn}(hD,m)}. \tag{221}$$

It is not clear if in general α_1 and α_2 have a definite sign. However, it is easily checked that at $m=1$, α_1, $\alpha_2 > 0$. This solution is equivalent to the continuum solution, Eqs. (72) and (80).

Note that the last three (i.e., IV, V, VI) solutions reduce to the (same) dark-dark soliton solution in the limit $m=1$. Since we do not know the Hamiltonian corresponding to Eqs. (193) and (194), we are unable to find the energy and soliton interaction explicitly for any of the above-noted discrete solutions. Similarly, for $H_z \neq 0$ we have not succeeded in finding exact solutions.

V. SOLUTIONS OF DISCRETE COUPLED ϕ^4-TYPE EQUATIONS WITH BILINEAR COUPLING

Coupled lattice chains, with a bilinear coupling, undergoing a second-order structural phase transition can represent this case. We start from the coupled static field Eqs. (182) and (183). The discrete analog of these field equations has the form

$$\frac{1}{h^2}(\phi_{n+1} + \phi_{n-1} - 2\phi_n) - 2[\alpha_1 + \delta_1 + \delta_2]\phi_n + 2[\delta_1 - \delta_2]\psi_n - 4\beta_1\phi_n^3 = 0, \tag{222}$$

$$\frac{1}{h^2}(\psi_{n+1} + \psi_{n-1} - 2\psi_n) - 2[\alpha_2 + \delta_1 + \delta_2]\psi_n + 2[\delta_1 - \delta_2]\phi_n - 4\beta_2\psi_n^3 = 0. \tag{223}$$

We are unable to find any solution to this coupled set of field equations. However, as in the Ablowitz-Ladik discretization of the discrete nonlinear Schrödinger equation,[24] if we replace ϕ_n and ψ_n in the last term in Eqs. (222) and (223) by their average, then we can find exact solutions to this coupled system. In particular, instead of Eqs. (222) and (223) we consider the discretized equations

$$\frac{1}{h^2}(\phi_{n+1} + \phi_{n-1} - 2\phi_n) - 2[\alpha_1 + \delta_1 + \delta_2]\phi_n + 2[\delta_1 - \delta_2]\psi_n - 2\beta_1\phi_n^2[\phi_{n+1} + \phi_{n-1}] = 0, \tag{224}$$

$$\frac{1}{h^2}(\psi_{n+1} + \psi_{n-1} - 2\psi_n) - 2[\alpha_2 + \delta_1 + \delta_2]\psi_n + 2[\delta_1 - \delta_2]\phi_n - 2\beta_2\psi_n^2[\psi_{n+1} + \psi_{n-1}] = 0. \tag{225}$$

It is easy to show that the field Eqs. (224) and (225) admit the kink-kink type solution

$$\phi_n = A\ \mathrm{sn}[hD(n + x_0), m], \quad \psi_n = B\ \mathrm{sn}[hD(n + x_0), m], \tag{226}$$

provided

$$\frac{m\ \mathrm{sn}^2(hD,m)}{h^2} = 2\beta_1 A^2 = 2\beta_2 B^2,$$
$$A^2 = \frac{-m\ \mathrm{sn}^2(hD,m)}{2\beta_1[1 - \mathrm{cn}(hD,m)\mathrm{dn}(hD,m)]}\left[\alpha_1 + \delta_1 + \delta_2 + (\delta_2 - \delta_1)\sqrt{\frac{\beta_1}{\beta_2}}\right], \tag{227}$$

and furthermore the parameters α_1, α_2, β_1, β_2, δ_1, δ_2 satisfy the constraint

$$\alpha_2 - \alpha_1 = (\delta_1 - \delta_2)\left[\sqrt{\frac{\beta_2}{\beta_1}} - \sqrt{\frac{\beta_1}{\beta_2}}\right]. \tag{228}$$

As expected, in the continuum limit of $h \to 0$, this solution smoothly goes over to the corresponding continuum solution, Eqs. (184)–(186), obtained in Sec. III. Since we do not know the Hamiltonian corresponding to Eqs. (224) and (225), we are unable to find the energy and soliton interaction explicitly for this discrete solution. Similarly, for $H_z \neq 0$ we have not succeeded in finding an exact solution.

VI. CONCLUSION

We have systematically provided an exhaustive set of exact periodic domain wall solutions for a coupled ϕ^4 model with and without an external field, and for both bilinear and biquadratic couplings. Only a bright-bright solution could be obtained for the bilinear case. For both the biquadratic and bilinear couplings the corresponding discrete case was also considered—with an Ablowitz-Ladik like modification of the coupled discrete equations—and we obtained several exact solutions. For the solutions of the discrete model, the calculation of the Peierls-Nabarro barrier[26–28] and soliton scattering[29,30] remain topics of further study. Similarly, scattering of solitons in the coupled ϕ^4 continuum and discrete models with either the biquadratic or bilinear coupling is an interesting open issue. To this end, the static solutions presented here need to be boosted with a certain velocity.

It would be instructive to explore whether the nine different solutions reported in Sec. II (or the six solutions in Sec. IV) are completely disjoint or if there are any possible bifurcations linking them via, for instance, analytical continuation. We have not tried to carry out an explicit stability analysis of various periodic solutions. However, the energy calculations and interaction energy between solitons (for $m \sim 1$) in the case of both the biquadratic and bilinear couplings could provide useful insight in this direction.

Our results are relevant for spin configurations, domain walls, and magnetic phase transitions in multiferroic materials;[3,4] periodic domain walls are yet to be observed in the hexagonal multiferroics.[3] Similarly, our solutions are important for understanding structural phase transitions in ferroelectrics[5,6] and elastic materials,[8] biophysics problems such as multilamellar lipid systems,[7] as well as field theoretic contexts.[9,10] These ideas and exact solutions can be generalized to other coupled models such as ϕ^6 (for first-order phase transitions) and are discussed elsewhere.[31]

(Received 2 May 2006; accepted 29 July 2006; published online 22 September 2006)

In this paper we develop a simple model for the steady state of two-dimensional self-gravitating incompressible gas which is based on the hydrodynamic equations for stratified fluid. These equations are then reduced to a system of two equations for the mass density and the gravitational field. Analytical analysis and numerical solutions of these equations under different modeling assumptions (with special attention to the isothermal case) are then used to study the structure of the resulting steady state of the fluid. © *2006 American Institute of Physics.*

I. INTRODUCTION

The steady states of self-gravitating fluid in three dimensions have been studied by a long list of illustrious mathematical physicists. (For an extensive list of references see Refs. 1–3). The motivation for this research was due to the interest in the shape and stability of celestial bodies. We now know however that many celestial objects such as galaxies exhibit (effectively) "two dimensional structure."[4–7] Similarly, recent discoveries are leading us to believe that systems similar to our solar system are "abundant" in the galaxy and their existence might be due to the collapse of a two-dimensional primordial gas cloud under gravitation.[8–11] This background motivates us to investigate in this paper the steady states of self-gravitating fluid in two dimensions. This problem has been explored by a large number of investigators using analytic methods and computer simulations (see Refs. 8–10 for a complete list of references). What is missing however is a simple analytic model that is able to capture the basic physics of this process and leads to some insights about the "parameters" that govern its outcome.

In this paper we attempt to develop such a model using the basic hydrodynamic equations that govern the steady state flow of an incompressible, stratified (i.e., nonconstant density) fluid in two dimensions under gravity but with no magnetic field.[1–3] Under these assumptions we show that the number of basic equations can be reduced to a system of two coupled equations. One for the mass density and the second for the gravitational field. The only "parameter" in this these equations is a function that encodes the information about the momentum distribution in the interstellar cloud. We then consider radial solutions to these equations with special attention to the steady state of a gas cloud with isothermal equation of state.[10] We find that under proper choices of the parameter function there will exist out-of-core regions where the mass density peaks out locally. These regions might therefore represent the formation of out-of-core structures in the primordial gas cloud. (The region close to the "center" of the cloud where the density and velocities are expected to be large is usually referred to as the core region. Other regions in the cloud are referred to as out-of-core regions.)

We emphasize, however, that the model we develop here is a steady state one. Accordingly, it cannot address questions about the stability of the mass distribution pattern that is predicted by the model equations. It might be argued also that the assumptions of steady state and incompressibility

[a)]Electronic mail: mhumi@wpi.edu

are not realistic from an astrophysical point of view. However, our main goal in this paper is to capture analytically (as far as possible) the nonlinear aspects of the processes under consideration. Accordingly, our results might be useful to provide some analytic insights for more realistic work on this topic. Moreover, they provide a natural extension to the results on the equilibrium states of three-dimensional bodies under gravity.

The plan of the paper is as follows: In Sec. II we present the basic hydrodynamic equations and show how one can reduce them to a coupled system of two equations. We also discuss the conditions under which the two-dimensional approximation is justified. In Sec. III we derive the pressure equation for the fluid under consideration with particular emphasis on isothermal conditions. In Sec. IV we discuss radial solutions to these equations and present the results of some simulations under these assumptions. We end up in Sec. V with a summary and conclusions.

II. DERIVATION OF THE MODEL EQUATIONS

Following the standard convention,[1,12–14] we model the steady state flow of an incompressible fluid in two dimensions (x,y) by the hydrodynamic equations of inviscid and incompressible stratified fluid

$$u_x + v_y = 0, \tag{2.1}$$

$$u\rho_x + v\rho_y = 0, \tag{2.2}$$

$$\rho(uu_x + vu_y) = -p_x - \rho\phi_x, \tag{2.3}$$

$$\rho(uv_x + vv_y) = -p_y - \rho\phi_y, \tag{2.4}$$

$$\nabla^2\phi = 4\pi G\rho, \tag{2.5}$$

where subscripts indicate differentiation with respect to the indicated variable, $\mathbf{u}=(u,v)$ is the fluid velocity, ρ is its density, p is the pressure, ϕ is the gravitational field, and G is the gravitational constant.

We can nondimensionalize these equations by introducing the following scalings:

$$x = L\tilde{x}, \quad y = L\tilde{y}, \quad u = U_0\tilde{u}, \quad v = U_0\tilde{u}, \quad \rho = \rho_0\tilde{\rho}, \quad p = \rho_0 U_0^2\tilde{p}, \quad \phi = U_0^2\tilde{\phi}, \tag{2.6}$$

where L, U_0, ρ_0 are some characteristic length, velocity, and mass density, respectively, that characterize the problem at hand. Substituting these scalings in Eqs. (2.1)–(2.5) and dropping the tildes, these equations remain unchanged (but the quantities that appear in these equations become nondimensional) while G is replaced by $\tilde{G}=G\rho_0 L^2/U_0^2$. (Once again we drop the tilde.)

At this point, we observe that in relativistic physics there is a natural velocity (viz. c-the speed of light) by which one scales the velocities. In the nonrelativistic approach (which we are adopting here) there is no such speed and accordingly U_0 is a "charateristic speed" which one chooses to nondimensionalize the velocities. From a practical (astrophysical) point of view $1 \leqslant U_0 \leqslant 100$ m/s in most typical cases.[3,8] In any case, all quantities (including velocities) in this paper are nondimensional.

Equations (2.1)–(2.5) form a two-dimensional approximation to the three-dimensional analog of these equations (which requires an additional equation for the flow in the z-direction which is similar to Eq. (2.3)). To justify this approximation in our context we assume in the following that we are considering matter distribution whose spatial extension (with characteristic length L) in the x,y directions is much larger than that in z direction (with characteristic "height" H). That is $H/L=O(\epsilon)$ where $0 \leqslant \epsilon \ll 1$. Furthermore we assume that

$$\frac{\partial \rho}{\partial x} = O(1), \quad \frac{\partial \rho}{\partial y} = O(1), \quad \frac{\partial \rho}{\partial z} = O(\epsilon). \tag{2.7}$$

Under these assumptions, the three-dimensional analog of Eq. (2.5) can be approximated by

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial^2 \phi}{\partial z^2} = 4\pi G\left[\rho(x,y,0) + z\frac{\partial \rho(x,y,0)}{\partial z}\right]. \tag{2.8}$$

Under the scaling introduced by Eq. (2.6) (with $z=L\bar{z}$) we then have

$$\bar{z}\frac{\partial \rho(x,y,0)}{\partial \bar{z}} = O(\epsilon^2) \tag{2.9}$$

while the other terms in Eq. (2.8) are of order $O(1)$. It follows then that we can approximate this equation by its two-dimensional analog

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 4\pi G\rho(x,y,0). \tag{2.10}$$

The justification for the two-dimensional approximation to the other equations follows along similar lines and has been discussed by many authors. (A lucid treatment is given in Ref. 12, pp. 1–12).

In view of Eq. (2.1), we can introduce a stream function ψ so that

$$u = \psi_y, \quad v = -\psi_x. \tag{2.11}$$

Using this stream function we can rewrite Eq. (2.2) as[13,15]

$$J\{\rho, \psi\} = 0, \tag{2.12}$$

where for any two (smooth) functions f, g,

$$J\{f,g\} = \frac{\partial f}{\partial x}\frac{\partial g}{\partial y} - \frac{\partial f}{\partial y}\frac{\partial g}{\partial x}. \tag{2.13}$$

Equation (2.12) implies that the functions ρ, ψ are dependent on each other and we can express each of them in terms of the other. Thus we can write ψ as $\psi(\rho)$ or ρ as $\rho(\psi)$.

Using ψ the momentum equations (2.3) and (2.4) become

$$\rho(\psi_y\psi_{yx} - \psi_x\psi_{yy}) = -p_x - \rho\phi_x, \tag{2.14}$$

$$\rho(-\psi_y\psi_{xx} + \psi_x\psi_{xy}) = -p_y - \rho\phi_y. \tag{2.15}$$

To eliminate p from these equations we differentiate Eqs. (2.14) and (2.15) with respect to y, x, respectively, and subtract. This leads to

$$\rho_y(\psi_y\psi_{yx} - \psi_x\psi_{yy}) + \rho(\psi_y\psi_{yx} - \psi_x\psi_{yy})_y - \rho_x(-\psi_y\psi_{xx} + \psi_x\psi_{xy}) - \rho(-\psi_y\psi_{xx} + \psi_x\psi_{xy})_x = -J\{\phi,\rho\}. \tag{2.16}$$

Using Eq. (2.12), we can rewrite this equation (after some algebra) as

$$\rho J\{\nabla^2\psi, \psi\} + J\left\{\tfrac{1}{2}(\psi_x^2 + \psi_y^2), \rho\right\} = -J\{\phi,\rho\}. \tag{2.17}$$

However, in view of Eq. (2.12) $\psi=\psi(\rho)$ and this fact can be used to eliminate ψ from Eq. (2.17). To this end we observe that

$$\psi_x = \psi_\rho \rho_x, \quad \psi_y = \psi_\rho \rho_y, \quad \nabla^2 \psi = \psi_{\rho\rho}[\rho_x^2 + \rho_y^2] + \psi_\rho \nabla^2 \rho \tag{2.18}$$

and note that for any function of $F(\rho)$ we have $J\{F(\rho), \rho\} = 0$. This leads after long algebra to the following relation:

$$J\left\{(\rho\psi_\rho^2)\nabla^2\rho + \tfrac{1}{2}(\rho\psi_\rho^2)_\rho[\rho_x^2 + \rho_y^2] + \phi, \rho\right\} = 0. \tag{2.19}$$

Hence, we infer that

$$h(\rho)\nabla^2\rho + \frac{1}{2}h'(\rho)[\rho_x^2 + \rho_y^2] + \phi = S(\rho), \quad h' = \frac{\mathrm{d}h(\rho)}{\mathrm{d}\rho}, \tag{2.20}$$

where

$$h(\rho) = \rho\psi_\rho^2 \tag{2.21}$$

and $S(\rho)$ is some function of ρ.

The function $h(\rho)$ can be considered as a parameter function which is determined by the momentum (and angular momentum) distribution in the fluid. From a practical point of view the choice of this function determines the structure of the steady state density distribution. The corresponding flow field can be computed then *a posteriori* (that is after solving for ρ) from the following relations:

$$u = \sqrt{\frac{h(\rho)}{\rho}}\frac{\partial\rho}{\partial y}, \quad v = -\sqrt{\frac{h(\rho)}{\rho}}\frac{\partial\rho}{\partial x}. \tag{2.22}$$

The function $S(\rho)$ that appears in Eq. (2.20) can be determined from the asymptotic values of ρ and ϕ on the boundaries of the domain on which Eqs. (2.5) and (2.20) are solved. When these asymptotic values are imposed or known one can evaluate the left-hand side of Eq. (2.20) on the domain boundaries and re-express it in terms of ρ only to determine $S(\rho)$ (on the boundary of the domain). However, the resulting functional relationship of S on ρ must then hold also within the domain itself since S does not depend on x, y directly. For example assume that on an infinite domain we let $h(\rho) = 1$ and

$$\lim_{r\to\infty} \rho(x,y) = e^{-r}, \quad \lim_{r\to\infty} \phi(x,y) = 1/r \tag{2.23}$$

(where $r^2 = x^2 + y^2$). Under these assumptions, the left-hand side of Eq. (2.20) evaluates asymptotically to $e^{-r}(1 - 1/r) + 1/r$. Rewriting this expression in terms of ρ, we obtain

$$S(\rho) = \rho + \frac{(\rho - 1)}{\ln\rho}. \tag{2.24}$$

When such asymptotic relations are not given, $S(\rho)$ can be viewed as a "gauge." In the following, we let $S(\rho) = 0$ under these circumstances.

We observe that Eq. (2.20) can be rewritten in the form

$$h(\rho)^{1/2}\,\nabla\cdot(h(\rho)^{1/2}\,\nabla\rho) + \phi = S(\rho). \tag{2.25}$$

Using this equation, we can eliminate ϕ from Eqs. (2.25) and (2.5) to obtain one fourth-order equation for ρ,

$$\nabla^2(h(\rho)^{1/2}\,\nabla\cdot(h(\rho)^{1/2}\,\nabla\rho)) + 4\pi G\rho = \nabla^2 S(\rho). \tag{2.26}$$

Equation (2.20) can be simplified considerably by introducing a new dependent variable

$$\eta(\rho) = \int^{\rho} h^{1/2}(s)\mathrm{d}s. \tag{2.27}$$

With this new variable, Eq. (2.20) transforms into

$$\nabla^2\eta + h^{-1/2}(\rho)(\phi - S(\rho)\ = 0, \tag{2.28}$$

where $h(\rho)$ and $S(\rho)$ have to be expressed in terms of η. (We assume implicitly that the transformation given by Eq. (2.27) is invertible).

Thus, we reduced the original nonlinear system of partial differential equations (2.1)–(2.5) to a coupled system of two equations consisting of Eqs. (2.5) and (2.28).

III. EQUATION FOR THE PRESSURE

In order to derive Eq. (2.20) we eliminated the pressure from Eqs. (2.14) and (2.15). However, in some practical astrophysical applications it is important to know the equation of state of the fluid under consideration. For this reason, we derive here an equation analogous to Eq. (2.20) for the pressure. To this end, we divide Eqs. (2.14) and (2.15) by ρ, differentiate the first with respect to y, the second with respect to x, and subtract. This leads to

$$\rho^2 J\{\nabla^2\psi, \psi\} = J\{p, \rho\}. \tag{3.1}$$

Eliminating ψ from this equation (using Eq. (2.18)) yields

$$J\{\rho^2\psi_\rho^2\nabla^2\rho + \rho^2\psi_\rho\psi_{\rho\rho}(\rho_x^2 + \rho_y^2) - p, \rho\} = 0. \tag{3.2}$$

Hence,

$$\rho\psi_\rho^2\nabla^2\rho + \rho\psi_\rho\psi_{\rho\rho}(\rho_x^2 + \rho_y^2) - \frac{p}{\rho} = R(\rho), \tag{3.3}$$

where $R(\rho)$ is some function of ρ. Re-expressing this equation using $h(\rho)$ we have

$$h(\rho)\nabla^2\rho + \frac{1}{2}[h'(\rho) - \psi_\rho^2](\rho_x^2 + \rho_y^2) - \frac{p}{\rho} = R(\rho). \tag{3.4}$$

Subtracting this equation from Eq. (2.20) we then have

$$\frac{p}{\rho} = S(\rho) - R(\rho) - \frac{1}{2}\psi_\rho^2(\rho_x^2 + \rho_y^2) - \phi. \tag{3.5}$$

Therefore, the solution of Eqs. (2.20) and (2.5) determines the pressure distribution in the fluid (assuming that the functions R, S have been determined from the boundary conditions).

Conversely, if the pressure distribution is known *a priori*, e.g., if we assume that the fluid is an isothermal gas where $p = c^2\rho$ (c is the isothermal sound speed which is a constant for this medium) then Eq. (3.5) can be used to eliminate ϕ from Eq. (2.5),

$$\nabla^2(R) = \nabla^2\left[S - \tfrac{1}{2}\psi_\rho^2(\rho_x^2 + \rho_y^2)\right] - 4\pi G\rho. \tag{3.6}$$

It follows then that for an isothermal gas Eqs. (3.3) and (3.6) form a closed system of coupled equations for ρ and R with a parameter function ψ_ρ^2. However, if we eliminate R from these two equations we recover Eq. (2.26).

IV. SOLUTIONS OF Eq. (2.26)

Equation (2.26) is, in general, a nonlinear equation which (to our best knowledge) cannot be solved analytically. The only exception is the case where $h=1$ under which the resulting equation is linear. (In the following we let $S(\rho)=0$.) For this choice of h, $\nabla\psi = (1/\sqrt{\rho})\nabla\rho$. That is with the

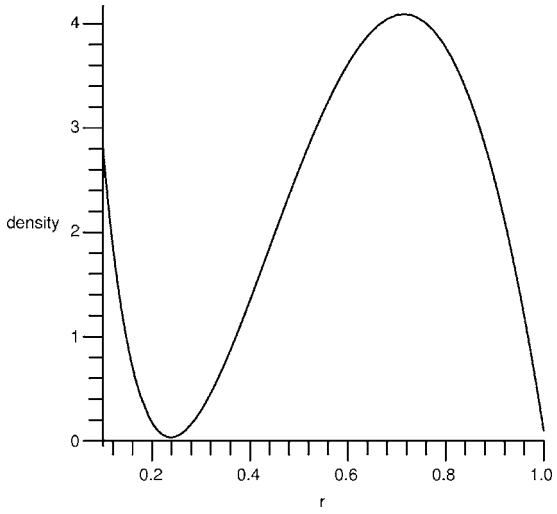

FIG. 1. Radial (analytic) solution of Eq. (2.26) with $h(\rho)=1$ subject to the conditions given by Eq. (4.3).

same gradient of ρ the gradient of ψ will increase as ρ decreases. We conclude then that, in general, matter in regions with low density might have higher momentum than in regions of higher density.

Under the constraint $h=1$ the general solution of Eq. (2.26) can be written in the form

$$\rho = f_0(r) + \sum_{m=1}^{\infty} f_m(r)(E_m \cos m\theta + F_m \sin m\theta), \tag{4.1}$$

where the real form of the solution for $f_m(r)$ is given by

$$f_m(r) = A_m[I_m(\beta R) + I_m(\bar{\beta} R)] + iB_m[I_m(\beta R) - I_m(\bar{\beta} R)] + C_m[K_m(\beta R) + K_m(\bar{\beta} R)] + iD_m[K_m(\beta R) - K_m(\bar{\beta} R)],$$

$$m = 0, 1, 2, \ldots . \tag{4.2}$$

Here $\beta=(\sqrt{2}/2)(-1+i)$, I_m, K_m are the modified Bessel functions of the first and second kinds, overbars denote complex conjugation and $R=(4\pi G)^{1/4}r$. (A_m, B_m, C_m, D_m are arbitrary real constants). However, since K_m have a singularity at the origin we must let $C_m=D_m=0$ if the origin is included in the domain. The remaining arbitary constants that appear in the solution must be adjusted to the boundary conditions one wishes to impose on ρ, ϕ (and subject to the physical requirement that $\rho \geqslant 0$ in the domain under consideration). Obviously various patterns can be obtained for ρ by a proper combination of these functions.

Figure 1 represents the solution given by Eq. (4.2) for $\rho=\rho(r)$, with $h(\rho)=1$ for $r\epsilon[0.1, 1]$ subject to the conditions

$$\rho(0.1) = 2.8, \quad \rho(0.5) = 2.6, \quad \rho(0.9) = 2.5, \quad \rho(1) = 0.1. \tag{4.3}$$

This solution exhibits clearly out-of-core region where the density is larger than its surroundings. It demonstrates also the existence of a region in which matter density is almost zero. This is in line with recent findings from simulations about planet formation in rings.[11] We observe that the parameters for this solution were chosen to accentuate the existence of a region in which the density is almost zero thus creating a "gap" between the core and the out-of-core region.

In polar coordinates the flow field is related to the stream function by the relations

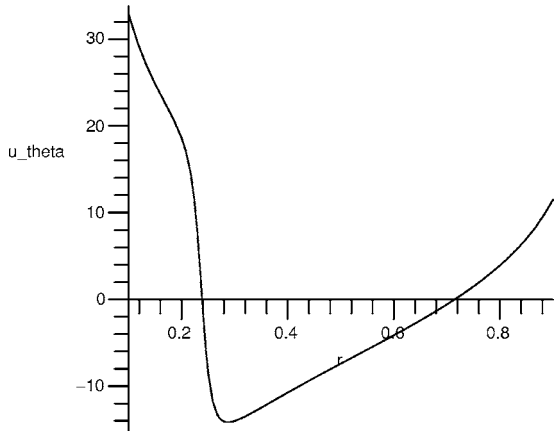

FIG. 2. u_θ as a function of r for solution presented in Fig. 1.

$$u_r = \frac{1}{r}\frac{\partial \psi}{\partial \theta}, \quad u_\theta = -\frac{\partial \psi}{\partial r}. \tag{4.4}$$

Since $\rho = \rho(r)$ it follows that $u_r = 0$ and

$$u_\theta = -\sqrt{\frac{h(\rho)}{\rho}}\frac{\partial \rho}{\partial r}. \tag{4.5}$$

Observe that u_θ is a nondimensional number. To obtain the actual "dimensional" velocities one has to multiply u_θ by U_0.

Figure 2 presents a plot of u_θ vs r for this case. From this figure we see that matter in the 2-d disk can be divided into three "rings." In the first ring where $0.1 \leqslant r \leqslant 0.24$ matter circulates counterclockwise. This is followed by a very narrow region where the u_θ is changing rapidly. (Observe that the density in this region is almost zero.) In the second ring where $0.24 \leqslant r \leqslant 0.72$ the circulation is clockwise. Finally for $0.72 \leqslant r \leqslant 1$ the circulation is counterclockwise again. (However, we have here a "smooth" transition between the second and third rings.)

For other choices of the function $h(\rho)$ one has to resort to numerical integration of Eq. (2.26). This was carried out in two cases for which $\rho = \rho(r)$. In the first case we let $h(\rho) = \rho^\alpha$ with $\alpha = -1, -0.5, 0, 0.5, 1$. In the second case, we choose $h(\rho) = \rho[1 + A \sin(n\pi\rho)]$ with $n = 2$ and $A = \pm 0.5, 0$.

The solutions to Eq. (2.26) for these two cases on the interval $r \epsilon [0.1, 1]$ with the boundary conditions

$$\rho(0.1) = 1, \quad \rho'(0) = 0, \quad \rho(1) = 0.1(0.2), \quad \rho'(1) = 0 \tag{4.6}$$

are presented in Figs. 3 and 4, respectively. The corresponding flow fields for these density profiles are presented in Figs. 5 and 6. These profiles and flow fields are physically "reasonable" in the sense that they contain no singularities and the circulation is unidirectional.

V. SUMMARY AND CONCLUSIONS

As a first task in this paper, we showed how to reduce the governing equations for the steady state of an incompressible stratified (two-dimensional) fluid under gravity (which comprise a set of five coupled nonlinear partial differential equations) to two equations. The resulting equations contain only one parameter function $h(\rho)$. We also derived a separate equation for the pressure in order to investigate the equation of state of the fluid under consideration. We then explored both analytically and numerically radial solutions to these equations with different choices of $h(\rho)$.

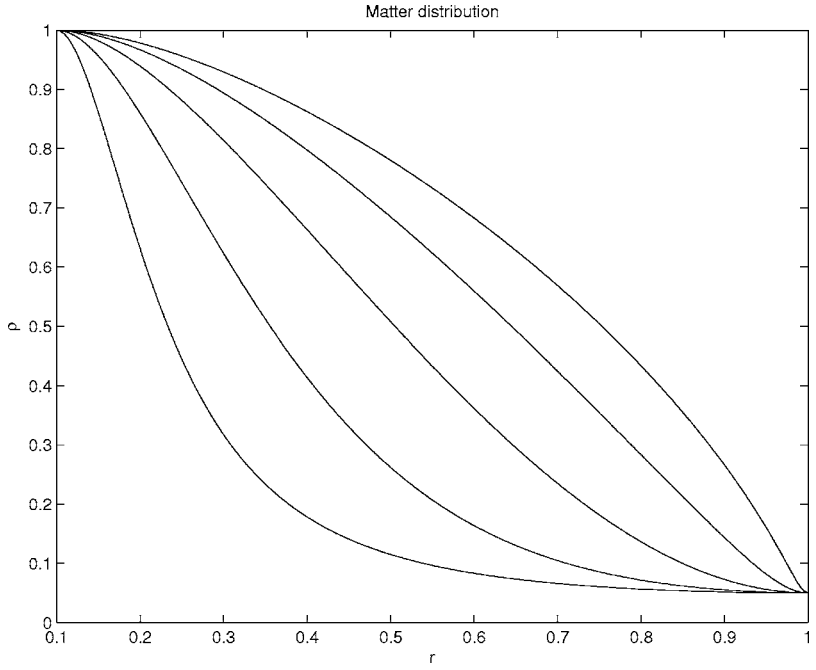

FIG. 3. Numerical solution of Eq. (2.26) with $h(\rho)=\rho^{\alpha}$ and $\alpha=-1,-0.5,0,0.5,1$. The lowest curve corresponds to $\alpha=-1$. The other curves correspond in progression to the other values of α.

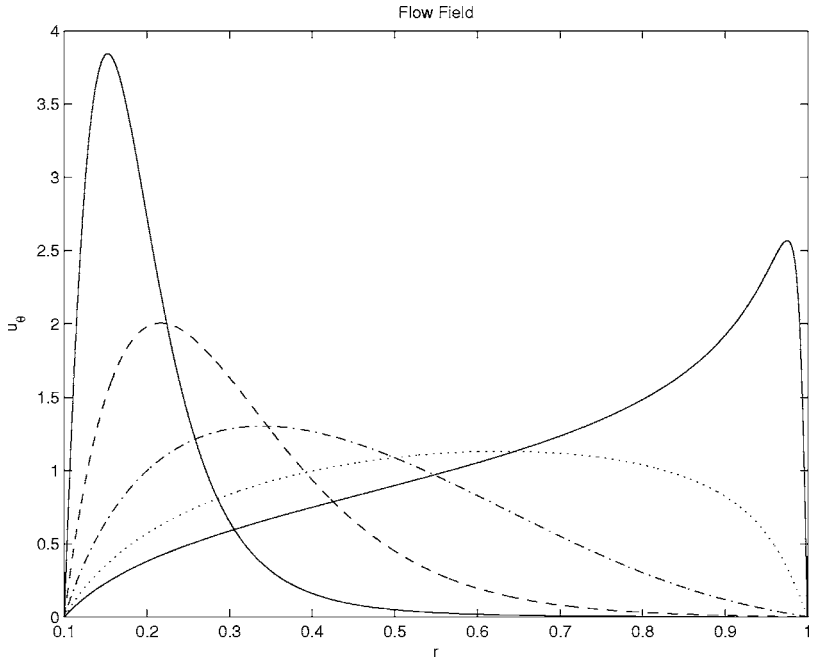

FIG. 4. u_θ as a function of r for the solutions presented in Fig. 3. The dashed, dash-dot and the dot-dot curves represent respectively u_θ for $\alpha=-0.5,0,0.5$. The solid line with a peak near the origin corresponds to $\alpha=-1$ while the other solid line corresponds to $\alpha=1$.

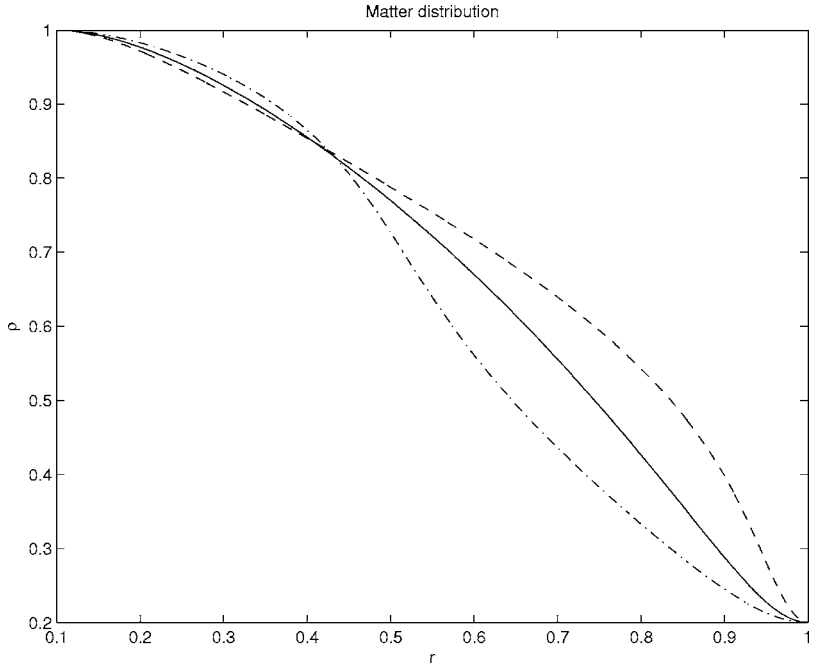

FIG. 5. Numerical solution of Eq. (2.26) with $h(\rho)=\rho(1+A\sin(n\pi\rho))$ with $n=2$. The dashed curve corresponds to $A=0.5$. The dash-dot curve corresponds to $A=-0.5$ and the solid one to $A=0$.

These solutions show that different choices of the parameter function $h(\rho)$ can lead to density profiles which contain out-of-core bands of matter whose density is higher than that of their surroundings. This is suggestive of the early stages of structure formation in these gas clouds. However this result might be sensitive to the choice of the function $h(\rho)$.

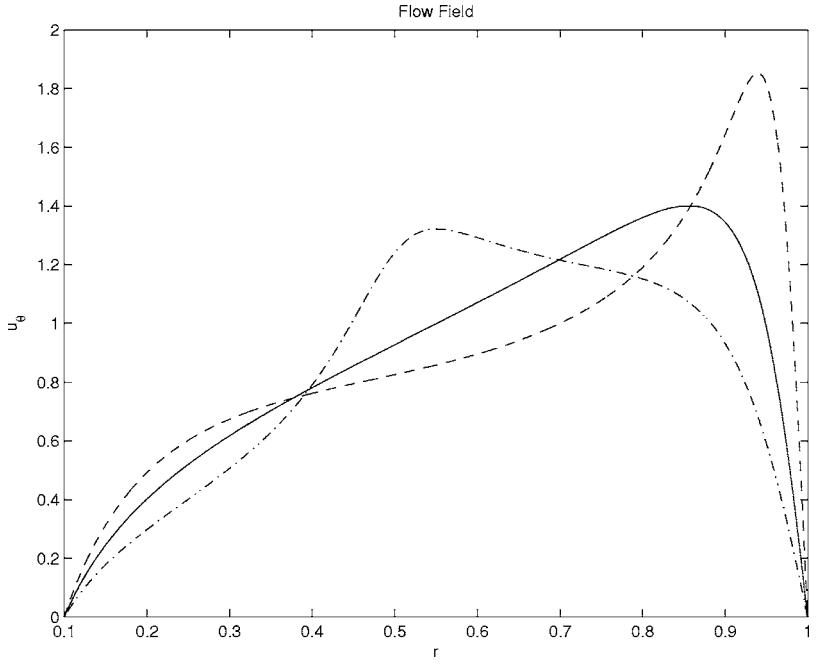

FIG. 6. u_θ as a function of r for the solutions presented in Fig. 5. The lines legend is the same as in Fig. 5.

A problem that our results raise but leave open is the determination of the general conditions on $h(\rho)$ which lead to a solution for ρ which is non-negative and oscillatory.

Particle-in-cell models for Stokes flow through a relatively homogeneous swarm of particles are of substantial practical interest, because they provide a relatively simple platform for the analytical or semianalytical solution of heat and mass transport problems. Despite the fact that many practical applications involve relatively small particles (inorganic, organic, biological) with axisymmetric shapes, the general consideration consists of rigid particles of arbitrary shape. The present work is concerned with some interesting aspects of the theoretical analysis of creeping flow in ellipsoidal, hence nonaxisymmetric domains. More specifically, the low Reynolds number flow of a swarm of ellipsoidal particles in an otherwise quiescent Newtonian fluid, that move with constant uniform velocity in an arbitrary direction and rotate with an arbitrary constant angular velocity, is analyzed with an ellipsoid-in-cell model. The solid internal ellipsoid represents a particle of the swarm. The external ellipsoid contains the ellipsoidal particle and the amount of fluid required to match the fluid volume fraction of the swarm. The nonslip flow condition on the surface of the solid ellipsoid is supplemented by the boundary conditions on the external ellipsoidal surface which are similar to those of the sphere-in-cell model of Happel (self-sufficient in mechanical energy). This model requires zero normal velocity component and shear stress. The boundary value problem is solved with the aim of the potential representation theory. In particular, the Papkovich–Neuber complete differential representation of Stokes flow, valid for nonaxisymmetric geometries, is considered here, which provides the velocity and total pressure fields in terms of harmonic ellipsoidal eigenfunctions. The flexibility of the particular representation is demonstrated by imposing some conditions, which made the calculations possible. It turns out that the velocity of first degree, which represents the leading term of the series, is sufficient for most engineering applications, so long as the aspect ratios of the ellipsoids remains within moderate bounds. Analytical expressions for the leading terms of the velocity, the total pressure, the angular velocity, and the stress tensor fields are obtained. Corresponding results for the prolate and the oblate spheroid, the needle and the disk, as well as for the sphere are recovered as degenerate cases. Novel relations concerning the ellipsoidal harmonics are included in the Appendix. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2345474]

I. INTRODUCTION

The behavior of systems involving the motion of aggregates of small particles relative to viscous fluids, in which they are immersed, covers a wide range of heat and mass transfer phe-

nomena of great importance in practical applications. In order to construct tractable mathematical models of the flow systems involving particles, it is necessary to resort to a number of simplifications. A dimensionless criterion, which determines the relative importance of inertial and viscous effects, is the Reynolds number.[1] The steady and creeping flow (low Reynolds number) of an incompressible, viscous fluid is described by the well-known Stokes equations which have been known for over one and a half centuries (1851) and connect the biharmonic vector velocity with the harmonic scalar pressure field.[1] For many interior and exterior flow problems involving small particles, spherical and spheroidal (either prolate or oblate) geometry[2] provides a very good approximation for many important applications where the flow is considered to be axisymmetric. Nevertheless, more realistic models include particles of arbitrary shape where it is impossible to take advantage of the symmetry and the orientation of the particle must be taken into account. Ellipsoidal geometry[2] provides the most widely used framework for representing small particles of arbitrary shape embedded within a fluid that flows according to Stokes law. This nonaxisymmetric flow is governed by the genuine three-dimensional (3D) ellipsoidal geometry.

The introduction of a stream function[1] serves to unify the method on all two-dimensional incompressible fluid motions, as we shall see in the historical comments that follow. For these situations, the solutions of the equations of motion are reduced to the search for a single scalar function. Unfortunately, in the general case of three-dimensional motions this unified method of approach is not possible. Of course, it should be noted here that fully 3D flow could also be represented by a *pair* of stream functions, in which case the streamlines are the intersections of the two families that correspond to the two stream functions. However, this causes a number of difficulties and the appearance of certain indeterminacies in the solution of physical problems forces us to look for more general approaches. In order to avoid such problems the introduction of three-dimensional representations[3] of the flow fields is necessary. This is probably due to the fact that these representations use more than one potential to represent the physical fields, allowing for more flexibility. Papkovich (1932) and Neuber (1934) proposed a differential representation of the flow fields in terms of harmonic functions.[3,4] Their representation holds true also for nonaxisymmetric problems and is derivable from the well-known Naghdi–Hsu solution.[5] Since the last one is proved to be complete,[3] the Papkovich–Neuber differential representation also forms a complete solution of Stokes equations.

One of the important areas of applications concern the construction of particle-in-cell models which are useful in the development of simple but reliable analytical expressions for heat and mass transfer in swarms of particles in the case of concentrated suspensions. In applied type analysis it is not usually necessary to have detailed solution of the flow field over the entire swarm of particles taking into account the exact positions of the particles, since such solutions are cumbersome to use. Thus, the technique of cell models is adopted where the mathematical treatment of each problem is based on the assumption that a three-dimensional assemblage may be considered to consist of a number of identical unit cells. Each of these cells contains a particle surrounded by a fluid envelope, containing a volume of fluid sufficient to make the fractional void volume in the cell identical to that in the entire assemblage.

Of course, a good approximation of the solution of flow through a swarm of particles is also possible with the help of powerful numerical methods, notably Stokesian dynamics[6] or lattice—Boltzmann simulation.[7] In addition, Refs. 8 and 9 provide an excellent exposure of numerical approaches for the solution of physical problems concerning ellipsoidal particles. However, these methods involve the use of elaborate computer codes for each case. There is always room and need for analytical methods, which capture the essential features of the transport process under consideration in an analytic formula. It is to this end that particle-in-cell flow models serve as platforms both for theoretical investigation and for checking the reliability of complicated numerical codes.

Uchida[10] proposed a cell model where a spherical particle is surrounded by a fluid envelope with cubic outer boundary. The cubic shape offers the advantage that it is space filling but the nature of the boundaries leads to a three-dimensional flow problem.

Happel[11] and Kuwabara[12] proposed cell models in which both the particle and the outer

envelope are spherical, having the significant advantage of preserving the axial symmetry of the flow and of providing a simple analytical solution in closed form. On the other hand, their models have the disadvantage that the outer envelope is not space filling, a difficulty that must be dealt with, when one tries to pass from the single unit cell to the assemblage of particles. The Happel and the Kuwabara formulations are slightly different in the sense that the Happel model assumes that the inner sphere moves with a constant velocity along the axis within a quiescent fluid, while the Kuwabara model assumes that the inner sphere is stationary and that the fluid passes through the unit cell with a constant velocity. Under the assumption of pseudosteady state, this difference effects the boundary conditions of each formulation. Hence, for the Happel model a nonslip flow condition in the inner sphere is imposed, and zero radial velocity and shear stress on the outer envelope. On the other hand, for the Kuwabara formulation the radial and the tangential velocity are assumed to be equal to zero on the inner sphere, while there exists a velocity with axial component equal to a constant approach velocity on the outer envelope. In addition, zero vorticity on the outer envelope is assumed. Despite the fact that both formulations give essentially the same velocity fields, with the appropriate change of frame of reference, it is the Happel model that is slightly superior. This is due to the fact that it does not require an exchange of mechanical energy between the cell and the environment. On the contrary, the Kuwabara model permits a small but significant exchange of mechanical energy with the environment.

Neale and Nader[13] improved the formulation of Happel and Kuwabara by considering that the unit cell under consideration is embedded in an unbounded, continuous, homogeneous, and isotropic permeable medium, which has the same permeability with that of the swarm of spheres. The Happel and the Kuwabara models also provide good agreement, but somewhat inferior to the Neale and Nader model.

Epstein and Masliyah[14] proposed a useful generalization by considering a spheroid-in-cell, instead of a sphere-in-cell, model for swarms of spheroidal particles. However, they had to solve the creeping flow problem numerically since the well-known equation of motion $E^4\psi=0$ (ψ: Stokes stream function) in spheroidal coordinates is not separable. This difficulty of nonseparation was resolved recently by Dassios *et al.*[15] with the use of semiseparation of solutions, which is based on an appropriate finite dimensional spectral decomposition of the operator E^4. This way an analytical solution for the Kuwabara model was obtained. Using this method, Dassios *et al.*[16] solved the Happel model in spheroidal coordinates analytically and the results were compared with those obtained by using the Kuwabara-type boundary conditions. Moreover, the problem of space filling, when we refer to the assemblage of particles as well as to the relation between the approach velocity and the mean interstitial velocity through the swarm, was discussed in detail in Ref. 16.

An indeterminacy appears when the Happel-type or the Kuwabara-type spheroidal models are solved in terms of the Stokes stream function. This indeterminacy does *not* appear in the case of a perfect sphere. The indeterminacy can be overcome through the imposition of an additional geometrical condition that secures the correct reduction to the perturbed-sphere case.[15,16] However, the introduction of the Papkovich–Neuber differential representation,[3,4] as we already mentioned, seems to offer certain advantages in solving such problems. More specific, despite the fact that a similar indeterminacy appears when the Papkovich–Neuber differential representation is used and it is handled in the same way, the degrees of freedom, which this representation offers,[17] make the Papkovich–Neuber solution a powerful tool. This representation was demonstrated recently by Dassios and Vafeas,[18] where the Kuwabara model is solved analytically in spheroidal domains and a comparison with the already solved flow problem with Kuwabara-type boundary conditions was made. The major advantage of the utilization of the Papkovich–Neuber differential representation is that it can be used to obtain solutions of creeping flow in cell models where the shape of the particles is genuine three-dimensional. Dassios and Vafeas[19] have demonstrated the practical efficiency of the above 3D representation by solving the three-dimensional Stokes flow problem in an assemblage of spherical particles, which translate and rotate, using Happel-type boundary conditions. The loss of symmetry is caused by the imposed rotation of the particles. The full solution is obtained in a closed form. The present work concerns the next step of our inves-

tigation where the sphere, that represents the isotropy, is replaced by a triaxial ellipsoid, which carries the complete anisotropy of the three-dimensional space.

The solution to the Stokes flow problem in an ellipsoid-in-cell with Happel-type boundary conditions is obtained here with the aim of the Papkovich–Neuber representation. The incentive for this is that the Happel-type boundary conditions are more compatible with the physics of the flow in a swarm, since they ensure that each unit cell is self-sufficient in mechanical energy. Under the assumption of very small Reynolds number and pseudosteady state, a three-dimensional Stokes flow in an ellipsoidal envelope of appropriate shape and dimensions is adopted as a fair approximation to the flow around a typical particle of the swarm, in accordance with the concept introduced by Happel.[11] The inner ellipsoid, which represents a particle in the assemblage, is solid, moves with a constant arbitrary velocity, and rotates arbitrarily with a constant angular velocity, whereas the outer ellipsoid represents a fictitious fluid envelope identifying the surface of a unit cell (ellipsoid-in-cell). The volume of the fluid cell is chosen so that the solid volume fraction in the cell coincides with the volume fraction of the swarm. The appropriate boundary conditions, resulting from these assumptions, are: nonslip flow on the inner ellipsoid, no normal flow, and zero tangential stresses on the outer ellipsoidal envelope.

In order to produce ready-to-use basic functions for Stokes flow in ellispoidal coordinates,[2] we calculate the Papkovich–Neuber eigensolutions, generated by the appropriate ellipsoidal eigenfunctions.[20,21] This way, we determine the flow fields as a full series expansion via the Papkovich–Neuber representation, which represents the velocity and the total pressure fields in terms of harmonic functions. The velocity, to the first degree, which represents the leading term of the series, is sufficient for most engineering applications and provides us, also, with the corresponding full 3D solution for the sphere given in Ref. 19 after a proper reduction. Besides, the first-order velocity field suits properly with the first-order nonslip flow condition on the surface of the ellipsoidal particle. Thus, this program offers us the opportunity to restrict to this appropriate degree of approximation. The application of the boundary conditions is accompanied by a set of extra conditions, which form the key to our work. They are based on the flexibility of the Papkovich–Neuber differential representation.[17] The imposition of these conditions is necessary in order to overcome certain difficulties caused by the geometry. Specifically, since we have two boundary surfaces to satisfy our conditions, we use twice the convenience that our representation offers[17] on each boundary. Hence, we adopt the so-called *techniques* mentioned during our analysis, as the result of the above-noted flexibility.

The whole analysis is based on the Lamé functions and the theory of ellipsoidal harmonics.[20,21] In fact, only harmonics of degree less than or equal to two are needed to obtain the velocity field of the first degree. Besides the velocity field, analytical expressions for the leading terms of the total pressure, the angular velocity, and the stress tensor fields are provided. Since the purely ellipsoidal expressions are not easy to handle, the results are given in the more tractable form where Cartesian coordinates are used for the interior harmonics plus the standard elliptic integrals that appear in the exterior Lamé products. Many relations involving the constants of the ellipsoidal harmonics as well as relations among the elliptic integrals had to be worked out in order to bring the result into its final form. The particular way the elliptic integrals are interconnected is provided in the Appendix, where one can also find useful relations that are used extensively and are necessary in order to transform from the Cartesian to the ellipsoidal system and vice versa. We must point out that our analytical method has been followed by the introduction of a new set of elliptic integrals, which do not differ from the aforementioned ones and which helped us to derive certain coefficients in a simple way as well as to overcome the difficulty of the corresponding boundary condition. Finally, the laborious task of reducing the results to the spheroidal and spherical geometry is included. The reduction of general results from the ellipsoidal to the spheroidal or spherical geometry is not a straightforward task because of the complicated indeterminacies that occur as the three semifocal distances of the ellipsoidal system approach zero. The only way to deal with these indeterminacies is to group appropriately the terms of the solution and to perform the algebraic manipulations, which eliminate the indeterminacies before the limiting process is applied.

Section II provides the mathematical formulation of the problem and Sec. III discusses the fundamentals of the ellipsoidal system and the eigenfunctions for the Papkovich–Neuber potentials in ellipsoidal coordinates. The Stokes flow fields are also provided as full series expansions and the boundary conditions are presented in the appropriate ellipsoidal shape. The Happel-type problem for an ellipsoid-in-cell model is solved explicitly in Sec. IV where the results are presented in a manageable Cartesian-ellipsoidal form. Section V is dedicated to the reduction of our expressions to the corresponding prolate–oblate spheroidal (including their limiting cases) and spherical ones. Section VI is devoted to a discussion of the obtained results. The necessary material from the theory of ellipsoidal harmonics as well as some useful formulas associated with ellipsoidal functions is collected in the Appendix. These formulas are the key identities of the present work.

II. MATHEMATICAL DEVELOPMENT

Under the assumption of pseudosteady, nonaxisymmetric, creeping flow (Reynolds number $\mathrm{Re} \ll 1$) which characterizes Stokes flow,[1] the governing equations of motion for an incompressible, viscous fluid in smooth, bounded domain $\Omega(\mathbb{R}^3)$, with dynamic viscosity μ_0 and mass density ρ_0, are a pair of partial differential equations connecting the biharmonic velocity field $\mathbf{v}$ with the harmonic total pressure field P,

$$\mu_0 \Delta \mathbf{v}(\mathbf{r}) = \nabla P(\mathbf{r}), \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{1}$$

$$\nabla \cdot \mathbf{v}(\mathbf{r}) = 0, \quad \mathbf{r} \in \Omega(\mathbb{R}^3). \tag{2}$$

Equation (1) states that, in creeping flow, the viscous force compensates for the force caused by the pressure gradient on any material point of the fluid, while Eq. (2) secures the incompressibility of the fluid. Once the velocity field is obtained, the harmonic vorticity field $\boldsymbol{\omega}$ is defined as

$$\boldsymbol{\omega}(\mathbf{r}) = \tfrac{1}{2} \nabla \times \mathbf{v}(\mathbf{r}), \quad \mathbf{r} \in \Omega(\mathbb{R}^3). \tag{3}$$

Papkovich–Neuber[3,4] proposed the following differential representation of the solution for Stokes flow, in terms of the harmonic potentials $\boldsymbol{\Phi}$ and Φ_0,

$$\mathbf{v}(\mathbf{r}) = \boldsymbol{\Phi}(\mathbf{r}) - \tfrac{1}{2} \nabla (\mathbf{r} \cdot \boldsymbol{\Phi}(\mathbf{r}) + \Phi_0(\mathbf{r})), \quad \mathbf{r} \in \Omega(\mathbb{R}^3) \tag{4}$$

and

$$P(\mathbf{r}) = P_0 - \mu_0 \nabla \cdot \boldsymbol{\Phi}(\mathbf{r}), \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{5}$$

whereas P_0 is a constant pressure of reference usually assigned at a convenient point. The potential functions $\boldsymbol{\Phi}$ and Φ_0 solve the equations

$$\Delta \boldsymbol{\Phi}(\mathbf{r}) = \mathbf{0}, \quad \Delta \Phi_0 = 0, \quad \mathbf{r} \in \Omega(\mathbb{R}^3). \tag{6}$$

If we define the thermodynamic pressure p, then the following relation gives the total pressure as a function of the thermodynamic pressure

$$P(\mathbf{r}) = p(\mathbf{r}) + \rho_0 g h, \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{7}$$

where the contribution of the term $\rho_0 g h$ (g is the acceleration of the gravity) refers to the gravitational pressure force, corresponding to a height of reference h.

The stress dyadic $\tilde{\boldsymbol{\Pi}}$ is defined as follows:

$$\tilde{\boldsymbol{\Pi}}(\mathbf{r}) = -p(\mathbf{r}) \tilde{\mathbf{I}} + \mu_0 [\nabla \otimes \mathbf{v}(\mathbf{r}) + (\nabla \otimes \mathbf{v}(\mathbf{r}))^{\mathsf{T}}], \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{8}$$

where $\tilde{\mathbf{I}}$ stands for the unit dyadic and the symbol "T" denotes transposition.

The Happel-type boundary conditions for a general 3D particle-in-cell model. By means of

Ref. 1, we consider a fluid–particle system consisting of any finite number of rigid particles of arbitrary shape. Introducing the particle-in-cell model, we examine the Stokes flow of one of the assemblage of particles neglecting the interaction with other particles or with the bounded walls of a container. Let S_i denote the surface of the particle of the swarm, which is solid, is moving with a constant translational velocity $\mathbf{U}$ in an arbitrary direction (the relation between the velocity $\mathbf{U}$ and the mean interstitial velocity through a swarm of spheroidal particles was discussed in Ref. 16 and is rotating, also arbitrarily, with a constant angular velocity $\mathbf{\Omega}$. It lives within an otherwise quiescent fluid layer, which is confined by the outer surface denoted by S_o. Following the formulation of Happel,[11] the velocity component normal to S_o and the tangential stresses are assumed to vanish on S_o. These boundary conditions are supplemented by the necessary nonslip flow conditions on the surface of the particle. Thus, the general BCs for a three-dimensional consideration of the Happel-type boundary value problem are:

$$\text{BC(1)}: \quad \mathbf{v}(\mathbf{r}) = \mathbf{U} + \mathbf{\Omega} \times \mathbf{r} \quad \text{for } \mathbf{r} \in S_i, \tag{9}$$

$$\text{BC(2)}: \quad \hat{\mathbf{n}} \cdot \mathbf{v}(\mathbf{r}) = 0 \quad \text{for } \mathbf{r} \in S_o, \tag{10}$$

$$\text{BC(3)}: \quad \hat{\mathbf{n}} \cdot \tilde{\mathbf{\Pi}}(\mathbf{r}) \cdot (\tilde{\mathbf{I}} - \hat{\mathbf{n}} \otimes \hat{\mathbf{n}}) = \mathbf{0} \quad \text{for } \mathbf{r} \in S_o, \tag{11}$$

where $\hat{\mathbf{n}}$ is the outer unit normal vector. Equations (1)–(11) define a well-posed Happel-type boundary value problem for 3D domains, $\mathbf{r} \in \Omega(\mathbb{R}^3)$, bounded by two arbitrary surfaces S_i and S_o.

Our goal is to solve the above-noted Happel problem with the appropriate boundary conditions given by Eqs. (9)–(11), with the aim of the Papkovich–Neuber differential representation using the ellipsoidal system, which represents the most general geometrical system, which is orthogonal and embodies the complete anisotropy of the three-dimensional space.

III. ELLIPSOIDAL GEOMETRY: FLOW FIELDS AND BOUNDARY CONDITIONS

The basic triaxial ellipsoid is defined by

$$\frac{x_1^2}{\alpha_1^2} + \frac{x_2^2}{\alpha_2^2} + \frac{x_3^2}{\alpha_3^2} = 1, \tag{12}$$

where $0 < \alpha_3 < \alpha_2 < \alpha_1 < +\infty$ are its semiaxes. The three positive numbers h_1, h_2, and h_3, which denote the semifocal distances of the system, are given by

$$h_1^2 = \alpha_2^2 - \alpha_3^2, \quad h_2^2 = \alpha_1^2 - \alpha_3^2, \quad h_3^2 = \alpha_1^2 - \alpha_2^2 = h_2^2 - h_1^2. \tag{13}$$

Define the system of ellipsoidal coordinates (ρ, μ, ν),[2,20] which are connected to the Cartesian ones (x_1, x_2, x_3), via

$$x_1 = \frac{\rho\mu\nu}{h_2 h_3}, \tag{14}$$

$$x_2 = \frac{\sqrt{\rho^2 - h_3^2}\sqrt{\mu^2 - h_3^2}\sqrt{h_3^2 - \nu^2}}{h_1 h_3}, \tag{15}$$

$$x_3 = \frac{\sqrt{\rho^2 - h_2^2}\sqrt{h_2^2 - \mu^2}\sqrt{h_2^2 - \nu^2}}{h_1 h_2}. \tag{16}$$

The three families of second-degree surfaces, which are shown in Fig. 1, share the same set of foci at the points $\pm h_1$, $\pm h_2$, and $\pm h_3$.

In terms of the position vector $\mathbf{r} = x_1\hat{\mathbf{x}}_1 + x_2\hat{\mathbf{x}}_2 + x_3\hat{\mathbf{x}}_3$ expressed via the Cartesian basis $\hat{\mathbf{x}}_\kappa$, $\kappa = 1, 2, 3$, the variable ρ, $h_2 \leqslant \rho < +\infty$ specifies the ellipsoid

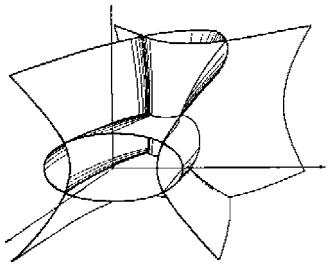

FIG. 1. Ellipsoidal geometry and coordinate surfaces.

$$\frac{x_1^2}{\rho^2}+\frac{x_2^2}{\rho^2-h_3^2}+\frac{x_3^2}{\rho^2-h_2^2}=\sum_{i=1}^{3}\frac{x_i^2}{\rho^2-\alpha_1^2+\alpha_i^2}=\mathbf{r}\cdot\sum_{i=1}^{3}\frac{\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_i}{\rho^2-\alpha_1^2+\alpha_i^2}\cdot\mathbf{r}=1, \tag{17}$$

the variable μ, $h_3\leqslant\mu\leqslant h_2$ specifies the hyperboloid of one sheet

$$\frac{x_1^2}{\mu^2}+\frac{x_2^2}{\mu^2-h_3^2}-\frac{x_3^2}{h_2^2-\mu^2}=\sum_{i=1}^{3}\frac{x_i^2}{\mu^2-\alpha_1^2+\alpha_i^2}=1 \tag{18}$$

and the variable ν, $-h_3\leqslant\nu\leqslant h_3$ specifies the hyperboloid of two sheets

$$\frac{x_1^2}{\nu^2}-\frac{x_2^2}{h_3^2-\nu^2}-\frac{x_3^2}{h_2^2-\nu^2}=\sum_{i=1}^{3}\frac{x_i^2}{\nu^2-\alpha_1^2+\alpha_i^2}=1. \tag{19}$$

In the limit as the semifocal distances tend to zero ($h_1=h_2=h_3\to 0$), our system degenerates to the corresponding spherical one with radial component r given by

$$\|\mathbf{r}\|=\sqrt{\rho^2+\mu^2+\nu^2-(h_2^2+h_3^2)}\to r,\quad 0\leqslant r<+\infty. \tag{20}$$

In terms of the metric coefficients of the system

$$h_\rho=\frac{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}},\quad h_\mu=\frac{\sqrt{\rho^2-\mu^2}\sqrt{\mu^2-\nu^2}}{\sqrt{\mu^2-h_3^2}\sqrt{h_2^2-\mu^2}},\quad h_\nu=\frac{\sqrt{\rho^2-\nu^2}\sqrt{\mu^2-\nu^2}}{\sqrt{h_3^2-\nu^2}\sqrt{h_2^2-\nu^2}}, \tag{21}$$

the Jacobian determinant is $J=h_\rho h_\mu h_\nu$ and the differential operators ∇, Δ, assume the forms

$$\nabla=\sum_{i=1}^{3}\hat{\mathbf{x}}_i\frac{\partial}{\partial x_i}=\frac{\hat{\boldsymbol{\rho}}}{h_\rho}\frac{\partial}{\partial\rho}+\frac{\hat{\boldsymbol{\mu}}}{h_\mu}\frac{\partial}{\partial\mu}+\frac{\hat{\boldsymbol{\nu}}}{h_\nu}\frac{\partial}{\partial\nu} \tag{22}$$

and

$$\Delta=\sum_{i=1}^{3}\frac{\partial^2}{\partial x_i^2}=\frac{1}{J}\left\{\frac{\partial}{\partial\rho}\left[\frac{J}{h_\rho^2}\frac{\partial}{\partial\rho}\right]+\frac{\partial}{\partial\mu}\left[\frac{J}{h_\mu^2}\frac{\partial}{\partial\mu}\right]+\frac{\partial}{\partial\nu}\left[\frac{J}{h_\nu^2}\frac{\partial}{\partial\nu}\right]\right\}, \tag{23}$$

where $\hat{\boldsymbol{\rho}},\hat{\boldsymbol{\mu}},\hat{\boldsymbol{\nu}}$ denote the orthonormal coordinate vectors of the system, i.e.,

$$\hat{\boldsymbol{\rho}}=\frac{\rho}{h_\rho}\sum_{i=1}^{3}\frac{x_i\hat{\mathbf{x}}_i}{\rho^2-\alpha_1^2+\alpha_i^2},\quad \hat{\boldsymbol{\mu}}=\frac{\mu}{h_\mu}\sum_{i=1}^{3}\frac{x_i\hat{\mathbf{x}}_i}{\mu^2-\alpha_1^2+\alpha_i^2},\quad \hat{\boldsymbol{\nu}}=\frac{\nu}{h_\nu}\sum_{i=1}^{3}\frac{x_i\hat{\mathbf{x}}_i}{\nu^2-\alpha_1^2+\alpha_i^2}. \tag{24}$$

The outward unit normal vector on the surface of the ellipsoid $\rho=$const coincides with the unit normal vector $\hat{\boldsymbol{\rho}}$, thus

$$\hat{\mathbf{n}}(\mathbf{r}) = \frac{\rho}{h_\rho}\left[\frac{x_1\hat{\mathbf{x}}_1}{\rho^2} + \frac{x_2\hat{\mathbf{x}}_2}{\rho^2 - h_3^2} + \frac{x_3\hat{\mathbf{x}}_3}{\rho^2 - h_2^2}\right] = \frac{\rho}{h_\rho}\sum_{i=1}^{3}\frac{\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i}{\rho^2 - \alpha_1^2 + \alpha_i^2}\cdot\mathbf{r} \equiv \hat{\boldsymbol{\rho}}, \tag{25}$$

while the unit dyadic assumes the ellipsoidal form

$$\tilde{\mathbf{I}} = \sum_{i=1}^{3}\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i = \hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\rho}} + \hat{\boldsymbol{\mu}} \otimes \hat{\boldsymbol{\mu}} + \hat{\boldsymbol{\nu}} \otimes \hat{\boldsymbol{\nu}}. \tag{26}$$

From now on we shall refer to ellipsoidal domains, in terms of which

$$\Omega(\mathbb{R}^3) \equiv \mathbb{R}^3 = \{(\rho,\mu,\nu):\rho \in [h_2, +\infty), \mu \in [h_3,h_2], \nu \in [-h_3,h_3]\}. \tag{27}$$

In order to construct the flow fields (3)–(5) and (8) in an appropriate form for the application of the boundary conditions (9)–(11), we need to represent the harmonic potentials $\mathbf{\Phi}$ and Φ_0 in this system by solving the corresponding Laplace's equations (6) in spectral form. This procedure leads to the Lamé equation[20]

$$(x^2 - h_3^2)(x^2 - h_2^2)E''(x) + x(2x^2 - h_3^2 - h_2^2)E'(x) + (Ax^2 + B)E(x) = 0, \tag{28}$$

for each one of the factors $E(\rho)$, $E(\mu)$, and $E(\nu)$ within the corresponding intervals $\rho \in [h_2, +\infty)$, $\mu \in [h_3,h_2]$, and $\nu \in [-h_3,h_3]$, where $A,B \in \mathbb{R}$ are constants. For each $n=0,1,\ldots$, which corresponds to the degree of the Lamé equation, and for each $m=1,2,\ldots,2n+1$, which stands for its order, Eq. (28) has two linearly independent solutions. The first one, E_n^m, is regular at the origin and it is known as the Lamé function of the first kind (interior solution), while the second one, F_n^m, is regular at infinity and gives the Lamé function of the second kind (exterior solution). In particular, the interior solution $E_n^m(\rho)$ is related to the exterior solution $F_n^m(\rho)$ via

$$F_n^m(\rho) = (2n+1)E_n^m(\rho)I_n^m(\rho), \quad \rho \in [h_2, +\infty), \tag{29}$$

where the elliptic integrals I_n^m are given by

$$I_n^m(\rho) = \int_\rho^{+\infty}\frac{\mathrm{d}u}{[E_n^m(u)]^2\sqrt{u^2 - h_2^2}\sqrt{u^2 - h_3^2}}, \quad \rho \in [h_2, +\infty) \tag{30}$$

for every value of $n=0,1,\ldots$ and $m=1,2,\ldots,2n+1$. In terms of the Lamé functions of the first and of the second kind, the Lamé products

$$\mathbb{E}_n^m(\mathbf{r}) = E_n^m(\rho)E_n^m(\mu)E_n^m(\nu), \quad n = 0,1,\ldots, \quad m = 1,2,\ldots,2n+1, \quad \mathbf{r} \in \Omega(\mathbb{R}^3) \tag{31}$$

define the interior solid ellipsoidal harmonics, while the products

$$\mathbb{F}_n^m(\mathbf{r}) = F_n^m(\rho)E_n^m(\mu)E_n^m(\nu), \quad n = 0,1,\ldots, \quad m = 1,2,\ldots,2n+1, \quad \mathbf{r} \in \Omega(\mathbb{R}^3) \tag{32}$$

define the exterior solid ellipsoidal harmonics. On the other hand, the complete orthogonal set $E_n^m(\mu)E_n^m(\nu)$ form the surface ellipsoidal harmonics on the surface of any ellipsoid $\rho=\rho_s$, which, with respect to the weighting function

$$l_{\rho_s}(\mu,\nu) = \frac{1}{\sqrt{(\rho_s^2 - \mu^2)(\rho_s^2 - \nu^2)}}, \quad \mu \in [h_3,h_2], \quad \nu \in [-h_3,h_3], \tag{33}$$

satisfy the orthogonality relation

$$\int\int_{\rho=\rho_s} E_n^m(\mu)E_n^m(\nu)E_{n'}^{m'}(\mu)E_{n'}^{m'}(\nu)l_{\rho_s}(\mu,\nu)\mathrm{d}S = \gamma_n^m\delta_{nn'}\delta_{mm'}, \tag{34}$$

for every $n,n'=0,1,\ldots$ and $m,m'=1,2,\ldots,2n+1$. Here, $\delta_{nn'}$ denotes the Kronecker delta function, whilst γ_n^m are the ellipsoidal normalization constants given by

$$\gamma_n^m = \int\int_{\rho=\rho_s} (E_n^m(\mu)E_n^m(\nu))^2 l_{\rho_s}(\mu,\nu)\mathrm{d}S, \quad n=0,1,\ldots, \quad m=1,2,\ldots,2n+1. \tag{35}$$

According to the aforementioned analysis of ellipsoidal harmonic functions, the complete representation of the Papkovich–Neuber potentials $\mathbf{\Phi}$ and Φ_0, which belong to the kernel space of Δ, assume the expressions

$$\mathbf{\Phi}(\mathbf{r}) = \sum_{n=0}^{\infty}\sum_{m=1}^{2n+1} [\mathbf{e}_n^{(i)m}\mathbb{E}_n^m(\mathbf{r}) + \mathbf{e}_n^{(e)m}\mathbb{F}_n^m(\mathbf{r})], \quad \mathbf{r}\in\Omega(\mathbb{R}^3) \tag{36}$$

and

$$\Phi_0(\mathbf{r}) = \sum_{n=0}^{\infty}\sum_{m=1}^{2n+1} [d_n^{(i)m}\mathbb{E}_n^m(\mathbf{r}) + d_n^{(e)m}\mathbb{F}_n^m(\mathbf{r})], \quad \mathbf{r}\in\Omega(\mathbb{R}^3). \tag{37}$$

Note that, for $n\geqslant 0$, the coefficients

$$\mathbf{e}_n^{(i/e)m} = a_n^{(i/e)m}\hat{\mathbf{x}}_1 + b_n^{(i/e)m}\hat{\mathbf{x}}_2 + c_n^{(i/e)m}\hat{\mathbf{x}}_3, \quad d_n^{(i/e)m}, \quad m=1,2,\ldots,2n+1 \tag{38}$$

denote the vector and the scalar coefficients of the harmonic potentials $\mathbf{\Phi}$ and Φ_0, respectively.

Let u, v and $\mathbf{f}$, $\mathbf{g}$ denote two scalar and two vector fields, respectively. Then, if we define by $\widetilde{\mathbb{S}}$ a dyadic, the basic identities that we are using in the sequel concern the action of the gradient operator on the following expressions, i.e.,

$$\nabla\otimes(u\mathbf{f}) = u\nabla\otimes\mathbf{f} + \nabla u\otimes\mathbf{f}, \tag{39}$$

$$\nabla\cdot(u\mathbf{f}) = u\nabla\cdot\mathbf{f} + \nabla u\cdot\mathbf{f}, \tag{40}$$

$$\nabla\times(u\mathbf{f}) = u\nabla\times\mathbf{f} + \nabla u\times\mathbf{f}, \tag{41}$$

$$\nabla(\mathbf{f}\cdot\mathbf{g}) = (\nabla\otimes\mathbf{f})\cdot\mathbf{g} + (\nabla\otimes\mathbf{g})\cdot\mathbf{f}, \tag{42}$$

$$\nabla(uv) = u\nabla v + v\nabla u, \tag{43}$$

$$\nabla\otimes(\widetilde{\mathbb{S}}\cdot\mathbf{f}) = (\nabla\otimes\widetilde{\mathbb{S}})\cdot\mathbf{f} + (\nabla\otimes\mathbf{f})\cdot\widetilde{\mathbb{S}}^{\mathrm{T}}, \tag{44}$$

$$\nabla\otimes(\mathbf{f}\otimes\mathbf{g}) = (\nabla\otimes\mathbf{f})\otimes\mathbf{g} + [\mathbf{f}\otimes(\nabla\otimes\mathbf{g})]^{213}, \tag{45}$$

whereas $\widetilde{\mathbb{S}}^{\mathrm{T}}$ is the inverted dyadic and the symbol $(\,)^{213}$ denotes left transposition for a triadic. Inserting the potentials (36) and (37) in the flow fields (4), (5), (3), (8) and making use of the above identities (39)–(45), we derive the relation

$$\begin{aligned}\mathbf{v}(\mathbf{r}) = \frac{1}{2}\sum_{n=0}^{\infty}\sum_{m=1}^{2n+1} \{&\mathbf{e}_n^{(i)m}\mathbb{E}_n^m(\mathbf{r}) \\ &- [(\mathbf{e}_n^{(i)m}\cdot\mathbf{r}) + d_n^{(i)m}]\nabla\mathbb{E}_n^m(\mathbf{r}) + \mathbf{e}_n^{(e)m}\mathbb{F}_n^m(\mathbf{r}) - [(\mathbf{e}_n^{(e)m}\cdot\mathbf{r}) + d_n^{(e)m}]\nabla\mathbb{F}_n^m(\mathbf{r})\}, \quad \mathbf{r}\in\Omega(\mathbb{R}^3)\end{aligned} \tag{46}$$

for the velocity field, while for the total pressure field, taking into account relation (7), we obtain

$$P(\mathbf{r}) = P_0 - \mu_0 \sum_{n=0}^{\infty} \sum_{m=1}^{2n+1} \{\mathbf{e}_n^{(i)m} \cdot \nabla \mathbb{E}_n^m(\mathbf{r}) + \mathbf{e}_n^{(e)m} \cdot \nabla \mathbb{F}_n^m(\mathbf{r})\} = p(\mathbf{r}) + \rho_0 g h, \tag{47}$$

for every $\mathbf{r} \in \Omega(\mathbb{R}^3)$. The vorticity field is then written as

$$\boldsymbol{\omega}(\mathbf{r}) = \frac{1}{2} \sum_{n=0}^{\infty} \sum_{m=1}^{2n+1} \{\nabla \mathbb{E}_n^m(\mathbf{r}) \times \mathbf{e}_n^{(i)m} + \nabla \mathbb{F}_n^m(\mathbf{r}) \times \mathbf{e}_n^{(e)m}\}, \quad \mathbf{r} \in \Omega(\mathbb{R}^3) \tag{48}$$

and the stress tensor field is expressed as

$$\widetilde{\mathbf{\Pi}}(\mathbf{r}) = -p(\mathbf{r})\widetilde{\mathbf{I}} - \mu_0 \sum_{n=0}^{\infty} \sum_{m=1}^{2n+1} \{[(\mathbf{e}_n^{(i)m} \cdot \mathbf{r}) + d_n^{(i)m}] \nabla \otimes \nabla \mathbb{E}_n^m(\mathbf{r}) + [(\mathbf{e}_n^{(e)m} \cdot \mathbf{r}) + d_n^{(e)m}] \nabla \otimes \nabla \mathbb{F}_n^m(\mathbf{r})\},$$
$$\mathbf{r} \in \Omega(\mathbb{R}^3). \tag{49}$$

The coefficients $\mathbf{e}_n^{(i)m}$, $\mathbf{e}_n^{(e)m}$, $d_n^{(i)m}$, and $d_n^{(e)m}$ for $n=0,1,\ldots$ and $m=1,2,\ldots,2n+1$ are to be determined from the boundary conditions (9)–(11), which also have to be expressed in ellipsoidal form. In accordance with the Happel formulation,[11] two confocal ellipsoids are considered. The inner one, indicated by S_a, at $\rho=\rho_a$ with semiaxes ρ_a, $\sqrt{\rho_a^2-h_3^2}$ and $\sqrt{\rho_a^2-h_2^2}$ is solid, it is moving with a constant translational velocity $\mathbf{U}$ in an arbitrary direction and is rotating arbitrarily with a constant angular velocity $\mathbf{\Omega}$, given by

$$\mathbf{U} = \sum_{i=1}^{3} U_i \hat{\mathbf{x}}_i, \quad \mathbf{\Omega} = \sum_{i=1}^{3} \Omega_i \hat{\mathbf{x}}_i, \tag{50}$$

where U_i and Ω_i, $i=1,2,3$ are the components at the Cartesian orthogonal basis. The outer ellipsoid indicated by S_b at $\rho=\rho_b$ with semiaxes ρ_b, $\sqrt{\rho_b^2-h_3^2}$ and $\sqrt{\rho_b^2-h_2^2}$ defines the quiescent fluid layer. Thus, the boundary conditions (9)–(11) are rewritten as follows:

$$\text{BC(1):} \quad \mathbf{v}(\mathbf{r}) = \mathbf{U} + \mathbf{\Omega} \times \mathbf{r} \quad \text{for } \mathbf{r} \in S_a, \tag{51}$$

$$\text{BC(2):} \quad \hat{\boldsymbol{\rho}} \cdot \mathbf{v}(\mathbf{r}) = 0 \quad \text{for } \mathbf{r} \in S_b, \tag{52}$$

$$\text{BC(3):} \quad \hat{\boldsymbol{\rho}} \cdot \widetilde{\mathbf{\Pi}}(\mathbf{r}) \cdot (\widetilde{\mathbf{I}} - \hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\rho}}) = \mathbf{0} \quad \text{for } \mathbf{r} \in S_b, \tag{53}$$

where $\hat{\boldsymbol{\rho}}$ is the unit curvilinear vector relative to the variable ρ. These BCs must be applied to Eqs. (46) and (49) in order to calculate the coefficients and obtain the flow fields (46)–(49). Note that the domain $\Omega(\mathbb{R}^3)$ (27) is specified by the variable ρ that varies in the interval $[\rho_a, \rho_b]$.

IV. SOLUTION OF THE 3D HAPPEL-TYPE ELLIPSOID-IN-CELL MODEL

The purpose of this section is to solve the 3D Stokes ellipsoid-in-cell model with the Happel-type BCs (51)–(53). In our related work, for the corresponding complete isotropic Stokes flow,[19] the solution was obtained by using the full series representation for the velocity, the total pressure, the vorticity, and the stress tensor. Unfortunately, this is not possible when the present complex ellipsoidal geometry is used. The reason is that, although the form of ellipsoidal harmonics is known, the analytical expressions of those harmonics in terms of the semiaxes $\alpha_1, \alpha_2, \alpha_3$ are manageable only for degree $n \leqslant 3$. This difficulty restricts the analytical solutions of related physical problems to the 16th-dimensional harmonic subspace spanned by the harmonics of degree less than or equal to three for $m=1,2,\ldots,2n+1$.[20] The interior Lamé functions of degree less than or equal to 3 are given by

$$E_0^1(x) = 1, \tag{54}$$

$$E_1^{\kappa}(x) = \sqrt{|x^2 - \alpha_1^2 + \alpha_{\kappa}^2|}, \quad \kappa = 1,2,3, \tag{55}$$

$$E_2^1(x) = x^2 - \alpha_1^2 + \Lambda, \tag{56}$$

$$E_2^2(x) = x^2 - \alpha_1^2 + \Lambda', \tag{57}$$

$$E_2^{6-\kappa}(x) = \frac{x\sqrt{|x^2 - h_3^2|}\sqrt{|x^2 - h_2^2|}}{\sqrt{|x^2 - \alpha_1^2 + \alpha_{\kappa}^2|}}, \quad \kappa = 1,2,3 \tag{58}$$

or in terms of the semiaxes,

$$E_2^{\kappa+l}(x) = \sqrt{|x^2 - \alpha_1^2 + \alpha_{\kappa}^2|}\sqrt{|x^2 - \alpha_1^2 + \alpha_l^2|}, \quad \kappa,l = 1,2,3, \quad \kappa \neq l \tag{59}$$

and

$$E_3^{2\kappa-1}(x) = \sqrt{|x^2 - \alpha_1^2 + \alpha_{\kappa}^2|}(x^2 - \alpha_1^2 + \Lambda_{\kappa}), \quad \kappa = 1,2,3, \tag{60}$$

$$E_3^{2\kappa}(x) = \sqrt{|x^2 - \alpha_1^2 + \alpha_{\kappa}^2|}(x^2 - \alpha_1^2 + \Lambda'_{\kappa}), \quad \kappa = 1,2,3, \tag{61}$$

$$E_3^7(x) = x\sqrt{|x^2 - h_3^2|}\sqrt{|x^2 - h_2^2|}, \tag{62}$$

where the variable x represents the values of $\rho \in [h_2, +\infty)$, $\mu \in [h_3, h_2]$, $\nu \in [-h_3, h_3]$, the constants

$$\left.\begin{matrix}\Lambda \\ \Lambda'\end{matrix}\right\} = \frac{1}{3}\sum_{i=1}^{3} \alpha_i^2 \pm \frac{1}{3}\left[\sum_{i=1}^{3}\left(\alpha_i^4 - \frac{\alpha_1^2\alpha_2^2\alpha_3^2}{\alpha_i^2}\right)\right]^{1/2} \tag{63}$$

satisfy the quadratic equation

$$\sum_{i=1}^{3} \frac{1}{\Lambda - \alpha_i^2} = 0, \tag{64}$$

and the constants

$$\left.\begin{matrix}\Lambda_{\kappa} \\ \Lambda'_{\kappa}\end{matrix}\right\} = \frac{2}{5}\sum_{i=1}^{3} \alpha_i^2 - \frac{1}{5}\alpha_{\kappa}^2 \pm \frac{1}{5}\left\{4\sum_{i=1}^{3} \alpha_i^4 - 3\alpha_{\kappa}^4 - \alpha_1^2\alpha_2^2\alpha_3^2\left(\sum_{i=1}^{3} \frac{1}{\alpha_i^2} + \frac{6}{\alpha_{\kappa}^2}\right)\right\}^{1/2} \tag{65}$$

for $\kappa = 1,2,3$ satisfy the relations

$$\sum_{i=1}^{3} \frac{1 + 2\delta_{i\kappa}}{(\Lambda_{\kappa} - \alpha_i^2)} = 0, \quad \kappa = 1,2,3. \tag{66}$$

The Cartesian representation of the ellipsoidal harmonics are given by

$$\mathbb{E}_0^1(\mathbf{r}) = 1, \tag{67}$$

$$\mathbb{E}_1^{\kappa}(\mathbf{r}) = \frac{h_1h_2h_3}{h_{\kappa}}x_{\kappa}, \quad \kappa = 1,2,3, \tag{68}$$

$$\mathbb{E}_2^1(\mathbf{r}) = (\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2)\left[\sum_{i=1}^{3} \frac{x_i^2}{\Lambda - \alpha_i^2} + 1\right] \equiv \mathbb{E}_2^1(\Lambda), \tag{69}$$

$$\mathbb{E}_2^2(\mathbf{r}) = \mathbb{E}_2^1(\Lambda'), \tag{70}$$

$$\mathbb{E}_2^{6-\kappa}(\mathbf{r}) = h_1 h_2 h_3 h_\kappa \frac{x_1 x_2 x_3}{x_\kappa}, \quad \kappa = 1,2,3 \tag{71}$$

or equivalently,

$$\mathbb{E}_2^{\kappa+l}(\mathbf{r}) = \frac{h_1^2 h_2^2 h_3^2}{h_\kappa h_l} x_\kappa x_l, \quad \kappa,l = 1,2,3, \quad \kappa \neq l \tag{72}$$

and

$$\mathbb{E}_3^{2\kappa-1}(\mathbf{r}) = h_1 h_2 h_3 (\Lambda_\kappa - \alpha_1^2)(\Lambda_\kappa - \alpha_2^2)(\Lambda_\kappa - \alpha_3^2) \frac{x_\kappa}{h_\kappa} \left[\sum_{i=1}^{3} \frac{x_i^2}{\Lambda_\kappa - \alpha_i^2} + 1 \right] \equiv \mathbb{E}_3^{2\kappa-1}(\Lambda_\kappa), \quad \kappa = 1,2,3, \tag{73}$$

$$\mathbb{E}_3^{2\kappa}(\mathbf{r}) = \mathbb{E}_3^{2\kappa-1}(\Lambda'_\kappa), \quad \kappa = 1,2,3, \tag{74}$$

$$\mathbb{E}_3^7(\mathbf{r}) = h_1^2 h_2^2 h_3^2 x_1 x_2 x_3, \tag{75}$$

where $\mathbf{r} \in \Omega(\mathbb{R}^3)$. On the other hand, the Cartesian monomials of degree less than or equal to three are expressed via the ellipsoidal harmonic functions as

$$1 = \mathbb{E}_0^1(\mathbf{r}) = E_0^1(\rho) E_0^1(\mu) E_0^1(\nu), \tag{76}$$

$$x_\kappa = \frac{h_\kappa}{h_1 h_2 h_3} \mathbb{E}_1^\kappa(\mathbf{r}) = \frac{h_\kappa}{h_1 h_2 h_3} E_1^\kappa(\rho) E_1^\kappa(\mu) E_1^\kappa(\nu), \quad \kappa = 1,2,3, \tag{77}$$

$$x_\kappa^2 = \frac{\rho^2 - \alpha_1^2 + \alpha_\kappa^2}{3} \left[1 - \frac{E_2^1(\mu) E_2^1(\nu)}{(\Lambda - \Lambda')(\Lambda - \alpha_\kappa^2)} + \frac{E_2^2(\mu) E_2^2(\nu)}{(\Lambda - \Lambda')(\Lambda' - \alpha_\kappa^2)} \right], \tag{78}$$

$$\frac{x_1 x_2 x_3}{x_\kappa} = \frac{1}{h_1 h_2 h_3 h_\kappa} \mathbb{E}_2^{6-\kappa}(\mathbf{r}) = \frac{1}{h_1 h_2 h_3 h_\kappa} E_2^{6-\kappa}(\rho) E_2^{6-\kappa}(\mu) E_2^{6-\kappa}(\nu), \quad \kappa = 1,2,3 \tag{79}$$

or

$$x_\kappa x_l = \frac{h_\kappa h_l}{h_1^2 h_2^2 h_3^2} \mathbb{E}_2^{\kappa+l}(\mathbf{r}) = \frac{h_\kappa h_l}{h_1^2 h_2^2 h_3^2} E_2^{\kappa+l}(\rho) E_2^{\kappa+l}(\mu) E_2^{\kappa+l}(\nu), \quad \kappa,l = 1,2,3, \quad \kappa \neq l, \tag{80}$$

$$x_\kappa x_l^2 = \frac{\sqrt{\rho^2 - \alpha_1^2 + \alpha_\kappa^2}(\rho^2 - \alpha_1^2 + \alpha_l^2) h_\kappa}{5 h_1 h_2 h_3} \{ (1 + 2\delta_{\kappa l}) E_1^\kappa(\mu) E_1^\kappa(\nu) \tag{81}$$

$$+ \frac{5(-1)^l h_l^2}{h_1^2 h_2^2 h_3^2 (\Lambda_\kappa - \Lambda'_\kappa)} [(\Lambda'_\kappa - \alpha_l^2) E_3^{2\kappa-1}(\mu) E_3^{2\kappa-1}(\nu) - (\Lambda_\kappa - \alpha_l^2) E_3^{2\kappa}(\mu) E_3^{2\kappa}(\nu)] \Big\}, \quad \kappa,l = 1,2,3, \tag{82}$$

$$x_1 x_2 x_3 = \frac{1}{h_1^2 h_2^2 h_3^2} \mathbb{E}_3^7(\mathbf{r}) = \frac{1}{h_1^2 h_2^2 h_3^2} E_3^7(\rho) E_3^7(\mu) E_3^7(\nu). \tag{83}$$

Relations (67)–(83) form the basis for moving from the Cartesian coordinates to the ellipsoidal ones and vice versa. Relations (76)–(83) are necessary for the application of the orthogonality relation (34). Note that

$$\mathbb{F}_n^m(\mathbf{r}) = (2n+1) I_n^m(\rho) \mathbb{E}_n^m(\mathbf{r}), \quad n = 0,1,2,3, \quad m = 1,2,\ldots,2n+1, \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{84}$$

while the set of

$$x_l^2 - x_\kappa^2 = \frac{\alpha_l^2 - \alpha_\kappa^2}{3} - \frac{\mathbb{E}_2^1(\mathbf{r})}{3(\Lambda - \Lambda')}\left[\frac{1}{\Lambda - \alpha_l^2} - \frac{1}{\Lambda - \alpha_\kappa^2}\right] + \frac{\mathbb{E}_2^2(\mathbf{r})}{3(\Lambda - \Lambda')}\left[\frac{1}{\Lambda' - \alpha_l^2} - \frac{1}{\Lambda' - \alpha_\kappa^2}\right], \quad \mathbf{r} \in \Omega(\mathbb{R}^3) \tag{85}$$

for every $\kappa, l = 1,2,3$, are harmonic functions.

Before we proceed to the full solution of our physical problem, it is necessary to write down the Cartesian-ellipsoidal representations for the single and the double action of the gradient operator (22) on the interior and on the exterior ellipsoidal harmonic eigenfunctions of degree $n \leqslant 3$. Consequently, some long but straightforward calculations lead to

$$\nabla \mathbb{E}_0^1(\mathbf{r}) = \mathbf{0}, \tag{86}$$

$$\nabla \mathbb{E}_1^\kappa(\mathbf{r}) = \frac{h_1 h_2 h_3}{h_\kappa} \hat{\mathbf{x}}_\kappa = \frac{h_1 h_2 h_3}{h_\kappa} \mathbb{E}_0^1(\mathbf{r}) \hat{\mathbf{x}}_\kappa, \quad \kappa = 1,2,3, \tag{87}$$

$$\begin{aligned} \nabla \mathbb{E}_2^1(\mathbf{r}) &= 2(\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2) \sum_{i=1}^3 \frac{x_i \hat{\mathbf{x}}_i}{\Lambda - \alpha_i^2} \\ &= 2 \frac{(\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2)}{h_1 h_2 h_3} \sum_{i=1}^3 \frac{h_i}{\Lambda - \alpha_i^2} \mathbb{E}_1^i(\mathbf{r}) \hat{\mathbf{x}}_i \equiv \nabla \mathbb{E}_2^1(\Lambda), \end{aligned} \tag{88}$$

$$\nabla \mathbb{E}_2^2(\mathbf{r}) = \nabla \mathbb{E}_2^1(\Lambda'), \tag{89}$$

$$\nabla \mathbb{E}_2^{6-\kappa}(\mathbf{r}) = h_1 h_2 h_3 h_\kappa \sum_{i=1}^3 (1 - \delta_{\kappa i}) \frac{x_1 x_2 x_3}{x_\kappa x_i} \hat{\mathbf{x}}_i = h_1 h_2 h_3 \sum_{i=1}^3 \frac{(1 - \delta_{\kappa i})}{h_i} \mathbb{E}_1^{6-(\kappa+i)}(\mathbf{r}) \hat{\mathbf{x}}_i, \quad \kappa = 1,2,3 \tag{90}$$

or with equivalent notation,

$$\nabla \mathbb{E}_2^{\kappa+l}(\mathbf{r}) = \frac{h_1^2 h_2^2 h_3^2}{h_\kappa h_l} (x_\kappa \hat{\mathbf{x}}_l + x_l \hat{\mathbf{x}}_\kappa) = h_1 h_2 h_3 \left(\frac{1}{h_l} \mathbb{E}_1^\kappa(\mathbf{r}) \hat{\mathbf{x}}_l + \frac{1}{h_\kappa} \mathbb{E}_1^l(\mathbf{r}) \hat{\mathbf{x}}_\kappa \right), \quad \kappa, l = 1,2,3, \quad \kappa \neq l, \tag{91}$$

and

$$\begin{aligned} \nabla \mathbb{E}_3^{2\kappa-1}(\mathbf{r}) &= \frac{h_1 h_2 h_3}{h_\kappa} (\Lambda_\kappa - \alpha_1^2)(\Lambda_\kappa - \alpha_2^2)(\Lambda_\kappa - \alpha_3^2) \left[\hat{\mathbf{x}}_\kappa \left(\sum_{i=1}^3 \frac{x_i^2}{\Lambda_\kappa - \alpha_i^2} + 1 \right) + 2 x_\kappa \sum_{i=1}^3 \frac{x_i \hat{\mathbf{x}}_i}{\Lambda_\kappa - \alpha_i^2} \right] \\ &\equiv \nabla \mathbb{E}_3^{2\kappa-1}(\Lambda_\kappa), \quad \kappa = 1,2,3, \end{aligned} \tag{92}$$

$$\nabla \mathbb{E}_3^{2\kappa}(\mathbf{r}) = \nabla \mathbb{E}_3^{2\kappa-1}(\Lambda_\kappa'), \quad \kappa = 1,2,3, \tag{93}$$

$$\nabla \mathbb{E}_3^7(\mathbf{r}) = h_1^2 h_2^2 h_3^2 \sum_{i=1}^{3} \frac{x_1 x_2 x_3}{x_i} \hat{\mathbf{x}}_i = h_1 h_2 h_3 \sum_{i=1}^{3} \frac{1}{h_i} \mathbb{E}_2^{6-i}(\mathbf{r}) \hat{\mathbf{x}}_i. \tag{94}$$

The form of the stress tensor (49) requires the double action of the gradient operator on the following ellipsoidal harmonics:

$$\nabla \otimes \nabla \mathbb{E}_0^1(\mathbf{r}) = \tilde{\mathbf{0}}, \tag{95}$$

$$\nabla \otimes \nabla \mathbb{E}_1^\kappa(\mathbf{r}) = \tilde{\mathbf{0}}, \quad \kappa = 1,2,3, \tag{96}$$

$$\begin{aligned} \nabla \otimes \nabla \mathbb{E}_2^1(\mathbf{r}) &= 2(\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2) \sum_{i=1}^{3} \frac{\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i}{\Lambda - \alpha_i^2} \\ &= 2(\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2) \mathbb{E}_0^1(\mathbf{r}) \sum_{i=1}^{3} \frac{\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i}{\Lambda - \alpha_i^2} \equiv \nabla \otimes \nabla \mathbb{E}_2^1(\Lambda), \end{aligned} \tag{97}$$

$$\nabla \otimes \nabla \mathbb{E}_2^2(\mathbf{r}) = \nabla \otimes \nabla \mathbb{E}_2^1(\Lambda'), \tag{98}$$

$$\begin{aligned} \nabla \otimes \nabla \mathbb{E}_2^{6-\kappa}(\mathbf{r}) &= h_1 h_2 h_3 h_\kappa \sum_{i=1}^{3} (1 - \delta_{\kappa i})(\hat{\mathbf{x}}_{6-(\kappa+i)} \otimes \hat{\mathbf{x}}_i) \\ &= h_1 h_2 h_3 h_\kappa \mathbb{E}_0^1(\mathbf{r}) \sum_{i=1}^{3} (1 - \delta_{\kappa i})(\hat{\mathbf{x}}_{6-(\kappa+i)} \otimes \hat{\mathbf{x}}_i), \quad \kappa = 1,2,3 \end{aligned} \tag{99}$$

and with equivalent notation for every $\kappa, l = 1,2,3$ and $\kappa \neq l$,

$$\nabla \otimes \nabla \mathbb{E}_2^{\kappa+l}(\mathbf{r}) = \frac{h_1^2 h_2^2 h_3^2}{h_\kappa h_l} (\hat{\mathbf{x}}_\kappa \otimes \hat{\mathbf{x}}_l + \hat{\mathbf{x}}_l \otimes \hat{\mathbf{x}}_\kappa) = \frac{h_1^2 h_2^2 h_3^2}{h_\kappa h_l} \mathbb{E}_0^1(\mathbf{r})(\hat{\mathbf{x}}_\kappa \otimes \hat{\mathbf{x}}_l + \hat{\mathbf{x}}_l \otimes \hat{\mathbf{x}}_\kappa) \tag{100}$$

and

$$\begin{aligned} \nabla \otimes \nabla \mathbb{E}_3^{2\kappa-1}(\mathbf{r}) &= \frac{2 h_1 h_2 h_3}{h_\kappa} (\Lambda_\kappa - \alpha_1^2)(\Lambda_\kappa - \alpha_2^2)(\Lambda_\kappa - \alpha_3^2) \\ &\quad \times \left[\sum_{i=1}^{3} \frac{x_\kappa}{\Lambda_\kappa - \alpha_i^2} (\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i) + \sum_{i=1}^{3} \frac{x_i}{\Lambda_\kappa - \alpha_i^2} (\hat{\mathbf{x}}_\kappa \otimes \hat{\mathbf{x}}_i + \hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_\kappa) \right] \\ &= \frac{2}{h_\kappa} (\Lambda_\kappa - \alpha_1^2)(\Lambda_\kappa - \alpha_2^2)(\Lambda_\kappa - \alpha_3^2) \\ &\quad \times \left[h_\kappa \mathbb{E}_1^\kappa(\mathbf{r}) \sum_{i=1}^{3} \frac{\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i}{\Lambda_\kappa - \alpha_i^2} + \sum_{i=1}^{3} \frac{h_i \mathbb{E}_1^i(\mathbf{r})}{\Lambda_\kappa - \alpha_i^2} (\hat{\mathbf{x}}_\kappa \otimes \hat{\mathbf{x}}_i + \hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_\kappa) \right] \\ &\equiv \nabla \otimes \nabla \mathbb{E}_3^{2\kappa-1}(\Lambda_\kappa), \quad \kappa = 1,2,3, \end{aligned} \tag{101}$$

$$\nabla \otimes \nabla \mathbb{E}_3^{2\kappa}(\mathbf{r}) = \nabla \otimes \nabla \mathbb{E}_3^{2\kappa-1}(\Lambda_\kappa'), \quad \kappa = 1,2,3, \tag{102}$$

$$\nabla \otimes \nabla \mathbb{E}_3^7(\mathbf{r}) = h_1^2 h_2^2 h_3^2 \sum_{i,j=1}^{3} (1 - \delta_{ij}) \frac{x_1 x_2 x_3}{x_i x_j} (\hat{\mathbf{x}}_j \otimes \hat{\mathbf{x}}_i) = h_1^2 h_2^2 h_3^2 \sum_{i,j=1}^{3} (1 - \delta_{ij}) \frac{\hat{\mathbf{x}}_j \otimes \hat{\mathbf{x}}_i}{h_i h_j} \mathbb{E}_1^{6-(i+j)}(\mathbf{r}). \tag{103}$$

Unfortunately, it is not possible to write similar Cartesian expressions for the gradient of the external harmonic eigenmodes, because of the existence of the elliptic integrals (30) in relation (84). As we shall see later, this is the reason for the appearance of a number of difficulties in the application of the boundary conditions. Thus, we keep a mixed ellipsoidal-Cartesian formula of the above-mentioned expressions. In view of Eq. (30), we obtain

$$I_n^{m\prime}(\rho) = -\frac{1}{[E_n^m(\rho)]^2\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}, \quad \rho \in [h_2, +\infty) \tag{104}$$

and according to relations (21) and (22)

$$\nabla \mathbb{F}_n^m(\mathbf{r}) = (2n+1)\left[I_n^m(\rho)(\nabla \mathbb{E}_n^m(\mathbf{r})) - \frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\frac{\mathbb{E}_n^m(\mathbf{r})}{[E_n^m(\rho)]^2}\right]. \tag{105}$$

Although expression (105) is the simplest one possible it is still problematic because of the appearance of the vectorial factor

$$\mathbf{R}^{\mathrm{el}}(\mathbf{r}) = \frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}, \quad \rho \in [h_2, +\infty), \quad \mu \in [h_3, h_2], \quad \nu \in [-h_3, h_3]. \tag{106}$$

This problem becomes even more complicated in the case of the double action of the gradient operator on the external harmonics, where

$$\begin{aligned}\nabla \otimes \nabla \mathbb{F}_n^m(\mathbf{r}) = (2n+1)[&I_n^m(\rho)(\nabla \otimes \nabla \mathbb{E}_n^m(\mathbf{r})) + \nabla I_n^m(\rho) \otimes \nabla \mathbb{E}_n^m(\mathbf{r}) + \nabla \mathbb{E}_n^m(\mathbf{r}) \otimes \nabla I_n^m(\rho) \\ &+ \mathbb{E}_n^m(\mathbf{r})(\nabla \otimes \nabla I_n^m(\rho))]\end{aligned} \tag{107}$$

for $n=0,1,2,\ldots$ and $m=1,2,\ldots,2n+1$. The dyadic $\nabla \otimes \nabla \mathbb{E}_n^m$ has been introduced earlier, and we can easily obtain the following relation:

$$\nabla I_n^m(\rho) = -\frac{\hat{\boldsymbol{\rho}}}{[E_n^m(\rho)]^2\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}} = -\frac{1}{[E_n^m(\rho)]^2}\mathbf{R}^{\mathrm{el}}(\mathbf{r}), \quad \mathbf{r} \in \Omega(\mathbb{R}^3). \tag{108}$$

As far as the factor $\nabla \otimes \nabla I_n^m$ is concerned that appears in (107), we actually need the formula

$$\nabla \otimes \hat{\boldsymbol{\rho}} = \frac{\rho}{h_\rho}\left[\frac{\hat{\boldsymbol{\mu}} \otimes \hat{\boldsymbol{\mu}}}{\rho^2-\mu^2} + \frac{\hat{\boldsymbol{\nu}} \otimes \hat{\boldsymbol{\nu}}}{\rho^2-\nu^2}\right] + \frac{\mu}{h_\mu}\frac{\hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\mu}}}{\rho^2-\mu^2} + \frac{\nu}{h_\nu}\frac{\hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\nu}}}{\rho^2-\nu^2} \tag{109}$$

with the metric coefficients given by Eq. (21) and

$$\frac{\partial}{\partial \rho}\mathbf{R}^{\mathrm{el}}(\mathbf{r}) = \frac{\partial}{\partial \rho}\left(\frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\right), \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{110}$$

which is also written as

$$\begin{aligned}\frac{\partial}{\partial \rho}\mathbf{R}^{\mathrm{el}}(\mathbf{r}) = \frac{1}{(\rho^2-\mu^2)(\rho^2-\nu^2)}\Bigg\{&-\frac{2\rho(2\rho^2-\mu^2-\nu^2)}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\hat{\boldsymbol{\rho}} + \frac{1}{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}[(2\rho^2-h_3^2-h_2^2)x_1\hat{\mathbf{x}}_1 \\ &+ (2\rho^2-h_2^2)x_2\hat{\mathbf{x}}_2 + (2\rho^2-h_3^2)x_3\hat{\mathbf{x}}_3]\Bigg\}\end{aligned} \tag{111}$$

or in ellipsoidal coordinates alone

$$\frac{\partial}{\partial\rho}\mathbf{R}^{\mathrm{el}}(\mathbf{r}) = \frac{1}{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\rho^2-\mu^2)(\rho^2-\nu^2)} \times\left[-2\rho(2\rho^2-\mu^2-\nu^2)\frac{\rho}{h_\rho}\hat{\boldsymbol{\rho}}+(\rho^2-\nu^2)\frac{\mu}{h_\mu}\hat{\boldsymbol{\mu}}+(\rho^2-\mu^2)\frac{\nu}{h_\nu}\hat{\boldsymbol{\nu}}\right],\quad \mathbf{r}\in\Omega(\mathbb{R}^3). \tag{112}$$

These formulas seem to be complicated, but they are given in the appropriate form for the application of the boundary condition (53).

The nature of condition (51), restricts the degree of the velocity field (46) to one. Hence, we use ellipsoidal harmonics of degree $n\leqslant 2$, which provide the appropriate flow fields that are adequate for most applications. Besides, these terms are enough to calculate the most important term of the velocity. Consequently, we observe that the potential $\mathbf{\Phi}$ in (36) must be of degree one and the potential Φ_0 in (37) must be of degree two in the surface variables μ and ν. This implies that all the coefficients $\mathbf{e}_n^{(i)m}$, $\mathbf{e}_n^{(e)m}$ for $n>2$ and $d_n^{(i)m}$, $d_n^{(e)m}$ for $n>3$, vanish, i.e.,

$$\mathbf{e}_n^{(i)m}=\mathbf{e}_n^{(e)m}=\mathbf{0},\quad n=2,3,\ldots,\quad m=1,2,\ldots,2n+1 \tag{113}$$

and

$$d_n^{(i)m}=d_n^{(e)m}=0,\quad n=3,4,\ldots,\quad m=1,2,\ldots,2n+1. \tag{114}$$

Hence, the expansions (46)–(49) degenerate to the following finite sums, where for particles of a particular size, the first term of the series is enough for most real applications. Our aim is to calculate the terms of the flow fields, which correspond to ellipsoidal harmonics of degree less or equal than two. Inserting the restrictions (113) and (114) into the flow fields, we conclude the finite dimensional projections that correspond to the first term of the velocity field, denoted by $\mathbf{v}^{(0)}$, $P^{(0)}$, $\boldsymbol{\omega}^{(0)}$, and $\widetilde{\mathbf{\Pi}}^{(0)}$. Thus,

$$\mathbf{v}^{(0)}(\mathbf{r})=\frac{1}{2}\Bigg\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}\left[\mathbf{e}_n^{(i)m}\cdot(\widetilde{\mathbf{I}}\mathbb{E}_n^m(\mathbf{r})-\mathbf{r}\otimes\nabla\mathbb{E}_n^m(\mathbf{r}))+\mathbf{e}_n^{(e)m}\cdot(\widetilde{\mathbf{I}}\mathbb{F}_n^m(\mathbf{r})-\mathbf{r}\otimes\nabla\mathbb{F}_n^m(\mathbf{r}))\right] -\sum_{n=0}^{2}\sum_{m=1}^{2n+1}\left[d_n^{(i)m}\nabla\,\mathbb{E}_n^m(\mathbf{r})+d_n^{(e)m}\nabla\,\mathbb{F}_n^m(\mathbf{r})\right]\Bigg\},\quad \mathbf{r}\in\Omega(\mathbb{R}^3) \tag{115}$$

defines the *first term* of the velocity field,

$$P^{(0)}(\mathbf{r})=P_0-\mu_0\sum_{n=0}^{1}\sum_{m=1}^{2n+1}\{\mathbf{e}_n^{(i)m}\cdot\nabla\mathbb{E}_n^m(\mathbf{r})+\mathbf{e}_n^{(e)m}\cdot\nabla\mathbb{F}_n^m(\mathbf{r})\}=p^{(0)}(\mathbf{r})+\rho_0 gh,\quad \mathbf{r}\in\Omega(\mathbb{R}^3) \tag{116}$$

defines the *first term* of the total pressure field,

$$\boldsymbol{\omega}^{(0)}(\mathbf{r})=\frac{1}{2}\sum_{n=0}^{1}\sum_{m=1}^{2n+1}\{\nabla\mathbb{E}_n^m(\mathbf{r})\times\mathbf{e}_n^{(i)m}+\nabla\mathbb{F}_n^m(\mathbf{r})\times\mathbf{e}_n^{(e)m}\},\quad \mathbf{r}\in\Omega(\mathbb{R}^3) \tag{117}$$

defines the *first term* of the vorticity field, and

$$\widetilde{\mathbf{\Pi}}^{(0)}(\mathbf{r})=-p^{(0)}(\mathbf{r})\widetilde{\mathbf{I}}-\mu_0\Bigg\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}\left[(\mathbf{e}_n^{(i)m}\cdot\mathbf{r})\,\nabla\otimes\nabla\mathbb{E}_n^m(\mathbf{r})+(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})\,\nabla\otimes\nabla\mathbb{F}_n^m(\mathbf{r})\right] +\sum_{n=0}^{2}\sum_{m=1}^{2n+1}\left[d_n^{(i)m}\nabla\otimes\nabla\mathbb{E}_n^m(\mathbf{r})+d_n^{(e)m}\nabla\otimes\nabla\mathbb{F}_n^m(\mathbf{r})\right]\Bigg\},\quad \mathbf{r}\in\Omega(\mathbb{R}^3) \tag{118}$$

defines the *first term* of the stress tensor field. Of course, the remaining coefficients $\mathbf{e}_0^{(i)1}$, $\mathbf{e}_0^{(e)1}$ for $n=0$ and $\mathbf{e}_1^{(i)\kappa}$, $\mathbf{e}_1^{(e)\kappa}$, $\kappa=1,2,3$ for $n=1$, as well as the coefficients $d_0^{(i)1}$, $d_0^{(e)1}$ for $n=0$, $d_1^{(i)\kappa}$, $d_1^{(e)\kappa}$, $\kappa=1,2,3$ for $n=1$ and $d_2^{(i)1}$, $d_2^{(e)1}$, $d_2^{(i)2}$, $d_2^{(e)2}$, $d_2^{(i)6-\kappa}$, $d_2^{(e)6-\kappa}$, $\kappa=1,2,3$ or $d_2^{(i)\kappa+l}$, $d_2^{(e)\kappa+l}$, $\kappa,l=1,2,3$, $\kappa\neq l$ for $n=2$ have to be determined from the boundary conditions (51)–(53).

Application of the BCs (51)–(53) to the velocity (115) and to the stress tensor (118). By virtue of the initial definitions (50), we insert the velocity field (115) to the boundary condition (51) on the surface S_a of the solid ellipsoid and we conclude that

$$2(\mathbf{U}+\boldsymbol{\Omega}\times\mathbf{r})=\left\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}[(\mathbf{e}_n^{(i)m}+(2n+1)I_n^m(\rho)\mathbf{e}_n^{(e)m})\cdot(\tilde{\mathbf{I}}\mathbb{E}_n^m(\mathbf{r})-\mathbf{r}\otimes\nabla\mathbb{E}_n^m(\mathbf{r}))]-\sum_{n=0}^{2}\sum_{m=1}^{2n+1}[(d_n^{(i)m}+(2n+1)I_n^m(\rho)d_n^{(e)m})\nabla\mathbb{E}_n^m(\mathbf{r})]\right\}+\mathbf{R}^{\mathrm{el}}(\mathbf{r})\left\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}[(2n+1)(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})\times[E_n^m(\rho)]^{-2}\mathbb{E}_n^m(\mathbf{r})]+\sum_{n=0}^{2}\sum_{m=1}^{2n+1}[(2n+1)d_n^{(e)m}[E_n^m(\rho)]^{-2}\mathbb{E}_n^m(\mathbf{r})]\right\},\quad \rho=\rho_a, \tag{119}$$

where we have used Eqs. (84) and (105) as well as the complicated ellipsoidal factor (106) for every $\mu\in[h_3,h_2]$ and $\nu\in[-h_3,h_3]$. The three sums in the first curly brace on the right-hand side of (119) are of the first degree in the variables μ, ν. The two sums inside the second curly brace are of the second degree. We observe that due to the factor $\mathbf{R}^{\mathrm{el}}$ it is not possible to express the second curly brace in terms of a finite expression of surface ellipsoidal harmonics. Therefore, in practice, it is impossible to evaluate the coefficients from BC (119) explicitly. Nevertheless, since the harmonic potentials $\boldsymbol{\Phi}$ and Φ_0 of the general solution (4) and (5) are not independent,[17] the corresponding d's and $\mathbf{e}$'s coefficients are also not independent as well. Thus, based on the flexibility of the Papkovich–Neuber differential representation, we *choose* to express the $d_n^{(e)m}$ in terms of the $\mathbf{e}_n^{(e)m}$ in such a way that the two sums on the right-hand side of (119), which are multiplied by $\mathbf{R}^{\mathrm{el}}$, vanish for $\mathbf{r}\in S_a$. When this is done the "bad term" of the BC (119) will disappear and we can apply orthogonality to obtain relations between the rest unknown coefficients $d_n^{(i)m}$, $e_n^{(i)m}$, and $e_n^{(e)m}$. In that sense, the use of the aforementioned *technique* on $\rho=\rho_a$ forms the key to our method. For $\rho=\rho_a$ the vanishing of the ellipsoidal part of the boundary condition (119) implies that

$$\left\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}[(2n+1)(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})[E_n^m(\rho)]^{-2}\mathbb{E}_n^m(\mathbf{r})]+\sum_{n=0}^{2}\sum_{m=1}^{2n+1}[(2n+1)d_n^{(e)m}[E_n^m(\rho)]^{-2}\mathbb{E}_n^m(\mathbf{r})]\right\}=0,\quad \mathbf{r}\in S_a. \tag{120}$$

Representing now the factor $\mathbf{r}\mathbb{E}_n^m$ via surface ellipsoidal harmonics at $\rho=\rho_a$ with the aim of the formulas (67), (68), and (76)–(80), as well as relations (A20), (A32), and (A33) from the Appendix and using orthogonality arguments, the assumption (120) provides the following relations between the coefficients, i.e.,

$$d_0^{(e)1}=-h_1h_2h_3\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i}, \tag{121}$$

$$d_1^{(e)\kappa}=-\frac{h_\kappa(E_1^\kappa(\rho_a))^2}{3h_1h_2h_3}(\mathbf{e}_0^{(e)1}\cdot\hat{\mathbf{x}}_\kappa),\quad \kappa=1,2,3, \tag{122}$$

$$d_2^{(e)1}=\frac{h_1h_2h_3}{5(\Lambda-\Lambda')}E_2^1(\rho_a)\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda-\alpha_i^2)}, \tag{123}$$

$$d_2^{(e)2} = -\frac{h_1 h_2 h_3}{5(\Lambda - \Lambda')} E_2^2(\rho_a) \sum_{i=1}^{3} \frac{(\mathbf{e}_1^{(e)i} \cdot \hat{\mathbf{x}}_i)}{h_i(\Lambda' - \alpha_i^2)}, \tag{124}$$

$$d_2^{(e)\kappa+l} = -\frac{3}{5h_1 h_2 h_3}[h_\kappa (E_1^\kappa(\rho_a))^2 (\mathbf{e}_1^{(e)l} \cdot \hat{\mathbf{x}}_\kappa) + h_l (E_1^l(\rho_a))^2 (\mathbf{e}_1^{(e)\kappa} \cdot \hat{\mathbf{x}}_l)] \tag{125}$$

for $\kappa, l = 1,2,3$, $\kappa \neq l$. Having expressed the external d-coefficients as a function of the external $\mathbf{e}$-coefficients and according to the *technique* (120), the ellipsoidal part of the boundary condition (119) is not present any more and eventually it becomes

$$2(\mathbf{U} + \boldsymbol{\Omega} \times \mathbf{r}) = \left\{ \sum_{n=0}^{1} \sum_{m=1}^{2n+1} [(\mathbf{e}_n^{(i)m} + (2n+1) I_n^m(\rho) \mathbf{e}_n^{(e)m}) \cdot (\tilde{\mathbf{I}} \mathbb{E}_n^m(\mathbf{r}) - \mathbf{r} \otimes \nabla \mathbb{E}_n^m(\mathbf{r}))] \right.$$
$$\left. - \sum_{n=0}^{2} \sum_{m=1}^{2n+1} [(d_n^{(i)m} + (2n+1) I_n^m(\rho) d_n^{(e)m}) \nabla \mathbb{E}_n^m(\mathbf{r})] \right\}, \quad \mathbf{r} \in S_a. \tag{126}$$

In order to handle the condition (126) properly, we perform the following actions. First we use the Cartesian form of the solid ellipsoidal harmonics $\mathbb{E}_n^m$ and of the gradient acting on it $\nabla \mathbb{E}_n^m$ from (67), (68), and (86)–(91), respectively. Next we calculate the factor $\mathbf{r} \otimes \nabla \mathbb{E}_n^m$ in Cartesian form and finally, by virtue of the definitions (38), of Eqs. (76) and (77), of the connection formulas (121)–(124) and of the orthogonality relation (34), the condition (126), after long and tedious calculations, results

$$\frac{h_1 h_2 h_3}{h_\kappa} d_1^{(i)\kappa} = -2(\mathbf{U} \cdot \hat{\mathbf{x}}_\kappa) + (\mathbf{e}_0^{(i)1} \cdot \hat{\mathbf{x}}_\kappa) + [I_0^1(\rho_a) + (E_1^\kappa(\rho_a))^2 I_1^\kappa(\rho_a)](\mathbf{e}_0^{(e)1} \cdot \hat{\mathbf{x}}_\kappa), \quad \kappa = 1,2,3, \tag{127}$$

as well as

$$-\left[\frac{(\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2)}{(\Lambda - \alpha_\kappa^2)} \frac{d_2^{(i)1}}{h_1 h_2 h_3} + \frac{(\Lambda' - \alpha_1^2)(\Lambda' - \alpha_2^2)(\Lambda' - \alpha_3^2)}{(\Lambda' - \alpha_\kappa^2)} \frac{d_2^{(i)2}}{h_1 h_2 h_3} \right]$$
$$= \frac{(\Lambda - \alpha_1^2)(\Lambda - \alpha_2^2)(\Lambda - \alpha_3^2)}{(\Lambda - \alpha_\kappa^2)} \frac{E_2^1(\rho_a) I_2^1(\rho_a)}{(\Lambda - \Lambda')} \sum_{i=1}^{3} \frac{(\mathbf{e}_1^{(e)i} \cdot \hat{\mathbf{x}}_i)}{h_i(\Lambda - \alpha_i^2)}$$
$$- \frac{(\Lambda' - \alpha_1^2)(\Lambda' - \alpha_2^2)(\Lambda' - \alpha_3^2)}{(\Lambda' - \alpha_\kappa^2)} \frac{E_2^2(\rho_a) I_2^2(\rho_a)}{(\Lambda - \Lambda')} \sum_{i=1}^{3} \frac{(\mathbf{e}_1^{(e)i} \cdot \hat{\mathbf{x}}_i)}{h_i(\Lambda' - \alpha_i^2)} \tag{128}$$

and

$$h_\kappa[(\mathbf{e}_1^{(i)l} \cdot \hat{\mathbf{x}}_\kappa) + 3I_1^l(\rho_a)(\mathbf{e}_1^{(e)l} \cdot \hat{\mathbf{x}}_\kappa)] - h_l[(\mathbf{e}_1^{(i)\kappa} \cdot \hat{\mathbf{x}}_l) + 3I_1^\kappa(\rho_a)(\mathbf{e}_1^{(e)\kappa} \cdot \hat{\mathbf{x}}_l)] - h_1 h_2 h_3$$
$$\times [d_2^{(i)\kappa+l} + 5I_2^{\kappa+l}(\rho_a) d_2^{(e)\kappa+l}] = \frac{2\lambda_{\kappa l}}{h_{6-(\kappa+l)}} (\boldsymbol{\Omega} \cdot \hat{\mathbf{x}}_{6-(\kappa+l)}), \quad \kappa, l = 1,2,3, \quad \kappa \neq l, \tag{129}$$

where

$$\lambda_{\kappa l} = \begin{cases} +1, & (\kappa, l) = (1,3),(2,1),(3,2) \\ -1, & (\kappa, l) = (1,2),(2,3),(3,1) \end{cases}, \quad \kappa, l = 1,2,3, \quad \kappa \neq l. \tag{130}$$

The next step now will be the investigation of the second condition on the boundary $\rho = \rho_b$ of the fictitious ellipsoidal surface S_b. In view of the boundary condition (52) we obtain

$$\left\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}[(\hat{\boldsymbol{\rho}}\cdot\mathbf{e}_n^{(i)m})\mathbb{E}_n^m(\mathbf{r})-(\mathbf{e}_n^{(i)m}\cdot\mathbf{r})(\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{E}_n^m(\mathbf{r}))+(\hat{\boldsymbol{\rho}}\cdot\mathbf{e}_n^{(e)m})\mathbb{F}_n^m(\mathbf{r})-(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})(\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{F}_n^m(\mathbf{r}))]\right.$$
$$\left.-\sum_{n=0}^{2}\sum_{m=1}^{2n+1}[d_n^{(i)m}(\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{E}_n^m(\mathbf{r}))+d_n^{(e)m}(\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{F}_n^m(\mathbf{r}))]\right\}=0,\quad \mathbf{r}\in S_b, \tag{131}$$

where we utilized the assumption for the velocity field (115). It is obvious that the appearance of the unit normal vector $\hat{\boldsymbol{\rho}}$, provided by expression (25), increases the degree of the harmonic eigenmodes in Eq. (131) up to $n=2$. More specifically using the Cartesian-ellipsoidal formulas (67)–(72), (76)–(80), and (86)–(91), as well as

$$\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{F}_n^m(\mathbf{r})=(2n+1)\left[I_n^m(\rho)(\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{E}_n^m(\mathbf{r}))-\frac{1}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\frac{\mathbb{E}_n^m(\mathbf{r})}{[E_n^m(\rho)]^2}\right] \tag{132}$$

for $\rho=\rho_b$ and $n=0,1,2$, $m=1,2,\ldots,2n+1$, we convert, after long calculations, condition (131) to a suitable form, which is appropriate for applying orthogonality via (34). Thus, after having produced the ellipsoidal form of the factors $(\hat{\boldsymbol{\rho}}\cdot\nabla\mathbb{E}_n^m)$ for $n=0,1,2$, $m=1,2,\ldots,2n+1$ and $(\hat{\boldsymbol{\rho}}\cdot\mathbf{e}_n^{(i/e)m})$, $(\mathbf{r}\cdot\mathbf{e}_n^{(i/e)m})$ for $n=0,1$, $m=1,2,\ldots,2n+1$, we apply orthogonality and obtain nine more relations involving the still unknown coefficients. The number of equations we obtain is a result of the scalar character of the boundary condition (131) and, of course, of the number of the surface ellipsoidal harmonics for $n\leqslant 2$. We mention that no indeterminacy appeared in our program and all the calculations were easily performed. Actually, orthogonality of the surface ellipsoidal harmonic $E_0^1(\mu)E_0^1(\nu)$ provides the already known relation (121), which is independent of the boundary. On the other hand, by orthogonality arguments of $E_1^\kappa(\mu)E_1^\kappa(\nu)$, $\kappa=1,2,3$ and relation (127) we evaluate the coefficient $\mathbf{e}_0^{(e)1}$ in the form

$$(\mathbf{e}_0^{(e)1}\cdot\hat{\mathbf{x}}_\kappa)=-\frac{2E_3^7(\rho_b)}{N_\kappa}(\mathbf{U}\cdot\hat{\mathbf{x}}_\kappa),\quad \kappa=1,2,3, \tag{133}$$

where

$$N_\kappa=E_3^7(\rho_b)[(I_0^1(\rho_b)-I_0^1(\rho_a))+(E_1^\kappa(\rho_a))^2(I_1^\kappa(\rho_b)-I_1^\kappa(\rho_a))]+(E_1^\kappa(\rho_b))^2-(E_1^\kappa(\rho_a))^2,\quad \kappa=1,2,3. \tag{134}$$

Until now, four of the nine equations, which came up from boundary condition (131), have been used. The five remaining equations correspond to orthogonality on the surface ellipsoidal harmonics of degree $n=2$ for every $m=1,2,\ldots,5$. Hence, the surface ellipsoidal harmonics $E_2^1(\mu)E_2^1(\nu)$ and $E_2^2(\mu)E_2^2(\nu)$ lead to

$$-5d_2^{(e)1}+2E_2^1(\rho_b)E_3^7(\rho_b)(d_2^{(i)1}+5I_2^1(\rho_b)d_2^{(e)1})+\frac{h_1h_2h_3E_2^1(\rho_b)}{(\Lambda-\Lambda')}\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda-\alpha_i^2)}=0 \tag{135}$$

and

$$-5d_2^{(e)2}+2E_2^2(\rho_b)E_3^7(\rho_b)(d_2^{(i)2}+5I_2^2(\rho_b)d_2^{(e)2})-\frac{h_1h_2h_3E_2^2(\rho_b)}{(\Lambda-\Lambda')}\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda'-\alpha_i^2)}=0, \tag{136}$$

respectively, where the identity (A20) has been used. Inserting Eqs. (123) and (124) to relation (128), we obtain the following 2×2 homogeneous system of linear equations, in the variables $(d_2^{(i)1}+5I_2^1(\rho_a)d_2^{(e)1})$ and $(d_2^{(i)2}+5I_2^2(\rho_a)d_2^{(e)2})$. For example, for $\kappa=1,2$ we have

$$(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)(d_2^{(i)1}+5I_2^1(\rho_a)d_2^{(e)1})+(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)(d_2^{(i)2}+5I_2^2(\rho_a)d_2^{(e)2})=0 \tag{137}$$

and

$$(\Lambda-\alpha_1^2)(\Lambda-\alpha_3^2)(d_2^{(i)1}+5I_2^1(\rho_a)d_2^{(e)1})+(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_3^2)(d_2^{(i)2}+5I_2^2(\rho_a)d_2^{(e)2})=0. \quad (138)$$

Since the determinant is not zero, it follows that

$$d_2^{(i)1}+5I_2^1(\rho_a)d_2^{(e)1}=d_2^{(i)2}+5I_2^2(\rho_a)d_2^{(e)2}=0 \quad (139)$$

or

$$d_2^{(i)1}=-5I_2^1(\rho_a)d_2^{(e)1}, \quad d_2^{(i)2}=-5I_2^2(\rho_a)d_2^{(e)2}. \quad (140)$$

We could come up with the same result if we had used expression (128) for $\kappa=1,3$ or for $\kappa=2,3$.

Our next step involves the substitution of the results (140) to (135) and (136), to obtain

$$\frac{h_1h_2h_3E_2^1(\rho_b)}{(\Lambda-\Lambda')}\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda-\alpha_i^2)}\left[1-\frac{E_2^1(\rho_a)}{E_2^1(\rho_b)}+2E_3^7(\rho_b)E_2^1(\rho_a)(I_2^1(\rho_b)-I_2^1(\rho_a))\right]=0 \quad (141)$$

and

$$\frac{h_1h_2h_3E_2^2(\rho_b)}{(\Lambda-\Lambda')}\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda'-\alpha_i^2)}\left[1-\frac{E_2^2(\rho_a)}{E_2^2(\rho_b)}+2E_3^7(\rho_b)E_2^2(\rho_a)(I_2^2(\rho_b)-I_2^2(\rho_a))\right]=0, \quad (142)$$

where the nonvanishing of the two square brackets implies

$$\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda-\alpha_i^2)}=\sum_{i=1}^{3}\frac{(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i)}{h_i(\Lambda'-\alpha_i^2)}=0. \quad (143)$$

As a consequence relations (123) and (124) force the coefficients $d_2^{(e)1}$ and $d_2^{(e)2}$ to vanish and then from (140) we obtain

$$d_2^{(i)1}=d_2^{(e)1}=0 \quad (144)$$

and

$$d_2^{(i)2}=d_2^{(e)2}=0. \quad (145)$$

In addition, working on the two summations (143) and with proper use of identities (A22) and (A23) we conclude that

$$(\mathbf{e}_1^{(e)3}\cdot\hat{\mathbf{x}}_3)=\frac{h_3}{h_1}(\mathbf{e}_1^{(e)1}\cdot\hat{\mathbf{x}}_1)=\frac{h_3}{h_2}(\mathbf{e}_1^{(e)2}\cdot\hat{\mathbf{x}}_2), \quad (146)$$

where two of the three diagonal scalar coefficients of $\mathbf{e}_1^{(e)\kappa}$, $\kappa=1,2,3$ have been evaluated via the third one. Finally, by means of orthogonality on the BC (131) of $E_2^{6-\kappa}(\mu)E_2^{6-\kappa}(\nu)$, $\kappa=1,2,3$, we derive the following elaborate relation, valid on the ellipsoidal surface S_b:

$$\begin{aligned}&E_3^7(\rho_b)h_{6-(\kappa+l)}^2\{h_\kappa[(\mathbf{e}_1^{(i)l}\cdot\hat{\mathbf{x}}_\kappa)+3I_1^l(\rho_b)(\mathbf{e}_1^{(e)l}\cdot\hat{\mathbf{x}}_\kappa)]-h_l[(\mathbf{e}_1^{(i)\kappa}\cdot\hat{\mathbf{x}}_l)+3I_1^\kappa(\rho_b)(e_1^{(\mathbf{e})\kappa}\cdot\hat{\mathbf{x}}_l)]\}\\&\quad+h_1h_2h_3[5d_2^{(e)\kappa+l}-E_3^7(\rho_b)((E_1^\kappa(\rho_b))^2+(E_1^l(\rho_b))^2)(d_2^{(i)\kappa+l}+5I_2^{\kappa+l}(\rho_b)d_2^{(e)\kappa+l})]\\&\quad+3[h_\kappa(E_1^\kappa(\rho_b))^2(\mathbf{e}_1^{(e)l}\cdot\hat{\mathbf{x}}_\kappa)+h_l(E_1^l(\rho_b))^2(\mathbf{e}_1^{(e)\kappa}\cdot\hat{\mathbf{x}}_l)]=0, \quad \kappa,l=1,2,3, \quad \kappa>l, \end{aligned} \quad (147)$$

where by $\kappa>l$ we mean all the possible combinations such as $(\kappa,l)=(2,1),(3,1),(3,2)$. At this point, we take advantage of the particular form of the three pairs of equations in relation (129) by substracting one relation from the other of each pair that contains the same components of the applied vorticity $\mathbf{\Omega}$, to obtain the three equations

$$d_2^{(i)\kappa+l}+5I_2^{\kappa+l}(\rho_a)d_2^{(e)\kappa+l}=0\Rightarrow d_2^{(i)\kappa+l}=-5I_2^{\kappa+l}(\rho_a)d_2^{(e)\kappa+l}, \quad \kappa,l=1,2,3, \quad \kappa\neq l. \quad (148)$$

If we return to condition (147), we observe that we have to deal with three different relations for every value of $(\kappa,l)=(2,1),(3,1),(3,2)$. Therefore, by virtue of (148) and inserting (125) and (129) to (147), we conclude the symmetric expression

$$P_\kappa^l h_\kappa(\mathbf{e}_1^{(e)l}\cdot\hat{\mathbf{x}}_\kappa)+P_l^\kappa h_l(\mathbf{e}_1^{(e)\kappa}\cdot\hat{\mathbf{x}}_l)=R^{\kappa+l},\quad \kappa,l=1,2,3,\quad \kappa\neq l \tag{149}$$

with

$$P_\kappa^l=\frac{\rho_b^2-\rho_a^2}{(E_2^{\kappa+l}(\rho_b))^2}+E_3^7(\rho_b)\frac{\alpha_l^2-\alpha_\kappa^2}{(E_2^{\kappa+l}(\rho_b))^2}(I_1^l(\rho_b)-I_1^l(\rho_a))+E_3^7(\rho_b)(E_1^\kappa(\rho_a))^2\left(\frac{1}{(E_1^\kappa(\rho_b))^2}+\frac{1}{(E_1^l(\rho_b))^2}\right)$$
$$\times(I_2^{\kappa+l}(\rho_b)-I_2^{\kappa+l}(\rho_a)) \tag{150}$$

for every $\kappa,l=1,2,3$ and $\kappa\neq l$, and

$$R^{\kappa+l}=\frac{2h_{6-(\kappa+l)}\Omega_{6-(\kappa+l)}}{3}(-1)^{\kappa+l}\frac{E_1^{6-(\kappa+l)}(\rho_b)}{E_2^{\kappa+l}(\rho_b)}$$
$$=\frac{2h_1h_2h_3\Omega_{6-(\kappa+l)}}{3}(-1)^{\kappa+l}\frac{E_3^7(\rho_b)}{(E_2^{\kappa+l}(\rho_b))^2},\quad \kappa,l=1,2,3,\quad \kappa\neq l. \tag{151}$$

Recapitulating, we see that the effect of the two first boundary conditions (51) and (52) to the evaluation of the unknown coefficients, in the flow fields (115)–(118), is to obtain nine unknown coefficients $\mathbf{e}_1^{(e)\kappa}$, $\kappa=1,2,3$ from five relations, two from (146) and three from (149). Thus, there remain four coefficients that must be calculated explicitly from the final condition (53) on the ellipsoid $\rho=\rho_b$. However, the diagonal components of $\mathbf{e}_1^{(e)\kappa}$, $\kappa=1,2,3$, appearing in Eq. (146), will not enter the flow fields, as we shall see later on. This means that in practice we need to calculate three instead of four coefficients.

The application of the boundary condition (53), where in view of the stress tensor field (118), and according to the form of the unit dyadic (26) gives

$$\hat{\boldsymbol{\rho}}\cdot\tilde{\mathbf{I}}\cdot(\tilde{\mathbf{I}}-\hat{\boldsymbol{\rho}}\otimes\hat{\boldsymbol{\rho}})=\hat{\boldsymbol{\rho}}\cdot\tilde{\mathbf{I}}\cdot(\hat{\boldsymbol{\mu}}\otimes\hat{\boldsymbol{\mu}}+\hat{\boldsymbol{\nu}}\otimes\hat{\boldsymbol{\nu}})=\mathbf{0}, \tag{152}$$

provides the following expression in terms of the unit normal vector $\hat{\boldsymbol{\rho}}$,

$$(\tilde{\mathbf{I}}-\hat{\boldsymbol{\rho}}\otimes\hat{\boldsymbol{\rho}})\cdot\left\{\sum_{n=0}^{1}\sum_{m=1}^{2n+1}[(\mathbf{e}_n^{(i)m}\cdot\mathbf{r})(\hat{\boldsymbol{\rho}}\cdot\nabla\otimes\nabla\mathbb{E}_n^m(\mathbf{r}))+(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})(\hat{\boldsymbol{\rho}}\cdot\nabla\otimes\nabla\mathbb{F}_n^m(\mathbf{r}))]\right.$$
$$\left.+\sum_{n=0}^{2}\sum_{m=1}^{2n+1}[d_n^{(i)m}(\hat{\boldsymbol{\rho}}\cdot\nabla\otimes\nabla\mathbb{E}_n^m(\mathbf{r}))+d_n^{(e)m}(\hat{\boldsymbol{\rho}}\cdot\nabla\otimes\nabla\mathbb{F}_n^m(\mathbf{r}))]\right\}=\mathbf{0},\quad \mathbf{r}\in S_b. \tag{153}$$

In order to deal with condition (153) we perform the following operations. First, we use the double action of the gradient operator on the interior solid ellipsoidal harmonics provided by relations (95)–(100) for the evaluation of the $\hat{\boldsymbol{\rho}}\cdot\nabla\otimes\nabla\mathbb{E}_n^m$, $n=0,1,2$, $m=1,2,\ldots,2n+1$. Then, using the expression

$$\hat{\boldsymbol{\rho}}=\frac{E_3^7(\rho)}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\sum_{i=1}^{3}\frac{x_i\hat{\mathbf{x}}_i}{(E_1^i(\rho))^2},\quad \rho=\rho_b \tag{154}$$

for the unit outward normal on S_b, we obtain

$$\hat{\boldsymbol{\rho}}\cdot\nabla I_n^m(\rho)=-\frac{1}{[E_n^m(\rho)]^2\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}},\quad \rho=\rho_b, \tag{155}$$

because

$$\mathbf{R}^{\mathrm{el}}(\mathbf{r}) = \frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}, \quad \rho=\rho_b. \tag{156}$$

Also, according to the definition (22), and with the help of relation (108), we reach at

$$\begin{aligned}\hat{\boldsymbol{\rho}}\cdot\nabla\nabla I_n^m(\rho) &= \frac{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\frac{\partial}{\partial\rho}\nabla I_n^m(\rho)\\ &= -\frac{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\left[\frac{\partial}{\partial\rho}[E_n^m(\rho)]^{-2}\mathbf{R}^{\mathrm{el}}(\mathbf{r})+[E_n^m(\rho)]^{-2}\frac{\partial}{\partial\rho}\mathbf{R}^{\mathrm{el}}(\mathbf{r})\right]\end{aligned} \tag{157}$$

for $\rho=\rho_b$. Some easy algebra on Eq. (157) furnishes

$$\hat{\boldsymbol{\rho}}\cdot\nabla\nabla I_n^m(\rho) = \frac{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}{[E_n^m(\rho)]^3\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}}\left[2E_n^{m\prime}(\rho)\mathbf{R}^{\mathrm{el}}(\mathbf{r})-E_n^m(\rho)\frac{\partial\mathbf{R}^{\mathrm{el}}(\mathbf{r})}{\partial\rho}\right], \tag{158}$$

where $\rho=\rho_b$, whilst the ρ-derivative of the factor $\mathbf{R}^{\mathrm{el}}$ has been calculated through its Cartesian (111) and its ellipsoidal (112) representation. Substituting expressions (155) and (158) into the double gradient of the exterior solid ellipsoidal harmonics (107), inserting relations (86)–(91) and (95)–(100) at (107) and using

$$\hat{\boldsymbol{\rho}}\otimes\hat{\boldsymbol{\rho}} = E_3^7(\rho)\sum_{i=1}^{3}\frac{x_i}{(E_1^i(\rho))^2}\hat{\mathbf{x}}_i\otimes\mathbf{R}^{\mathrm{el}}(\mathbf{r}) = E_3^7(\rho)\sum_{i=1}^{3}\frac{x_i}{(E_1^i(\rho))^2}\mathbf{R}^{\mathrm{el}}(\mathbf{r})\otimes\hat{\mathbf{x}}_i, \quad \rho=\rho_b, \tag{159}$$

the boundary condition (153), on $\rho=\rho_b$, is written as

$$\begin{aligned}&(-\widetilde{\mathbf{I}}+\hat{\boldsymbol{\rho}}\otimes\hat{\boldsymbol{\rho}})\cdot\left\{\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}\frac{\partial\mathbf{R}^{\mathrm{el}}(\mathbf{r})}{\partial\rho}\left[\sum_{n=0}^{1}\sum_{m=1}^{2n+1}\frac{(2n+1)}{[E_n^m(\rho)]^2}\mathbb{E}_n^m(\mathbf{r})(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})\right.\right.\\ &\left.+\sum_{n=0}^{2}\sum_{m=1}^{2n+1}\frac{(2n+1)}{[E_n^m(\rho)]^2}\mathbb{E}_n^m(\mathbf{r})d_n^{(e)m}\right]-\sum_{m=1}^{5}[(d_2^{(i)m}+5I_2^m(\rho)d_2^{(e)m})\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}(\hat{\boldsymbol{\rho}}\cdot\nabla\otimes\nabla\mathbb{E}_n^m(\mathbf{r}))]\\ &\left.+\left[\sum_{n=0}^{1}\sum_{m=1}^{2n+1}\frac{(2n+1)}{[E_n^m(\rho)]^2}\nabla\mathbb{E}_n^m(\mathbf{r})(\mathbf{e}_n^{(e)m}\cdot\mathbf{r})+\sum_{n=0}^{2}\sum_{m=1}^{2n+1}\frac{(2n+1)}{[E_n^m(\rho)]^2}\nabla\mathbb{E}_n^m(\mathbf{r})d_n^{(e)m}\right]\right\}=\mathbf{0}, \quad \rho=\rho_b.\end{aligned} \tag{160}$$

A careful observation of condition (160) reveals the difficulty to manipulate it in Cartesian coordinates and the impossibility of direct application of orthogonality arguments. Nevertheless, the use of purely ellipsoidal terms simplifies Eq. (160). In particular, we perform all the necessary calculations, use (67)–(72), (76)–(80), and (86)–(91), insert the already known coefficients, and use the fact that

$$\begin{aligned}(\hat{\boldsymbol{\mu}}\otimes\hat{\boldsymbol{\mu}}+\hat{\boldsymbol{\nu}}\otimes\hat{\boldsymbol{\nu}})\cdot\sum_{i=1}^{3}x_i\hat{\mathbf{x}}_i\frac{3h_1h_2h_3}{h_i(E_1^i(\rho_b))^2}(\mathbf{e}_1^{(e)i}\cdot\hat{\mathbf{x}}_i) &= 3h_1h_2(\mathbf{e}_1^{(e)3}\cdot\hat{\mathbf{x}}_3)(\hat{\boldsymbol{\mu}}\otimes\hat{\boldsymbol{\mu}}+\hat{\boldsymbol{\nu}}\otimes\hat{\boldsymbol{\nu}})\cdot\sum_{i=1}^{3}\frac{x_i\hat{\mathbf{x}}_i}{(E_1^i(\rho_b))^2}\\ &= 3h_1h_2(\mathbf{e}_1^{(e)3}\cdot\hat{\mathbf{x}}_3)(\hat{\boldsymbol{\mu}}\otimes\hat{\boldsymbol{\mu}}+\hat{\boldsymbol{\nu}}\otimes\hat{\boldsymbol{\nu}})\cdot\left(\frac{h_\rho}{\rho_b}\hat{\boldsymbol{\rho}}\right)=\mathbf{0},\\ \rho&=\rho_b,\end{aligned} \tag{161}$$

to rewrite the boundary condition (160) in the simple form

$$\mathrm{A}(\rho_b,\mu,\nu)\hat{\boldsymbol{\mu}}+\mathrm{B}(\rho_b,\mu,\nu)\hat{\boldsymbol{\nu}}=\mathbf{0}, \tag{162}$$

where the quantities A and B contain surface ellipsoidal harmonics, the coefficients under evaluation, and some known constants. The orthogonality of the unit normal vectors $\hat{\boldsymbol{\mu}}$ and $\hat{\boldsymbol{\nu}}$ implies that A and B are equal to zero, i.e.,

$$\sum_{i=1}^{3} B_i\left(\frac{(E_1^i(\rho_a))^2}{x^2-\alpha_1^2+\alpha_i^2}-1\right)E_1^i(\mu)E_1^i(\nu)+\sum_{\substack{i,j=1\\ i\neq j}}^{3}\left(\frac{A_i^j+(E_1^i(\rho_b))^2C_i^j}{x^2-\alpha_1^2+\alpha_i^2}-C_i^j\right)E_2^{i+j}(\mu)E_2^{i+j}(\nu)=0, \tag{163}$$

where x assumes the values μ and ν, and

$$A_\kappa^l=\frac{3(E_1^\kappa(\rho_b))^2(\rho_b^2-\rho_a^2)h_l}{E_2^{\kappa+l}(\rho_b)}(\mathbf{e}_1^{(e)\kappa}\cdot\hat{\mathbf{x}}_l),\quad \kappa,l=1,2,3,\quad \kappa\neq l, \tag{164}$$

$$B_\kappa=\frac{2E_3^7(\rho_b)E_1^\kappa(\rho_b)h_\kappa U_\kappa}{N_\kappa},\quad \kappa=1,2,3, \tag{165}$$

with N_κ, $\kappa=1,2,3$ given in (134), while

$$C_\kappa^l=\frac{3}{E_2^{\kappa+l}(\rho_b)}[-h_\kappa(E_1^\kappa(\rho_a))^2(\mathbf{e}_1^{(e)l}\cdot\hat{\mathbf{x}}_\kappa)+E_3^7(\rho_b)(E_1^\kappa(\rho_b))^2(I_2^{\kappa+l}(\rho_b)-I_2^{\kappa+l}(\rho_a))(h_\kappa(E_1^\kappa(\rho_a))^2(\mathbf{e}_1^{(e)l}\cdot\hat{\mathbf{x}}_\kappa)$$
$$+h_l(E_1^l(\rho_a))^2(\mathbf{e}_1^{(e)\kappa}\cdot\hat{\mathbf{x}}_l))],\quad \kappa,l=1,2,3,\quad \kappa\neq l. \tag{166}$$

On the other hand, $(\mathbf{e}_1^{(e)\kappa}\cdot\hat{\mathbf{x}}_l)$ for $\kappa,l=1,2,3$ and $\kappa\neq l$ provide the six unknown coefficients, which must be evaluated with the aid of (149).

At this stage we have to deal with two major problems. The first one reflects the difficulty of applying orthogonality of the surface ellipsoidal harmonics $E_n^m(\mu)E_n^m(\nu)$ in (163), and the second concerns the number of the equations that we have to satisfy. In fact, we are left with five relations (three from (149) and two from (163)) to evaluate the six coefficients mentioned earlier. As far as the first difficulty is concerned, we introduce the new set of elliptic integrals on the surface of the ellipsoid $\rho=\rho_s$,

$$J_{n,\kappa}^m(\rho_s)=\int\int_{\rho=\rho_s}\frac{E_n^m(\mu)E_n^m(\nu)}{(x^2-\alpha_1^2+\alpha_\kappa^2)\sqrt{\rho_s^2-\mu^2}\sqrt{\rho_s^2-\nu^2}}\mathrm{d}S,\quad \kappa=1,2,3 \tag{167}$$

for $\mu\in[h_3,h_2]$, $\nu\in[-h_3,h_3]$, where we define the following values of x:

$$\text{for } x=\mu\Rightarrow J_{n,\kappa}^m\equiv M_{n,\kappa}^m \quad\text{and for } x=\nu\Rightarrow J_{n,\kappa}^m\equiv N_{n,\kappa}^m. \tag{168}$$

Therefore, we multiply (163) by the weighting function (33) and use the orthogonality relation (34) and the zeroth degree eigenfunction $E_0^1(\mu)E_0^1(\nu)\equiv 1$ to obtain

$$\sum_{\substack{i,j=1\\ i\neq j}}^{3} X_i^j h_i(\mathbf{e}_1^{(e)j}\cdot\hat{\mathbf{x}}_i)=Q_x,\quad x=\mu,\nu,\quad \mu\in[h_3,h_2],\quad \nu\in[-h_3,h_3], \tag{169}$$

with

$$X_\kappa^l = \frac{3}{E_2^{\kappa+l}(\rho_b)}\{(E_1^l(\rho_b))^4 J_{2,l}^{\kappa+l}(\rho_b) - (E_1^\kappa(\rho_a))^2[J_{2,l}^{\kappa+l}(\rho_b)(E_1^l(\rho_b))^2(1 - E_3^7(\rho_b)(E_1^l(\rho_b))^2(I_2^{\kappa+l}(\rho_b) - I_2^{\kappa+l}(\rho_a))) + J_{2,\kappa}^{\kappa+l}(\rho_b)(E_1^\kappa(\rho_b))^2(1 - E_3^7(\rho_b)(E_1^\kappa(\rho_b))^2(I_2^{\kappa+l}(\rho_b) - I_2^{\kappa+l}(\rho_a)))]\} \tag{170}$$

for every $\kappa, l = 1,2,3$ and $\kappa \neq l$, and

$$Q_x = -\sum_{i=1}^{3} \frac{2E_3^7(\rho_b)E_1^i(\rho_b)(E_1^i(\rho_a))^2 h_i U_i}{N_i} J_{1,i}^i(\rho_b) \tag{171}$$

for $x = \mu, \nu$. The constants N_κ, $\kappa = 1,2,3$ are given in (134). Relation (169) refers to two different equations for the values of $x = \mu, \nu$ containing the two different types of elliptic integrals appearing in (168). Despite the simplification of the final boundary condition by the introduction of a new set of elliptic integrals, our already reduced potential problem remains undetermined as far as one coefficient is concerned. Indeed, combining (149) with relation (169) we see that we are missing one more condition. Hence, we adopt, once more, our previous analysis, which springs from the flexibility of the Papkovich–Neuber differential representation.[17] In fact, since we have two boundary surfaces to satisfy our conditions, we use our technique twice, one for each boundary. Therefore, in terms of the elliptic integrals

$$L_{n,\kappa}^m(\rho_s) = N_{n,\kappa}^m(\rho_s) - M_{n,\kappa}^m(\rho_s) = \int\int_{\rho=\rho_s} \frac{(\mu^2 - \nu^2)E_n^m(\mu)E_n^m(\nu)}{(\mu^2 - \alpha_1^2 + \alpha_\kappa^2)(\nu^2 - \alpha_1^2 + \alpha_\kappa^2)} \frac{\mathrm{d}S}{\sqrt{\rho_s^2 - \mu^2}\sqrt{\rho_s^2 - \nu^2}}, \quad \kappa = 1,2,3, \tag{172}$$

we substract by parts Eq. (169) for the different values of $x = \mu, \nu$ and we *choose* the following condition for the unknown coefficients, i.e.,

$$Q_\kappa^l h_\kappa(\mathbf{e}_1^{(e)l} \cdot \hat{\mathbf{x}}_\kappa) + Q_l^\kappa h_l(\mathbf{e}_1^{(e)\kappa} \cdot \hat{\mathbf{x}}_l) \equiv \tfrac{1}{3}(Q_\nu - Q_\mu) = Q, \quad \kappa, l = 1,2,3, \quad \kappa \neq l, \tag{173}$$

where

$$Q_\kappa^l = \frac{3}{E_2^{\kappa+l}(\rho_b)}\{(E_1^l(\rho_b))^4 L_{2,l}^{\kappa+l}(\rho_b) - (E_1^\kappa(\rho_a))^2[L_{2,l}^{\kappa+l}(\rho_b)(E_1^l(\rho_b))^2(1 - E_3^7(\rho_b)(E_1^l(\rho_b))^2(I_2^{\kappa+l}(\rho_b) - I_2^{\kappa+l}(\rho_a))) + L_{2,\kappa}^{\kappa+l}(\rho_b)(E_1^\kappa(\rho_b))^2(1 - E_3^7(\rho_b)(E_1^\kappa(\rho_b))^2(I_2^{\kappa+l}(\rho_b) - I_2^{\kappa+l}(\rho_a)))]\} \tag{174}$$

and

$$Q = -\frac{2E_3^7(\rho_b)}{3}\sum_{i=1}^{3} \frac{E_1^i(\rho_b)(E_1^i(\rho_a))^2 h_i U_i}{N_i} L_{1,i}^i(\rho_b), \tag{175}$$

with the constants N_κ, $\kappa = 1,2,3$ given by (134). This way we generate an additional relation for the evaluation of the coefficients through condition (173). This is the second and final restriction to our problem, which provided the three explicit equations (173).

We solve a system of six equations for the last six unknown coefficients $(\mathbf{e}_1^{(e)l} \cdot \hat{\mathbf{x}}_\kappa)$, $\kappa, l = 1,2,3$, $\kappa \neq l$, taking into account relations (149) and (173). Defining $(\mathbf{e}_1^{(e)l} \cdot \hat{\mathbf{x}}_\kappa) \equiv e_\kappa^l$, we rewrite the solution as

$$(\mathbf{e}_1^{(e)l} \cdot \hat{\mathbf{x}}_\kappa) \equiv \mathbf{e}_\kappa^l = \frac{P_l^\kappa Q - Q_l^\kappa R^{\kappa+l}}{h_\kappa(P_l^\kappa Q_\kappa^l - P_\kappa^l Q_l^\kappa)}, \quad \kappa, l = 1,2,3, \quad \kappa \neq l, \tag{176}$$

where the constants P_κ^l, Q_κ^l, $R^{\kappa+l}$ for $\kappa, l = 1,2,3$, $\kappa \neq l$, and Q are given by (150), (174), (151), and (175), respectively. It is easily proved that $P_l^\kappa Q_\kappa^l - P_\kappa^l Q_l^\kappa \neq 0$. Hence, having used all the boundary conditions (51)–(53) we evaluated all the coefficients.

The final step contains the presentation of a mixed Cartesian-ellipsoidal form of the *first terms*

of the flow fields formulated by expressions (115)–(118), using the information (67)–(112). Introducing all the evaluated coefficients from the previous steps and using the Cartesian-ellipsoidal formulation of the interior and exterior ellipsoidal harmonics, as well as their gradients, some extended algebra on the velocity field (115) leads to

$$\mathbf{v}^{(0)}(\mathbf{r}) = \mathbf{U} + \mathbf{\Omega} \times \mathbf{r} + \mathbf{Z}(\rho) + \sum_{j=1}^{3} \mathbf{H}_j(\rho)\mathbb{E}_1^j(\mathbf{r}) + \frac{\hat{\boldsymbol{\rho}}}{2\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}} \times \left[\sum_{j=1}^{3} \Theta_j(\rho)\mathbb{E}_1^j(\mathbf{r}) + \sum_{\substack{i,j=1 \\ i\neq j}}^{3} \Phi_i^j(\rho)\mathbb{E}_2^{i+j}(\mathbf{r}) \right], \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{177}$$

where for every $\rho_a \leqslant \rho \leqslant \rho_b$ we define the vector quantities

$$\mathbf{Z}(\rho) = -E_3^7(\rho_b)\mathbf{U} \cdot \sum_{i=1}^{3} [(I_0^1(\rho) - I_0^1(\rho_a)) + (E_1^i(\rho_a))^2(I_1^i(\rho) - I_1^i(\rho_a))] \frac{\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i}{N_i} \tag{178}$$

and

$$\mathbf{H}_\kappa(\rho) = \frac{3}{2} \sum_{\substack{i=1 \\ i\neq\kappa}}^{3} \{h_i e_i^\kappa (I_1^\kappa(\rho) - I_1^\kappa(\rho_a)) - h_\kappa e_\kappa^i (I_1^i(\rho) - I_1^i(\rho_a)) + [h_i e_i^\kappa (E_1^i(\rho_a))^2 + h_\kappa e_\kappa^i (E_1^\kappa(\rho_a))^2](I_2^{i+\kappa}(\rho) - I_2^{i+\kappa}(\rho_a))\} \frac{\hat{\mathbf{x}}_i}{h_i}, \quad \kappa = 1,2,3. \tag{179}$$

Furthermore, the scalar products for the same interval $\rho_a \leqslant \rho \leqslant \rho_b$ are

$$\Theta_\kappa(\rho) = -\frac{2h_\kappa E_3^7(\rho_b)}{h_1h_2h_3} \frac{(\mathbf{U} \cdot \hat{\mathbf{x}}_\kappa)}{N_\kappa} \left[1 - \left(\frac{E_1^\kappa(\rho_a)}{E_1^\kappa(\rho)} \right)^2 \right], \quad \kappa = 1,2,3 \tag{180}$$

and

$$\Phi_\kappa^l(\rho) = \frac{3h_\kappa}{h_1h_2h_3} e_\kappa^l \left[1 - \left(\frac{E_1^\kappa(\rho_a)}{E_1^\kappa(\rho)} \right)^2 \right] \frac{1}{(E_1^l(\rho))^2}, \quad \kappa,l = 1,2,3, \quad \kappa \neq l. \tag{181}$$

Once the constants N_κ for $\kappa=1,2,3$ in (134) and e_κ^l for $\kappa,l=1,2,3$, $\kappa \neq l$ in (176) are calculated, the velocity field is obtained in terms of the applied fields $\mathbf{U}$ and $\mathbf{\Omega}$ via Eq. (50). The total pressure field (116) assumes the expression

$$P^{(0)}(\mathbf{r}) = P_0 + \mu_0 \frac{E_3^7(\rho)}{(\rho^2-\mu^2)(\rho^2-\nu^2)} \left[\sum_{j=1}^{3} \frac{\Theta_j(\rho)}{\rho^2-\rho_a^2} \mathbb{E}_1^j(\mathbf{r}) + \frac{3}{h_1h_2h_3} \sum_{\substack{i,j=1 \\ i\neq j}}^{3} \frac{h_i e_i^j}{(E_2^{i+j}(\rho))^2} \mathbb{E}_2^{i+j}(\mathbf{r}) \right]$$
$$= p^{(0)}(\mathbf{r}) + \rho_0 g h, \quad \mathbf{r} \in \Omega(\mathbb{R}^3), \tag{182}$$

where the coefficients e_κ^l for $\kappa,l=1,2,3$, $\kappa \neq l$ are given by (176), where the identity (A4) and formula

$$\sum_{i=1}^{3} \frac{x_i^2}{(E_1^i(\rho))^2} = \frac{h_\rho^2}{\rho^2}, \quad \rho_a \leqslant \rho \leqslant \rho_b \tag{183}$$

have been used. The reference constant h is appropriately chosen depending upon the physical requirements. Here, we must mention that the constant pressure of reference P_0 is written as

$$P_0 = -\mu_0 h_1 h_2 h_3 \sum_{j=1}^{3} \frac{1}{h_j}(\mathbf{e}_1^{(i)j} \cdot \hat{\mathbf{x}}_j), \tag{184}$$

which actually contains the coefficients $(\mathbf{e}_1^{(i)\kappa} \cdot \hat{\mathbf{x}}_\kappa)$, $\kappa = 1,2,3$ that were not evaluated by the boundary conditions. Nevertheless, P_0 enter Stokes equations (1) and (2) under the action of the gradient operator, providing that way $\nabla P_0 = \mathbf{0}$. Thus, we can use the very same physical arguments to specify this constant pressure. As far as the vorticity field is concerned we can expand relation (117) in view of (67)–(112), and substitute the obtained coefficients. Nevertheless, an easier root is followed with respect to the definition (3), by taking the rotation of the velocity field (177). After the application of certain identities we obtain

$$\nabla \times \mathbf{U} = \mathbf{0}, \quad \nabla \times (\mathbf{\Omega} \times \mathbf{r}) = 2\mathbf{\Omega} \tag{185}$$

and some extensive algebra leads to

$$\nabla \times \frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2 - \mu^2}\sqrt{\rho^2 - \nu^2}} = \mathbf{0}, \quad \mathbf{r} \in \Omega(\mathbb{R}^3). \tag{186}$$

Matching (185) and (186) and utilizing definitions (178)–(181), we arrive at

$$\begin{aligned}\boldsymbol{\omega}^{(0)}(\mathbf{r}) = \mathbf{\Omega} + \frac{h_1 h_2 h_3}{2} \sum_{j=1}^{3} \frac{1}{h_j}(\hat{\mathbf{x}}_j \times \mathbf{H}_j(\rho)) + \frac{\sqrt{\rho^2 - h_3^2}\sqrt{\rho^2 - h_2^2}\hat{\boldsymbol{\rho}}}{2\sqrt{\rho^2 - \mu^2}\sqrt{\rho^2 - \nu^2}} \times \left[\mathbf{Z}'(\rho) + \sum_{j=1}^{3} \mathbf{H}_j'(\rho)\mathbb{E}_1^j(\mathbf{r}) \right] \\ - \frac{h_1 h_2 h_3 \hat{\boldsymbol{\rho}}}{4\sqrt{\rho^2 - \mu^2}\sqrt{\rho^2 - \nu^2}} \times \left[\sum_{j=1}^{3} \frac{\Theta_j(\rho)}{h_j}\hat{\mathbf{x}}_j + \sum_{\substack{i,j=1 \\ i \neq j}}^{3} \Phi_i^j(\rho)\left(\frac{\mathbb{E}_1^i(\mathbf{r})}{h_j}\hat{\mathbf{x}}_j + \frac{\mathbb{E}_1^j(\mathbf{r})}{h_i}\hat{\mathbf{x}}_i \right) \right]\end{aligned} \tag{187}$$

for every $\mathbf{r} \in \Omega(\mathbb{R}^3)$, where $\mathbf{\Omega}$ stands for the constant vorticity (50), with

$$\mathbf{Z}'(\rho) = \frac{E_3^7(\rho_b)\mathbf{U}}{\sqrt{\rho^2 - h_3^2}\sqrt{\rho^2 - h_2^2}} \cdot \sum_{i=1}^{3} \frac{\hat{\mathbf{x}}_i \otimes \hat{\mathbf{x}}_i}{N_i}\left[1 + \left(\frac{E_1^i(\rho_a)}{E_1^i(\rho)} \right)^2 \right], \quad \rho_a \leqslant \rho \leqslant \rho_b \tag{188}$$

and

$$\begin{aligned}\mathbf{H}_\kappa'(\rho) = \frac{3}{2\sqrt{\rho^2 - h_3^2}\sqrt{\rho^2 - h_2^2}} \sum_{\substack{i=1 \\ i \neq \kappa}}^{3} \frac{\hat{\mathbf{x}}_i}{h_i}\Bigg\{ - \frac{h_i e_i^\kappa}{(E_1^\kappa(\rho))^2}\left[1 + \left(\frac{E_1^i(\rho_a)}{E_1^i(\rho)} \right)^2 \right] \\ + \frac{h_\kappa e_\kappa^i}{(E_1^i(\rho))^2}\left[1 - \left(\frac{E_1^\kappa(\rho_a)}{E_1^\kappa(\rho)} \right)^2 \right] \Bigg\}, \quad \kappa = 1,2,3\end{aligned} \tag{189}$$

for $\rho_a \leqslant \rho \leqslant \rho_b$. The constants N_κ for $\kappa = 1,2,3$ are given by (134) and the coefficients e_κ^l for $\kappa, l = 1,2,3$, $\kappa \neq l$ are provided by (176). Next, in order to obtain the expression for the stress tensor field, we use identities (39)–(45) so that

$$\nabla \otimes \mathbf{U} = (\nabla \otimes \mathbf{U})^{\mathsf{T}} = \widetilde{\mathbf{0}}, \quad \nabla \otimes (\mathbf{\Omega} \times \mathbf{r}) = \mathbf{\Omega} \times \widetilde{\mathbf{I}} \tag{190}$$

and we use relations (22) and (109) to obtain the dyadic $\widetilde{\mathbf{S}}$ in the form

$$\widetilde{\mathbf{S}}(\mathbf{r}) \equiv \nabla \otimes \left(\frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}} \right) + \left[\nabla \otimes \left(\frac{\hat{\boldsymbol{\rho}}}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}} \right) \right]^{\mathsf{T}}$$
$$= \frac{2}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}} \left\{ \frac{\rho}{h_\rho} \left[-\left(\frac{1}{\rho^2-\mu^2} + \frac{1}{\rho^2-\nu^2} \right) \hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\rho}} + \frac{\hat{\boldsymbol{\mu}} \otimes \hat{\boldsymbol{\mu}}}{\rho^2-\mu^2} + \frac{\hat{\boldsymbol{\nu}} \otimes \hat{\boldsymbol{\nu}}}{\rho^2-\nu^2} \right] \right.$$
$$\left. + \frac{\mu}{h_\mu(\rho^2-\mu^2)} (\hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\mu}} + \hat{\boldsymbol{\mu}} \otimes \hat{\boldsymbol{\rho}}) + \frac{\nu}{h_\nu(\rho^2-\nu^2)} (\hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\nu}} + \hat{\boldsymbol{\nu}} \otimes \hat{\boldsymbol{\rho}}) \right\}. \tag{191}$$

Further calculations lead to

$$\widetilde{\mathbf{\Pi}}^{(0)}(\mathbf{r}) = (\rho_0 g h - P^{(0)}(\mathbf{r}))\widetilde{\mathbf{I}} - \mu_0 \left\{ \frac{1}{h_\rho} (\hat{\boldsymbol{\rho}} \otimes \mathbf{Z}'(\rho) + \mathbf{Z}'(\rho) \otimes \hat{\boldsymbol{\rho}}) + \sum_{j=1}^{3} \left[\frac{\mathbb{E}_1^j(\mathbf{r})}{h_\rho} (\hat{\boldsymbol{\rho}} \otimes \mathbf{H}_j'(\rho) + \mathbf{H}_j'(\rho) \right.\right.$$
$$\left.\left. \otimes \hat{\boldsymbol{\rho}}) + \frac{h_1 h_2 h_3}{h_j} (\hat{\mathbf{x}}_j \otimes \mathbf{H}_j(\rho) + \mathbf{H}_j(\rho) \otimes \hat{\mathbf{x}}_j) \right] \right\} - \frac{\mu_0}{2} \widetilde{\mathbf{S}}(\mathbf{r}) \left[\sum_{j=1}^{3} \Theta_j(\rho) \mathbb{E}_1^j(\mathbf{r}) \right.$$
$$\left. + \sum_{\substack{i,j=1 \\ i \neq j}}^{3} \Phi_i^j(\rho) \mathbb{E}_2^{i+j}(\mathbf{r}) \right] - \frac{\mu_0}{\sqrt{\rho^2-\mu^2}\sqrt{\rho^2-\nu^2}} \left\{ \frac{\hat{\boldsymbol{\rho}} \otimes \hat{\boldsymbol{\rho}}}{h_\rho} \left[\sum_{j=1}^{3} \Theta_j'(\rho) \mathbb{E}_1^j(\mathbf{r}) + \sum_{\substack{i,j=1 \\ i \neq j}}^{3} \Phi_i^{j'}(\rho) \mathbb{E}_2^{i+j}(\mathbf{r}) \right] \right.$$
$$+ \frac{h_1 h_2 h_3}{2} \left[\sum_{j=1}^{3} \frac{\Theta_j(\rho)}{h_j} (\hat{\boldsymbol{\rho}} \otimes \hat{\mathbf{x}}_j + \hat{\mathbf{x}}_j \otimes \hat{\boldsymbol{\rho}}) + \sum_{\substack{i,j=1 \\ i \neq j}}^{3} \Phi_i^j(\rho) \left(\frac{\mathbb{E}_1^i(\mathbf{r})}{h_j} (\hat{\boldsymbol{\rho}} \otimes \hat{\mathbf{x}}_j + \hat{\mathbf{x}}_j \otimes \hat{\boldsymbol{\rho}}) \right.\right.$$
$$\left.\left.\left.\left. + \frac{\mathbb{E}_1^j(\mathbf{r})}{h_i} (\hat{\boldsymbol{\rho}} \otimes \hat{\mathbf{x}}_i + \hat{\mathbf{x}}_i \otimes \hat{\boldsymbol{\rho}}) \right) \right] \right\} \tag{192}$$

for $\mathbf{r} \in \Omega(\mathbb{R}^3)$, where $P^{(0)}$ is the total pressure (182), while in view of the applied field $\mathbf{U}$ (50)

$$\Theta_\kappa'(\rho) = -\frac{4 h_\kappa E_3^7(\rho_b)}{h_1 h_2 h_3} \frac{(\mathbf{U} \cdot \hat{\mathbf{x}}_\kappa)}{N_\kappa} \frac{(E_1^\kappa(\rho_a))^2}{(E_1^\kappa(\rho))^4} \rho, \quad \kappa = 1,2,3 \tag{193}$$

and

$$\Phi_\kappa^{l'}(\rho) = -\frac{6 h_\kappa}{h_1 h_2 h_3} \frac{\rho e_\kappa^l}{(E_1^l(\rho))^4} \left\{ 1 - \left(\frac{E_1^\kappa(\rho_a)}{E_1^\kappa(\rho)} \right)^2 \left[1 + \left(\frac{E_1^l(\rho)}{E_1^\kappa(\rho)} \right)^2 \right] \right\}, \quad \kappa,l = 1,2,3, \quad \kappa \neq l \tag{194}$$

for every $\rho_a \leqslant \rho \leqslant \rho_b$. We remind that the coefficients e_κ^l for $\kappa,l=1,2,3$, $\kappa \neq l$ are satisfied by (176), the metric coefficient h_ρ is given by Eq. (21), N_κ for $\kappa=1,2,3$ are provided by (134) and expressions (178)–(181), (188), and (189) have been used. Recapitulating, the *first terms*, of the velocity field (177), of the total pressure field (182), of the vorticity field (187), and of the stress tensor field (192) have been analytically calculated on the basis of the Happel-type boundary conditions.

V. GEOMETRICALLY DEGENERATE CASES

The strict inequalities

$$0 < \alpha_3 < \alpha_2 < \alpha_1 < +\infty \tag{195}$$

form the basic reason why the triaxial ellipsoid reflects the general anisotropy of the three-dimensional space. As it is well known,[20] the reduction of general results from the ellipsoidal to the spheroidal, or to the spherical geometry is not straightforward, since certain indeterminacies appear during the limiting process. This is due to the fact that the spherical system springs from a zero-dimensional manifold (i.e., the center), while the ellipsoidal system springs from a two-dimensional manifold (i.e., the focal ellipse). Nevertheless, formulas (A42)–(A51) ensure the appropriate reductions. In particular, we consider every case separately.

The geometrically degenerate cases of spheroids: The equality of the two of the axis (195) of an ellipsoid degenerates it to a spheroid, whose axial symmetry coincides with the third axis. More specific, *a prolate spheroid* is obtained whenever

$$0 < \alpha_3 = \alpha_2 < \alpha_1 < +\infty, \tag{196}$$

while the case of an *oblate spheroid* corresponds to

$$0 < \alpha_3 < \alpha_2 = \alpha_1 < +\infty. \tag{197}$$

The axis of symmetry is the x_1 axis for the prolate spheroid and the x_3 axis for the oblate spheroid. The asymptotic case of the *needle* can be reached by a prolate spheroid where

$$0 < \alpha_3 = \alpha_2 \ll \alpha_1 < +\infty, \tag{198}$$

while in the case where

$$0 < \alpha_3 \ll \alpha_2 = \alpha_1 < +\infty, \tag{199}$$

the oblate spheroid takes the shape of a circular *disk*. As far as the semifocal distances are concerned, we have that

$$h_1 = 0, \quad h_2 = h_3 = c, \quad c > 0 \tag{200}$$

for the case of a prolate spheroid with semifocal distance c, and

$$h_3 = 0, \quad h_1 = h_2 = \bar{c}, \quad \bar{c} > 0 \tag{201}$$

for the case of an oblate spheroid with semifocal distance $\bar{c}$. The simple transformation

$$c \to -i\bar{c}, \quad c, \bar{c} > 0 \tag{202}$$

allows the transition from the prolate to the oblate spheroid, while the replacement

$$\bar{c} \to ic, \quad c, \bar{c} > 0 \tag{203}$$

secures the converse. In terms of the notation $\tau \equiv \cosh \eta$, $\zeta \equiv \cos \theta$, and φ for $1 \leqslant \tau < +\infty$, $-1 \leqslant \zeta \leqslant 1$ and $\varphi \in [0, 2\pi)$, respectively, for the prolate spheroid, the corresponding results for the oblate spheroid can be obtained through the transformation

$$\tau \to i\lambda, \quad 1 \leqslant \tau < +\infty, \tag{204}$$

where $0 \leqslant \lambda \equiv \sinh \eta < +\infty$ is the characteristic variable of the oblate system λ, ζ, and φ. Obviously the inverse transformation

$$\lambda \to -i\tau, \quad 0 \leqslant \lambda < +\infty \tag{205}$$

leads to the converse. Consequently, from this point on we shall refer to the prolate spheroidal geometry, since the oblate spheroidal geometry is recovered via

$$\tau \to i\lambda, \quad c \to -i\bar{c}. \tag{206}$$

In terms of the unit normal vector $\hat{\boldsymbol{\tau}}$ for the prolate spheroidal coordinates, the ellipsoidal variables are connected with the τ, ζ, and φ by

$$\rho = c\tau, \quad \hat{\boldsymbol{\rho}} \to \hat{\boldsymbol{\tau}}, \quad \rho \in [h_2, +\infty), \quad 1 \leqslant \tau < +\infty \tag{207}$$

and

$$\frac{\mu\nu}{h_2 h_3} = \zeta, \tag{208}$$

$$\frac{\sqrt{\mu^2 - h_3^2}\sqrt{h_3^2 - \nu^2}}{h_1 h_3} = \sqrt{1-\zeta^2}\cos\varphi, \tag{209}$$

$$\frac{\sqrt{h_2^2 - \mu^2}\sqrt{h_2^2 - \nu^2}}{h_1 h_2} = \sqrt{1-\zeta^2}\sin\varphi, \tag{210}$$

whereas $\mu \in [h_3, h_2]$, $\nu \in [-h_3, h_3]$ and $1 \leqslant \tau < +\infty$, $\varphi \in [0, 2\pi)$. For $\alpha_2 = \alpha_3$ (prolate spheroid) the constants (63) provide

$$\lim_{\alpha_2 \to \alpha_3} \Lambda = \frac{2\alpha_1^2 + \alpha_2^2}{3}, \quad \lim_{\alpha_2 \to \alpha_3} \Lambda' = \alpha_2^2, \tag{211}$$

while as a consequence of the limits (211) for $\alpha_2 = \alpha_3$,

$$\lim_{\alpha_2 \to \alpha_3} (\Lambda - \Lambda') = \lim_{\alpha_2 \to \alpha_3} (\Lambda - \alpha_2^2) = \lim_{\alpha_2 \to \alpha_3} (\Lambda - \alpha_3^2) = \frac{2c^2}{3}, \tag{212}$$

$$\lim_{\alpha_2 \to \alpha_3} (\Lambda - \alpha_1^2) = -\frac{c^2}{3}, \tag{213}$$

$$\lim_{\alpha_2 \to \alpha_3} (\Lambda' - \alpha_1^2) = -c^2, \tag{214}$$

$$\lim_{\alpha_2 \to \alpha_3} (\Lambda' - \alpha_2^2) = \lim_{\alpha_2 \to \alpha_3} (\Lambda' - \alpha_3^2) = 0. \tag{215}$$

Moreover, the constants (65) for $\alpha_2 = \alpha_3$ ($\Lambda_2 = \Lambda_3$, $\Lambda_2' = \Lambda_3'$, prolate spheroid) become

$$\lim_{\alpha_2 \to \alpha_3} \left.\begin{matrix} \Lambda_\kappa \\ \Lambda_\kappa' \end{matrix}\right\} = \frac{2}{5}(\alpha_1^2 + 2\alpha_2^2) - \frac{1}{5}\alpha_\kappa^2 \pm \frac{1}{5}\left\{ 4(\alpha_1^4 + 2\alpha_2^4) - 3\alpha_\kappa^4 - \alpha_1^2\alpha_2^4\left[\left(\frac{1}{\alpha_1^2} + \frac{2}{\alpha_2^2}\right) + \frac{6}{\alpha_\kappa^2}\right]\right\}^{1/2}, \quad \kappa = 1,2, \tag{216}$$

where one can calculate the $(\Lambda_\kappa - \alpha_l^2)$ and $(\Lambda_\kappa' - \alpha_l^2)$ for $\kappa, l = 1,2,3$. On the other hand, the integrals I_n^m in prolate spheroidal geometry ($\alpha_2 = \alpha_3$)

$$\lim_{\alpha_2\to\alpha_3} I_n^m(\rho)=\int_\rho^{+\infty}\frac{\mathrm{d}u}{[\lim_{\alpha_2\to\alpha_3} E_n^m(u)]^2|u^2-\alpha_1^2+\alpha_2^2|},\quad \rho\in[h_2,+\infty) \tag{217}$$

for $n=0,1,\ldots$ and $m=1,2,\ldots,2n+1$ are no more elliptic and they can be evaluated with analytic manipulations. Specifically, the determination of I_0^1 demands the calculation of the corresponding integral (217) for $n=0$ and $m=1$ in terms of the variable τ, that is

$$\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)=\frac{1}{2c}\ln\frac{\tau+1}{\tau-1},\quad \rho\in[h_2,+\infty),\quad 1\leqslant\tau<+\infty. \tag{218}$$

The other elliptic integrals, which concern the already known exterior ellipsoidal harmonic eigenfunctions for degree $n=1,2,3$ and order $m=1,2,\ldots,2n+1$, are given explicitly in terms of the $\lim_{\alpha_2\to\alpha_3} I_0^1$ and their prolate spheroidal expressions ($\alpha_2=\alpha_3$) give

$$\lim_{\alpha_2\to\alpha_3} I_1^1(\rho)=\frac{1}{c^2}\left(\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{1}{c\tau}\right),\quad c>0, \tag{219}$$

$$\lim_{\alpha_2\to\alpha_3} I_1^2(\rho)=\lim_{\alpha_2\to\alpha_3} I_1^3(\rho)=-\frac{1}{2c^2}\left(\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{\tau}{c(\tau^2-1)}\right),\quad c>0, \tag{220}$$

$$\lim_{\alpha_2\to\alpha_3} I_2^1(\rho)=\frac{9}{4c^4}\left(\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{\tau}{c(3\tau^2-1)}\right),\quad c>0, \tag{221}$$

$$\lim_{\alpha_2\to\alpha_3} I_2^2(\rho)=\lim_{\alpha_2\to\alpha_3} I_2^5(\rho)=\frac{3}{8c^4}\left(\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{\tau(3\tau^2-5)}{3c(\tau^2-1)^2}\right),\quad c>0, \tag{222}$$

$$\lim_{\alpha_2\to\alpha_3} I_2^3(\rho)=\lim_{\alpha_2\to\alpha_3} I_2^4(\rho)=-\frac{3}{2c^4}\left(\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{3\tau^2-2}{3c\tau(\tau^2-1)}\right),\quad c>0. \tag{223}$$

Much more complicated calculations leads us to

$$\lim_{\alpha_2\to\alpha_3} I_3^1(\rho)=\frac{25}{c^6}\left(\frac{1}{4}\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{25\tau}{36c(5\tau^2-3)}-\frac{1}{9c\tau}\right), \tag{224}$$

$$\lim_{\alpha_2\to\alpha_3} I_3^2(\rho)=\lim_{\alpha_2\to\alpha_3} I_3^7(\rho)=\frac{1}{c^6}\left(\frac{15}{8}\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)+\frac{\tau}{4c(\tau^2-1)^2}-\frac{7\tau}{8c(\tau^2-1)}-\frac{1}{c\tau}\right), \tag{225}$$

$$\lim_{\alpha_2\to\alpha_3} I_3^3(\rho)=\lim_{\alpha_2\to\alpha_3} I_3^5(\rho)=-\frac{25}{c^6}\left(\frac{3}{16}\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{\tau}{32c(\tau^2-1)}-\frac{25\tau}{32c(5\tau^2-1)}\right), \tag{226}$$

$$\lim_{\alpha_2\to\alpha_3} I_3^4(\rho)=\lim_{\alpha_2\to\alpha_3} I_3^6(\rho)=-\frac{1}{c^6}\left(\frac{5}{16}\lim_{\alpha_2\to\alpha_3} I_0^1(\rho)-\frac{\tau}{6c(\tau^2-1)^3}+\frac{5\tau}{24c(\tau^2-1)^2}-\frac{5\tau}{16c(\tau^2-1)}\right) \tag{227}$$

for $c>0$. As far as the interior solid ellipsoidal harmonics as well as their gradients are concerned, their Cartesian representation easily implies the relative reductions. Finally, the limiting cases of the needle and of the disk are asymptotic reductions of the prolate and the oblate spheroidal geometry, respectively. For the *needle* we obtain

$$\alpha_1/\alpha_2 = \tau/\sqrt{\tau^2 - 1} \to +\infty, \quad 1 \leqslant \tau < +\infty, \tag{228}$$

and for the *disk* we obtain

$$\alpha_3/\alpha_2 = \lambda/\sqrt{\lambda^2 + 1} \to 0^+, \quad 0 \leqslant \lambda < +\infty. \tag{229}$$

The geometrically degenerate case of sphere: The sphere corresponds to

$$\alpha_1 = \alpha_2 = \alpha_3 = \alpha, \tag{230}$$

where α is the radius. In this case,

$$h_\kappa = 0, \quad \kappa = 1,2,3, \tag{231}$$

which means that all the semifocal distances of the ellipsoid coincide at the origin. Defining the limit from the ellipsoid to the sphere as "$\lim_{e\to s}$", the constants (63) give

$$\lim_{e\to s} \Lambda = \lim_{e\to s} \Lambda' = \alpha^2, \tag{232}$$

while from Eq. (65) we derive

$$\lim_{e\to s} \Lambda_\kappa = \lim_{e\to s} \Lambda'_\kappa = \alpha^2, \quad \kappa = 1,2,3 \tag{233}$$

so that

$$\lim_{e\to s}(\Lambda - \Lambda') = \lim_{e\to s}(\Lambda_\kappa - \Lambda'_\kappa) = 0, \quad \kappa = 1,2,3, \tag{234}$$

$$\lim_{e\to s}(\Lambda - \alpha_\kappa^2) = \lim_{e\to s}(\Lambda' - \alpha_\kappa^2) = 0, \quad \kappa = 1,2,3, \tag{235}$$

$$\lim_{e\to s}(\Lambda_\kappa - \alpha_l^2) = \lim_{e\to s}(\Lambda'_\kappa - \alpha_l^2) = 0, \quad \kappa,l = 1,2,3. \tag{236}$$

The intervals of variation of the variables μ and ν imply that

$$\lim_{e\to s} \mu = \lim_{e\to s} \nu = 0, \quad \kappa = 1,2,3. \tag{237}$$

In terms of the unit normal vector $\hat{\mathbf{r}}$ of the spherical system, the connection between the ellipsoidal variables and the corresponding spherical variables r, $\zeta \equiv \cos\theta$, and φ for $0 \leqslant r < +\infty$, $-1 \leqslant \zeta \leqslant 1$ and $\varphi \in [0, 2\pi)$ is

$$\lim_{e\to s} \rho = \lim_{e\to s}(\sqrt{\rho^2 - h_2^2}) = \lim_{e\to s}(\sqrt{\rho^2 - h_3^2}) = r, \quad \hat{\boldsymbol{\rho}} \to \hat{\mathbf{r}}, \quad \rho \in [h_2, +\infty), \quad r \geqslant 0 \tag{238}$$

for the radial component and

$$\frac{\mu\nu}{h_2 h_3} = \zeta, \tag{239}$$

$$\frac{\sqrt{\mu^2 - h_3^2}\sqrt{h_3^2 - \nu^2}}{h_1 h_3} = \sqrt{1 - \zeta^2}\cos\varphi, \tag{240}$$

$$\frac{\sqrt{h_2^2-\mu^2}\sqrt{h_2^2-\nu^2}}{h_1 h_2}=\sqrt{1-\zeta^2}\sin\varphi \tag{241}$$

for the angular dependence. The integrals I_n^m assume the values,

$$\lim_{e\to s} I_n^m(\rho)=\frac{1}{(2n+1)r^{2n+1}},\quad n\geqslant 0,\quad m=1,2,\ldots,2n+1,\quad \kappa=1,2,3 \tag{242}$$

for every $\rho\in[h_2,+\infty)$ and $r\geqslant 0$.

We mention that a proper reduction of our results for the velocity field (177) gives the *first term* of the series. The full solution of the above-mentioned Happel-type boundary value problem in spherical coordinates is given in Ref. 19, where the three-dimensional complete solution is obtained. For the sake of completeness, we provide the solution from Ref. 19 in the following.

If we define the sphere

$$B_r=\{\mathbf{r}\in\mathbb{R}^3 | x_1^2+x_2^2+x_3^2\leqslant r^2\}, \tag{243}$$

where

$$\mathbf{r}=\sum_{i=1}^{3} x_i\hat{\mathbf{x}}_i=r\zeta\hat{\mathbf{x}}_1+r\sqrt{1-\zeta^2}\cos\varphi\hat{\mathbf{x}}_2+r\sqrt{1-\zeta^2}\sin\varphi\hat{\mathbf{x}}_3, \tag{244}$$

then the *total* velocity assumes the form

$$\mathbf{v}^{(\text{sphere})}(\mathbf{r})=\mathbf{U}+\boldsymbol{\Omega}\times\mathbf{r}+\mathbf{Z}(r)+f(r)(x_1\mathbf{r}),\quad \mathbf{r}\in\Omega(\mathbb{R}^3). \tag{245}$$

We introduce the expression

$$\mathbf{Z}(r)=\frac{\mathbf{U}\cdot(\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_1)}{K}\left[-2(3\gamma^5+2)+4\gamma^5\left(\frac{r}{a}\right)^2+\left(\frac{a}{r}\right)^3+(2\gamma^5+3)\left(\frac{a}{r}\right)\right] \tag{246}$$

and

$$f(r)=\frac{1}{a^2}\left[(2\gamma^5+3)\left(\frac{a}{r}\right)^3-3\left(\frac{a}{r}\right)^5-2\gamma^5\right], \tag{247}$$

whereas

$$\gamma=\frac{a}{b}<1,\quad K=2-3\gamma+3\gamma^5-2\gamma^6,\quad \mathbf{U}=U_1\hat{\mathbf{x}}_1. \tag{248}$$

Note that, a,b are the radii of the concentric spheres of the corresponding Happel boundary value problem for Stokes flow around spherical particles.

VI. DISCUSSION

The physical interpretation of the mathematical problem analyzed in this work involves a method for solving three-dimensional Stokes flow problems with Happel-type boundary conditions. Based on this method we examine the flow in an ellipsoidal cell as a means of modeling flow through a swarm of ellipsoidal particles with the aim of the Papkovich–Neuber differential representation, which offers solutions for such problems in several orthogonal curvilinear geometries. The terms of major significance of the important physical flow fields such as the velocity, the total pressure, the vorticity, and the stress tensor are evaluated in closed form. The difficulty of this problem is focused on the determination of the coefficients, which characterize the nature of the corresponding potentials. This is caused by the appearance of certain indeterminacies, which reflect the complexity of the ellipsoidal geometry. The present work invoked a useful tool for dealing with nonaxisymmetric problems, which is the differential representation theory. The free-

dom that 3D representations offer, makes the solution of creeping flow problems within such domains feasible, a fact which is justified by the freedom, which this kind of representation offers. Consequently, a convenient handling of those extra conditions in order to cancel the singular behavior of the calculated expressions makes the calculations possible and leads to the explicit evaluation of the coefficients. It turns out that the velocity, to the first degree, which represents the leading term of the series, is sufficient for most real life applications, so long as the aspect ratios of the ellipsoids remains within moderate bounds. This is feasible, since the Stokes flow approximation requires a strict consideration of small particles and, then, our method stays valid. We conclude by showing the means for obtaining the corresponding results for the prolate and the oblate spheroid, the needle and the disk, and the sphere as degenerate ellipsoids.

ACKNOWLEDGMENT

Part of this work was performed while G.D. was at the University of Cambridge under the Marie Curie Chair of Excellence program ("BRAIN", EXC023928), funded by the European Union.

APPENDIX: RELATIONS ON ELLIPSOIDAL HARMONICS

For a detailed analysis of the ellipsoidal harmonics and related useful properties, one can refer to Ref. 20. However, in the interest of making this work complete and independent, we provide some useful material on ellipsoids and ellipsoidal harmonics, which were used in this work and most of them cannot be found in literature. They appear here for the first time.

We begin with the following connection formulas:

$$\rho^2+\mu^2+\nu^2=\sum_{i=1}^{3}x_i^2+h_2^2+h_3^2, \tag{A1}$$

$$\rho^2\mu^2+\rho^2\nu^2+\mu^2\nu^2=\sum_{i=1}^{3}h_i^2x_i^2+2x_1^2h_3^2+h_2^2h_3^2, \tag{A2}$$

$$\rho^2\mu^2\nu^2=x_1^2h_2^2h_3^2 \tag{A3}$$

for every $\rho\in[h_2,+\infty)$, $\mu\in[h_3,h_2]$, and $\nu\in[-h_3,h_3]$.

The elliptic integrals that enter the exterior ellipsoidal harmonics $\mathbb{F}_n^m$ are interconnected via the following relations:

$$\sum_{i=1}^{3}I_1^i(\rho)=\frac{1}{\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}=\frac{1}{E_3^7(\rho)}, \tag{A4}$$

$$\sum_{i=1}^{3}\alpha_i^2I_1^i(\rho)=I_0^1(\rho)-\frac{\rho^2-\alpha_1^2}{\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}, \tag{A5}$$

$$I_2^1(\rho)=\frac{1}{2(\Lambda-\alpha_1^2+\rho^2)\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}-\frac{1}{2}\sum_{i=1}^{3}\frac{I_1^i(\rho)}{\Lambda-\alpha_i^2}, \tag{A6}$$

$$I_2^2(\rho)=\frac{1}{2(\Lambda'-\alpha_1^2+\rho^2)\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}-\frac{1}{2}\sum_{i=1}^{3}\frac{I_1^i(\rho)}{\Lambda'-\alpha_i^2}, \tag{A7}$$

$$I_2^{\kappa+l}(\rho)=\frac{I_1^l(\rho)-I_1^\kappa(\rho)}{\alpha_\kappa^2-\alpha_l^2},\quad \kappa,l=1,2,3,\quad \kappa\neq l, \tag{A8}$$

$$I_3^7(\rho)=\frac{1}{h_1^2h_2^2h_3^2}\sum_{i=1}^{3}(-1)^{i+1}h_i^2I_1^i(\rho)=\frac{1}{h_1^2h_2^2h_3^2}\sum_{i=1}^{3}(-1)^{i+1}\alpha_i^2h_i^2I_2^{6-i}(\rho), \tag{A9}$$

$$\sum_{i=1}^{3}\frac{I_1^i(\rho)}{(\Lambda-\alpha_i^2)(\Lambda'-\alpha_i^2)}=3I_3^7(\rho), \tag{A10}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^2I_1^i(\rho)}{(\Lambda-\alpha_i^2)(\Lambda'-\alpha_i^2)}=\frac{3}{h_1^2}[I_1^2(\rho)-I_1^3(\rho)]+3\alpha_1^2I_3^7(\rho)=-3I_2^5(\rho)+3\alpha_1^2I_3^7(\rho), \tag{A11}$$

$$[\alpha_l^2I_1^\kappa(\rho)+\alpha_\kappa^2I_1^l(\rho)]=[\alpha_l^2I_1^l(\rho)+\alpha_\kappa^2I_1^\kappa(\rho)]+(\alpha_l^2-\alpha_\kappa^2)^2I_2^{\kappa+l}(\rho),\quad \kappa,l=1,2,3,\quad \kappa\neq l, \tag{A12}$$

$$\sum_{i=1}^{3}(-1)^ih_i^2I_2^{6-i}(\rho)=0. \tag{A13}$$

The essence of relations (A4)–(A13) is that between the ten integrals I_n^m, $n\leqslant 2$, and I_3^7 only two are linearly independent. For example, if I_0^1 and I_3^7 are known, then the other eight integrals can be written via these two.

The constants Λ and Λ', from Eq. (63), the semifocal distances h_κ, $\kappa=1,2,3$ and the semiaxes α_κ, $\kappa=1,2,3$ satisfy the following useful expressions:

$$\Lambda+\Lambda'=\frac{2}{3}\sum_{i=1}^{3}\alpha_i^2, \tag{A14}$$

$$\Lambda-\Lambda'=\frac{2}{3}\sqrt{h_1^4+h_2^2h_3^2}, \tag{A15}$$

$$\Lambda\Lambda'=\frac{\alpha_1^2\alpha_2^2\alpha_3^2}{3}\sum_{i=1}^{3}\frac{1}{\alpha_i^2} \tag{A16}$$

and

$$\sum_{i=1}^{3}(-1)^i(\Lambda-\alpha_i^2)h_i^2=\sum_{i=1}^{3}(-1)^i(\Lambda'-\alpha_i^2)h_i^2=0, \tag{A17}$$

$$\sum_{i=1}^{3}(-1)^i(\Lambda-\alpha_i^2)h_i^2\alpha_i^2=\sum_{i=1}^{3}(-1)^i(\Lambda'-\alpha_i^2)h_i^2\alpha_i^2=h_1^2h_2^2h_3^2, \tag{A18}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^2}{\Lambda-\alpha_i^2}=\sum_{i=1}^{3}\frac{\alpha_i^2}{\Lambda'-\alpha_i^2}=-3. \tag{A19}$$

Furthermore,

$$(\Lambda-\alpha_\kappa^2)(\Lambda'-\alpha_\kappa^2)=\frac{(-1)^{\kappa+1}h_1^2h_2^2h_3^2}{3h_\kappa^2},\quad \kappa=1,2,3, \tag{A20}$$

which implies that

$$\tfrac{3}{2}(\Lambda-\Lambda')-3(\Lambda-\alpha_1^2)=-\tfrac{3}{2}(\Lambda-\Lambda')-3(\Lambda'-\alpha_1^2)=h_2^2+h_3^2, \tag{A21}$$

$$(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)+(\Lambda-\alpha_1^2)(\Lambda-\alpha_3^2)+(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)=0, \tag{A22}$$

$$(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)+(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_3^2)+(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)=0 \tag{A23}$$

and

$$\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{(\Lambda-\alpha_\kappa^2)}=(-1)^{\kappa+1}\frac{h_1^2h_2^2h_3^2}{3h_\kappa^2}-\frac{(\Lambda-\alpha_\kappa^2)(\Lambda-\Lambda')}{2}, \tag{A24}$$

$$\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{(\Lambda'-\alpha_\kappa^2)}=(-1)^{\kappa+1}\frac{h_1^2h_2^2h_3^2}{3h_\kappa^2}+\frac{(\Lambda'-\alpha_\kappa^2)(\Lambda-\Lambda')}{2} \tag{A25}$$

for every $\kappa=1,2,3$. It is also easy to show that

$$\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{(\Lambda-\alpha_\kappa^2)(\Lambda-\alpha_l^2)}=\alpha_\kappa^2+\alpha_l^2-\frac{\Lambda+3\Lambda'}{2}+3(\Lambda'-\alpha_l^2)\delta_{\kappa l}, \tag{A26}$$

$$\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{(\Lambda'-\alpha_\kappa^2)(\Lambda'-\alpha_l^2)}=\alpha_\kappa^2+\alpha_l^2-\frac{3\Lambda+\Lambda'}{2}+3(\Lambda-\alpha_l^2)\delta_{\kappa l}. \tag{A27}$$

An important group of relations is given by

$$\sum_{i=1}^{3}\frac{\alpha_i^4}{\Lambda-\alpha_i^2}=-\frac{3}{2}(3\Lambda+\Lambda'), \tag{A28}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^4}{\Lambda'-\alpha_i^2}=-\frac{3}{2}(3\Lambda'+\Lambda), \tag{A29}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^4}{(\Lambda-\alpha_i^2)^2}=3-3\frac{\Lambda^2(\Lambda-\Lambda')}{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}, \tag{A30}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^4}{(\Lambda'-\alpha_i^2)^2}=3+3\frac{\Lambda'^2(\Lambda-\Lambda')}{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}, \tag{A31}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^2}{(\Lambda-\alpha_i^2)^2}=\Lambda\sum_{i=1}^{3}\frac{1}{(\Lambda-\alpha_i^2)^2}=-\frac{3\Lambda(\Lambda-\Lambda')}{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}, \tag{A32}$$

$$\sum_{i=1}^{3}\frac{\alpha_i^2}{(\Lambda'-\alpha_i^2)^2}=\Lambda'\sum_{i=1}^{3}\frac{1}{(\Lambda'-\alpha_i^2)^2}=\frac{3\Lambda'(\Lambda-\Lambda')}{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)} \tag{A33}$$

and

$$\sum_{i=1}^{3}\frac{(-1)^{i+1}h_i^2}{\Lambda-\alpha_i^2}=\frac{h_1^2h_2^2h_3^2}{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}, \tag{A34}$$

$$\sum_{i=1}^{3}\frac{(-1)^{i+1}h_i^2}{\Lambda'-\alpha_i^2}=\frac{h_1^2h_2^2h_3^2}{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}. \tag{A35}$$

The following relations connect the semifocal distances and the semiaxes of an ellipsoid:

$$\alpha_1^2h_1^2-\alpha_2^2h_2^2+\alpha_3^2h_3^2=0, \tag{A36}$$

$$\alpha_1^2h_1^2(h_2^2+h_3^2)-\alpha_2^2h_2^4+\alpha_3^2h_3^4=h_1^2h_2^2h_3^2, \tag{A37}$$

$$\alpha_1^4h_1^2-\alpha_2^4h_2^2+\alpha_3^4h_3^2=h_1^2h_2^2h_3^2, \tag{A38}$$

$$h_1^2\alpha_2^2\alpha_3^2-\alpha_1^2h_2^2\alpha_3^2+\alpha_1^2\alpha_2^2h_3^2=h_1^2h_2^2h_3^2, \tag{A39}$$

$$(\alpha_1^4\alpha_2^2-\alpha_1^2\alpha_2^4)+(\alpha_2^4\alpha_3^2-\alpha_2^2\alpha_3^4)+(\alpha_3^4\alpha_1^2-\alpha_3^2\alpha_1^4)=h_1^2h_2^2h_3^2, \tag{A40}$$

$$h_lh_\kappa h_{6-(\kappa+l)}=h_1h_2h_3,\quad \kappa,l=1,2,3,\quad \kappa\neq l. \tag{A41}$$

The tricky task of reducing the results from the ellipsoidal to the spheroidal and to the spherical geometry requires gathering terms containing ellipsoidal and Cartesian factors so as to eliminate the generated indeterminacies. We shall give some formulas, where these indeterminacies are suitably grouped. These are

$$(\alpha_\kappa^2-\alpha_l^2)(\Lambda-\alpha_s^2)\sum_{i=1}^{3}\frac{x_i^2}{\Lambda-\alpha_i^2}=3(\Lambda'-\alpha_\kappa^2)x_\kappa^2-3(\Lambda'-\alpha_l^2)x_l^2+(\alpha_\kappa^2-\alpha_l^2)\|\mathbf{r}\|^2, \tag{A42}$$

$$(\alpha_\kappa^2-\alpha_l^2)(\Lambda'-\alpha_s^2)\sum_{i=1}^{3}\frac{x_i^2}{\Lambda'-\alpha_i^2}=3(\Lambda-\alpha_\kappa^2)x_\kappa^2-3(\Lambda-\alpha_l^2)x_l^2+(\alpha_\kappa^2-\alpha_l^2)\|\mathbf{r}\|^2, \tag{A43}$$

where $\kappa,l,s=1,2,3$ and $\kappa\neq l$, $\kappa\neq s$, $l\neq s$, while

$$\frac{\mathbb{E}_2^1(\mathbf{r})}{(\Lambda-\Lambda')(\Lambda-\alpha_\kappa^2)}-\frac{\mathbb{E}_2^2(\mathbf{r})}{(\Lambda-\Lambda')(\Lambda'-\alpha_\kappa^2)}=\|\mathbf{r}\|^2-3x_\kappa^2+\alpha_\kappa^2-\frac{1}{3}\sum_{i=1}^{3}\alpha_i^2 \tag{A44}$$

for every $\kappa=1,2,3$. This is a useful relation, which with the aim of the identity

$$\frac{I_2^1(\rho)-I_2^2(\rho)}{\Lambda-\Lambda'}=\frac{3}{2}I_3^7(\rho)-\frac{1}{2\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\Lambda-\alpha_1^2+\rho^2)(\Lambda'-\alpha_1^2+\rho^2)} \tag{A45}$$

implies that

$$\frac{\mathbb{E}_2^1(\mathbf{r})I_2^1(\rho)}{(\Lambda-\Lambda')(\Lambda-\alpha_\kappa^2)}-\frac{\mathbb{E}_2^2(\mathbf{r})I_2^2(\rho)}{(\Lambda-\Lambda')(\Lambda'-\alpha_\kappa^2)}=\left(\|\mathbf{r}\|^2-3x_\kappa^2+\alpha_\kappa^2-\frac{1}{3}\sum_{i=1}^{3}\alpha_i^2\right)\times I_2^1(\rho)+\frac{\mathbb{E}_2^2(\mathbf{r})}{\Lambda'-\alpha_\kappa^2}\left[\frac{3}{2}I_3^7(\rho)-\frac{1}{2\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\Lambda-\alpha_1^2+\rho^2)(\Lambda'-\alpha_1^2+\rho^2)}\right] \tag{A46}$$

for $\kappa=1,2,3$. The factor that multiplies the square brackets on the second part of the right-hand side of Eq. (A46) has no indeterminacy, since

$$\frac{\mathbb{E}_2^1(\mathbf{r})}{\Lambda-\alpha_\kappa^2}=(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)\left[\sum_{i=1}^{3}\frac{x_i^2-x_\kappa^2}{\Lambda-\alpha_i^2}+1\right]\frac{1}{\Lambda-\alpha_\kappa^2} \tag{A47}$$

and

$$\frac{\mathbb{E}_2^2(\mathbf{r})}{\Lambda'-\alpha_\kappa^2}=(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)\left[\sum_{i=1}^{3}\frac{x_i^2-x_\kappa^2}{\Lambda'-\alpha_i^2}+1\right]\frac{1}{\Lambda'-\alpha_\kappa^2}, \tag{A48}$$

where $\kappa=1,2,3$. Two important expressions are

$$\frac{\Lambda'\mathbb{E}_2^1(\mathbf{r})}{(\Lambda-\Lambda')(\Lambda-\alpha_\kappa^2)}-\frac{\Lambda\mathbb{E}_2^2(\mathbf{r})}{(\Lambda-\Lambda')(\Lambda'-\alpha_\kappa^2)}=\sum_{i=1}^{3}x_i^2\left[\frac{3}{2}(\Lambda+\Lambda')-\alpha_i^2-\alpha_\kappa^2+3\delta_{i\kappa}(\alpha_i^2-\Lambda-\Lambda')\right]+\Lambda\Lambda'-\frac{\alpha_1^2\alpha_2^2\alpha_3^2}{\alpha_\kappa^2},\quad \kappa=1,2,3 \tag{A49}$$

and

$$\begin{aligned}&\frac{(\alpha_\kappa^2-\alpha_l^2)\Lambda\mathbb{E}_2^1(\mathbf{r})I_2^1(\rho)}{(\Lambda-\Lambda')(\Lambda-\alpha_\kappa^2)(\Lambda-\alpha_l^2)}-\frac{(\alpha_\kappa^2-\alpha_l^2)\Lambda'\mathbb{E}_2^2(\mathbf{r})I_2^2(\rho)}{(\Lambda-\Lambda')(\Lambda'-\alpha_\kappa^2)(\Lambda'-\alpha_l^2)}\\&=\alpha_\kappa^2\left(\|\mathbf{r}\|^2-3x_\kappa^2+\alpha_\kappa^2-\frac{1}{3}\sum_{i=1}^{3}\alpha_i^2\right)I_2^1(\rho)-\alpha_l^2\left(\|\mathbf{r}\|^2-3x_l^2+\alpha_l^2-\frac{1}{3}\sum_{i=1}^{3}\alpha_i^2\right)I_2^1(\rho)+\left(\frac{\alpha_\kappa^2\mathbb{E}_2^2(\mathbf{r})}{\Lambda'-\alpha_\kappa^2}\right.\\&\left.-\frac{\alpha_l^2\mathbb{E}_2^2(\mathbf{r})}{\Lambda'-\alpha_l^2}\right)\left[\frac{3}{2}I_3^7(\rho)-\frac{1}{2\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\Lambda-\alpha_1^2+\rho^2)(\Lambda'-\alpha_1^2+\rho^2)}\right]\end{aligned} \tag{A50}$$

for every $\kappa,l=1,2,3$, $\kappa\neq l$. Finally, we provide the relation

$$\frac{\Lambda I_2^1(\rho)-\Lambda' I_2^2(\rho)}{\Lambda-\Lambda'}=\frac{3}{2}[\alpha_1^2 I_3^7(\rho)-I_2^5(\rho)]+\frac{(\rho^2-\alpha_1^2)}{2\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\Lambda-\alpha_1^2+\rho^2)(\Lambda'-\alpha_1^2+\rho^2)},\quad \rho\in[h_2,+\infty), \tag{A51}$$

which also eliminates the indeterminacies in an appropriate way. We observe that relations (A42)–(A51) contain ellipsoidal functions of the second degree ($n=2$) and of order $m=1,2$. This is due to the fact that these ellipsoidal harmonics carry the indeterminacies, which enter the expressions, via the factors $\Lambda-\Lambda'$, $\Lambda-\alpha_\kappa^2$ and $\Lambda'-\alpha_\kappa^2$, $\kappa=1,2,3$ in the dominators. Similar expressions containing the factors $\Lambda_\kappa-\Lambda'_\kappa$, $\Lambda_\kappa-\alpha_l^2$ and $\Lambda'_\kappa-\alpha_l^2$ for $\kappa,l=1,2,3$ are much more complicated but they do not concern the present work.

This paper is the conclusion of a series that lays the groundwork for a structure and classification theory of second-order superintegrable systems, both classical and quantum, in conformally flat spaces. For two-dimensional and for conformally flat three-dimensional spaces with nondegenerate potentials we have worked out the structure of the classical systems and shown that the quadratic algebra always closes at order 6. Here we describe the quantum analogs of these results. We show that, for nondegenerate potentials, each classical system has a unique quantum extension. We also correct an error in an earlier paper in the series (that does not alter the structure results) and we elucidate the distinction between superintegrable systems with bases of functionally linearly independent and functionally linearly dependent symmetries. © *2006 American Institute of Physics.*

I. INTRODUCTION

This is the conclusion of a series[1–4] whose purpose is to lay the groundwork for a structure and classification theory of second-order superintegrable systems, both classical and quantum, in complex conformally flat spaces. Real spaces are considered as restrictions of these to the various real forms. In Refs. 1 and 3 we have given examples in two and three dimensions (2D and 3D), described the background as well as the interest and importance of these systems in mathematical physics, and given dozens of relevant references. Observed features of the systems are multiseparability, closure of the quadratic algebra of second-order symmetries at order 6, use of representation theory of the quadratic algebra to derive spectral properties of the quantum Schrödinger operator, and a close relationship with exactly solvable and quasi-exactly solvable problems.[5] Our approach is, rather than focus on particular spaces and systems, to use a general theoretical method based on integrability conditions to derive structure common to all systems.

We recall some basic facts and results about conformally flat superintegrable systems. An n-dimensional complex Riemannian space is conformally flat if and only if it admits a set of local coordinates $x_1,\ldots,x_n$ such that the contravariant metric tensor takes the form $g^{ij}=\delta^{ij}/\lambda(\mathbf{x})$. A classical superintegrable system $\mathcal{H}=\Sigma_{ij}g^{ij}p_ip_j+V(\mathbf{x})$ on the phase space of this manifold is one that admits $2n-1$ functionally independent generalized symmetries (or constants of the motion) $\mathcal{S}_k$, $k=1,\ldots,2n-1$ with $\mathcal{S}_1=\mathcal{H}$ where the $\mathcal{S}_k$ are polynomials in the momenta p_j.[6–11] It is easy to

[a)]Electronic mail: j.kress@unsw.edu.au
[b)]Electronic mail: miller@ima.umn.edu

see that $2n-1$ is the maximum possible number of functionally independent symmetries and, locally, such (in general nonpolynomial) symmetries always exist. The system is second-order superintegrable if the $2n-1$ functionally independent symmetries can be chosen to be quadratic in the momenta. Second-order superintegrable systems, though complicated, are tractable because standard orthogonal separation of variables techniques are associated with second-order symmetries, e.g., Refs. 12–17, and these techniques can be brought to bear. Thus we concentrate on second-order superintegrable systems in which the symmetries take the form $\mathcal{S}=\Sigma a^{ij}(\mathbf{x})p_ip_j+W(\mathbf{x})$, quadratic in the momenta.

There is an analogous definition for second-order quantum superintegrable systems with Schrödinger operator

$$H=\Delta+V(\mathbf{x}),\quad \Delta=\frac{1}{\sqrt{g}}\sum_{ij}\partial_{x_i}(\sqrt{g}g^{ij})\partial_{x_j},$$

the Laplace-Beltrami operator plus a potential function.[12] Here there are $2n-1$ second-order symmetry operators

$$S_k=\frac{1}{\sqrt{g}}\sum_{ij}\partial_{x_i}(\sqrt{g}a^{ij}_{(k)})\partial_{x_j}+W^{(k)}(\mathbf{x}),\quad k=1,\ldots,2n-1$$

with $S_1=H$ and $[H,S_k]\equiv HS_k-S_kH=0$. Again multiseparable systems yield many examples of superintegrability.

The structure theory for classical second-order superintegrable systems with nondegenerate potential for 2D spaces and for 3D conformally flat spaces has been worked out recently.[1–4,18] (This paper depends heavily on the results and methods of those papers and we shall refer to them repeatedly.) Each such system has quadratic algebra structure. Let $\{\mathcal{S}_j\}$ be a basis for the second-order constants of the motion for the Hamiltonian $\mathcal{H}$. By the superintegrability assumption, the Poisson brackets $\{\mathcal{S}_i,\mathcal{S}_j\}$ must be functionally dependent on the basis symmetries $\mathcal{S}_k$, as are $\{\{\mathcal{S}_i,\mathcal{S}_j\},\mathcal{S}_h\}$ and $\{\{\mathcal{S}_i,\mathcal{S}_j\},\{\mathcal{S}_h,\mathcal{S}_s\}\}$. For these systems it is always true that the squares $\{\mathcal{S}_i,\mathcal{S}_j\}^2$ and products $\{\mathcal{S}_i,\mathcal{S}_j\}\{\mathcal{S}_k,\mathcal{S}_\ell\}$ as well as $\{\{\mathcal{S}_i,\mathcal{S}_j\},\mathcal{S}_h\}$ and $\{\{\mathcal{S}_i,\mathcal{S}_j\},\{\mathcal{S}_h,\mathcal{S}_s\}\}$ are always uniquely expressible as *polynomials* in the $\{\mathcal{S}_k\}$. This remarkable closure of the algebra generated by the second-order symmetries leads to the very special properties enjoyed by the classical superintegrable systems.

Observed common features of the quantum analogs of these systems are that they are usually multiseparable and that the eigenfunctions of one separable system can be expanded in terms of the eigenfunctions of another. This is the source of nontrivial special function expansion theorems in the quantum case.[19] The quantum symmetry operators are in formal self-adjoint form and suitable for spectral analysis. Also, the quadratic algebra identities allow us to relate eigenbases and eigenvalues of one symmetry operator to those of another. The representation theory of the abstract quadratic algebra can be used to derive spectral properties of the second-order generators in a manner analogous to the use of Lie algebra representation theory to derive spectral properties of quantum systems that admit Lie symmetry algebras.[19–22]

The structure theory of classical superintegrable systems is simpler than for the quantum case, and we studied it first. However, we now show that each of the classical superintegrable systems with nondegenerate potential has a unique extension to a quantum superintegrable system.

We review, briefly, some basic definitions and notation in the classical 3D case; the corresponding 2D definitions can be obtained by obvious restriction. For a classical 3D system on a conformally flat space (note that all 2D spaces are conformally flat) we can always choose local coordinates x,y,z, not unique, such that the Hamiltonian takes the form $\mathcal{H}=(p_1^2+p_2^2+p_3^2)/\lambda(x,y,z)+V(x,y,z)$. This system is *second-order superintegrable* with *nondegenerate* potential $V=V(x,y,z,\alpha,\beta,\gamma,\delta)$ if it admits five functionally independent quadratic constants of the motion (i.e., generalized symmetries)

$$\mathcal{S}_k = \sum_{ij} a^{ij}_{(k)} p_i p_j + W_{(k)}(x,y,\alpha,\beta,\gamma). \tag{1}$$

As described in Ref. 3, the potential V is *nondegenerate* if it satisfies a system of coupled PDEs of the form

$$V_{22} = V_{11} + A^{22}(x,y,z)V_1 + B^{22}(x,y,z)V_2 + C^{22}(x,y,z)V_3,$$

$$V_{33} = V_{11} + A^{33}(x,y,z)V_1 + B^{33}(x,y,z)V_2 + C^{33}(x,y,z)V_3,$$

$$V_{12} = A^{12}(x,y,z)V_1 + B^{12}(x,y,z)V_2 + C^{12}(x,y,z)V_3,$$

$$V_{13} = A^{13}(x,y,z)V_1 + B^{13}(x,y,z)V_2 + C^{13}(x,y,z)V_3,$$

$$V_{23} = A^{23}(x,y,z)V_1 + B^{23}(x,y,z)V_2 + C^{23}(x,y,z)V_3, \tag{2}$$

whose integrability conditions are satisfied identically. Here, $V_1 = \partial V/\partial x$, $V_2 = \partial V/\partial y$, etc. The analytic functions A^{ij}, B^{ij}, C^{ij} are determined uniquely from the Bertrand-Darboux equations for the five constants of the motion (under the assumption that the quadratic constants of the motion are functionally linearly independent) and are analytic except for a finite number of poles. At any regular point $\mathbf{x}_0 = (x_0, y_0, z_0)$, i.e., a point where the A^{ij}, B^{ij}, C^{ij} are defined and analytic and the constants of the motion are functionally independent, we can prescribe the values of $V(\mathbf{x}_0)$, $V_1(\mathbf{x}_0)$, $V_2(\mathbf{x}_0)$, $V_3(\mathbf{x}_0)$, $V_{11}(\mathbf{x}_0)$ arbitrarily and obtain a unique solution of (2). The significance of the four parameters for a nondegenerate potential (in addition to the usual additive constant) is that it is the maximum dimension of the space of solutions to the Bertrand-Darboux equations that can appear in a superintegrable system with functionally linearly independent symmetries. If the number of parameters is fewer than four, we say that the superintegrable potential is *degenerate*.

We clarify our definition of nondegenerate potential and our parameter count by considering the generalized Calogero potential

$$V^{(1)} = \frac{a}{(x-y)^2} + \frac{b}{(y-z)^2} + \frac{c}{(z-x)^2}, \tag{3}$$

and its further generalization

$$V^{(2)} = \frac{a}{(m_1 x - m_2 y)^2} + \frac{b}{(m_2 y - m_3 z)^2} + \frac{c}{(m_3 z - m_1 x)^2}, \tag{4}$$

where $m_i \neq 0$, see Refs. 11 and 23–25. These potentials are superintegrable on Euclidean space and the second contains six parameters, which exceeds the count of four for nondegenerate superintegrable systems. How can this be?

Our definition of the number of parameters in a superintegrable system is that it is the dimension of the space of solutions of the set of Bertrand-Darboux equations for this system (ignoring the trivial added constant). Let us consider the system of symmetries defining the system with potential $V^{(1)}$. A basis for the space of symmetries is (using $P_x = p_1, P_y = p_2, P_z = p_3, J_1 = yp_3 - zp_2, J_2 = zp_1 - xp_3, J_3 = xp_2 - yp_1$),

$$\mathcal{S}_1 = \mathcal{H} = P_x^2 + P_y^2 + P_z^2 + V_1, \quad \mathcal{S}_2 = (P_x + P_y + P_z)^2, \quad \mathcal{S}_3 = J_1^2 + J_2^2 + J_3^2 + W_3,$$

$$\mathcal{S}_4 = P_x(J_2 - J_3) + P_y(J_3 - J_1) + P_z(J_1 - J_2) + W_4, \quad \mathcal{S}_5 = J_3 J_2 + J_1 J_3 + J_2 J_1 + W_5,$$

where the potential terms W_i contain the parameters.

We can write the Bertrand-Darboux equations for each symmetry $\mathcal{S} = \Sigma a^{jk} p_j p_k + W$ of $\mathcal{H} = (p_1^2 + p_2^2 + p_3^3)/\lambda(\mathbf{x}) + V$ in the matrix form

$$0=\begin{pmatrix} 0 & a^{12} & a^{11}-a^{22} & a^{31} & -a^{32} \\ a^{13} & 0 & -a^{23} & a^{21} & a^{11}-a^{33} \\ a^{32} & -a^{32} & -a^{13} & a^{22}-a^{33} & a^{12} \end{pmatrix}\begin{pmatrix} V_{33}-V_{11} \\ V_{22}-V_{11} \\ V_{12} \\ V_{32} \\ V_{31} \end{pmatrix}-\frac{1}{\lambda}\begin{pmatrix} (\lambda a^{12})_1-(\lambda a^{11})_2 \\ (\lambda a^{31})_1-(\lambda a^{11})_3 \\ (\lambda a^{31})_2-(\lambda a^{21})_3 \end{pmatrix}V_1$$
$$-\frac{1}{\lambda}\begin{pmatrix} (\lambda a^{22})_1-(\lambda a^{21})_2 \\ (\lambda a^{32})_1-(\lambda a^{12})_3 \\ (\lambda a^{32})_2-(\lambda a^{22})_3 \end{pmatrix}V_2-\frac{1}{\lambda}\begin{pmatrix} (\lambda a^{32})_1-(\lambda a^{31})_2 \\ (\lambda a^{33})_1-(\lambda a^{13})_3 \\ (\lambda a^{33})_2-(\lambda a^{23})_3 \end{pmatrix}V_3. \tag{5}$$

In the Euclidean case, $\lambda=1$. Evaluating these equations for potential $V^{(1)}$ we find that they are

$$V_1+V_2+V_3=0,\quad (x-y)V_{12}+(z-y)V_{23}-V_1+2V_2-V_3=0,$$
$$(x-z)V_{13}+(y-z)V_{23}-V_1-V_2+2V_3=0, \tag{6}$$

and their differential consequences. The complete system of equations is in involution and a particular solution is determined unquely by choosing V_2, V_3, V_{23} at a regular point. Thus we have a three parameter potential. The apparent six parameter potential $V^{(2)}$ is actually three parameter by our count, because the m_i are parametrizing a family of defining symmetries $\mathcal{S}(m_1,m_2,m_3)$, i.e., the Bertrand-Darboux equations themselves are functions of the m_1. For example, the symmetry $\mathcal{S}_2$ is replaced by $\mathcal{S}_2(m_1,m_2,m_3)=(P_x/m_1+P_y/m_2+P_z/m_3)^2$. Another way to see this is to note that the potentials $V^{(2)}$ do not form a vector space. For each fixed value of the m_i, i.e., for each fixed choice of the space of defining quadratic symmetries, we have a three parameter potential.

What is important to notice here is the occurrence of the first-order condition $V_1+V_2+V_3=0$ for the potential as a consequence of the Bertrand-Darboux equations. Thus the potential is a function of only two variables, impossible for nondegenerate potentials. To understand this, observe the relation

$$(x+y+z)^2\hat{\mathcal{S}}_1-(x^2+y^2+x^2)\hat{\mathcal{S}}_2+2\hat{\mathcal{S}}_3-2(x+y+z)\hat{\mathcal{S}}_4-2\hat{\mathcal{S}}_5=0$$

obeyed by the purely quadratic terms in the symmetries, i.e., where we have set $\mathcal{S}_i=\hat{\mathcal{S}}_i+W_i$. This means that the five functionally independent symmetries $\mathcal{S}_i$ are functionally linearly dependent. This dependence reduces the rank of second derivative terms in the system of 12 Bertrand-Darboux equations so that we do not obtain the canonical form (2) which is required for nondegeneracy. As shown in Ref. 3, if we have a 3D superintegrable system with a basis of functionally linear independent symmetries, then we always obtain the canonical system (2) and its differential consequences.

Functional linear dependence of a functionally independent maximal set of symmetries is hard to achieve. In 2D it is well known that essentially, there is only one example, corresponding to Lie form. In 3D Theorem 1 of Ref. 3 stated, incorrectly, that all functionally independent superintegrable systems were functionally linearly independent. The Calogero potential is a counterexample. Thus the results of papers Refs. 3 and 4 hold under the explicit assumption that the functionally independent basis of symmetries is also functionally linearly independent. This is exactly the same situation as in the 2D case.[1]

For the following result the system need not be superintegrable.

Theorem 1: *Let the functionally independent set* $\{\mathcal{H}=\mathcal{S}_1,\mathcal{S}_2,\ldots,\mathcal{S}_t\}$, $(t>2)$ *be a functionally linearly dependent basis of second-order symmetries for the system* $\mathcal{H}=(p_1^2+p_2^2+p_3^3)/\lambda(\mathbf{x})+V$ *with nontrivial potential* V, *i.e., there is a relation* $\Sigma_h c^{(h)}(x)\hat{\mathcal{S}}_h\equiv 0$ *in an open set, where not all* $c^{(h)}\times(x)$ *are constants, and no such relation holds for the* $c^{(h)}$ *all constant, except if the constants are all zero. (Here* $\mathcal{S}_i=\hat{\mathcal{S}}+W_i$ *where the* W_i *are the potential terms.) Then the potential must satisfy a first-order relation* $AV_1+BV_2+CV_3=0$ *where not all of the functions* A,B,C *are zero.*

Proof: By relabeling, we can express one of the quadratic parts of the constants of the motion

$\hat{\mathcal{S}}_0$ as a linear combination of a functionally independent subset $\{\hat{\mathcal{S}}_1,\ldots,\hat{\mathcal{S}}_r, 1\leqslant r\leqslant 4\}$: $\hat{\mathcal{S}}_0 = \Sigma_{\ell=1}^r c^{(\ell)}(x)\hat{\mathcal{S}}_\ell$. Taking the Poisson bracket of both sides of this equation with $(p_1^2+p_2^2+p_3^3)/\lambda$ and using the fact that each of the $\mathcal{S}_h$ is a constant of the motion, we obtain the identity

$$\sum_{\ell=1}^{r}\sum_{i,j=1}^{3}(\partial_{x_k}c^{(\ell)})a_{(\ell)}^{ij}p_ip_jp_k=0, \tag{7}$$

where $(x,y,z)\equiv(x_1,x_2,x_3)$. It is straightforward to check that this identity can be satisfied if and only if the functions

$$c_k^{ij}=\sum_{\ell=1}^{r}(\partial_{x_k}c^{(\ell)})a_{(\ell)}^{ij},\quad 1\leqslant i,j,k\leqslant 3$$

satisfy

$$c_i^{ii}=0,\quad c_j^{ii}+2c_i^{ij}=0,\quad (i\neq j),\quad c_3^{12}+c_1^{23}+c_2^{31}=0. \tag{8}$$

Note that $c_k^{ij}=c_k^{ji}$. Corresponding to each of the basis symmetries $\mathcal{S}_h$ there is a linear set $C_h=0$ of Bertrand-Darboux equations (5). A straightforward substitution into the identity $C_0-\Sigma_{\ell=1}^r c^{(\ell)}\times(x)C_\ell=0$ yields the relation

$$\begin{pmatrix}c_1^{12}-c_2^{11}\\ c_1^{31}-c_3^{11}\\ c_2^{31}-c_3^{21}\end{pmatrix}V_1+\begin{pmatrix}c_1^{22}-c_2^{21}\\ c_1^{32}-c_3^{12}\\ c_2^{32}-c_3^{22}\end{pmatrix}V_2+\begin{pmatrix}c_1^{32}-c_2^{31}\\ c_1^{33}-c_3^{13}\\ c_2^{33}-c_3^{23}\end{pmatrix}V_3=0.$$

These first-order differential equations for the potential cannot all vanish identically. Indeed if they did all vanish then we would have the conditions

$$c_1^{12}=c_2^{11},\quad c_1^{31}=c_3^{11},\quad c_2^{31}=c_3^{21},\quad c_1^{22}=c_2^{21},\quad c_1^{32}=c_3^{12},$$

$$c_2^{32}=c_3^{22},\quad c_1^{32}=c_2^{31},\quad c_1^{33}=c_3^{13},\quad c_2^{33}=c_3^{23}.$$

These conditions, together with conditions (8), show that $c_i^{jk}=0$ for all i,j,k. Thus we have $\Sigma_{\ell=1}^r(\partial_{x_k}c^{(\ell)})a_{(\ell)}^{ij}=0$, $1\leqslant i,j,k\leqslant 3$. Since the set $\{\hat{\mathcal{S}}_1,\ldots,\hat{\mathcal{S}}_r\}$, is functionally linearly independent, we have $\partial_{x_k}c^{(\ell)}\equiv 0$ for $1\leqslant k\leqslant 3, 1\leqslant \ell\leqslant r$. Hence the $c^{(\ell)}$ are constants, which means that $\hat{\mathcal{S}}_0-\Sigma_{\ell=1}^r c^{(\ell)}\hat{\mathcal{S}}_\ell=0$. Thus the set $\{\mathcal{S}_0,\ldots,\mathcal{S}_4\}$ is functionally dependent. This is a contradiction.

Q.E.D.

This shows that the potential function for any system, superintegrable or not, with a basis of symmetries that is functionally linearly dependent must satisfy at least one nontrivial first-order partial differential equation $AV_1+BV_2+CV_3=0$ where the functions A,B,C are parameter free. The method of proof of the Theorem shows how to find such equations. This means that all such potentials depend on either one or two coordinates. The 3D nondegenerate potentials that are the primary subject of this series depend essentially on all three coordinates.

II. NONDEGENERATE 2D QUANTUM SYSTEMS

Here we discuss how the analysis of classical 2D superintegrable systems with nondegenerate potentials carries over to the quantum case. The quantization is much simpler in the 2D case than for dimensions greater than two. For a manifold with metric $ds^2=\lambda(x,y)(dx^2+dy^2)$ the Hamiltonian system $\mathcal{H}=(p_1^2+p_2^2)/\lambda(x,y)+V(x,y)$ is replaced by the Hamiltonian (Schrödinger) operator with potential

$$H = \frac{1}{\lambda(x,y)}(\partial_{11} + \partial_{22}) + V(x,y) \tag{9}$$

in local orthogonal coordinates. A second-order symmetry of the Hamiltonian system $\mathcal{S} = \Sigma_{k,j=1}^{2} a^{kj}(x,y)p_k p_j + W(x,y)$, with $a^{kj} = a^{jk}$, corresponds to the operator

$$S = \frac{1}{\lambda(x,y)} \sum_{k,j=1}^{2} \partial_k (a^{kj}(x,y)\lambda(x,y)\partial_j) + W(x,y), \quad a^{kj} = a^{jk}.$$

These operators are formally self-adjoint with respect to the bilinear product

$$\langle f,g \rangle = \int f(x,y)g(x,y)\lambda(x,y)\mathrm{d}x\mathrm{d}y$$

on the manifold, i.e.,

$$\langle f,Hg \rangle = \langle Hf,g \rangle, \quad \langle f,Sg \rangle = \langle Sf,g \rangle$$

for all local C^∞ functions f,g with compact support on the manifold, where we set all boundary terms equal to 0.

A first-order symmetry of the Hamiltonian system $\mathcal{L} = \Sigma_{k=1}^{2} a^k(x,y)p_k$ corresponds to the operator

$$L = \sum_{k=1}^{2} a^k(x,y)\partial_k.$$

It is easy to show that L_1 is formally skew-adjoint, i.e.,

$$\langle f,Lg \rangle = -\langle Lf,g \rangle.$$

The following results that relate the operator commutator $[A,B] = AB - BA$ and the Poisson bracket are straightforward to verify.

Lemma 1:

$$\{\mathcal{H},\mathcal{S}\} = 0 \Leftrightarrow [H,S] = 0.$$

This result is not generally true for higher dimensional manifolds.

Lemma 2:

$$\{\mathcal{H},\mathcal{L}\} = 0 \Leftrightarrow [H,L] = 0.$$

The definition of a nondegenerate potential $V(x,y)$ is identical with that for the classical case, i.e., it obeys

$$V_{22} = V_{11} + A^{22}V_1 + B^{22}V_2,$$

$$V_{12} = A^{12}V_1 + B^{12}V_2 \tag{10}$$

Again, V_1, V_2, V_{11} can be prescribed arbitrarily at a fixed regular point. Note that if V is a nondegenerate potential then there will be *no* first-order symmetries.

It follows from Lemma 1 that the classical results for the space of second-order symmetries corresponding to a nondegenerate potential can be taken over without change. The space is three dimensional and at any regular point $\mathbf{x}_0$ there exists exactly one symmetry, up to an additive constant, such that $a^{jk}(\mathbf{x}_0) = \alpha^{jk}$ for any constant symmetric matrix α.

Now we investigate the space of third-order symmetries, i.e., third-order differential operators K that commute with the Hamiltonian: $[H,K] = 0$. In general, determination of the possible operators K is very difficult, but in this case, simplifications make the problem tractable:

1. We are interested, principally, in the space of third-order symmetries that is spanned by the commutators of second-order symmetries S. Since the second-order symmetries are formally self-adjoint, the commutators will be skew-adjoint. Thus we can limit ourselves to K that are skew adjoint.

2. A second reason for considering only skew adjoint K follows from the well-known unique decomposition of a symmetry into a formally skew-adjoint part and a formally self-adjoint part, each of which must itself be a symmetry. Clearly the self-adjoint part of a third-order symmetry must be at most a second-order symmetry, i.e., the third-order terms vanish. For a nondegenerate superintegrable system we already know the three-dimensional space of these second-order symmetries.

3. Since H encodes a three-parameter family of potentials, the symmetry K must also be a function of the parameters. The highest order terms $a^{kji}\partial_{kji}$ in K (symmetric in k,j,i) will be independent of the parameters but lower order terms may have linear parameter dependence.

4. The skew-adjoint requirement uniquely determines the coefficients of the second-order terms in K. They are

$$\frac{3}{2\lambda}(a^{kji}\lambda)_i\partial_{kj}.$$

5. Further, the skew-adjoint requirement means that there exist functions $a^{kji},\tilde{b}^i$ such that K has the unique representation

$$K=\sum_{k,j,i=1}^{2}\left(a^{kji}\partial_{kji}+\frac{3}{2\lambda}(a^{kji}\lambda)_i\partial_{kj}+\frac{1}{2\lambda}(a^{kji}\lambda)_{kj}\partial_i\right)+\sum_{i=1}^{2}\left(\tilde{b}^i\partial_i+\frac{1}{2\lambda}(\tilde{b}^i\lambda)_i\right), \tag{11}$$

where the functions $\tilde{b}^i(x,y,z)$ contain the parameter dependence.

6. Equating coefficients of the fourth-order terms in the operator condition $[H,K]=0$ where K is given by (11) we obtain the relations

$$2\frac{\partial a^{iii}}{\partial x_i}=-3\left(\frac{\partial \ln\lambda}{\partial_{x_i}}a^{iii}+\frac{\partial \ln\lambda}{\partial_{xj}}a^{jii}\right),\quad i\neq j,$$

$$3\frac{\partial a^{jii}}{\partial x_i}+\frac{\partial a^{iii}}{\partial x_j}=3\left(-\frac{\partial \ln\lambda}{\partial_{x_i}}a^{iij}-\frac{\partial \ln\lambda}{\partial_{x_j}}a^{ijj}\right),\quad i\neq j,$$

$$2\left(\frac{\partial a^{122}}{\partial x_1}+\frac{\partial a^{112}}{\partial x_2}\right)=-\frac{\partial \ln\lambda}{\partial_{x_1}}a^{122}-\frac{\partial \ln\lambda}{\partial_{x_1}}a^{111}-\frac{\partial \ln\lambda}{\partial_{x_2}}a^{222}-\frac{\partial \ln\lambda}{\partial_{x_2}}a^{112}, \tag{12}$$

which are just the requirements that the a^{kji} be the components of a third-order Killing tensor.

7. Equating coefficients of the third-order terms in the condition $[H,K]=0$ we obtain relations that are consequences of the Killing tensor relations (12).

8. The remaining conditions on K intertwine λ, a^{kji}, $\tilde{b}^i$, and V, and are complicated. Rather than solve them directly, we note that we can make the unique decomposition

$$\tilde{b}^i(x_1,x_2,V_{x_1},V_{x_2})=c^i(x_1,x_2)+b^i(x_1,x_2,V_{x_1},V_{x_2}),$$

where

$$b^i = \sum_{j=1}^{2} f^{\ell,j}(x_1,x_2)\frac{\partial V}{\partial x_j}(x_1,x_2), \tag{13}$$

i.e., we can split off the parameter-dependent terms of $\tilde{b}^i$ from the rest. Then, equating the linear parameter-dependent coefficients of the second-order terms in the symmetry operator condition, we obtain the requirements

$$\frac{\partial b^1}{\partial x_2} + \frac{\partial b^2}{\partial x_1} = 3\sum_{s=1}^{2} \lambda a^{s21}\frac{\partial V}{\partial x_s},$$

$$\frac{\partial b^j}{\partial x_j} = \frac{3}{2}\sum_{s=1}^{2} a^{sjj}\frac{\partial V}{\partial x_s} - \frac{1}{2}\sum_{s=1}^{2}\frac{\partial \ln \lambda}{\partial x_s}b^s, \quad j=1,2, \tag{14}$$

identical to the corresponding classical equations in Ref. 1. Equating the quadratic parameter-dependent coefficients of the zeroth-order terms in the symmetry operator condition, we obtain the requirement

$$\sum_{s=1}^{2} b^s\frac{\partial V}{\partial x_s} = 0, \tag{15}$$

again identical to the corresponding classical equation in Ref. 1.

9. Conditions (14) and (15), and third-order Killing tensor conditions are clearly necessary for K to be a skew-adjoint symmetry. To see that they are sufficient will take several steps.

10. Uniqueness: Suppose K,K' are two third-order skew-adjoint symmetries with the same functions a^{kji},b^i (but possibly different c^i). Note that $K-K'$ is a skew-adjoint, parameter-independent symmetry that is first order (since the third- and second-order terms in K and K' are the same). However, there can be no nonzero parameter-independent symmetry for a nondegenerate superintegrable system. Therefore $K=K'$. Though we have not given an explicit expression for the c^i we see that they are uniquely determined by the functions a^{kji},b^i.

11. Existence: This also involves several steps. We first employ the results of our construction of third-order symmetries for the classical case. There we used (13) to show

$$f^{\ell,j} + f^{j,\ell} = 0, \quad 1 \leqslant \ell,j \leqslant 2,$$

and (14) to show that

$$b_1^1 = f_1^{1,2}V_2 + f^{1,2}V_{12}, \quad b_2^1 = f_2^{1,2}V_2 + f^{1,2}V_{22},$$

$$b_1^2 = f_1^{2,1}V_1 + f^{2,1}V_{11}, \quad b_2^2 = f_2^{2,1}V_1 + f^{2,1}V_{12},$$

and

$$\lambda a^{111} = \tfrac{1}{3}f^{1,2}(2A^{12} - (\ln\lambda)_2), \quad \lambda a^{222} = \tfrac{1}{3}f^{1,2}(-2B^{12} + (\ln\lambda)_1),$$

$$\lambda a^{112} = \tfrac{1}{9}f^{1,2}(2A^{22} + 2B^{12} + (\ln\lambda)_1),$$

$$\lambda a^{122} = \tfrac{1}{9}f^{1,2}(-2A^{12} + 2B^{22} - (\ln\lambda)_2),$$

$$f_1^{1,2} = \tfrac{1}{3}f^{1,2}(A^{22} - 2B^{12} - (\ln\lambda)_1), \quad f_2^{1,2} = \tfrac{1}{3}f^{1,2}(-2A^{12} - B^{22} + (\ln\lambda)_2).$$

Thus the a^{ijk} can be expressed in terms of $f^{1,2}$ and the $A^{k\ell},B^{k\ell}$ functions, and we have an involutive system for $f^{1,2}$. Thus any third symmetry is uniquely determined by the constant

$f^{1,2}(x_0,y_0)$ at some regular point (x_0,y_0). This means that the space of third-order skew-adjoint symmetries is at most one dimensional.

12. Consider the case where all $a^{ijk}\equiv 0$. Then $2A^{12}=B^{22}=(\ln\lambda)_2$, $2B^{12}=-A^{22}=(\ln\lambda)_1$. The integrability conditions require $(\ln\lambda)_{11}+(\ln\lambda)_{22}=0$, which is the condition for flat space, Thus by an appropriate orthogonal change of coordinates we can assume that $\lambda\equiv 1$. In these new coordinates we see that $A^{ij}=B^{ij}\equiv 0$ for all i,j. The general solution is

$$f^{1,2}=c_1,$$

where c_1, is a constant. This is the *homogeneous isotropic oscillator:*

$$V(x,y)=\alpha x+\beta y+\gamma(x^2+y^2).$$

One can easily check that for this very special case a nonzero commutator of two second-order symmetries is first order, parameter-dependent.

13. The second case is that not all a^{ijk} vanish. We show that the space of symmetries is exactly one dimensional. Let

$$S_1=\frac{1}{\lambda}\sum \partial_k(\,a^{kj}_{(1)}\lambda)\partial_j)+W_{(1)},\quad S_2=\sum \partial_k(a^{kj}_{(2)}\lambda\partial_j)+W_{(2)}$$

be second-order symmetries and let $\mathcal{A}_{(i)}(x_1,x_2)=\{a^{kj}_{(i)}(x_1,x_2)\}$, $i=1,2$ be 2×2 matrix functions. Then the commutator $[S_1,S_2]$ of these symmetries is a third-order symmetry K with a^{kji} and $f^{k,\ell}$ such that

$$f^{k,\ell}=2\lambda\sum_j (a^{kj}_{(2)}a^{j\ell}_{(1)}-a^{kj}_{(1)}a^{j\ell}_{(2)}).$$

Thus $K=[S_1,S_2]$ is uniquely determined by the skew-symmetric matrix

$$[\mathcal{A}_{(2)},\mathcal{A}_{(1)}]\equiv\mathcal{A}_{(2)}\mathcal{A}_{(1)}-\mathcal{A}_{(1)}\mathcal{A}_{(2)},$$

hence by the constant matrix $[\mathcal{A}_{(2)}(x_0,y_0),\mathcal{A}_{(1)}(x_0,y_0)]$ evaluated at a regular point.

Theorem 2: *Let K be a third-order skew-adjoint symmetry (11) for a superintegrable system with nondegenerate potential V and* $\tilde{b}^i=c^i(x,y)+b^i(x,y,V_1,V_2)$ *where*

$$b^i=\sum_{j=1}^{2} f^{i,j}(x,y)\frac{\partial V}{\partial x_j}(x,y).$$

Then

$$f^{\ell,j}+f^{j,\ell}=0,\quad 1\leqslant \ell,j\leqslant 2$$

and K is uniquely determined by the number

$$f^{1,2}(x_0,y_0)$$

at some regular point (x_0,y_0) *of V.*

Corollary 1: Let V be a superintegrable nondegenerate potential, Then the space of third-order skew-adjoint symmetries is one dimensional and is spanned by commutators of the second-order self-adjoint symmetries.

Corollary 2: Let V be a superintegrable nondegenerate potential and S_1,S_2 *be second-order formally self-adjoint symmetries with matrices* $\mathcal{A}_{(1)},\mathcal{A}_{(2)}$, *respectively. Then*

$$[S_1,S_2]\equiv 0\Leftrightarrow[\mathcal{A}_{(1)},\mathcal{A}_{(2)}]\equiv 0\Leftrightarrow[\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]=0$$

at a regular point $\mathbf{x}_0$.

III. A STANDARD FORM FOR 2D QUANTUM SYSTEMS

In analogy with the classical case, there is a standard structure for 2D quantum nondegenerate superintegrable systems allowing the identification of the space of second-order symmetry operators with the space of 2×2 symmetric matrices, and identification of the space of third-order symmetry operators with the space of 2×2 skew-symmetric matrices. Indeed, if $\mathbf{x}_0$ is a regular point then there is a 1-1 linear correspondence between second-order operators S and their associated symmetric matrices $\mathcal{A}(\mathbf{x}_0)$. Let $[S_1,L_2]'=[S_2,S_1]$ be the reversed operator commutator. Then the map

$$[S_1,S_2]' \leftrightarrow [\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]$$

is an algebraic isomorphism. Here, S_1,S_2 are in involution if and only if matrices $\mathcal{A}_{(1)}(\mathbf{x}_0),\mathcal{A}_{(2)}\times(\mathbf{x}_0)$ commute. If $[S_1,S_2]\neq 0$ then it is a truly third-order symmetry operator (except in the isotropic oscillator case) and can be uniquely associated with the skew-symmetric matrix $[\mathcal{A}_{(1)}\times(\mathbf{x}_0),\mathcal{A}_{(2)}(\mathbf{x}_0)]$. Since commutators of second-order symmetries span the space of third-order symmetries, we can identify these 1-1 with 2×2 skew-symmetric matrices. Let $\mathcal{E}^{ij}$ be the 2×2 matrix with a 1 in row i, column j and 0 for every other matrix element. Then the symmetric matrices

$$\mathcal{A}^{(ij)}=\tfrac{1}{2}(\mathcal{E}^{ij}+\mathcal{E}^{ji})=\mathcal{A}^{(ji)},\quad i,j=1,2 \tag{16}$$

form a basis for the three-dimensional space of symmetric matrices. Moreover,

$$[\mathcal{A}^{(ij)},\mathcal{A}^{(k\ell)}]=\tfrac{1}{2}(\delta_{jk}\mathcal{B}^{(i\ell)}+\delta_{j\ell}\mathcal{B}^{(ik)}+\delta_{ik}\mathcal{B}^{(j\ell)}+\delta_{i\ell}\mathcal{B}^{(jk)}), \tag{17}$$

where

$$\mathcal{B}^{(ij)}=\tfrac{1}{2}(\mathcal{E}^{ij}-\mathcal{E}^{ji})=-\mathcal{B}^{(ji)},\quad i,j=1,2.$$

Here $\mathcal{B}^{(ii)}=0$ and $\mathcal{B}^{(12)}$ forms a basis for the space of skew-symmetric matrices. Thus (17) gives the commutation relations for the second-order symmetry operators. If V is the isotropic oscillator then there is no truly third-order symmetry. For any other nondegenerate potential, the space of symmetries is exactly one dimensional.

We reformulate the problem of determining the second-order symmetry operators of (9) by setting

$$W(x)=f^1V_1+f^2V_2+f^{11}V_{11}$$

and substituting this expression into $W_i=\lambda\Sigma_{j=1}^2a^{ij}V_j$. Additionally we must impose the Killing tensor conditions. We obtain the equations for the a^{ij}:

$$\lambda a^{11}=f^1_1+f^2A^{12}+f^{11}A^{13},$$

$$\lambda a^{12}=f^1_2+f^1A^{12}+f^2A^{22},$$

$$\lambda a^{22}=f^2_2+f^1B^{12}+f^2B^{22}, \tag{18}$$

and the condition on the first derivatives of the f^i:

$$f^1_2-f^2_1=-f^1A^{12}+f^2(A^{22}-B^{12})-f^{11}B^{13}. \tag{19}$$

Note the expressions for f^{11}_1 and f^{11}_2 in terms of f^1,f^2,f^{11}:

$$f^{11}_1+f^1+f^{11}(B^{12}-A^{22})=0,\quad f^{11}_2+f^2+f^{11}A^{12}=0.$$

It follows that we can express each of the second derivatives of f^1,f^2 in terms of lower order derivatives of f^1,f^2,f^{11}. Thus the system is in involution at the second derivative level, but not at

the first derivative level because we have only one condition for the four derivatives $f_1^1, f_2^1, f_1^2, f_2^2$. We can uniquely determine a symmetry operator at a regular point by choosing the six parameters $(f^1, f^2, f^{11}, f_1^1, f_2^1, f_2^2)$. The values of f^1, f^2, f^{11} at the regular point are analogous to the three parameters that we can add to the potentials in the three parameter family. For our standard basis, we fix $(f^1, f^2, f^{11})_{\mathbf{x}_0} = (0,0,0)$. Then from (18) and (19), we have

$$\begin{pmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{pmatrix} = \lambda \begin{pmatrix} a^{11} & a^{12} \\ a^{21} & a^{22} \end{pmatrix}.$$

Thus we can define a standard set of basis symmetry operators $S^{(jk)} = \lambda^{-1}(\mathbf{x})(\Sigma \partial_i (a^{ij}(\mathbf{x})\lambda(\mathbf{x})\partial_j) + W^{(ij)}(\mathbf{x})$ corresponding to a regular point $\mathbf{x}_0$ by

$$\begin{pmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{pmatrix}_{\mathbf{x}_0} = \lambda(\mathbf{x}_0) \begin{pmatrix} a^{11} & a^{12} \\ a^{21} & a^{22} \end{pmatrix}_{\mathbf{x}_0} = \lambda(\mathbf{x}_0)\mathcal{A}^{(jk)}, \quad W^{(jk)}(\mathbf{x}_0) = 0.$$

The condition on $W^{(jk)}$ is actually three conditions since $W^{(jk)}$ depends on three parameters. Note that the derivative terms a_i^{ij} in the expression for the basis symmetries can be computed explicitly from the conditions for classical second order symmetries in Ref. 1.

In exact analogy with the classical case, we can use the standard form to prove multiseparabilty for quantum systems.

Theorem 3. *Let V be a quantum superintegrable nondegenerate potential and S be a second-order symmetry operator with matrix function $\mathcal{A}(\mathbf{x})$. If at some regular point $\mathbf{x}_0$ the matrix $\mathcal{A}(\mathbf{x}_0)$ has two distinct eigenvalues, then H, S characterize an orthogonal separable coordinate system.*

Since a generic 2×2 symmetric matrix has distinct roots, it follows that any such superintegrable nondegenerate potential is multiseparable.

IV. THE QUANTUM QUADRATIC ALGEBRA

We investigate the space of fourth-order differential operators F that commute with the Hamiltonian: $[H,F]=0$. Determination of all possible operators F is very difficult but, again, there are simplifications that make the problem tractable:

1. We are interested, principally, in the space of fourth-order symmetries that is spanned by the double commutators $[[S^{(1)}, S^{(2)}], S^{(3)}]$ of second-order formally self-adjoint symmetries $S^{(j)}$ of the superintegrable system. The double commutators will be formally self-adjoint, so we can limit ourselves to F that are self-adjoint.

2. Since H encodes a three-parameter family of potentials, the symmetry F must also be a function of the parameters. The highest order terms $a^{\ell kji}\partial_{kji}$ in F (symmetric in ℓ, k, j, i) will be independent of the parameters but lower order terms may have linear or quadratic parameter dependence.

3. The self-adjoint requirement uniquely determines the third-order terms in F. They are

$$\sum_{\ell,k,j,i} \frac{2}{\lambda}(a^{\ell kji}\lambda)_i \partial_{\ell kj}.$$

4. Further, the self-adjoint requirement means that there exist functions $a^{\ell kji}, \tilde{b}^{ij}, \tilde{W}$ such that F has the unique representation

$$F = \sum_{\ell,k,j,i=1}^{2} \frac{1}{\lambda}\partial_{ij}(a^{\ell kji}\lambda\partial_{k\ell}) + \sum_{i,j=1}^{2} \frac{1}{\lambda}\partial_i(\tilde{b}^{ij}\lambda\partial_j) + \tilde{W}, \tag{20}$$

where the functions $\tilde{b}^{ij}(x_1,x_2), \tilde{W}(x_1,x_2)$ contain the parameter dependence.

5. Equating coefficients of the fifth-order terms in the operator condition $[H,F]=0$ where F is given by (20) we obtain the relations

$$\frac{\partial a^{iiii}}{\partial x_i} = -2\sum_{s=1}^{2} a^{siii}\frac{\partial \ln \lambda}{\partial x_s},$$

$$4\frac{\partial a^{jiii}}{\partial x_i} + \frac{\partial a^{iiii}}{\partial x_j} = -6\sum_{s=1}^{2} a^{siij}\frac{\partial \ln \lambda}{\partial x_s}, \quad i \neq j,$$

$$3\frac{\partial a^{jjii}}{\partial x_i} + 2\frac{\partial a^{iiij}}{\partial x_j} = -\sum_{s=1}^{2} a^{siii}\frac{\partial \ln \lambda}{\partial x_s} - 3\sum_{s=1}^{2} a^{sijj}\frac{\partial \ln \lambda}{\partial x_s}, \quad i \neq j, \tag{21}$$

which are the conditions for $a^{\ell kji}$ to be a fourth-order Killing tensor.

6. The remaining conditions on F intertwine λ, $a^{\ell kji}$, $\tilde{b}^{ji}$, $\tilde{W}$, and V, and are complicated. Rather than solve them directly, we make the unique decomposition

$$\tilde{b}^{ji}(x_1,x_2,V_{x_1},V_{x_2},V_{x_1x_1}) = c^{ji}(x_1,x_2) + b^{ji}(x_1,x_2,V_{x_1},V_{x_2},V_{x_1x_1}),$$

where

$$b^{ji} = \sum_{\alpha=1}^{3} f^{ji,\alpha}W^{(\alpha)}, \quad f^{ji,\alpha} = f^{ij,\alpha},$$

and $W^{(\alpha)}$ is defined by

$$\begin{pmatrix} W^{(1)} \\ W^{(2)} \\ W^{(3)} \end{pmatrix} = \begin{pmatrix} V_{x_1} \\ V_{x_2} \\ V_{x_1x_1} \end{pmatrix}.$$

Then, equating the linear parameter-dependent terms of third order in the derivatives we obtain the conditions

$$\frac{\partial}{\partial x_h}f^{jk,\alpha} + \frac{\partial}{\partial x_k}f^{hj,\alpha} + \frac{\partial}{\partial x_j}f^{kh,\alpha} - 2\lambda a^{\alpha hjk} = -\sum_{\gamma=1}^{3}(f^{jk,\gamma}A^{(h)}_{\gamma\alpha} + f^{hj,\gamma}A^{(k)}_{\gamma\alpha} + f^{kh,\gamma}A^{(j)}_{\gamma\alpha}) - \sum_{s=1}^{2}(f^{sk,\alpha}\delta_{hk} + f^{sj,\alpha}\delta_{kh} + f^{sh,\alpha}\delta_{jk})\frac{\partial}{\partial x_s}\ln\lambda, \tag{22}$$

where $1 \leqslant j,k,h \leqslant 2$ and we set $a^{3hjk} \equiv 0$. These conditions are identical to the corresponding classical conditions in Ref. 1. Similarly, we set

$$\tilde{W} = U^{(0)}(x_1,x_2) + U^{(1)}(x_1,x_2,W^{(\alpha)}) + W(x_1,x_2,W^{(\alpha)}),$$

where $U^{(1)}$ depends linearly and W depends quadratically on the $W^{(\alpha)}$ and equate the quadratic parameter-dependent terms of first order in the derivatives. We obtain the conditions

$$\lambda\sum_{s=1}^{3} b^{si}\frac{\partial V}{\partial x_s} = \frac{\partial W}{\partial x_i}. \tag{23}$$

Equating the quadratic parameter-dependent coefficients of the zeroth-order terms in the symmetry operator condition, we obtain the requirement

$$\sum_{s=1}^{2} b^s \frac{\partial V}{\partial x_s} = 0, \tag{24}$$

identical to (13). From the integrabilty conditions $(\partial/\partial x_j)(\partial W/\partial x_i) = (\partial/\partial x_i)(\partial W/\partial x_j), i \neq j$ for Eq. (23) we obtain the conditions

$$\begin{aligned}\partial_{x_j} f^{\beta k,\alpha} + \partial_{x_j} f^{\alpha k,\beta} - \partial_{x_k} f^{\beta j,\alpha} - \partial_{x_k} f^{\alpha j,\beta} = \sum_{s=1}^{2} (A^{(k)}_{\beta s} f^{sj,\alpha} + A^{(k)}_{\alpha s} f^{sj,\beta} - A^{(j)}_{\beta s} f^{sk,\alpha} - A^{(j)}_{\alpha s} f^{sk,\beta}) + \sum_{\gamma=1}^{3} (f^{\beta j,\gamma} A^{(k)}_{\gamma\alpha} \\ + f^{\alpha j,\gamma} A^{(k)}_{\gamma\beta} - f^{\beta k,\gamma} A^{(j)}_{\gamma\alpha} - f^{\alpha k,\gamma} A^{(j)}_{\gamma\beta}) - (f^{\beta k,\alpha} + f^{\alpha k,\beta}) \frac{\partial}{\partial x_j} \ln \lambda \\ + (f^{\beta j,\alpha} + f^{\alpha j,\beta}) \frac{\partial}{\partial x_k} \ln \lambda,\end{aligned} \tag{25}$$

where $j \neq k, 1 \leqslant \alpha, \beta \leqslant 3$, and we set $f^{3j,\alpha} \equiv 0$.

7. There are eight independent equations (22) with $\alpha \neq 3$ and we use five of these to define the five components a^{ihjk} as linear combinations of $(\partial/\partial x_h) f^{jk,\alpha}$ and $f^{jk,\alpha}$. We can then eliminate the a^{ihjk} from the remaining three equations to obtain three conditions relating $(\partial/\partial x_h) f^{jk,\alpha}$ and $f^{jk,\alpha}$. There are six terms of the form $(\partial/\partial x_h) f^{jk,3}$. Equation (25) with $\alpha = \beta = 3$ is satisfied identically. There are two equations (25) with $\beta = 3$, $1 \leqslant \alpha \leqslant 2$ and four equations (22) with $\alpha = 3$. Thus all six terms of the form $(\partial/\partial x_h) f^{jk,3}$ can be expressed as linear combinations of $f^{jk,\alpha}$. There are a total of twelve distinct terms of the form $(\partial/\partial x_h) f^{jk,m}, 1 \leqslant h, j, k, m \leqslant 2$. We have seen that there are three conditions on these terms remaining from (22); there are an additional three such conditions from (25) with $\alpha, \beta \neq 3$. Thus there is a shortfall of six conditions on the first derivatives $(\partial/\partial x_h) f^{jk,m}$.

8. There are a total of eighteen distinct terms of the form $(\partial^2/\partial x_h \partial x_\ell) f^{jk,m}$ with $1 \leqslant h, j, k, \ell, m \leqslant 2$. Differentiating with respect to x_1, x_2 the three first-order conditions of (22), from which the a^{ihjk} have been eliminated, we obtain six independent conditions on these second derivatives. Differentiating each of our expressions for the a^{ihjk} and substituting into Eq. (21) we find six additional conditions on the second derivatives. Also, we can differentiate the three equations from (23) with $\alpha, \beta \neq 3$ to obtain six additional conditions on the second derivatives. This allows us to express each second-order derivative as a linear combination of lower order derivatives. Thus the system is in involution.

9. Conditions (22) and (23), and the fourth-order Killing tensor conditions are clearly necessary for F to be a skew-adjoint symmetry. To see that they are sufficient will take several steps.

10. Suppose F, F' are two fourth-order self-adjoint symmetries with the same functions $a^{\ell kji}, b^{ij}, W$ (but possibly different $c^{ij}, U^{(j)}$). Then $F - F'$ is a self-adjoint, symmetry that is second order and at most linear in the parameters in the zeroth-order term. Thus the only ambiguity is a second-order symmetry operator and we already know these.

11. We conclude that any (truly) fourth-order symmetry operator is uniquely determined, up to an additive second-order symmetry operator, by the values $f^{jk,\alpha}(\mathbf{x}_0)$ and a subset of six of the values $(\partial/\partial_{x_h}) f^{jk,m}(\mathbf{x}_0)$ at a regular point $\mathbf{x}_0$. Note that by adding an appropriate linear combination of purely second-order symmetry operators to the fourth-order symmetry we can achieve $f^{jk,\alpha}(\mathbf{x}_0) = 0$ for all j, k, α, so the maximum possible dimension of the space of purely fourth-order symmetries is six.

Now any symmetric second-order polynomial in the second-order symmetry operators is a fourth-order symmetry operator, and the subspace of polynomial symmetries is at least five and at most six. We show that it is exactly six. If A, B are linear operators, we define their symmetrized product by

$$\{A, B\} \equiv \tfrac{1}{2}(AB + BA).$$

Theorem 4: *The six distinct monomials*

$$\{S^{(11)},S^{(11)}\},\quad \{S^{(22)},S^{(22)}\},\quad \{S^{(12)},S^{(12)}\},\quad \{S^{(11)},S^{(22)}\},\quad \{S^{(11)},S^{(12)}\},\quad \{S^{(12)},S^{(22)}\},$$

form a basis for the space of fourth-order symmetry operators.

Proof: Since the second-order parts of the three symmetry operators $S^{(11)},S^{(22)},S^{(12)}$ are functionally independent, the six monomials listed above are linearly independent. Hence they form a basis. Q.E.D.

We can use this result to expand explicitly a general fourth-order self-adjoint symmetry

$$F=\sum_{\ell,k,j,i=1}^{2}\frac{1}{\lambda}\partial_{ij}(a^{\ell kji}\lambda\partial_{k\ell})+\sum_{i,j=1}^{2}\frac{1}{\lambda}\partial_{i}(\tilde{b}^{ij}\lambda\partial_{j})+\tilde{W}$$

in terms of the standard basis. Without loss of generality we can assume that $(0,0)=\mathbf{0}$ is a regular point. Then F is uniquely determined (up to an additive second-order self-adjoint symmetry) by the data $a^{\ell kji}(\mathbf{0}),\partial_m a^{\ell kji}(\mathbf{0}),b^{mq}(\mathbf{0}),W(\mathbf{0})$. We can uniquely match the data $a^{\ell kji}(\mathbf{0})$ by taking a linear combination of the basis symmetries

$$\{S^{(11)},S^{(11)}\},\quad \{S^{(22)},S^{(22)}\},\quad \{S^{(12)},S^{(12)}\},\quad \{S^{(11)},S^{(12)}\},\quad \{S^{(12)},S^{(22)}\},\quad \{S^{(11)},S^{(11)}\}.$$

This leaves the symmetry $\{S^{(11)},S^{(22)}\}-\{S^{(12)},S^{(12)}\}$ whose leading order terms vanish at the regular point. The expansion coefficient for this term is obtained uniquely from the derivative data $\partial_m a^{\ell kji}(\mathbf{0})$. Now we have matched all of the fourth-order terms in F with an expansion of the self-adjoint form $F'=\Sigma\xi_{ijk\ell}\{S^{(ij)},S^{(k\ell)}\}$. The difference $F-F'$ is a second-order self-adjoint symmetry. The second derivative terms are uniquely determined by the data $b^{mq}(\mathbf{0})$, $W(\mathbf{0})$, which has not changed since $W^{(ij)}(\mathbf{0})=0$ for all terms in the standard basis, by the data $\partial_m a^{\ell kji}(\mathbf{0})$, $\partial_{ms}a^{\ell kji}(\mathbf{0})$, and by the coefficients $\xi_{ijk\ell}$ which have changed. Thus we can expand the original symmetry in terms of second-order polynomials in the standard basis, and finally add any constant parameter-dependent terms. In contrast to the classical case, however, this expansion is more complicated because the expansion coefficients at the fourth-order level effect the expansion coefficients at the second-order level

Using an approach very similar to the above we can easily show that the space of truly sixth-order formally self-adjoint operator symmetries of H cannot exceed the classical maximal dimension of ten. The difference between any two such sixth-order symmetries with the same classical data will be a formally self-adjoint fourth-order symmetry. It remains to show that the maximum possible dimension is actually achieved. If A, B, C are linear operators, we define their symmetrized product by

$$\{A,B,C\}\equiv\tfrac{1}{6}(ABC+BAC+CAB+ACB+BCA+CBA).$$

Theorem 5: *The ten distinct monomials*

$$\{S^{(ii)},S^{(ii)},\quad S^{(ii)}\},\quad \{S^{(ij)},S^{(ij)},S^{(ij)}\},\quad \{S^{(ii)},S^{(ii)},S^{(ij)}\},$$

$$\{S^{(ij)},S^{(ij)},S^{(ii)}\},\quad \{S^{(11)},S^{(12)},S^{(22)}\},$$

for $i,j=1,2$, $i\neq j$ form a basis for the space of sixth-order symmetries.

Proof: Since the three symmetries $S^{(11)}$, $S^{(22)}$, $S^{(12)}$ have functionally independent second-order terms, the ten monomials listed above are linearly independent. Hence they form a basis. Q.E.D.

These theorems establish the closure of the quadratic algebra for 2D quantum superintegrable potentials: All fourth-order and sixth-order symmetry operators can be expressed as symmetric polynomials in the second-order symmetry operators.

Again, we can use these results to expand explicitly a general sixth-order formally self-adjoint symmetry operator

$$G=\sum_{n,m,\ell,k,j,i=1}^{2}\frac{1}{\lambda}\partial_{nm\ell}(a^{nm\ell kji}\lambda\partial_{kji})+\sum_{\ell,k,j,i=1}^{2}\frac{1}{\lambda}\partial_{ij}(\tilde{b}^{\ell kji}\lambda\partial_{k\ell})+\sum_{i,j=1}^{2}\frac{1}{\lambda}\partial_{i}(\tilde{c}^{ij}\lambda\partial_{j})+\tilde{W}$$

in terms of the standard symmetrized basis. Here $\tilde{b}^{\ell kji},\tilde{c}^{ij},\tilde{W}$ are at most linear, quadratic, and cubic in the parameters of the potential, respectively. Without loss of generality we can assume that $(0,0)=\mathbf{0}$ is a regular point. We can uniquely match the data $a^{ijklmn}(\mathbf{0})$ by taking a linear combination of the seven symmetries

$$\{S^{(ii)},S^{(ii)},S^{(ii)}\},\quad \{S^{(ij)},S^{(ij)},S^{(ij)}\},\quad \{S^{(ii)},S^{(ii)},S^{(jj)}\},\quad \{S^{(ii)},S^{(ii)},S^{(ij)}\},$$

for $i,j=1,2$, $i\neq j$. This leaves the three symmetries

$$\{S^{(11)},S^{(11)},S^{(22)}\}-\{S^{(11)},S^{(12)},S^{(12)}\},\quad \{S^{(12)},S^{(11)},S^{(22)}\}-\{S^{(12)},S^{(12)},S^{(12)}\},$$

$$\{S^{(22)},S^{(22)},S^{(11)}\}-\{S^{(22)},S^{(12)},S^{(12)}\},$$

whose leading order terms vanish at the regular point. The expansion coefficients for these three terms are obtained uniquely from the derivative data $\partial_q a^{ijklmn}$. Now we have matched all of the sixth-order terms in G with a self-adjoint expansion of the form $G'=\Sigma\xi_{ijklmn}\{S^{(ij)},S^{(kl)},S^{(mn)}\}$. The difference $G-G'$ is a fourth-order self-adjoint symmetry. It is uniquely determined by the data for the even order terms of G and by the new data for the even order terms of G'. Now we can use the above-presented argument to expand this fourth-order symmetry in terms of polynomials in the standard basis. The expansion coefficients ξ_{ijklmn} will be the same as for the classical case, but the lower order expansion coefficients will differ.

V. THE STÄCKEL TRANSFORM FOR 2D QUANTUM SYSTEMS

The quantum analog of the Stäckel transform[26] or coupling constant metamorphosis[27] for classical systems is straightforward in the 2D case. Suppose we have a superintegrable system

$$H=\frac{1}{\lambda(x,y)}(\partial_{11}+\partial_{22})+V(x,y)=H_0+V \tag{26}$$

in local orthogonal coordinates, with nondegenerate potential $V(x,y)$:

$$V_{22}=V_{11}+A^{22}V_1+B^{22}V_2,$$

$$V_{12}=A^{12}V_1+B^{12}V_2 \tag{27}$$

and suppose $U(x,y)$ is a particular solution of Eq. (27), nonzero in an open set. Then the transformed system

$$\tilde{H}=\frac{1}{\tilde{\lambda}(x,y)}(\partial_{11}+\partial_{22})+\tilde{V}(x,y) \tag{28}$$

with nondegenerate potential $\tilde{V}(x,y)$:

$$\tilde{V}_{22}=\tilde{V}_{11}+\tilde{A}^{22}\tilde{V}_1+\tilde{B}^{22}\tilde{V}_2,$$

$$\tilde{V}_{12}=\tilde{A}^{12}\tilde{V}_1+\tilde{B}^{12}\tilde{V}_2 \tag{29}$$

is also superintegrable, where

$$\tilde{\lambda}=\lambda U,\quad \tilde{V}=\frac{V}{U},$$

$$\tilde{A}^{12} = A^{12} - \frac{U_2}{U}, \quad \tilde{A}^{22} = A^{22} + 2\frac{U_1}{U}, \quad \tilde{B}^{12} = B^{12} - \frac{U_1}{U}, \quad \tilde{B}^{22} = B^{22} - 2\frac{U_2}{U}.$$

Indeed, let $S=\Sigma 1/\lambda\partial_i(a^{ij}\lambda\partial_j)+W=S_0+W$ be a second-order formally self-adjoint symmetry operator of H and $S_U=\Sigma 1/\lambda\partial_i(a^{ij}\lambda\partial_j)+W_U=S_0+W_U$ be the special case of this that is in involution with $(1/\lambda)(\partial_{11}+\partial_{22})+U$. Then

$$\tilde{S} = S_0 - \frac{W_U}{U}H + \frac{1}{U}H$$

is the corresponding formally self-adjoint symmetry operator of $\tilde{H}$, with respect to the metric $d\tilde{s}^2=\lambda U(dx^2+dy^2)$.

Theorem 6:

1.

$$[\tilde{H},\tilde{S}] = 0 \Leftrightarrow [H,S] = 0.$$

2.

$$\tilde{S} = \sum_{ij} \frac{1}{\lambda U}\partial_i\left(\left(a^{ij} + \delta^{ij}\frac{1-W_U}{\lambda U}\right)\lambda U\right)\partial_j + \left(W - \frac{W_U V}{U} + \frac{V}{U}\right).$$

Proof:

1. This is a straightforward verification, using the identities

$$[H_0,S_0] = 0, \quad [H_0+V,S_0+W] = 0, \quad [H_0+U,S_0+W_U] = 0$$

and

$$[A,BC] = B[A,C] + [A,B]C, \quad \left[A,\frac{1}{U}\right] = -\frac{1}{U}[A,U]\frac{1}{U}$$

for linear operators A, B, C and nonzero function U.

2. This follows from the fact that $\partial_i W_U = \lambda\Sigma_j a^{ij}U_j$.

Q.E.D.

Corollary 3: If $S^{(1)}, S^{(2)}$ are second-order symmetry operators for H, then

$$[\tilde{S}^{(1)},\tilde{S}^{(2)}] = 0 \Leftrightarrow [S^{(1)},S^{(2)}] = 0.$$

Since one can always add a constant to a nondegenerate potential, it follows that $1/U$ defines an inverse Stäckel transform of $\tilde{H}$ to H. We say that two quantum superintegrable systems are *Stäckel equivalent* if one can be obtained from the other by a Stäckel transform. We can now use Theorem 6 to carry over immediately the basic result for 2D Stäckel transforms of classical superintegrable systems to 2D quantum superintegrable systems.[2]

Theorem 7: *Every nondegenerate second-order quantum superintegrable system in two variables is Stäckel equivalent to a superintegrable system on a constant curvature space.*

VI. NONDEGENERATE 3D QUANTUM SYSTEMS

Here we extend our analysis of classical 3D superintegrable systems with nondegenerate potentials to the quantum case. (This is less straightforward than in the 2D case.) As mentioned earlier, these systems arise only for functionally linearly independent bases of symmetries. For a manifold with metric $ds^2=\lambda(x,y,z)(dx^2+dy^2+dz^2)$ we replace the Hamiltonian $\mathcal{H}=(p_1^2+p_2^2+p_3^2)/\lambda(x,y,z)+V(x,y,z)$ by a formally self-adjoint operator

$$\hat{H} = \frac{1}{\mu(x,y,z)} \sum_{k,j=1}^{3} \partial_k \left(\frac{\delta^{kj}}{\lambda(x,y,z)} \mu(x,y,z) \partial_j \right) + V(x,y,z) \tag{30}$$

in local orthogonal coordinates. Here δ^{kj} is the Kronecker delta and the weight function μ is to be determined. Similarly, we replace a second-order symmetry of the Hamiltonian system $\mathcal{S} = \Sigma_{k,j=1}^{3} a^{kj}(x,y,z) p_k p_j + W(x,y,z)$, with $a^{kj} = a^{jk}$, by the formally self-adjoint operator

$$\hat{S} = \frac{1}{\mu} \sum_{k,j=1}^{3} \partial_k (a^{kj} \mu \partial_j) + W + \hat{W}, \quad a^{kj} = a^{jk}, \tag{31}$$

where the function $\hat{W}(x,y,z)$ is to be determined. These operators are formally self-adjoint with respect to the bilinear product

$$\langle f,g \rangle = \int f(x,y,z) g(x,y,z) \mu(x,y,z) \mathrm{d}x\, \mathrm{d}y\, \mathrm{d}z \tag{32}$$

on the manifold, i.e.,

$$\langle f, \hat{H} g \rangle = \langle \hat{H} f, g \rangle, \quad \langle f, \hat{S} g \rangle = \langle \hat{S} f, g \rangle$$

for all local C^∞ functions f,g with compact support on the manifold, where we set all boundary terms equal to 0.

Now we assume that $\{\mathcal{H},\mathcal{S}\}=0$ and require $[\hat{H},\hat{S}]=0$. Since $\hat{H},\hat{S}$ are formally self-adjoint, $[\hat{H},\hat{S}]$ must be formally skew-adjoint. From our assumption $\{\mathcal{H},\mathcal{S}\}=\mathbf{0}$ it is clear that the coefficients of the third-derivative terms ∂_{ijk} in the commutator must vanish, hence also the coefficients of the second-order terms vanish. Thus there are functions b_i such that

$$[\hat{H},\hat{S}] = \frac{1}{\mu} \sum_{i=1}^{3} \partial_i (b^i \mu) = \sum_{i=1}^{3} \left(b^i \partial_i + \frac{(b^i \mu)_i}{\mu} \right).$$

Using $\{\mathcal{H},\mathcal{S}\}=0$, we see that

$$b^j = \sum_{i=1}^{3} \left(\frac{1}{\lambda} \partial_{ii} + \frac{1}{\mu} \left(\frac{\mu}{\lambda} \right)_i \partial_i \right) \left(\frac{1}{\mu} \sum_{k=1}^{3} (a^{kj} \mu)_k \right) - \sum_{i,\ell=1}^{3} \left(a^{i\ell} \partial_{i\ell} + \frac{1}{\mu} (a^{i\ell} \mu)_i \partial_\ell \right) \left(\frac{1}{\mu} \left(\frac{\mu}{\lambda} \right)_j \right) + \frac{2}{\lambda} \hat{W}_j.$$

This formula simplifies greatly if we choose $\mu=\lambda$. Indeed, we find

$$b^j = -\frac{1}{\lambda} \partial_{jik} a^{ik} + \frac{2}{\lambda} \hat{W}_j.$$

Here i,j, and k are pairwise distinct. We can choose $\hat{W}_j = \frac{1}{2} \partial_{jik} a^{ik}$, so that $b^j \equiv 0$ provided the integrability conditions

$$\partial_{iijk} a^{ik} = \partial_{ijjk} a^{jk}$$

hold for i,j,k pairwise distinct. These conditions are satisfied, as we can verify from the explicit expressions for second-order conformal Killing tensors contained in Ref. 3

Theorem 8:

$$\{\mathcal{H},\mathcal{S}\} = 0 \Leftrightarrow [\hat{H},\hat{S}] = 0,$$

where $\hat{H},\hat{S}$ are given by (30) and (31) with $\mu=\lambda$ and $\hat{W}_j = \frac{1}{2} \partial_{jik} a^{ik}$ (for i,j,k pairwise distinct).

We can follow a similar approach to find the quantum analogies of first-order symmetries $\mathcal{L}=\Sigma_{j=1}^{2}a^{j}(x,y,z)p_j$, by the formally skew-adjoint first-order operator (with respect to the bilinear product (32))

$$\hat{L}=\frac{1}{\lambda}\sum_{j=1}^{3}\partial_j(a^{kj}\lambda). \tag{33}$$

It is straightforward to prove the following result.

Theorem 9:

$$\{\mathcal{H},\mathcal{L}\}=0\Leftrightarrow[\hat{H},\hat{L}]=0,$$

where $\hat{H},\hat{L}$ *are given by* (30) and (33) *with* $\mu=\lambda$.

VII. THE SPACE OF THIRD-ORDER SYMMETRIES

Now we investigate the third-order differential operators K that commute with the Hamiltonian: $[H,K]=0$. The treatment for the conformally flat 3D case proceeds in almost exact analogy to the 2D case, so we just sketch the results.

1. Since the second-order symmetries are formally self-adjoint, the commutators will be skew-adjoint. Thus we can limit ourselves to K that are skew adjoint.

2. Since H encodes a four-parameter family of potentials, the symmetry K must also be a function of the parameters. The highest order terms $a^{kji}\partial_{kji}$ in K (symmetric in k,j,i) will be independent of the parameters but lower order terms may have linear parameter dependence.

3. The skew-adjoint requirement uniquely determines the coefficients of the second-order terms in K. They are

$$\frac{3}{2\lambda}(a^{kji}\lambda)_i\partial_{kj}.$$

4. The skew-adjoint requirement means that there exist functions $a^{kji},\tilde{b}^i$ such that K has the unique representation

$$K=\sum_{k,j,i=1}^{3}\left(a^{kji}\partial_{kji}+\frac{3}{2\lambda}(a^{kji}\lambda)_i\partial_{kj}+\frac{1}{2\lambda}(a^{kji}\lambda)_{kj}\partial_i\right)+\sum_{i=1}^{3}\left(\tilde{b}^i\partial_i+\frac{1}{2\lambda}(\tilde{b}^i\lambda)_i\right), \tag{34}$$

where the functions $\tilde{b}^i(x,y,z)$ contain the parameter dependence.

5. Equating coefficients of the fourth-order terms in the operator condition $[H,K]=0$ where K is given by (34) we obtain the classical requirements that the a^{kji} be the components of a third-order Killing tensor.

6. Equating coefficients of the third-order terms in the condition $[H,K]=0$ we obtain relations that are consequences of the Killing tensor requirements.

7. The remaining conditions on K intertwine $\lambda,a^{kji},\tilde{b}^i$, and V, and are complicated. Rather than solve them directly, we make the unique decomposition

$$\tilde{b}^i(x_1,x_2,x_3,V_{x_1},V_{x_2},V_{x_3})=c^i(x_1,x_2,x_3)+b^i(x_1,x_2,x_3,V_{x_1},V_{x_2},V_{x_3}),$$

where

$$b^i = \sum_{j=1}^{3} f^{\ell,j}(x_1,x_2,x_3)\frac{\partial V}{\partial x_j}(x_1,x_2,x_3),$$

i.e., we can split off the parameter-dependent terms of $\tilde{b}^i$ from the rest. Then, equating the linear parameter-dependent coefficients of the second-order terms in the symmetry operator condition, we obtain the conditions

$$b_k^j + b_j^k = 3\lambda \sum_s a^{skj} V_s, \quad j \neq k, \quad j,k = 1,2,3,$$

$$b_j^j = \frac{3}{2}\lambda \sum_s a^{sjj} V_s - \frac{1}{2}\sum_s b^s (\ln \lambda)_s, \quad j = 1,2,3, \tag{35}$$

identical to the classical requirement.

8. Equating the quadratic parameter-dependent coefficients of the zeroth-order terms in the symmetry operator condition, we obtain the requirement

$$\sum_s b^s V_s = 0, \tag{36}$$

identical to the classical equation. There can be at most one skew adjoint K with given a^{ijk}, b^ℓ.

Theorem 10: *Let K be a third-order skew-adjoint symmetry* (11) *for a superintegrable system with nondegenerate potential V and $\tilde{b}^i = c^i(x,y,z) + b^i(x,y,z,V_1,V_2,V_3)$ where*

$$b^i = \sum_{j=1}^{3} f^{i,j}(x,y)\frac{\partial V}{\partial x_j}(x,y,z).$$

Then

$$f^{\ell,j} + f^{j,\ell} = 0, \quad 1 \leqslant \ell, j \leqslant 3$$

and K is uniquely determined by the four numbers

$$f^{1,2}(x_0,y_0,z_0), \quad f^{1,3}(x_0,y_0,z_0), \quad f^{2,3}(x_0,y_0,z_0), \quad f_3^{1,2}(x_0,y_0,z_0)$$

at any regular point (x_0,y_0,z_0) of V.

Corollary 4: Let V be a superintegrable nondegenerate potential. Then the space of third-order skew-adjoint symmetries is four-dimensional and is spanned by commutators of the second-order self-adjoint symmetries.

In exact analogy with the classical case, we can use the standard form to prove multiseparabilty for conformally flat 3D quantum systems.[4]

Theorem 11: *Let V be a quantum superintegrable nondegenerate potential. Then the associated system is multiseparable.*

VIII. THE QUANTUM 3D QUADRATIC ALGEBRA

We investigate the space of fourth-order differential operators F that commute with the Hamiltonian: $[H,F]=0$. The treatment for the conformally flat 3D case proceeds in almost exact analogy to the 2D case, so we sketch the results.

1. We are interested in the space of fourth-order symmetries that is spanned by the double commutators $[[S^{(1)},S^{(2)}],S^{(3)}]$ of second-order formally self-adjoint symmetries $S^{(j)}$ of the superintegrable system. The double commutators will be formally self-adjoint, so we can limit ourselves to F that are self-adjoint.

2. Since H encodes a three-parameter family of potentials, the symmetry F must also be a function of the parameters. The highest order terms $a^{\ell kji}\partial_{kji}$ in F (symmetric in ℓ,k,j,i) will be independent of the parameters but lower order terms may have linear or quadratic parameter dependence.

3. The self-adjoint requirement uniquely determines the third-order terms in F. They are

$$\sum_{\ell,k,j,i}\frac{2}{\lambda}(a^{\ell kji}\lambda)_i\partial_{\ell kj}.$$

4. The self-adjoint requirement means that there exist functions $a^{\ell kji},\tilde{b}^{ij},\tilde{W}$ such that F has the unique representation

$$F=\sum_{\ell,k,j,i=1}^{3}\frac{1}{\lambda}\partial_{ij}(a^{\ell kji}\lambda\partial_{k\ell})+\sum_{i,j=1}^{3}\frac{1}{\lambda}\partial_i(\tilde{b}^{ij}\lambda\partial_j)+\tilde{W}, \tag{37}$$

where the functions $\tilde{b}^{ij}(x_1,x_2,x_3),\tilde{W}(x_1,x_2,x_3)$ contain the parameter dependence.

5. Equating coefficients of the fifth-order terms in the operator condition $[H,F]=0$ we obtain the conditions for $a^{\ell kji}$ to be a fourth-order Killing tensor.

6. The remaining conditions on F intertwine $\lambda,a^{\ell kji},\tilde{b}^{ji},\tilde{W}$, and V, and are complicated. However, we can make the unique decomposition

$$\tilde{b}^{ji}(x_1,x_2,x_3,V_{x_1},V_{x_2},V_{x_3})=c^{ji}(x_1,x_2,x_3)+b^{ji}(x_1,x_2,x_3,V_{x_1},V_{x_2},V_{x_3})$$

where

$$b^{ji}=\sum_{\alpha=1}^{4}f^{ji,\alpha}W^{(\alpha)},\quad f^{ji,\alpha}=f^{ij,\alpha},$$

and $W^{(j)}=V_{x_j}$, $W^{(4)}=V_{x_1x_1}$.

Then, equating the linear parameter-dependent terms of third order in the derivatives, and the quadratic parameter-dependent terms of first order in the derivatives, we obtain exactly the classical conditions on the $f^{ji,\alpha}$.

Since at most one self-adjoint F can have data $a^{\ell kji},b^{kj}$, we find[3]

Theorem 12: *The subspace of truly fourth-order self-adjoint symmetry operators is of dimension at most twenty-one.*

If A,B are linear operators, we define their symmetrized product by

$$\{A,B\}\equiv\tfrac{1}{2}(AB+BA).$$

Theorem 13: *The twenty-one distinct monomials* $\{S^{(ij)},S^{(jk)}\}$ *form a basis for the space of fourth-order self-adjoint symmetry operators.*

Using an approach very similar to the above we can easily show that the space of truly sixth-order formally self-adjoint operator symmetries of H cannot exceed the classical maximal dimension of fifty-six. If A,B,C are linear operators, we define their symmetrized product by

$$\{A,B,C\}\equiv\tfrac{1}{6}(ABC+BAC+CAB+ACB+BCA+CBA).$$

Theorem 14: *The fifty-six distinct standard monomials* $\{S^{(hi)},S^{(jk)},S^{(\ell m)}\}$ *form a basis for the space of sixth-order self-adjoint symmetry operators.*

These theorems establish the closure of the quadratic algebra for 3D quantum superintegrable potentials: All fourth-order and sixth-order symmetry operators can be expressed as symmetric polynomials in the second-order symmetry operators.

IX. COVARIANT FORMULATION FOR THE 3D QUANTUM CASE

Theorem 8 yields an operator realization of the classical commutator brackets for second-order symmetries but the differential operator part of $\hat{H}$, though formally self-adjoint with respect to the weight function λ, is not the Laplace-Beltrami operator on the manifold. We can obtain the Laplace-Beltrami operator, at the expense of altering the potential V, by means of an appropriate gauge transformation. We now turn to this construction.

Set

$$H = e^{-\mathcal{R}}\hat{H}e^{\mathcal{R}}, \quad S = e^{-\mathcal{R}}\hat{S}e^{\mathcal{R}},$$

where $\mathcal{R}(x,y,z)$ is a function to be determined. Then $[H,S]=0$ if and only if $[\hat{H},\hat{S}]=0$. We will choose $\mathcal{R}$ such that the differential operator part of H is the Laplace-Beltrami operator on the manifold with metric $ds^2=\lambda(dx^2+dy^2+dz^2)$.

It is straightforward to show that

$$H = e^{-\mathcal{R}}\hat{H}e^{\mathcal{R}} = \frac{1}{\lambda}\sum_{i=1}^{3}(\partial_{ii} + 2\mathcal{R}_i\partial_i + \mathcal{R}_{ii} + \mathcal{R}_i^2) + V$$

so, if we set $\mathcal{R}=1/4\ln\lambda$, we have

$$H = \sum_{i=1}^{3}\left(\frac{1}{\lambda^{3/2}}\partial_i(\lambda^{1/2}\partial_i) + \frac{\mathcal{R}_{ii}+\mathcal{R}_i^2}{\lambda}\right) + V.$$

Similarly

$$S = \sum_{i,j=1}^{3}\left(\frac{1}{\lambda^{3/2}}\partial_i(a^{ij}\lambda^{3/2}\partial_j) + a^{ij}(\mathcal{R}_{ij} + 5\mathcal{R}_i\mathcal{R}_j) + a_i^{ij}\mathcal{R}_j\right) + W + \hat{W}.$$

The eigenvalue equation for $\hat{H}$ on the space with weight function $\mu=\lambda$ is $\hat{H}\Psi=E\Psi$. Setting $\Psi=e^{\mathcal{R}}\Phi=\lambda^{1/4}\Phi$ we see that the eigenvalue equation for Φ is $H\Phi=E\Phi$ and the eigenfunctions Φ lie in the space with weight function $\lambda^{3/2}$. Note that

$$\sum_{i=1}^{3}(\mathcal{R}_{ii}+\mathcal{R}_i^2)/\lambda = -\frac{1}{8}R,$$

where R is the Riemannian scalar curvature. The quantum potential is

$$\tilde{V} = -\tfrac{1}{8}R + V. \tag{38}$$

If we supplement the classical symmetries with quantum adjustments the corresponding operators are

$$H = \frac{1}{\sqrt{g}}\partial_i(g^{ij}\sqrt{g}\partial_j) + \frac{1}{8}R,$$

$$S = \frac{1}{\sqrt{g}}\partial_i(a^{ij}\sqrt{g}\partial_j) + \frac{1}{16}a_i^iR - \frac{5}{16}a^{ij}R_{ij} - \frac{1}{16}\nabla_i\nabla_j a^{ij}.$$

Here ∇_j is the usual covariant derivative on the Riemannian space. This formula always works, though a^{ij} must be a Killing tensor for a conformally flat space, Indeed for a Hamiltonian $\mathcal{H}=\lambda(x,y,z)(p_x^2+p_y^2+p_z^2)$ with symmetry $\mathcal{S}=a^{ij}p_ip_j$ the following conditions must be satisfied. If a_{ij} is a Killing tensor for a conformally flat space with infinitesimal distance

$$ds^2 = e^{-J(x,y,z)}(dx^2 + dy^2 + dz^2)$$

then it must satisfy the equations

$$\partial_{(i}a_{jk)} = g_{(ij}a_{k)}, \tag{39}$$

where

$$a_1 = e^{2J(x,y,z)}(a_{11}J_x - a_{12}J_y - a_{13}J_z), \quad a_2 = e^{2J(x,y,z)}(-a_{12}J_x + a_{22}J_y - a_{23}J_z),$$

$$a_3 = e^{2J(x,y,z)}(-a_{13}J_x - a_{23}J_y + a_{33}J_z).$$

Here (39) are the necessary and sufficient conditions that a_{ij} is a conformal Killing tensor in flat space. We know all solutions for this set of equations. The only constraint is that there exist a function $J(x,y,z)$ such that the a_l have the form indicated. Indeed, if we found the a_l from the considerations of flat space it is clear that

$$a_k = \frac{1}{5}\sum_j (\partial_j a_{jk} + \partial_k a_{jj}).$$

These results carry over in a very satisfactory manner for superintegrable systems with nondegenerate potential. In this case the parameters occurring in the potential appear only in the V and W terms, exactly as before. The quantum corrections are independent of these parameters.

Theorem 15: *Let $\mathcal{H}$, $\hat{H}$, and H be defined as above where $\mathcal{H}$ defines a classical superintegrable system with nondegenerate potential V. Let $\mathcal{S}^{(1)}, \mathcal{S}^{(2)}$ be second-order symmetries of $\mathcal{H}$, with corresponding symmetry operators $\hat{S}^{(j)}, S^{(j)}$. Then*

$$\{\mathcal{S}^{(1)}, \mathcal{S}^{(2)}\} = 0 \Leftrightarrow [\hat{S}^{(1)}, \hat{S}^{(2)}] = 0 \Leftrightarrow [S^{(1)}, S^{(2)}] = 0.$$

Corollary 5: Every conformally flat 3D classical superintegrable system with nondegenerate potential extends to a unique covariant quantum superintergrable system. The symmetries of the quantum system admit a quadratic algebra structure.

X. THE STÄCKEL TRANSFORM FOR 3D QUANTUM SYSTEMS

We work out the quantum analog of the Stäckel transform[26,27] for classical systems. Suppose we have a superintegrable system with Schrödinger operator

$$H = \frac{1}{\lambda^{3/2}(x,y,z)}\sum_{i=1}^{3} \partial_i(\lambda^{1/2}(x,y,z)\partial_i) - \frac{1}{8}R_\lambda(x,y,z) + V(x,y,z) \tag{40}$$

in local orthogonal coordinates, with scalar curvature R_λ and nondegenerate potential $V(x,y,z)$:

$$V_{33} = V_{11} + A^{33}V_1 + B^{33}V_2 + C^{33}V_3,$$

$$V_{22} = V_{11} + A^{22}V_1 + B^{22}V_2 + C^{22}V_3,$$

$$V_{23} = A^{23}V_1 + B^{23}V_2 + C^{23}V_3,$$

$$V_{13} = A^{13}V_1 + B^{13}V_2 + C^{13}V_3,$$

$$V_{12} = A^{12}V_1 + B^{12}V_2 + C^{12}V_3 \tag{41}$$

and suppose $U(x,y,z)$ is a particular solution of Eq. (41), nonzero in an open set. Then the transformed system

$$\tilde{H} = H = \frac{1}{\tilde{\lambda}^{3/2}(x,y,z)} \sum_{i=1}^{3} \partial_i (\tilde{\lambda}^{1/2}(x,y,z)\partial_i) - \frac{1}{8} R_{\tilde{\lambda}}(x,y,z) + \tilde{V}(x,y,z) \tag{42}$$

with nondegenerate potential $\tilde{V}(x,y,z)$:

$$\tilde{V}_{33} = \tilde{V}_{11} + \tilde{A}^{33}\tilde{V}_1 + \tilde{B}^{33}\tilde{V}_2 + \tilde{C}^{33}\tilde{V}_3,$$

$$\tilde{V}_{22} = \tilde{V}_{11} + \tilde{A}^{22}\tilde{V}_1 + \tilde{B}^{22}\tilde{V}_2 + \tilde{C}^{22}\tilde{V}_3,$$

$$\tilde{V}_{23} = \tilde{A}^{23}\tilde{V}_1 + \tilde{B}^{23}\tilde{V}_2 + \tilde{C}^{23}\tilde{V}_3,$$

$$\tilde{V}_{13} = \tilde{A}^{13}\tilde{V}_1 + \tilde{B}^{13}\tilde{V}_2 + \tilde{C}^{13}\tilde{V}_3,$$

$$\tilde{V}_{12} = \tilde{A}^{12}\tilde{V}_1 + \tilde{B}^{12}\tilde{V}_2 + \tilde{C}^{12}\tilde{V}_3, \tag{43}$$

is also superintegrable, where

$$\tilde{\lambda} = \lambda U, \quad \tilde{V} = \frac{V}{U},$$

$$\tilde{A}^{33} = A^{33} + 2\frac{U_1}{U}, \quad \tilde{B}^{33} = B^{33}, \quad \tilde{C}^{33} = C^{33} - 2\frac{U_3}{U},$$

$$\tilde{A}^{22} = A^{22} + 2\frac{U_1}{U}, \quad \tilde{B}^{22} = B^{22} - 2\frac{U_2}{U}, \quad \tilde{C}^{22} = C^{22},$$

$$\tilde{A}^{23} = A^{23}, \quad \tilde{B}^{23} = B^{23} - \frac{U_3}{U}, \quad \tilde{C}^{23} = C^{23} - \frac{U_2}{U},$$

$$\tilde{A}^{13} = A^{13} - \frac{U_3}{U}, \quad \tilde{B}^{13} = B^{13}, \quad \tilde{C}^{13} = C^{13} - \frac{U_1}{U},$$

$$\tilde{A}^{12} = A^{12} - \frac{U_2}{U}, \quad \tilde{B}^{12} = B^{12} - \frac{U_1}{U}, \quad \tilde{C}^{12} = C^{12}.$$

Indeed, let $S = \Sigma(1/\lambda^{3/2})\partial_i(a^{ij}\lambda^{3/2}\partial_j) + \mathcal{W}_R + W = S_0 + \mathcal{W}_R + W$ be a second-order formally self-adjoint symmetry operator of H, where $\mathcal{W}_R$ is the potential term that depends on the curvature R and W is the part that depends on V. Let $S_U = \Sigma(1/\lambda^{3/2})\partial_i(a^{ij}\lambda^{3/2}\partial_j) + \mathcal{W}_R + W_U = S_0 + \mathcal{W}_R + W_U$ be the special case of this that is in involution with

$$\frac{1}{\lambda^{3/2}} \sum_{i=1}^{3} \partial_i(\lambda^{1/2}\partial_i) - \frac{1}{8} R_\lambda + U.$$

Then

$$\tilde{S} = S_0 - \frac{W_U}{U}H + \frac{1}{U}H$$

is the corresponding formally self-adjoint symmetry operator of $\tilde{H}$, with respect to the metric $d\tilde{s}^2 = \lambda U(dx^2 + dy^2 + dz^2)$.

Theorem 16:

1.

$$[\tilde{H}, \tilde{S}] = 0 \Leftrightarrow [H, S] = 0.$$

2.

$$\tilde{S} = \sum_{ij} \frac{1}{(\lambda U)^{3/2}} \partial_i \left(\left(a^{ij} + \delta^{ij} \frac{1 - W_U}{\lambda U} \right) (\lambda U)^{3/2} \right) \partial_j + \left(\mathcal{W}_R + \left(\frac{W_U}{U} - \frac{1}{U} \right) \frac{R_\lambda}{8} + \left(W - \frac{W_U V}{U} + \frac{V}{U} \right) \right).$$

Proof:

1. We perform an inverse gauge transformation on H, S to return them to the forms $\hat{H}, \hat{S}$, (30) and (31), with $\mu = \lambda$ and $\hat{W}_j = \frac{1}{2}\partial_{jik} a^{ik}$ (for i, j, k pairwise distinct). Similarly we perform an inverse gauge transformation on $\tilde{H}, \tilde{S}$ to return them to the forms $\hat{\tilde{H}}, \hat{\tilde{S}}$, (30) and (31), with $\mu = U\lambda$. These commuting operators are formally self-adjoint with respect to the weight function $U\lambda$. Then it is a straightforward computation to verify that $[\hat{\tilde{H}}, \hat{\tilde{S}}] = 0 \Leftrightarrow [\hat{H}, \hat{S}] = 0$. Indeed, just as in the 2D case, one needs only the identities

$$[\hat{H}_0, \hat{S}_0] = 0, \quad [\hat{H}_0 + V, \hat{S}_0 + W] = 0, \quad [\hat{H}_0 + U, \hat{S}_0 + W_U] = 0$$

and

$$[A, BC] = B[A, C] + [A, B]C, \quad \left[A, \frac{1}{U} \right] = -\frac{1}{U}[A, U]\frac{1}{U}$$

for linear operators A, B, C and nonzero function U. Then the first part of the theorem follows from applying the original gauge transformations to take $\hat{H}, \hat{S}$ to H, S and $\hat{\tilde{H}}, \hat{\tilde{S}}$ to $\tilde{H}, \tilde{S}$.

2. This follows from the fact that $\partial_i W_U = \lambda \Sigma_j a^{ij} U_j$.

Q.E.D.

Corollary 6: If $S^{(1)}, S^{(2)}$ are second-order symmetry operators for H, then

$$[\tilde{S}^{(1)}, \tilde{S}^{(2)}] = 0 \Leftrightarrow [S^{(1)}, S^{(2)}] = 0.$$

At this point it is clear that the basic classical result for 3D Stäckel transforms of conformally flat classical superintegrable systems contained in Ref. 4 can be carried over to 3D quantum superintegrable systems.

Theorem 17: *Every nondegenerate second-order quantum superintegrable system on a 3D conformally flat space is Stäckel equivalent to a superintegrable system on a constant curvature space.*

XI. CONCLUSIONS AND OUTLOOK

We showed that 2D classical second-order superintegrable systems with nondegenerate potential and the corresponding 3D conformally flat systems each have a unique quantum superintegrable extension, and that the closure of the quadratic algebra and basic structure theory is unchanged at the quantum level. A critical feature of the proofs is use of the formal self-adjoint and skew-adjoint properties of the higher order symmetry operators. For the 2D case the extension is completely straightforward and the quantum extension has the same nondegenerate potential as the classical system. For the 3D systems a two-step procedure is required. First the classical

system is extended to a quantum system with appropriate formal self and skew adjoint symmetries and such that the potential remains unchanged. This quantum system, however, is not covariant, i.e., the Schrödinger operator does not correspond to a Laplace-Beltrami operator on a curved manifold. The second step in the procedure is to perform a gauge transformation to obtain covariantly correct Schrödinger operators. This alters the potential by adding a term that depends on the scalar curvature. We also showed that the Stäckel transform has a unique quantum extension and it remains true that all of our quantum superintegrable systems are Stäckel transforms of constant curvature superintegrable systems.

All 2D systems have been classified and we are making considerable progress on the 3D classification theory for systems with functionally linearly independent bases of symmetries,[4] though the problem is complicated. The next steps in our program are (1) to study 3D superintegrable systems with degenerate potentials and (2) to study nondegenerate superintegrable systems in higher dimensions.

ACKNOWLEDGMENTS

A referee's suggestion that we show how our structure theory relates to the generalized Calogero potential enabled us to clarify this relation and to point out the importance of the concept of functional linear independence for functionally independent symmetries. In the process we found and corrected an error in a paper (Ref. 3) of the series.

(Received 27 May 2006; accepted 11 July 2006; published online 18 September 2006)

Models of the quantum oscillator, based on the discrete series representations of the quantum algebra $su_q(1,1)$, are constructed. The position and momentum operators in these models are twisted generators J_2 and J_1 for such $su_q(1,1)$-representations, respectively. As in the case of the standard harmonic oscillator in quantum mechanics, the position and momentum operators here have continuous simple spectra. These spectra cover a finite interval on the real line, which depends on a value of q. Eigenfunctions of these operators are explicitly found. It is shown that the Macfarlane–Biedenharn q-oscillator is a limit case of the oscillators under discussion. The $q=1$ limit case, in which spectra of the position and momentum operators cover the whole real line, is also considered in detail. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2338141]

I. INTRODUCTION

A $su_q(1,1)$-model of the quantum oscillator is a model that obeys the dynamics of the harmonic oscillator, with the position and momentum operators and Hamiltonian being functions of elements of the quantum algebra $su_q(1,1)$. The aim of this paper is to develop the theory of such oscillators by using the discrete series representations of the quantum algebra $su_q(1,1)$.

There exist many algebraic constructions which can be used for building up different models of quantum oscillators. For most of them it is difficult to construct a complete theory of such an oscillator: spectra of observables, explicit form of eigenfunctions of observables, the description of time evolution, etc. Only for some such models is it possible to develop a corresponding theory. In Refs. 1 and 2 the so-called q-oscillator was constructed, which is a q-deformed analogue of the standard linear harmonic oscillator in quantum mechanics. A theory of this oscillator was elaborated in detail. There are physical problems for which the q-oscillator is more adequate than the quantum harmonic oscillator (see, for example, Refs. 3 and 4). Unlike the quantum field theory, constructed on the base of the standard quantum harmonic oscillator, the quantum field theory, built on the base of the q-oscillator, is free of some divergences. The q-oscillator has many useful properties, which are absent in the common quantum harmonic oscillator (see, for example, Refs. 5 and 6).

However, in the case of the q-oscillator the basic commutator relations

$$[H,Q] = -\mathrm{i}P, \quad [H,P] = \mathrm{i}Q, \tag{1}$$

are broken. That is why the q-oscillator is not so attractive for many physicists.

For this reason, many efforts have been made to construct those models of the quantum oscillator that preserve the relations (1). Postulates, which have to be satisfied for constructing such models of the quantum oscillator, were formulated in Ref. 7. These postulates are:

1. There exists an essentially self-adjoint (Hermitian) *position* operator, denoted as Q, whose spectrum Spec Q is the set of positions of the system.

[a)]Electronic mail: aklimyk@bitp.kiev.ua

2. There exists a self-adjoint *Hamiltonian* operator, H, which generates time evolution through the Newton–Lie, or equivalent Hamilton–Lie, equations:

$$[H,[H,Q]] = Q \Leftrightarrow \begin{cases} [H,Q] =: -\mathrm{i}P \\ [H,P] = \mathrm{i}Q, \end{cases} \tag{2}$$

where $[\cdot,\cdot]$ is the commutator. The first Hamilton equation in (2) defines the *momentum* operator P, while the second one contains the harmonic oscillator dynamics. The set of momentum values of the system is the spectrum Spec P of P.

3. The three operators, Q, P, and H, closed into an *associative algebra*, satisfy the Jacobi identity,

$$[P,[H,Q]] + [Q,[P,H]] + [H,[Q,P]] = 0. \tag{3}$$

The second and third postulates determine that $[Q,P]$ must commute with H, which implies that it can only be of the form $[Q,P]=\mathrm{i}f(H)$, where f is some function of H (including constants) and the i is placed to make $f(H)$ self-adjoint, but do not otherwise specify this basic commutator further. For a constant $f(H)=\hbar\hat{1}$, one recovers the standard oscillator algebra $H_4 = \mathrm{span}\{H,Q,P,\hat{1}\}$, which contains the basic Heisenberg-Weyl subalgebra $W_1=\mathrm{span}\{Q,P,\hat{1}\}$ of quantum mechanics. In Ref. 8 the authors examined the cases which, in the unitary irreducible representations of spin $j=\frac{1}{2}N$ ($N\in\{0,1,\ldots\}$ is fixed), correspond to the linear function $f(H)=H-\left(j+\frac{1}{2}\right)\hat{1}=:J_3$, and so the operators close into the Lie algebra $\mathrm{so}(3)\equiv\mathrm{su}(2)=\mathrm{span}\{Q,P,J_3\}$. In Ref. 9 the above-noted postulates are used to construct the so-called finite q-oscillator, for which (contrary to the Macfarlane–Biedenharn q-oscillator, mentioned earlier) the relations $[H,Q] = -\mathrm{i}P$ and $[H,P]=\mathrm{i}Q$ take place.

The quantum oscillators, constructed in Refs. 8 and 9, are characterized by the property that the position and momentum operators have finite *discrete spectra*. In the present paper we use the quantum algebra $\mathrm{su}_q(1,1)$ in order to construct, by means of the above-presented postulates, models of the quantum oscillator, which have *continuous bounded spectra* of the position and momentum operators.

For deriving properties of oscillators under discussion, we essentially employ the theory of special functions and orthogonal polynomials. Namely, using the interrelation between self-adjoint operators (in our case they are the position and momentum operators) and orthogonal polynomials, we find spectra of the position and momentum operators and derive an explicit form of their eigenfunctions. We define an explicit form of the evolution operator in the coordinate space. An analogue of the Fourier integral transform, which connects the coordinate and momentum spaces, is also constructed.

We show that oscillators under study, parametrized by a positive number l, in the limit as $l \to \infty$ coincide with the Macfarlane–Biedenharn q-oscillator.

At the end of the paper we study the limit case when $q=1$. In this case we obtain models of the quantum oscillator, also parametrized by a positive number l. In the limit $l\to\infty$ these models give the standard quantum harmonic oscillator, that is, these models give us new deformations of the standard model, for which (contrary to the case of the Macfarlane–Biedenharn q-oscillator) the relations (1) are fulfilled.

We employ the standard notations of the theory of basic hypergeometric functions and q-orthogonal polynomials (see, for example, Ref. 10). We shall use q-numbers, defined as

$$[a]_q := \frac{q^{a/2} - q^{-a/2}}{q^{1/2} - q^{-1/2}}$$

for any complex number a. Everywhere in the following it is assumed that $0<q<1$.

II. DISCRETE SERIES REPRESENTATIONS OF $su_q(1,1)$

The quantum algebra $su_q(1,1)$ is defined as the associative algebra, generated by the elements J_+, J_-, J_3, satisfying the commutation relations

$$[J_3,J_\pm] = \pm J_\pm, \quad [J_-,J_+] = \frac{q^{J_3} - q^{-J_3}}{q^{1/2} - q^{-1/2}} \equiv [2J_3]_q, \tag{4}$$

and the conjugation relations

$$J_3^* = J_3, \quad J_+^* = J_-. \tag{5}$$

(Observe that here we have replaced J_- by $-J_-$ in the usual definition of the algebra $sl_q(2)$.)

Introducing the elements $J_1 = \frac{1}{2}(J_+ + J_-)$ and $J_2 = (1/2i)(J_+ - J_-)$, we characterize the algebra $su_q(1,1)$ by the relations

$$[J_3,J_1] = iJ_2, \quad [J_2,J_3] = iJ_1, \quad [J_1,J_2] = -\frac{i}{2}[2J_3]_q. \tag{6}$$

The Casimir element of the algebra $su_q(1,1)$ is given by the formula

$$C_q := [J_3 - 1/2]_q^2 + \tfrac{1}{2}[2J_3]_q - J_1^2 - J_2^2 - 1/4 = [J_3 - 1/2]_q^2 - J_+J_- - 1/4.$$

We are interested in the discrete series representations of $su_q(1,1)$ with lowest weights. These irreducible representations will be denoted by T_l, where l is a lowest weight, which may be any positive number (see, for example, Ref. 11).

In order to realize these representations, we consider the space $\mathcal{P}$ of all polynomials in one variable y. We fix l and introduce the monomials

$$e_n^l \equiv e_n^l(y) := c_n^l y^n, \quad n = 0,1,2,3, \ldots, \tag{7}$$

where

$$c_0^l = 1, \quad c_n^l = \prod_{k=1}^{n} \frac{[2l+k-1]_q^{1/2}}{[k]_q^{1/2}} = q^{(1-2l)n/4} \frac{(q^{2l};q)_n^{1/2}}{(q;q)_n^{1/2}}, \quad n = 1,2,3, \ldots,$$

and $(a;q)_n := (1-a)(1-aq)\ldots(1-aq^{n-1})$. They form a basis in $\mathcal{P}$. The representation T_l is then realized by the operators (see Ref. 12)

$$J_3 = y\frac{d}{dy} + l, \quad J_\pm = y^{\pm 1}[J_3 \pm l]_q.$$

In this explicit realization one has

$$J_+e_n^l = \sqrt{[2l+n]_q[n+1]_q}\,e_{n+1}^l, \quad J_-e_n^l = \sqrt{[2l+n-1]_q[n]_q}\,e_{n-1}^l,$$

$$J_3e_n^l = (l+n)e_n^l.$$

Obviously, these operators satisfy the commutation relations (4). The basis functions $e_n^l(y)$ are eigenfunctions of the operators J_3 and C_q: $C_qe_n^l = \left([l-1/2]_q^2 - \frac{1}{4}\right)e_n^l$.

It is known that the discrete series representations T_l can be realized on a Hilbert space, on which the conjugation relations (5) hold. In order to obtain such a Hilbert space, we assume that the monomials $e_n^l(y)$, $n=0,1,2,\ldots$, constitute an orthonormal basis in this Hilbert space. This introduces a scalar product into the space $\mathcal{P}$. Then one closes this space with respect to this scalar product and obtains the Hilbert space, which will be denoted by $\mathcal{H}_l$. The Hilbert space $\mathcal{H}_l$ consists of functions (series)

$$f(y)=\sum_{n=0}^{\infty} b_n e_n^l(y)=\sum_{n=0}^{\infty} b_n c_n^l y^n=\sum_{n=0}^{\infty} a_n y^n,$$

where $a_n=b_n c_n^l$. Since $\langle e_n^l, e_m^l\rangle=\delta_{nm}$ by definition, for $f(y)=\Sigma_{n=0}^{\infty} a_n y^n$ and $f'(y)=\Sigma_{n=0}^{\infty} a_n' y^n$ we have

$$\langle f,f'\rangle=\sum_{n=0}^{\infty} a_n a_n'/|c_n^l|^2.$$

This means that the Hilbert space $\mathcal{H}_l$ consists of functions $f(y)=\Sigma_{n=0}^{\infty} a_n y^n$, such that

$$\|f\|^2\equiv\sum_{n=0}^{\infty}|a_n/c_n^l|^2<\infty.$$

III. DESCRIPTION OF $su_q(1,1)$-MODELS

In order to describe models of the quantum oscillator, which are based on irreducible representations of the algebra $su_q(1,1)$, we fix a positive number l and consider the discrete series representation T_l from Sec. II. We define Hamiltonian H and position and momentum operators Q and P in terms of the generators J_3, J_2, J_1 of this representation as

$$H=J_3-l+1/2,\quad Q=q^{J_3/4}J_2q^{J_3/4},\quad P=q^{J_3/4}J_1q^{J_3/4}. \tag{8}$$

Then, due to (6), for Q, P, and H we have the commutation relations

$$[H,Q]=-\mathrm{i}P,\quad [H,P]=\mathrm{i}Q, \tag{9}$$

$$\begin{aligned}[Q,P]&=\frac{\mathrm{i}}{2}q^{(1/2)J_3}(q^{-(1/2)}J_+J_--q^{(1/2)}J_-J_+)q^{(1/2)J_3}=:\mathrm{i}F_q(C_q,J_3)\\&=\mathrm{i}\left(e^{-\kappa J_3}\left[\left(C_q+\frac{1}{4}\right)\sinh\frac{\kappa}{2}+\frac{1}{2}\operatorname{csch}\frac{\kappa}{2}\right]-\frac{1}{2}e^{-2\kappa J_3}\coth\frac{\kappa}{2}\right),\end{aligned} \tag{10}$$

where $q:=e^{-\kappa}$. The operator $F_q(C_q,J_3)$, defined in (10), commutes with J_3 and therefore is also diagonal in the standard basis $\{e_n^l\}$; in the irreducible representation T_l we have

$$F_q e_m^j=\frac{e^{-2m\kappa}\cosh\frac{\kappa}{2}-e^{-m\kappa}\cosh\left(j+\frac{1}{2}\right)\kappa}{2\sinh\frac{\kappa}{2}}e_m^j,$$

but its spectrum is *not* a good candidate for an oscillator Hamiltonian, because it is not equally spaced, and so the corresponding time evolution would be dispersive rather than harmonic.

The basis e_n^l, $n=0,1,2,\ldots$, in the Hilbert space $\mathcal{H}_l$ consists of eigenfunctions of the Hamiltonian H:

$$He_n^l=(n+1/2)e_n^l,\quad n=0,1,2,\ldots, \tag{11}$$

that is, the spectrum of H coincides with the spectrum of the Hamiltonian of the standard quantum harmonic oscillator.

The operators (8) satisfy the postulates 1–3 of Sec. I. The time evolution of our system is the harmonic motion with

$$e^{i\tau H}\begin{pmatrix} Q \\ P \end{pmatrix} e^{-i\tau H} =: \begin{pmatrix} Q(\tau) \\ P(\tau) \end{pmatrix} = \begin{pmatrix} \cos\tau & \sin\tau \\ -\sin\tau & \cos\tau \end{pmatrix}\begin{pmatrix} Q \\ P \end{pmatrix}.$$

This is a group U(1) of inner automorphisms of the algebra $su_q(1,1)$ and of rotations of the phase-space surface. We have

$$\exp(i\tau H) = \exp[i\tau(J_3 - l + 1/2)] = e^{-i(l-1/2)\tau}\exp(i\tau J_3). \tag{12}$$

Explicit form of the time evolution in the coordinate space will be derived in the following.

Thus, to each positive number l there corresponds a model of the quantum oscillator: distinct values of l give rise to mutually nonequivalent models.

IV. SPECTRUM AND EIGENFUNCTIONS OF THE MOMENTUM OPERATOR

Since $P = q^{J_3/4} J_1 q^{J_3/4}$, the momentum operator P in the basis of the Hamiltonian eigenfunctions e_n^l, $n = 0,1,2,\ldots$, has the form

$$Pe_n^l = \frac{q^{(l+n)/2}}{2}\left(q^{1/4}\sqrt{[2l+n]_q[n+1]_q}e_{n+1}^l + q^{-1/4}\sqrt{[2l+n-1]_q[n]_q}e_{n-1}^l\right)$$

$$= \frac{1}{2(q^{-1/2}-q^{1/2})}\left(\sqrt{(1-q^{n+1})(1-q^{2l+n})}e_{n+1}^l + \sqrt{(1-q^n)(1-q^{2l+n-1})}e_{n-1}^l\right).$$

We wish to find the spectrum and eigenfunctions of this operator. Let $\psi_p(y)$ be an eigenfunction of P, corresponding to the eigenvalue p, $P\psi_p(y) = p\psi_p(y)$. Then

$$\psi_p(y) = \sum_{n=0}^{\infty} h_n(p)e_n^l(y), \tag{13}$$

where $h_n(p)$ are coefficients, which may depend on the eigenvalues p.

In order to find an explicit form of eigenfunctions $\psi_p(y)$, we substitute expression (13) for $\psi_p(y)$ into equation $P\psi_p(y) = p\psi_p(y)$:

$$\frac{1}{2}\sum_{n=0}^{\infty} h_n(p)\left(\frac{\sqrt{(1-q^{n+1})(1-q^{2l+n})}}{q^{-1/2}-q^{1/2}}e_{n+1}^l + \frac{\sqrt{(1-q^n)(1-q^{2l+n-1})}}{q^{-1/2}-q^{1/2}}e_{n-1}^l\right) = p\sum_{n=0}^{\infty} h_n(p)e_n^l.$$

Equating coefficients of a fixed basis element e_n^l, we obtain a three-term recurrence relation for the coefficients $h_n(p)$:

$$2ph_n(p) = \frac{\sqrt{(1-q^{n+1})(1-q^{2l+n})}}{q^{-1/2}-q^{1/2}}h_{n+1}(p) + \frac{\sqrt{(1-q^n)(1-q^{2l+n-1})}}{q^{-1/2}-q^{1/2}}h_{n-1}(p). \tag{14}$$

It is clear from (14) that the coefficients $h_n(p)$ are uniquely determined up to a common constant factor. We have $h_{-1}(p) = 0$ and setting $h_0(p) = 1$, we see that $h_n(p)$, $n = 1,2,\ldots$, are evaluated uniquely. Moreover, relation (14) shows that the $h_n(p)$ are polynomials in p of degree n.

To solve the recurrence relation (14), make the substitution

$$h_n(p) = \left(\frac{(q;q)_n}{(q^{2l};q)_n}\right)^{1/2} h_n'(p).$$

Then (14) turns into the equality

$$2(q^{-1/2}-q^{1/2})ph_n'(p) = (1-q^{n+1})h_{n+1}'(p) + (1-q^{2l+n-1})h_{n-1}'(p). \tag{15}$$

Comparing this relation with the recurrence relation

$$(1-q^{n+1})P_{n+1}(z;a|q)-2[z-2aq^n\cos\varphi]P_n(z;a|q)+(1-a^2q^{n-1})P_{n-1}(z;a|q)=0$$

[see formula (3.9.3) in Ref. 13] for the q-Meixner–Pollaczek polynomials

$$P_n(z;a|q)=\frac{(a^2;q)_n}{(q;q)_n}a^{-n}e^{-in\varphi}{}_3\phi_2(q^{-n},ae^{i(\theta+2\varphi)},ae^{-i\theta};a^2,0;q,q),$$

$$z=\cos(\theta+\varphi),$$

with $a=q^l$ and $\varphi=\pi/2$, one finds that

$$h_n'(p)=P_n((q^{-1/2}-q^{1/2})p;q^l|q)=i^{-n}q^{-ln}\frac{(q^{2l};q)_n}{(q;q)_n}{}_3\phi_2(q^{-n},-q^le^{i\theta},q^le^{-i\theta};q^{2l},0;q,q),$$

where $\sin\theta=(q^{-1/2}-q^{1/2})p$ and ${}_3\phi_2\ (q^{-n},\dots)$ is the basic hypergeometric polynomial. Consequently, for the coefficients in (13) one obtains that

$$h_n(p)=\left(\frac{(q;q)_n}{(q^{2l};q)_n}\right)^{1/2}P_n((q^{-1/2}-q^{1/2})p;q^l|q). \tag{16}$$

Thus, the eigenfunctions of the momentum operator P are of the form

$$\psi_p(y)=\sum_{n=0}^{\infty}\left(\frac{(q;q)_n}{(q^{2l};q)_n}\right)^{1/2}P_n(\sin\theta;q^l|q)e_n^l(y)=\sum_{n=0}^{\infty}q^{(1-2l)n/4}P_n(p(q^{-1/2}-q^{1/2});q^l|q)y^n, \tag{17}$$

where expression (7) for the basis elements has been taken into account. This result agrees with those derived in Refs. 12 and 14.

Expression (17) for the eigenfunctions $\psi_p(y)$ can be summed up by employing generating function (3.9.11) in Ref. 13 and we finally conclude that *the eigenfunctions of the momentum operator are of the form*

$$\psi_p(y)=\frac{(ciy;q)_\infty(-ciy;q)_\infty}{(-c'ie^{i\theta}y;q)_\infty(c'ie^{-i\theta}y;q)_\infty}, \tag{18}$$

where $c=q^{(2l+1)n/4}$, $c'=q^{(1-2l)n/4}$ and, as before, $p=(\sin\theta)/(q^{-1/2}-q^{1/2})$.

The spectrum of the momentum operator P can be found with the aid of formula (17). Indeed, it is easy to verify that the operator P, coinciding with the operator $q^{J_3/4}J_1q^{J_3/4}$ of the discrete series representation T_l, is bounded and self-adjoint. Moreover, P is representable in the basis $\{e_n^l\}$ by a Jacobi matrix, that is, by a tridiagonal matrix of the form

$$M=\begin{pmatrix} b_0 & a_0 & 0 & 0 & 0 & \cdots \\ a_0 & b_1 & a_1 & 0 & 0 & \cdots \\ 0 & a_1 & b_2 & a_2 & 0 & \cdots \\ 0 & 0 & a_2 & b_3 & a_3 & \cdots \\ \cdots & \cdots & \cdots & \cdots & \cdots & \cdots \end{pmatrix}, \quad a_i\neq 0.$$

There exists a theory (see Ref. 15, Chap. VII; a short description of this theory can be found in Ref. 6), which allows one to connect spectra of operators of such type with orthogonality measures for appropriate orthogonal polynomials. To employ this theory, we note that the eigenfunctions $\psi_p(y)$ are expressed in terms of the basis elements e_n^l by formula (13) with the *polynomial* coefficients (16). According to the results of Chap. VII in Ref. 15, these polynomials are orthogonal with respect to some measure $d\mu(p)$. (This measure is unique, up to a constant factor, since the operator P is self-adjoint; see Ref. 6.) A set (a subset of $\mathbb{R}$), on which the polynomials are orthogonal, coincides with the spectrum of the operator P and $d\mu(p)$ determines the spectral measure of this operator. Moreover, the spectrum of P is simple.

Thus, to find the spectrum of the momentum operator P, we recall that the q-Meixner–Pollaczek polynomials $P_n(z) \equiv P_n(z;a|q)$ are orthogonal and the orthogonality relation is of the form

$$\frac{1}{2\pi}\int_{-\pi}^{\pi} P_m(\sin\theta)P_n(\sin\theta)w(\sin\theta)\mathrm{d}\theta = \frac{(q^{2l};q)_n}{(q;q)_n}\delta_{mn},$$

where [see formula (3.9.2) in Ref. 13]

$$w(\sin\theta) = (q;q)_\infty(q^{2l};q)_\infty\left|\frac{(-e^{2i\theta};q)_\infty}{(-q^l e^{i\theta};q)_\infty(q^l e^{i\theta};q)_\infty}\right|^2.$$

This orthogonality relation can be written as

$$\frac{(q;q)_n}{(q^{2l};q)_n}\int_{-b}^{b} P_m(p/b)P_n(p/b)\tilde{w}(p)\mathrm{d}p = \delta_{mn}, \tag{19}$$

where $b := (q^{-1/2}-q^{1/2})^{-1}$ and $\tilde{w}(p) = w(p/b)/b\cos\theta$. This means that the spectrum of P coincides with the finite interval,

$$\mathrm{Spec}\ P = [-b,b], \quad b = (q^{-1/2}-q^{1/2})^{-1}.$$

Thus, the spectrum is continuous and simple. Continuity of the spectrum means that the eigenfunctions $\psi_p(y)$ are not elements of the Hilbert space $\mathcal{H}_l$. These functions of y for $p \in [-b,b]$ form a continuous basis in $\mathcal{H}_l$ (similar to the basis $\{e^{ipx}\}$ in the Hilbert space $L^2(\mathbb{R})$ of square-integrable functions on $\mathbb{R}$).

We see that the spectrum of P covers the infinite interval $(-\infty,\infty)$ in the limit as $q\to 1$. When $q\to 0$, the spectrum accumulates into the zero point.

Eigenfunctions of P are determined up to constant factors. In order to normalize the eigenfunctions $\psi_p(y)$, we take into account the orthogonality relation (19) for q-Meixner–Pollaczek polynomials. Since these polynomials are associated with the determinate moment problem (see, for example, Ref. 6 for the description of this correspondence), the set $P_n(p/b)$, $n=0,1,2,\ldots$, is complete in the Hilbert space $L^2([-b,b],\tilde{w})$ with the scalar product

$$\langle f_1,f_2\rangle = \int_{-b}^{b} f_1(p)\overline{f_2(p)}\tilde{w}(p)\mathrm{d}p, \tag{20}$$

where b and $\tilde{w}(p)$ are the same as in (19). This means that

$$\sum_{n=0}^{\infty}\frac{(q;q)_n}{(q^{2l};q)_n}\tilde{w}(p)P_n(p/b;q^{2l}|q)P_n(p'/b;q^{2l}|q) = \delta(p-p').$$

Then, on account of (17), one gets

$$\langle\psi_p(y),\psi_{p'}(y)\rangle = \sum_{n=0}^{\infty}\frac{(q;q)_n}{(q^{2l};q)_n}P_n(p/b;q^{2l}|q)P_n(p'/b;q^{2l}|q) = \frac{\delta(p-p')}{\tilde{w}(p)}.$$

Therefore, the normalized functions are

$$\tilde{\psi}_p(y) = \tilde{w}(p)^{1/2}\psi_p(y), \quad p\in[-b,b],$$

that is, $\langle\tilde{\psi}_p(y),\tilde{\psi}_{p'}(y)\rangle = \delta(p-p')$.

V. SPECTRUM AND EIGENFUNCTIONS OF THE POSITION OPERATOR

The position operator Q in the basis e_n^l, $n=0,1,2,\ldots$, has the form

$$Qe_n^l = \frac{q^{(l+n)/2}}{2\mathrm{i}}[q^{1/4}\sqrt{[2l+n]_q[n+1]_q}e_{n+1}^l - q^{-1/4}\sqrt{[2l+n-1]_q[n]_q}e_{n-1}^l].$$

By changing the basis $\{e_n^l\}$ to the basis $\{\tilde{e}_n^l\}$, where $\tilde{e}_n^l = \mathrm{i}^{-n}e_n^l$, we see that the position operator Q is given in the latter basis by the same formula as the momentum operator is given in the former basis $\{e_n^l\}$ (see Sec. IV). This means that the spectrum of the operator Q coincides with the spectrum of P, that is,

$$\mathrm{Spec}\ Q = [-b,b], \quad b = (q^{-1/2} - q^{1/2})^{-1}.$$

Eigenfunctions of the position operator can be found (by using the basis $\{\tilde{e}_n^l\}$) in the same way as in the case of the momentum operator. For this reason, we exhibit here only the result.

Let $\phi_x(y)$ be an eigenfunction of Q, corresponding to the eigenvalue x, $Q\phi_x(y) = x\phi_x(y)$. Then

$$\phi_x(y) = \sum_{n=0}^{\infty} \tilde{h}_n(x)e_n^l(y), \tag{21}$$

where, as before, the $e_n^l(y)$ are given by (7) and the $\tilde{h}_n(x)$ are coefficients, which may depend on the eigenvalues x.

Repeating the reasoning of Sec. IV, one derives a three-term recurrence relation for the polynomials $\tilde{h}_n(x)$ and concludes that

$$\tilde{h}_n(x) = \mathrm{i}^{-n}h_n(x) = \mathrm{i}^{-n}\left(\frac{(q;q)_n}{(q^{2l};q)_n}\right)^{1/2} P_n(x/b;q^l|q), \quad b := (q^{-1/2} - q^{1/2})^{-1}, \tag{22}$$

where $P_n(z;q^l|q)$ is the q-Meixner–Pollaczek polynomial as in Sec. IV. One thus deduces that eigenfunctions of the position operator Q are of the form

$$\phi_x(y) = \sum_{n=0}^{\infty} \mathrm{i}^{-n}\left(\frac{(q;q)_n}{(q^{2l};q)_n}\right)^{1/2} P_n(x/b;q^l|q)e_n^l(y) = \sum_{n=0}^{\infty} \mathrm{i}^{-n}q^{(1-2l)n/4}P_n(x/b;q^l|q)y^n. \tag{23}$$

One can sum up expression (23) for the eigenfunctions $\phi_x(y)$ by employing formula (3.9.11) in Ref. 13. Thus *the eigenfunctions of the position operator Q are of the form*

$$\phi_x(y) = \frac{(-cy;q)_\infty (cy;q)_\infty}{(c'e^{\mathrm{i}\theta}y;q)_\infty (-c'e^{-\mathrm{i}\theta}y;q)_\infty},$$

where $c = q^{(2l+1)n/4}$, $c' = q^{(1-2l)n/4}$, and $x = b\sin\theta$ with $b = (q^{-1/2} - q^{1/2})^{-1}$.

Eigenfunctions of Q are determined up to constant factors. To normalize the eigenfunctions $\phi_x(y)$, we employ the orthogonality relation (19) for q-Meixner–Pollaczek polynomials. The set $P_n(x/b)$, $n = 0,1,2,\ldots$, is complete in the Hilbert space $L^2([-b,b],\tilde{w}(x))$, $b = (q^{-1/2} - q^{1/2})^{-1}$, with the scalar product

$$\langle f_1, f_2\rangle = \int_{-b}^{b} f_1(x)\overline{f_2(x)}\tilde{w}(x)\mathrm{d}x,$$

where $\tilde{w}$ is the same as in (19). Consequently, the normalized functions are

$$\tilde{\phi}_x(y) = \tilde{w}(x)^{1/2}\phi_x(y), \quad x \in [-b,b],$$

that is, $\langle \tilde{\phi}_x(y), \tilde{\phi}_{x'}(y)\rangle = \delta(x-x')$.

VI. MOMENTUM REALIZATION OF THE OSCILLATOR

We have constructed in Sec. III a realization of the oscillator (depending on a value of l) on the space of functions in the supplementary variable y. It is natural to look for its realization on the space of functions in the coordinate x and on the space of functions in the momentum p.

Let $L^2([-b,b],\tilde{w})$, $b=(q^{-1/2}-q^{1/2})^{-1}$, be the space of square-integrable functions $f(p)$ (where p is the momentum of the oscillator) with respect to the scalar product (20). From (19) it is clear that the polynomials (16) constitute an orthonormal basis in $L^2([-b,b],\tilde{w})$.

We construct first a one-to-one linear isometry Ω from the Hilbert space $\mathcal{H}_l$, considered in Sec. II, onto the Hilbert space $L^2([-b,b],\tilde{w})$, given by the formula

$$\Omega\colon \mathcal{H}_l \ni e(y) \to f(p) := \langle e(y), \psi_p(y)\rangle_{\mathcal{H}_l} \in L^2([-b,b],\tilde{w}), \tag{24}$$

where $\psi_p(y)$ are the eigenfunctions (18) of P. It follows from (17) that

$$\mathcal{H}_l \ni e_n^l(y) \to \langle e_n^l(y), \psi_p(y)\rangle_{\mathcal{H}_l} = h_n(p), \tag{25}$$

that is, Ω maps the orthonormal basis $\{e_n^l(y)\}$ of $\mathcal{H}_l$ onto the orthonormal basis $\{h_n(p)\}$ in $L^2([-b,b],\tilde{w})$. This means that Ω indeed is a one-to-one isometry.

The operator P acts on $L^2([-b,b],\tilde{w})$ as the multiplication operator,

$$Pf(p) = pf(p).$$

Indeed, according to (25) if $\Omega e(y)=f(p)=\langle e(y), \psi_p(y)\rangle_{\mathcal{H}_l}$, then

$$Pe(y) \to Pf(p) = \langle Pe(y), \psi_p(y)\rangle_{\mathcal{H}_l} = \langle e(y), P\psi_p(y)\rangle_{\mathcal{H}_l} = \langle e(y), p\psi_p(y)\rangle_{\mathcal{H}_l} = pf(p).$$

We can find how P acts upon the basis elements $h_n(p)$, $n=0,1,2,\ldots$, of the Hilbert space $L^2([-b,b],\tilde{w})$. According to the recurrence relation for the polynomials (16) (which follows from the recurrence relation for the polynomials $P_n(z;q^l|q)$), we have

$$Ph_n(p) = ph_n(p) = \frac{1}{2(q^{-1/2}-q^{1/2})}\left(\sqrt{(1-q^{n+1})(1-q^{2l+n})}h_{n+1}(p) + \sqrt{(1-q^n)(1-q^{2l+n-1})}h_{n-1}(p)\right).$$

The Hamiltonian H acts upon the polynomials $h_n(p)$ in the Hilbert space $L^2([-b,b],\tilde{w})$ as

$$Hh_n(p) = (n+1/2)h_n(p).$$

Indeed, since $He_n^l(y)=(n+1/2)e_n^l(y)$, then according to (25) one has

$$Hh_n(p) = \langle He_n^l(y), \psi_p(y)\rangle_{\mathcal{H}_l} = (n+1/2)\langle e_n^l(y), \psi_p(y)\rangle_{\mathcal{H}_l} = (n+1/2)h_n(p).$$

Let us find how the operator Q acts on the Hilbert space $L^2([-b,b],\tilde{w})$. To achieve this we use the results of Ref. 16.

The polynomials $h_n(p)$ from (16) can be expressed in terms of the Askey–Wilson polynomials, defined as

$$p_n\left(\frac{1}{2}(z+z^{-1});a,b,c,d|q\right) \equiv p_n[z] = \frac{(ab,ac,ad;q)_n}{a^n}\,{}_4\phi_3\left(\begin{matrix}q^{-n},q^{n-1}abcd,az,az^{-1}\\ ab,ac,ad\end{matrix}\Big|q,q\right),$$

where $(\alpha,\beta,\gamma;q)_n := (\alpha;q)_n(\beta;q)_n(\gamma;q)_n$. We have

$$h_n(p) = [(q^{2l};q)_n(q;q)_n]^{-1/2}p_n\left(\frac{1}{2}(z+z^{-1});iq^l,-iq^l,0,0|q\right), \tag{26}$$

where $z=e^{i(\theta+\pi/2)}$. For convenience we denote the polynomials $h_n(p)$ by $h_n[z]$, where z is the same as in (26). It follows from (26) and from formula (4.5) in Ref. 16 that the polynomials $h_n[z]$ satisfy the difference equation

$$Dh_n[z] = \frac{2(q^{-n}-1)}{1-q^{-1}} h_n[z],$$

where the difference operator D acts as

$$Df(z) = \frac{1-q^{2l}z}{(1-z^2)(1-qz^2)} f(qz) - \left(\frac{1-q^{2l}z}{(1-z^2)(1-qz^2)} + \frac{1-q^{2l}z^{-1}}{(1-z^{-2})(1-qz^{-2})} \right) f(z) + \frac{1-q^{2l}z^{-1}}{(1-z^{-2})(1-qz^{-2})} f(q^{-1}z).$$

We shall also need an operator of the form

$$D' := \tfrac{1}{2}(1-q^{-1})D + 1,$$

whose action on the polynomials $h_n[z]$ is

$$D'h_n[z] = q^{-n}h_n[z].$$

This means that the operator D' acts on the polynomials $h_n[z]$ as q^{-N}, where N is the number operator,

$$Nh_n[z] = nh_n[z].$$

In order to find a difference form for the momentum operator, we need the operator L, which is defined as

$$Lf(z) = (z-z^{-1})^{-1}[(1-q^{2l}z^2)z^{-2}f(qz) - (1-q^{2l}z^{-2})z^2 f(q^{-1}z)].$$

This is the operator (4.7) in Ref. 16 for our case. Then from formulas (4.11) and (4.12) from Ref. 16 one derives that

$$(L - q^{1-n}(z+z^{-1}))h_n[z] = -\frac{1+q}{q^n}\sqrt{(1-q^{n+1})(1-q^{2l+n})}h_{n+1}[z] = -(1+q)q^{(n+l+1/2)/2}\sqrt{[2l+n]_q[n+1]_q}h_{n+1}[z],$$

and

$$(L + q^{-n}(z+z^{-1}))h_n[z] = \frac{1+q}{q^n}\sqrt{(1-q^n)(1-q^{2l+n-1})}h_{n-1}[z] = (1+q)q^{(n+l-1/2)/2}\sqrt{[2l+n-1]_q[n]_q}h_{n-1}[z].$$

Note that the operators

$$J_+ := -\frac{q^{-(l+1/2)/2}}{(1+q)}(L - q(z+z^{-1})q^{-N})q^{-N/2}, \tag{27}$$

$$J_- := \frac{q^{-(l-1/2)/2}}{(1+q)}(L + (z+z^{-1})q^{-N})q^{-N/2}, \tag{28}$$

act upon the polynomials $h_n[z]$ as

$$J_+h_n[z] = \sqrt{[2l+n]_q[n+1]_q}h_{n+1}[z], \quad J_-h_n[z] = \sqrt{[2l+n-1]_q[n]_q}h_{n-1}[z].$$

One may express the position operator $Q = q^{J_3/4}J_2q^{J_3/4}$ in terms of the difference operators (27) and (28) as

$$Q = \mathrm{i}\frac{q^{1/2}}{2(1-q^2)}[L - q(z+z^{-1})q^{-N} + L + (z+z^{-1})q^{-N}]q^N = \mathrm{i}\frac{q^{1/2}}{2(1-q^2)}[2L + (1-q)(z+z^{-1})q^{-N}]q^N,$$

which can be represented in the form

$$Q = \mathrm{i}\frac{q^{1/2}}{2(1-q^2)}[2Lq^N + (1-q)(z+z^{-1})]. \tag{29}$$

It is easy to find that Q acts upon the polynomials $h_n[z]$ as

$$Qh_n(p) = \frac{1}{2\mathrm{i}(q^{-1/2}-q^{1/2})}[\sqrt{(1-q^{n+1})(1-q^{2l+n})}h_{n+1}(p) - \sqrt{(1-q^n)(1-q^{2l+n-1})}h_{n-1}(p)],$$

that is, this is the position operator. Thus, formula (29) gives us the difference form of the position operator.

VII. COORDINATE REALIZATION OF THE OSCILLATOR

Let $\widetilde{L}^2([-b,b],\widetilde{w})$, $b=(q^{-1/2}-q^{1/2})^{-1}$, be the space of square-integrable functions $f(x)$ (where x is the coordinate of the oscillator) with respect to the same scalar product as in (20). It follows from (19) that the polynomials $\widetilde{h}_n(x)$ from (22) constitute an orthonormal basis in $\widetilde{L}^2([-b,b],\widetilde{w})$.

We construct a one-to-one linear isometry $\widetilde{\Omega}$ from the Hilbert space $\mathcal{H}_l$, considered in Sec. II, onto the Hilbert space $\widetilde{L}^2([-b,b],\widetilde{w})$ given by the formula

$$\widetilde{\Omega}\colon \mathcal{H}_l \ni e(y) \to f(x) := \langle e(y), \phi_x(y)\rangle_{\mathcal{H}_l} \in \widetilde{L}^2([-b,b],\widetilde{w}), \tag{30}$$

where $\phi_x(y)$ are the eigenfunctions (23) of Q. From (23) it is then evident that

$$\mathcal{H}_l \ni e_n^l(y) \to \langle e_n^l(y), \phi_x(y)\rangle_{\mathcal{H}_l} = \widetilde{h}_n(x),$$

that is, $\widetilde{\Omega}$ maps the orthonormal basis $\{e_n^l(y)\}$ from $\mathcal{H}_l$ onto the orthonormal basis $\{\widetilde{h}_n(x)\}$ in $\widetilde{L}^2([-b,b],\widetilde{w})$. This means that $\widetilde{\Omega}$ indeed is a one-to-one isometry.

The operator Q acts on $\widetilde{L}^2([-b,b],\widetilde{w})$ as the multiplication operator,

$$Qf(x) = xf(x).$$

We can find how Q acts upon the basis elements $\widetilde{h}_n(x)$, $n=0,1,2,\ldots$, in the Hilbert space $\widetilde{L}^2([-b,b],\widetilde{w})$. According to the recurrence relation for the polynomials (22), one has

$$Q\widetilde{h}_n(x) = x\widetilde{h}_n(x) = \frac{\mathrm{i}}{2(q^{-1/2}-q^{1/2})}[\sqrt{(1-q^{n+1})(1-q^{2l+n})}\widetilde{h}_{n+1}(x) - \sqrt{(1-q^n)(1-q^{2l+n-1})}\widetilde{h}_{n-1}(x)].$$

Clearly, $H\widetilde{h}_n(x) = (n+1/2)\widetilde{h}_n(x)$.

One can also find a difference form for the momentum operator P in the coordinate space. To this end, one has to repeat the reasoning of Sec. VI.

VIII. THE EVOLUTION OPERATOR IN THE COORDINATE SPACE

According to (12), the time evolution operator $\exp(\mathrm{i}\tau H)$ acts upon the basis elements e_n^l, $n=0,1,2,\cdots$, of the Hilbert space $\mathcal{H}_l$ as

$$\exp(\mathrm{i}\tau H)e_n^l = e^{-\mathrm{i}(l-1/2)\tau}e^{\mathrm{i}(l+n)\tau}e_n^l = e^{\mathrm{i}(n+1/2)\tau}e_n^l.$$

We wish to find how this operator acts in the coordinate space, that is, on the Hilbert space $\widetilde{L}^2([-b,b],\widetilde{w})$ from Sec. VII. If the isometry $\widetilde{\Omega}$ maps a function $e(y)\in\mathcal{H}_l$ to a function $f(x)$

$\in \widetilde{L}^2([-b,b],\tilde{w})$, then to $\exp(\mathrm{i}\tau H)e(y) \in \mathcal{H}_l$ there corresponds the function

$$\begin{aligned}
\exp(\mathrm{i}\tau H)f(x) &= \langle \exp(\mathrm{i}\tau H)e(y), \phi_x(y)\rangle_{\mathcal{H}_l} = \langle e(y), \exp(-\mathrm{i}\tau H)\phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \sum_{n=0}^{\infty} \langle e(y), e_n^l\rangle_{\mathcal{H}_l}\langle e_n^l, \exp(-\mathrm{i}\tau H)\phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \sum_{n=0}^{\infty} \langle e(y), e_n^l\rangle_{\mathcal{H}_l}\langle \exp(\mathrm{i}\tau H)e_n^l, \phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \sum_{n=0}^{\infty} \int_{-b}^{b} \langle e(y), \widetilde{\phi}_{x'}(y)\rangle_{\mathcal{H}_l}\langle \widetilde{\phi}_{x'}(y), e_n^l\rangle_{\mathcal{H}_l} \mathrm{d}x' \cdot \exp(\mathrm{i}\tau(n+1/2))\langle e_n^l, \phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \int_{-b}^{b} f(x')K^{\tau}(x,x')\tilde{w}(x')\mathrm{d}x',
\end{aligned}$$

where the kernel $K^{\tau}(x,x')$ is given by

$$K^{\tau}(x,x') = \sum_{n=0}^{\infty} \langle \phi_{x'}(y), e_n^l\rangle_{\mathcal{H}_l}\langle e_n^l, \phi_x(y)\rangle_{\mathcal{H}_l} \exp(\mathrm{i}\tau(n+1/2)).$$

Taking into account the expression for $\widetilde{h}_n(x) = \langle e_n^l, \phi_x(y)\rangle_{\mathcal{H}_l}$ with $x = b\sin\theta$, one finds that

$$\begin{aligned}
K^{\tau}(x,x') &= \sum_{n=0}^{\infty} \exp(\mathrm{i}\tau(n+1/2))\widetilde{h}_n(x)\overline{\widetilde{h}_n(x')} \\
&= e^{\mathrm{i}\pi/2}\sum_{n=0}^{\infty} e^{\mathrm{i}n\tau}q^{-2ln}\frac{(q^{2l};q)_n}{(q;q)_n}\,{}_3\phi_2(q^{-n},-q^l e^{\mathrm{i}\theta},q^l e^{-\mathrm{i}\theta};q^{2l},0;q,q) \\
&\quad \times {}_3\phi_2(q^{-n},-q^l e^{\mathrm{i}\theta'},q^l e^{-\mathrm{i}\theta'};q^{2l},0;q,q),
\end{aligned}$$

upon employing the explicit expression for the q-Meixner-Pollaczek–polynomials from Sec. IV. Due to formula (8.15) in Ref. 17, one finally obtains that

$$\begin{aligned}
K^{\tau}(x,x') = e^{\mathrm{i}\pi/2}&\frac{(q^l e^{\mathrm{i}\theta'}e^{\mathrm{i}\tau},-q^l e^{-\mathrm{i}\theta'}e^{\mathrm{i}\tau},q^l e^{\mathrm{i}\theta}e^{\mathrm{i}\tau},-q^l e^{-\mathrm{i}\theta}e^{\mathrm{i}\tau},e^{\mathrm{i}\tau};q)_{\infty}}{(e^{\mathrm{i}(\theta+\theta')}e^{\mathrm{i}\tau},-e^{\mathrm{i}(\theta'-\theta)}e^{\mathrm{i}\tau},-e^{\mathrm{i}(\theta-\theta')}e^{\mathrm{i}\tau},e^{-\mathrm{i}(\theta+\theta')}e^{\mathrm{i}\tau},q^{2l}e^{\mathrm{i}\tau};q)_{\infty}} \\
&\times {}_8W_7(q^{2l-1}e^{\mathrm{i}\tau};-q^l e^{\mathrm{i}\theta},q^l e^{-\mathrm{i}\theta},-q^l e^{\mathrm{i}\theta'},q^l e^{-\mathrm{i}\theta'},e^{\mathrm{i}\tau};q,e^{\mathrm{i}\tau}),
\end{aligned} \tag{31}$$

where $(a_1,a_2,\ldots,a_r;q)_{\infty} \equiv (a_1;q)_{\infty}(a_2,q)_{\infty}\cdots(a_r;q)_{\infty}$ and ${}_8W_7$ is the basic hypergeometric function (2.1.11) from Ref. 10. Expressing the function ${}_8W_7$ in (31) in terms of the basic hypergeometric function ${}_8\phi_7$ (see Ref. 10, Sec. 2.1) and using relation (III.17) from Appendix III in Ref. 10, one can reduce the ${}_8W_7$ in (31) to the basic hypergeometric function ${}_4\phi_3$:

$$\begin{aligned}
&{}_8W_7(q^{2l-1}e^{\mathrm{i}\tau};-q^l e^{\mathrm{i}\theta},q^l e^{-\mathrm{i}\theta},-q^l e^{\mathrm{i}\theta'},q^l e^{\mathrm{i}\theta'},e^{\mathrm{i}\tau};q,e^{\mathrm{i}\tau}) \\
&\quad = \frac{(q^{2l}e^{\mathrm{i}\tau},-e^{\mathrm{i}\tau},-q^l e^{-\mathrm{i}\theta'},q^l e^{\mathrm{i}\theta'};q)_{\infty}}{(-q^l e^{-\mathrm{i}\theta'}e^{\mathrm{i}\tau},q^l e^{\mathrm{i}\theta'}e^{\mathrm{i}\tau},q^{2l},-1;q)_{\infty}}\,{}_4\phi_3\left(\begin{matrix}-e^{\mathrm{i}\tau},e^{\mathrm{i}\tau},-q^l e^{\mathrm{i}\theta'},q^l e^{-\mathrm{i}\theta'} \\ -q^l e^{-\mathrm{i}\theta}e^{\mathrm{i}\tau},q^l e^{\mathrm{i}\theta}e^{\mathrm{i}\tau},-q\end{matrix}\,\middle|\,q,q\right).
\end{aligned}$$

As a result, one arrives at the following expression for the kernel $K^{\tau}(x,x')$:

$$K^{\tau}(x,x') = \frac{(q^l e^{i\theta} e^{i\tau}, -q^l e^{-i\theta} e^{i\tau}, e^{i\tau}, -e^{i\tau}, -q^l e^{-i\theta'}, q^l e^{i\theta'}; q)_\infty}{(e^{i(\theta+\theta')} e^{i\tau}, -e^{i(\theta'-\theta)} e^{i\tau}, -e^{i(\theta-\theta')} e^{i\tau}, e^{-i(\theta+\theta')} e^{i\tau}, q^{2l} e^{i\tau}, q^{2l}, -1; q)_\infty}$$
$$\times e^{i\pi/2} {}_4\phi_3\left(\begin{matrix} -e^{i\tau}, e^{i\tau}, -q^l e^{i\theta'}, q^l e^{-i\theta'} \\ -q^l e^{-i\theta} e^{i\tau}, q^l e^{i\theta} e^{i\tau}, -q \end{matrix} \middle| q, q \right). \tag{32}$$

Thus, *the evolution operator* $\exp(i\tau H)$ *is given by the formula*

$$\exp(i\tau H) f(x) = \int_{-b}^{b} K^{\tau}(x,x') f(x') \tilde{w}(x') dx',$$

where the kernel $K^{\tau}(x,x')$ *is given by* (32). Since $e^{i\tau H} e^{i\tau' H} = e^{i(\tau+\tau')H}$, this kernel satisfies the relation

$$\int_{-b}^{b} K^{\tau}(x,x') \overline{K^{\tau}(x',x'')} \tilde{w}(x') dx' = K^{\tau+\tau'}(x,x'').$$

Observe that the above-presented relation leads to the corresponding integral relation for the basic hypergeometric function ${}_4\phi_3$ in (32).

IX. AN ANALOGUE OF THE FOURIER TRANSFORM

Let us first recall the case of the standard linear harmonic oscillator in quantum mechanics, determined by the commutator

$$aa^+ - a^+ a = 1.$$

For the position and momentum operators $\mathcal{Q}$ and $\mathcal{P}$ we have

$$\mathcal{Q} = \frac{1}{\sqrt{2}}(a^+ + a), \quad \mathcal{P} = \frac{i}{\sqrt{2}}(a^+ - a).$$

The Hilbert space of states $\mathcal{H}$ is spanned by the orthonormal vectors $|n\rangle$, $n=0,1,2,\ldots$. For eigenvectors of $\mathcal{Q}$ and $\mathcal{P}$, we have

$$\mathcal{Q}|x\rangle = x|x\rangle, \quad \mathcal{P}|p\rangle = p|p\rangle,$$

and Spec $\mathcal{Q}$=Spec $\mathcal{P}$=$\mathbb{R}$.

For $h \in \mathcal{H}$, one gets

$$\langle h,x\rangle_{\mathcal{H}} = h(x), \quad \langle h,p\rangle_{\mathcal{H}} = \tilde{h}(p). \tag{33}$$

In this way one obtains a realization of $\mathcal{H}$ as a space of functions either in the coordinate or in the momentum. Then the functions $h(x)$ and $\tilde{h}(p)$ from (33) are related with each other by the well-known integral Fourier transform:

$$h(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \tilde{h}(p) e^{ipx} dp.$$

Our aim in this section is to find an analogue of the Fourier transform for the model of the oscillator under discussion. Let $e(y)$ be a function on the Hilbert space $\mathcal{H}_l$. Then

$$\Omega: e(y) \to f(p) \in L^2([-b,b],\tilde{w}), \quad \tilde{\Omega}: e(y) \to \tilde{f}(x) \in \tilde{L}^2([-b,b],\tilde{w}).$$

We need to find out how the functions $f(p)$ and $\tilde{f}(x)$ are connected with each other. One has

$$\widetilde{f}(x)=\langle e(y),\phi_x(y)\rangle_{\mathcal{H}_l}=\int_{-b}^{b}\langle e(y),\widetilde{\psi}_p(y)\rangle_{\mathcal{H}_l}\langle\widetilde{\psi}_p(y),\phi_x(y)\rangle_{\mathcal{H}_l}\mathrm{d}p=\int_{-b}^{b}f(p)\langle\psi_p(y),\phi_x(y)\rangle_{\mathcal{H}_l}\widetilde{w}(p)\mathrm{d}p$$

$$=\int_{-b}^{b}f(p)F(x,p)\widetilde{w}(p)\mathrm{d}p,$$

where the kernel $F(x,p)$ is given as

$$F(x,p)=\langle\psi_p(y),\phi_x(y)\rangle_{\mathcal{H}_l}=\sum_{n=0}^{\infty}\langle\psi_p(y),e_n^l\rangle_{\mathcal{H}_l}\langle e_n^l,\phi_x(y)\rangle_{\mathcal{H}_l}=\sum_{n=0}^{\infty}\mathrm{i}^{-n}h_n(x)\overline{h_n(p)}$$

$$=\sum_{n=0}^{\infty}\mathrm{i}^{-n}q^{-2ln}\frac{(q^{2l};q)_n}{(q;q)_n}{}_3\phi_2(q^{-n},-q^le^{\mathrm{i}\theta},q^le^{-\mathrm{i}\theta};q^{2l},0;q,q){}_3\phi_2(q^{-n},-q^le^{\mathrm{i}\theta'},q^le^{-\mathrm{i}\theta'};q^{2l},0;q,q),$$

with $x=b\sin\theta$ and $p=b\sin\theta'$. Taking into account formula (8.15) in Ref. 17 and repeating the reasoning of Sec. VIII, one obtains that

$$F(x,p)=\frac{(\mathrm{i}q^le^{-\mathrm{i}\theta},-\mathrm{i}q^le^{\mathrm{i}\theta},\mathrm{i},-\mathrm{i},-q^le^{-\mathrm{i}\theta'},q^le^{\mathrm{i}\theta'};q)_\infty}{(\mathrm{i}e^{\mathrm{i}(\theta-\theta')},-\mathrm{i}e^{\mathrm{i}(\theta+\theta')},\mathrm{i}e^{\mathrm{i}(\theta'-\theta)},-\mathrm{i}e^{-\mathrm{i}(\theta+\theta')},-\mathrm{i}q^{2l},q^{2l},-1;q)_\infty}$$
$$\times{}_4\phi_3\left(\begin{matrix}\mathrm{i},-\mathrm{i},-q^le^{\mathrm{i}\theta'},q^le^{-\mathrm{i}\theta'}\\ \mathrm{i}q^le^{-\mathrm{i}\theta},-\mathrm{i}q^le^{\mathrm{i}\theta},-q\end{matrix}\middle|q,q\right).\tag{34}$$

Thus, *an analogue of the Fourier transform* $\mathcal{F}:f(p)\to\widetilde{f}(x)$ *for our oscillator is given by the formula*

$$\mathcal{F}f(p)=\widetilde{f}(x)=\int_{-b}^{b}f(p)F(x,p)\widetilde{w}(p)\mathrm{d}p,$$

where the kernel $F(x,p)$ *is defined by formula* (34). The integral transform $\mathcal{F}$ is linear and isometric, that is, it preserves the scalar product. Therefore, the inverse transform $\mathcal{F}^{-1}$ is given by

$$\mathcal{F}^{-1}\widetilde{f}(x)=f(p)=\int_{-b}^{b}\widetilde{f}(x)\overline{F(x,p)}\widetilde{w}(x)\mathrm{d}x,\tag{35}$$

where $\overline{F(x,p)}$ means the complex conjugate of $F(x,p)$. Obviously, the Plancherel formula

$$\int_{-b}^{b}|f(p)|^2|\widetilde{w}(p)\mathrm{d}p=\int_{-b}^{b}|\widetilde{f}(x)|^2\widetilde{w}(x)\mathrm{d}x$$

holds.

X. A LIMIT TO THE MACFARLANE–BIEDENHARN *q*-OSCILLATOR

We have constructed an infinite number of models of quantum oscillator, characterized by the number l. The corresponding models will be denoted by osc_l. We prove in the following that

$$\lim_{l\to\infty}\sqrt{2}(q^{-1/2}-q^{1/2})\mathrm{osc}_l=\mathrm{osc}_q,$$

where osc_q denotes the Macfarlane–Biedenharn q-oscillator. This formula means that

$$\lim_{l\to\infty}\sqrt{2}(q^{-1/2}-q^{1/2})Q_l=\mathcal{Q},\quad \lim_{l\to\infty}\sqrt{2}(q^{-1/2}-q^{1/2})P_l=\mathcal{P}, \tag{36}$$

where $Q\equiv Q_l$, $P\equiv P_l$ are the position and momentum operators for osc_l, and $\mathcal{Q}$, $\mathcal{P}$ are the position and momentum operators for osc_q. The validity of the relations (36) follows from the fact that in this limit the operators Q_l and P_l turn into

$$\mathcal{Q}\tilde{e}_n=\frac{1}{\sqrt{2}}\left[\left(\frac{1-q^{n+1}}{1-q}\right)^{1/2}e_{n+1}+\left(\frac{1-q^n}{1-q}\right)^{1/2}e_{n-1}\right],$$

$$\mathcal{P}\tilde{e}_n=\frac{\mathrm{i}}{\sqrt{2}}\left[\left(\frac{1-q^{n+1}}{1-q}\right)^{1/2}e_{n+1}-\left(\frac{1-q^n}{1-q}\right)^{1/2}e_{n-1}\right].$$

Considering that

$$\mathcal{Q}=\frac{1}{\sqrt{2}}(a^+ + a),\quad \mathcal{P}=\frac{\mathrm{i}}{\sqrt{2}}(a^+ - a),$$

one readily derives that

$$a^+e_n=\left(\frac{1-q^{n+1}}{1-q}\right)^{1/2}e_{n+1},\quad ae_n=\left(\frac{1-q^n}{1-q}\right)^{1/2}e_{n-1}.$$

These operators together with the operator q^N, given as $q^Ne_n=q^ne_n$, satisfy the relations

$$aa^+-qa^+a=1,\quad q^Na^+=qa^+q^N,\quad q^Na=q^{-1}aq^N,$$

that is, they generate the q-oscillator algebra of Macfarlane–Biedenharn.

XI. THE CASE $q=1$: DESCRIPTION OF THE MODELS

The models, which correspond to the case $q=1$, can be considered either by setting $q=1$ into the previous results or by repeating the foregoing reasoning, based now on the Lie algebra su(1,1) instead of the quantum algebra $su_q(1,1)$. The latter case is simpler and we prefer to adopt it.

The Lie algebra su(1,1) has the generators I_0,I_1,I_2, which satisfy the commutation relations

$$[I_0,I_1]=\mathrm{i}I_2,\quad [I_1,I_2]=-\mathrm{i}I_0,\quad [I_2,I_0]=\mathrm{i}I_1.$$

The generators $I_\pm$ and I_0 are also used, where $I_\pm=I_1\pm\mathrm{i}I_2$; they obey the commutation relations $[I_0,I_\pm]=\pm I_\pm$ and $[I_-,I_+]=2I_0$.

For constructing the su(1,1)-models of the quantum oscillator the positive discrete series of irreducible representations of su(1,1) are employed. They are given by a positive number l and are denoted by R_l. The representation R_l acts on the Hilbert space $\tilde{\mathcal{H}}_1$ of functions in the variable y, such that the monomials

$$\tilde{e}_n^l(y)=\tilde{a}_n^l y^n,\quad \tilde{a}_n^l=\left(\frac{\Gamma(2l+n)}{n!}\right)^{1/2},\quad n=0,1,2,3,\ldots, \tag{37}$$

are orthonormal, that is, $\langle\tilde{e}_m^l,\tilde{e}_n^l\rangle=\delta_{mn}$ (see Ref. 18, Chap. 7). An explicit realization of the generators I_i, $i=0,1,2$, in the representation R_l is given in terms of the first-order differential operators as

$$I_0=y\frac{\mathrm{d}}{\mathrm{d}y}+l,\quad I_1=\frac{1}{2}(1+y^2)\frac{\mathrm{d}}{\mathrm{d}y}+ly,\quad I_2=\frac{\mathrm{i}}{2}(1-y^2)\frac{\mathrm{d}}{\mathrm{d}y}-\mathrm{i}ly.$$

Acting by these operators upon the basis elements $\tilde{e}_n^l\equiv\tilde{e}_n^l(y)$, $n=0,1,2\ldots$, one readily verifies that

$$I_0\tilde{e}_n^l = (l+n)\tilde{e}_n^l, \quad I_+\tilde{e}_n^l = \sqrt{(2l+n)(n+1)}\tilde{e}_{n+1}^l, \quad I_-\tilde{e}_n^l = \sqrt{(2l+n-1)n}\tilde{e}_{n-1}^l.$$

If one defines the Hamiltonian H and position and momentum operators Q and P as

$$H = I_0 - l + 1/2, \quad Q = I_2, \quad P = I_1,$$

then Q, P, and H obey the commutation relations

$$[H,Q] = -\mathrm{i}P, \quad [H,P] = \mathrm{i}Q, \quad [Q,P] = \mathrm{i}(H + l - 1/2). \tag{38}$$

These operators satisfy the postulates 1–3 of Sec. I. The time evolution of this system is the harmonic motion with

$$e^{\mathrm{i}\tau H}\begin{pmatrix} Q \\ P \end{pmatrix} e^{-\mathrm{i}\tau H} = \begin{pmatrix} Q(\tau) \\ P(\tau) \end{pmatrix} = \begin{pmatrix} \cos\tau & \sin\tau \\ -\sin\tau & \cos\tau \end{pmatrix}\begin{pmatrix} Q \\ P \end{pmatrix}.$$

This is a group U(1) of inner automorphisms of the Lie algebra su(1,1) and of rotations of the phase-space surface. Explicit form of the time evolution in the coordinate space will be given in the following.

The basis $\tilde{e}_n^l$, $n=0,1,2,\ldots$, in the Hilbert space $\tilde{\mathcal{H}}_l$ consists of eigenfunctions of the Hamiltonian H:

$$H\tilde{e}_n^l = (n + 1/2)\tilde{e}_n^l, \quad n = 0,1,2, \ldots,$$

that is, the spectrum of H coincides with the spectrum of the Hamiltonian for the standard harmonic oscillator in quantum mechanics.

Let us show that in the limit as $l \to \infty$ the oscillators (38) reduce to the standard linear harmonic oscillator in quantum mechanics. We denote the model (38), which corresponds to l, by osc_l. Then we state that

$$\lim_{l\to\infty} (2l)^{-1/2}\mathrm{osc}_l = \mathrm{osc},$$

where osc denotes the standard quantum harmonic oscillator, that is,

$$\lim_{l\to\infty} (2l)^{-1/2}Q_l = \mathsf{Q}, \quad \lim_{l\to\infty} (2l)^{-1/2}P_l = \mathsf{P},$$

$Q \equiv Q_l$ and $P \equiv P_l$ are the position and momentum operators for osc_l, whereas Q, P are the position and momentum operators for osc. The validity of these limit relations follows from the fact that the relations (38) in this limit turn into

$$[H,\mathsf{Q}] = -\mathrm{i}\mathsf{P}, \quad [H,\mathsf{P}] = \mathrm{i}\mathsf{Q}, \quad [\mathsf{Q}, \quad \mathsf{P}] = \mathrm{i}.$$

These are the standard formulas for $\mathsf{Q} = (1/\sqrt{2})(a^+ + a)$ and $\mathsf{P} = (\mathrm{i}/\sqrt{2})(a^+ - a)$. Thus, *the oscillators* (38) *can be considered as deformations of the standard quantum harmonic oscillator*. Contrary to the q-oscillators of Macfarlane and Biedenharn, for these deformations the relations (1) remain valid.

XII. COORDINATE AND MOMENTUM SPACES FOR $q=1$

Using the explicit differential form of the operators $P=I_1$, one finds that *the eigenfunctions of the momentum operators P are of the form*

$$\psi_p(y) = (1 + \mathrm{i}y)^{-l-\mathrm{i}p}(1 - \mathrm{i}y)^{-l+\mathrm{i}p}. \tag{39}$$

Expanding the expressions $(1+\mathrm{i}y)^{-l-\mathrm{i}p}$ and $(1-\mathrm{i}y)^{-l+\mathrm{i}p}$ into power series in y and multiplying then these two series, one can obtain an expansion for the eigenfunctions $\psi_p(y)$ in terms of the basis functions $\tilde{e}_n^l(y)$ of the Hilbert space $\tilde{\mathcal{H}}_l$,

$$\psi_p(y)=\sum_{n=0}^{\infty}\left(\frac{n!}{\Gamma(2l+n)}\right)^{1/2}P_n^{(l)}(p;\pi/2)\tilde{e}_n^l(y)=\sum_{n=0}^{\infty}P_n^{(l)}(p;\pi/2)y^n \tag{40}$$

with the coefficients $P_n^{(l)}(p,\pi/2)$, which are the Meixner–Pollaczek polynomials

$$P_n^{(\lambda)}(z;\varphi)=\frac{(2\lambda)_n}{n!}e^{in\varphi}{}_2F_1(-n,\lambda+iz;2\lambda;1-e^{-2i\varphi})$$

(see Ref. 13, formula (1.7.3)) with $\varphi=\pi/2$ and $\lambda=l$.

To find the spectrum of the momentum operator P, we recall that the Meixner–Pollaczek polynomials $P_n^{(l)}(p;\pi/2)$ are orthogonal and this orthogonality relation is of the form

$$\frac{1}{2\pi}\int_{-\infty}^{\infty}|\Gamma(l+ip)|^2P_m^{(l)}(p;\pi/2)P_n^{(l)}(p;\pi/2)dp=\frac{\Gamma(n+2l)}{2^{2l}n!}\delta_{mn}$$

(see formula (1.7.2) in Ref. 13). Repeating the same reasoning as in Sec. IV, one concludes that the spectrum of P coincides with the whole real line:

$$\text{Spec } P=\mathbb{R}.$$

The spectrum is continuous and simple. The continuity of the spectrum means that the eigenfunctions $\psi_p(y)$ are not elements of the Hilbert space $\mathcal{H}_l$. They form a continuous basis in $\mathcal{H}_l$ (similar to the basis $\{e^{ipx}\}$ in the Hilbert space $L^2(\mathbb{R})$).

Eigenfunctions of P are determined up to constants. One may normalize the eigenfunctions $\psi_p(y)$ with the aid of the orthogonality relation for Meixner–Pollaczek polynomials. Since these polynomials correspond to determinate moment problem, the set $P_n^{(l)}(p,\pi/2)$, $n=0,1,2,\ldots$, is complete in the Hilbert space $L^2(\mathbb{R},\mu(p))$ with respect to the orthogonality measure $\mu(p):=|\Gamma(l+ip)|^2$ for these polynomials. This means that

$$\sum_{n=0}^{\infty}\frac{2^{2l}n!}{2\pi\Gamma(n+2l)}|\Gamma(l+ip)|^2P_n^{(l)}(p,\pi/2)P_n^{(l)}(p',\pi/2)=\delta(p-p').$$

Then, by (40),

$$\langle\psi_p(y),\psi_{p'}(y)\rangle=\sum_{n=0}^{\infty}\frac{n!}{\Gamma(2l+n)}P_n^{(l)}(p,\pi/2)P_n^{(l)}(p',\pi/2)=\frac{2\pi\delta(p-p')}{2^{2l}|\Gamma(l+ip)|^2}.$$

Therefore, the normalized functions are

$$\tilde{\psi}_p(y)=(2\pi)^{-1/2}2^l|\Gamma(l+ip)|\psi_p(y),\quad p\in\mathbb{R},$$

that is, $\langle\tilde{\psi}_p(y),\tilde{\psi}_{p'}(y)\rangle=\delta(p-p')$.

Similarly, *the eigenfunctions of the position operator Q are of the form*

$$\phi_x(y)=(1+y)^{-l-ix}(1-y)^{-l+ix}. \tag{41}$$

We have

$$\phi_x(y)=\sum_{n=0}^{\infty}i^{-n}\left(\frac{n!}{\Gamma(2l+n)}\right)^{1/2}P_n^{(l)}(x;\pi/2)\tilde{e}_n^l(y)=\sum_{n=0}^{\infty}i^{-n}P_n^{(l)}(x;\pi/2)y^n. \tag{42}$$

Consequently, the normalized functions are

$$\tilde{\phi}_x(y) = \frac{2^l|\Gamma(l+\mathrm{i}x)|}{\sqrt{2\pi}}\phi_x(y),$$

that is, they satisfy the normalization condition $\langle\tilde{\phi}_x(y), \tilde{\phi}_{x'}(y)\rangle_{\mathcal{H}_l} = \delta(x-x')$.

The spectrum of the position operator coincides with the whole real line:

$$\mathrm{Spec}\ Q = \mathbf{R}.$$

This spectrum is simple.

Let us consider now the coordinate realization of the oscillator. Let $L^2(\mathbb{R};\mu(x))$ be the space of square-integrable functions $f(x)$ (where x is the coordinate of the oscillator and $\mu(x) := |\Gamma(l+\mathrm{i}x)|^2$) with the scalar product

$$\langle f(x), g(x)\rangle = \frac{2^{2l}}{2\pi}\int_{-\infty}^{\infty} f(x)\overline{g(x)}|\Gamma(l+\mathrm{i}x)|^2\mathrm{d}x.$$

From the orthogonality relation for the Meixner–Pollaczek polynomials it follows that the polynomials

$$\tilde{h}_n(x) = \mathrm{i}^{-n}\left(\frac{n!}{\Gamma(2l+n)}\right)^{1/2} P_n^{(l)}(x;\pi/2),$$

which are coefficients in the expansion (42) with respect to $\tilde{e}_n^l$, constitute an orthonormal basis in $L^2(\mathbb{R};\mu(x))$.

The next step is to construct a one-to-one linear isometry Ω from the Hilbert space $\mathcal{H}_l$ onto the Hilbert space $L^2(\mathbb{R};\mu(x))$ given by the formula

$$\Omega{:}\mathcal{H}_l \ni g(y) \to f(x) = \langle g(y), \phi_x(y)\rangle_{\mathcal{H}_l} \in L^2(\mathbb{R};\mu(x)),$$

where $\phi_x(y)$ are the eigenfunctions (42) of Q. Then

$$\mathcal{H}_l \ni \tilde{e}_n^l(y) \to \langle\tilde{e}_n^l(y), \phi_x(y)\rangle_{\mathcal{H}_l} = \tilde{h}_n(x),$$

that is, Ω maps the orthonormal basis $\{\tilde{e}_n^l(y)\}$ in $\mathcal{H}_l$ onto the orthonormal basis $\{\tilde{h}_n(x)\}$ in $L^2(\mathbb{R};\mu(x))$.

The operator Q acts on $L^2(\mathbb{R};\mu(x))$ as the multiplication operator,

$$Qf(x) = xf(x).$$

Indeed, if $\Omega g(y) = f(x) = \langle g(y), \phi_x(y)\rangle_{\mathcal{H}_l}$, then one has

$$Qg(y) \to Qf(x) = \langle Qg(y), \phi_x(y)\rangle_{\mathcal{H}_l} = \langle g(y), Q\phi_x(y)\rangle_{\mathcal{H}_l} = \langle g(y), x\phi_x(y)\rangle_{\mathcal{H}_l} = xf(x).$$

Clearly, $H\tilde{h}_n(x) = (n+1/2)\tilde{h}_n(x)$.

We note that in Ref. 19 it was shown that one can construct a relativistic model of the linear harmonic oscillator in the configuration x-representation, which is governed by a difference Hamiltonian with the square-integrable eigenfunctions of the form

$$\psi_n(x) := \frac{\mathrm{i}^n 2^l}{\sqrt{2\pi}}[l(l-1)]^{-\mathrm{i}x/2}\tilde{h}_n(x)\Gamma(l+\mathrm{i}x).$$

Let $\tilde{L}^2(\mathbb{R};\mu(p))$ be the Hilbert space of square-integrable functions $f(p)$ (where p is the momentum of the oscillator) with respect to the scalar product

$$\langle f(p), g(p)\rangle = \frac{2^{2l}}{2\pi}\int_{-\infty}^{\infty} f(p)\overline{g(p)}|\Gamma(l+\mathrm{i}p)|^2\mathrm{d}p.$$

The polynomials

$$h_n(x) = \left(\frac{n!}{\Gamma(2l+n)}\right)^{1/2} P_n^{(l)}(x;\pi/2),$$

which are coefficients of $\tilde{e}_n^l$ in expansion (40), constitute an orthonormal basis in $\tilde{L}^2(\mathbb{R};\mu(x))$.

One can construct a one-to-one isometry $\tilde{\Omega}$ from the Hilbert space $\mathcal{H}_l$ onto the Hilbert space $\tilde{L}^2(\mathbb{R};\mu(p))$, given by the formula

$$\tilde{\Omega}\colon \mathcal{H}_l \ni g(y) \to \tilde{f}(p) := \langle g(y), \psi_p(y)\rangle_{\mathcal{H}_l} \in \tilde{L}^2(\mathbb{R};\mu(p)),$$

where $\psi_p(y)$ are the eigenfunctions of the momentum operator P. Then

$$\mathcal{H}_l \ni \tilde{e}_n^l(y) \to \langle \tilde{e}_n^l(y), \psi_p(y)\rangle_{\mathcal{H}_l} = h_n(p),$$

that is, $\tilde{\Omega}$ maps the orthonormal basis $\{\tilde{e}_n^l(y)\}$ in $\mathcal{H}_l$ onto the orthonormal basis $\{h_n(p)\}$ in $\tilde{L}^2(\mathbb{R};\mu(p))$.

The operator P acts on $\tilde{L}^2(\mathbb{R};\mu(p))$ as the multiplication operator, $Pf(p)=pf(p)$.

It is noteworthy that in the limit as the representation label l tends to infinity, one returns to the standard linear harmonic oscillator wave functions on account of the limit relation

$$\lim_{l\to\infty} l^{-n/2} P_n^{(l)}(\sqrt{l}x;\pi/2) = \frac{H_n(x)}{n!}$$

between the Meixner–Pollaczek and Hermite polynomials (see Ref. 13, formula (2.7.2)).

XIII. THE EVOLUTION OPERATOR FOR THE CASE $q=1$

We wish to find how the evolution operator $\exp(\mathrm{i}\tau H)$ acts on the coordinate space, that is, on the Hilbert space $L^2(\mathbb{R};\mu(x))$. If the isometry Ω maps a function $g(y)\in\mathcal{H}_l$ to a function $f(x)\in L^2(\mathbb{R};\mu(x))$, then to the function $\exp(\mathrm{i}\tau H)g(y)\in\mathcal{H}_l$ there corresponds the function

$$\begin{aligned}
\exp(\mathrm{i}\tau H)f(x) &= \langle \exp(\mathrm{i}\tau H)g(y), \phi_x(y)\rangle_{\mathcal{H}_l} = \langle g(y), \exp(-\mathrm{i}\tau H)\phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \sum_{n=0}^{\infty} \langle g(y), \tilde{e}_n^l\rangle_{\mathcal{H}_l}\langle \tilde{e}_n^l, \exp(-\mathrm{i}\tau H)\phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \sum_{n=0}^{\infty} \langle g(y), \tilde{e}_n^l\rangle_{\mathcal{H}_l}\langle \exp(\mathrm{i}\tau H)\tilde{e}_n^l, \phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \sum_{n=0}^{\infty} \int_{-\infty}^{\infty} \langle g(y), \tilde{\phi}_{x'}(y)\rangle_{\mathcal{H}_l}\langle \tilde{\phi}_{x'}(y), \tilde{e}_n^l\rangle_{\mathcal{H}_l}\mathrm{d}x' \exp(\mathrm{i}\tau(n+1/2))\langle \tilde{e}_n^l, \phi_x(y)\rangle_{\mathcal{H}_l} \\
&= \frac{2^{2l}}{2\pi}\int_{-\infty}^{\infty} f(x')K^{\tau}(x,x')|\Gamma(l+ix')|^2\mathrm{d}x',
\end{aligned}$$

where the kernel $K^{\tau}(x,x')$ is defined as

$$K^{\tau}(x,x') = \sum_{n=0}^{\infty} \langle \phi_{x'}(y), \tilde{e}_n^l \rangle_{\mathcal{H}_l} \langle \tilde{e}_n^l, \phi_x(y) \rangle_{\mathcal{H}_l} \exp(\mathrm{i}\tau(n+1/2)).$$

Taking into account the explicit expression for $\langle \tilde{e}_n^l, \phi_x(y) \rangle_{\mathcal{H}_l}$, one finds that

$$K^{\tau}(x,x') = \sum_{n=0}^{\infty} \exp(\mathrm{i}\tau(n+1/2)) \tilde{h}_n(x) \overline{\tilde{h}_n(x')}$$

$$= \frac{e^{\mathrm{i}\pi/2}}{\Gamma(2l)} \sum_{n=0}^{\infty} e^{\mathrm{i}n\tau} \frac{(2l)_n}{n!} {}_2F_1(-n, l+\mathrm{i}x; 2l; 2)\, {}_2F_1(-n, l-\mathrm{i}x'; 2l; 2),$$

upon taking into account the fact that $\tilde{h}_n(x) = (1/\Gamma(2l))\sqrt{\Gamma(2l+n)/n!}\, {}_2F_1(-n, l+\mathrm{i}x; 2l; 2)$. Due to formula (12) from Sec. 2.5.2 in Ref. 20, one finally concludes that

$$K^{\tau}(x,x') = \frac{e^{\mathrm{i}\pi/2}}{\Gamma(2l)} (1+e^{\mathrm{i}\tau})^{-2l} \left[\frac{1-e^{\mathrm{i}\tau}}{1+e^{\mathrm{i}\tau}} \right]^{\mathrm{i}(x+x')} {}_2F_1\left(l+\mathrm{i}x, l-\mathrm{i}x'; 2l; \frac{1}{\cos^2 \pi/2} \right). \tag{43}$$

Thus, *the evolution operator* $\exp(\mathrm{i}\tau H)$ *acts by the formula*

$$\exp(\mathrm{i}\tau H) f(x) = \frac{2^{2l}}{2\pi} \int_{-\infty}^{\infty} K^{\tau}(x,x') f(x') |\Gamma(l+ix')|^2 \mathrm{d}x',$$

where the kernel $K^{\tau}(x,x')$ *is given by* (43).

XIV. AN ANALOGUE OF THE FOURIER TRANSFORM AT $q=1$

Let us briefly discuss here an analogue of the Fourier integral transform for our oscillators. If $g(y)$ is a function on the Hilbert space $\mathcal{H}_l$ from Sec. XI, then

$$\Omega: g(y) \to f(x) \in L^2(\mathbb{R}, \mu(x)), \quad \tilde{\Omega}: g(y) \to \tilde{f}(p) \in \tilde{L}^2(\mathbb{R}, \mu(p)).$$

We have to find how the functions $f(x)$ and $\tilde{f}(p)$ are connected with each other. One has

$$\tilde{f}(p) = \langle g(y), \psi_p(y) \rangle_{\mathcal{H}_l} = \int_{-\infty}^{\infty} \langle g(y), \tilde{\phi}_x(y) \rangle_{\mathcal{H}_l} \langle \tilde{\phi}_x(y), \psi_p(y) \rangle_{\mathcal{H}_l} \mathrm{d}x$$

$$= \frac{2^{2l}}{2\pi} \int_{-\infty}^{\infty} |\Gamma(l+\mathrm{i}x)|^2 f(x) \langle \phi_x(y), \psi_p(y) \rangle_{\mathcal{H}_l} \mathrm{d}x$$

$$= \frac{2^{2l}}{2\pi} \int_{-\infty}^{\infty} f(x) K(x,p) |\Gamma(l+\mathrm{i}x)|^2 \mathrm{d}x,$$

where the kernel $K(x,p)$ is given by

$$K(x,p) = \langle \phi_x(y), \psi_p(y) \rangle_{\mathcal{H}_l} = \sum_{n=0}^{\infty} \frac{\mathrm{i}^{-n} n!}{\Gamma(2l+n)} P_n^{(l)}(x, \pi/2) \overline{P_n^{(l)}(p, \pi/2)}$$

$$= \frac{1}{\Gamma(2l)} \sum_{n=0}^{\infty} i^{-n} \frac{(2l)_n}{n!} {}_2F_1(-n, l+\mathrm{i}x; 2l; 2)\, {}_2F_1(-n, l-\mathrm{i}p; 2l; 2).$$

Taking into account formula (12) of Sec. 2.5.2 in Ref. 20, one finally obtains that

$$K(x,p) = \frac{1}{\Gamma(2l)(1-\mathrm{i})^{2l}} \left[\frac{1+\mathrm{i}}{1-\mathrm{i}} \right]^{\mathrm{i}(x+p)} {}_2F_1(l+\mathrm{i}x, l-\mathrm{i}p; 2l; 2). \tag{44}$$

Thus, *an analogue* $\mathsf{F}: f(x) \to \tilde{f}(p)$ *of the Fourier transform for our oscillator is given by the formula*

$$\mathsf{F}f(x) = \tilde{f}(p) = \frac{2^{2l}}{2\pi} \int_{-\infty}^{\infty} f(x) K(x,p) |\Gamma(l + \mathrm{i}x)|^2 \mathrm{d}x,$$

where the kernel $K(x,p)$ *is defined by formula* (44). The integral transform F is linear and isometric, that is, it preserves the scalar product. Therefore, the inverse transform F^{-1} is given by

$$\mathsf{F}^{-1}\tilde{f}(p) = f(x) = \frac{2^{2l}}{2\pi} \int_{-\infty}^{\infty} \tilde{f}(p) \overline{K(x,p)} |\Gamma(l + \mathrm{i}p)|^2 \mathrm{d}p,$$

where $\overline{K(x,p)}$ means the complex conjugate of $K(x,p)$. The Plancherel formula

$$\int_{-\infty}^{\infty} |f(x)|^2 |\Gamma(l + \mathrm{i}x)|^2 \mathrm{d}x = \int_{-\infty}^{\infty} |\tilde{f}(p)|^2 |\Gamma(l + \mathrm{i}p)|^2 \mathrm{d}p$$

holds.

(Received 24 May 2006; accepted 19 July 2006; published online 18 September 2006)

In the first part of this paper we consider the transformation of the cubic identities for general Korteweg–de Vries (KdV) tau functions from [Mishev, J. Math. Phys. **40**, 2419–2428 (1999)] to the specific identities for trigonometric KdV tau functions. Afterwards, we consider the Fay identity as a functional equation and provide a wide set of solutions of this equation. The main result of this paper is Theorem 3.4, where we generalize the identities from Mishev. An open problem is the transformation of the cubic identities from Mishev to the specific identities for elliptic KdV tau functions. © *2006 American Institute of Physics.*

I. INTRODUCTION

We consider the relation (functional Fay identity)

$$f(z_0-z_1)f(z_2-z_3)g(t+[z_0]+[z_1])g(t+[z_2]+[z_3])+f(z_0-z_2)f(z_3-z_1)g(t+[z_0]+[z_2])g(t+[z_3]+[z_1])+f(z_0-z_3)f(z_1-z_2)g(t+[z_0]+[z_3])g(t+[z_1]+[z_2])=0$$

as an equation for the functions $f(z)$ and $g(t)$, $t\equiv(t_1,t_2,t_3,\ldots)\in\mathbb{C}^\infty$, $z\in\mathbb{C}$. We know that $f(z)=z$ and $g(t)=\tau(t)$ (KP tau function) are solutions of this equation (i.e., we have the Fay identity for Kadomtzev–Petviashvili (KP) tau functions.) Studying the relation as a functional equation will give us unification of the results from Ref. 3.

In our previous publication (Ref. 3) we have obtained some cubic (and more generally (2^n-1) – order, $n=2,3,\ldots$) identities, specific for Korteweg–de Vries (KdV) tau functions only. These tau functions are related to the KdV hierarchy of completely integrable equations; the first of them is the famous KdV equation $u_t=6uu_x-u_{xxx}$, $u=u(x,t)$. The KdV tau functions satisfy the conditions $\partial_{t_{2n}}\tau(t)=0$, $n=1,2,\ldots$, and these conditions are equivalent to $\tau(t-[z])=\tau(t+[-z])$ (for the notations see Sec. I).

It is well known that examples of KdV tau functions are some polynomials, and some modifications of trigonometric and hyperelliptic theta functions. In Ref. 3 it was pointed out that we cannot easily translate the Fay identity for KdV tau functions to the trigonometric and hyperelliptic cases. The problem in the hyperelliptic case is that in the original Fay identity for theta functions[2] the prime form is used (e.g., in the $g=1$ case $\theta_{11}(z_0-z_1)\theta_{11}'^{-1}(0)$) instead of the difference (z_0-z_1). Shiota showed that after suitable change of the variables it is possible to obtain the trigonometric form of the Fay identity starting from the Fay identity for KdV tau functions.[7]

In Sec. II we give some preliminary results and the transition from the cubic identity for KdV tau functions to its trigonometric form. In Sec. III we introduce the functional Fay identity and prove the main result in this article—Theorem 3.4. In Sec. IV we relate the functional Fay identity to the Fay identity for tau functions.

II. PRELIMINARY RESULTS

Let $\tau(t)$, $t \equiv (t_1, t_2, t_3, \ldots) \in \mathbb{C}^\infty$, $t_1 \equiv x$ is an arbitrary tau function, related to the KP hierarchy.[1] Let us denote ($z \in \mathbb{C}$):

$$[z] := (z, z^2/2, z^3/3, \ldots) \in \mathbb{C}^\infty,$$

$$\tau(t + [z]) := \tau(t_1 + z, t_2 + z^2/2, t_3 + z^3/3, \ldots).$$

The following identity ($z_0, z_1, z_2, z_3 \in \mathbb{C}$):

$$\begin{aligned}(z_0 - z_1)(z_2 - z_3)\tau(t + [z_0] + [z_1])\tau(t + [z_2] + [z_3]) + (z_0 - z_2)(z_3 - z_1)\tau(t + [z_0] + [z_2]) \\ \times \tau(t + [z_3] + [z_1]) + (z_0 - z_3)(z_1 - z_2)\tau(t + [z_0] + [z_3])\tau(t + [z_1] + [z_2]) = 0\end{aligned} \tag{2.1}$$

is called Fay identity[6] for the KP tau function $\tau(t)$. It was first obtained[2] for theta functions related to Jacobians. In genus $g = 1$ case its form is

$$\begin{aligned}\theta_{11}(z_0 - z_1)\theta_{11}(z_2 - z_3)\theta_{11}(x + z_0 + z_1)\theta_{11}(x + z_2 + z_3) + \theta_{11}(z_0 - z_2)\theta_{11}(z_3 - z_1)\theta_{11}(x + z_0 + z_2) \\ \times \theta_{11}(x + z_3 + z_1) + \theta_{11}(z_0 - z_3)\theta_{11}(z_1 - z_2)\theta_{11}(x + z_0 + z_3)\theta_{11}(x + z_1 + z_2) = 0\end{aligned} \tag{2.2}$$

(we use the notations for thetas from Ref. 4). It was used[4] in geometric treatment of soliton equations. Later it was generalized for tau functions.[6]

Let $\tau(t)$ be a KdV tau function, i.e., $\tau(t - [z]) = \tau(t + [-z])$. In Ref. 3 the following cubic identity was obtained:

$$\begin{aligned}(z_2 - z_1)[\tau(t + [z_1] + [z_2])\tau(t - [z_1])\tau(t - [z_2]) - \tau(t - [z_1] - [z_2])\tau(t + [z_1])\tau(t + [z_2])] \\ = (z_2 + z_1)[\tau(t + [z_1] - [z_2])\tau(t - [z_1])\tau(t + [z_2]) - \tau(t - [z_1] + [z_2])\tau(t + [z_1])\tau(t - [z_2])]\end{aligned} \tag{2.3}$$

and its trigonometric and elliptic versions were considered:

$$\begin{aligned}\sin(z_2 - z_1)[\sin(x + z_1 + z_2)\sin(x - z_1)\sin(x - z_2) - \sin(x - z_1 - z_2)\sin(x + z_1)\sin(x + z_2)] \\ = \sin(z_1 + z_2)[\sin(x + z_1 - z_2)\sin(x - z_1)\sin(x + z_2) - \sin(x - z_1 + z_2)\sin(x + z_1)\sin(x - z_2)],\end{aligned} \tag{2.4}$$

$$\begin{aligned}\theta_{11}(z_2 - z_1)[\theta_{11}(x + z_1 + z_2)\theta_{11}(x - z_1)\theta_{11}(x - z_2) - \theta_{11}(x - z_1 - z_2)\theta_{11}(x + z_1)\theta_{11}(x + z_2)] \\ = \theta_{11}(z_1 + z_2)[\theta_{11}(x + z_1 - z_2)\theta_{11}(x - z_1)\theta_{11}(x + z_2) - \theta_{11}(x - z_1 + z_2)\theta_{11}(x + z_1)\theta_{11}(x - z_2)].\end{aligned} \tag{2.5}$$

In this section we will explain how starting from (2.3) we can obtain (2.4). The possibility for this is based on the correct choice of trigonometric KdV tau function.

Lemma 2.1: (T. Shiota) The function:

$$\tau(t) = \sin\left(\sum_{k=0}^{\infty} (-1)^k t_{2k+1}\right) \tag{2.6}$$

is a trigonometric KdV tau function. The Fay identity (2.1) *for it has the form:*

$$\begin{aligned}\sin(z_0 - z_1)\sin(z_2 - z_3)\sin(x + z_0 + z_1)\sin(x + z_2 + z_3) + \sin(z_0 - z_2)\sin(z_3 - z_1)\sin(x + z_0 + z_2) \\ \times \sin(x + z_3 + z_1) + \sin(z_0 - z_3)\sin(z_1 - z_2)\sin(x + z_0 + z_3)\sin(x + z_1 + z_2) = 0,\end{aligned} \tag{2.7}$$

where $x \equiv \Sigma_{k=0}^{\infty}(-1)^k t_{2k+1}$.

Proof: If we find a trigonometric Baker–Akhiezer function in the form: $w(t, z)$

$=\exp(\Sigma_{k=0}^{\infty} t_{2k+1} z^{2k+1})(z+c(t))$ with restriction $w(t,i)=w(t,-i)$, $i=\sqrt{-1}$, and compare the result with the well-known expression:

$$w(t,z)=\exp\left(\sum_{k=0}^{\infty} t_{2k+1} z^{2k+1}\right)\frac{\tau(t-[z^{-1}])}{\tau(t)}$$

we obtain (2.6).

For given shifts: $s_j, j=0,1,2,3$ let us introduce the new shifts: $z_j, j=0,1,2,3$ by the relations: $z_j=\tan(s_j)$. Then for the tau function (2.6) we have

$$\tau(t+[z_j])=\sin\left(\sum_{k=0}^{\infty}(-1)^k t_{2k+1}+\sum_{k=0}^{\infty}\frac{(-1)^k}{2k+1}z_j^{2k+1}\right)=\sin\left(\sum_{k=0}^{\infty}(-1)^k t_{2k+1}+s_j\right),$$

where we have used: $\Sigma_{k=0}^{\infty}[(-1)^k/2k+1]z_j^{2k+1}=\arctan(z_j)=s_j$. So, we have

$$\tau(t+[z_0]+[z_1])=\sin\left(\sum_{k=0}^{\infty}(-1)^k t_{2k+1}+s_0+s_1\right),\quad \text{etc.}$$

We have also

$$(z_0-z_1)=(\tan(s_0)-\tan(s_1))=\frac{\sin(s_0-s_1)}{\cos(s_0)\cos(s_1)},\quad \text{etc.}$$

So, from the Fay identity (2.1) we obtain the form (2.7) ($x\equiv\Sigma_{k=0}^{\infty}(-1)^k t_{2k+1}$) for the tau function given by (2.6). □

Theorem 2.2: *From the cubic identity for KdV tau functions* (2.3) *follows its trigonometric version* (2.4).

Proof: Let us substitute in the identity (2.1) the form (2.6) of trigonometric KdV tau function, with the new shifts: $z_j=\tan(s_j), j=0,1,2,3$. The same way as in the proof of Lemma 1.1 we obtain (2.4) (with $x\equiv\Sigma_{k=0}^{\infty}(-1)^k t_{2k+1}$). □

III. FUNCTIONAL FAY IDENTITY

Let us consider the Fay identity as our starting point. Let $f(z)$ and $g(t)$ be arbitrary functions (we use the notations from Sec. II: $t\equiv(t_1,t_2,t_3,\ldots)\in\mathbb{C}^{\infty}$, $z\in\mathbb{C}$).

Definition 3.1: The following relation we will call the *functional Fay identity*:

$$f(z_0-z_1)f(z_2-z_3)g(t+[z_0]+[z_1])g(t+[z_2]+[z_3])+f(z_0-z_2)f(z_3-z_1)g(t+[z_0]+[z_2])g(t+[z_3]+[z_1])+f(z_0-z_3)f(z_1-z_2)g(t+[z_0]+[z_3])g(t+[z_1]+[z_2])=0 \tag{3.1}$$

Lemma 3.2: Let functions $f(z)$ and $g(t)$ be once differentiable and $f(z)$ is odd. Let them satisfy the functional Fay identity. Then $f(z)$ and $g(t)$ satisfy the differential functional Fay identity:

$$W(g(t+[z_1]),g(t+[z_2]))=\left(\frac{f'(0)f(z_2-z_1)}{f(z_1)f(z_2)}\right)g(t)g(t+[z_1]+[z_2])+\left(\frac{f(z_1)f'(z_2)-f'(z_1)f(z_2)}{f(z_1)f(z_2)}\right)\times g(t+[z_1])g(t+[z_2]),$$

where the Wronskian is: $W(g_1(t),g_2(t)):=g_1(t)\partial_{t_1}g_2(t)-g_2(t)\partial_{t_1}g_1(t)$, and $'\equiv\partial_z$.

Proof: The proof is the same as for obtaining the differential Fay identity for KP taus, starting from the Fay identity for them:[1] differentiate (3.1) with respect to z_0, put $z_0=z_3=0$, and divide by $f(z_1)f(z_2)$. □

Shifting the argument t to $(t-[z_1]-[z_2])$ we could obtain an expression for the Wronskian: $W(g(t-[z_1]),g(t-[z_2]))$. But, shifting t we cannot obtain an expression, e.g., for the Wronskian: $W(g(t+[z_1]),g(t-[z_2]))$. This is possible only if we pose an additional condition on $g(t)$, namely

that $g(t)$ is of *KdV type*, i.e.,

$$\partial_{t_{2n}} g(t) = 0, n = 1,2,\ldots, \quad \text{or equivalently} \quad g(t-[z]) = g(t+[-z]).$$

As a corollary of Lemma 3.2 we obtain:

Lemma 3.3: Let functions $f(z)$ and $g(t)$ satisfy the functional Fay identity (3.2), *as well as the following conditions:*

(i) *$f(z)$ and $g(t)$ are once differentiable;*
(ii) *$f(-z)=-f(z)$;*
(iii) *$g(t)$ is of KdV type.*

Then we have the following forms of the differential functional Fay identity:

$$W(g(t\pm[z_1]),g(t\pm[z_2])) = \left(\frac{f'(0)f(z_2-z_1)}{f(z_1)f(z_2)}\right) g(t)g(t\pm[z_1]\pm[z_2]) \pm \left(\frac{f(z_1)f'(z_2)-f'(z_1)f(z_2)}{f(z_1)f(z_2)}\right) \times g(t\pm[z_1])g(t\pm[z_2]),$$

$$W(g(t\pm[z_1]),g(t\mp[z_2])) = \pm\left(\frac{f'(0)f(z_1+z_2)}{f(z_1)f(z_2)}\right) g(t)g(t\pm[z_1]\mp[z_2]) \mp \left(\frac{f(z_1)f'(z_2)+f'(z_1)f(z_2)}{f(z_1)f(z_2)}\right) \times g(t\pm[z_1])g(t\mp[z_2]).$$

Now it is easy to obtain the analog of the cubic identity for KdV taus (2.3).

Theorem 3.4: *Let functions $f(z)$ and $g(t)$ satisfy the functional Fay identity and conditions* (*i*), (*ii*), (*iii*) *from Lemma* 3.3. *Then $f(z)$ and $g(t)$ satisfy the cubic functional identity*:

$$\begin{aligned} &f(z_2-z_1)[g(t+[z_1]+[z_2])g(t-[z_1])g(t-[z_2]) - g(t-[z_1]-[z_2])g(t+[z_1])g(t+[z_2])] \\ &\quad = f(z_2+z_1)[g(t+[z_1]-[z_2])g(t-[z_1])g(t+[z_2]) - g(t-[z_1]+[z_2])g(t+[z_1])g(t-[z_2])], \end{aligned} \tag{3.2}$$

as well as

$$\begin{aligned} &f'(0)[g(t+2[z])g^2(t-[z]) - g(t-2[z])g^2(t+[z])] \\ &\quad = f(2z)\sum_{k=0}^{\infty} z^{2k}[g(t-[z])W_{2k+1}(g(t),g(t+[z])) + g(t+[z])W_{2k+1}(g(t),g(t-[z]))], \end{aligned} \tag{3.3}$$

where $W_{2k+1}(f,g) := f(\partial_{t_{2k+1}}g) - (\partial_{t_{2k+1}}f)g, k=0,1,2,\ldots$.

Proof: The proof is the same as for obtaining the cubic identity for KdV tau functions:[3] we evaluate the Wronskian:

$$W(g(t+[z_1])g(t-[z_1]),g(t+[z_2])g(t-[z_2])),$$

using the results from Lemma 3.3 and the obvious identity for Wronskians:

$$W(f_1f_2,g_1g_2) = f_1g_1W(f_2,g_2) + f_2g_2W(f_1,g_1) = f_1g_2W(f_2,g_1) + f_2g_1W(f_1,g_2).$$

The identity (3.3) follows from (3.2) after letting $z_2 \to z_1$ (cf. Ref. 3). □

Corollary 3.5: If, the same way, we evaluate the Wronskian:

$$W\left(\prod_{k=1}^{2^n} g(t+[z_{2k-1}])g(t-[z_{2k-1}]), \prod_{k=1}^{2^n} g(t+[z_{2k}])g(t-[z_{2k}])\right)$$

we will obtain (2^n-1)*-order in g identity* (cf. Ref. 3).

Corollary 3.6: We know some solutions of the functional equation (3.1), *which satisfy the conditions from Lemma 3.3:*

(i) $f(z)=z$ *and* $g(t)=\tau(t)$, *where* $\tau(t)$ *is an arbitrary KdV tau function*;
(ii) $f(z)=\sin(z)$ *and* $g(t)=\sin(t_1)$, $t_1\equiv x$;
(iii) $f(z)=\theta_{11}(z)$ *and* $g(t)=\theta_{11}(t_1)$, $t_1\equiv x$.

They correspond, respectively, to the (known) identities (2.1), (2.7), and (2.2). *This way the relations* (2.3)–(2.5) *are particular cases of the cubic functional identity* (3.2).

In order to clarify the range of the cubic identity (3.2), it is necessary to solve the functional equation (3.1) in the class of functions f and g satisfying conditions (i), (ii), (iii) from Lemma 3.3. As a first step in this direction, let us find a class of solutions of Eq. (3.1), for which the differential functional Fay identity has the form of the differential Fay identity for KP taus. Let us pose an additional condition on the function $f(z)$:

Condition **F**: *For every* $z_1,z_2\in\mathbb{C}$, $f(z)$ *satisfies the relation*:

$$f(z_1+z_2)=f(z_1)f'(z_2)+f'(z_1)f(z_2). \tag{3.4}$$

Then, the differential functional Fay identity has the form:

$$W(g(t+[z_1]),g(t+[z_2]))=\frac{f(z_2-z_1)}{f(z_1)f(z_2)}[f'(0)g(t)g(t+[z_1]+[z_2])-g(t+[z_1])g(t+[z_2])]$$

(moreover, we will see that $f'(0)=1$).

First, let us show that condition **F** gives us a solution of (3.1).

Lemma 3.7: Let $f(z)$ *be a twice differentiable*, *odd function that satisfies the condition* **F**. *Then the functions* $f(z)$ *and* $g(t)=f(t_1)$ *satisfy the identity* (3.1).

Proof: From

$$f(z_1+z_2)=f(z_1)f'(z_2)+f'(z_1)f(z_2),$$

$$f(z_1-z_2)=f(z_1)f'(z_2)-f'(z_1)f(z_2)$$

it follows that for every z_0 we have

$$f'(z)=\frac{f(z+z_0)-f(z-z_0)}{2f(z_0)}.$$

Letting $z_0\to 0$ we obtain $f'(0)=1$. Moreover, expanding $f'(z_1+z_2)$ in two ways:

$$\frac{f((z_1+z_0)+z_2)-f((z_1-z_0)+z_2)}{2f(z_0)},$$

$$\frac{f((z_2+z_0)+z_1)-f((z_2-z_0)+z_1)}{2f(z_0)}$$

and letting $z_0\to 0$, we obtain: $f''(z_1)f(z_2)=f(z_1)f''(z_2)$, i.e., $f''(z_1)/f(z_1)=f''(z_2)/f(z_2)=c=\text{const}$. So, we have

$$f'(z_1+z_2)=f'(z_1)f'(z_2)+cf(z_1)f(z_2).$$

From here and from (3.4) it follows that

$$f(z_1+z_2+z_3)=f(z_1)f'(z_2)f'(z_3)+f'(z_1)f(z_2)f'(z_3)+f'(z_1)f'(z_2)f(z_3)+cf(z_1)f(z_2)f(z_3).$$

From here and from (3.4) it follows that the identity (3.1) for the functions $f(z)$ and $g(t)=f(t_1)$ is equivalent to a trivial identity, which can be checked directly. □

Now we can generalize the construction from Lemma 2.1 to all functions $f(z)$, which satisfy the condition **F**. We will explain such a change of variables that $f(z)$ will be replaced by z. Let us define the function $s=h(z)$ by its inverse function:

$$z = h^{-1}(s) := \frac{f(s)}{f'(s)}. \tag{3.5}$$

Then, as a corollary of (3.4) we have ($s_j := h(z_j)$, $j=1,2$):

$$(z_1 - z_2) = \frac{f(s_1 - s_2)}{f'(s_1)f'(s_2)}. \tag{3.6}$$

From (3.5) it follows that the function $h^{-1}(s)$ is odd, and so $h(z)$ is also odd function. Let us write its power series expansion: $h(z)=\Sigma_{k=0}^{\infty}[h^{(2k+1)}(0)/(2k+1)!]z^{2k+1}$, where $h^{(n)}$ is the nth derivative of h. Following the idea of the proof of Lemma 2.1, let us pose additional restriction on the function $g(t)$:

Condition **G***: Function* $g(t)$ *has the form*:

$$g(t) := f\left(\sum_{k=0}^{\infty} \frac{h^{(2k+1)}(0)}{(2k)!} t_{2k+1}\right), \tag{3.7}$$

where $h(z)$ *is given by* (3.5).

Then we have

$$g(t+[z]) = f\left(\sum_{k=0}^{\infty} \frac{h^{(2k+1)}(0)}{(2k)!}\left(t_{2k+1} + \frac{z^{2k+1}}{2k+1}\right)\right) = f\left(\sum_{k=0}^{\infty} \frac{h^{(2k+1)}(0)}{(2k)!} t_{2k+1} + \sum_{k=0}^{\infty} \frac{h^{(2k+1)}(0)}{(2k+1)!} z^{2k+1}\right)$$
$$= f\left(\sum_{k=0}^{\infty} \frac{h^{(2k+1)}(0)}{(2k)!} t_{2k+1} + h(z)\right). \tag{3.8}$$

In this way we are in a position to prove the following

Lemma 3.8: Let $f(z)$ *be an odd function and* $f(z)$, $g(t)$ *satisfy the conditions* **F** *and* **G**. *Than* $f(z)$ *and* $g(t)$ *satisfy the functional Fay identity* (3.1).

Proof: Let the shifts z_j, $j=0,1,2,3$ be given and let us define new shifts by: $s_j=h(z_j)$, $j=0,1,2,3$, where $h(z)$ is given by (3.5). Then from (3.8) and the condition **G** it follows that:

$$g(t+[z_0]+[z_1]) = f(x+s_0+s_1), \quad \text{etc.}$$

($x=\Sigma_{k=0}^{\infty}[h^{(2k+1)}(0)/(2k)!]t_{2k+1}$). From here and relation (3.6) it is clear that the statement of this Lemma follows from Lemma 3.7. □

This construction does not give us some new solutions of (3.1), because Eq. (3.4) and the condition that $f(z)$ is odd function are too strong restrictions.

Lemma 3.9: The odd solutions of Eq. (3.4) *are the functions*: $f(z)=z$, $\sin(z)$, $\sinh(z)$, *up to the obvious symmetry*: *if* $f(z)$ *is a solution of* (3.4), *than for every* $0 \neq a \in \mathbb{C}$ *the functions* $f_a(z) := (1/a)f(az)$ *are also solutions of* (3.4).

Proof: In the proof of Lemma 3.7 we came to the equality: $f''(z_1)/f(z_1)=f''(z_2)/f(z_2)=c=\text{const}$. It is equivalent to the differential equation: $f''=cf$. Now using the conditions that $f(z)$ is an odd function and $f'(0)=1$ we obtain the statement of this Lemma. □

Corollary 3.10: The functions: $f(z)=\sinh(z)$ *and* $g(t)=\sinh(t_1)$ *give a solution of Eq.* (3.1). *For them the cubic identity* (3.2) *is fulfilled.*

Remark 2.11: The condition **G** is too restrictive. If we take the solution $f(z)=z$ of (3.4), we know solutions of (3.1) for which the functions $g(t)$ do not satisfy the condition **G**. These are all KP tau functions.

Remark 3.12: The condition **F** is also too restrictive. The Fay identity (2.2) for the elliptic

theta function θ_{11} shows that $f(z)=\theta_{11}(z)$ is a possible choice for the function $f(z)$, but for it the condition **F** is not fulfilled.

IV. THE RANGE OF THE FUNCTIONAL FAY IDENTITY

Let us mention that from the result of Ref. 8 (Proposition B.3) follows that under some conditions on $f(z)$, for general functions $g(t)$ (i.e., non KdV type), the functional Fay identity (3.1) is equivalent to the Fay identity for KP tau functions. We have the following

Lemma 4.1: Let $f(z)$ be an odd function, for which: $f'(0)\neq 0$, and the following expansion holds: $\ln[f(z)/z]=\Sigma_{n=0}^{\infty}a_n z^n$. *Then for every KP tau function $\tau(t)$, there exists set of numbers b_{ij}, $i,j=1,2,\ldots$ (depending on $f(z)$), such that the pair:*

$$f(z),\quad g(t) := \tau(t)\exp\left[-\frac{1}{2}\sum_{i,j=1}^{\infty} b_{ij}t_i t_j\right]$$

is a solution of the functional Fay identity (3.1). *Every solution of* (3.1) (*with the posed restrictions on $f(z)$, and $g(t)$ - of general type*) *can be obtained this way.*

Proof: Let us take:

$$\ln\left[\frac{f(z_1-z_2)}{z_1-z_2}\right]=\sum_{n=0}^{\infty}a_n(z_1-z_2)^n=\sum_{i,j=0}^{\infty}c_{ij}z_1^i z_2^j,\quad \text{where } c_{ij}=c_{ji}.$$

But $\Sigma_{i=0}^{\infty}c_{i0}z_1^i=\ln[f(z1)/z_1]$ and $\Sigma_{i=0}^{\infty}c_{0j}z_2^j=\ln[f(z_2)/z_2]$. So, we can rewrite:

$$\ln\left[\frac{f(z_1-z_2)}{z_1-z_2}\right]=\ln\left[\frac{f(z_2)}{z_2}\right]+\ln\left[\frac{f(z_1)}{z_1}\right]+\sum_{i,j=1}^{\infty}c_{ij}z_1^i z_2^j=\ln\left[\frac{f(z_2)}{z_2}\right]+\ln\left[\frac{f(z_1)}{z_1}\right]$$
$$+\sum_{i,j=1}^{\infty}b_{ij}\frac{z_1^i}{i}\frac{z_2^j}{j},\quad \text{where } b_{ij}=b_{ji}.$$

We state that the numbers b_{ij}, $i,j=1,2,\ldots$ are suitable for our aim. We have:

$$g(t+[z_0]+[z_1])=\tau(t+[z_0]+[z_1])\exp\left[-\frac{1}{2}\sum_{i,j=1}^{\infty}b_{ij}\left(t_i+\frac{z_0^i}{i}+\frac{z_1^i}{i}\right)\left(t_j+\frac{z_0^j}{j}+\frac{z_1^j}{j}\right)\right]$$
$$=\tau(t+[z_0]+[z_1])\exp\left[-\frac{1}{2}\sum_{i,j=1}^{\infty}b_{ij}\left[t_i t_j+2t_i\left(\frac{z_0^j+z_1^j}{j}\right)+\left(\frac{z_0^{i+j}+z_1^{i+j}}{ij}\right)+2\left(\frac{z_0^i z_1^j}{ij}\right)\right]\right],$$

and from here:

$$g(t+[z_0]+[z_1])g(t+[z_2]+[z_3])=\tau(t+[z_0]+[z_1])\tau(t+[z_2]+[z_3])$$
$$\times\exp\left[-\sum_{i,j=1}^{\infty}b_{ij}\left(\frac{z_0^i z_1^j+z_2^i z_3^j}{ij}\right)\right]\psi(t,z_0,z_1,z_2,z_3),$$

where

$$\psi(t,z_0,z_1,z_2,z_3)=\exp\left[-\frac{1}{2}\sum_{i,j=1}^{\infty}b_{ij}\left[2t_i t_j+2t_i\left(\frac{z_0^j+z_1^j+z_2^j+z_3^j}{j}\right)+\left(\frac{z_0^{i+j}+z_1^{i+j}+z_2^{i+j}+z_3^{i+j}}{ij}\right)\right]\right].$$

But, we have also

$$f(z_0-z_1)f(z_2-z_3)=(z_0-z_1)(z_2-z_3)\exp\left[\sum_{i,j=1}^{\infty}b_{ij}\left(\frac{z_0^i z_1^j+z_2^i z_3^j}{ij}\right)\right]\frac{f(z_0)}{z_0}\frac{f(z_1)}{z_1}\frac{f(z_2)}{z_2}\frac{f(z_3)}{z_3}.$$

So, it is clear that we have

$$(z_0-z_1)(z_2-z_3)\tau(t+[z_0]+[z_1])\tau(t+[z_2]+[z_3])=f(z_0-z_1)f(z_2-z_3)g(t+[z_0]+[z_1])g(t+[z_2]+[z_3])\Psi(t,z_0,z_1,z_2,z_3),$$

and analogous expressions for the second and the third terms in (2.1), where $\Psi(t,z_0,z_1,z_2,z_3)$ is a common factor for the three expressions. So, if $\tau(t)$ is a KP tau function, then the Fay identity for $\tau(t)$ is fulfilled, and hence (3.1) is fulfilled. The statement, that all solutions of (3.1) (with the posed restrictions on $f(z)$ and $g(t)$ - of general type) can be obtained this way, follows from Ref. 8. □

Remark 4.2: The construction from Lemma 4.1 is not applicable to the functions $g(t)$ of KdV type, because in the expression $\exp\left[-1/2\Sigma_{i,j=1}^{\infty}b_{ij}t_it_j\right]$ there are even t-variables t_{2k}. As an example, for $f(z)=\sin(z)$ we have

$$\ln\left[\frac{\sin(z_1-z_2)}{z_1-z_2}\right]=-\frac{z_1^2}{6}-\frac{z_2^2}{6}+\frac{z_1z_2}{3}-\frac{z_1^4}{180}-\frac{z_2^4}{180}+\frac{z_1^3z_2}{45}+\frac{z_1z_2^3}{45}-\frac{z_1^2z_2^2}{30}+\cdots$$

and hence

$$\exp\left[-\frac{1}{2}\sum_{i,j=1}^{\infty}b_{ij}t_it_j\right]=\exp\left[-\frac{1}{6}t_1^2-\frac{1}{15}t_1t_3+\frac{1}{15}t_2^2+\cdots\right].$$

The critical observation here is that it is possible to overcome the dependence from even variables of the form: $e^{Q(t)}$, ($Q(t)$ - quadratic in t_n), by linear change of the variables t_n. This kind of dependence is irrelevant for us, because roughly speaking we have a lot of freedom with tau functions. As an example, it is well known that the KP theory is not sensitive to the following transformation of tau functions: $\tau(t)\to\tau(t)e^{\Sigma c_nt_n}$, where c_n are constants.

It is known that the expressions of the coefficients of the Lax operator $L(t)$ in terms of tau functions[1] are differential polynomials of $\partial_{t_it_j}^2\log\tau(t)$:[5]

$$L(t)=\partial_x+[\partial_{t_1t_1}^2\log\tau(t)]\partial_x^{-1}+\left[\tfrac{1}{2}(-\partial_{t_1t_1t_1}^3+\partial_{t_2t_1}^2)\log\tau(t)\right]\partial_x^{-2}+\left[\tfrac{1}{6}(\partial_{t_1t_1t_1t_1}^4-3\partial_{t_2t_1t_1}^3+2\partial_{t_3t_1}^2)\log\tau(t)-(\partial_{t_1t_1}^2\log\tau(t))^2\right]\partial_x^{-3}+\cdots.$$

But we have

$$\partial_{t_it_j}^2\log\left[\tau(t)\exp\left(-\frac{1}{2}\sum_{i,j=1}^{\infty}b_{ij}t_it_j\right)\right]=[\partial_{t_it_j}^2\log\tau(t)]-b_{ij},$$

so the effect of the multiplier $\exp\left(-1/2\Sigma_{i,j=1}^{\infty}b_{ij}t_it_j\right)$ is simply additional constants in the coefficients of L-operator, not some of t-variables which appear in exp(…).

Lemma 4.3: Let $\tau_0(t)$ be an arbitrary kdV tau function. Let for arbitrary $b_{i,j}\in\mathbb{C}$, $i,j=1,2,\ldots$ define the function:

$$\tau(t):=\tau_0(t)\exp\left(-\frac{1}{2}\sum_{i,j=1}^{\infty}b_{ij}t_it_j\right)$$

and $L(t)$ is the Lax operator, related to $\tau(t)$. Then, there exists a change of variables $t_n\to t_n'$, another KdV tau function $\tau_1(t')$ and Lax operator $L_1(t')$ related to $\tau_1(t')$, such that the KP flows for $\tau(t)$ and $\tau_1(t')$ coincide, i.e., operators $L(t)$ and $L_1(t')$ are equivalent (cf. Ref. 6, p. 339).

Proof: Let $L(t)$ be the Lax operator related to the function $\tau(t)$:

$$L(t)=\sum_{i,j=0}^{\infty}\frac{p_i(-\tilde{\partial})\tau(t)}{\tau(t)}\partial_x^{1-i-j}\frac{p_j(\tilde{\partial})\tau(t)}{\tau(t)}.$$

Because of: $\partial^2_{t_it_j}\log\left[\tau(t)\exp\left(-1/2\Sigma_{i,j=1}^{\infty}b_{ij}t_it_j\right)\right]=[\partial^2_{t_it_j}\log\tau(t)]-b_{ij}$, we have $\partial_{t_{2n}}L(t)=0$ and hence $[(L^{2n})_+,L]=0$. In this case we have ($a_k,k=1,2,\ldots$ are some constants):

$$(L^2)_+=L^2+\sum_{k=1}^{\infty}a_kL^{-k}.$$

Let us define the operator L' ($b_k,k=1,2,\ldots$ are another constants):

$$L':=\sqrt{(L^2)_+}=\sqrt{L^2+\sum_{k=1}^{\infty}a_kL^{-k}}=L\left[\sum_{m=0}^{\infty}\binom{\frac{1}{2}}{m}\left(\sum_{k=1}^{\infty}a_kL^{-2-k}\right)^m\right]=L+\sum_{k=2}^{\infty}b_kL^{-k}.$$

Then $(L')^2$ is a differential operator, i.e., $\partial_{2n}(L')^2=0$.

From $L'=L+\Sigma_{k=2}^{\infty}b_kL^{-k}$ follows $((L')^n)_+=\Sigma_{k=1}^{n}c_{n,k}(L^k)_+$ ($c_{n,k}$, $n=1,2,\ldots$, $k=1,2,\ldots,n$ are constants). We have $\partial_{t_n}L=[(L^n)_+,L]$, so let us define new t'_n-derivatives by the following connection with the old t_n-derivatives: $\partial_{t'_n}:=\Sigma_{k=1}^{n}c_{n,k}\partial_{t_n}$. Then the new variables t'_n could be expressed linearly by t_n and this is the change of variables we were searching for. If we denote $L_1(t')=L'(t_n\rightarrow t'_n)$ and $\tau_1(t')$—a tau function related to $L_1(t')$, we obtain the statement of this Lemma. □

Remark 4.4: The proof of Lemma 4.3 is not constructive and hence it is difficult to apply the result for translating, for example, the original Fay identity for genus $g=1$-case 2.2 (where $f(z)=\theta_{11}(z)$) to the Fay identity for tau functions (2.1).

Combining the results of Lemmas 4.1 and 4.3 we obtain the following

Theorem 4.5: Modulo the restrictions on the function $f(z)$ from Lemma 4.1 *the functional Fay identity* (3.1) *for functions $g(t)$ of KdV type is equivalent to the Fay identity* (2.1) *for KdV tau functions*.

Remark 4.6: An open problem remains to clarify the *geometrical interpretation* of the cubic identity (3.2) from the viewpoint of the theory of theta functions.

Clifford-Finsler algebroids and nonholonomic Einstein–Dirac structures

Sergiu I. Vacaru[a)]
Department of Mathematics, Brock University, St. Catharines, Ontario L2S 3A1, Canada

(Received 15 March 2006; accepted 29 July 2006; published online 21 September 2006)

We propose a new framework for constructing geometric and physical models on nonholonomic manifold provided both with Clifford-Lie algebroid symmetry and nonlinear connection structure. Explicit parametrizations of generic off-diagonal metrics and linear and nonlinear connections define different types of Finsler, Lagrange, and/or Riemann–Cartan spaces. A generalization to spinor fields and Dirac operators on nonholonomic manifolds motivates the theory of Clifford algebroids defined as Clifford bundles, in general, enabled with nonintegrable distributions defining the nonlinear connection. In this work, we elaborate the algebroid spinor differential geometry and formulate the (scalar, Proca, graviton, spinor, and gauge) field equations on Lie algebroids. The paper communicates new developments in geometrical formulation of physical theories and this approach is grounded on a number of previous examples when exact solutions with generic off-diagonal metrics and generalized symmetries in modern gravity define nonholonomic spacetime manifolds with uncompactified extra dimensions. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2339016]

I. INTRODUCTION

A class of spacetimes possessing noncommutative and/or Lie algebroid symmetries can be defined as exact solutions in string and Einstein gravity.[1,2] This leads to new developments in formulation of classical and quantum field theories following the geometry of nonholonomic manifolds[3] possessing Lie algebroid symmetry.[4] Lie algebroid structures in gravity are modeled by generic off-diagonal metrics and nonholonomic frames (vielbeins) with associated nontrivial nonlinear connection (*N*-connection). The spacetimes provided with compatible metric, linear connection, and *N*-connection structures and possessing Lie algebroid symmetry are called Einstein–Cartan algebroids, or (in a more general context, for various extensions of the Riemann–Cartan geometry) Lie *N*-algebroids. Usually, the Lie algebroids can be defined for a vector, or tangent, bundle but, in general, they can be considered for any nonholonomic manifold provided with a nonintegrable (nonholonomic) distribution. [In our works we use distributions defining *N*-connection structures with the coefficients induced by the metric's off-diagonal terms and corresponding vielbein's coefficients. The geometric constructions are performed for nonholonomic manifolds, i.e., spaces provided with nonintegrable distributions. In a particular case, when such distributions are related to the exact sequences of subspaces defining an *N*–connection, the spaces are called *N* anholonomic]. In brief, such spaces are called Lie *N*-algebroids. Similar constructions elaborated for the Einstein–Dirac spaces give rise to the geometry of Clifford algebroids. If the curved spinor spaces are also enabled with Finsler, or Lagrange, structures, we deal with Clifford–Finsler, or Clifford–Lagrange, algebroids.

We note that the methods of Finsler and Lagrange geometry[5,6] were recently reconsidered in a new way in order to solve physical problems related to standard theories of gravity and field

[a)]Electronic mail: svacaru@brocku.ca

interactions.[1,7,6,8,9] If the former physical applications of Finsler geometry were elaborated on tangent/vector bundles, with less straightforward connections to standard physical theories (see reviews and references in Refs. 1, 7, and 6), in our approach we tried to define Finsler-type structures as exact solutions in Einstein and extra dimension gravity[8,9] when certain dimensions are not compactified. Such constructions are related to the geometry of nonholonomic manifolds possessing generalized symmetries (Lie algebroid and/or Clifford symmetries, noncommutative structures induced by anholonomic frames, etc.) and a number of ideas and methods from Finsler geometry seem to be of general interest and significant importance for physical applications. Here we note that this paper is not just on Clifford–Finsler geometry and related Lie algebroid structures but rather on (pseudo) Riemann geometry and gravitational and field interactions (and extensions to nontrivial torsion induced, for instance, from string theory and/or by nonholonomic frame effects) when the spinor and Lie algebroid structures are defined in nonholonomic form and certain methods from Finsler geometry became very important and efficient in order to solve nonlinear physical problems.[10]

This work develops the geometry of Clifford *N*-algebroids and generalized Finsler–spinor spaces elaborated in Refs. 11–13 and 7. If the first applications of algebroid methods were in geometric mechanics,[14–17] the recent works suggest a very promising route toward the theory of gauge fields, gravity and strings and noncommutative geometry.[7,18,1] We cite Ref. 4 for details on algebroid theory and related bibliography.

In the present paper, we address essentially the following two purposes: The *first one* is to define and study the geometry of Clifford algebroids and their *N*-anholonomic deformations, Clifford *N*-algebroids, and analysis of their main properties in relation to spinors in gravity theories and on nonholonomic manifolds. The *second* aim is the formulation of the field equations on Lie algebroids.

The structure of the paper is the following: The theory of Clifford algebroids is formulated in Sec. II: we remember the main definitions of nonholonomic manifolds provided with *N*-connection structure, define Clifford *N*-algebroids, and study the related spinor differential geometry. Section III is devoted to the field equations on *N*-anholonomic manifolds and their redefinition on Clifford *N*-anholonomic algebroids. We start with a study of the Dirac operator and spin connections on nonholonomic manifolds. Then the constructions are completed with spinor formulations of the basic equations for scalar, Proca, graviton, Dirac, and gauge fields interactions and related Lie/Clifford *N*-algebroid structures. In Sec. IV, we present conclusions and outlook.

II. CLIFFORD ALGEBROIDS AND *N*-CONNECTIONS

The geometry of spinor spaces enabled with nonlinear connection (*N*-connection) structure was elaborated in a series of works[11–13] (see also Refs. 19–21 for general references on Clifford and spinor differential geometry and applications to physics). Here we note that the concept of *N*-connection was originally proposed in the framework of Finsler geometry and geometric mechanics but such nonholonomic structures [defined by exact sequences of subspaces of the tangent space to the spacetime manifold and related nonintegrable distributions] may be also considered on (pseudo) Riemannian and Einstein–Cartan–Weyl spaces, see the discussion and historical remarks in Ref. 7. A class of nonholonomic spinor configurations can be defined by exact solutions of the Einstein–Dirac equations parametrized by generic off-diagonal metric ansatz, nonholonomic vielbeins associated to nontrivial *N*-connections, and arbitrary linear connections with nontrivial torsion.

The aim of this section is to formulate the theory of Clifford algebroids provided with nonlinear connection (*N*-connection) structures, i.e., the theory of Clifford *N*-algebroids. For holonomic configurations, the Clifford algebroids can be defined as usual Lie algebroids[4] but associated to a Clifford bundle instead of a vector or tangent bundle.

A. Nonholonomic manifolds and nonlinear connections

We outline some basic definitions and formulas from the geometry of manifolds provided with N-connection structure, see details in Refs. 6 and 7.

Let us consider a Riemann–Cartan manifold V of dimension $n+m$ and necessary smooth class and provided with general metric (of arbitrary signature) and linear connection structures. The local coordinates are denoted $u=(x,y)$, or $u^{\alpha}=(x^i,y^a)$, where the abstract, or coordinate, indices take, respectively, the values $i,j,k,\ldots=1,2,\ldots,n$ and $a,b,c,\ldots=n+1,n+2,\ldots,n+m$. Such a splitting of dimension and coordinates will be adapted below to the nonlinear connection structure. We denote by M a subspace of V, $\dim M=n$, provided with local coordinates x^i. The metric on V is parametrized in the form

$$\mathbf{g}=g_{\alpha\beta}\mathbf{e}^{\alpha}\otimes\mathbf{e}^{\beta}=g_{ij}(u)\mathbf{e}^{i}\otimes\mathbf{e}^{j}+h_{ab}(u)\mathbf{e}^{a}\otimes\mathbf{e}^{b}, \tag{1}$$

where

$$\mathbf{e}^{\mu}=[e^i=\mathrm{d}x^i,\mathbf{e}^a=\mathrm{d}y^a+N_i^a(u)\mathrm{d}x^i] \tag{2}$$

is the dual frame to

$$\mathbf{e}_{\nu}=\left[e_i=\frac{\partial}{\partial x^i}-N_i^a(u)\frac{\partial}{\partial y^a},e_a=\frac{\partial}{\partial y^a}\right]. \tag{3}$$

Such vielbeins are called N-adapted frames. [In order to preserve a relation with the previous denotations,[7,11–13] we note that $\mathbf{e}_{\nu}=(e_i,e_a)$ and $\mathbf{e}^{\mu}=(e^i,e^a)$ are, respectively, the former $\delta_{\nu}=\delta/\partial u^{\nu}=(\delta_i,\partial_a)$ and $\delta^{\mu}=\delta u^{\mu}=(d^i,\delta^a)$ which emphasize that operators (3) and (2) define, correspondingly, certain "N-elongated" partial derivatives and differentials which are more convenient for calculations on such nonholonomic manifolds].

We denote by $\pi^{\intercal}:TV\to TM$ the differential of a map $\pi:TV\to hV$, where hV is locally isomorphic to M, defined by fiber preserving morphisms of the tangent bundles TV and TM. The kernel of $\pi^{\intercal}$ is just the vertical subspace vV, $\dim(vV)=m$, with a related inclusion mapping $i:vV\to TV$ and hV is a horizontal subspace. It should be emphasized that such maps and local decompositions exist when $V\to M$ is a surjective submersion. A particular case is that of a fiber bundle but we can obtain the results in the general case [see the discussions and references in Refs. 3 and 7 related to almost sympletic manifolds, (pseudo) Riemannian spaces, and vector bundles and generalizations]. A *nonlinear connection* (*N-connection*) N on a manifold V is defined by the splitting on the left of an exact sequence

$$0\to vV\to TV\to TV/vV\to 0,$$

i.e., by a morphism of submanifolds $\mathbf{N}:TV\to vV$ such that $\mathbf{N}\circ\mathbf{i}$ is the unity in vV.

Equivalently, a N-connection is defined by a Whitney sum of horizontal (h) subspace, $hV\simeq M$ (we shall use the symbol "$\simeq$" in order to emphasize some isomorphisms of spaces) and vertical (v) subspace, vV,

$$T\mathbf{V}=hV\oplus vV. \tag{4}$$

The spaces provided with N-connection structure are denoted by boldface symbols. For instance, we write $\mathbf{V}$ for a manifold V provided with a distribution (4) (being, in general, nonintegrable, i.e., nonholonomic—in the literature an equivalent term it is also used: anholonomic). Such manifolds are called N-anholonomic with the nonholonomy defined by a N-connection structure. In a similar manner, we can define nonholonomic manifolds enabled with certain more general nonintegrable (nonholonomic) distributions of subspaces in TV, or in TTV, and so on, but in this paper we shall restrict our considerations only to N-anholonomic manifolds with N-connection splitting on TV. We shall use boldfaced indices for the geometric objects adapted to the N-connection.

Locally, a N-connection is defined by its coefficients $N_i^a(u)$,

$$\mathbf{N} = N_i^a(u)\mathrm{d}x^i \otimes \frac{\partial}{\partial y^a}.$$

The well-known class of linear connections consists on a particular subclass with the coefficients being linear on y^a, i.e., $N_i^a(u)=\Gamma_{bj}^a(x)y^b$. Any N-connection is characterized by its N-connection curvature

$$\mathbf{\Omega} = \frac{1}{2}\Omega_{ij}^a \mathrm{d}x^i \wedge \mathrm{d}x^j \otimes \frac{\partial}{\partial y^a},$$

with N-connection curvature coefficients

$$\Omega_{ij}^a = \delta_{[j}N_{i]}^a = \delta_j N_i^a - \delta_i N_j^a = \frac{\partial N_i^a}{\partial x^j} - \frac{\partial N_j^a}{\partial x^i} + N_i^b \frac{\partial N_j^a}{\partial y^b} - N_j^b \frac{\partial N_i^a}{\partial y^b},$$

and states the condition that the vielbeins (2) satisfy the nonholonomy (equivalently, anholonomy) relations

$$[\mathbf{e}_\alpha, \mathbf{e}_\beta] = \mathbf{e}_\alpha \mathbf{e}_\beta - \mathbf{e}_\beta \mathbf{e}_\alpha = W_{\alpha\beta}^\gamma \mathbf{e}_\gamma$$

with (antisymmetric) nontrivial anholonomy coefficients $W_{ia}^b = \partial_a N_i^b$ and $W_{ji}^a = \Omega_{ij}^a$.

All our further geometric constructions will be for spaces with nonholonomic splitting (4) and performed in "N-adapted" form with respect to local frames of type (2) and (3).

B. Clifford *N*-algebroids

Let us state the notations for abstract (coordinate) d-tensor indices of geometrical objects defined with respect to an arbitrary (coordinate) local basis, i.e., system of reference. For a local basis on $\mathbf{V}$, we write $e_\alpha=(e_i,v_a)$. The small Greek indices $\alpha,\beta,\gamma,\ldots$ are considered to be general ones, running values $1,2,\ldots,n+m$ and $i,j,k,\ldots$ and $a,b,c,\ldots$, respectively, label the geometrical objects on the base and typical "fiber" and run, correspondingly, the values $1,2,\ldots,n$ and $1,2,\ldots,m$. The dual base is denoted by $e^\alpha=(e^i,v^a)$. The local coordinates of a point $u\in\mathbf{V}$ are written $\mathbf{u}=(x,y)$, or $u^\alpha=(x^i,y^a)$, where y^a is the ath coordinate with respect to the basis (v_a) and (x^i) are local coordinates on $h\mathbf{V}$ with respect to e_i. We shall use "boldface" symbols in order to emphasize that the objects are defined on spaces provided with N-connection structure.

We suppose that the N-anholonomic manifold $\mathbf{V}$ admits a d-spinor structure which allows us to introduce spinor coordinates and parametrizations of geometrical objects. Let

$$\mathbf{e}_{\acute{\alpha}}{}^{\acute{\boldsymbol{\alpha}}} = (e_{\acute{i}}{}^{\acute{\mathbf{1}}}, e_{\acute{i}}{}^{\acute{\mathbf{2}}}, \ldots, e_{\acute{i}}{}^{\tilde{\mathbf{k}}_{(n)}}, e_{\acute{a}}{}^{\acute{\mathbf{1}}}, e_{\acute{a}}{}^{\acute{\mathbf{2}}}, \ldots, e_{\acute{a}}{}^{\tilde{\mathbf{k}}_{(m)}}),$$

with boldfaced indices running coordinate values on dimensions of d-spinor spaces, $\tilde{\mathbf{k}}_{(n)}$ and $\tilde{\mathbf{k}}_{(m)}$, being the coefficients of a d-spinor basis

$$\mathbf{e}_{\acute{\alpha}} = (e_{\acute{i}}, e_{\acute{a}}). \tag{5}$$

The dual basis (co-basis)

$$\mathbf{e}^{\acute{\alpha}} = (e^{\acute{i}}, e^{\acute{a}}) \tag{6}$$

has the coefficients

$$\mathbf{e}_{\acute{\boldsymbol{\alpha}}}{}^{\acute{\alpha}} = (e_{\acute{\mathbf{1}}}{}^{\acute{i}}, e_{\acute{\mathbf{2}}}{}^{\acute{i}}, \ldots, e_{\tilde{\mathbf{k}}_{(n)}}{}^{\acute{i}}, e_{\acute{\mathbf{1}}}{}^{\acute{a}}, e_{\acute{\mathbf{2}}}{}^{\acute{a}}, \ldots, e_{\tilde{\mathbf{k}}_{(m)}}{}^{\acute{a}}).$$

Similar formulas hold for the associated d-spinor spaces provided with local bases $\mathbf{e}_{\grave{\boldsymbol{\alpha}}}{}^{\grave{\alpha}}$ and $\mathbf{e}_{\grave{\alpha}}{}^{\grave{\alpha}}$. Such spinor bases are stated to be compatible to the N-connection splitting, i.e. to the vielbeins (3) and (2). For a given d-metric structure on $\mathbf{V}$ and its spinor decomposition, with associated spinor

bases $\mathbf{e}_{\grave{\alpha}}=(e_{\grave{i}},e_{\grave{a}})$, which allows us to introduce the γ objects, we can define, for instance, a N-adapted basis

$$\mathbf{e}_{\alpha}=(\gamma_{\alpha})^{\acute{\alpha}\grave{\alpha}}\mathbf{e}_{\acute{\alpha}}\mathbf{e}_{\grave{\alpha}}=[e_i=(\gamma_i)^{\hat{i}\acute{i}}e_{\acute{i}}e_{\grave{i}},e_a=(\gamma_a)^{\acute{a}\grave{a}}e_{\acute{a}}e_{\grave{a}}].$$

As a result, we can alternatively consider spinor coordinates, for instance,

$$u^{\alpha}=(x^i,y^a)\to u^{\acute{\alpha}\grave{\alpha}}=(x^{\hat{i}\hat{i}},y^{\acute{a}\grave{a}}).$$

For even dimensions of n, or m, further reductions are possible, when $x^{\hat{i}\hat{i}}\to x^{II'}$, or $y^{\acute{a}\grave{a}}\to y^{AA'}$. This way, the d-tensor indices can be transformed into the d-spinor ones and inversely.

The standard definition of a Lie algebroid $\mathcal{A}\doteq(E,[\cdot,\cdot],\rho)$ is associated to a vector bundle $\mathcal{E}=(E,\pi,M)$, with a surjective map $\pi:E\to M$ of the total spaces E to the base manifold M, of respective dimensions dim $E=n+m$ and dim $M=n$. The algebroid structure is stated by the anchor map $\rho:E\to TM$ (TM is the tangent bundle to M) and a Lie bracket on the $C^{\infty}(M)$-module of sections of E, denoted Sec(E), such that

$$[X,fY]=f[X,Y]+\rho(X)(f)Y$$

for any $X,Y\in\mathrm{Sec}(E)$ and $f\in C^{\infty}(M)$. The anchor also induces a homomorphism of $C^{\infty}(M)$-modules $\rho:\mathrm{Sec}(A)\to\mathcal{X}^1(M)$ where $\wedge^r(M)$ and $\mathcal{X}^r(M)$ will denote, respectively, the spaces of differential r-forms and r-multivector fields on M.

In local form, the Lie algebroid structure on the manifold $\mathbf{V}$ is defined by its structure functions $\rho^i_a(x)$ and $C^f_{ab}(x)$ defining the relations

$$\rho(e_a)=\rho^i_a(x)e_i=\rho^{\underline{i}}_a(x)\partial_{\underline{i}}, \tag{7}$$

$$[e_a,e_b]=C^c_{ab}(x)e_c \tag{8}$$

and subjected to the structure equations

$$\rho^j_a\frac{\partial\rho^i_b}{\partial x^j}-\rho^j_b\frac{\partial\rho^i_a}{\partial x^j}=\rho^j_cC^c_{ab},\qquad\sum_{\mathrm{cyclic}(a,b,c)}\left(\rho^j_a\frac{\partial C^d_{bc}}{\partial x^j}+C^d_{af}C^f_{bc}\right)=0; \tag{9}$$

for simplicity, we shall omit underlying coordinate indices if it will not result in ambiguities. Such equations are standard ones for the Lie algebroids but defined on N-anholonomic manifolds. In brief, we call them Lie N-algebroids.

Definition 2.1: *A Clifford algebroid* $\mathcal{C}(E)\doteq(\mathbb{C}l(E),{}^s[\cdot,\cdot],{}^s\rho)$ *is associated to a Clifford bundle* $\mathbb{C}l(E)\doteq\mathbb{C}l(T^*E)$ *defined by the vector bundle* $\mathcal{E}=(E,\pi,M)$ *and provided with* "*spin*" *anchor* ${}^s\rho$ and (*Lie type*) *commutator structure* ${}^s[\cdot,\cdot]$ *defined on the Clifford module* Sec($\mathbb{C}l(M)$).

The Clifford algebroid structure on a manifold M is defined $\mathcal{C}(TM)\doteq(\mathbb{C}l(TM),{}^s[\cdot,\cdot],{}^s\rho)$.

In local form, the spinor structure functions are written

$$\rho(e_{\acute{a}\grave{a}})=\rho^i_{\acute{a}\grave{a}}(x)e_i=\rho^{\underline{i}}_{\acute{a}\grave{a}}(x)\partial_{\underline{i}}, \tag{10}$$

$$[e_{\acute{a}\grave{a}},e_{\acute{b}\grave{b}}]=C^{\acute{c}\grave{c}}_{\acute{a}\grave{a}\acute{b}\grave{b}}(x)e_{\acute{c}\grave{c}}, \tag{11}$$

where we can consider a spinor decomposition on M with redefinition of indices like $i\to\acute{i},\grave{i}$. Such structure functions can be induced by pure spinor ones,

$$\hat{\rho}(e_{\acute{a}})=\rho^i_{\acute{a}}(x)e_i \tag{12}$$

and

$$[e_{\acute{a}}, e_{\acute{b}}] = C^{\acute{c}}_{\acute{a}\acute{b}}(x) e_{\acute{c}},$$

where, for instance, we can consider $\rho^i_{\acute{a}\grave{a}}(x) = \rho^i_{\acute{a}}(x)\rho^i_{\grave{a}}(x)$ for any fixed value of i. The structure equations (9) can be written in spinor form by introducing spinor variables (see examples of calculus with spinors in the next section).

We can write down the Lie algebroid and N-connection structures in a compatible form by introducing the "N-adapted" anchor

$$\hat{\rho}^j_a(x,u) \doteq \mathbf{e}^j{}_{\underline{j}}(x,u)\mathbf{e}_a{}^{\underline{a}}(x,u)\rho^{\underline{j}}_{\underline{a}}(x) \tag{13}$$

and "N-adapted" (boldfaced) structure functions

$$\mathbf{C}^f_{ag}(x,u) = \mathbf{e}^f{}_{\underline{f}}(x,u)\mathbf{e}_a{}^{\underline{a}}(x,u)\mathbf{e}_g{}^{\underline{g}}(x,u)C^{\underline{f}}_{\underline{a}\underline{g}}(x), \tag{14}$$

respectively, into formulas (7)–(9). In general, the RC-algebroids are defined by the corresponding sets of functions $\hat{\rho}^i_a(x,y)$ and $\mathbf{C}^f_{ag}(x,y)$ with additional dependencies on v-variables y^b for the N-adapted structure functions. For such Lie N-algebroids, the structure relations became

$$\hat{\rho}(e_b) = \hat{\rho}^i_b(x,y)e_i, \tag{15}$$

$$[e_d, e_b] = \mathbf{C}^f_{db}(x,y)e_f \tag{16}$$

and the structure equations of the Lie N-algebroid are written

$$\begin{gathered}\hat{\rho}^j_a e_j(\hat{\rho}^i_b) - \hat{\rho}^j_b e_j(\hat{\rho}^i_a) = \hat{\rho}^j_e \mathbf{C}^e_{ab}, \\ \sum_{\text{cyclic}(a,b,e)} (\hat{\rho}^j_a e_j(\mathbf{C}^f_{be}) + \mathbf{C}^f_{ag}\mathbf{C}^g_{be} - \mathbf{C}^{f'}_{b'e'}\hat{\rho}^j_a \mathbf{Q}^{fb'e'}_{f'bej}) = 0,\end{gathered} \tag{17}$$

for $\mathbf{Q}^{fb'e'}_{f'bej} = \mathbf{e}^{b'}{}_{\underline{b}}\mathbf{e}^{e'}{}_{\underline{e}}\mathbf{e}_{f'}{}^{\underline{f}}e_j(\mathbf{e}_b{}^{\underline{b}}\mathbf{e}_{e'}{}^{\underline{e}}\mathbf{e}^f{}_{\underline{f}})$ with the values $\mathbf{e}^{b'}{}_{\underline{b}}$ and $\mathbf{e}_{f'}{}^{\underline{f}}$ defined by the N-connection. The Lie N-algebroid structure will be characterized by the data $\hat{\rho}^i_b(x,y)$ and $\mathbf{C}^f_{db}(x,y)$ stated with respect to the N-adapted frames (3) and (2).

A Riemann–Cartan algebroid (in brief, RC–algebroid) is a Lie algebroid $\mathcal{A} \doteq (\mathbf{V}, [\cdot,\cdot], \rho)$ associated to a N-anholonomic manifold $\mathbf{V}$ provided with a N-connection $\mathbf{N}$, symmetric metric $\mathbf{g}(\mathbf{u})$ and linear connection $\mathbf{\Gamma}(\mathbf{u})$ structures resulting in a metric compatible and N-adapted covariant derivative $\mathbf{D}$, when $\mathbf{Dg}=\mathbf{0}$, but, in general, with nonvanishing torsion. In spinor variables, the RC-algebroids transform into Clifford N-algebroids associated to corresponding N-anholonomic manifolds instead of vector bundles. They are characterized by the same set of relations (13)–(17) rewritten in d-spinor variables.

C. *N*-algebroid spinor differential geometry

The goal of the section is to outline the main results from the differential geometry of d-spinors for the Clifford N-algebroids and related N-anholonomic manifolds. The d-tensor and d-connection formulas and basic equations are investigated in details in Ref. 2. Such Lie N-algebroid relations can be obtained by "anchoring" the formulas for d-connections, d-torsions and d-curvatures stated. In result, one obtains certain differential geometric objects on the set of sections like $\mathrm{Sec}(v\mathbf{V})$ or $\mathrm{Sec}(\mathbf{E})$, when the "fiber" derivatives are changed into horizontal ones, $\partial/\partial y^a \to \rho^i_a \partial/\partial x^a$, or in N-adapted form, $e_a \to \hat{\rho}^j_a e_j$. In spinor/ d-spinor variables, such formulas transform into certain analogous on Clifford N-algebroids provided with arbitrary but N-adapted and compatible d-metric and d-connection structure.

We use denotations

$$e^{\alpha}=(e^{i},e^{a})\in\gamma^{\alpha}=(\gamma^{i},\gamma^{a}),\quad \zeta^{\acute{\alpha}}=(\zeta^{\acute{i}},\zeta^{\acute{a}})\in\gamma^{\acute{\alpha}}=(\gamma^{\acute{i}},\gamma^{\acute{a}})$$

for, respectively, elements of modules of d-vector and irreduced d-spinor fields (see details in Ref. 11). D-tensors and d-spinor tensors (irreduced or reduced) will be interpreted as elements of corresponding γ–modules, for instance,

$$q^{\alpha}{}_{\beta\ldots}\in\gamma^{\alpha}{}_{\beta},\psi^{\acute{\alpha}\ \acute{\gamma}}{}_{\acute{\beta}\ \ldots}\in\gamma^{\acute{\alpha}\ \acute{\gamma}}{}_{\acute{\beta}\ \ldots},\xi^{II'}{}_{JK'N'}\in\gamma^{II'}{}_{JK'N'},\ldots\ .$$

We can establish a correspondence between the d-metric $g_{\alpha\beta}$ (1) and d-spinor metric $\epsilon_{\acute{\alpha}\acute{\beta}}$ for both h- and v-subspaces of $\mathbf{V}$ by using the relation

$$g_{\alpha\beta}=\frac{1}{\widetilde{k}_{(n)}+\widetilde{k}_{(m)}}((\gamma_{(\alpha}(u))^{\acute{\alpha}\grave{\alpha}}(\gamma_{\beta)}(u))^{\acute{\beta}\grave{\beta}}\epsilon_{\acute{\alpha}\grave{\beta}}\epsilon_{\acute{\beta}\grave{\alpha}},\tag{18}$$

where $(\alpha\beta)$ denotes symmetrization on such indices and

$$(\gamma_{\alpha}(u))^{\acute{\alpha}\grave{\alpha}}=l_{\alpha}^{\hat{\alpha}}(u)(\gamma_{\hat{\alpha}})^{\acute{\alpha}\grave{\alpha}}.\tag{19}$$

In brief, we can write (18) in the form

$$g_{\alpha\beta}=\epsilon_{\acute{\alpha}\grave{\beta}}\epsilon_{\acute{\beta}\grave{\alpha}}\tag{20}$$

if the γ-objects are considered as a fixed structure, whereas ϵ-objects are treated as caring for the metric "dynamics". This variant is used, for instance, in the so-called two-spinor geometry[19,20] and should be preferred if we have to make explicit the algebraic symmetry properties of d-spinor objects. An alternative way is to consider as fixed the algebraic structure of ϵ-objects and to use variable components of γ-objects of type (19) for developing a variational d-spinor approach to gravitational and matter field interactions (the spinor Ashtekar variables[26] are introduced in this manner). In this paper we shall follow in the bulk the first approach but we note that the second type of spinor calculus is more convenient for finding exact solutions with nonholonomic variables.

We note that a d-spinor metric

$$\epsilon_{\acute{\alpha}\grave{\beta}}=\begin{pmatrix}\epsilon_{\hat{i}\hat{j}} & 0\\ 0 & \epsilon_{\acute{a}\grave{b}}\end{pmatrix}$$

on the d-spinor space $\mathbf{S}=(S_{(h)},S_{(v)})$ may have symmetric or antisymmetric $h(v)$ -components $\epsilon_{\hat{i}\hat{j}}$ $(\epsilon_{\acute{a}\grave{b}})$. For simplicity, in this section (in order to avoid cumbersome calculations connected with eight fold periodicity on dimensions n and m on a N-anholonomic manifold) we shall develop a general d-spinor formalism only by using irreduced spinor spaces $\mathbf{S}_{(h)}$ and $\mathbf{S}'_{(h)}$.

1. D-covariant derivation

For a d-covariant operator

$$\mathbf{D}_{\alpha}=(D_{i},D_{a})=(\gamma_{\alpha})^{\acute{\alpha}\grave{\alpha}}\mathbf{D}_{\acute{\alpha}\grave{\alpha}}=((\gamma_{i})^{\hat{i}\hat{i}}D_{\hat{i}\hat{i}},(\gamma_{a})^{\acute{a}\grave{a}}D_{\acute{a}\grave{a}}),$$

in brief, we shall write

$$\mathbf{D}_{\alpha}=\mathbf{D}_{\acute{\alpha}\grave{\alpha}}=(D_{\hat{i}\hat{i}},D_{\acute{a}\grave{a}}),$$

being constructed by using the coefficients of a d-connection, we define the action on a d-spinor $\gamma^{\acute{\beta}}$ as a map

$$\mathbf{D}_{\acute{\alpha}\grave{\alpha}}:\ \gamma^{\acute{\beta}} \to \gamma^{\acute{\beta}}_{\alpha} = \gamma^{\acute{\beta}}_{\acute{\alpha}\grave{\alpha}}$$

satisfying conditions

$$\mathbf{D}_{\alpha}(\xi^{\acute{\beta}} + \eta^{\acute{\beta}}) = \mathbf{D}_{\alpha}\xi^{\acute{\beta}} + \mathbf{D}_{\alpha}\eta^{\acute{\beta}}, \quad \mathbf{D}_{\alpha}(f\xi^{\acute{\beta}}) = f\mathbf{D}_{\alpha}\xi^{\acute{\beta}} + \xi^{\acute{\beta}}\mathbf{D}_{\alpha}f,$$

for every $\xi^{\acute{\beta}}, \eta^{\acute{\beta}} \in \gamma^{\acute{\beta}}$ and f being a scalar field on $\mathbf{V}$. It is also required that one holds the Leibnitz rule

$$(\mathbf{D}_{\alpha}\zeta_{\acute{\beta}})\,\eta^{\acute{\beta}} = \mathbf{D}_{\alpha}(\zeta_{\acute{\beta}}\eta^{\acute{\beta}}) - \zeta_{\acute{\beta}}\mathbf{D}_{\alpha}\eta^{\acute{\beta}}$$

and that $\mathbf{D}_{\alpha}$ is a real operator, i.e., it commuters with the operation of complex conjugation:

$$\overline{\mathbf{D}_{\alpha}\psi_{\underline{\alpha\beta\gamma}\ldots}} = \mathbf{D}_{\alpha}(\overline{\psi}_{\underline{\alpha\beta\gamma}\ldots}).$$

Let us now analyze the question on uniqueness of action on d-spinors of an operator $\mathbf{D}_{\alpha}$ satisfying some necessary conditions. Denoting by $\mathbf{D}^{(1)}_{\alpha}$ and $\mathbf{D}_{\alpha}$ two such d-covariant operators, we consider the map

$$(\mathbf{D}^{(1)}_{\alpha} - \mathbf{D}_{\alpha}):\ \gamma^{\acute{\beta}} \to \gamma^{\acute{\beta}}_{\acute{\alpha}\grave{\alpha}}. \tag{21}$$

Because the action on a scalar f of both operators $\mathbf{D}^{(1)}_{\alpha}$ and $\mathbf{D}_{\alpha}$ must be identical, i.e.

$$\mathbf{D}^{(1)}_{\alpha}f = \mathbf{D}_{\alpha}f, \tag{22}$$

the action (21) on $f = \omega_{\acute{\beta}}\xi^{\acute{\beta}}$ must be written as

$$(\mathbf{D}^{(1)}_{\alpha} - \mathbf{D}_{\alpha})(\omega_{\acute{\beta}}\xi^{\acute{\beta}}) = 0.$$

We conclude that there is an element $\Theta_{\acute{\alpha}\grave{\alpha}\acute{\beta}}{}^{\acute{\gamma}} \in \gamma_{\acute{\alpha}\grave{\alpha}\acute{\beta}}{}^{\acute{\gamma}}$ for which

$$\mathbf{D}^{(1)}_{\acute{\alpha}\grave{\alpha}}\xi^{\acute{\gamma}} = \mathbf{D}_{\acute{\alpha}\grave{\alpha}}\xi^{\acute{\gamma}} + \Theta_{\acute{\alpha}\grave{\alpha}\acute{\beta}}{}^{\acute{\gamma}}\xi^{\acute{\beta}} \tag{23}$$

and

$$\mathbf{D}^{(1)}_{\acute{\alpha}\grave{\alpha}}\omega_{\acute{\beta}} = \mathbf{D}_{\acute{\alpha}\grave{\alpha}}\omega_{\acute{\beta}} - \Theta_{\acute{\alpha}\grave{\alpha}\acute{\beta}}{}^{\acute{\gamma}}\omega_{\acute{\gamma}}.$$

The action of the operator (21) on a d-vector $v^{\beta} = v^{\acute{\beta}\grave{\beta}}$ can be written by using formula (23) for both indices $\acute{\beta}$ and $\grave{\beta}$:

$$(\mathbf{D}^{(1)}_{\alpha} - \mathbf{D}_{\alpha})v^{\acute{\beta}\grave{\beta}} = \Theta_{\alpha\acute{\gamma}}{}^{\acute{\beta}}v^{\acute{\gamma}\grave{\beta}} + \Theta_{\alpha\grave{\gamma}}{}^{\grave{\beta}}v^{\acute{\beta}\grave{\gamma}} = (\Theta_{\alpha\acute{\gamma}}{}^{\acute{\beta}}e^{\grave{\beta}}_{\grave{\gamma}} + \Theta_{\alpha\grave{\gamma}}{}^{\grave{\beta}}e^{\acute{\beta}}_{\acute{\gamma}})v^{\acute{\gamma}\grave{\gamma}} = Q^{\beta}_{\alpha\gamma}v^{\gamma},$$

where

$$Q^{\beta}{}_{\alpha\gamma} = Q^{\acute{\beta}\grave{\beta}}{}_{\acute{\alpha}\grave{\alpha}\acute{\gamma}\grave{\gamma}} = \Theta_{\alpha\acute{\gamma}}{}^{\acute{\beta}}e^{\grave{\beta}}_{\grave{\gamma}} + \Theta_{\alpha\grave{\gamma}}{}^{\grave{\beta}}e^{\acute{\beta}}_{\acute{\gamma}}. \tag{24}$$

The commutator $\mathbf{D}_{[\alpha}\mathbf{D}_{\beta]}$ defines the d-torsion. Applying operators $\mathbf{D}^{(1)}_{[\alpha}\mathbf{D}^{(1)}_{\beta]}$ and $\mathbf{D}_{[\alpha}\mathbf{D}_{\beta]}$ on $f = \omega_{\acute{\beta}}\xi^{\acute{\beta}}$, we can write

$$T^{(1)\gamma}{}_{\alpha\beta} - T^{\gamma}{}_{\alpha\beta} = Q^{\gamma}{}_{\beta\alpha} - Q^{\gamma}{}_{\alpha\beta}$$

with $Q^{\gamma}{}_{\alpha\beta}$ from (24).

The action of operator $\mathbf{D}^{(1)}_{\alpha}$ on d-spinor tensors must be constructed by using formula (23) for every upper indices and formula (24) for every lower indices.

2. N-adapted Infeld–van der Waerden coefficients

A d-spinor $\kappa^{\acute{\alpha}} \in \gamma^{\acute{\alpha}}$ has the components $\kappa^{\acute{\alpha}}=\kappa^{\acute{\alpha}}\mathbf{e}^{\acute{\alpha}}_{\acute{\alpha}}=(\kappa^{\acute{i}}, \kappa^{\acute{\mathbf{a}}})$ defined with respect to the N-adapted spinor basis (5). Taking into account that

$$\mathbf{e}_{\acute{\alpha}}{}^{\acute{\alpha}}\mathbf{e}_{\grave{\beta}}{}^{\grave{\beta}}\mathbf{D}_{\acute{\alpha}\grave{\beta}}=\mathbf{D}_{\acute{\alpha}\grave{\beta}},$$

we compute the components $\mathbf{D}_{\acute{\alpha}\grave{\beta}}\kappa^{\acute{\gamma}}$,

$$\mathbf{e}_{\acute{\alpha}}{}^{\acute{\alpha}}\mathbf{e}_{\grave{\beta}}{}^{\grave{\beta}}\mathbf{e}^{\acute{\gamma}}_{\acute{\gamma}}\mathbf{D}_{\acute{\alpha}\grave{\beta}}\kappa^{\acute{\gamma}}=\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\tau}}\mathbf{e}_{\acute{\tau}}{}^{\acute{\gamma}}\mathbf{D}_{\acute{\alpha}\grave{\underline{\beta}}}\kappa^{\acute{\epsilon}}+\kappa^{\acute{\epsilon}}\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\gamma}}\mathbf{D}_{\acute{\alpha}\grave{\beta}}\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\epsilon}}=\mathbf{D}_{\acute{\alpha}\grave{\beta}}\kappa^{\acute{\gamma}}+\kappa^{\acute{\epsilon}}\varpi^{\acute{\gamma}}{}_{\acute{\alpha}\grave{\beta}\acute{\epsilon}}, \tag{25}$$

where the coordinate components of the d-spinor connection are defined

$$\varpi^{\acute{\gamma}}{}_{\acute{\alpha}\grave{\beta}\acute{\epsilon}} \doteq \mathbf{e}_{\acute{\tau}}{}^{\acute{\gamma}}\mathbf{D}_{\acute{\alpha}\grave{\beta}}\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\tau}}. \tag{26}$$

We call the Infeld–van der Waerden d-symbols a set of objects $\varpi^{\acute{\gamma}}{}_{\acute{\alpha}\grave{\beta}\acute{\epsilon}}$ parametrized with respect to a coordinate d-spinor basis. Defining $\mathbf{D}_{\alpha}=(\gamma_{\alpha})^{\acute{\alpha}\grave{\beta}}\mathbf{D}_{\acute{\alpha}\grave{\beta}}$, introducing denotations $\varpi^{\gamma}{}_{\alpha\acute{\tau}} \doteq \varpi^{\acute{\gamma}}{}_{\acute{\alpha}\grave{\beta}\acute{\tau}}(\gamma_{\alpha})^{\acute{\alpha}\grave{\beta}}$and using properties (25), we write the relations

$$l^{\alpha}_{\alpha}\mathbf{e}^{\acute{\beta}}_{\acute{\beta}}\mathbf{D}_{\alpha}\kappa^{\acute{\beta}}=\mathbf{D}_{\alpha}\kappa^{\acute{\beta}}+\kappa^{\acute{\delta}}\varpi^{\acute{\beta}}{}_{\alpha\acute{\delta}} \tag{27}$$

and

$$l^{\alpha}_{\alpha}\mathbf{e}^{\acute{\beta}}_{\acute{\beta}}\mathbf{D}_{\alpha}\mu_{\acute{\beta}}=\mathbf{D}_{\alpha}\mu_{\acute{\beta}}-\mu_{\acute{\delta}}\varpi^{\acute{\delta}}{}_{\alpha\acute{\beta}} \tag{28}$$

for d-covariant derivations $\mathbf{D}_{\alpha}\kappa^{\acute{\beta}}$ and $\mathbf{D}_{\alpha}\mu_{\acute{\beta}}$.

We can consider expressions similar to (27) and (28) for values having both types of d-spinor and d-tensor indices, for instance,

$$l^{\alpha}_{\alpha}l^{\gamma}_{\gamma}\mathbf{e}^{\acute{\delta}}_{\acute{\delta}}\mathbf{D}_{\alpha}\theta^{\gamma}_{\acute{\delta}}=\mathbf{D}_{\alpha}\theta^{\gamma}_{\acute{\delta}}-\theta^{\gamma}_{\acute{\epsilon}}\varpi^{\acute{\epsilon}}{}_{\alpha\acute{\delta}}+\theta^{\tau}_{\acute{\delta}}\Gamma^{\gamma}{}_{\alpha\tau}$$

(we can prove this by a straightforward calculation of the derivation $\mathbf{D}_{\alpha}(\theta^{\tau}_{\acute{\delta}}\,\mathbf{e}^{\acute{\delta}}_{\acute{\delta}}l^{\gamma}_{\tau})$).

Now we shall consider some possible relations between components of d-connections $\varpi^{\acute{\epsilon}}_{\alpha\acute{\delta}}$ and $\Gamma^{\gamma}_{\alpha\tau}$ and derivations of $(\gamma_{\alpha})^{\acute{\alpha}\grave{\beta}}$. We can write

$$\begin{aligned}\Gamma^{\alpha}_{\beta\tau}&=l^{\alpha}_{\alpha}\mathbf{D}_{\tau}l^{\alpha}_{\beta}=l^{\alpha}_{\alpha}\mathbf{D}_{\tau}(\gamma_{\beta})^{\acute{\epsilon}\grave{\tau}}=l^{\alpha}_{\alpha}\mathbf{D}_{\tau}((\gamma_{\beta})^{\acute{\epsilon}\grave{\tau}}\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\epsilon}}\mathbf{e}_{\grave{\tau}}{}^{\grave{\tau}})=l^{\alpha}_{\alpha}\mathbf{e}_{\acute{\alpha}}{}^{\acute{\alpha}}\mathbf{e}_{\acute{\epsilon}}{}^{\grave{\epsilon}}\mathbf{D}_{\tau}(\gamma_{\beta})^{\acute{\alpha}\grave{\epsilon}}+l^{\alpha}_{\alpha}(\gamma_{\beta})^{\acute{\epsilon}\grave{\tau}}(\mathbf{e}_{\grave{\tau}}{}^{\grave{\tau}}\mathbf{D}_{\tau}\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\epsilon}}+\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\epsilon}}\mathbf{D}_{\tau}\mathbf{e}_{\grave{\tau}}{}^{\grave{\tau}})\\&=l^{\boldsymbol{\alpha}}_{\acute{\alpha}\acute{\epsilon}}\mathbf{D}_{\tau}(\gamma_{\beta})^{\acute{\alpha}\grave{\epsilon}}+l^{\alpha}_{\acute{\alpha}\grave{\epsilon}}\mathbf{e}_{\acute{\alpha}}{}^{\acute{\alpha}}\mathbf{e}_{\acute{\epsilon}}{}^{\grave{\epsilon}}(\gamma_{\beta})^{\acute{\epsilon}\grave{\tau}}(\mathbf{e}_{\grave{\tau}}{}^{\grave{\tau}}\mathbf{D}_{\tau}\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\epsilon}}+\mathbf{e}_{\acute{\epsilon}}{}^{\acute{\epsilon}}\mathbf{D}_{\tau}\mathbf{e}_{\grave{\tau}}{}^{\grave{\tau}}),\end{aligned}$$

where $l^{\alpha}_{\alpha}=(\gamma_{\acute{\alpha}\grave{\alpha}})^{\alpha}$, from which one follows

$$(\gamma_{\alpha})^{\acute{\mu}\grave{\nu}}(\gamma^{\beta})_{\acute{\alpha}\grave{\beta}}\Gamma^{\alpha}_{\gamma\beta}=(\gamma^{\beta})_{\acute{\alpha}\grave{\beta}}\mathbf{D}_{\gamma}(\gamma_{\beta})^{\acute{\mu}\grave{\nu}}+\mathbf{e}_{\grave{\beta}}{}^{\grave{\nu}}\varpi^{\acute{\mu}}{}_{\gamma\acute{\alpha}}+\mathbf{e}_{\acute{\alpha}}{}^{\acute{\mu}}\varpi^{\grave{\nu}}{}_{\gamma\grave{\beta}}.$$

Contracting the last expression on $\grave{\nu}$ and $\grave{\beta}$ and using an orthonormalized d-spinor basis when $\varpi^{\boldsymbol{\beta}}{}_{\gamma\acute{\beta}}=0$ (a consequence from (26)), we have

$$\varpi^{\acute{\mu}}{}_{\gamma\acute{\alpha}}=\frac{1}{\widetilde{k}_{(n)}+\widetilde{k}_{(m)}}(\Gamma^{\acute{\mu}\grave{\beta}}{}_{\boldsymbol{\gamma}\,\acute{\alpha}\grave{\beta}}-(\gamma^{\beta})_{\acute{\alpha}\grave{\beta}}\mathbf{D}_{\gamma}(\gamma_{\beta})^{\acute{\mu}\grave{\beta}}), \tag{29}$$

where

$$\Gamma^{\acute{\mu}\grave{\beta}}_{\boldsymbol{\gamma}\,\acute{\alpha}\grave{\beta}}=(\gamma_\alpha)^{\acute{\mu}\grave{\beta}}(\gamma^\beta)_{\acute{\alpha}\grave{\beta}}\Gamma^\alpha_{\gamma\beta}. \tag{30}$$

The *d*-spinor connection (30) can be defined by various type of *d*-connections, inclusively, by the canonical one, see Ref. 1. Such formulas can be applied on Clifford algebroid $\mathcal{C}(E)\doteq(\mathbb{C}l(E),{}^s[\cdot,\cdot],{}^s\rho)$ or on a Clifford *N*-algebroid $\mathcal{C}(v\mathbf{V})\doteq(\mathbb{C}l(v\mathbf{V}),{}^s[\cdot,\cdot],{}^s\rho)$. We have to change the *v*-derivatives into anchored ones, $\partial/\partial y^a\rightarrow\rho^i_a\partial/\partial x^a$, or in *N*-adapted form, $e_a\rightarrow\hat{\rho}^j_a e_j$, and put the results in formulas (29) and (30). As a result, one defines a canonical covariant spinor differential calculus, adapted to the *N*-connection structure, acting on the set of sections Sec(**E**) or Sec($v\mathbf{V}$).

3. D-spinors of curvature and torsion on N-anholonomic manifolds

The *d*-tensor indices of the commutator $\Delta_{\alpha\beta}$ can be transformed into *d*-spinor ones:

$$\Box_{\acute{\alpha}\grave{\beta}}=(\gamma^{\alpha\beta})_{\acute{\alpha}\grave{\beta}}\Delta_{\alpha\beta}=(\Box_{\hat{\imath}\hat{\imath}},\Box_{\acute{a}\grave{a}}), \tag{31}$$

with *h*- and *v*-components,

$$\Box_{\hat{\imath}\hat{\imath}}=(\gamma^{\alpha\beta})_{\hat{\imath}\hat{\imath}}\Delta_{\alpha\beta},\quad\text{and}\quad\Box_{\acute{a}\grave{a}}=(\gamma^{\alpha\beta})_{\acute{a}\grave{a}}\Delta_{\alpha\beta},$$

being symmetric or antisymmetric in dependence of corresponding values of dimensions *n* and *m*. Considering the actions of operator (31) on *d*-spinors $\pi^{\acute{\gamma}}$ and $\mu_{\acute{\gamma}}$ we introduce the *d*-spinor curvature $X^{\acute{\gamma}}_{\acute{\tau}\acute{\alpha}\grave{\beta}}$ satisfying

$$\Box_{\acute{\alpha}\grave{\beta}}\pi^{\acute{\gamma}}=X^{\acute{\gamma}}_{\acute{\tau}\acute{\alpha}\grave{\beta}}\pi^{\acute{\tau}} \tag{32}$$

and

$$\Box_{\acute{\alpha}\grave{\beta}}\mu_{\acute{\gamma}}=X^{\acute{\tau}}_{\acute{\gamma}\acute{\alpha}\grave{\beta}}\mu_{\acute{\tau}}.$$

The gravitational *d*-spinor $\Psi_{\acute{\tau}\acute{\gamma}\acute{\alpha}\grave{\beta}}$ is defined by a corresponding symmetrization of *d*-spinor indices:

$$\Psi_{\acute{\tau}\acute{\gamma}\acute{\alpha}\grave{\beta}}=X_{(\acute{\tau}\acute{\gamma}\acute{\alpha})\grave{\beta}}. \tag{33}$$

We note that *d*-spinor tensors $X^{\acute{\tau}}_{\acute{\gamma}\acute{\alpha}\grave{\beta}}$ and $\Psi_{\acute{\tau}\acute{\gamma}\acute{\alpha}\grave{\beta}}$ are transformed into similar two-spinor objects if the *N*-connection vanishes and the spinor constructions are defined in global form on $\mathbf{V}$.[19,20]

Putting $\mathbf{e}_{\acute{\gamma}}{}^{\acute{\gamma}}$ instead of $\mu_{\acute{\gamma}}$ in (32) and using (33), we can express, respectively, the curvature and gravitational *d*-spinors as

$$X_{\acute{\gamma}\acute{\delta}\acute{\alpha}\grave{\beta}}=\mathbf{e}_{\acute{\gamma}\acute{\tau}}\Box_{\acute{\alpha}\grave{\beta}}\mathbf{e}_{\acute{\delta}}{}^{\acute{\tau}}$$

and

$$\Psi_{\acute{\delta}\acute{\gamma}\acute{\alpha}\grave{\beta}}=\mathbf{e}_{\acute{\delta}(\acute{\tau}}\Box_{\acute{\alpha}|\grave{\beta}|}\mathbf{e}_{\acute{\gamma})}{}^{\acute{\tau}}$$

where we omit symmetrization on $\grave{\beta}$.

The *d*-spinor torsion $T^{\acute{\gamma}\grave{\gamma}}_{\acute{\alpha}\grave{\beta}}$ is defined by using the *d*-spinor commutator (31) and

$$\Box_{\acute{\alpha}\grave{\beta}}f=T^{\acute{\gamma}\grave{\gamma}}_{\acute{\alpha}\grave{\beta}}\nabla_{\acute{\gamma}\grave{\gamma}}f.$$

The *d*-spinor components $R^{\acute{\delta}\grave{\delta}}{}_{\acute{\gamma}\grave{\gamma}\acute{\alpha}\grave{\beta}}$ of the curvature *d*-tensor $R^\delta{}_{\gamma\alpha\beta}$ can be computed by using relations (30), (31), and (33) and

$$(\Box_{\acute{\alpha}\grave{\beta}} - T^{\acute{\gamma}\grave{\gamma}}{}_{\acute{\alpha}\grave{\beta}}\nabla_{\acute{\gamma}\grave{\gamma}})V^{\acute{\delta}\grave{\delta}} = R^{\acute{\delta}\grave{\delta}}{}_{\acute{\gamma}\grave{\gamma}\acute{\alpha}\grave{\beta}}V^{\acute{\gamma}\grave{\gamma}}, \tag{34}$$

here d-vector $V^{\acute{\gamma}\grave{\gamma}}$ is considered as a product of d-spinors, i.e., $V^{\acute{\gamma}\grave{\gamma}}=\nu^{\acute{\gamma}}\mu^{\grave{\gamma}}$. We find

$$R^{\acute{\delta}\grave{\delta}}{}_{\acute{\gamma}\grave{\gamma}\acute{\alpha}\grave{\beta}} = (X^{\acute{\delta}}{}_{\acute{\gamma}\acute{\alpha}\grave{\beta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}}\boldsymbol{\varpi}^{\acute{\delta}}{}_{\hat{\tau}\hat{\tau}\acute{\gamma}})\mathbf{e}_{\grave{\gamma}}{}^{\grave{\delta}} + (X^{\grave{\delta}}{}_{\grave{\gamma}\acute{\alpha}\grave{\beta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}}\boldsymbol{\varpi}^{\grave{\delta}}{}_{\hat{\tau}\hat{\tau}\grave{\gamma}})\mathbf{e}_{\acute{\gamma}}{}^{\acute{\delta}}.$$

It is convenient to use this d-spinor expression for the curvature d-tensor in order to get the d-spinor components of the Ricci d-tensor,

$$R_{\acute{\gamma}\grave{\gamma}\acute{\alpha}\grave{\beta}} = R^{\acute{\delta}\grave{\delta}}{}_{\acute{\gamma}\grave{\gamma}\acute{\alpha}\grave{\beta}\acute{\delta}\grave{\delta}} = X^{\acute{\delta}}{}_{\acute{\gamma}\acute{\alpha}\grave{\beta}\acute{\delta}\acute{\gamma}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}\acute{\gamma}}\boldsymbol{\varpi}^{\acute{\delta}}{}_{\hat{\tau}\hat{\tau}\acute{\gamma}} + X^{\grave{\delta}}{}_{\grave{\gamma}\acute{\alpha}\grave{\beta}\grave{\gamma}\grave{\delta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}\acute{\gamma}\grave{\delta}}\boldsymbol{\varpi}^{\grave{\delta}\hat{\tau}\hat{\tau}\grave{\gamma}}{}_{\hat{\tau}\hat{\tau}\grave{\gamma}} \tag{35}$$

and this d-spinor decomposition of the scalar curvature $\overleftarrow{R}=R^{\acute{\alpha}\grave{\beta}}{}_{\acute{\alpha}\grave{\beta}}$,

$$\overleftarrow{R} = R^{\acute{\delta}\grave{\delta}\acute{\alpha}\grave{\beta}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}\grave{\delta}} = X^{\acute{\delta}\acute{\alpha}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}}{}^{\grave{\beta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}}{}^{\grave{\beta}}\boldsymbol{\varpi}^{\acute{\delta}\hat{\tau}\hat{\tau}\acute{\alpha}} + X^{\grave{\delta}\grave{\beta}\acute{\alpha}}{}_{\acute{\alpha}\grave{\beta}\grave{\delta}} + T^{\hat{\tau}\hat{\tau}\acute{\alpha}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}}\boldsymbol{\varpi}^{\grave{\delta}\grave{\beta}}{}_{\hat{\tau}\hat{\tau}}.$$

Finally, we write down the d-spinor components of the Einstein d-tensor $\mathbf{G}_{\gamma\beta}$,

$$\begin{aligned}\mathbf{G}_{\acute{\gamma}\grave{\gamma}\acute{\beta}\grave{\beta}} &= X^{\acute{\delta}}{}_{\acute{\gamma}\acute{\beta}\grave{\beta}\acute{\delta}\grave{\gamma}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\beta}\grave{\beta}\acute{\delta}\grave{\gamma}}\boldsymbol{\varpi}^{\acute{\delta}}{}_{\hat{\tau}\hat{\tau}\acute{\gamma}} + X^{\grave{\delta}}{}_{\grave{\gamma}\acute{\beta}\grave{\beta}\grave{\gamma}\grave{\delta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\beta}\grave{\beta}\acute{\gamma}\grave{\delta}}\boldsymbol{\varpi}^{\grave{\delta}}{}_{\hat{\tau}\hat{\tau}\grave{\gamma}} \\ &\quad - \frac{1}{2}\boldsymbol{\epsilon}_{\acute{\gamma}\grave{\beta}}\boldsymbol{\epsilon}_{\acute{\beta}\grave{\gamma}}[X^{\acute{\delta}\acute{\alpha}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}}{}^{\grave{\beta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}\acute{\delta}}{}^{\grave{\beta}}\boldsymbol{\varpi}^{\acute{\delta}}{}_{\hat{\tau}\hat{\tau}}{}^{\acute{\alpha}} + X^{\grave{\delta}\grave{\beta}}{}_{\acute{\alpha}\grave{\beta}}{}^{\acute{\alpha}}{}_{\grave{\delta}} + T^{\hat{\tau}\hat{\tau}}{}_{\acute{\alpha}\grave{\beta}}{}^{\acute{\alpha}}{}_{\grave{\delta}}\boldsymbol{\varpi}^{\grave{\delta}}{}_{\hat{\tau}\hat{\tau}}{}^{\grave{\beta}}].\end{aligned} \tag{36}$$

It should be noted that further reductions of (35) and (36) depend on dimensions n and m of the, respectively, h- and v-subspaces, and that the symmetry properties are defined by the $\boldsymbol{\epsilon}$-objects. On Clifford N-algebroids, such formulas have to be considered for anchored v-derivatives (15) and (7) (for d-spinor considerations, we have to apply spinor anchors (10) and (12)), for instance, in the case of canonical d-connections and their spinor variants (29).

III. FIELD EQUATIONS AND LIE ALGEBROIDS

Lie algebroid structures can be modeled as spacetime geometries with generalized symmetries (defined by anchors and Lie algebra commutators and nontrivial N-connection structure).[2] It is possible to extend the constructions on Clifford N-algebroids by introducing spinor variables. In this section we shall analyze the basic field equations for gravitational and matter field interactions modeled on N-anholonomic manifolds and Clifford N-algebroids.

A. The Dirac operator on *N*-anholonomic spaces

The aim of this section is to elucidate the possibility of definition of Dirac operators for general N-anholonomic manifolds. It should be noted that such geometric constructions depend on the type of linear connections which are used for the complete definition of the Dirac operator. They are metric compatible and N-adapted if the canonical d-connection is used (we can similarly use any of its deformations resulting in a metric compatible d-connection).

1. Noholonomic vielbeins and spin d-connections

For a local dual coordinate basis $e^{\underline{i}}\doteq \mathrm{d}x^{\underline{i}}$ on a manifold M, $\dim M=n$, we may respectively, introduce certain classes of orthonormalized vielbeins and the N-adapted vielbeins (depending both on the base coordinates $x\doteq x^i$ and some "fiber" coordinates $y\doteq y^a$)

$$e^{\hat{i}} \doteq e^{\hat{i}}_{\underline{i}}(x,y)e^{\underline{i}}, \quad e^{i} \doteq e^{i}_{\underline{i}}(x,y)e^{\underline{i}}, \tag{37}$$

where

$$g^{\underline{ij}}(x,y)e^{\hat{i}}_{\underline{i}}(x,y)e^{\hat{j}}_{\underline{j}}(x,y)=\delta^{\hat{i}\hat{j}},\quad g^{\underline{ij}}(x,y)e^{i}_{\underline{i}}(x,y)e^{j}_{\underline{j}}(x,y)=g^{ij}(x,y).$$

We define the algebra of Dirac's gamma matrices (in brief, h-gamma matrices defined by self-adjoint matrices $M_k(\mathbb{C})$ where $k=2^{n/2}$ is the dimension of the irreducible representation of $\mathbb{C}l(M)$ for even dimensions, or of $\mathbb{C}l(M)^+$ for odd dimensions) from the relation

$$\gamma^{\hat{j}}\gamma^{\hat{j}}+\gamma^{\hat{j}}\gamma^{\hat{j}}=2\delta^{\hat{i}\hat{j}}\mathbb{I}. \tag{38}$$

We can consider the action of $\mathrm{d}x^i\in\mathbb{C}l(M)$ on a spinor $\psi\in S$ via representations

$$^{-}c(\mathrm{d}x^{\hat{i}})\doteq\gamma^{\hat{j}},\quad {}^{-}c(\mathrm{d}x^{i})\psi\doteq\gamma^{j}\psi\equiv e^{i}_{\ \hat{i}}\gamma^{\hat{j}}\psi. \tag{39}$$

For any type of spaces T_xM, TM or $\mathbf{V}$ possessing a local (in any point) or global fibered structure and enabled with a N-connection structure, we can introduce similar definitions of the gamma matrices following algebraic relations and metric structures on fiber subspaces,

$$e^{\hat{a}}\doteq e^{\hat{a}}_{\underline{a}}(x,y)e^{\underline{a}},\quad e^{a}\doteq e^{a}_{\underline{a}}(x,y)e^{\underline{a}}, \tag{40}$$

where

$$g^{\underline{ab}}(x,y)e^{\hat{a}}_{\underline{a}}(x,y)e^{\hat{b}}_{\underline{b}}(x,y)=\delta^{\hat{a}\hat{b}},\quad g^{\underline{ab}}(x,y)e^{a}_{\underline{a}}(x,y)e^{b}_{\underline{b}}(x,y)=h^{ab}(x,y).$$

Similarly, we define the algebra of Dirac's matrices related to typical fibers (in brief, v-gamma matrices described by self-adjoint matrices $M'_k(\mathbb{C})$ where $k'=2^{m/2}$ is the dimension of the irreducible representation of $\mathbb{C}l(F)$ for even dimensions, or of $\mathbb{C}l(F)^+$ for odd dimensions, of the typical fiber F) from the relation

$$\gamma^{\hat{a}}\gamma^{\hat{b}}+\gamma^{\hat{b}}\gamma^{\hat{a}}=2\delta^{\hat{a}\hat{b}}\mathbb{I}. \tag{41}$$

The formulas (38) and (41) are respectively, the h- and v-components of relation (18) (with redefined coefficients which is more convenient for further constructions). The action of $\mathrm{d}y^a\in\mathbb{C}l(F)$ on a spinor ${}^{\star}\psi\in{}^{\star}S$ is considered via representations

$$^{\star}c(\mathrm{d}y^{\hat{a}})\doteq\gamma^{\hat{a}},\quad {}^{\star}c(\mathrm{d}y^{a})^{\star}\psi\doteq\gamma^{a\star}\psi\equiv e^{a}_{\ \hat{a}}\gamma^{\hat{a}\star}\psi. \tag{42}$$

We note that in additionally to formulas (39) and (42) we may write, respectively,

$$c(\mathrm{d}x^{\underline{i}})\psi\doteq\gamma^{\underline{i}}\psi\equiv e^{\underline{i}}_{\ i}\gamma^{\hat{j}}\psi,\quad c(\mathrm{d}y^{\underline{a}})^{\star}\psi\doteq\gamma^{\underline{a}\star}\psi\equiv e^{\underline{a}}_{e^{a}\ \hat{a}}\gamma^{\hat{a}\star}\psi$$

but such operators are not adapted to the N-connection structure.

A more general gamma matrix calculus with distinguished gamma matrices (in brief, d-gamma matrices) can be elaborated for any N-anholonomic manifold $\mathbf{V}$ provided with d-metric structure $\mathbf{g}=[g,{}^{\star}g]$ and for d-spinors $\breve{\psi}\doteq(\psi,{}^{\star}\psi)\in\mathbf{S}\doteq(S,{}^{\star}S)$. First, we should write in a unified form, related to a d-metric (1), formulas (37) and (40),

$$e^{\ \hat{\alpha}}\doteq e^{\hat{\alpha}}_{\underline{a}}(u)e^{\underline{\alpha}},\quad e^{\alpha}\doteq e^{\alpha}_{\ \underline{a}}(u)e^{\underline{\alpha}}, \tag{43}$$

where

$$g^{\underline{\alpha\beta}}(u)e^{\hat{\alpha}}_{\ \underline{\alpha}}(u)e^{\hat{\beta}}_{\ \underline{\beta}}(u)=\delta^{\hat{\alpha}\hat{\beta}},\quad g^{\underline{\alpha\beta}}(u)e^{\alpha}_{\ \underline{\alpha}}(u)e^{\beta}_{\ \underline{\beta}}(u)=g^{\alpha\beta}(u).$$

The second step is to consider gamma d-matrix relations (unifying (38) and (41))

$$\gamma^{\hat{\alpha}}\gamma^{\hat{\beta}}+\gamma^{\hat{\beta}}\gamma^{\hat{\alpha}}=2\delta^{\hat{\alpha}\hat{\beta}}\mathbb{I}, \tag{44}$$

with the action of $\mathrm{d}u^{\alpha}\in\mathbb{C}l(\mathbf{V})$ on a d-spinor $\breve{\psi}\in\mathbf{S}$ resulting in distinguished irreducible representations (unifying (39) and (42))

$$\mathbf{c}(\mathrm{d}u^{\hat{\alpha}})\doteq\gamma^{\hat{\alpha}},\quad \mathbf{c}=(\mathrm{d}u^{\alpha})\breve{\psi}\doteq\gamma^{\alpha}\breve{\psi}\equiv e^{\alpha}_{\ \hat{\alpha}}\gamma^{\hat{\alpha}}\breve{\psi}, \tag{45}$$

which allows one to write

$$\gamma^{\alpha}(u)\gamma^{\beta}(u)+\gamma^{\beta}(u)\gamma^{\alpha}(u)=2g^{\alpha\beta}(u)\mathbb{I}. \tag{46}$$

In the canonical representation, we can write in irreducible form $\breve{\gamma}\doteq\gamma\oplus{}^{\star}\gamma$ and $\breve{\psi}\doteq\psi\oplus{}^{\star}\psi$, for instance, by using block type of h- and v-matrices, or, writing alternatively as couples of gamma and/or h- and v-spinor objects written in N-adapted form,

$$\gamma^{\alpha}\doteq(\gamma^{i},\gamma^{a}),\quad \breve{\psi}\doteq(\psi,{}^{\star}\psi). \tag{47}$$

The decomposition (46) holds with respect to a N-adapted vielbein (3). We also note that for a spinor calculus, the indices of spinor objects should be treated as abstract spinorial ones possessing certain reducible, or irreducible, properties depending on the space dimension. For simplicity, we shall consider that spinors like $\breve{\psi},\psi,{}^{\star}\psi$ and all types of gamma objects can be enabled with corresponding spinor indices running certain values which are different from the usual coordinate space indices.

The spin connection ∇^{S} for the Riemannian manifolds is induced by the Levi-Civita connection ${}^{\nabla}\Gamma$,

$$\nabla^{S}\doteq d-\frac{1}{4}{}^{\nabla}\Gamma^{i}_{jk}\gamma_{i}\gamma^{j}\mathrm{d}x^{k}. \tag{48}$$

On N-anholonomic spaces, it is possible to define spin connections which are N-adapted by replacing the Levi-Civita connection by any d-connection.

The canonical spin d-connection is defined by the canonical d-connection,

$$\hat{\nabla}^{\mathbf{S}}\doteq\delta-\frac{1}{4}\hat{\mathbf{\Gamma}}^{\alpha}_{\ \beta\mu}\gamma_{\alpha}\gamma^{\beta}\delta u^{\mu}, \tag{49}$$

where the absolute differential δ acts in N-adapted form resulting in one-forms decomposed with respect to N-elongated differentials $\delta u^{\mu}=(\mathrm{d}x^{i},\delta y^{a})$ (2).

We note that the canonical spin d-connection $\hat{\nabla}^{\mathbf{S}}$ is metric compatible and contains nontrivial d-torsion coefficients induced by the N-anholonomy relations. It is possible to introduce more general spin d-connections $\mathbf{D}^{\mathbf{S}}$ by using the same formula (49) but for arbitrary metric compatible d-connection $\mathbf{\Gamma}^{\alpha}_{\beta\mu}$. For the spaces provided with generic off-diagonal metric structure (1) on a N-anholonomic manifold, there is a canonical spin d-connection (49) induced by the off-diagonal metric coefficients with nontrivial N^{a}_{i} and associated nonholonomic frames in gravity theories.

In a particular case of N-anholonomic manifolds of even dimensions, we can define, for instance, the canonical spin d-connections for a local modeling of a tangent bundle space with the canonical d-connection $\hat{\mathbf{\Gamma}}^{\gamma}_{\alpha\beta}=(\hat{L}^{i}_{jk},\hat{B}^{i}_{jk})$. The N-connection structure N^{j}_{i} states a global h- and v-splitting of the spin d-connection operators, for instance,

$$\hat{\nabla}\doteq\delta-\frac{1}{4}\hat{L}^{i}_{\ jk}\gamma_{i}\gamma^{j}\mathrm{d}x^{k}-\frac{1}{4}\hat{B}^{a}_{\ bc}\gamma_{a}\gamma^{b}\delta y^{c}. \tag{50}$$

So, any spin d-connection is a d-operator with conventional splitting of action like $\nabla^{(\mathbf{S})}\equiv({}^{-}\nabla^{(\mathbf{S})},{}^{\star}\nabla^{(\mathbf{S})})$, or $\nabla\equiv({}^{-}\nabla,{}^{\star}\nabla)$. For instance, for $\hat{\nabla}\equiv({}^{-}\hat{\nabla},{}^{\star}\hat{\nabla})$, the operators ${}^{-}\hat{\nabla}$ and ${}^{\star}\hat{\nabla}$ act, respectively, on a h-spinor ψ as

$$^{-}\hat{\nabla}\psi \doteq \mathrm{d}x^i \frac{\delta\psi}{\partial x^i} - \mathrm{d}x^k \frac{1}{4}\hat{L}^i_{jk}\gamma_i\gamma^j\psi \tag{51}$$

and

$$^{\star}\hat{\nabla}\psi \doteq \delta y^a \frac{\partial\psi}{\partial y^a} - \delta y^c \frac{1}{4}\hat{B}^a_{bc}\gamma_a\gamma^b\psi$$

being defined by the canonical d-connection, which (in its turn) is completely defined by $N^j_i(x,y)$ and $g_{ij}(x,y)$.

The operators (51) can be adapted to the Lie algebroid structure by anchoring the partial v-derivatives. For instance,

$$\frac{\delta\psi}{\partial x^i}(x^k,y^b(x^j)) = \frac{\partial\psi}{\partial x^i} - N^a_i\frac{\partial\psi}{\partial y^a} = \left(\frac{\partial\psi}{\partial x^i} - N^a_i\rho^k_a(x^j)\frac{\partial\psi}{\partial x^k}\right) = \left(\frac{\partial\psi}{\partial x^i} - {}^{\rho}N^k_i\frac{\partial\psi}{\partial x^k}\right)(x^k,y^b(x^j))$$

where the anchor ρ^k_a (7) induces a N-connection ${}^{\rho}N^k_i \doteq N^a_i\rho^k_a$. We can also perform a N-adapted Clifford algebroid calculus by using the "boldface" algebroid $\hat{\rho}^j_a$ (15) with explicit dependence on variables y^b,

$$\frac{\delta\psi}{\partial x^i}(x^k,y^b) = \frac{\partial\psi}{\partial x^i} - N^a_i e_a\psi = \left(\frac{\partial\psi}{\partial x^i} - N^a_i\hat{\rho}^k_a\frac{\partial\psi}{\partial x^k}\right) = \left(\frac{\partial\psi}{\partial x^i} - {}^{\rho}\hat{N}^k_i\frac{\partial\psi}{\partial x^k}\right)$$

for ${}^{\rho}\hat{N}^k_i = N^a_i\hat{\rho}^k_a$. Such anchoring of partial/N-elongated derivatives has to be considered for the canonical d-connection $\hat{L}^i_{jk}$ and $\hat{B}^a_{bc}$.

2. Dirac d-operators

We consider a vector bundle $\mathbf{E}$ on an N-anholonomic manifold M (with two compatible N-connections defined as h- and v-splittings of $T\mathbf{E}$ and TM)). A d-connection

$$\mathcal{D}:\mathrm{Sec}^{\infty}(\mathbf{E}) \to \mathrm{Sec}^{\infty}(\mathbf{E}) \otimes \Omega^1(M)$$

preserves by parallelism splitting of the tangent total and base spaces and satisfy the Leibniz condition

$$\mathcal{D}(f\sigma) = f(\mathcal{D}\sigma) + \delta f \otimes \sigma$$

for any $f \in C^{\infty}(M)$, and $\sigma \in \mathrm{Sec}^{\infty}(\mathbf{E})$ and δ defining an N-adapted exterior calculus by using N-elongated operators (3) and (2) which emphasize d-forms instead of usual forms on M, with the coefficients taking values in $\mathbf{E}$.

The metricity and Leibniz conditions for $\mathcal{D}$ are written, respectively,

$$\mathbf{g}(\mathcal{D}\mathbf{X},\mathbf{Y}) + \mathbf{g}(\mathbf{X},\mathcal{D}\mathbf{Y}) = \delta[\mathbf{g}(\mathbf{X},\mathbf{Y})], \tag{52}$$

for any $\mathbf{X},\mathbf{Y} \in \chi(M)$, and

$$\mathcal{D}(\sigma\beta) \doteq \mathcal{D}(\sigma)\beta + \sigma\mathcal{D}(\beta), \tag{53}$$

for any $\sigma,\beta \in \mathrm{Sec}^{\infty}(\mathbf{E})$.

For local computations, we may define the corresponding coefficients of the geometric d-objects and write

$$\mathcal{D}\sigma_{\check{\beta}} \doteq \mathbf{\Gamma}^{\check{\alpha}}_{\check{\beta}\mu}\sigma_{\check{\alpha}} \otimes \delta u^{\mu} = \mathbf{\Gamma}^{\check{\alpha}}_{\check{\beta}i}\sigma_{\check{\alpha}} \otimes \mathrm{d}x^i + \mathbf{\Gamma}^{\check{\alpha}}_{\check{\beta}a}\sigma_{\check{\alpha}} \otimes \delta y^a,$$

where fiber "inverse-caret" indices, in their turn, may split $\check{\alpha} \doteq (\check{i},\check{a})$ if any N-connection structure is defined on $T\mathbf{E}$. For some constructions of particular interest, we can take $\mathbf{E} = T^*\mathbf{V}$, $= T^*V_{(g)}$

and/or any Clifford d-algebra $\mathbf{E}=\mathbb{C}l(\mathbf{V}),\mathbb{C}l(V_{(g)}),\ldots$ with a corresponding treating of "acute" indices to d-tensor and/or d-spinor type as well when the d-operator $\mathcal{D}$ transforms into respective d-connection $\mathbf{D}$ and spin d-connections $\hat{\nabla}^{\mathbf{S}}$ (49), $\hat{\nabla}^{(g)}\ldots$. All such, adapted to the N-connections, computations are similar for both N-anholonomic (co) vector and spinor bundles.

The respective actions of the Clifford d-algebra and the Clifford-Lagrange algebra can be transformed into maps $\mathrm{Sec}^{\infty}(\mathbf{S})\otimes\mathrm{Sec}(\mathbb{C}l(\mathbf{V}))$ and $\mathrm{Sec}^{\infty}(S_{(g)})\otimes\mathrm{Sec}(\mathbb{C}l(V_{(g)}))$ to $\mathrm{Sec}^{\infty}(\mathbf{S})$ and, respectively, $\mathrm{Sec}^{\infty}(S_{(g)})$ by considering maps of type (39) and (45)

$$\hat{\mathbf{c}}(\breve{\psi}\otimes\mathbf{a})\doteqdot\mathbf{c}(\mathbf{a})\breve{\psi},\quad \hat{c}(\psi\otimes a)\doteqdot c(a)\psi.$$

Definition 3.1: *The Dirac d-operator* (*or Dirac N-anholonomic operator*) *on a spin N-anholonomic manifold* $(\mathbf{V},\mathbf{S},J)$ (*or on a spin manifold* $(M_{(g)},S_{(g)},J)$) *is defined*

$$\mathbb{D}\doteqdot -i(\hat{\mathbf{c}}\circ\nabla^{\mathbf{S}})$$

$$=({}^{-}\mathbb{D}=-i({}^{-}\hat{c}\circ{}^{-}\nabla^{\mathbf{S}}),{}^{\star}\mathbb{D}=-\mathbf{i}({}^{\star}\hat{c}\circ{}^{\star}\nabla^{\mathbf{S}})) \tag{54}$$

$$({}_{(g)}\mathbb{D}\doteqdot -i(\hat{c}\circ\nabla^{(g)}))$$

$$=({}_{(g)}{}^{-}\mathbb{D}=-i({}^{-}\hat{c}\circ{}^{-}\nabla^{(g)}),{}^{\star}_{(g)}\mathbb{D}=-i({}^{\star}\hat{c}\circ{}^{\star}\nabla^{(g)})). \tag{55}$$

Such N-adapted Dirac d-operators are called canonical and denoted $\hat{\mathbb{D}}=({}^{-}\hat{\mathbb{D}},{}^{-\star}\hat{\mathbb{D}})$ $({}_{(g)(g)}\hat{\mathbb{D}}=({}_{(g)}{}^{-}\hat{\mathbb{D}},{}^{\star}_{(g)}\hat{\mathbb{D}}))$ *if they are defined for the canonical d-connection and respective spin d-connection* (49).

Now we can formulate the

Theorem 3.1: *Let* $(\mathbf{V},\mathbf{S},J)$ $((M_{(g)},S_{(g)},J)$ *be a spin N-anholonomic manifold. There is the canonical Dirac d-operator* (*Dirac N-anholonomic operator*) *defined by the almost Hermitian spin d-operator*

$$\hat{\nabla}^{\mathbf{S}}:\mathrm{Sec}^{\infty}(\mathbf{S})\to\mathrm{Sec}^{\infty}(\mathbf{S})\otimes\Omega^{1}(\mathbf{V})$$

(*N-anholonomic spin operator*

$$\hat{\nabla}^{(g)}:\mathrm{Sec}^{\infty}(S_{(g)})\to\mathrm{Sec}^{\infty}(S_{(g)})\otimes\Omega^{1}(M_{(g)})$$

commuting with J and satisfying the conditions

$$(\hat{\nabla}^{\mathbf{S}}\breve{\psi}|\breve{\phi})+(\breve{\psi}|\hat{\nabla}^{\mathbf{S}}\breve{\phi})=\delta(\breve{\psi}|\breve{\phi}) \tag{56}$$

and

$$\hat{\nabla}^{\mathbf{S}}(\mathbf{c}(\mathbf{a})\breve{\psi})=\mathbf{c}(\hat{\mathbf{D}}\mathbf{a})\breve{\psi}+\mathbf{c}(\mathbf{a})\hat{\nabla}^{\mathbf{S}}\breve{\psi}$$

for $\mathbf{a}\in\mathbb{C}l(\mathbf{V})$ *and* $\breve{\psi}\in\mathrm{Sec}^{\infty}(\mathbf{S})$,

$$((\hat{\nabla}^{(g)}\breve{\psi}|\breve{\phi})+(\breve{\psi}|\hat{\nabla}^{(g)}\breve{\phi})=\delta(\breve{\psi}|\breve{\phi}) \tag{57}$$

and

$$\hat{\nabla}^{(g)}(\mathbf{c}(\mathbf{a})\breve{\psi})=\mathbf{c}(\hat{\mathbf{D}}\mathbf{a})\breve{\psi}+\mathbf{c}(\mathbf{a})\hat{\nabla}^{(g)}\breve{\psi}$$

for $\mathbf{a}\in\mathbb{C}l(M_{(g)})$ *and* $\breve{\psi}\in\mathrm{Sec}^{\infty}(S_{(g)})$ *determined by the metricity* (52) *and Leibnitz* (53) *conditions.*[22,23]

Proof: We sketch the main idea of such a proof being similar to that given in Ref. 24, Theorem 9.8, for the Levi-Civita connection, see also Ref. 25. In our case, we have to extend the constructions for d-metrics and canonical d-connections by applying N-elongated operators for differentials and partial derivatives and distinguishing the formulas into h- and v-irreducible components. □

The canonical Dirac d-operator has very similar properties for spin N-anholonomic manifolds and spin Lagrange, or Finsler spaces.[11–13,7]

B. Field equations on *N*-anholonomic manifolds

The general idea is to formulate such equations with respect to a nonholonomic frame on (pseudo) Riemann–Cartan space. Then the constructions are N-adapted by considering N-elongated frames. For Lie/Clifford N-algebroid structures, we have to anchor the formulas.

1. Scalar field on N-anholonomic manifolds

Let $\varphi(u)=(\varphi_1(u),\varphi_2(u);\ldots,\varphi_k(u))$ be a complex k-component scalar field of mass μ on a N-anholonomic manifold $\mathbf{V}$. The d-covariant generalization of the conformally invariant (in the massless case) scalar field equation[19,20] can be defined by using the d'Alambert operator $\Box=\mathbf{D}^{\alpha}\mathbf{D}_{\alpha}$, where $\mathbf{D}_{\alpha}$ is a metric compatible d-connection,

$$\left(\Box+\frac{n+m-2}{4(n+m-1)}\overleftarrow{R}+\mu^2\right)\varphi(u)=0. \tag{58}$$

We have to elongate the covariant d-operator, $\check{D}_{\alpha}=\mathbf{D}_{\alpha}+ieA_{\alpha}$, and take into account the d-vector current

$$J^{(0)}_{\alpha}(u)=i((\overline{\varphi}(u)\mathbf{D}_{\alpha}\varphi(u)-\mathbf{D}_{\alpha}\overline{\varphi}(u))\varphi(u))$$

if there are considered interactions with the electromagnetic field (d-vector potential A_{α}), where e is the electromagnetic constant, and a charged scalar field φ. Equation (58) is just the Euler equations for the Lagrangian

$$\mathcal{L}^{(0)}(u)=\sqrt{|g|}\left[\mathbf{g}^{\alpha\beta}e_{\alpha}\overline{\varphi}(u)e_{\beta}\varphi(u)-\left(\mu^2+\frac{n+m-2}{4(n+m-1)}\right)\overline{\varphi}(u)\varphi(u)\right], \tag{59}$$

where $|g|=\det|\mathbf{g}_{\alpha\beta}|$ and $\mathbf{e}_{\alpha}$ is defined by (3), and must be anchored for Lie algebroid structures.

The N-adapted variations of the action with Lagrangian (59) on variables $\varphi(u)$ and $\overline{\varphi}(u)$ lead to the energy-momentum d-tensor,

$$E^{(0,c)}_{\alpha\beta}(u)=\mathbf{e}_{\alpha}\overline{\varphi}(u)\mathbf{e}_{\beta}\varphi(u)+\mathbf{e}_{\beta}\overline{\varphi}(u)\mathbf{e}_{\alpha}\varphi(u)-\frac{1}{\sqrt{|g|}}\mathbf{g}_{\alpha\beta}\mathcal{L}^{(0)}(u), \tag{60}$$

and a similar variation on the components of a d-metric (1) leads to a symmetric energy-momentum d-tensor,

$$E^{(0)}_{\alpha\beta}(u)=E^{(0,c)}_{(\alpha\beta)}(u)-\frac{n+m-2}{2(n+m-1)}[\mathbf{R}_{(\alpha\beta)}+\mathbf{D}_{(\alpha\mathbf{D}_{\beta)}}-\mathbf{g}_{\alpha\beta}\Box]\overline{\varphi}(u)\varphi(u). \tag{61}$$

We also conclude that the N-connection results in a nonequivalence of energy–momentum d-tensors (60) and (61), nonsymmetry of the Ricci tensor, non-vanishing of the d-covariant derivation of the Einstein d-tensor, $\mathbf{D}_{\alpha}\overleftarrow{\mathbf{G}}^{\alpha\beta}\neq 0$ and, in consequence, a corresponding modification of conservation laws on N-anholonomic manifolds.[27]

2. Proca equations

Let us consider a d-vector field $\varphi_\alpha(u)$ with mass μ^2 (Proca field) interacting with exterior gravitational field. From the Lagrangian

$$\mathcal{L}^{(1)}(u) = \sqrt{|\mathbf{g}|}\left[-\tfrac{1}{2}\overline{f}_{\alpha\beta}(u)f^{\alpha\beta}(u) + \mu^2\overline{\varphi}_\alpha(u)\varphi^\alpha(u)\right], \tag{62}$$

where

$$f_{\alpha\beta} = \mathbf{D}_\alpha\varphi_\beta - \mathbf{D}_\beta\varphi_\alpha,$$

one follows the Proca equations on N-anholonomic manifolds

$$\mathbf{D}_\alpha f^{\alpha\beta}(u) + \mu^2\varphi^\beta(u) = 0. \tag{63}$$

Equation (63) transforms into a first type constraints for $\beta=0$. Acting with $\mathbf{D}_\alpha$ on (63), for $\mu \neq 0$ we obtain second type constraints

$$\mathbf{D}_\alpha\varphi^\alpha(u) = 0. \tag{64}$$

Putting (64) into (63) we obtain second-order field equations with respect to φ_α:

$$\Box\varphi_\alpha(u) + \mathbf{R}_{\alpha\beta}\varphi^\beta(u) + \mu^2\varphi_\alpha(u) = 0. \tag{65}$$

Anchoring of derivatives has to be considered for the operators $\mathbf{D}_\alpha$ and (as a consequence) for $\Box$ and $\mathbf{R}_{\alpha\beta}$. The energy-momentum d-tensor and d-vector current following from the (65) can be written

$$E^{(1)}_{\alpha\beta}(u) = -\mathbf{g}^{\varepsilon\tau}(\overline{f}_{\beta\tau}f_{\alpha\varepsilon} + \overline{f}_{\alpha\varepsilon}f_{\beta\tau}) + \mu^2(\overline{\varphi}_\alpha\varphi_\beta + \overline{\varphi}_\beta\varphi_\alpha) - \frac{\mathbf{g}_{\alpha\beta}}{\sqrt{|\mathbf{g}|}}\mathcal{L}^{(1)}(u).$$

and

$$J^{(1)}_\alpha(u) = i(\overline{f}_{\alpha\beta}(u)\varphi^\beta(u) - \overline{\varphi}^\beta(u)f_{\alpha\beta}(u)).$$

For $\mu=0$ the d-tensor $f_{\alpha\beta}$ and the Lagrangian (62) are invariant with respect to gauge transforms of type

$$\varphi_\alpha(u) \to \varphi_\alpha(u) + \delta_\alpha\Lambda(u),$$

where $\Lambda(u)$ is a d-differentiable scalar function, and we obtain a variant of Maxwell theory on N-anholonomic manifolds.

3. Gravitons N-anholonomic backgrounds

Let us consider a massless d-tensor field $\mathbf{q}_{\alpha\beta}(u)$ as a small perturbation of the d-metric $\mathbf{g}_{\alpha\beta}(u)$. Considering, for simplicity, a torsionless background we have the Fierz–Pauli equations

$$\Box\mathbf{q}_{\alpha\beta}(u) + 2\mathbf{R}_{\tau\alpha\beta\nu}(u)\mathbf{q}^{\tau\nu}(u) = 0 \tag{66}$$

and d-gauge conditions

$$D_\alpha\mathbf{q}^\alpha_\beta(u) = 0, \quad \mathbf{q}(u) \equiv \mathbf{q}^\alpha_\beta(u) = 0, \tag{67}$$

where $\mathbf{R}_{\tau\alpha\beta\nu}(u)$ is curvature d-tensor (these formulas can be obtained by using a perturbation formalism with respect to $\mathbf{q}_{\alpha\beta}(u)$; in our case we must take into account the distinguishing of geometrical objects.

We note that we can rewrite d-tensor formulas (58)–(67) into similar d-spinor ones by considering spinor variables.

4. N-anholonomic Dirac equation

Let us denote the Dirac d-spinor field by $\psi(u)=(\psi^{\acute{\alpha}}(u))$ and consider as the generalized Lorentz transforms the group of automorphysm of the metric $g_{\hat{\alpha}\hat{\beta}}$ (for a N-adapted frame decomposition of d-metric). The d-covariant derivation of field $\psi(u)$ is written as

$$\overrightarrow{\nabla}_{\alpha}\psi=\left[\mathbf{e}_{\alpha}+\tfrac{1}{4}C_{\hat{\alpha}\hat{\beta}\hat{\gamma}}(u)l^{\hat{\alpha}}_{\alpha}(u)\gamma^{\hat{\beta}}\gamma^{\hat{\gamma}}\right]\psi, \tag{68}$$

where coefficients $C_{\hat{\alpha}\hat{\beta}\hat{\gamma}}=(\mathbf{D}_{\gamma}l^{\alpha}_{\hat{\alpha}})l_{\hat{\beta}\alpha}l^{\gamma}_{\hat{\gamma}}$ generalize for N-anholonomic spaces the corresponding Ricci coefficients on Riemannian spaces. Using γ-objects $\gamma^{\alpha}(u)$ (see (19)), we define the Dirac equations on N-anholonomic manifolds:

$$(i\gamma^{\alpha}(u)\overrightarrow{\nabla}_{\alpha}-\mu)\psi=0, \tag{69}$$

which are the Euler equations for the Lagrangian

$$\mathcal{L}^{(1/2)}(u)=\sqrt{|g|}\{[\psi^{+}(u)\gamma^{\alpha}(u)\overrightarrow{\nabla}_{\alpha}\psi(u)-(\overrightarrow{\nabla}_{\alpha}\psi^{+}(u))\gamma^{\alpha}(u)\psi(u)]-\mu\psi^{+}(u)\psi(u)\}, \tag{70}$$

where $\psi^{+}(u)$ is the complex conjugation and transposition of the column $\psi(u)$. We have to consider anchoring of the operator $\overrightarrow{\nabla}_{\alpha}$ on the N-anholonomic manifolds.

From (70), we obtain the d-metric energy-momentum d-tensor

$$E^{(1/2)}_{\alpha\beta}(u)=\frac{i}{4}[\psi^{+}(u)\gamma_{\alpha}(u)\overrightarrow{\nabla}_{\beta}\psi(u)+\psi^{+}(u)\gamma_{\beta}(u)\overrightarrow{\nabla}_{\alpha}\psi(u)-(\overrightarrow{\nabla}_{\alpha}\psi^{+}(u))\gamma_{\beta}(u)\psi(u)$$
$$-(\overrightarrow{\nabla}_{\beta}\psi^{+}(u))\gamma_{\alpha}(u)\psi(u)]$$

and the d-vector source

$$J^{(1/2)}_{\alpha}(u)=\psi^{+}(u)\gamma_{\alpha}(u)\psi(u).$$

We emphasize that interactions with exterior gauge fields can be introduced by changing the locally anisotropic partial derivation from (68) in this manner:

$$e_{\alpha}\rightarrow e_{\alpha}+ie^{\star}B_{\alpha}, \tag{71}$$

where $e^{\star}$ and B_{α} are, respectively, the constant and the d-vector potential of gauge fields.

5. Yang–Mills equations in d-spinor form

We consider a vector bundle $\mathcal{B}_E,\pi_B:\mathcal{B}\rightarrow\mathbf{V}$ on $\mathbf{V}$. Additionally to the d-tensor and d-spinor indices, we use capital Greek letters, $\Phi,\Upsilon,\Xi,\Psi,\ldots$ for fiber (of this bundle) indices (see details in Refs. 19 and 20). Let $\underline{\nabla}_{\alpha}$ be, for simplicity, a torsionless, linear connection in $\mathcal{B}_E$ satisfying conditions:

$$\underline{\nabla}_{\alpha}:\Upsilon^{\Theta}\rightarrow\Upsilon^{\Theta}_{\alpha}[\text{or}\Xi^{\Theta}\rightarrow\Xi^{\Theta}_{\alpha}],$$

$$\underline{\nabla}_{\alpha}(\lambda^{\Theta}+\nu^{\Theta})=\underline{\nabla}_{\alpha}\lambda^{\Theta}+\underline{\nabla}_{\alpha}\nu^{\Theta},$$

$$\underline{\nabla}_{\alpha}(f\lambda^{\Theta})=\lambda^{\Theta}\underline{\nabla}_{\alpha}f+f\underline{\nabla}_{\alpha}\lambda^{\Theta},\quad f\in\Upsilon^{\Theta}[\text{or}\Xi^{\Theta}],$$

where by $\Upsilon^{\Theta}(\Xi^{\Theta})$ we denote the module of sections of the real (complex) v-bundle $\mathcal{B}_E$ provided with the abstract index Θ. The curvature of connection $\underline{\nabla}_{\alpha}$ is defined as

$$K_{\alpha\beta\Omega}{}^{\Theta}\lambda^{\Omega}=(\underline{\nabla}_{\alpha}\underline{\nabla}_{\beta}-\underline{\nabla}_{\beta}\underline{\nabla}_{\alpha})\lambda^{\Theta}.$$

For Yang–Mills fields, as a rule, one considers that $\mathcal{B}_E$ is enabled with a unitary (complex) structure (complex conjugation changes mutually the upper and lower Greek indices). It is useful to introduce instead of $K_{\alpha\beta\Omega}{}^{\Theta}$ a Hermitian matrix $F_{\alpha\beta\Omega}{}^{\Theta}=i\,K_{\alpha\beta\Omega}{}^{\Theta}$ connected with components of the Yang–Mills d-vector potential $B_{\alpha\Xi}{}^{\Phi}$ according the formula:

$$\frac{1}{2}F_{\alpha\beta\Xi}{}^{\Phi}=\underline{\nabla}_{[\alpha}B_{\beta]\Xi}{}^{\Phi}-iB^{\Phi}_{[\alpha|\Lambda|}B_{\beta]\Xi}{}^{\Lambda}, \tag{72}$$

where the spacetime indices commute with capital Greek indices. The gauge transforms are written in the form:

$$B_{\alpha\Theta}{}^{\Phi}\mapsto B_{\alpha\hat{\Theta}}{}^{\hat{\Phi}}=B^{\Phi}_{\alpha\Theta}s^{\hat{\Phi}}_{\Phi}q^{\Theta}_{\hat{\Theta}}+is^{\hat{\Phi}}_{\Theta}\underline{\nabla}_{\alpha}q_{\hat{\Theta}}{}^{\Theta},$$

$$F_{\alpha\beta\Xi}{}^{\Phi}\mapsto F_{\alpha\beta\hat{\Xi}}{}^{\hat{\Phi}}=F_{\alpha\beta\Xi}{}^{\Phi}s^{\hat{\Phi}}_{\Phi}q_{\hat{\Xi}}{}^{\Xi},$$

where matrices $s^{\hat{\Phi}}_{\Phi}$ and $q^{\Xi}_{\hat{\Xi}}$ are mutually inverse (Hermitian conjugated in the unitary case). The Yang–Mills d-equations are written

$$\underline{\nabla}^{\alpha}F_{\alpha\beta\Theta}{}^{\Psi}=J_{\beta\Theta}{}^{\Psi}, \tag{73}$$

$$\underline{\nabla}_{[\alpha}F_{\beta\gamma]\Theta}{}^{\Xi}=0. \tag{74}$$

We must introduce deformations of connection of type, $\nabla^{\star}_{\alpha}-\rightarrow\underline{\nabla}_{\alpha}+P_{\alpha}$, (the deformation d-tensor P_{α} is induced by the torsion in the vector bundle $\mathcal{B}_E$) into the definition of the curvature of gauge fields (72) and motion equations (73) and (74) if the interactions are considered for nontrivial torsions.

IV. CONCLUSIONS AND OUTLOOK

In this work we formulated a spinor approach to the geometry of nonholonomic spacetimes and classical field interactions with constraints possessing Lie algebroid symmetry. Such geometric constructions are performed for a special case of nonholonomic distributions defining nonlinear connection (N-connection) structures resulting in preferred classes of vielbein (frame) systems of reference. The main goals we have achieved are the following:

(1) We gave an intrinsic formulation of the geometry of Clifford N-anholonomic structures. In addition, we investigated the N-anholonomic spin structures (i.e., spinor nonholonomic spaces with associated N-connection).
(2) We defined and analyzed the main properties of the Dirac operator on N-anholonomic manifolds. We showed how the formulas may be "anchored" in order to be considered on spacetimes with Lie/ Clifford algebroid symmetries.
(3) We formulated a geometric approach to field equations on N-anholonomic manifolds. There were considered the examples of scalar, Proca, graviton, spinor and gauge filed interactions when the formulas have a straightforward redefinition on Lie/Clifford N-algebroids (i.e., spacetimes with algebroid symmetries and nonholonomic distributions).

Among the subjects we will study in forthcoming papers, we note the following points:

- To construct exact solutions of the gravitational field equations in string gravity with nontrivial limits to general relativity, parametrized by generic off-diagonal metrics and nonholonomic frames and possessing Lie algebroid symmetries (the first examples of "gravitational" algebroids were analyzed in Ref. 2).

- Certain extension of the metrics to configurations defining solutions of the Einstein–Dirac equations will be considered. We shall analyze the symmetries of such spacetimes and possible physical applications in modern gravity.
- In explicit form, we shall construct nonholonomically deformed metrics, with algebroid symmetries, describing locally anisotropic cosmological models, black holes, anholonomic wormholes, solitons, and gravitational monopoles and instantons.
- To make a detailed investigation of classical field theories and their quantum deformations possessing nontrivial noncommutative symmetries and possible Lie/ Clifford algebroid structure.

Finally, we note that the method of anholonomic frames with associated *N*-connection structure elaborated in Finsler geometry and further, in our works, applied to constructing exact solutions in gravity was applied in this paper for a study of Dirac operators on nonholonomic manifolds possessing Lie algebroid symmetry. The constructions can be extended for spacetimes with uncompactified extra dimensions and such investigations are regarded as interesting research in modern physics and noncommutative geometry.

We show that the three-body Calogero model with inverse square potentials can be interpreted as a maximally superintegrable and multiseparable system in Euclidean three-space. As such it is a special case of a family of systems involving one arbitrary function of one variable. © *2006 American Institute of Physics.*

I. INTRODUCTION

The purpose of this article is to investigate the relation between the rational three-body Calogero model in one dimension[3] and superintegrable systems in two and three dimensions.[5,7,16]

The original (quantum) Calogero model was written in the form

$$\left\{-\left(\frac{\partial^2}{\partial x_1^2}+\frac{\partial^2}{\partial x_2^2}+\frac{\partial^2}{\partial x_3^2}\right)+\frac{1}{8}\omega^2[(x_1-x_2)^2+(x_2-x_3)^2+(x_3-x_1)^2]+\frac{g_1}{(x_2-x_3)^2}+\frac{g_2}{(x_1-x_3)^2}+\frac{g_3}{(x_1-x_2)^2}\right\}\Psi=E\Psi. \tag{1}$$

Upon introducing the center-of-mass coordinate R and the Jacobi relative coordinates ρ and λ,[13]

$$R=\frac{1}{3}(x_1+x_2+x_3),\quad \rho=\frac{1}{\sqrt{2}}(x_1-x_2),\quad \lambda=\frac{1}{\sqrt{6}}(x_1-x_2-2x_3) \tag{2}$$

Eq. (1) was rewritten[3] as follows:

$$\left\{-\left(\frac{\partial^2}{\partial\rho^2}+\frac{\partial^2}{\partial\lambda^2}\right)+\frac{3}{8}\omega^2(\rho^2+\lambda^2)+\frac{1}{2}\frac{g_1}{(\sqrt{3}\lambda-\rho)^2}+\frac{1}{2}\frac{g_2}{(\sqrt{3}\lambda+\rho)^2}+\frac{1}{2}\frac{g_3}{\rho^2}\right\}\Psi=E\Psi, \tag{3}$$

where the motion of the center-of-mass has been factored out.

A superintegrable system is one that admits more integrals of motion than it has degrees of freedom. Systematic searches for superintegrable systems of the form

$$H(\boldsymbol{x},\boldsymbol{p})=\tfrac{1}{2}\boldsymbol{p}^2+V(\boldsymbol{x}) \tag{4}$$

have been conducted in Euclidean spaces $\mathbb{E}^n$ for $n=2$ and 3.[5,7,16] The classical or quantum Hamiltonian (4) is said to be *superintegrable* if it admits $n+k$, $1\leqslant k\leqslant n-1$ integrals of motion, n of them in involution. It is *minimally superintegrable* for $k=1$ and *maximally superintegrable* for

[a)]Electronic mail: smirnov@mathstat.dal.ca
[b)]Electronic mail: wintern@CRM.UMontreal.CA

$k=n-1$. For $n=2$ the two cases coincide and superintegrability simply means the existence of three functionally independent integrals of motion (including the Hamiltonian). For $n=3$ a superintegrable system can have either four or five functionally independent integrals of motion.

The N-body Calogero model[4] (and, in particular, the three-body one[3]) is known to be superintegrable.[1,2,12,20,21,26] An extensive literature exists on superintegrability in classical and quantum systems of the form (4) (see Refs. 14, 22, and 24, and references therein) devoted mainly, though not exclusively[9,8] to systems with integrals of motion of at most second order in the momenta. Superintegrable systems with complete sets of commuting quadratic integrals of motion are *multiseparable*. This means that the corresponding Hamilton-Jacobi, or Schrödinger equation allows the separation of variables in more than one system of (orthogonal) coordinates. Alternatively, multiseparability can be described in terms of the geometric properties of the Killing two-tensors determined by the first integrals of motion that are quadratic in the momenta (see Ref. 12 as well as the relevant references therein).

In what follows, we shall deal with the quantum mechanical problem, but all conclusions are the same (mutatis mutandis) for the classical ones. For the systems admitting integrals of motion of order three or higher, this is not necessarily the case.[9,8,11]

II. THE CALOGERO MODEL IN THE CLASSIFICATION OF SUPERINTEGRABLE SYSTEMS

In a recent article[12] the *invariant theory of Killing tensors* (see also Refs. 17, 18, and 25, and relevant references therein) was used to classify orthogonally separable Hamiltonian systems in the Euclidean space $\mathbb{E}^3$. In particular, it was shown that the inverse square Calogero model with the potential

$$V=\frac{1}{(x_1-x_2)^2}+\frac{1}{(x_2-x_3)^2}+\frac{1}{(x_3-x_1)^2} \tag{5}$$

allows the (orthogonal) separation of variables in five different coordinate systems, namely spherical, circular cylindrical, rotational parabolic, prolate spheroidal, and oblate spheroidal (see also Refs. 2 and 21).

In this study[12] the potential (5) was viewed as a potential in the Hamiltonian (4), corresponding to a single particle in a potential field in $\mathbb{E}^3$. The potential (5) was shown to allow five functionally independent first integrals (including the Hamiltonian). From them it is possible to construct five inequivalent pairs of integrals in involution (in addition to the Hamiltonian). Each such pair is determined by two Killing tensors that share the same orthogonal eigenvectors, thus generating an orthogonal separable system of coordinates. For example, the spherical coordinate system is generated by the following pencil of Killing tensors (including the metric) whose components given in terms of the Cartesian coordinates (x_1,x_2,x_3) are as follows:[12]

$$\begin{bmatrix} a_1+c_2x_3^2+c_3x_2^2 & -c_3x_1x_2 & -c_2x_1x_3 \\ -c_3x_1x_2 & a_1+c_3x_1^2+c_2x_3^2 & -c_2x_2x_3 \\ -c_2x_1x_3 & -c_2x_2x_3 & a_1+c_2x_1^2+c_2x_2^2 \end{bmatrix}. \tag{6}$$

The formula (6) can be rewritten as

$$a_1g^{ij}+c_2K_1^{ij}+c_3K_2^{ij}, \quad i,j=1,2,3, \tag{7}$$

where K_1^{ij} and K_2^{ij} are the components of two *canonical* Killing tensors $\boldsymbol{K}_1$, $\boldsymbol{K}_2$ that share the same orthogonally integrable (i.e., surface forming) eigenvectors and g^{ij} are the components of the metric $\boldsymbol{g}$ of $\mathbb{E}^3$ (see Ref. 12 for more details).

That notwithstanding, the Calogero potential (5) does not appear (at least explicitly) in the list of superintegrable systems in $\mathbb{E}^3$, established earlier[5,16] under the assumption that the first integrals that afford maximal or minimal superintegrability were to be quadratic in the momenta. To unravel this mystery we first observe that the Killing tensors that determine the corresponding integrals of

motion obtained for the potential (5) in Ref. 12 are not in a *canonical* form (as in (6), for example), but are rotated with respect to this form. As an example, let us consider again spherical coordinates (r,θ,ϕ) in $\mathbb{E}^3$ generated by the hypersurfaces of the orthogonally integrable eigenvectors of the Killing tensor (6) given by the following coordinate transformations to the Cartesian coordinates (x_1,x_2,x_3):

$$x_1 = r\sin\theta\cos\phi, \quad x_2 = r\sin\theta\sin\phi, \quad x_3 = r\cos\theta. \tag{8}$$

A potential that allows separation in these coordinates must have the form

$$V(r,\theta,\phi) = f(r) + \frac{1}{r^2}g(\theta) + \frac{1}{r^2\sin^2\theta}k(\phi) \tag{9}$$

and the corresponding additional integrals of motion quadratic in the momenta will be in their standard form, namely

$$F_1 = L_1^2 + L_2^2 + L_3^2 + 2\left[g(\theta) + \frac{1}{\sin^2\theta}k(\phi)\right],$$

$$F_2 = L_3^2 + 2k(\phi), \tag{10}$$

where $L_i, i=1,2,3$ are the infinitesimal generators of SO(3), that can be determined in terms of the Cartesian coordinates x_i, $i=1,2,3$ as follows: $L_1=x_2p_3-x_3p_2$, $L_2=x_3p_1-x_1p_3$, $L_3=x_1p_2-x_2p_1$. Note that the first integrals (10) in terms of the Cartesian coordinates can be rewritten as

$$\begin{aligned} F_1 &= K_1^{ij}p_ip_j + U_1(x_1,x_2,x_3), \\ F_2 &= K_2^{ij}p_ip_j + U_2(x_1,x_2,x_3), \end{aligned} \tag{11}$$

where $i,j=1,2,3$, K_1^{ij}, K_2^{ij} are the components of the "spherical" Killing tensors (7) and (p_1,p_2,p_3) are the operators $(\partial/\partial x_1, \partial/\partial x_2, \partial/\partial x_3)$, respectively (quantum mechanics case) or the momenta components corresponding to the Cartesian coordinates (x_1,x_2,x_3) (classical mechanics case).

If we rotate the x_1, x_2, and x_3 axes in (8), the form of the potential (9) changes, so do the integrals (10), but separation of variables will still occur (in spherical coordinates with different axes).

In the case of the potential (5) the rotation taking the Killing tensors into their standard form is a nontrivial one, given by12 (compare with (2))

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \frac{1}{\sqrt{6}}\begin{pmatrix} 2 & 0 & \sqrt{2} \\ -1 & \sqrt{3} & \sqrt{2} \\ -1 & -\sqrt{3} & \sqrt{2} \end{pmatrix}\begin{pmatrix} \tilde{x}_1 \\ \tilde{x}_2 \\ \tilde{x}_3 \end{pmatrix}. \tag{12}$$

Accordingly, for the Calogero potential (5) we obtain

$$V = 2\left[\frac{1}{(\sqrt{3}\tilde{x}_1 - \tilde{x}_2)^2} + \frac{1}{(\sqrt{3}\tilde{x}_1 + \tilde{x}_2)^2} + \frac{1}{\tilde{x}_2^2}\right] \tag{13}$$

and we see that the variable $\tilde{x}_3$ is absent from (13). Expressing $\tilde{x}_1$ and $\tilde{x}_2$ in terms of spherical coordinates (8), we get

$$V = \frac{2}{r^2\sin^2\theta}\left[\frac{1}{(\sqrt{3}\cos\phi - \sin\phi)^2} + \frac{1}{(\sqrt{3}\cos\phi + \sin\phi)^2} + \frac{1}{\sin^2\phi}\right], \tag{14}$$

i.e., a potential in the form (9) with $f(r)=0$, $g(\theta)=0$ and $k(\phi)$ specified.

In what follows we show that after the rotation (12) it is possible to see that the Calogero potential (13) is a member of an infinite family of potentials, depending on one arbitrary function and sharing a number of important properties, such as superintegrability. Indeed, recall that all superintegrable potentials that separate in spherical coordinates plus at least one other system were derived in Ref. 16. The potential

$$V = \frac{k(\phi)}{r^2 \sin^2 \theta} \tag{15}$$

occurs several times. In what follows we list five *functionally independent* first integrals (including the Hamiltonian H) that afford multiseparability for the potential (15):

$$\begin{aligned} H &= \frac{1}{2}(p_1^2 + p_2^2 + p_3^2) + \frac{k(\phi)}{r^2 \sin^2 \theta}, \\ F_1 &= L_1^2 + L_2^2 + L_3^2 + \frac{2k(\phi)}{\sin^2 \theta}, \\ F_2 &= L_3^2 + 2k(\phi), \\ F_3 &= \tfrac{1}{2}p_3^2, \\ F_4 &= L_1 p_2 + p_2 L_1 - p_1 L_2 - L_2 p_1 - 4\frac{\cos \theta}{r \sin^2 \theta} k(\phi), \end{aligned} \tag{16}$$

where $k(\phi)$ is an arbitrary function. The functional independence of the first integrals (16) has been verified with the aid of a computer algebra package (i.e., the Jacobian $\partial(H, F_1, F_2, F_3, F_4)/\partial(x_1, x_2, x_3, p_1, p_2, p_3)$ is of rank 5 at a generic point). It is important to note that the functionally independent first integrals (16) are *linearly connected*, which means that they are subject to an additional constraint specified by the following expression in terms of the coordinates $\boldsymbol{x} = (x_1, x_2, x_3)$:

$$f_0(\boldsymbol{x})H + f_1(\boldsymbol{x})F_1 + f_2(\boldsymbol{x})F_2 + f_3(\boldsymbol{x})F_3 + f_4(\boldsymbol{x})F_4 = 0, \tag{17}$$

where $f_0(\boldsymbol{x}) = 2x_3^2$, $f_1(\boldsymbol{x}) = 1$, $f_2(\boldsymbol{x}) = -1$, $f_3(\boldsymbol{x}) = -2(x_1^2 + x_2^2 + x_3^2)$, $f_4 = x_3$. This formula is a consequence of the following "rotational" symmetry, that can be defined in a coordinate-free way. We can write all of the expressions in formula (16) as $F_k = K_k^{ij} p_i p_j + U_k$, where $i, j = 1, 2, 3$. Then the Killing tensor $\boldsymbol{K}_k$ with the components K_k^{ij} (including the metric) is subject to the following formula:

$$\mathcal{L}_{L_3} \boldsymbol{K}_k = 0, \tag{18}$$

where $\mathcal{L}$ denotes the Lie derivative. We also note that the vector space spanned by the quadratic parts of the first integrals (16) are invariant with respect to translations along the x_3 axis.

It is easy to show now that the potential (15) is orthogonally separable with respect to other systems of coordinates as well. Indeed, the pairs of involutive first integrals leading to the orthogonal separation of variables in the Schrödinger equation are $\{F_1, F_2\}$ (spherical), $\{F_2, F_3\}$ (circular cylindrical), $\{F_2, F_4\}$ (rotational parabolic), and $\{F_2, F_1 \mp a^2 2F_3\}$ (oblate, and prolate spheroidal). Another way to see this is by looking at the separable potentials derived in Ref. 16. In terms of Cartesian coordinates the potential (15) is given by

$$V = \frac{k(x_2/x_1)}{x_1^2 + x_2^2}. \tag{19}$$

Recall[16] that the separable potentials corresponding to "rotational" coordinates, namely spherical, circular cylindrical, rotational parabolic, oblate and prolate spheroidal in the Cartesian coordinates (x_1, x_2, x_3) all have the form

$$V = f + g + \frac{k(x_2/x_1)}{x_1^2 + x_2^2}, \tag{20}$$

where k are arbitrary functions, while f and g are specified differently in each case. The common part of the five separable potentials is exactly the potential (19).

These observations put in evidence that the potential (19) defines a family of maximally superintegrable potentials separable with respect to the five "rotational" orthogonal coordinate systems, namely spherical, circular cylindrical, rotational parabolic, oblate, and prolate spheroidal whose Killing tensors are constrained by the rotational symmetry condition (18). As for the Calogero potential (13), in the coordinates $(\tilde{x}_1, \tilde{x}_2, \tilde{x}_3)$ determined by the transformation (14), it assumes the form (19) for

$$k(t) = 2(1 + t^2)\left[\frac{3 + t^2}{(3 - t^2)^2} + 1\right], \tag{21}$$

where $t = \tilde{x}_2/\tilde{x}_1$.

The potential (15) can be imbedded into more general families of potentials in $\mathbb{E}^3$ that are *minimally* superintegrable. In contrast to maximally superintegrable potentials they admit three additional integrals rather than four. They are

$$V_1 = \alpha(x_1^2 + x_2^2 + x_3^2) + \frac{\beta}{x_3^2} + \frac{1}{x_1^2 + x_2^2} h(\phi),$$

$$V_2 = \frac{\alpha}{r} + \beta \frac{\cos\theta}{r^2 \sin^2\theta} + \frac{1}{r^2 \sin^2\theta} h(\phi), \tag{22}$$

$$V_3 = k(x_1^2 + x_2^2) + 4k x_3^2 + \frac{1}{x_1^2 + x_2^2} h(\phi).$$

The potential V_1 with $(\alpha, \beta) \neq (0, 0)$ separates in all of the five "rotational" coordinate systems considered above except rotational parabolic ones. V_2 separates only in spherical and rotational parabolic, while V_3 in cylindrical and rotational parabolic. We mention that a special case of V_2 with $\beta = 0$ and $h(\phi) = \text{const}$ is the Hartmann potential used in molecular physics to describe ring-shaped molecules.[10,15]

The rotation (12) in $\mathbb{E}^3$ has a simple meaning for three particles on a line with inverse square potentials. Comparing (3) with (14), we see that the rotation corresponds to introducing center-of-mass coordinates (2). If we factor out the center-of-mass motion (i.e., drop the term $1/2p_3^2$ in the kinetic energy), we reobtain the Hamiltonian (3) with $\omega = 0$.

The system (3) can be viewed as one particle in a potential in the Euclidean plane $\mathbb{E}^2$. Interestingly, it is not multiseparable. For both $\omega = 0$ and $\omega \neq 0$ it separates only in polar coordinates, so it allows only one second-order integral of motion (in addition to the Hamiltonian), namely

$$F = L_3^2 - \left[\frac{g_1}{(\sqrt{3}\sin\phi - \cos\phi)^2} + \frac{g_2}{(\sqrt{3}\sin\phi + \cos\phi)^2} + \frac{g_3}{\cos^2\phi} \right]. \tag{23}$$

If the system (3) is superintegrable in $\mathbb{E}^2$, the second integral of motion must be of higher order in the momenta, not commuting with F given by (23). Multiseparability of a physical system, in particular the Calogero model, may also be of interest from the point of view of different possible quantizations. In a recent article Féher *et al.*[6] have used separation of variables in circular cylindrical coordinates in the three-body Calogero model to investigate all possible self-adjoint extensions of the corresponding angular and radial Hamiltonians. The question arises whether separation of variables in other coordinates might not lead to different quantizations.

III. CONCLUSIONS

The beauty of the Calogero model is lost when its potential is written in the form (13). The formula (13) does however show that this system is a member of a family of maximally superintegrable systems determined by the general formula (15), involving an arbitrary function of one variable, the azimuthal angle ϕ. All of them allow the orthogonal separation of variables in the five different "rotational" coordinate systems. The complete set of commuting operators (first integrals) in each case consists of the Hamiltonian H and F_2 of (16) and one more operator (F_1, F_3, F_4 and $F_1 \mp a^2 p_3^2$, respectively). The operator F_2 that is thus singled out corresponds, in the case of the free motion, to a one-dimensional subgroup of the (orientation-preserving) isometry group $I(\mathbb{E}^3)$, which is the symmetry group of the Schrödinger equation without a potential. This subgroup generates the angle ϕ, common to all five "rotational" orthogonally separable coordinate systems.

This raises the question whether other maximally superintegrable systems involving arbitrary functions exist. All superintegrable systems in $\mathbb{E}^3$ separating in spherical coordinates and in one further system were found in Ref. 16. All further systems separable in (at least) two coordinate systems were found in Ref. 5. In the lists provided by Evans[5] five systems are maximally superintegrable and each one depends on artibrary constants. In addition, eight systems are listed as minimally superintegrable, each depending on one arbitrary function and up to three constants. One of the minimally superintegrable systems has the potential

$$V_1 = F(r) + \frac{c_1}{x_1^2} + \frac{c_2}{x_2^2} + \frac{c_3}{x_3^2}, \tag{24}$$

where c_1, c_2, and c_3 are arbitrary constants. Here and in the following, r, θ, and ϕ are spherical coordinates as specified by (8). Its superintegrability is due to the fact that the corresponding Hamiltonian commutes with the operators

$$F_1 = L_1^2 + \frac{2c_2\cos^2\theta}{\sin^2\theta\sin^2\phi} + \frac{2c_3\sin^2\theta\sin^2\phi}{\cos^2\theta},$$

$$F_2 = L_2^2 + \frac{2c_1\cos^2\theta}{\sin^2\theta\cos^2\phi} + \frac{2c_3\sin^2\theta\cos^2\phi}{\cos^2\theta}, \tag{25}$$

$$F_3 = L_3^2 + \frac{2c_1}{\cos^2\phi} + \frac{2c_2}{\sin^2\phi}.$$

This potential becomes maximally superintegrable for $F=\omega(x_1^2+x_2^2+x_3^2)$. For $c_1=c_2=c_3=0$ it simply becomes rotationally invariant (but not maximally superintegrable). Four of the minimally superintegrable potentials have the form

$$V_i(x_1,x_2,x_3) = \tilde{V}_i(x_1,x_2) + f(x_3), \quad i = 2,3,4,5, \tag{26}$$

where $\tilde{V}_i(x,y)$ is one of the four multiseparable potentials in $\mathbb{E}^2$.[7] In each case the set of integrals of motion consists of

$$F_1 = \tfrac{1}{2}p_3^2 + f(x_3) \tag{27}$$

and three further operators, the principal parts of which lie in the enveloping algebra of the Lie algebra of the isometry group $I(\mathbb{E}^2)$. In particular, for $\tilde{V}_i(x_1,x_2)=0$ the Hamiltonian and F_1 of (27) commutes with the Lie algebra $\{L_3,p_1,p_2\}$, i.e., H and F_1 are invariant under the orientation-preserving isometry group $I(\mathbb{E}^2)$. This provides a total of four integrals of motion, never five. Out of these four functionally independent integrals of motion we can form four inequivalent triplets of integrals of motion in involution, namely (H,F_1,X_i), $i=1,2,3,4$ with

$$X_1 = p_1^2, \quad X_2 = L_3^2, \quad X_3 = L_3p_1 + p_1L_3, \quad X_4 = L_3^2 + a^2(p_1^2 - p_2^2),$$

where $a \neq 0$.These triplets correspond to the separation of variables in the Cartesian, polar, parabolic translational, and elliptic translational, coordinates, respectively. Within the x_1x_2 plane the origin and the orientation of axes can be chosen arbitrarily.

Finally, three of the minimally superintegrable systems depend on an arbitrary function of the azimuthal angle ϕ. They all have the form

$$V_i(r,\theta,\phi) = \tilde{V}_i(r,\theta) + \frac{k(\phi)}{r^2\sin^2\theta}, \quad i = 4,7,8. \tag{28}$$

The integral F_2 of (16) is present in each case, together with H and one of F_1, F_3, or F_4. In particular, for $\tilde{V}_i(r,\theta)=0$ all of the operators (16) are integrals of motion.

We conclude that in $\mathbb{E}^3$ the potential (15) is the only potential that is maximally superintegrable and depends on an arbitrary function (of one variable). The three-body Calogero model corresponds to one particular choice of this function, namely that given in (15) and (21).

An important question arises in this context. Namely, what are the physical consequences in classical and quantum mechanics, of the existence of a maximally superintegrable system, depending on an arbitrary function? In classical mechanics maximally superintegrable sysetms have the property that their finite trajectories are closed.[19] In quantum mechanics they have degenerate energy levels and it has been conjectured[23,22] that they are exactly solvable. We cannot expect these properties to hold for the potential (15) with $k(\phi)$ arbitrary. We suspect that the reason for this paradox is that the five integrals (16) are functionally independent, but linearly connected.

One of the messages that we arrive at is that results considered to be "canonical" in one approach to a problem may be quite nonobvious in another. Thus, the Killing tensors obtained in Ref. 12 were not in canonical (standard) form for the Calogero model viewed as an $\mathbb{E}^3$ problem. The advantage of the invariant approach used in Refs. 12, 17, 18, and 25 is the following. For a given isometry group action in a vector space of Killing tensors one can employ the approach developed in Refs. 12, 17, 18, and 25 to determine which orbit a Killing tensor belongs to and then find the corresponding isometry group action mapping the Killing tensor in question to its canonical form (i.e., the corresponding *moving frames map*).

(Received 3 January 2006; accepted 1 August 2006; published online 29 September 2006)

We give a proof of the nonintegrability of an important three-body problem in atomic physics. We consider the classical model for the helium atom in full dimension, thus completing our previous proof for the frozen planetary approximation. To our knowledge there is not any such a proof in the literature. We apply a theorem due to Morales-Ruiz and Ramis: if a Hamiltonian system, derived from a homogeneous potential is integrable, then all integrability factors, related to the Hessian of the homogeneous potentials, satisfy certain conditions related to the degree of homogeneity. In the helium atom case, these coefficients should *all* be discrete. We exhibit a set of nondiscrete values determined analytically. This implies the nonintegrability of the helium atom without any computer aid. We also extend this theorem to various two-electron atoms. In the case of strange helium atoms we provide a computer aided proof of nonintegrability. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2339013]

I. INTRODUCTION

The three-body problem, either Coulombian or gravitational, is one the most important problems in Physics. The two-electron atoms, e.g., the helium atom, is a subclass of that problem. The helium atom is a model to study the classical, semiclassical, and quantum mechanics of a generic nonintegrable system,[1] although so far there has not appeared in the literature an analytical proof of its nonintegrability, as opposed to studies with the gravitational three-body problem that goes back to Euler, Lagrange, and Poincaré. For example, the two fixed center problem, largely used in many areas of Physics, was integrated by Euler, in two and three dimension. Numerical studies on the classical helium atom can be found for example in Yamamoto and Kaneko[2] and Carati.[3]

The quest for criteria of integrability in Hamiltonian systems has been a very active field. The results of Morales-Ruiz and Ramis[4] is on the connection between two different concepts of integrability: the integrability of a Hamiltonian system of equations and the integrability of the variational equations along a particular solution of these equations. The main theorems on integrability[4] from Poincaré, Kowalevski, Arnold and Krylov, Ziglin to Morales-Ruiz and Ramis, can all be cast in this context. The version of Ziglin's theorem, due to Yoshida[5] for homogeneous two degrees of freedom, has been applied to many important problems, including Calogero-Moser

[a)]Electronic mail: tstuchi@if.ufrj.br

collinear three-body problem for some values of the degree, say k, of the potential. The study of Calogero-Moser integrability problem was completed in Ref. 4, using the more general theorem due to Morales-Ruiz and Ramis. This theorem is used in this work.

In Almeida *et al.*[10] we have found that the "frozen planetary approximation" (FPA) is nonintegrable, since the algebraic equations to be solved are easily solvable due to the restriction to the x axis. The extension to the full helium problem is not trivial. The main difficulty in applying the above-noted theorem to the helium atom stems from the three dimension nature of the model. To solve the correspondent full coupled algebraic set of equations is not feasible even using software like MAPLE and MATHEMATICA. However, we avoid this difficulty by considering a particular symmetric configuration; then we evaluate the integrability coefficients using the full 6×6 Hessian matrix, thus extending our previous result on the FPA case.

We consider here classical heliumlike atoms only. Of course, the corresponding microscopic systems are governed by quantum mechanics or at least described by semiclassical techniques. The classical integrability does not guarantee quantum integrability (see Refs. 6–9 and reference therein). However, we remark that if a problem is not classically integrable there are no action-angle variables that can become the corresponding quantum operators. We hope that our contribution on the classical case may shed some light on the discussion of the quantum counterparts.

II. THEORY AND METHOD

The Hamiltonian for the three-dimensional (3D) heliumlike atom in infinite nuclear mass approximation is shown as follows:

$$H=\frac{1}{2}(\mathbf{p}_1^2+\mathbf{p}_2^2)-\frac{Z}{|\mathbf{r}_1|}-\frac{Z}{|\mathbf{r}_2|}+\frac{1}{|\mathbf{r}_{12}|}, \tag{1}$$

where $\mathbf{r}_i$ is the position of the ith electron, $\mathbf{r}_{12}$ the distance between the electrons, and $\mathbf{p}_i$ are the corresponding momentum of the electrons. This six degree of freedom system is usually reduced to four degrees by energy and momentum conservation. In this case, even if the three particles are constrained to move in the plane the number of degrees of freedom is three.

In Almeida *et al.*[10] we have found that the "frozen planetary approximation" of this problem (two electrons on the same side of the atom with two degrees of freedom) and its modifications (heliumlike atoms) are not integrable. The motivation was the apparently integrable Poincaré section of this approximation in the case of the one-dimensional helium atom ($Z=2$). In this paper, we extend our previous result on nonintegrability to the full 3D problem (as well as for the 2D case) since we devised a way of overcoming the difficulty in solving the full set of equations. The result is also extended to the case of finite values of the alpha-particle mass. We also consider the case where the place of one of the electrons is taken by heavier particles with the same charge: muon, pion, kaon, and antiproton.

To prove the nonintegrability we use a theorem by Morales and Ramis for homogeneous potentials,[4,10] which is a generalization of Yoshida's[5] theorem for more than two degrees of freedom, and without its limitations at resonances. Briefly, consider a Hamiltonian system with n-degree of freedom with the Hamiltonian $H(\mathbf{p},\mathbf{q})=\mathbf{p}^2/2+V(\mathbf{q})$, where $\mathbf{q}=(q_1,\ldots,q_n)$ and $\mathbf{p}=(p_1,\ldots,p_n)$. If $V(\mathbf{q})$ is a homogeneous potential of degree k, $V(a\mathbf{q})=a^kV(\mathbf{q})$, there exists in general straight-line solutions of the corresponding Hamilton's equations as follows:

$$q_i=c_if(t),\quad p_i=c_i\dot{f}(t),\quad i=1,\ldots,n. \tag{2}$$

The f's are solution of the differential equation

$$\dot{f}^2=\frac{2}{k}(1-f^k),\quad k\neq 0.$$

Then, it is possible to show that c_i's are solutions of the n equations given by

$$c_j = \frac{\partial V}{\partial q_j}(c_1, \ldots, c_n), \quad j = 1, \ldots, n. \tag{3}$$

Orbits that are described by this condition are known as homographic solutions in the literature of Celestial Mechanics. The linear variational equations (VE) of the system around the above particular solution are given by ($\delta\mathbf{q} = \xi$ and $\delta\mathbf{p} = \eta$):

$$\dot{\xi} = \eta \quad and \quad \dot{\eta} = -f^{k-2}\frac{\partial^2 V}{\partial q_i \partial q_j}(\mathbf{c})\xi,$$

or

$$\ddot{\xi} = -f^{k-2}\frac{\partial^2 V}{\partial q_i \partial q_j}(\mathbf{c})\xi, \quad i = 1, \ldots, n.$$

In terms of the eigenvalues of the Hessian matrix the VE can be expressed as the n second-order differential equations:

$$\ddot{\xi} = -f^{k-2}(\lambda_i)\xi, \quad i = 1, \ldots, n,$$

the λ_i are still called Yoshida's integrability coefficients, although the theorem of Morales-Ruiz and Ramis applies to n degrees of freedom. The equation with $i=n$, corresponding to the eigenvalue $\lambda_n = k-1$, is the tangential variational equation which is trivially solvable. The NVE (normal variational equation) are the $n-1$ remaining equations. By the symmetries of this problem the NVE is a system of independent hypergeometric differential equations in the independent variable $x=f^k$,

$$x(1-x)\frac{\mathrm{d}^2\xi}{\mathrm{d}x^2} + \left(\frac{k-1}{k} - \frac{3k-2}{2k}x\right)\frac{\mathrm{d}\xi}{\mathrm{d}x} + \frac{\lambda_i}{2k}\xi = 0, \quad i = 1,2, \ldots, n-1.$$

This system of equations is called the algebraic normal variational equation (ANVE). The identity component of the Galois Group of the NVE is the same as the identity component of the Galois Group of the ANVE. The ANVE_i for the scalar second-order equation corresponding to the integrability coefficient λ_i, can be written as

$$\mathrm{ANVE}_i = \mathrm{ANVE}_1 + \mathrm{ANVE}_2 + \cdots + \mathrm{ANVE}_{n-1}.$$

The ANVE is integrable if, and only if, each ANVE_i is integrable, that is, if each one of the identities of the Galois Group is solvable. This leads to the following result.[4]

Morales-Ruiz and Ramis theorem: A Hamiltonian system, with a homogeneous potential of degree k, to be completely integrable (with the holomorphic or meromorphic first integrals), is that each pair (k, λ_i) belongs to one of the following list (with the exception of the trivial case $k=0$):

(1) $(k, p+p(p-1)k/2)$

(2) (2, arbitrary complex number)

(3) (−2, arbitrary complex number)

(4) $\left(-5, \frac{49}{40} - \frac{1}{40}\left(\frac{10}{3}+10p\right)^2\right)$

(5) $\left(-5, \frac{49}{40} - \frac{1}{40}(4+10p)^2\right)$

(6) $\left(-4, \frac{9}{8} - \frac{1}{8}\left(\frac{4}{3}+4p\right)^2\right)$

(7) $\left(-3, \frac{25}{24} - \frac{1}{24}(2+6p)^2\right)$,

(8) $\left(-3, \frac{25}{24} - \frac{1}{24}\left(\frac{3}{2}+6p\right)^2\right)$

(9) $\left(-3, \frac{25}{24} - \frac{1}{24}\left(\frac{6}{5}+6p\right)^2\right)$

(10) $\left(-3, \frac{25}{24} - \frac{1}{24}\left(\frac{12}{5}+6p\right)^2\right)$

(11) $\left(3, -\frac{1}{24} + \frac{1}{24}(2+6p)^2\right)$,

(12) $\left(3, -\frac{1}{24} + \frac{1}{24}\left(\frac{3}{2}+6p\right)^2\right)$

(13) $\left(3, -\frac{1}{24} + \frac{1}{24}\left(\frac{6}{5}+6p\right)^2\right)$

(14) $\left(3, -\frac{1}{24} + \frac{1}{24}\left(\frac{12}{5}+6p\right)^2\right)$

(15) $\left(4,-\frac{1}{8}+\frac{1}{8}\left(\frac{4}{3}+4p\right)^2\right)$ (16) $\left(5,-\frac{9}{40}+\frac{1}{40}\left(\frac{10}{3}+10p\right)^2\right)$

(17) $\left(5,-\frac{9}{40}+\frac{1}{40}(4+10p)^2\right)$ (18) $\left(k,\frac{1}{2}\left(\frac{k-1}{k}+p(p+1)k\right)\right)$,

where p is an arbitrary integer.

III. RESULTS

A. Helium and heliumlike atoms in infinite mass approximation

The potential of the two-electron atoms is homogeneous of degree $k=-1$ in Cartesian coordinates (x_i,y_i,z_i), $i=1,2$. In the infinite nuclear mass approximation, it takes the form ($Z=2$ for He):

$$V=-\frac{Z}{(x_1^2+y_1^2+z_1^2)^{1/2}}-\frac{Z}{(x_2^2+y_2^2+z_2^2)^{1/2}}+\frac{1}{((x_2-x_1)^2+(y_2-y_1)^2+(z_1-z_2)^2)^{1/2}}.$$

Note that in order to apply the above-mentioned theorem we have considered six degrees of freedom without reduction to four, a price we pay to have the homogeneity of the potential. Therefore, system (3) corresponds to six scalar coupled equations in the variables $(x_1,y_1,z_1,x_2,y_2,z_2)$, whose whole set of solutions is very hard to find. However, if we consider a subset of particular solutions of the type $(c_1,0,0,c_2,0,0)$ in (3) of the six scalar equations there remain only two:

$$\begin{aligned}\frac{Zx_1}{|x_1|^3}+\frac{x_2-x_1}{|x_2-x_1|^3}-x_1=0,\\ \frac{Zx_2}{|x_2|^3}-\frac{x_2-x_1}{|x_2-x_1|^3}-x_2=0.\end{aligned} \tag{4}$$

This simple idea allows us to solve what looked to be at first sight an unsurmountable difficulty. With this particular set of solutions of Eq. (4) [or full Eq. (3)] we proceed to the next step, the calculation of the eigenvalues of the (full) Hessian matrix of the potential at these solutions. Our strategy makes the problem easier to handle and the Hess$[V(c_1,0,0,c_2,0,0)]$ matrix is still a 6×6 blocked matrix.

We first have to discuss the allowed values of λ according to the Morales-Ruiz and Ramis theorem. As the degree of homogeneity is $k=-1$, the eigenvalue in the tangential direction is $\lambda=k-1=-2$, and only cases (1) and (18) of the above-mentioned theorem apply:

$$\begin{aligned}(i)\ p-p(p-1)/2=\lambda,\\ (ii)\ 1-p(p+1)/2=\lambda.\end{aligned} \tag{5}$$

We note that in the case of $k=-1$ the above two expressions are equivalent by making $p=q\pm 2$. Therefore the solution given by one of these equations for integer p is the presumed values of the λ's for which the system could be integrable. If we look at the set generated in Almeida *et al.*,[10] for $-8<p<8$:

$$\{\ldots-44,-35,-27,-20,-14,-9,-5,-2,0,1\}. \tag{6}$$

These values of λ form open sets in which we can be sure that the system is nonintegrable. If just one value of λ is sufficiently far from these presumed integer values or complex, then the nonintegrability for the helium atom can be guaranteed. We note that the converse is not true since the Morales-Ruiz and Ramis theorem is a necessary condition only.

Therefore, in order to prove nonintegrability the first step is to find *any* solution of Eq. (3),

like Eq. (4), substitute them in the Hessian matrix and find the corresponding eigenvalues λ_i. If just one of these eigenvalues does not satisfy Eq. (5) for any integer p (one obvious case being complex λ) then we can assure that the system is not integrable. Therefore, our strategy has been to exhaust the possibilities starting with a subset of particular solutions of Eq. (3) with higher symmetry to facilitate the calculation. We stress that our strategy permits us to find feasible solution in contrast with the near nonsolvable full Eq. (3).

We observed that if Eq. (4) were to have two real solutions then it should have the symmetry $R_1=(r,-r)$ and $R_2=(-r,r)$. Thus, substituting R_1 or R_2 in Eq. (4) (or $R_1=(r,0,0,-r,0,0)$ or $R_2=(-r,0,0,r,0,0)$ in Eq. (3)) we obtain analytically that

$$r=(Z-1/4)^{1/3}$$

and the analytical eigenvalues of the Hessian matrix for these real roots are

$$\{-2,1,1,-2/(1-1/4Z),1/(1-1/4Z),1/(1-1/4Z)\}. \tag{7}$$

For $Z=2$ the value of $\lambda_4=-2/(1-1/4Z)=-16/7\approx-2.285\,714\,3$. Note that it does not coincide with any of the presumed *integer* values in (6). Therefore, the system He atom cannot be integrable since the theorem requires that all values of λ should satisfy (5). Note that the eigenvalue in the tangential direction, which is known to be $k-1=-2$, has been obtained independently of this assumption. Therefore, the helium atom is not integrable in the approximation of infinite nuclear mass and the result has been established analytically. We note that according to MAPLE and MATHEMATICA software there are ten solutions for Eq. (4): a pair of real solutions and an octet of complex values, of course the real values are the same as the ones found analytically. The above-found values allow one to examine the integrability of a series of heliumlike atoms, i.e., for any value of Z. In fact, taking one of the real eigenvalues of the set above, say

$$\lambda_4=\frac{-2}{\left(1-\frac{1}{4Z}\right)}$$

we find that $-5<-2/(1-1/4Z)<-2$ for $Z>5/12\approx0.417$. Therefore, all the heliumlike atoms with $Z>(5/12)$ are not integrable. Note that for $Z=1/4$ the values of the $\lambda_i's$, $i=4,5,6$ diverge and for $Z\to\infty$, e.g., $\lambda_4=-2$ (independent particle approximation).

B. Helium, heliumlike, and strange helium atoms

The helium atom ($Z=2$) can be modified by substituting one of its electrons by a heavier particle. In this case we need a Hamiltonian which takes into account the relative masses of the particles:[11]

$$H(r_1,r_2,p_1,p_2)=\frac{\mathbf{p}_1^2}{2\mu_{12}}+\frac{\mathbf{p}_2^2}{2\mu_3}-\frac{Z}{|\mathbf{r}_1|}-\frac{Z}{\left|\mathbf{r}_2+\frac{m_2}{m_1+m_2}\mathbf{r}_1\right|}+\frac{1}{\left|\mathbf{r}_2-\frac{m_1}{m_1+m_2}\mathbf{r}_1\right|}, \tag{8}$$

where the reduced masses are: $\mu_{12}=m_1m_2/(m_1+m_2)$ and $\mu_3=m_3(m_1+m_2)/(m_1+m_2+m_3)$, being $m_1=m_\alpha$ and m_i, $i=2,3$ are either the electron or a heavier particle. Before proceeding to calculations we make a canonical change of variables in the Hamiltonian (8). We take $r_i'=r_i/u_i$ and $p_i'=p_iu_i$, where $u_1=1/\sqrt{\mu_{12}}$ and $u_2=1/\sqrt{\mu_3}$. Now the problem is isotropic in the masses and we use Eq. (3) obtaining for the particular solution $(c_1,0,0,c_2,0,0)$ the following system:

$$\frac{Z\sqrt{\mu_{12}}\chi_1}{|\chi_1|^3}+\frac{Z\sqrt{\mu_{12}}\left(\frac{\chi_2}{\sqrt{\mu_3}}+\frac{\sqrt{\mu_{12}}\chi_1}{m_1}\right)}{\left|\frac{\chi_2}{\sqrt{\mu_3}}+\frac{\sqrt{\mu_{12}}\chi_1}{m_1}\right|^3m_1}-\frac{\sqrt{\mu_{12}}\left(\frac{\chi_2}{\sqrt{\mu_3}}-\frac{\sqrt{\mu_{12}}\chi_1}{m_2}\right)}{\left|\frac{\chi_2}{\sqrt{\mu_3}}-\frac{\sqrt{\mu_{12}}\chi_1}{m_2}\right|^3m_2}-\chi_1=0,$$

$$\frac{Z\left(\frac{\chi_2}{\sqrt{\mu_3}}+\frac{\sqrt{\mu_{12}}\chi_1}{m_1}\right)}{\left|\frac{\chi_2}{\sqrt{\mu_3}}+\frac{\sqrt{\mu_{12}}\chi_1}{m_1}\right|^3\sqrt{\mu_3}}+\frac{\left(\frac{\chi_2}{\sqrt{\mu_3}}-\frac{\sqrt{\mu_{12}}\chi_1}{m_2}\right)}{\left|\frac{\chi_2}{\sqrt{\mu_3}}-\frac{\sqrt{\mu_{12}}\chi_1}{m_2}\right|^3\sqrt{\mu_3}}-\chi_2=0. \tag{9}$$

In particular, we have been able to find an analytic solution for the case of the helium atom ($Z=2$) and all heliumlike atoms (any Z), that is, when $m_2=m_3=m_e$. We find that the potential of (8) is reduced to that of the infinite α-particle mass by means of the linear transformation:

$$\chi_1=\sqrt{\mu_{12}}x_1, \quad \chi_2=\sqrt{\mu_3}\left(x_2-\frac{m_2}{m_1+m_2}x_1\right), \tag{10}$$

where χ_i and x_i denote the coordinates for finite and infinite mass systems, respectively.

Then using the symmetry discussed in the previous section we find the solutions $R_1=(-r,r)$ and $R_2=(r,-r)$ for the Jacobi variables; recall that $r=(Z-1/4)^{1/3}$. Using this guess (10) with $x_1=-x_2$ in (9) we find that

$$R_{1,2}=\left[\pm\sqrt{\mu_{12}}\left(\frac{Z-1/4}{m_e}\right)^{1/3}, \mp\sqrt{\mu_3}\left(\frac{Z-1/4}{m_e}\right)^{1/3}\left(1+\frac{m_e}{m_\alpha+m_e}\right)\right] \tag{11}$$

solves the system of equations if $m_2=m_3=m_e$.

The corresponding eigenvalues for the Hessian matrix are

$$\lambda=\left\{-2,1,1,\frac{-2\left(\frac{2m_e}{m_\alpha}+1\right)}{1-\frac{1}{4Z}},\frac{\left(\frac{2m_e}{m_\alpha}+1\right)}{1-\frac{1}{4Z}},\frac{\left(\frac{2m_e}{m_\alpha}+1\right)}{1-\frac{1}{4Z}}\right\},$$

where m_e is the electron mass. Taking $Z=2$ we find

$$\lambda=\{-2,1,1,-2.286\,340,1.143\,170,1.143\,170\}$$

to be compared with the first value evaluated numerically in the table to follow. Note that it is not in the end of the intervals generated by the set (6) required for integrability. This completes the study of the nonintegrability for the helium atom.

Solving Eq. (3) numerically (MAPLE or MATHEMATICA) using the strategy used so far, we find the following set of eigenvalues for Hess$[V(\mathbf{c})]$:

particle	λ
Electron	$\{-2,1,1,-2.286\,340,1.143\,170,1.143\,170\}$
Muon	$\{-2,1,1,-2.212\,536,1.106\,268,1.106\,268\}$,
Pion	$\{-2,1,1,-2.207\,143,1.103\,571,1.103\,571\}$,
Kaon	$\{-2,1,1,-2.190\,079,1.095\,040,1.095\,040\}$,
Antiproton	$\{-2,1,1,-2.188\,614,1.094\,307,1.094\,307\}$,

for the masses $5.485\,799\times10^{-4}\mu$, $0.113\,428\,92\mu$, $0.149\,837\,65\mu$, $0.529\,994\,32\mu$, and $1.007\,295\,93\mu$, respectively. For the mass of the α particle (He nucleus) we have used $4.002\,602\mu$, $\mu=931.494\,32$ MeV/c^2. We have not been able to find an analytical solution for the strange helium case.

It is easy to see that there are eigenvalues which are not the end of the intervals shown in set (6), as required for possible integrability. So none of these heliumlike problems are integrable.

C. CONCLUSION

We apply the theorem of Morales-Ramis, one of the latest theorems on integrability of Hamiltonian systems, and prove mainly that the helium atom as well as several heliumlike atoms are not integrable in any physical dimension. We thus have extended our previous result on the frozen planetary approximation to the full helium system. We remark that in this paper the proof is completely analytic. The proof is also extended to several strange helium atoms. In the case of the strange helium atoms we have not been able to solve the equations by radicals but our proof is a rigorous computer aided proof because the integrability coefficients are a set of integers, and the actual numerical values are sufficiently far from these integers.

Explicit solutions for *N*-dimensional Schrödinger equations with position-dependent mass

B. Gönül[a] and M. Koçak
Department of Engineering Physics, University of Gaziantep, 27310, Gaziantep, Turkey

(Received 15 June 2006; accepted 21 August 2006; published online 5 October 2006)

With the consideration of spherical symmetry for the potential and mass function, one-dimensional solutions of nonrelativistic Schrödinger equations with spatially varying effective mass are successfully extended to arbitrary dimensions within the frame of recently developed elegant nonperturbative technique, where the BenDaniel-Duke effective Hamiltonian in one dimension is assumed like the unperturbed piece, leading to well-known solutions, whereas the modification term due to possible use of other effective Hamiltonians in one dimension and, together with the corrections coming from the treatments in higher dimensions, are considered as an additional term like the perturbation. Application of the model and its generalization for the completeness are discussed. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2354333]

I. INTRODUCTION

Gaining confidence from the successful applications[1] of the recently developed simple model[2] in different fields of physics, we have investigated[3] the relation between the solutions of physically acceptable effective mass Hamiltonians proposed in the literature for the treatment of one-dimensional problems. Using the spirit of the prescription suggested in Ref. 3, we aim here to tackle the more difficult problem of generating exact solutions for position-dependent mass Schrödinger equations (PDMSE) in N dimension, as most of the related works in the literature have been devoted to one-dimensional systems except the ones in Ref. 4.

The concept of PDMSE is known to play an important role in different branch of physics. This formalism has been extensively used in nuclei, quantum liquids, ^{3}He, and metal clusters. Another area wherein such concepts provide a very useful tool is the study of electronic properties of many condensed-matter systems, such as semiconductors and quantum dots. In particular, recent progress in crystal-growth techniques for producing nonuniform semiconductor specimens, wherein the carrier effective mass depends on position, has considerably enhanced the interest in the theoretical description of semiconductor heterostructures. It has also recently been signaled in the rapidly growing field of PT-symmetric or more generally pseudo-Hermitian quantum mechanics. For an excellent recent review, leading to the related references, the reader is referred to Ref. 4.

In Sec. II, the systematic treatment of N-dimensional PDMSE is presented and closed expressions corresponding to the full wave function and energy spectrum for exactly solvable potentials are given. Section III contains the application of the model while the generalization of the formalism is discussed in Sec. IV. Concluding remarks are given in the last section.

II. THEORETICAL CONSIDERATION

Tracking down solvable potentials in PDMSE has always aroused interest. Apart from being useful in understanding of many physical phenomena, the importance of searching for them also stems from the fact that they very often provide a good starting point for undertaking perturbative calculations of more complex systems.

As is well known (see, e.g., Refs. 3 and 5), the general form of radial PDMSE with Hermitian Hamiltonians in one dimension gives rise to

$$-\frac{\mathrm{d}}{\mathrm{dz}}\left[\frac{1}{M(z)}\frac{\mathrm{d}\Phi(z)}{\mathrm{dz}}\right]+V^{\mathrm{eff}}(z)\Phi(z)=\lambda\Phi(z), \tag{1}$$

where the effective potential

$$V^{\mathrm{eff}}(z)=V_0(z)+U_{\alpha\gamma}(z)=V_0(z)-\frac{(\alpha+\gamma)}{2}\frac{M''}{M^2}+(\alpha\gamma+\alpha+\gamma)\frac{M'^2}{M^3}, \tag{2}$$

depends on the mass term and ambiguity parameters. Here a prime denotes derivative with respect to the variable, $M(z)$ is the dimensionless form of the mass function $m(z)=m_0M(z)$ and we have set $\hbar=2m_0=1$. The effective potential is the sum of the real potential profile $V_0(z)$ and the modification $U_{\alpha\gamma}(z)$ emerged from the location dependence of the effective mass. A different Hamiltonian leads to a different modification term. Some of them are the ones proposed by[6] BenDaniel-Duke ($\alpha=\gamma=0$), Bastard ($\alpha=-1$), Zhu-Kroemer ($\alpha=\gamma=-1/2$), and Li-Kuhn ($\gamma=-1/2,\alpha=0$).

Considering the works in Refs. 3 and 7, the radial piece of PDMSE in arbitrary dimensions for spherically symmetric potentials and mass functions reads

$$\left\{\frac{\mathrm{d}^2}{\mathrm{d}r^2}+\frac{M'}{M}\left(\frac{N-1}{2r}-\frac{\mathrm{d}}{\mathrm{d}r}\right)-\frac{L(L+N+2)+(N-1)(N-3)/4}{r^2}+M[E-V_{\mathrm{eff}}(r)]\right\}\Psi(r)=0, \tag{3}$$

where we assume that $\Psi(r)=F(r)G(r)$, which leads to

$$\frac{1}{M}\left(\frac{F''}{F}+\frac{G''}{G}+2\frac{F'}{F}\frac{G'}{G}\right)-\frac{M'}{M^2}\left(\frac{F'}{F}+\frac{G'}{G}\right)=U_{\mathrm{eff}}-E. \tag{4}$$

The effective potential in higher dimensions ($N>1$) now is transformed to the form

$$U_{\mathrm{eff}}(r)=V_0(r)+U_{\alpha\gamma}(r)-\frac{M'}{M^2}\frac{(N-1)}{2r}+\frac{L(L+N-2)+(N-1)(N-3)/4}{Mr^2}, \tag{5}$$

in which L is the angular momentum. As the one-dimensional calculations require $N=1$ and $L=0$, Eq. (5) reduces in this case to $U_{\mathrm{eff}}=V_{\mathrm{eff}}=V_0+U_{\alpha\gamma}$ as in Ref. 3, which provides a safe testing ground.

Keeping in mind the spirit of the technique used simply in Ref. 3, we split Eq. (4) in two parts deviating from the treatments in[4]

$$W^2(r)-\left[\frac{W(r)}{\sqrt{M}}\right]'=V_0(r)-\varepsilon, \quad W=-\frac{F'}{\sqrt{M}F}, \tag{6}$$

where ε is the corresponding energy of the required quantum state F_n ($n=0,1,2,\ldots$) for V_0 which is assumed in this model as an exactly solvable mass-dependent potential, and

$$\Delta W^2(r) - \left[\frac{\Delta W(r)}{\sqrt{M}}\right]' + 2W(r)\Delta W(r) = \Delta V(r) - \Delta E, \quad \Delta W = -\frac{G'}{\sqrt{M}G}, \tag{7}$$

where

$$\Delta V(r) = U_{\alpha\gamma}(r) - \frac{M'}{M^2}\frac{(N-1)}{2r} + \frac{L(L+N-2)+(N-1)(N-3)/4}{Mr^2}. \tag{8}$$

Note that the total energy appearing in (4) is $E=\varepsilon+\Delta E$ and, in one dimension the modification term ΔV becomes $U_{\alpha\gamma}$ as in Ref. 3. This clarifies that the corrections due to the higher dimensions arise because of the second and third terms on the right-hand side of Eq. (8).

From the present theoretical consideration, Eq. (6) has an algebraic solution leading to closed analytical expressions for the wave functions and energy eigenvalues, hence one needs to solve Eq. (7) exactly. To proceed further, with the consideration of relativistic Dirac equations having no ambiquity parameters, we confidently choose

$$\Delta W(r) = \frac{(\alpha+\gamma)}{2}\frac{M'}{M^{3/2}} - \frac{(N+2L-1)}{2\sqrt{M}r}, \tag{9}$$

in which the second term disappears for $N=1$ as in Ref. 3. Within the frame of Eq. (7), this choice leads us to

$$W(r)\Delta W(r) = \frac{M'}{2rM^2}\left[\frac{(\alpha+\gamma)(N-1)}{2} + (\alpha+\gamma+1)L\right] - \frac{\Delta E}{2}, \tag{10}$$

which is the main result of the present work.

From the definition of the effective potential in Eq. (2), we also note that the use of Eqs. (7) and (8) naturally restricts the choice of some ambiguity parameters yielding different physically acceptable effective mass Hamiltonians, allowing only $\alpha=\gamma=0$ (Ben-Daniel Duke Hamiltonian) and $\alpha=\gamma=-1/2$ (Zhu-Kroemer Hamiltonian) cases. This observation clarifies that the unperturbed part (V_0) of the effective potential in (6) should correspond to the case $\alpha=\gamma=0$, having well-known solutions in one dimension, while $\alpha=\gamma=-1/2$ is used to calculate $U_{\alpha\gamma}$ in (8). Obviously, all the corrections coming from the higher dimensions to the energy and well-behaved wave function terms can be systematically calculated for a given M with the consideration of Eqs. (7)–(10) in light of the corresponding W in (6).

III. APPLICATION

Recently, some research has been devoted to the analysis of the classification of quantum systems with position-dependent mass regarding their exact solvability (Refs. 3–5, and references therein). On a similar basis, Plastino and his co-workers[8] applied an approach within the supersymmetric quantum mechanical framework, for the case $\alpha=\gamma=0$, to such systems and succeed to show that some one-dimensional systems with nonconstant mass have a supersymmetric partner with the same effective mass. They were also able to solve exactly some particular cases by constructing the superpotential $[W(r)]$ from the form of the effective mass $[M(r)]$ and generalize the concept of the shape invariance for these systems.

For illustration, the superpotential expressions given by Ref. 8 for the systems having harmonic oscillator and Morse-like spectra can be easily used in Eq. (6) to serve explicit expressions for the corrections to the one-dimensional solutions obtained by considering the Ben-Daniel-Duke effective Hamiltonian in their[8] calculations. This simple investigation enables us to test our results, because all the corrections should disappear in case $N=1$ and $\alpha=\gamma=0$ leading to the expressions in Ref. 8. For clarity, this section involves only the application on the harmonic oscillator system. However, the generalization of the present model yielding self-consistent calculations, reproducing $W(r)$ term within the model for any system of interest, will be discussed in the next section.

According to Ref. 8, $W(r)$ term in Eqs. (6) and (10) is

$$W(r)=\frac{\omega}{2}\int^{r}\sqrt{M(z)}\mathrm{d}z+\frac{1}{2}\left(\frac{1}{\sqrt{M}}\right)', \quad \omega=2\varepsilon_{n=0}, \tag{11}$$

for the systems having harmonic oscillator spectra. Hence, use of Eqs. (7)–(10) gives

$$\Delta E=\frac{M'}{rM^{2}}\left[\frac{(\alpha+\gamma)(N-1)}{2}+L(\alpha+\gamma+1)\right]+\frac{(N+2L-1)\omega}{2r\sqrt{M}}\int^{r}\sqrt{M(z)}\mathrm{d}z$$
$$+\left(\frac{1}{\sqrt{M}}\right)'\left\{(\alpha+\gamma)\left[\omega\int^{r}\sqrt{M(z)}\mathrm{d}z+\left(\frac{1}{\sqrt{M}}\right)'\right]+\frac{(N+2L-1)}{2r\sqrt{M}}\right\}, \tag{12}$$

which is the explicit form of the energy corrections for a given smooth mass. Clearly, it can be seen that for a constant mass $M\rightarrow 1$, Eq. (12) reduces to $(N+2L-1)w/2$ for arbitrary dimensions[7] while in one dimension it goes to zero for a nonconstant mass in case $\alpha=\gamma=0$.[8] Furthermore, from Eqs. (7) and (9), the modification term for the corresponding wave function is

$$G(r)=\exp\left(-\int^{r}\sqrt{M(z)}\Delta W(z)\mathrm{d}z\right)=r^{(N+2L-1)/2}M^{-(\alpha+\gamma)/2}. \tag{13}$$

As Eq. (6) is analytically solvable having a closed expression for $W(r)$ given by (11) reproducing explicit expressions for ε and F, the corresponding total energy and wave function can easily be calculated through $E=\varepsilon+\Delta E$ and $\Psi=FG$ for the system of interest with a location dependent mass. At this stage it is also noted that the formalism suggested here seems superior to the usual treatment in supersymmetric quantum theory that in principle starts with the ground state and builds up excited state wave functions by the use of some linear operators ($A^{\pm}$) whereas there is no such restriction in the present theory providing flexible investigations.

IV. DISCUSSION

Although the procedure used in the formalism seems reasonable, the use of other works as in the previous section for an appropriate $W(r)$term to solve Eq. (6) may be seen as a drawback of the model. To remove this seeming deficiency, we propose here a unified treatment within the model considering the recent work in Ref. 9.

Many of the special functions $H(g)$ of mathematics represent solutions to differential equations of the form

$$\frac{\mathrm{d}^{2}H(g)}{\mathrm{d}g^{2}}+Q(g)\frac{\mathrm{d}H(g)}{\mathrm{d}g}+R(g)H(g)=0, \tag{14}$$

where the functions $Q(g)$and $R(g)$ are well defined for any particular function.[10] Since in this article we are interested in bound state wave functions, we should restrict ourselves to polynomial solutions of Eq. (14). Bearing in mind Eq. (14), the substitution of $\Phi(z)=H[g(z)]f(z)$ in Eq. (1) leads to the second-order differential equation

$$\frac{1}{M}\left(\frac{f''}{f}+\frac{H''g'^{2}}{H}+\frac{g''H'}{H}+2\frac{H'g'f'}{Hf}\right)-\frac{M'}{M^{2}}\left(\frac{f'}{f}+\frac{H'g'}{H}\right)=V_{\mathrm{eff}}-\lambda, \tag{15}$$

in which primes denote derivatives with respect to g and z for the functions $H(g)$, $g(z)$, and $f(z)$, respectively. With the confidence gained by the similarity between Eqs. (15) and (4), one can safely use the present treatment splitting Eq. (15) in two pieces

$$W^{2}(z)-\left[\frac{W(z)}{\sqrt{M}}\right]'=V_{0}(z)-\varepsilon, \quad W=-\frac{f'}{\sqrt{M}f}, \tag{16}$$

and

$$\Delta W^2(z) - \left[\frac{\Delta W(z)}{\sqrt{M}}\right]' + 2W(z)\Delta W(z) = \Delta V(z) - \Delta E, \quad \Delta W = -\frac{H'g'}{\sqrt{MH}}, \tag{17}$$

which are similar to Eqs. (6) and (7), where $\lambda = \varepsilon + \Delta E$ and $V_{\text{eff}} = V_0 + \Delta V$.

After all, it can be clearly seen that Eq. (16) is the one required for obtaining an explicit expression for W term used in Eq. (6) corresponding to an exactly solvable system considered in one dimension ($\alpha = \gamma = 0$). However, to proceed further, the functions f and g should be solved as H, Q, and R are known in principle. Now, equating like terms between the resulting expression in (15) and (14) gives

$$Q[g(z)] = \frac{1}{g'}\left(\frac{g''}{g'} + \frac{2f'}{f} - \frac{M'}{M}\right), \quad R[g(z)] = \frac{1}{g'^2}\left[\frac{f''}{f} - \frac{M'}{M}\frac{f'}{f} + M(E - V)\right], \tag{18}$$

where, from the definition of Q,

$$f(z) \approx \left(\frac{M}{g'}\right)^{1/2} \exp\left[\frac{1}{2}\int^{g(z)} Q(g)\mathrm{d}g\right]. \tag{19}$$

Consideration of Eqs. (15)–(18) suggests a novel prescription

$$\Delta V(z) - \Delta E = -\frac{g'^2}{M} R[g(z)], \tag{20}$$

which, for plausible M and R functions, provides a reliable expression for $g(z)$. It is remarked that in the constant mass case $M \to 1$ this procedure reduces to the well-known formalism which has been thoroughly investigated[11] that, together with Ref. 9, justify our new proposal in solving PDMSE. The more detailed investigation of this treatment will be discussed elsewhere.

V. CONCLUDING REMARKS

In this article, a general method has been presented to address the question of corrections to the solution in one dimension for a large class of N-dimensional and exactly solvable PDMSE. We have also described how to extend the method to the case where the necessary function $W(r)$ in (6) generating algebraically solvable potentials in one dimension are present, which initiates calculations in the model leading to explicit expressions for the modifications due to both the use of physically plausible Zho-Kroemer effective Hamiltonian ($\alpha = \gamma = -1/2$) and higher dimensional treatments. The main results are consistent with the other related works in the literature, which allow a nonperturbative treatment of these issues.

Although, for clarity, we have illustrated an application of the method for an easily accessible case of interest, it can be readily employed in various typical situations. In view of the importance in calculating such corrections in physics, we believe that the present model would serve as a useful toolbox to treat even more realistic situations which now occur in experimental observations with the advent of the quantum technology.

Ryu Sasaki
Yukawa Institute for Theoretical Physics, Kyoto University, Kyoto 606-8502, Japan

(Received 27 May 2006; accepted 15 August 2006; published online 6 October 2006)

The annihilation-creation operators $a^{(\pm)}$ are defined as the positive/negative frequency parts of the exact Heisenberg operator solution for the "sinusoidal coordinate". Thus $a^{(\pm)}$ are hermitian conjugate to each other and the relative weights of various terms in them are solely determined by the energy spectrum. This unified method applies to most of the solvable quantum mechanics of single degree of freedom including those belonging to the "discrete" quantum mechanics. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2349485]

I. INTRODUCTION

The annihilation and creation operators are probably the most basic and important tools in quantum mechanics. Modern quantum physics is almost unthinkable without them. Approximately 80 years after its birth, the list of exactly solvable systems in quantum mechanics[1] is quite long now, including those of the so-called "discrete" quantum mechanics.[2,3] One natural question is that if these exactly solvable quantum mechanical systems also possess the algebraic solution method embodied in the annihilation-creation operators. We will answer the question in the affirmative and give a *unified dynamical* derivation of the annihilation-creation operators for most of the solvable quantum mechanics of single degree of freedom including those belonging to the discrete quantum mechanics.

The method is quite simple and elementary. One identifies a special function $\eta(x)$ of the space-coordinate x, which undergoes "sinusoidal motion" at the classical and quantum levels (2.10) and (2.14). The latter is simply the exact Heisenberg operator solution for $\eta(x)$. The function η is the argument of the orthogonal polynomial (2.3) constituting the eigenfunctions of the system. The positive/negative frequency parts of the exact Heisenberg operator solution of the "sinusoidal coordinate" $\eta(x)$ [(2.28) and (2.29)] give the annihilation-creation operators. This is essentially the same recipe as used by Heisenberg for solving the harmonic oscillator in matrix mechanics. To the best of our knowledge, the sinusoidal coordinate was first introduced in a rather broad sense for general (not necessarily solvable) potentials as a useful means for coherent state research by Nieto and Simmons.[4]

By similarity transformation in terms of the ground state wave function, the results of the present article will be translated to those of the corresponding orthogonal polynomials. In particular, the exact Heisenberg operator solution of the sinusoidal coordinate corresponds to the so-called *structure relation*[5] for the orthogonal polynomials. Our method provides the unified derivation of the structure relations for the Askey-Wilson, Wilson, continuous dual Hahn, continuous Hahn and Meixner-Pollaczek polynomials[6] based on the Hamiltonian principle. These polynomials are the eigenfunctions of the various discrete quantum mechanical systems[2,3] and they are the deformations of the Jacobi, Laguerre, and Hermite polynomials.[7]

This article is organized as follows. The general theory of the annihilation-creation operators is explained with typical examples; one from the ordinary quantum mechanics and two from the discrete version in Sec. II. Further explicit results are presented in Sec. III. They include the

(symmetric) Pöshl-Teller, symmetric Rosen-Morse, Morse and x^2+1/x^2 potentials on top of the five examples belonging to the discrete quantum mechanics mentioned previously. Section IV is for a summary and comments. In Appendix A, the necessary and sufficient condition for the existence of the sinusoidal coordinate is analyzed within the context of ordinary quantum mechanics. It turns out that those potentials having the sinusoidal coordinate are all *shape invariant*.[8] In Appendix B, interpretation of the annihilation-creation operators within the framework of shape invariance is given. It is the mechanism underlying the solvability of all systems considered in this article. Appendix C gives various definitions of the orthogonal polynomials, hypergeometric functions and their q analog.[7,6]

II. GENERAL THEORY WITH TYPICAL EXAMPLES

The purpose of the present paper is to present a *unified dynamical* theory of **annihilation-creation** operators. It is applicable to most of the *exactly solvable* quantum mechanical systems of one degree of freedom, including the so-called discrete quantum mechanics which are certain deformation of the solvable quantum mechanics.[2,3] They satisfy certain *difference equations* instead of the second order differential equations. Generalization to the systems of many degrees of freedom will be discussed elsewhere. The restriction to the solvable quantum systems is rather trivial and inevitable, since a system is obviously solvable if it possesses explicitly defined annihilation and creation operators and any one single eigenstate to work on. Then the entire set of exact eigenstates are easily and concretely generated.

Except for the simple harmonic oscillator, which gives probably the only so far universally accepted example of the annihilation-creation operators, there are quite a wide variety of proposed annihilation and creation operators in the literature.[9] Historically most of these annihilation-creation operators are connected to the so-called *algebraic theory of coherent states*, which are usually defined as eigenstates of *annihilation operators*. Therefore, for a given potential or a quantum Hamiltonian, there could be as many coherent states as the definitions of the annihilation operators.

Our new unified definition of the annihilation-creation operators is, on the contrary, based on the dynamical properties of a special coordinate, the sinusoidal coordinate shared by a class of solvable dynamical systems discussed in this article. A quantum mechanical system with a self-adjoint Hamiltonian $\mathcal{H}$ is solvable (or solved) if the entire set of its energy eigenvalues $\{\mathcal{E}_n\}$ and the corresponding eigenvectors $\{\phi_n\}$, $n=0,1,\ldots$ are known:

$$\mathcal{H}\phi_n = \mathcal{E}_n\phi_n, \quad n=0,1,\ldots. \tag{2.1}$$

As is well-known a quantum Hamiltonian (together with its discrete analog) has in general discrete as well as continuous spectrum. In this article we will concentrate on the discrete energy levels only, either finite or infinite in number. Then, because of the one dimensionality, the eigenvalues are not degenerate

$$\mathcal{E}_0 < \mathcal{E}_1 < \cdots, \tag{2.2}$$

and the eigenvectors have finite norms $\|\phi_n\|^2=N_n^2<\infty$. (When normalized vectors are needed we denote them by adding a hat, $\{\hat{\phi}_n \overset{\text{def}}{=} \phi_n/N_n\}$, $\|\hat{\phi}_n\|=1$.) This is the solution in the Schrödinger picture and the eigenvectors $\{\phi_n\}$ are usually expressed as functions $\{\phi_n(x)\}$ of the space-coordinate x. For the majority of the solvable quantum systems, the nth eigenfunction has the following general structure[1]:

$$\phi_n(x) = \phi_0(x)P_n(\eta(x)) \tag{2.3}$$

in which $\phi_0(x)$ is the *ground state* wave function. It has no nodes and we may choose it to be always real and positive. The second factor $P_n(\eta(x))$ is a polynomial of degree n in a real variable η. We also take $P_n(\eta)$ as real and use a convention $P_{-1}(\eta)=0$. Reflecting the orthogonality

theorem of the eigenvectors of a self-adjoint Hamiltonian, $\{P_n(\eta)\}$ form *orthogonal polynomials* with respect to a weight function (measure)

$$\phi_0(x)^2 dx \propto w(\eta) d\eta. \tag{2.4}$$

Throughout this article we follow the definition and notation of Szegö's book[7] for the classical orthogonal polynomials and the review by Koekoek and Swarttouw[6] for the Askey scheme of hypergeometric orthogonal polynomials and its q analog, which are deformations of the classical orthogonal polynomials.

There are certain exactly solvable quantum systems, for example, the one-dimensional Kepler problem, etc., for which the general form of eigenfunction (2.3) does not hold. For them, the present unified theory does not apply. See Appendix A.

Our main claim is that this $\eta(x)$ undergoes a *sinusoidal motion* under the given Hamiltonian $\mathcal{H}$, at the classical as well as quantum level, by mimicking the simple harmonic oscillator. This fact is the basis of our dynamical and unified definition of the annihilation-creation operators. To be more specific, at the classical level we have

$$\{\mathcal{H},\{\mathcal{H},\eta\}\} = -\eta R_0(\mathcal{H}) - R_{-1}(\mathcal{H}) \tag{2.5}$$

in which the canonical Poisson bracket relations are defined for the canonical coordinate x, its conjugate momentum p and for any functions $A(x,p)$ and $B(x,p)$ as

$$\{x,p\} = 1, \quad \{x,x\} = \{p,p\} = 0, \quad \{A,B\} = \frac{\partial A}{\partial x}\frac{\partial B}{\partial p} - \frac{\partial A}{\partial p}\frac{\partial B}{\partial x}. \tag{2.6}$$

The two coefficients R_0 and R_{-1} are, in general, polynomials in the Hamiltonian $\mathcal{H}$. The effect of R_{-1} is to shift the origin of $\eta(x)$ by a quantity (possibly) depending on $\mathcal{H}$. It is convenient to introduce a shifted sinusoidal coordinate $\tilde{\eta}(x)$

$$\tilde{\eta}(x) \overset{\text{def}}{=} \eta(x) + R_{-1}(\mathcal{H})/R_0(\mathcal{H}) \quad (\Rightarrow \{\mathcal{H},\{\mathcal{H},\tilde{\eta}\}\} = -\tilde{\eta}R_0(\mathcal{H})). \tag{2.7}$$

Relation (2.5) would allow to evaluate the multiple Poisson brackets of η with $\mathcal{H}$ easily:

$$\text{ad}\,\mathcal{H}\,\eta \overset{\text{def}}{=} \{\mathcal{H},\eta\}, \quad (\text{ad}\,\mathcal{H})^2\eta = \{\mathcal{H},\{\mathcal{H},\eta\}\}, \quad (\text{ad}\,\mathcal{H})^n\eta = \{\mathcal{H},(\text{ad}\,\mathcal{H})^{n-1}\eta\}, \tag{2.8}$$

which leads to a simple sinusoidal time evolution:

$$\tilde{\eta}(x;t) = \sum_{n=0}^{\infty} \frac{(-t)^n}{n!}(\text{ad}\,\mathcal{H})^n\tilde{\eta}, = -\{\mathcal{H},\tilde{\eta}\}_0 \frac{\sin[t\sqrt{R_0(\mathcal{H}_0)}]}{\sqrt{R_0(\mathcal{H}_0)}} + \tilde{\eta}(x)_0 \cos[t\sqrt{R_0(\mathcal{H}_0)}]. \tag{2.9}$$

In the original variable it reads

$$\eta(x;t) = -\{\mathcal{H},\eta\}_0 \frac{\sin[t\sqrt{R_0(\mathcal{H}_0)}]}{\sqrt{R_0(\mathcal{H}_0)}} - R_{-1}(\mathcal{H}_0)/R_0(\mathcal{H}_0) + (\eta(x)_0 + R_{-1}(\mathcal{H}_0)/R_0(\mathcal{H}_0))\cos[t\sqrt{R_0(\mathcal{H}_0)}], \tag{2.10}$$

in which $\eta(x)_0$ ($\tilde{\eta}(x)_0$), and $\{\mathcal{H},\eta\}_0$ are the initial values (at $t=0$) of these variables and $\mathcal{H}_0$ denotes the value of the Hamiltonian (the energy) for these initial data. In general, the frequency of the simple oscillation $\sqrt{R_0(\mathcal{H}_0)}$ can depend on the initial data. This is the reason why we call $\eta(x)$ the sinusoidal coordinate avoiding the more appealing but misleading "harmonic coordinate."

At the quantum level with the canonical commutation relations

$$[x,p] = i, \quad [x,x] = [p,p] = 0, \quad \hbar \equiv 1, \tag{2.11}$$

the formula corresponding to (2.5) reads

$$[\mathcal{H},[\mathcal{H},\eta]] = \eta R_0(\mathcal{H}) + [\mathcal{H},\eta]R_1(\mathcal{H}) + R_{-1}(\mathcal{H}). \tag{2.12}$$

In other words, the multiple commutators of $\mathcal{H}$ with η form a closed algebra at level two. Here, the quantum coefficients R_0 and R_{-1} could differ from the classical ones by quantum corrections. But we use the same symbols as there is no risk of confusion. Obviously $R_1(\mathcal{H})$ is the quantum effect. As in the classical case, the multiple commutators of η with $\mathcal{H}$

$$\text{ad}\,\mathcal{H}\,\eta \overset{\text{def}}{=} [\mathcal{H},\eta], \quad (\text{ad}\,\mathcal{H})^2\eta = [\mathcal{H},[\mathcal{H},\eta]], \quad (\text{ad}\,\mathcal{H})^n\eta = [\mathcal{H},(\text{ad}\,\mathcal{H})^{n-1}\eta], \tag{2.13}$$

can be easily evaluated from (2.12). This leads to the *exact operator solution* in the Heisenberg picture:

$$e^{it\mathcal{H}}\eta(x)e^{-it\mathcal{H}} = \sum_{n=0}^{\infty}\frac{(it)^n}{n!}(\text{ad}\,\mathcal{H})^n\eta, = [\mathcal{H},\eta(x)]\frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H})} - R_{-1}(\mathcal{H})/R_0(\mathcal{H})$$
$$+ (\eta(x) + R_{-1}(\mathcal{H})/R_0(\mathcal{H}))\frac{-\alpha_-(\mathcal{H})e^{i\alpha_+(\mathcal{H})t} + \alpha_+(\mathcal{H})e^{i\alpha_-(\mathcal{H})t}}{\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H})}, \tag{2.14}$$

in which the two "frequencies" $\alpha_\pm(\mathcal{H})$ are

$$\alpha_\pm(\mathcal{H}) = (R_1(\mathcal{H}) \pm \sqrt{R_1(\mathcal{H})^2 + 4R_0(\mathcal{H})})/2, \tag{2.15}$$

$$\alpha_+(\mathcal{H}) + \alpha_-(\mathcal{H}) = R_1(\mathcal{H}), \quad \alpha_+(\mathcal{H})\alpha_-(\mathcal{H}) = -R_0(\mathcal{H}). \tag{2.16}$$

If the quantum effects are neglected, i.e., $R_1 \equiv 0$ and $\mathcal{H} \to \mathcal{H}_0$ [on the right-hand side (r.h.s.)], we have $\alpha_+ = -\alpha_- = \sqrt{R_0(\mathcal{H}_0)}$, the previous Heisenberg operator solution reduces to the classical one (2.10) in terms of the quantum-classical correspondence:

$$[A,B]/i\hbar \to \{A,B\}, \quad (\hbar \to 0). \tag{2.17}$$

The above-mentioned exact operator solution looks slightly simpler if the shifted sinusoidal coordinate is used

$$e^{it\mathcal{H}}\tilde{\eta}(x)e^{-it\mathcal{H}} = [\mathcal{H},\tilde{\eta}(x)]\frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H})} + \tilde{\eta}(x)\frac{-\alpha_-(\mathcal{H})e^{i\alpha_+(\mathcal{H})t} + \alpha_+(\mathcal{H})e^{i\alpha_-(\mathcal{H})t}}{\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H})}. \tag{2.18}$$

Like the exact classical solution (2.10), the exact quantum solution (2.14) contains all the dynamical information of the quantum system. One can, for example, determine the entire discrete spectrum $\{\mathcal{E}_n\}$ by following Heisenberg and Pauli's arguments for the harmonic oscillator and the hydrogen atom. Let us first note that the ground state energy $\mathcal{E}_0 = 0$ is known explicitly, because of our choice of the factorised form of the exactly solvable Hamiltonian (see the following examples):

$$\mathcal{H} = \mathcal{A}^\dagger\mathcal{A}/2, \quad \mathcal{A}\phi_0 = 0 \Rightarrow \mathcal{H}\phi_0 = 0, \quad \mathcal{E}_0 = 0. \tag{2.19}$$

Let us apply (2.14) to the nth eigenvector ϕ_n:

$$e^{it(\mathcal{H}-\mathcal{E}_n)}\eta(x)\phi_n = ([\mathcal{H},\eta(x)]\phi_n + (-\eta(x)\alpha_-(\mathcal{E}_n) + R_{-1}(\mathcal{E}_n)/\alpha_+(\mathcal{E}_n))\phi_n)e^{i\alpha_+(\mathcal{E}_n)t}/(\alpha_+(\mathcal{E}_n) - \alpha_-(\mathcal{E}_n))$$
$$+ (-[\mathcal{H},\eta(x)]\phi_n + (\eta(x)\alpha_+(\mathcal{E}_n) - R_{-1}(\mathcal{E}_n)/\alpha_-(\mathcal{E}_n))\phi_n)e^{i\alpha_-(\mathcal{E}_n)t}/(\alpha_+(\mathcal{E}_n) - \alpha_-(\mathcal{E}_n))$$
$$- (R_{-1}(\mathcal{E}_n)/R_0(\mathcal{E}_n))\phi_n. \tag{2.20}$$

As the r.h.s. has only two different time dependences except for the constant term, the left-hand-side (l.h.s.) can only have two nonvanishing matrix elements when sandwiched by ϕ_m, except for the obvious ϕ_n corresponding to the constant term. In accordance with the general structure of the eigenfunctions (2.3), they are $\phi_{n\pm1}$:

$$\langle \phi_m | \eta(x) | \phi_n \rangle = 0 \quad \text{for } m \neq n \pm 1, n. \tag{2.21}$$

This imposes the following conditions on the energy eigenvalues:

$$\mathcal{E}_{n+1} - \mathcal{E}_n = \alpha_+(\mathcal{E}_n), \quad \mathcal{E}_{n-1} - \mathcal{E}_n = \alpha_-(\mathcal{E}_n). \tag{2.22}$$

Likewise we obtain the "hermitian conjugate" conditions

$$\mathcal{E}_n - \mathcal{E}_{n-1} = \alpha_+(\mathcal{E}_{n-1}), \quad \mathcal{E}_n - \mathcal{E}_{n+1} = \alpha_-(\mathcal{E}_{n+1}) \tag{2.23}$$

relating these three neighboring eigenvalues. These overdetermined conditions (2.22), (2.23), and $\mathcal{E}_0 = 0$ determine the entire energy spectrum $\{\mathcal{E}_n\}$ completely for each Hamiltonian. The consistency of the procedure requires that the second term on r.h.s. of (2.20) should vanish when applied to the ground state ϕ_0:

$$-[\mathcal{H}, \eta(x)]\phi_0 + (\eta(x)\alpha_+(0) - R_{-1}(0)/\alpha_-(0))\phi_0 = 0, \tag{2.24}$$

which could be interpreted as the equation determining the ground state eigenvector ϕ_0 in the Heisenberg picture. If the number of the discrete levels is finite $(M+1)$ a corresponding condition must be met that the first term on r.h.s. of (2.20) should not belong to the Hilbert space of normalizable vectors when applied to the highest discrete level eigenvector ϕ_M:

$$\|[\mathcal{H}, \eta(x)]\phi_M + (-\eta(x)\alpha_-(\mathcal{E}_M) + R_{-1}(\mathcal{E}_M)/\alpha_+(\mathcal{E}_M))\phi_M\| = \infty. \tag{2.25}$$

As is clear by now, (2.14) and (2.21) are the physical embodiment of the **three term recursion relations** satisfied by any orthogonal polynomial of single variable:

$$\eta P_n(\eta) = A_n P_{n+1}(\eta) + B_n P_n(\eta) + C_n P_{n-1}(\eta). \tag{2.26}$$

The coefficients A_n, B_n, and C_n are also real for a real polynomial $P_n(\eta)$. For the systems treated in this article, that is those having the general structure of the eigenvectors (2.3), this implies the three term recurrence relations of the eigenfunctions

$$\eta(x)\phi_n(x) = A_n\phi_{n+1}(x) + B_n\phi_n(x) + C_n\phi_{n-1}(x). \tag{2.27}$$

At the same time the above-mentioned arguments and the treatment of the harmonic oscillator by Heisenberg clearly show that the operator coefficient of $e^{it\alpha_-(\mathcal{H})}$ on the r.h.s. of the Heisenberg operator solution (2.14) is the annihilation operator, that is, acting on ϕ_n it produces a state ϕ_{n-1}. Likewise, the operator coefficient of $e^{it\alpha_+(\mathcal{H})}$ of the Heisenberg operator solution (2.14) is the creation operator. Thus we arrive at a *dynamical and unified definition* of the **annihilation-creation operators**:

$$e^{it\mathcal{H}}\eta(x)e^{-it\mathcal{H}} = a^{(+)}(\mathcal{H}, \eta)e^{i\alpha_+(\mathcal{H})t} + a^{(-)}(\mathcal{H}, \eta)e^{i\alpha_-(\mathcal{H})t} - R_{-1}(\mathcal{H})/R_0(\mathcal{H}), \tag{2.28}$$

$$a^{(\pm)} = a^{(\pm)}(\mathcal{H}, \eta) \overset{\text{def}}{=} (\pm[\mathcal{H}, \eta(x)] \mp (\eta(x) + R_{-1}(\mathcal{H})/R_0(\mathcal{H}))\alpha_\mp(\mathcal{H}))/(\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H})). \tag{2.29}$$

When acting on the eigenvector ϕ_n, they read

$$a^{(\pm)}\phi_n(x) = \frac{\pm 1}{\mathcal{E}_{n+1} - \mathcal{E}_{n-1}}\left([\mathcal{H}, \eta(x)] + (\mathcal{E}_n - \mathcal{E}_{n\mp 1})\eta(x) + \frac{R_{-1}(\mathcal{E}_n)}{\mathcal{E}_{n\pm 1} - \mathcal{E}_n}\right)\phi_n(x). \tag{2.30}$$

Before going to the detailed discussion of the annihilation-creation operators for various Hamiltonians in Secs. II A and III, let us analyze annihilation-creation operators in a more general context. A minimal requirement for annihilation-creation operators is the following: (0) Annihilation-creation operators map ϕ_n to ϕ_{n-1} and ϕ_{n+1} (up to an overall constant), respectively. It should be stressed that there is no *a priori* principle for fixing the normalization of the operators.

Sometimes it is convenient to introduce the annihilation-creation operators with a different normalization

$$a'^{(\pm)} \overset{\text{def}}{=} a^{(\pm)}(\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H})) = \pm[\mathcal{H}, \eta(x)] \mp (\eta(x) + R_{-1}(\mathcal{H})/R_0(\mathcal{H}))\alpha_\mp(\mathcal{H}), \tag{2.31}$$

which gives

$$a'^{(\pm)}\phi_n(x) = \pm\left([\mathcal{H}, \eta(x)] + (\mathcal{E}_n - \mathcal{E}_{n\mp1})\eta(x) + \frac{R_{-1}(\mathcal{E}_n)}{\mathcal{E}_{n\pm1} - \mathcal{E}_n}\right)\phi_n(x). \tag{2.32}$$

On the r.h.s. the coefficients of the operator $\eta(x)$ and the identity operator depend on n in general.

The annihilation-creation operators of the **harmonic oscillator** have several remarkable properties:

(i) Annihilation/creation operator is the positive/negative frequency part of the Heisenberg operator of the sinusoidal coordinate;
(ii) (annihilation operator)†=(creation operator);
(iii) $\mathcal{H}$=const. (creation operator)(annihilation operator).

The first property (i) is the principle leading to our unified definition of the annihilation-creation operators as in (2.28) and (2.29). Next we show that they are hermitian conjugate to each other. That is, they satisfy the property (ii), too. By using the three-term recursion relation, we obtain

$$e^{it\mathcal{H}}\eta e^{-it\mathcal{H}}\phi_n = e^{it(\mathcal{E}_{n+1}-\mathcal{E}_n)}A_n\phi_{n+1} + B_n\phi_n + e^{it(\mathcal{E}_{n-1}-\mathcal{E}_n)}C_n\phi_{n-1}. \tag{2.33}$$

Comparing this with (2.28) and (2.29), we arrive at

$$a^{(+)}\phi_n = A_n\phi_{n+1}, \quad a^{(-)}\phi_n = C_n\phi_{n-1}, \quad R_{-1}(\mathcal{E}_n)/R_0(\mathcal{E}_n) = -B_n. \tag{2.34}$$

Here use is made of the facts

$$\alpha_+(\mathcal{E}_n) = \mathcal{E}_{n+1} - \mathcal{E}_n, \quad \alpha_-(\mathcal{E}_n) = \mathcal{E}_{n-1} - \mathcal{E}_n,$$

$$R_1(\mathcal{E}_n) = \mathcal{E}_{n+1} + \mathcal{E}_{n-1} - 2\mathcal{E}_n, \quad R_0(\mathcal{E}_n) = -(\mathcal{E}_{n+1} - \mathcal{E}_n)(\mathcal{E}_{n-1} - \mathcal{E}_n), \tag{2.35}$$

and that $\alpha_\pm(\mathcal{H})$ and $R_i(\mathcal{H})$ $(i=1,0,-1)$ are hermitian. Hermitian conjugate of $a^{(-)}$ is

$$a^{(-)\dagger} = (\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H}))^{-1}([\mathcal{H}, \eta(x)] + \alpha_+(\mathcal{H})(\eta(x) + R_{-1}(\mathcal{H})/R_0(\mathcal{H}))), \tag{2.36}$$

and its action on ϕ_n is

$$\begin{aligned} a^{(-)\dagger}\phi_n &= (\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H}))^{-1}(\mathcal{H}\eta\phi_n - \eta\mathcal{E}_n\phi_n + \alpha_+(\mathcal{H})(\eta\phi_n + R_{-1}(\mathcal{E}_n)/R_0(\mathcal{E}_n)\phi_n)) \\ &= (\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H}))^{-1}((\mathcal{E}_{n+1} - \mathcal{E}_n)A_n\phi_{n+1} + (\mathcal{E}_{n-1} - \mathcal{E}_n)C_n\phi_{n-1} + \alpha_+(\mathcal{H})(A_n\phi_{n+1} + C_n\phi_{n-1})) \\ &= (\alpha_+(\mathcal{H}) - \alpha_-(\mathcal{H}))^{-1}(\mathcal{E}_{n+2} - \mathcal{E}_n)A_n\phi_{n+1} = A_n\phi_{n+1} = a^{(+)}\phi_n. \end{aligned} \tag{2.37}$$

Therefore $a^{(\pm)}$ are hermitian conjugate to each other, $a^{(-)\dagger}=a^{(+)}$. This also means that

$$e^{-it\alpha_-(\mathcal{H})}a^{(+)} = a^{(+)}e^{it\alpha_+(\mathcal{H})}, \quad e^{-it\alpha_+(\mathcal{H})}a^{(-)} = a^{(-)}e^{it\alpha_-(\mathcal{H})}, \tag{2.38}$$

reflecting the obvious hermiticity of the l.h.s. of (2.28). Note that $a'^{(\pm)}$ are not hermitian conjugate to each other, $a'^{(-)\dagger} \neq a'^{(+)}$, in general.

In the special case of the equi-spaced spectrum $\mathcal{E}_n=an$ (a: constant), to which many interesting examples belong including the harmonic oscillator and its deformation, we have $\alpha_\pm(\mathcal{H})=\pm a$, $R_1(\mathcal{H})=0$, $R_0(\mathcal{H})=a^2$ and

$$2aa^{(\pm)} = a'^{(\pm)} = \pm[\mathcal{H}, \eta(x)] + a\eta(x) + R_{-1}(\mathcal{H})/a. \tag{2.39}$$

For the simplest harmonic oscillator $\mathcal{H}=(p+ix)(p-ix)/2$, we have $\eta(x)=x$, $R_0=1$, $R_1=R_{-1}=0$ and $[\mathcal{H},x]=-ip$ and $2a^{(+)}=x-ip$, $2a^{(-)}=x+ip$, which differ from the conventional ones by a factor $\sqrt{2}$.

In contrast to the above two properties, the third the property (iii) of the annihilation-creation operators is achieved by a very specific modification of the definition as follows:

$$a''^{(-)} \overset{\text{def}}{=} a^{(-)} f(\mathcal{H}), \quad a''^{(+)} \overset{\text{def}}{=} a''^{(-)\dagger} = f(\mathcal{H}) a^{(+)}, \tag{2.40}$$

where $f(\mathcal{H})=f(\mathcal{H})^\dagger$ is an as yet unspecified function of $\mathcal{H}$. Then we have

$$a''^{(+)} a''^{(-)} \phi_n = f(\mathcal{E}_n)^2 A_{n-1} C_n \phi_n. \tag{2.41}$$

If $f(\mathcal{H})$ is chosen to satisfy

$$f(\mathcal{E}_n)^2 = \mathcal{E}_n/(A_{n-1}C_n) \overset{\text{def}}{(=g(n))}, \tag{2.42}$$

then we obtain

$$\mathcal{H} = a''^{(+)} a''^{(-)}. \tag{2.43}$$

Such an operator $f(\mathcal{H})$ function can be constructed as $f(\mathcal{H})=\sqrt{g(\mathcal{N})}$, where the number (or level) operator $\mathcal{N}$ is defined by

$$\mathcal{N}\phi_n = n\phi_n. \tag{2.44}$$

This operator $\mathcal{N}$ can be expressed in terms of the Hamiltonian, for example,

$$\mathcal{E}_n = an \Rightarrow \mathcal{N} = \mathcal{H}/a, \tag{2.45}$$

$$\mathcal{E}_n = an^2 + bn \Rightarrow \mathcal{N} = (\sqrt{4a\mathcal{H} + b^2} - b)/(2a), \tag{2.46}$$

$$\mathcal{E}_n = a(q^{-n} - 1)(1 - bq^n) \Rightarrow q^{\mathcal{N}} = (\mathcal{H}/a + b + 1 - \sqrt{(\mathcal{H}/a + b + 1)^2 - 4b})/(2b), \tag{2.47}$$

where a, b, and q are constant ($b>0$ in the second equation, $b<1$ in the third equation). This $a''^{(\pm)}$ satisfies the property (ii) by definition, but the property (i) becomes ugly or unnatural in general.

Let us close the general theory by a brief discussion of the coherent states. One definition of the coherent state ψ is the eigenvector of the annihilation operator [annihilation operator coherent state (AOCS)]:

$$a^{(-)}\psi = \lambda\psi, \quad \lambda \in \mathbb{C}. \tag{2.48}$$

In terms of the simple parametrization $\psi=\Sigma_{n=0}^{\infty} c_n \phi_n(x)$ (with $c_0=1$ as normalization) and the formula (2.34), we arrive at

$$\psi = \psi(\lambda, x) = \phi_0(x) \sum_{n=0}^{\infty} \frac{\lambda^n}{\prod_{k=1}^{n} C_n} \cdot P_n(\eta(x)). \tag{2.49}$$

For the equispaced spectrum $\mathcal{E}_n=an$ (a: constant), the coherent state has the property of temporal stability

$$e^{it\mathcal{H}}\psi(\lambda, x) = \psi(e^{iat}\lambda, x). \tag{2.50}$$

It should be remarked that the concrete form of the AOCS depends on the specific normalization of the annihilation operator. For the annihilation operators $a'^{(-)}$, $a''^{(-)}$ and others, we denote the

corresponding coherent states as ψ', ψ'', etc. Which coherent state is useful depends on the physics of the system.

A. Some typical examples

Now let us look at typical examples[1–3] to show the actual content of our new unified theory of annihilation-creation operators. In their pioneering work, Nieto and Simmons[4] treated four solvable cases, those discussed in Secs. II A 1, III A 1, III A 3, and III A 4. Some of our results were reported in Ref. 4. Here and throughout this article we put the dimensionfull quantities as unity, including the Planck's constant.

1. $1/\sin^2 x$ *potential, or symmetric Pöschl-Teller potential*

The first example has the $1/\sin^2 x$ potential, which is the one-body case of the well-known Sutherland model.[10,11] This provides the simplest example of the annihilation-creation operators depending on n. The corresponding coherent state (2.72) or (2.75) had not yet been known, to the best of our knowledge. The system is confined in a finite interval, say $(0,\pi)$ and it has an infinite number of discrete eigenstates. Although this potential is a special $(g=h)$ case of the Pöschl-Teller potential discussed in Sec. III A 2, it merits separate analysis. The Hamiltonian, the eigenvalues and the eigenfunctions are as follows:

$$\mathcal{H} \overset{\text{def}}{=} (p - ig\cot x)(p + ig\cot x)/2, \quad (\overset{\text{Q.M.}}{\Rightarrow} 2\mathcal{H} + g^2 = p^2 + g(g-1)/\sin^2 x), \tag{2.51}$$

$$\mathcal{E}_n = n(n/2+g), \quad n = 0,1,2,\ldots, \quad g > 0, \quad 0 < x < \pi, \quad \eta(x) = \cos x, \tag{2.52}$$

$$\phi_n(x) = (\sin x)^g P_n^{(\beta,\beta)}(\cos x), \quad \beta \overset{\text{def}}{=} g - 1/2, \tag{2.53}$$

in which $P_n^{(\alpha,\beta)}(\eta)$ is the Jacobi polynomial (C8) and $P_n^{(\beta,\beta)}(\eta)$ is proportional to the Gegenbauer polynomial $C_n^{(\beta+1/2)}(\eta)$ (C9)

$$\frac{P_n^{(\beta,\beta)}(\eta)}{(\beta+1)_n} = \frac{C_n^{(\beta+1/2)}(\eta)}{(2\beta+1)_n}. \tag{2.54}$$

Hereafter we often use the Pochhammer symbol $(a)_n$, see (C1).

It is straightforward to evaluate the Poisson brackets

$$\{\mathcal{H},\cos x\} = p\sin x, \quad \{\mathcal{H},\{\mathcal{H},\cos x\}\} = -\cos x\, 2\mathcal{H}', \quad \mathcal{H}' \overset{\text{def}}{=} \mathcal{H} + g^2/2, \tag{2.55}$$

leading to the solution of the initial value problem:

$$\cos x(t) = \cos x(0)\cos[t\sqrt{2\mathcal{H}_0'}] - p(0)\sin x(0)\frac{\sin[t\sqrt{2\mathcal{H}_0'}]}{\sqrt{2\mathcal{H}_0'}}. \tag{2.56}$$

It is straightforward to verify $|\cos x(t)| < 1$. The corresponding quantum expressions are

$$[\mathcal{H},\cos x] = i\sin x\, p + \cos x/2, \tag{2.57}$$

$$[\mathcal{H},[\mathcal{H},\cos x]] = \cos x(2\mathcal{H}' - 1/4) + [\mathcal{H},\cos x], \tag{2.58}$$

$$\alpha_\pm(\mathcal{H}) = 1/2 \pm \sqrt{2\mathcal{H}'}. \tag{2.59}$$

The exact operator solution reads

$$e^{it\mathcal{H}}\cos x\, e^{-it\mathcal{H}} = (i\sin x\, p + \cos x/2)\frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}} + \cos x\frac{-\alpha_-(\mathcal{H})e^{i\alpha_+(\mathcal{H})t} + \alpha_+(\mathcal{H})e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}}. \tag{2.60}$$

The annihilation and creation operators are

$$a'^{(\pm)} = a^{(\pm)}2\sqrt{2\mathcal{H}'} = \pm i\sin x\, p + \cos x\,\sqrt{2\mathcal{H}'} = \pm\sin x\frac{\mathrm{d}}{\mathrm{d}x} + \cos x\,\sqrt{2\mathcal{H}'}. \tag{2.61}$$

It is now obvious that they ($a'^{(\pm)}$) are not hermitian conjugate to each other. The square root sign is neatly removed when applied to the eigenvector ϕ_n as $2\mathcal{E}_n+g^2=(n+g)^2$:

$$a'^{(-)}\phi_n = -\sin x\frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (n+g)\cos x\,\phi_n = (n+\beta)\phi_{n-1}, \tag{2.62}$$

$$a'^{(+)}\phi_n = \sin x\frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (n+g)\cos x\,\phi_n = \frac{2(n+1)(n+2g)}{2n+2g+1}\phi_{n+1}. \tag{2.63}$$

This is a rule rather than exception as expected from the relations between the neighboring energy levels, (2.22) and (2.23). The right-hand sides are the results of the application. In particular, when acting on the ground state ϕ_0, the annihilation ($a'^{(-)}$) and creation ($a'^{(+)}$) operators are proportional to the factorization operators $\mathcal{A}$ and $\mathcal{A}^\dagger$ of the Hamiltonian $\mathcal{H}=\mathcal{A}^\dagger\mathcal{A}/2$, respectively:

$$a'^{(-)}\phi_0 = \left(-\sin x\frac{\mathrm{d}}{\mathrm{d}x} + g\cos x\right)\phi_0 = -\sin x\left(\frac{\mathrm{d}}{\mathrm{d}x} - g\cot x\right)\phi_0 = \eta'(x)\mathcal{A}\phi_0 = 0,$$

$$a'^{(+)}\phi_0 = \left(\sin x\frac{\mathrm{d}}{\mathrm{d}x} + g\cos x\right)\phi_0 = -\sin x\left(-\frac{\mathrm{d}}{\mathrm{d}x} - g\cot x\right)\phi_0 = \eta'(x)\mathcal{A}^\dagger\phi_0. \tag{2.64}$$

In a rough sense, the factor $\eta'(x)=-\sin x$, in the creation operator, compensates the downward shift of the parameter (g) caused by $\mathcal{A}^\dagger$. Similar situations are encountered in all the other quantum systems. In particular, for the systems with equispaced spectrum $\mathcal{E}_n=an$ (a: constant), the factorization of $a'^{(-)}$ and $a'^{(+)}$ into $\mathcal{A}$ and $\mathcal{A}^\dagger$ is n independent, (2.94), (3.14), (3.15), and (3.92). Their significance will be discussed in some detail for the "discrete" quantum mechanics cases in Appendix B.

The following interesting commutation relations ensue from (2.62) and (2.63):

$$[\mathcal{H},a'^{(\pm)}] = \pm(\sqrt{2\mathcal{H}'}a'^{(\pm)} + a'^{(\pm)}\sqrt{2\mathcal{H}'})/2, \tag{2.65}$$

$$[a'^{(-)},a'^{(+)}] = 2\sqrt{2\mathcal{H}'}, \tag{2.66}$$

$$a'^{(-)}a'^{(+)} + a'^{(+)}a'^{(-)} = 4\mathcal{H} + 2g. \tag{2.67}$$

The relation (2.67) could be accepted as a substitute of the property (iii) of the annihilation-creation operators discussed previously.

By the similarity transformation in terms of the ground state wave function $\phi_0(x)=(\sin x)^g$, we obtain the so-called shift down and up operators for the Jacobi (Gegenbauer) polynomial ($\beta=g-1/2$):

$$\text{down:}\quad (1-\eta^2)\frac{\mathrm{d}}{\mathrm{d}\eta}P_n^{(\beta,\beta)}(\eta) + n\eta P_n^{(\beta,\beta)}(\eta) = (n+\beta)P_{n-1}^{(\beta,\beta)}(\eta), \tag{2.68}$$

$$\text{up:}\quad -(1-\eta^2)\frac{\mathrm{d}}{\mathrm{d}\eta}P_n^{(\beta,\beta)}(\eta)+(n+2g)\,\eta P_n^{(\beta,\beta)}(\eta)=\frac{2(n+1)(n+2g)}{2n+2g+1}P_{n+1}^{(\beta,\beta)}(\eta). \tag{2.69}$$

As expected they are the same Jacobi polynomials of degree $n-1$ and $n+1$. It should be stressed that these shift down-up operators are naturally derived from our annihilation-creation operators without assuming the explicit form of the three term recursion relation.

The coherent state ψ (2.48) is

$$\psi(x)=\phi_0(x)\sum_{n=0}^{\infty}(2\lambda)^n\frac{(\beta+3/2)_n}{(\beta+1)_n}P_n^{(\beta,\beta)}(\cos x)=\phi_0(x)\sum_{n=0}^{\infty}(2\lambda)^n\frac{(g+1)_n}{(2g)_n}C_n^{(g)}(\cos x), \tag{2.70}$$

where we have used $a^{(-)}\phi_n=a'^{(-)}\phi_n/(2(n+g))$, (2.62) and (2.54). A generating function of the Gegenbauer polynomials (γ: arbitrary),[6]

$$\sum_{n=0}^{\infty}t^n\frac{(\gamma)_n}{(2g)_n}C_n^{(g)}(\eta)=(1-\eta t)^{-\gamma}{}_2F_1\left(\begin{matrix}\gamma/2,(\gamma+1)/2\\ g+1/2\end{matrix}\middle|\frac{(\eta^2-1)t}{(1-\eta t)^2}\right), \tag{2.71}$$

gives a concise expression of the coherent state ψ:

$$\psi(x)=(1-2\lambda\cos x)^{-g-1}\,{}_2F_1\left(\begin{matrix}(g+1)/2,g/2+1\\ g+1/2\end{matrix}\middle|\frac{-2\lambda\sin^2 x}{(1-2\lambda\cos x)^2}\right). \tag{2.72}$$

Here ${}_2F_1$ is the hypergeometric function (C3). For the annihilation operator $a'^{(-)}$, the corresponding coherent state ψ' is

$$\psi'(x)=\phi_0(x)\sum_{n=0}^{\infty}\frac{\lambda^n}{(\beta+1)_n}P_n^{(\beta,\beta)}(\cos x)=\phi_0(x)\sum_{n=0}^{\infty}\frac{\lambda^n}{(2g)_n}C_n^{(g)}(\cos x). \tag{2.73}$$

A generating function of the Gegenbauer polynomials,[6]

$$\sum_{n=0}^{\infty}\frac{t^n}{(2g)_n}C_n^{(g)}(\eta)=e^{\eta t}{}_0F_1\left(\begin{matrix}-\\ g+1/2\end{matrix}\middle|\frac{(\eta^2-1)t^2}{4}\right), \tag{2.74}$$

gives a concise expression of the coherent state ψ':

$$\psi'(x)=\Gamma(g+1/2)e^{\lambda\cos x}(\lambda/2)^{1/2-g}\sqrt{\sin x}J_{g-1/2}(\lambda\sin x), \tag{2.75}$$

in which $J_a(x)$ is the Bessel function (C5).

2. Deformed harmonic oscillator ⇒ Meixner-Pollaczek polynomial

The deformed harmonic oscillator is a simplest example of shape invariant discrete quantum mechanics. The Hamiltonian of discrete quantum mechanics studied in this article has the following form[2] (with some modification for the Askey-Wilson case in Sec. II A 3):

$$\mathcal{H}\overset{\text{def}}{=}(\sqrt{V(x)}e^p\sqrt{V(x)}^*+\sqrt{V(x)}^*e^{-p}\sqrt{V(x)}-V(x)-V(x)^*)/2. \tag{2.76}$$

The eigenvalue problem for $\mathcal{H}$, $\mathcal{H}\phi=\mathcal{E}\phi$ is a difference equation, instead of a second order differential equation. Let us define $S_\pm$, $T_\pm$, and $\mathcal{A}$ by

$$S_+\overset{\text{def}}{=}e^{p/2}\sqrt{V(x)}^*,\quad S_-\overset{\text{def}}{=}e^{-p/2}\sqrt{V(x)},\quad S_+^\dagger=\sqrt{V(x)}e^{p/2},\quad S_-^\dagger=\sqrt{V(x)}^*e^{-p/2}, \tag{2.77}$$

$$T_+\overset{\text{def}}{=}S_+^\dagger S_+=\sqrt{V(x)}e^p\sqrt{V(x)}^*,\quad T_-\overset{\text{def}}{=}S_-^\dagger S_-=\sqrt{V(x)}^*e^{-p}\sqrt{V(x)}, \tag{2.78}$$

$$\overset{\text{def}}{\mathcal{A}} = i(S_+ - S_-), \quad \mathcal{A}^\dagger = -i(S_+^\dagger - S_-^\dagger). \tag{2.79}$$

Then the Hamiltonian is factorized

$$\mathcal{H} = (T_+ + T_- - V(x) - V(x)^*)/2 = (S_+^\dagger - S_-^\dagger)(S_+ - S_-)/2 = \mathcal{A}^\dagger \mathcal{A}/2. \tag{2.80}$$

The potential function $V(x)$ of the deformed harmonic oscillator is

$$V(x) = a + ix, \quad -\infty < x < \infty, \quad a > 0. \tag{2.81}$$

As shown in some detail in our previous paper,[2] it has an equispaced spectrum and the corresponding eigenfunctions are a special case of the Meixner-Pollaczek polynomial $P_n^{(a)}(x;\pi/2)$ (C10),

$$\mathcal{E}_n = n, \quad n = 0,1,2,\ldots, \tag{2.82}$$

$$\phi_0(x) = \sqrt{\Gamma(a+ix)\Gamma(a-ix)}, \quad \eta(x) = x, \tag{2.83}$$

$$\phi_n(x) = \phi_0(x)P_n(x), \quad \overset{\text{def}}{P_n(x)} = P_n^{(a)}\left(x;\tfrac{\pi}{2}\right), \tag{2.84}$$

which could be considered as a deformation of the Hermite polynomial.

The Poisson bracket relations are

$$\{\mathcal{H},x\} = -\sqrt{a^2+x^2}\sinh p, \quad \{\mathcal{H},\{\mathcal{H},x\}\} = -x, \tag{2.85}$$

leading to the harmonic oscillation,

$$x(t) = x(0)\cos t + \sqrt{a^2+x^2(0)}\sinh p(0)\sin t, \tag{2.86}$$

which endorses the naming of the deformed harmonic oscillator. The corresponding quantum expressions are also simple:

$$[\mathcal{H},x] = -i(T_+ - T_-)/2, \quad [\mathcal{H},[\mathcal{H},x]] = x, \tag{2.87}$$

$$e^{it\mathcal{H}}xe^{-it\mathcal{H}} = x\cos t + i[\mathcal{H},x]\sin t = x\cos t + (T_+ - T_-)/2\sin t. \tag{2.88}$$

The annihilation and creation operators are

$$a'^{(\pm)} = 2a^{(\pm)} = x \pm [\mathcal{H},x] = x \mp i(T_+ - T_-)/2, \tag{2.89}$$

which are hermitian conjugate to each other. These operators were also introduced by Degasperis and Ruijsenaars[12] by a different reasoning from ours. By similarity transformation in terms of the ground state wave function $\phi_0(x) = \sqrt{\Gamma(a+ix)\Gamma(a-ix)}$, we obtain

$$\phi_0(x)^{-1}a'^{(\pm)}\phi_0(x) = x \mp i(V(x)e^p - V(x)^*e^{-p})/2. \tag{2.90}$$

The action of the annihilation creation operators on the eigenvectors

$$a'^{(-)}\phi_n = (n+2a-1)\phi_{n-1}, \quad a'^{(+)}\phi_n = (n+1)\phi_{n+1} \tag{2.91}$$

is consistent with the three term recurrence relation of the Meixner-Pollaczek polynomial:

$$(n+1)P_{n+1}^{(a)}\left(x;\tfrac{\pi}{2}\right) - 2xP_n^{(a)}\left(x;\tfrac{\pi}{2}\right) + (n+2a-1)P_{n-1}^{(a)}\left(x;\tfrac{\pi}{2}\right) = 0. \tag{2.92}$$

From these it is easy to verify the su(1,1) commutation relations including the Hamiltonian $\mathcal{H}$:

$$[\mathcal{H},a'^{(\pm)}]=\pm a'^{(\pm)},\quad [a'^{(-)},a'^{(+)}]=2(\mathcal{H}+a). \tag{2.93}$$

It is interesting to note that $a^{(\pm)}$ are factorized by the factors of the Hamiltonian $\mathcal{H}=\mathcal{A}^\dagger\mathcal{A}/2$,

$$4a^{(-)}=X^\dagger\mathcal{A},\quad 4a^{(+)}=\mathcal{A}^\dagger X, \tag{2.94}$$

$$\overset{\text{def}}{X}=S_+ +S_-,\quad X^\dagger=S_+^\dagger+S_-^\dagger. \tag{2.95}$$

These X and $X^\dagger$ compensate the shift of the parameter a caused by $\mathcal{A}^\dagger$ and $\mathcal{A}$. See Appendix B for more details.

The coherent state (2.48), (2.49), is simply obtained from formula (2.91) and $a'^{(-)}=2a^{(-)}$:

$$\psi(x)=\phi_0(x)\sum_{n=0}^{\infty}\frac{(2\lambda)^n}{(2a)_n}P_n^{(a)}\left(x;\tfrac{\pi}{2}\right). \tag{2.96}$$

A generating function of the Meixner-Pollaczek polynomial,[6]

$$\sum_{n=0}^{\infty}\frac{t^n}{(2a)_n}P_n^{(a)}\left(x;\tfrac{\pi}{2}\right)=e^{it}{}_1F_1\left(\begin{matrix}a+ix\\2a\end{matrix}\middle|-2it\right), \tag{2.97}$$

gives a concise expression of the coherent state ψ:

$$\psi(x)=\phi_0(x)e^{2i\lambda}{}_1F_1\left(\begin{matrix}a+ix\\2a\end{matrix}\middle|-4i\lambda\right), \tag{2.98}$$

in which ${}_1F_1$ is the hypergeometric function (C3).

3. Askey-Wilson polynomial

The Askey-Wilson polynomial belongs to the so-called q-scheme of hypergeometric polynomials.[6] It has four parameters a_1,a_2,a_3, and a_4 on top of q $(0<q<1)$, and is considered as a three-parameter deformation of the Jacobi polynomial. As shown in previous articles,[3,2] it also describes the equilibrium positions of the trigonometric Ruijsenaars-Schneider systems based on the BC root system.[13] Thus, as a dynamical system, it could be called a deformed Pöschl-Teller potential or one body case of the trigonometric BC Ruijsenaars-Schneider systems. The quantum-classical correspondence has some more subtlety than the other discrete quantum mechanical systems treated in Sec. III B because of another "classical" limit $q\to 1$.

The factorized Hamiltonian of the Askey-Wilson polynomial has a bit different form from that of the Meixner-Pollaczek polynomial (2.76):

$$\overset{\text{def}}{\mathcal{H}}=(\sqrt{V(z)}q^D\sqrt{V(z)}^*+\sqrt{V(z)}^*q^{-D}\sqrt{V(z)}-V(z)-V(z)^*)/2, \tag{2.99}$$

with a potential function $V(z)$:

$$V(z)=\frac{\prod_{j=1}^4(1-a_jz)}{(1-z^2)(1-qz^2)},\quad z=e^{ix},\quad 0<x<\pi,\quad \overset{\text{def}}{D}=z\frac{d}{dz}=-i\frac{\mathrm{d}}{\mathrm{d}x}=p. \tag{2.100}$$

We assume $-1<a_1,a_2,a_3,a_4<1$ and $a_1a_2a_3a_4<q$. This Hamiltonian is also factorized $\mathcal{H}=\mathcal{A}^\dagger\mathcal{A}/2$, where $\mathcal{A}$ and $\mathcal{A}^\dagger$ are given in (2.77)–(2.79) with the replacement $V(x)\Rightarrow V(z)$, $e^{\pm p/2}\Rightarrow q^{\pm D/2}$, etc. The eigenvalues and eigenfunctions are:[2,3]

$$\mathcal{E}_n=(q^{-n}-1)(1-a_1a_2a_3a_4q^{n-1})/2,\quad n=0,1,2,\dots, \tag{2.101}$$

$$\phi_0(x) = \sqrt{\frac{(z^2;q)_\infty}{\prod_{j=1}^4 (a_j z;q)_\infty}\frac{(z^{-2};q)_\infty}{\prod_{j=1}^4 (a_j z^{-1};q)_\infty}}, \quad \eta(x) = \frac{z+z^{-1}}{2} = \cos x, \tag{2.102}$$

$$\phi_n(x) = \phi_0(x) P_n(\cos x), \quad P_n(\eta) \overset{\text{def}}{=} p_n(\eta;a_1,a_2,a_3,a_4|q), \tag{2.103}$$

in which $p_n(\eta;a_1,a_2,a_3,a_4|q)$ is the Askey-Wilson polynomial (C14).

The presence of the q factor has only superficial effects at the classical level with the Hamiltonian ($\gamma = \log q$):

$$\mathcal{H}_c = \sqrt{V_c(z)V_c(z)^*}\cosh\gamma p - (V_c(z) + V_c(z)^*)/2, \quad V_c(z) = \frac{\prod_{j=1}^4 (1-a_j z)}{(1-z^2)^2}, \tag{2.104}$$

$$\{\mathcal{H}_c, \cos x\} = \gamma\sqrt{\prod_{j=1}^4 (1-a_j z)\prod_{j=1}^4 (1-a_j/z)}/(4\sin x)\sinh\gamma p, \tag{2.105}$$

$$\{\mathcal{H}_c, \{\mathcal{H}_c, \cos x\}\} = -\cos x\, R_0(\mathcal{H}_c) - R_{-1}(\mathcal{H}_c), \tag{2.106}$$

$$R_0(\mathcal{H}_c) = \gamma^2(\mathcal{H}_c^2 + c_1\mathcal{H}_c + c_2), \quad R_{-1}(\mathcal{H}_c) = -\gamma^2(c_3\mathcal{H}_c + c_4), \tag{2.107}$$

with coefficients $c_1, \ldots, c_4$:

$$c_1 = 1 + b_4, \quad c_2 = (1-b_4)^2/4, \quad c_3 = (b_1+b_3)/4, \quad c_4 = (1-b_4)(b_1-b_3)/8. \tag{2.108}$$

Here we use the abbreviation

$$b_1 \overset{\text{def}}{=} \sum_{1\le j\le 4} a_j, \quad b_3 \overset{\text{def}}{=} \sum_{1\le j<k<l\le 4} a_j a_k a_l, \quad b_4 \overset{\text{def}}{=} \prod_{j=1}^4 a_j. \tag{2.109}$$

The corresponding quantum expressions are

$$[\mathcal{H}, \cos x] = (q^{-1}-1)(z^{-1}(1-qz^2)T_+ + z(1-qz^{-2})T_-)/4, \tag{2.110}$$

$$[\mathcal{H}, [\mathcal{H}, \cos x]] = \cos x R_0(\mathcal{H}) + [\mathcal{H}, \cos x]R_1(\mathcal{H}) + R_{-1}(\mathcal{H}), \tag{2.111}$$

$$R_0(\mathcal{H}) = q(q^{-1}-1)^2((\mathcal{H}')^2 - (1+q^{-1})^2 b_4/4), \tag{2.112}$$

$$R_1(\mathcal{H}) = q(q^{-1}-1)^2\mathcal{H}', \quad \mathcal{H}' \overset{\text{def}}{=} \mathcal{H} + (1+q^{-1}b_4)/2, \tag{2.113}$$

$$R_{-1}(\mathcal{H}) = -q(q^{-1}-1)^2((b_1+q^{-1}b_3)\mathcal{H}/4 + (1-q^{-2}b_4)(b_1-b_3)/8). \tag{2.114}$$

The two frequencies are:

$$\alpha_\pm(\mathcal{H}) = (q^{-1}-1)((1-q)\mathcal{H}' \pm (1+q)\sqrt{(\mathcal{H}')^2 - q^{-1}b_4})/2, \tag{2.115}$$

in which

$$\mathcal{H}'\phi_n = (q^{-n} + b_4 q^{n-1})/2\phi_n, \quad ((\mathcal{H}')^2 - q^{-1}b_4)\phi_n = (q^{-n} - b_4 q^{n-1})^2/4\phi_n. \tag{2.116}$$

The annihilation-creation operators are

$$a^{(\pm)} = (\pm(q^{-1}-1)(z^{-1}(1-qz^2)T_+ + z(1-qz^{-2})T_-)/4 \mp \cos x\ \alpha_{\mp}(\mathcal{H}) \pm R_{-1}(\mathcal{H})\alpha_{\pm}(\mathcal{H})^{-1})/(\alpha_+(\mathcal{H})-\alpha_-(\mathcal{H})). \tag{2.117}$$

Their effects on the eigenvectors are

$$a^{(-)}\phi_n = \frac{(1-q^n)\prod_{1\le j<k\le 4}(1-a_ja_kq^{n-1})}{2(1-b_4q^{2n-2})(1-b_4q^{2n-1})}\phi_{n-1}, \tag{2.118}$$

$$a^{(+)}\phi_n = \frac{1-b_4q^{n-1}}{2(1-b_4q^{2n-1})(1-b_4q^{2n})}\phi_{n+1}, \tag{2.119}$$

which are consistent with the three-term recurrence relation of the Askey-Wilson polynomial. The "annihilation-creation" operators on the polynomial $P_n(\cos x)$ read

$$\phi_0(x)^{-1}a^{(\pm)}\phi_0(x)\cdot P_n(\cos x) = \frac{1}{\mathcal{E}_{n+1}-\mathcal{E}_{n-1}}\left(\pm(q^{-1}-1)(z^{-1}(1-qz^2)V(z)q^D + z(1-qz^{-2})V(z)^*q^{-D})/4 \pm (\mathcal{E}_n-\mathcal{E}_{n\mp 1})\cos x \pm \frac{R_{-1}(\mathcal{E}_n)}{\mathcal{E}_{n\pm 1}-\mathcal{E}_n}\right)P_n(\cos x). \tag{2.120}$$

The coherent state is

$$\psi(x) = \phi_0(x)\sum_{n=0}^{\infty}\frac{(2\lambda)^n}{(q;q)_n}\frac{(a_1a_2a_3a_4;q)_{2n}}{\prod_{1\le j<k\le 4}(a_ja_k;q)_n}P_n(\cos x). \tag{2.121}$$

We are not aware if a concise summation formula exists or not.

III. VARIOUS RESULTS

In this section we will briefly present many interesting results on the annihilation-creation operators, their algebraic properties and coherent states, etc., for various exactly solvable quantum mechanical systems, including the discrete quantum mechanical systems. All these solvable systems share *shape invariance*[8,1,2] which is a purely quantum mechanical notion that guarantees quantum solvability. But that property plays no active role in the present theory. On the other hand, the sinusoidal motion exists at the classical and quantum levels. In Appendix A we will show that a system realizing the exact sinusoidal motion is quite limited and that all of them belong to the known shape invariant systems. In other words there are shape invariant systems that do not have sinusoidal motion.

A. Ordinary quantum mechanical systems

1. x^2+1/x^2 potential

When a centrifugal barrier (a $1/x^2$ potential) is added, the harmonic oscillator keeps its exact solvability, but the particle is restricted to a half line, either $x>0$ or $x<0$. This is the one-body case of the well-known Calogero model.[10,11] The eigenfunctions are described by the Laguerre polynomial and the annihilation-creation operators within the su(1,1) scheme are well-known.[4,14] Our unified theory predicts these operators naturally. The coherent and squeezed states in the su(1,1) were already known.[14] Its Hamiltonian, the eigenvalues and the eigenfunctions are:

$$\mathcal{H} \overset{\text{def}}{=} (p+ix-ig/x)(p-ix+ig/x)/2, \quad 0<x<\infty, \quad g>0, \tag{3.1}$$

$$\mathcal{E}_n = 2n, \quad n = 0,1,2,\ldots, \quad \eta(x) = x^2, \tag{3.2}$$

$$\phi_n(x) = \phi_n(x;g) = e^{-x^2/2}x^g L_n^{(\beta)}(x^2), \quad \beta \overset{\text{def}}{=} g - 1/2, \tag{3.3}$$

in which $L_n^{(\beta)}(\eta)$ is the Laguerre polynomial (C7).

The Poisson bracket relations are simple

$$\{\mathcal{H},x^2\} = -2px, \quad \{\mathcal{H},\{\mathcal{H},x^2\}\} = -4(x^2 - \mathcal{H} - g), \tag{3.4}$$

leading to the simple sinusoidal motion

$$x^2(t) = x^2(0)\cos 2t + (1 - \cos 2t)(\mathcal{H}_0 + g) + p(0)x(0)\sin 2t. \tag{3.5}$$

It is straightforward to verify $x^2(t) > 0$. The quantum theory is almost the same as the classical one:

$$[\mathcal{H},x^2] = -i(xp + px), \quad [\mathcal{H},[\mathcal{H},x^2]] = 4(x^2 - \mathcal{H}'), \quad \mathcal{H}' \overset{\text{def}}{=} \mathcal{H} + g + 1/2, \tag{3.6}$$

$$e^{it\mathcal{H}}x^2e^{-it\mathcal{H}} = x^2\cos 2t + (1 - \cos 2t)\mathcal{H}' + (xp + px)/2\sin 2t, \tag{3.7}$$

which leads to the following annihilation and creation operators:

$$a^{(\pm)} = (x^2 - \mathcal{H}')/2 \mp i(xp + px)/4 = \left(\left(\frac{\mathrm{d}}{\mathrm{d}x} \mp x\right)^2 - \frac{g(g-1)}{x^2}\right) \Big/ 4. \tag{3.8}$$

The action of these operators are ($\beta = g - 1/2$)

$$a^{(-)}\phi_n = -(n + \beta)\phi_{n-1}, \quad a^{(+)}\phi_n = -(n + 1)\phi_{n+1}, \tag{3.9}$$

which are consistent with the three term recurrence relation of the Laguerre polynomial

$$(n + 1)L_{n+1}^{(\beta)}(\eta) + (\eta - 2n - \beta - 1)L_n^{(\beta)}(\eta) + (n + \beta)L_{n-1}^{(\beta)}(\eta) = 0. \tag{3.10}$$

From these follow the su(1,1) relations

$$[\mathcal{H},a^{(\pm)}] = \pm 2a^{(\pm)}, \quad [a^{(-)},a^{(+)}] = \mathcal{H}' = \mathcal{H} + g + 1/2. \tag{3.11}$$

The coherent state (AOCS) (2.49) is obtained simply as

$$\psi(x) = \sum_{n=0}^{\infty} \frac{(-\lambda)^n}{(\beta + 1)_n}\phi_n(x) = \phi_0(x)\frac{e^{-\lambda}\Gamma(\beta + 1)}{(-x^2\lambda)^{\beta/2}}J_\beta(2x\sqrt{-\lambda}), \tag{3.12}$$

in which a generating function of the Laguerre polynomial.[6]

$$\sum_{n=0}^{\infty} \frac{t^n}{(\alpha + 1)_n}L_n^{(\alpha)}(x) = e^t{}_0F_1\left(\begin{array}{c|} - \\ \alpha + 1 \end{array} -xt\right) \tag{3.13}$$

and (C5) are used.

The annihilation and creation operators (3.8) are factorised by the factors of the Hamiltonian $\mathcal{H} = \mathcal{A}^\dagger\mathcal{A}/2$:

$$4a^{(-)} = \left(\frac{\mathrm{d}}{\mathrm{d}x} + x + \frac{g}{x}\right)\cdot\mathcal{A}, \quad \mathcal{A} = i(p - ix + ig/x), \tag{3.14}$$

$$4a^{(+)} = \mathcal{A}^\dagger \cdot \left(-\frac{\mathrm{d}}{\mathrm{d}x} + x + \frac{g}{x} \right), \quad \mathcal{A}^\dagger = -i(p + ix - ig/x). \tag{3.15}$$

This is a degenerate case of (3.92) and the action of the other factors is to compensate the parameter shifts caused by the operators $\mathcal{A}^\dagger$ and $\mathcal{A}$:

$$\left(-\frac{\mathrm{d}}{\mathrm{d}x} + x + \frac{g}{x} \right) \phi_n(x;g) = 2\phi_n(x;g+1), \tag{3.16}$$

$$\left(\frac{\mathrm{d}}{\mathrm{d}x} + x + \frac{g}{x} \right) \phi_n(x;g+1) = (2n + 2g + 1)\phi_n(x;g). \tag{3.17}$$

2. Pöschl-Teller potential

The Pöschl-Teller potential has two parameters g and h and its eigenfunctions are related to the Jacobi polynomial. It is the one body case of the BC type Sutherland systems.[10,11] Its Hamiltonian, the eigenvalues and the eigenfunctions are:

$$\overset{\text{def}}{\mathcal{H}} = (p - ig\cot x + ih\tan x)(p + ig\cot x - ih\tan x)/2, \quad 0 < x < \pi/2, \tag{3.18}$$

$$\mathcal{E}_n = 2n(n + g + h), \quad n = 0,1,2,\ldots, \quad g,h > 0, \quad \eta(x) = \cos 2x, \tag{3.19}$$

$$\phi_n(x) = (\sin x)^g (\cos x)^h P_n^{(\alpha,\beta)}(\cos 2x), \quad \overset{\text{def}}{\alpha} = g - 1/2, \quad \overset{\text{def}}{\beta} = h - 1/2, \tag{3.20}$$

in which $P_n^{(\alpha,\beta)}(\eta)$ is the Jacobi polynomial (C8). It is straightforward to evaluate the Poisson brackets

$$\{\mathcal{H}, \cos 2x\} = 2p \sin 2x, \tag{3.21}$$

$$\{\mathcal{H}, \{\mathcal{H}, \cos 2x\}\} = -\cos 2x\, 8\mathcal{H}' - 4(g^2 - h^2), \quad \overset{\text{def}}{\mathcal{H}'} = \mathcal{H} + (g+h)^2/2, \tag{3.22}$$

leading to the solution of the initial value problem:

$$\cos 2x(t) = \left(\cos 2x(0) + \frac{g^2 - h^2}{2\mathcal{H}_0'} \right) \cos[2t\sqrt{2\mathcal{H}_0'}] - p(0)\sin 2x(0) \frac{\sin[2t\sqrt{2\mathcal{H}_0'}]}{\sqrt{2\mathcal{H}_0'}} - \frac{g^2 - h^2}{2\mathcal{H}_0'}. \tag{3.23}$$

Note that $|\cos 2x(t)| < 1$ is satisfied. The corresponding quantum expressions are

$$[\mathcal{H}, \cos 2x] = 2(i \sin 2x p + \cos 2x), \tag{3.24}$$

$$[\mathcal{H}, [\mathcal{H}, \cos 2x]] = \cos 2x(8\mathcal{H}' - 4) + 4[\mathcal{H}, \cos 2x] + 4(\alpha^2 - \beta^2), \tag{3.25}$$

$$\alpha_\pm(\mathcal{H}) = 2 \pm 2\sqrt{2\mathcal{H}'}. \tag{3.26}$$

The exact operator solution reads

$$e^{it\mathcal{H}}\cos 2x\, e^{-it\mathcal{H}} = (i\sin 2x\, p + \cos 2x)\frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}} - \frac{\alpha^2-\beta^2}{2\mathcal{H}'-1}$$
$$+ (\cos 2x(2\mathcal{H}'-1) + \alpha^2 - \beta^2)\frac{1}{\sqrt{2\mathcal{H}'}}\left(\frac{e^{i\alpha_+(\mathcal{H})t}}{\alpha_+(\mathcal{H})} - \frac{e^{i\alpha_-(\mathcal{H})t}}{\alpha_-(\mathcal{H})}\right). \tag{3.27}$$

The annihilation and creation operators are

$$a'^{(\pm)}/2 = a^{(\pm)}2\sqrt{2\mathcal{H}'} = \pm\sin 2x\frac{\mathrm{d}}{\mathrm{d}x} + \cos 2x\sqrt{2\mathcal{H}'} + \frac{\alpha^2-\beta^2}{\sqrt{2\mathcal{H}'}\pm 1}. \tag{3.28}$$

It is now obvious that they ($a'^{(\pm)}$) are not hermitian conjugate to each other. When applied to the eigenvector ϕ_n as $2\mathcal{E}_n+(g+h)^2=(2n+g+h)^2$, we obtain:

$$a'^{(-)}/2\phi_n = -\sin 2x\frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (2n+g+h)\cos 2x\phi_n + \frac{\alpha^2-\beta^2}{2n+\alpha+\beta}\phi_n = \frac{4(n+\alpha)(n+\beta)}{2n+\alpha+\beta}\phi_{n-1}, \tag{3.29}$$

$$a'^{(+)}/2\phi_n = \sin 2x\frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (2n+g+h)\cos 2x\ \phi_n + \frac{\alpha^2-\beta^2}{2n+\alpha+\beta+2}\phi_n = \frac{4(n+1)(n+\alpha+\beta+1)}{2n+\alpha+\beta+2}\phi_{n+1}. \tag{3.30}$$

The right-hand sides are the results of the application. From (3.29) and $a'^{(-)}\phi_n=4(2n+g+h)a^{(-)}\phi_n$, the coherent state ψ and ψ' are

$$\psi(x) = \phi_0(x)\sum_{n=0}^{\infty}(\lambda/2)^n\frac{(\alpha+\beta+2)_{2n}}{(\alpha+1)_n(\beta+1)_n}P_n^{(\alpha,\beta)}(\cos 2x), \tag{3.31}$$

$$\psi'(x) = \phi_0(x)\sum_{n=0}^{\infty}(\lambda/4)^n\frac{\left(\frac{\alpha+\beta}{2}+1\right)_n}{(\alpha+1)_n(\beta+1)_n}P_n^{(\alpha,\beta)}(\cos 2x). \tag{3.32}$$

We are not aware if concise summation formulas exist or not.

3. Soliton potential, or the symmetric Rosen-Morse potential

As is well-known $-g(g+1)/\cosh^2 x$ potential is *reflectionless* for integer coupling constant g, corresponding to the Korteweg de Vries (KdV) soliton. It has a finite number $1+[g]'$ (the greatest integer not equal or exceeding g) of bound states:

$$\mathcal{H} \overset{\text{def}}{=} (p+ig\tanh x)(p-ig\tanh x)/2, \quad -\infty < x < \infty, \quad g>0, \tag{3.33}$$

$$\mathcal{E}_n = n(-n/2+g), \quad n=0,1,\ldots,[g]', \quad \eta(x)=\sinh x, \tag{3.34}$$

$$\phi_n(x) = i^{-n}(\cosh x)^{-g}P_n^{(\beta,\beta)}(i\sinh x), \quad \beta \overset{\text{def}}{=} -g-1/2. \tag{3.35}$$

These eigenfunctions are real due to the parity $P_n^{(\alpha,\beta)}(-x)=(-1)^nP_n^{(\beta,\alpha)}(x)$. The Poisson brackets are

$$\{\mathcal{H},\sinh x\} = -p\cosh x, \quad \{\mathcal{H},\{\mathcal{H},\sinh x\}\} = \sinh x\, 2\mathcal{H}', \quad \mathcal{H}' \overset{\text{def}}{=} \mathcal{H} - g^2/2, \tag{3.36}$$

leading to the solution of the initial value problem:

$$\sinh x(t) = \sinh x(0)\cos[t\sqrt{-2\mathcal{H}_0'}] + p(0)\cosh x(0)\frac{\sin[t\sqrt{-2\mathcal{H}_0'}]}{\sqrt{-2\mathcal{H}_0'}}. \tag{3.37}$$

It describes sinusoidal motion for bound states $\mathcal{H}_0' < 0$ only. But the previous expression is valid for the unbound motion $\mathcal{H}_0' > 0$, too.

The corresponding quantum expressions are

$$[\mathcal{H}, \sinh x] = -i\cosh x\, p - \sinh x/2, \tag{3.38}$$

$$[\mathcal{H}, [\mathcal{H}, \sinh x]] = -\sinh x(2\mathcal{H}' + 1/4) - [\mathcal{H}, \sinh x], \tag{3.39}$$

$$\alpha_\pm(\mathcal{H}) = -1/2 \pm \sqrt{-2\mathcal{H}'}. \tag{3.40}$$

The exact operator solution reads

$$e^{it\mathcal{H}}\sinh x\, e^{-it\mathcal{H}} = (-i\cosh xp - \sinh x/2)\frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{-2\mathcal{H}'}} - \sinh x\frac{2\mathcal{H}' + 1/4}{2\sqrt{-2\mathcal{H}'}}\left(\frac{e^{i\alpha_+(\mathcal{H})t}}{\alpha_+(\mathcal{H})} - \frac{e^{i\alpha_-(\mathcal{H})t}}{\alpha_-(\mathcal{H})}\right). \tag{3.41}$$

The annihilation and creation operators are

$$a'^{(\pm)} = a^{(\pm)}2\sqrt{-2\mathcal{H}'} = \mp\cosh x\frac{\mathrm{d}}{\mathrm{d}x} + \sinh x\sqrt{-2\mathcal{H}'}. \tag{3.42}$$

When applied to the eigenvector ϕ_n, we obtain as $2\mathcal{E}_n - g^2 = -(g-n)^2$:

$$a'^{(-)}\phi_n = \cosh x\frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (g-n)\sinh x\,\phi_n = (n+\beta)\phi_{n-1}, \tag{3.43}$$

$$a'^{(+)}\phi_n = -\cosh x\frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (g-n)\sinh x\,\phi_n = -\frac{(n+1)(n+2\beta+1)}{n+\beta+1}\phi_{n+1}. \tag{3.44}$$

We obtain the following interesting commutation relations:

$$[\mathcal{H}, a'^{(\pm)}] = \pm(\sqrt{-2\mathcal{H}'}a'^{(\pm)} + a'^{(\pm)}\sqrt{-2\mathcal{H}'})/2, \tag{3.45}$$

$$[a'^{(-)}, a'^{(+)}] = 2\sqrt{-2\mathcal{H}'}, \quad a'^{(-)}a'^{(+)} + a'^{(+)}a'^{(-)} = 4\mathcal{H} + 2g, \tag{3.46}$$

which look very similar to those for the $1/\sin^2 x$ potential (2.65)–(2.67). In contrast to the $1/\sin^2 x$ case, the present case has only finite dimensional representation, $n = 0, 1, \ldots, [g]'$, that is from the ground state to the highest level. There is no coherent state as the eigenvector of the annihilation operator (3.42).

4. Morse potential

This is another well-known example of exactly solvable potential with a finite number of bound states:[1]

$$\mathcal{H} \overset{\text{def}}{=} (p + i\mu e^x - ig)(p - i\mu e^x + ig)/2, \quad -\infty < x < \infty, \quad \mu, g > 0, \tag{3.47}$$

$$\mathcal{E}_n = n(-n/2 + g), \quad n = 0, 1, \ldots, [g]', \quad \eta(x) = e^{-x}, \tag{3.48}$$

$$\phi_n(x) = e^{-\mu e^x + gx} e^{-nx} L_n^{(2g-2n)}(2\mu e^x). \tag{3.49}$$

The Poisson brackets are

$$\{\mathcal{H}, e^{-x}\} = pe^{-x}, \quad \{\mathcal{H}, \{\mathcal{H}, e^{-x}\}\} = e^{-x} 2\mathcal{H}' + \mu g, \quad \mathcal{H}' \overset{\text{def}}{=} \mathcal{H} - g^2/2, \tag{3.50}$$

leading to the solution of the initial value problem:

$$e^{-x(t)} = \left(e^{-x(0)} + \frac{\mu g}{2\mathcal{H}_0'} \right) \cos[t\sqrt{-2\mathcal{H}_0'}] - p(0) e^{-x(0)} \frac{\sin[t\sqrt{-2\mathcal{H}_0'}]}{\sqrt{-2\mathcal{H}_0'}} - \frac{\mu g}{2\mathcal{H}_0'}. \tag{3.51}$$

It describes sinusoidal motion for bound states $\mathcal{H}_0' < 0$ only. But the previous expression is valid for the unbound motion $\mathcal{H}_0' > 0$, too. It is easy to verify $e^{-x(t)} > 0$.

The corresponding quantum expressions are

$$[\mathcal{H}, e^{-x}] = ie^{-x} p - e^{-x}/2, \tag{3.52}$$

$$[\mathcal{H}, [\mathcal{H}, e^{-x}]] = -e^{-x}(2\mathcal{H}' + 1/4) - [\mathcal{H}, e^{-x}] - \mu(g + 1/2), \tag{3.53}$$

$$\alpha_\pm(\mathcal{H}) = -1/2 \pm \sqrt{-2\mathcal{H}'}. \tag{3.54}$$

The exact operator solution reads

$$\begin{aligned} e^{it\mathcal{H}} e^{-x} e^{-it\mathcal{H}} = (ie^{-x} p - e^{-x}/2) \frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{-2\mathcal{H}'}} - \frac{\mu(g + 1/2)}{2\mathcal{H}' + 1/4} - (e^{-x}(2\mathcal{H}' + 1/4) \\ + \mu(g + 1/2)) \frac{1}{2\sqrt{-2\mathcal{H}'}} \left(\frac{e^{i\alpha_+(\mathcal{H})t}}{\alpha_+(\mathcal{H})} - \frac{e^{i\alpha_-(\mathcal{H})t}}{\alpha_-(\mathcal{H})} \right). \end{aligned} \tag{3.55}$$

The annihilation and creation operators are

$$a'^{(\pm)} = a^{(\pm)} 2\sqrt{-2\mathcal{H}'} = \pm e^{-x} \frac{\mathrm{d}}{\mathrm{d}x} + e^{-x}\sqrt{-2\mathcal{H}'} - \frac{\mu(2g + 1)}{2\sqrt{-2\mathcal{H}'} \mp 1}. \tag{3.56}$$

When applied to the eigenvector ϕ_n, we obtain as $2\mathcal{E}_n - g^2 = -(g-n)^2$:

$$a'^{(-)}\phi_n = -e^{-x} \frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (g - n) e^{-x} \phi_n - \frac{\mu(2g + 1)}{2(g - n) + 1} \phi_n = \frac{4\mu^2}{2(g - n) + 1} \phi_{n-1}, \tag{3.57}$$

$$a'^{(+)}\phi_n = e^{-x} \frac{\mathrm{d}\phi_n}{\mathrm{d}x} + (g - n) e^{-x} \phi_n - \frac{\mu(2g + 1)}{2(g - n) - 1} \phi_n = \frac{(n + 1)(2g - n)}{2(g - n) - 1} \phi_{n+1}. \tag{3.58}$$

B. Discrete quantum mechanical systems

For specifying the dynamical systems belonging to the discrete quantum mechanics,[2,3] we use the name of the polynomial eigenfunctions for want of universally accepted naming. The factorized Hamiltonian is given by (2.76).

1. Continuous Hahn polynomial (special case)

The factorized Hamiltonian of the continuous Hahn polynomial (special case) has a potential function V depending on two parameters:

$$V(x)=(a_1+ix)(a_2+ix),\quad -\infty<x<\infty,\quad a_1,a_2>0. \tag{3.59}$$

The eigenvalues and eigenfunctions are

$$\mathcal{E}_n=n(n+2a_1+2a_2-1)/2,\quad n=0,1,2,\dots, \tag{3.60}$$

$$\phi_0(x)=\sqrt{\prod_{j=1}^{2}\Gamma(a_j+ix)\Gamma(a_j-ix)},\quad \eta(x)=x, \tag{3.61}$$

$$\phi_n(x)=\phi_0(x)P_n(x),\quad P_n(x)\overset{\text{def}}{=}p_n(x;a_1,a_2,a_1,a_2), \tag{3.62}$$

in which $p_n(x;a_1,a_2,a_1,a_2)$ is a special case of the continuous Hahn polynomial (C11). This is a two parameter deformation of the Hermite polynomial. Thus this dynamical system is a deformed oscillator. The classical solution shows this fact clearly:

$$\{\mathcal{H},x\}=-\sqrt{(a_1^2+x^2)(a_2^2+x^2)}\sinh p,\quad \{\mathcal{H},\{\mathcal{H},x\}\}=-x(2\mathcal{H}+(a_1+a_2)^2), \tag{3.63}$$

$$x(t)=x(0)\cos[t\sqrt{2\mathcal{H}_0+(a_1+a_2)^2}]+\sqrt{(a_1^2+x(0)^2)(a_2^2+x(0)^2)}\sinh p(0)\frac{\sin[t\sqrt{2\mathcal{H}_0+(a_1+a_2)^2}]}{\sqrt{2\mathcal{H}_0+(a_1+a_2)^2}}. \tag{3.64}$$

The corresponding quantum solution is also simple:

$$[\mathcal{H},x]=-i(T_+-T_-)/2, \tag{3.65}$$

$$[\mathcal{H},[\mathcal{H},x]]=x(2\mathcal{H}'-1/4)+[\mathcal{H},x],\quad 2\mathcal{H}'\overset{\text{def}}{=}2\mathcal{H}+(a_1+a_2-1/2)^2, \tag{3.66}$$

$$e^{it\mathcal{H}}xe^{-it\mathcal{H}}=[\mathcal{H},x]\frac{e^{i\alpha_+(\mathcal{H})t}-e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}}+x\frac{-\alpha_-(\mathcal{H})e^{i\alpha_+(\mathcal{H})t}+\alpha_+(\mathcal{H})e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}}, \tag{3.67}$$

$$\alpha_\pm(\mathcal{H})=1/2\pm\sqrt{2\mathcal{H}'}. \tag{3.68}$$

The annihilation and creation operators are:

$$a'^{(\pm)}=a^{(\pm)}2\sqrt{2\mathcal{H}'}=\pm[\mathcal{H},x]\mp x\alpha_\mp(\mathcal{H})=\mp i(T_+-T_-)/2+x(\sqrt{2\mathcal{H}'}\mp 1/2). \tag{3.69}$$

When applied to the eigenvector ϕ_n, we obtain as $2\mathcal{E}_n+(a_1+a_2-1/2)^2=(n+a_1+a_2-1/2)^2$:

$$2a'^{(-)}\phi_n=i(T_+-T_-)\phi_n+2x(n+a_1+a_2)\phi_n=(n+a_1+a_2-1)(n+2a_1-1)(n+2a_2-1)\phi_{n-1}, \tag{3.70}$$

$$2a'^{(+)}\phi_n=-i(T_+-T_-)\phi_n+2x(n+a_1+a_2-1)\phi_n=\frac{(n+1)(n+2a_1+2a_2-1)}{n+a_1+a_2}\phi_{n+1}. \tag{3.71}$$

The similarity transformed operators act as

$$\phi_0(x)^{-1}a'^{(\pm)}\phi_0(x)\cdot P_n(x)=\left(x\left(n+a_1+a_2-\tfrac{1}{2}\mp\tfrac{1}{2}\right)\mp\tfrac{i}{2}(V(x)e^p-V(x)^*e^{-p})\right)P_n(x). \tag{3.72}$$

The coherent state ψ and ψ' are

$$\psi(x) = \phi_0(x)\sum_{n=0}^{\infty} \frac{\lambda^n (2a_1 + 2a_2)_{2n}}{(2a_1)_n (2a_2)_n (a_1 + a_2)_n^2} P_n(x), \tag{3.73}$$

$$\psi'(x) = \phi_0(x)\sum_{n=0}^{\infty} \frac{(2\lambda)^n}{(2a_1)_n (2a_2)_n (a_1 + a_2)_n} P_n(x). \tag{3.74}$$

We do not know if these sums have concise expressions or not.

2. Continuous dual Hahn polynomial

The continuous dual Hahn polynomial has three parameters (a_1, a_2, a_3) and is considered as a two parameter deformation of the Laguerre polynomial $L_n^{(\alpha)}$. The factorized Hamiltonian of the continuous dual Hahn polynomial has a potential function V:

$$V(x) = \frac{\prod_{j=1}^{3} (a_j + ix)}{2ix(2ix + 1)}, \quad 0 < x < \infty, \quad a_1, a_2, a_3 > 0. \tag{3.75}$$

As a dynamical system this is a deformed Calogero model, or a deformed $x^2 + 1/x^2$ potential. Like the Calogero model it has a linear spectrum and the eigenfunctions are:

$$\mathcal{E}_n = n/2, \quad n = 0, 1, 2, \ldots, \tag{3.76}$$

$$\phi_0(x) = \sqrt{\frac{\prod_{j=1}^{3} \Gamma(a_j + ix)}{\Gamma(2ix)} \frac{\prod_{j=1}^{3} \Gamma(a_j - ix)}{\Gamma(-2ix)}}, \quad \eta(x) = x^2, \tag{3.77}$$

$$\phi_n(x) = \phi_0(x) P_n(x^2), \quad P_n(\eta) \overset{\text{def}}{=} S_n(\eta; a_1, a_2, a_3), \tag{3.78}$$

in which $S_n(\eta; a_1, a_2, a_3)$ is the continuous dual Hahn polynomial (C12). For deriving the classical solution, let us note that the quantum potential (3.75) has acquired quantum corrections from the classical one:

$$V_c(x) = \frac{\prod_{j=1}^{3} (a_j + ix)}{(2ix)^2}. \tag{3.79}$$

The classical motion is simple:

$$\{\mathcal{H}_c, x^2\} = -\frac{\sqrt{\prod_{j=1}^{3} (a_j^2 + x^2)}}{2x} \sinh p, \tag{3.80}$$

$$\{\mathcal{H}_c, \{\mathcal{H}_c, x^2\}\} = -x^2/4 + 2\mathcal{H}_c^2 + b_1 \mathcal{H}_c + b_2/4, \quad b_1 \overset{\text{def}}{=} \sum_{1 \le j \le 3} a_j, \quad b_2 \overset{\text{def}}{=} \sum_{1 \le j < k \le 3} a_j a_k, \tag{3.81}$$

$$\begin{aligned} x^2(t) = {} & (x^2(0) - 8\mathcal{H}_{c0}^2 - 4b_1 \mathcal{H}_{c0} - b_2)\cos[t/2] + 8\mathcal{H}_{c0}^2 + 4b_1 \mathcal{H}_{c0} + b_2 \\ & + \frac{\sqrt{\prod_{j=1}^{3} (a_j^2 + x^2(0))}}{x(0)} \sinh p(0) \sin[t/2]. \end{aligned} \tag{3.82}$$

The quantum version is almost the same:

$$[\mathcal{H}, x^2] = -ix(T_+ - T_-) - (T_+ + T_-)/2, \tag{3.83}$$

$$[\mathcal{H},[\mathcal{H},x^2]]=x^2/4+R_{-1}(\mathcal{H}),\quad R_{-1}(\mathcal{H})=-(2\mathcal{H}^2+(b_1-1/2)\mathcal{H}+b_2/4), \tag{3.84}$$

$$e^{it\mathcal{H}}x^2e^{-it\mathcal{H}}=2i[\mathcal{H},x^2]\sin[t/2]+(x^2+4R_{-1}(\mathcal{H}))\cos[t/2]-4R_{-1}(\mathcal{H}). \tag{3.85}$$

The annihilation and creation operators are:

$$a^{(\pm)}=\pm[\mathcal{H},x^2]+x^2/2+2R_{-1}(\mathcal{H})=\mp ix(T_+-T_-)\mp(T_++T_-)/2+x^2/2+2R_{-1}(\mathcal{H}). \tag{3.86}$$

When applied to the eigenvector ϕ_n, we obtain:

$$a^{(-)}\phi_n=-n\prod_{1\le j<k\le 3}(n+a_j+a_k-1)\cdot\phi_{n-1}, \tag{3.87}$$

$$a^{(+)}\phi_n=-\phi_{n+1}. \tag{3.88}$$

The similarity transformed operators are:

$$\phi_0(x)^{-1}a^{(\pm)}\phi_0(x)=x^2/2-4\tilde{\mathcal{H}}^2-2(b_1-1/2)\tilde{\mathcal{H}}-b_2/2\mp((1/2+ix)V(x)e^p+(1/2-ix)V(x)^*e^{-p}), \tag{3.89}$$

in which $\tilde{\mathcal{H}}=\phi_0(x)^{-1}\mathcal{H}\phi_0(x)=(V(x)e^p+V(x)^*e^{-p}-V(x)-V(x)^*)/2$ is the Hamiltonian counterpart at the polynomial level satisfying $\tilde{\mathcal{H}}P_n(x^2)=n/2P_n(x^2)$, see Appendix C. The coherent state is

$$\psi(x)=\phi_0(x)\sum_{n=0}^{\infty}\frac{(-\lambda)^n}{n!\prod_{1\le j<k\le 3}(a_j+a_k)_n}P_n(x^2). \tag{3.90}$$

We do not know if this sum has a concise expression or not. The commutation relations among $\mathcal{H}$, and $a^{(\pm)}$ are more complicated than su(1,1):

$$[\mathcal{H},a^{(\pm)}]=\pm a^{(\pm)}/2,$$

$$[a^{(-)},a^{(+)}]=32\mathcal{H}^3+24(b_1-1/2)\mathcal{H}^2+(4(b_1-1/2)^2+4b_2+1)\mathcal{H}+b_1b_2-a_1a_2a_3. \tag{3.91}$$

As in the Meixner-Pollaczek case (2.94), the annihilation and creation operators for the continuous dual Hahn polynomial factorise into the operators $\mathcal{A}$ and $\mathcal{A}^\dagger$ appearing in the Hamiltonian $\mathcal{H}=\mathcal{A}^\dagger\mathcal{A}/2$:

$$a^{(-)}=X^\dagger\mathcal{A},\quad a^{(+)}=\mathcal{A}^\dagger X. \tag{3.92}$$

The operator X in this case reads

$$\begin{aligned}X=&-iS_+T_+ +\left(x-iV\left(x-\tfrac{i}{2}\right)^*-i\frac{\prod_{j=1}^3(2a_j-1)}{8(1+x^2)}\right)S_+ +iS_-T_-\\&+\left(x+iV\left(x-\tfrac{i}{2}\right)+i\frac{\prod_{j=1}^3(2a_j-1)}{8(1+x^2)}\right)S_-.\end{aligned} \tag{3.93}$$

These X and $X^\dagger$ compensate the shift of the parameters (a_1,a_2,a_3) caused by $\mathcal{A}^\dagger$ and $\mathcal{A}$, respectively. See Appendix B for more details.

3. Wilson polynomial

The Wilson polynomial has four parameters (a_1,a_2,a_3,a_4) and is considered as a three parameter deformation of the Laguerre polynomial $L_n^{(\alpha)}$. The factorized Hamiltonian (2.76) of the Wilson polynomial has a potential function V:

$$V(x)=\frac{\prod_{j=1}^{4}(a_j+ix)}{2ix(2ix+1)},\quad 0<x<\infty,\quad a_1,a_2,a_3,a_4>0. \tag{3.94}$$

As a dynamical system this is another deformation of the Calogero model, or a deformed x^2+1/x^2 potential. The spectrum is now quadratic in n and the eigenfunctions are:

$$\mathcal{E}_n=n\left(n+\sum_{j=1}^{4}a_j-1\right)/2,\quad n=0,1,2,\ldots, \tag{3.95}$$

$$\phi_0(x)=\sqrt{\frac{\prod_{j=1}^{4}\Gamma(a_j+ix)}{\Gamma(2ix)}\frac{\prod_{j=1}^{4}\Gamma(a_j-ix)}{\Gamma(-2ix)}},\quad \eta(x)=x^2, \tag{3.96}$$

$$\phi_n(x)=\phi_0(x)P_n(x^2),\quad P_n(\eta)\overset{\text{def}}{=}W_n(\eta;a_1,a_2,a_3,a_4), \tag{3.97}$$

in which $W_n(\eta;a_1,a_2,a_3,a_4)$ is the Wilson polynomial (C13). The classical motion looks like a cross between those of the continuous Hahn and the continuous dual Hahn potentials with the classical potential V_c:

$$\{\mathcal{H}_c,x^2\}=-\frac{\sqrt{\prod_{j=1}^{4}(a_j^2+x^2)}}{2x}\sinh p,\quad V_c(x)=\frac{\prod_{j=1}^{4}(a_j+ix)}{(2ix)^2} \tag{3.98}$$

$$\{\mathcal{H}_c,\{\mathcal{H}_c,x^2\}\}=-2x^2(\mathcal{H}_c+c_1)-R_{-1}(\mathcal{H}_c), \tag{3.99}$$

$$R_{-1}(\mathcal{H}_c)=-2(\mathcal{H}_c^2+c_2\mathcal{H}_c+c_3),\quad c_1=b_1^2/8,\quad c_2=b_2,\quad c_3=b_1b_3/4, \tag{3.100}$$

$$\begin{aligned}x^2(t)=&\left(x^2(0)+\frac{R_{-1}(\mathcal{H}_{c0})}{2(\mathcal{H}_{c0}+c_1)}\right)\cos\left[t\sqrt{2(\mathcal{H}_{c0}+c_1)}\right]-\frac{R_{-1}(\mathcal{H}_{c0})}{2(\mathcal{H}_{c0}+c_1)}\\&+\frac{\sqrt{\prod_{j=1}^{4}(a_j^2+x^2(0))}}{2x(0)}\sinh p(0)\frac{\sin[t\sqrt{2(\mathcal{H}_{c0}+c_1)}]}{\sqrt{2(\mathcal{H}_{c0}+c_1)}},\end{aligned} \tag{3.101}$$

where we use the abbreviation

$$b_1\overset{\text{def}}{=}\sum_{1\le j\le 4}a_j,\quad b_2\overset{\text{def}}{=}\sum_{1\le j<k\le 4}a_ja_k,\quad b_3\overset{\text{def}}{=}\sum_{1\le j<k<l\le 4}a_ja_ka_l. \tag{3.102}$$

The quantum version has almost the same form with quantum corrections in the coefficients c_1, c_2, and c_3:

$$[\mathcal{H},x^2]=-ix(T_+-T_-)-(T_++T_-)/2, \tag{3.103}$$

$$[\mathcal{H},[\mathcal{H},x^2]]=[\mathcal{H},x^2]+2x^2(\mathcal{H}+c_1)+R_{-1}(\mathcal{H}), \tag{3.104}$$

$$R_{-1}(\mathcal{H}) = -2(\mathcal{H}^2 + c_2\mathcal{H} + c_3), \tag{3.105}$$

$$c_1 = b_1(b_1-2)/8, \quad c_2 = b_2 - b_1/2, \quad c_3 = (b_1-2)b_3/4, \tag{3.106}$$

$$e^{it\mathcal{H}}x^2e^{-it\mathcal{H}} = [\mathcal{H},x^2]\frac{e^{i\alpha_+(\mathcal{H})t} - e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}} - \frac{R_{-1}(\mathcal{H})}{2(\mathcal{H}+c_1)} + \left(x^2 + \frac{R_{-1}(\mathcal{H})}{2(\mathcal{H}+c_1)}\right)\frac{-\alpha_-(\mathcal{H})e^{i\alpha_+(\mathcal{H})t} + \alpha_+(\mathcal{H})e^{i\alpha_-(\mathcal{H})t}}{2\sqrt{2\mathcal{H}'}}. \tag{3.107}$$

$$\alpha_\pm(\mathcal{H}) = 1/2 \pm \sqrt{2\mathcal{H}'}, \quad 2\mathcal{H}' \overset{\text{def}}{=} 2\mathcal{H} + 2c_1 + 1/4. \tag{3.108}$$

The annihilation and creation operators are

$$a'^{(\pm)} = a^{(\pm)}2\sqrt{2\mathcal{H}'} = \pm[\mathcal{H},x^2] \mp x^2\alpha_\mp(\mathcal{H}) + \frac{R_{-1}(\mathcal{H})}{\sqrt{2\mathcal{H}'} \pm 1/2}$$
$$= \mp ix(T_+ - T_-) \mp (T_+ + T_-)/2 \mp x^2\alpha_\mp(\mathcal{H}) + \frac{R_{-1}(\mathcal{H})}{\sqrt{2\mathcal{H}'} \pm 1/2}. \tag{3.109}$$

When applied to the eigenvector ϕ_n, we obtain as $2\mathcal{E}_n + 2c_1 + 1/4 = (2n+b_1-1)^2/4$:

$$a'^{(-)}\phi_n = -\frac{n\prod_{1\le j<k\le 4}(n+a_j+a_k-1)}{(2n+b_1-2)(2n+b_1-1)}\phi_{n-1}, \tag{3.110}$$

$$a'^{(+)}\phi_n = -\frac{n+b_1-1}{(2n+b_1-1)(2n+b_1)}\phi_{n+1}. \tag{3.111}$$

The similarity transformed operators act as

$$\phi_0(x)^{-1}a'^{(\pm)}\phi_0(x)\cdot P_n(x^2) = \left(\pm(\mathcal{E}_n - \mathcal{E}_{n\mp1})x^2 \pm \frac{R_{-1}(\mathcal{E}_n)}{\mathcal{E}_{n\pm1} - \mathcal{E}_n} \mp ((1/2+ix)V(x)e^p + (1/2-ix)V(x)^*e^{-p})\right)P_n(x^2). \tag{3.112}$$

The coherent state ψ and ψ' are

$$\psi(x) = \phi_0(x)\sum_{n=0}^{\infty}\frac{(-\lambda)^n}{n!}\frac{(a_1+a_2+a_3+a_4)_{2n}}{\prod_{1\le j<k\le 4}(a_j+a_k)_n}P_n(x^2), \tag{3.113}$$

$$\psi'(x) = \phi_0(x)\sum_{n=0}^{\infty}\frac{(-2\lambda)^n}{n!}\frac{((a_1+a_2+a_3+a_4)/2)_n}{\prod_{1\le j<k\le 4}(a_j+a_k)_n}P_n(x^2). \tag{3.114}$$

IV. SUMMARY AND COMMENTS

Unified theory of annihilation-creation operators $a^{(\pm)}$ is developed for various exactly solvable quantum mechanical systems possessing the sinusoidal coordinate. It applies to most of the degree one solvable quantum mechanical systems as well as the solvable discrete quantum mechanical

systems, which are also shape invariant.[2] The eigenfunctions of the latter are described by the Askey-scheme of hypergeometric orthogonal polynomials.[6] The method provides an independent *algebraic solution* of these quantum systems. The energy spectrum is obtained à la Heisenberg and Pauli from the Heisenberg operator solution for the 'sinusoidal coordinate' η, $e^{it\mathcal{H}}\eta e^{-it\mathcal{H}}$ and the entire eigenfunctions are explicitly obtained as $\{(a^{(+)})^n\phi_0\}$, $n=0,1,\ldots$, in which ϕ_0 is determined by $a^{(-)}\phi_0=0$. Various examples are worked out in Secs. II and III. It also applies to theories with a finite number of bound states. It should be stressed that these annihilation-creation operators are *natural* ones containing the differential (difference) operators, in contradistinction to those annihilation-creation operators introduced in the algebraic theory of coherent states.[9] By a similarity transformation in terms of the ground state wavefunction ϕ_0, the Heisenberg operator solution gives the structure relation for the corresponding orthogonal polynomials[5] and the annihilation-creation operators provide their shift down-up operators. Another characteristic feature is the uniqueness. Except for the overall factor, which is intrinsically undetermined, the action $a^{(\pm)}\phi_n$ is completely determined by the Hamiltonian of the system. This means that the relative weights of the terms in $a^{(\pm)}\phi_n$ are governed by the energy spectrum. We have shown in some detail that this type of algebraic exact solvability is valid at both classical and quantum levels. This is in good contrast with shape-invariance, which is a strictly quantum notion. The necessary and sufficient condition for the existence of the sinusoidal coordinate is worked out for the ordinary quantum mechanical systems in Appendix A. It is a good challenge to derive a corresponding result for the 'discrete' quantum mechanical systems.

Generalization of the present formalism to multiparticle systems is highly desirable. Simplest multiparticle systems possessing the sinusoidal coordinate and the corresponding Heisenberg operator solution is the Calogero systems based on any root system.[11] In fact a more general Hamiltonian

$$\mathcal{H}=\frac{1}{2}\sum_{j=1}^{n}(p_j^2+x_j^2)+V(x),\quad \sum_{j=1}^{n}x_j\frac{\partial}{\partial x_j}V(x)=-2V(x), \tag{4.1}$$

$$[\mathcal{H},[\mathcal{H},\eta]]=4(\eta-\mathcal{H}),\quad \eta=\sum_{j=1}^{n}x_j^2, \tag{4.2}$$

of harmonic oscillators modified by a generic homogeneous degree minus two potential has the same property. The corresponding eigenfunctions are the Laguerre polynomials again.[15,11] As is well known the annihilation-creation operators of the harmonic oscillator have a quite wide applicability in many branches of physics. We wonder if the newly found annihilation-creation operators for the other solvable quantum mechanical systems might find an equally wide range of applications.

ACKNOWLEDGEMENTS

The authors thank F. Calogero for stimulating discussion. This work is supported in part by Grant-in-Aid for Scientific Research from the Ministry of Education, Culture, Sports, Science and Technology, No. 18340061 and No. 16340040.

APPENDIX A: DETERMINATION OF THE POTENTIALS HAVING THE SINUSOIDAL COORDINATE

We have seen that the existence of the sinusoidal coordinate or the exact Heisenberg operator solution (2.14) leads to the unified definition of the annihilation-creation operators. All the examples discussed in the text share the common property of "shape-invariance," thanks to which the corresponding quantum systems are exactly solvable. Here in Appendix A we analyse, within the context of ordinary quantum mechanics, the necessary and sufficient condition for the existence of the sinusoidal coordinate and show that such systems constitute a sub-group of known

shape-invariant quantum mechanics. For the discrete quantum mechanical systems, writing down corresponding conditions is easy. It would be a good challenge to provide a complete list of discrete quantum mechanical systems admitting the sinusoidal coordinate or the exact Heisenberg operator solution.

For a given pair $(\eta(x),\mathcal{H})$ of a coordinate function $\eta(x)$ and a Hamiltonian $\mathcal{H}$ to satisfy the exact Heisenberg operator solution (2.14) is equivalent to the condition (2.12) that the multiple commutators of $\mathcal{H}$ with η form a closed algebra at level two

$$(\mathrm{ad}\mathcal{H})^2\eta(x) \equiv [\mathcal{H},[\mathcal{H},\eta(x)]] = \eta R_0(\mathcal{H}) + [\mathcal{H},\eta(x)]R_1(\mathcal{H}) + R_{-1}(\mathcal{H}). \tag{A1}$$

Here the coefficients $R_0(\mathcal{H})$, $R_1(\mathcal{H})$, and $R_{-1}(\mathcal{H})$ are polynomials in the Hamiltonian $\mathcal{H}$. It should be stressed that this condition is purely algebraic and the knowledge that the eigenfunctions have the general structure (2.3) is irrelevant. The latter (2.3) is a consequence of the condition (A1). For the ordinary quantum mechanical system with potential $V(x)$

$$\mathcal{H} = -\frac{1}{2}\frac{\mathrm{d}^2}{\mathrm{d}x^2} + V(x), \tag{A2}$$

the commutator between $\mathcal{H}$ and η reads

$$[\mathcal{H},\eta] = -\eta'\frac{\mathrm{d}}{\mathrm{d}x} - \frac{1}{2}\eta'', \tag{A3}$$

$$(\mathrm{ad}\,\mathcal{H})^2\eta = \eta''\frac{\mathrm{d}^2}{\mathrm{d}x^2} + \eta'''\frac{\mathrm{d}}{\mathrm{d}x} + \frac{1}{4}\eta'''' + \eta' V', \tag{A4}$$

in which primes denote differentiation with respect to x. From (A4) we see that the l.h.s. of (A1) contains the derivative operator (the momentum operator) at most quadratic degree. So must be the r.h.s. since the momentum operator can come in as a part of $\mathcal{H}$ (as $p^2/2$) or as $[\mathcal{H},\eta]$, see (A3). Then we can parametrize

$$R_0(\mathcal{H}) = r_0^{(1)}\mathcal{H} + r_0^{(0)}, \quad R_1(\mathcal{H}) = r_1, \quad R_{-1}(\mathcal{H}) = r_{-1}^{(1)}\mathcal{H} + r_{-1}^{(0)}, \tag{A5}$$

in which $r_j^{(k)}$ are all constants. Then the coefficients of the operators $\mathrm{d}^2/\mathrm{d}x^2$, $\mathrm{d}/\mathrm{d}x$, and the function part of (A1) give the conditions:

$$\frac{\mathrm{d}^2\eta}{\mathrm{d}x^2} = -\frac{1}{2}(r_0^{(1)}\eta + r_{-1}^{(1)}), \tag{A6}$$

$$\frac{\mathrm{d}^3\eta}{\mathrm{d}x^3} = -r_1\frac{\mathrm{d}\eta}{\mathrm{d}x}, \tag{A7}$$

$$\frac{1}{4}\frac{\mathrm{d}^4\eta}{\mathrm{d}x^4} + \frac{\mathrm{d}\eta}{\mathrm{d}x}\frac{\mathrm{d}V}{\mathrm{d}x} = -\frac{1}{2}r_1\frac{\mathrm{d}^2\eta}{\mathrm{d}x^2} + (r_0^{(1)}\eta + r_{-1}^{(1)})V + r_0^{(0)}\eta + r_{-1}^{(0)}. \tag{A8}$$

The first condition (A6) simply means that $\eta(x)$ is either a *trigonometric* or a *hyperbolic* function of x which gives an *exponential* function or a *quadratic* and *linear polynomial* in x in the degenerate limits. By comparing (A6) and (A7) we obtain

$$r_0^{(1)} = 2r_1. \tag{A9}$$

Then (A8) reduces to

$$\frac{\mathrm{d}\eta}{\mathrm{d}x}\frac{\mathrm{d}V}{\mathrm{d}x}+\frac{\mathrm{d}^2\eta}{\mathrm{d}x^2}\left(2V+\frac{1}{4}r_1\right)=r_0^{(0)}\eta+r_{-1}^{(0)},$$

which integrates easily when multiplied by $d\eta/dx$:

$$\left(\frac{\mathrm{d}\eta}{\mathrm{d}x}\right)^2\left(V+\frac{r_1}{8}\right)=\frac{r_0^{(0)}}{2}\eta^2+r_{-1}^{(0)}\eta+c. \tag{A10}$$

Here c is the constant of integration. Thus we have determined the possible form of the potential V in terms of the 'sinusoidal coordinate' $\eta(x)$ and its first derivative $d\eta/dx$, with five parameters r_1, $r_0^{(0)}$, $r_{-1}^{(1)}$, $r_{-1}^{(0)}$ and c in (A10) and two more possible constants of integration of (A6):

$$V(x)=\frac{1}{\left(\frac{\mathrm{d}\eta}{\mathrm{d}x}\right)^2}\left(\frac{r_0^{(0)}}{2}\eta^2+r_{-1}^{(0)}\eta+c\right)-\frac{r_1}{8}. \tag{A11}$$

The actual number of essentially free parameters is much less, as the origin of the quadratic potential, or the location of the singularity, etc, could be freely adjusted by introducing new variable $x_{\mathrm{new}}=\alpha x+\beta$ ($\mathcal{H}_{\mathrm{new}}=\mathcal{H}/\alpha^2$). The condition that the Hamiltonian must be bounded from below imposes some constraints on the parameters. The overall additive constant is fixed uniquely when the ground state energy is required to be vanishing $\mathcal{E}_0=0$.

It is rather straightforward to determine all the potentials possessing the 'sinusoidal coordinate' and thus algebraically exactly solvable. They all belong to the known group of shape-invariant potentials. Except for the trivial case $V=0$, we have

1. Rational case, $r_1=0$. The generic solution of (A6) is

$$\eta(x)=-\frac{1}{4}r_{-1}^{(1)}x^2+c_1x+c_2, \tag{A12}$$

with c_1 and c_2 being the constant of integration. Two special cases are of interest: $\eta(x)=x$ gives the harmonic oscillator and $\eta(x)=x^2$ leads to the x^2+1/x^2 potential discussed in Sec. III A 1.

2. Trigonometric case, $r_1>0$. The generic solution of (A6) is

$$\eta(x)=-\frac{r_{-1}^{(1)}}{2r_1}+c_1\cos\sqrt{r_1}x+c_2\sin\sqrt{r_1}x, \tag{A13}$$

with c_1 and c_2 being real constants of integration due to the reality (hermiticity) of η. By rescaling and shift of the coordinate x, it reduces to the Pöschl-Teller potential discussed in Sec. III A 2. The $1/\sin^2 x$ potential in Sec. II A 1 and the symmetric top are obtained as degenerate cases.

3. Hyperbolic and exponential cases, $r_1<0$. The generic solution of (A6) is

$$\eta(x)=-\frac{r_{-1}^{(1)}}{2r_1}+c_1\cosh\sqrt{-r_1}x+c_2\sinh\sqrt{-r_1}x, \tag{A14}$$

in which the constants of integration c_1 and c_2 could be vanishing or equal $c_1=\pm c_2$. The generic case leads to the hyperbolic Pöschl-Teller potential and the degenerate cases contain the soliton potential in Sec. III A 3 and hyperbolic symmetric tops and the Morse potential in Sec. III A 4, etc. We could not discuss all due to space limitation.

In all these examples, the prepotential W has also a simple expression in terms of η and $\mathrm{d}\eta/\mathrm{d}x$:

$$\frac{\mathrm{d}W}{\mathrm{d}x}=\frac{a\eta+b}{\frac{\mathrm{d}\eta}{\mathrm{d}x}},\quad a=-\sqrt{r_0^{(0)}+r_1^2/4},\quad b=\frac{2r_{-1}^{(0)}}{2a+r_1}+\frac{r_{-1}^{(1)}}{4}. \tag{A15}$$

Here the prepotential W is related to the ground state wave function ϕ_0 and thus to the potential V as

$$\phi_0(x)=e^{W(x)},\quad V=\frac{1}{2}\left(\left(\frac{\mathrm{d}W}{\mathrm{d}x}\right)^2+\frac{\mathrm{d}^2W}{\mathrm{d}x^2}\right),$$

and it plays an important role in supersymmetric (shape-invariant) quantum mechanics.[1,16]

It should be stressed that not all shape-invariant and exactly solvable potentials admit the sinusoidal coordinate. Such examples are the Kepler problems in rational, spherical and hyperbolic coordinates and the Rosen-Morse potential, respectively:

$$V(x)=\frac{1}{2}\left(-\frac{2}{x}+\frac{g(g-1)}{x^2}+\frac{1}{g^2}\right), \tag{A16}$$

$$V(x)=\frac{1}{2}\left(-2\mu\cot x+\frac{g(g-1)}{\sin^2 x}+\frac{\mu^2}{g^2}-g^2\right), \tag{A17}$$

$$V(x)=\frac{1}{2}\left(-2\mu\coth x+\frac{g(g-1)}{\sinh^2 x}+\frac{\mu^2}{g^2}+g^2\right), \tag{A18}$$

$$V(x)=\frac{1}{2}\left(2\mu\tanh x-\frac{g(g+1)}{\cosh^2 x}+\frac{\mu^2}{g^2}+g^2\right). \tag{A19}$$

Their wave functions do not have the general structure (2.3), either.

APPENDIX B: INTERPRETATION IN TERMS OF SHAPE INVARIANCE

As shown in Sec. II, the annihilation-creation operators are completely determined once the closed relationship (2.12) among η, $[\mathcal{H},\eta]$ and $[\mathcal{H},[\mathcal{H},\eta]]$ is obtained. Although it plays no active role in the determination of the annihilation-creation operators, *shape invariance* is the common property underlying all these exactly solvable Hamiltonians discussed in this paper. Therefore it is interesting as well as illuminating to understand the mechanism of the annihilation-creation operators within the framework of shape invariance. For this purpose we concentrate on the annihilation-creation operators of the Meixner-Pollaczek polynomials (2.94) and of the continuous dual Hahn polynomials (3.92), which factorize into the operators $\mathcal{A}$ and $\mathcal{A}^\dagger$ constituting the shape invariant Hamiltonian $\mathcal{H}=\mathcal{A}^\dagger\mathcal{A}/2$. Another motivation of this appendix is to provide a bridge between the physics of discrete quantum mechanics[2] and the analysis of Askey-scheme of hypergeometric polynomials.[6] The latter focuses on the polynomial part of the eigenfunctions, whose orthogonal measure is provided by the ground state wave function (2.4).

Let us start with recapitulating the rudimentary facts of the shape-invariant discrete quantum mechanics as developed in Ref. 2. Knowledgeable readers may jump to the main results (B26)–(B29), but some intermediate results (B7) and (B13)–(B17) would also be interesting in connection with the sinusoidal coordinate $\eta(x)$.

A shape invariant quantum mechanical system consists of a series of isospectral Hamiltonians $\{\mathcal{H}(\boldsymbol{\lambda})\}$ parametrised by (a set of) parameters $\boldsymbol{\lambda}=(\lambda_1,\lambda_2,\ldots)$:

$$\mathcal{H}(\boldsymbol{\lambda})=\mathcal{A}(\boldsymbol{\lambda})^\dagger\mathcal{A}(\boldsymbol{\lambda})/2,\quad \phi_n(x;\boldsymbol{\lambda})=\phi_0(x;\boldsymbol{\lambda})P_n(\eta(x);\boldsymbol{\lambda}),\quad \mathcal{E}_n(\boldsymbol{\lambda}),\ \text{etc}.$$

Shape invariance is tersely expressed as

$$\mathcal{A}(\boldsymbol{\lambda})\mathcal{A}(\boldsymbol{\lambda})^{\dagger} = \mathcal{A}(\boldsymbol{\lambda}+\boldsymbol{\delta})^{\dagger}\mathcal{A}(\boldsymbol{\lambda}+\boldsymbol{\delta}) + 2\mathcal{E}_1(\boldsymbol{\lambda}), \tag{B1}$$

where $\boldsymbol{\delta}$ is a shift of the parameter. [In the case of the Askey-Wilson polynomials, this is modified to $\mathcal{A}(\boldsymbol{\lambda})\mathcal{A}(\boldsymbol{\lambda})^{\dagger} = q^{2\delta'}\mathcal{A}(\boldsymbol{\lambda} * q^{\boldsymbol{\delta}})^{\dagger}\mathcal{A}(\boldsymbol{\lambda} * q^{\boldsymbol{\delta}}) + 2\mathcal{E}_1(\boldsymbol{\lambda})$, where δ' is a constant and $\boldsymbol{\lambda} * q^{\boldsymbol{\delta}} = (\lambda_1 q^{\delta_1}, \lambda_2 q^{\delta_2}, \cdots)$]. The operator $\mathcal{A}(\boldsymbol{\lambda})$ maps the eigenvectors of $\mathcal{H}(\boldsymbol{\lambda})$ to those of $\mathcal{H}(\boldsymbol{\lambda}+\boldsymbol{\delta})$ and the other operator $\mathcal{A}(\boldsymbol{\lambda})^{\dagger}$ acts in the opposite direction. In each case studied in this article, the parameter $\boldsymbol{\lambda}$ and the shift $\boldsymbol{\delta}$ are

$$\text{Meixner-Pollaczek:} \quad \boldsymbol{\lambda} = a, \quad \boldsymbol{\delta} = 1/2, \tag{B2}$$

$$\text{continuous Hahn:} \quad \boldsymbol{\lambda} = (a_1, a_2), \quad \boldsymbol{\delta} = (1/2, 1/2), \tag{B3}$$

$$\text{continuous dual Hahn:} \quad \boldsymbol{\lambda} = (a_1, a_2, a_3), \quad \boldsymbol{\delta} = (1/2, 1/2, 1/2), \tag{B4}$$

$$\text{Wilson:} \quad \boldsymbol{\lambda} = (a_1, a_2, a_3, a_4), \quad \boldsymbol{\delta} = (1/2, 1/2, 1/2, 1/2), \tag{B5}$$

$$\text{Askey} - \text{Wilson:} \quad \boldsymbol{\lambda} = (a_1, a_2, a_3, a_4), \quad \boldsymbol{\delta} = (1/2, 1/2, 1/2, 1/2), \quad \delta' = -1/2. \tag{B6}$$

The ground state $\phi_0(x)$ and the orthogonal polynomial $P_n(\eta(x))$ are given in (2.83) and (2.84), (3.61) and (3.62), (3.77) and (3.78), (3.96) and (3.97), and (2.102) and (2.103). These ground states satisfy [for the Askey-Wilson polynomials, this relation reads $\phi_0(x - i\gamma/2; \boldsymbol{\lambda} * q^{\boldsymbol{\delta}}) = \sqrt{V(z;\boldsymbol{\lambda})}\varphi(x - i\gamma/2)\phi_0(x;\boldsymbol{\lambda})$, where $\gamma = \log q$]

$$\phi_0(x - i/2; \boldsymbol{\lambda} + \boldsymbol{\delta}) = \sqrt{V(x;\boldsymbol{\lambda})}\varphi(x - i/2)\phi_0(x;\boldsymbol{\lambda}), \tag{B7}$$

where $\varphi(x) \propto \eta'(x)$ is given by

$$\text{Meixner-Pollaczek:} \quad \varphi(x) = 1, \tag{B8}$$

$$\text{continuous Hahn:} \quad \varphi(x) = 1, \tag{B9}$$

$$\text{continuous dual Hahn:} \quad \varphi(x) = 2x, \tag{B10}$$

$$\text{Wilson:} \quad \varphi(x) = 2x, \tag{B11}$$

$$\text{Askey-Wilson:} \quad \varphi(x) = -2\sin x = i(z - z^{-1}). \tag{B12}$$

Let us consider $S_{\pm}(\boldsymbol{\lambda})$, $T_{\pm}(\boldsymbol{\lambda})$, $\mathcal{A}(\boldsymbol{\lambda})$ given in (2.77)–(2.79). By using the property (B7), we have

$$\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta})^{-1}\, S_{\pm}(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda}) = \varphi(x)^{-1}e^{\pm p/2}, \tag{B13}$$

$$\phi_0(x;\boldsymbol{\lambda})^{-1}\, S_{\pm}(\boldsymbol{\lambda})^{\dagger}\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta}) = \begin{cases} V(x;\boldsymbol{\lambda})e^{p/2}\varphi(x) \\ V(x;\boldsymbol{\lambda})^{*}e^{-p/2}\varphi(x). \end{cases} \tag{B14}$$

(In the case of the Askey-Wilson polynomials, the following replacement is needed: $\boldsymbol{\lambda} + \boldsymbol{\delta} \Rightarrow \boldsymbol{\lambda} * q^{\boldsymbol{\delta}}$, $e^{\pm p/2} \Rightarrow q^{\pm D/2}$, $V(x;\boldsymbol{\lambda}) \Rightarrow V(z;\boldsymbol{\lambda})$. Hereafter we will omit similar remarks.) From this, we obtain

$$F(\boldsymbol{\lambda}) \overset{\text{def}}{=} \phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta})^{-1}\mathcal{A}(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda}) = i\varphi(x)^{-1}(e^{p/2} - e^{-p/2}), \tag{B15}$$

$$B(\boldsymbol{\lambda}) \overset{\text{def}}{=} \phi_0(x;\boldsymbol{\lambda})^{-1}\mathcal{A}(\boldsymbol{\lambda})^{\dagger}\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta}) = -i(V(x;\boldsymbol{\lambda})e^{p/2} - V(x;\boldsymbol{\lambda})^{*}e^{-p/2})\varphi(x), \tag{B16}$$

$$\widetilde{T}_{\pm}(\boldsymbol{\lambda}) \overset{\text{def}}{=} \phi_0(x;\boldsymbol{\lambda})^{-1}T_{\pm}(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda}) = \begin{cases} V(x;\boldsymbol{\lambda})e^{p} \\ V(x;\boldsymbol{\lambda})^{*}e^{-p}. \end{cases} \tag{B17}$$

Therefore the similarity transformed Hamiltonian is

$$\widetilde{\mathcal{H}}(\boldsymbol{\lambda}) \overset{\text{def}}{=} \phi_0(x;\boldsymbol{\lambda})^{-1}\mathcal{H}(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda}) = B(\boldsymbol{\lambda})F(\boldsymbol{\lambda})/2 = (\widetilde{T}_{+}(\boldsymbol{\lambda}) + \widetilde{T}_{-}(\boldsymbol{\lambda}) - V(x;\boldsymbol{\lambda}) - V(x;\boldsymbol{\lambda})^{*})/2. \tag{B18}$$

which acts on $P_n(\eta(x);\boldsymbol{\lambda})$ as $\widetilde{H}(\boldsymbol{\lambda})P_n(\eta(x);\boldsymbol{\lambda}) = \mathcal{E}_n(\boldsymbol{\lambda})P_n(\eta(x);\boldsymbol{\lambda})$.

The forward shift operator $F(\boldsymbol{\lambda})$ and backward shift operator $B(\boldsymbol{\lambda})$ act on $P_n(\eta;\boldsymbol{\lambda})$ as

$$F(\boldsymbol{\lambda})P_n(\eta;\boldsymbol{\lambda}) = f_n(\boldsymbol{\lambda})P_{n-1}(\eta;\boldsymbol{\lambda}+\boldsymbol{\delta}), \tag{B19}$$

$$B(\boldsymbol{\lambda})P_n(\eta;\boldsymbol{\lambda}+\boldsymbol{\delta}) = b_n(\boldsymbol{\lambda})P_{n+1}(\eta;\boldsymbol{\lambda}), \tag{B20}$$

where $f_n(\boldsymbol{\lambda})$ and $b_n(\boldsymbol{\lambda})$ are constants satisfying the relation $f_n(\boldsymbol{\lambda})b_{n-1}(\boldsymbol{\lambda})/2 = \mathcal{E}_n(\boldsymbol{\lambda})$:

$$\text{Meixner-Pollaczek:} \quad f_n(\boldsymbol{\lambda}) = 2, \quad b_n(\boldsymbol{\lambda}) = n+1, \tag{B21}$$

$$\text{continuous Hahn:} \quad f_n(\boldsymbol{\lambda}) = n + 2a_1 + 2a_2 - 1, \quad b_n(\boldsymbol{\lambda}) = n+1, \tag{B22}$$

$$\text{continuous dual Hahn:} \quad f_n(\boldsymbol{\lambda}) = -n, \quad b_n(\boldsymbol{\lambda}) = -1, \tag{B23}$$

$$\text{Wilson:} \quad f_n(\boldsymbol{\lambda}) = -n\Big(n + \textstyle\sum_{j=1}^{4} a_j - 1\Big), \quad b_n(\boldsymbol{\lambda}) = -1, \tag{B24}$$

$$\text{Askey-Wilson:} \quad f_n(\boldsymbol{\lambda}) = -q^{n/2}(q^{-n}-1)(1-a_1a_2a_3a_4q^{n-1}), \quad b_n(\boldsymbol{\lambda}) = -q^{-(n+1)/2}. \tag{B25}$$

For the Meixner-Pollaczek and the continuous dual Hahn cases, we have seen that the annihilation-creation operators are factorized $a^{(-)} \propto X^{\dagger}\mathcal{A}$ and $a^{(+)} \propto \mathcal{A}^{\dagger}X$, (2.94), (3.92). By using (B13), (B14), and (B17), $\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta})^{-1}X(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda})$ and $\phi_0(x;\boldsymbol{\lambda})^{-1}\,X(\boldsymbol{\lambda})^{\dagger}\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta})$ can be written down explicitly. They act on $P_n(\eta;\boldsymbol{\lambda})$ as for the Meixner-Pollaczek case:

$$\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta})^{-1}X(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda}) \cdot P_n(\eta;\boldsymbol{\lambda}) = 2P_n(\eta;\boldsymbol{\lambda}+\boldsymbol{\delta}), \tag{B26}$$

$$\phi_0(x;\boldsymbol{\lambda})^{-1}X(\boldsymbol{\lambda})^{\dagger}\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta}) \cdot P_n(\eta;\boldsymbol{\lambda}+\boldsymbol{\delta}) = (n+2a)P_n(\eta;\boldsymbol{\lambda}), \tag{B27}$$

and for the continuous dual Hahn case:

$$\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta})^{-1}X(\boldsymbol{\lambda})\phi_0(x;\boldsymbol{\lambda}) \cdot P_n(\eta;\boldsymbol{\lambda}) = P_n(\eta;\boldsymbol{\lambda}+\boldsymbol{\delta}), \tag{B28}$$

$$\phi_0(x;\boldsymbol{\lambda})^{-1}X(\boldsymbol{\lambda})^{\dagger}\phi_0(x;\boldsymbol{\lambda}+\boldsymbol{\delta}) \cdot P_n(\eta;\boldsymbol{\lambda}+\boldsymbol{\delta}) = \prod_{1\le j<k\le 3}(n+a_j+a_k) \cdot P_n(\eta;\boldsymbol{\lambda}). \tag{B29}$$

Therefore $X^{\dagger}$ (X) compensates the parameter shift caused by $\mathcal{A}$ ($\mathcal{A}^{\dagger}$), so that the effect of $a^{(-)}$ ($a^{(+)}$) is to give the polynomial with the same parameter $\boldsymbol{\lambda}$ of degree one lower (higher). This result is new.

Let us close this appendix with a remark on the formal definition of the annihilation-creation operators used within the framework of shape-invariant quantum mechanics.[9,2] A unitary operator $\mathcal{U}$ ($\mathcal{U}^{\dagger}$) is defined as a map between two orthonormal bases with neighbouring parameters, $\{\hat{\phi}_n(x;\boldsymbol{\lambda})\}$ and $\{\hat{\phi}_n(x;\boldsymbol{\lambda}+\boldsymbol{\delta})\}$:

$$\mathcal{U}\hat{\phi}_n(x;\boldsymbol{\lambda}) \overset{\text{def}}{=} \hat{\phi}_n(x;\boldsymbol{\lambda}+\boldsymbol{\delta}), \quad \mathcal{U}^\dagger\hat{\phi}_n(x;\boldsymbol{\lambda}+\boldsymbol{\delta}) = \hat{\phi}_n(x;\boldsymbol{\lambda}). \tag{B30}$$

This allows to introduce new annihilation-creation operators in a factorized form

$$\hat{a} \overset{\text{def}}{=} \mathcal{U}^\dagger\mathcal{A}(\boldsymbol{\lambda}), \quad \hat{a}^\dagger = \mathcal{A}(\boldsymbol{\lambda})^\dagger\mathcal{U}, \tag{B31}$$

which satisfy $\mathcal{H}=\hat{a}^\dagger\hat{a}/2=\mathcal{A}(\boldsymbol{\lambda})^\dagger\mathcal{A}(\boldsymbol{\lambda})/2$. The operator $\mathcal{U}$ is rather formal and it cannot be expressed as a differential or a difference operator. This operator $\mathcal{U}$ can be considered as unitarisation of the natural factorization operator X discussed above.

APPENDIX C: SOME DEFINITIONS RELATED TO THE HYPERGEOMETRIC AND *q*-HYPERGEOMETRIC FUNCTIONS

For reader's convenience we collect several definitions related to the (q-)hypergeometric functions.[6]

- Pochhammer symbol $(a)_n$:

$$(a)_n \overset{\text{def}}{=} \prod_{k=1}^{n}(a+k-1) = a(a+1)\cdots(a+n-1) = \Gamma(a+n)/\Gamma(a). \tag{C1}$$

- q-Pochhammer symbol $(a;q)_n$:

$$(a;q)_n \overset{\text{def}}{=} \prod_{k=1}^{n}(1-aq^{k-1}) = (1-a)(1-aq)\cdots(1-aq^{n-1}). \tag{C2}$$

- hypergeometric series ${}_rF_s$:

$${}_rF_s\left(\begin{matrix}a_1,\ldots,a_r\\ b_1,\ldots,b_s\end{matrix}\middle| z\right) \overset{\text{def}}{=} \sum_{n=0}^{\infty}\frac{(a_1,\ldots,a_r)_n}{(b_1,\ldots,b_s)_n}\frac{z^n}{n!}, \tag{C3}$$

  where $(a_1,\ldots,a_r)_n \overset{\text{def}}{=} \prod_{j=1}^{r}(a_j)_n = (a_1)_n\cdots(a_r)_n$.
- q-hypergeometric series (the basic hypergeometric series) ${}_r\phi_s$:

$${}_r\phi_s\left(\begin{matrix}a_1,\ldots,a_r\\ b_1,\ldots,b_s\end{matrix}\middle| q;z\right) \overset{\text{def}}{=} \sum_{n=0}^{\infty}\frac{(a_1,\ldots,a_r;q)_n}{(b_1,\ldots,b_s;q)_n}(-1)^{(1+s-r)n}q^{(1+s-r)n(n-1)/2}\frac{z^n}{(q;q)_n}, \tag{C4}$$

  where $(a_1,\ldots,a_r;q)_n \overset{\text{def}}{=} \prod_{j=1}^{r}(a_j;q)_n = (a_1;q)_n\cdots(a_r;q)_n$.
- Bessel function $J_a(z)$:

$$J_a(z) \overset{\text{def}}{=} \frac{(z/2)^a}{\Gamma(a+1)}{}_0F_1\left(\begin{matrix}-\\ a+1\end{matrix}\middle| -\frac{z^2}{4}\right). \tag{C5}$$

- Hermite polynomial $H_n(x)$:

$$H_n(x) \overset{\text{def}}{=} (2x)^n{}_2F_0\left(\begin{matrix}-n/2,-(n-1)/2\\ -\end{matrix}\middle| -\frac{1}{x^2}\right). \tag{C6}$$

- Laguerre polynomial $L_n^{(\alpha)}(x)$:

$$L_n^{(\alpha)}(x) \overset{\text{def}}{=} \frac{(\alpha+1)_n}{n!}{}_1F_1\left(\begin{matrix}-n\\ \alpha+1\end{matrix}\middle| x\right). \tag{C7}$$

- Jacobi polynomial $P_n^{(\alpha,\beta)}(x)$:

$$P_n^{(\alpha,\beta)}(x)\overset{\text{def}}{=}\frac{(\alpha+1)_n}{n!}{}_2F_1\left(\begin{matrix}-n,n+\alpha+\beta+1\\ \alpha+1\end{matrix}\middle|\frac{1-x}{2}\right), \tag{C8}$$

which satisfies $P_n^{(\beta,\alpha)}(x)=(-1)^nP_n^{(\alpha,\beta)}(-x)$.

- Gegenbauer polynomial $C_n^{(\lambda)}(x)$:

$$C_n^{(\lambda)}(x)\overset{\text{def}}{=}\frac{(2\lambda)_n}{(\lambda+1/2)_n}P_n^{(\lambda-1/2,\lambda-1/2)}(x). \tag{C9}$$

- Meixner-Pollaczek polynomial $P_n^{(a)}(x;\phi)$:

$$P_n^{(a)}(x;\phi)\overset{\text{def}}{=}\frac{(2a)_n}{n!}e^{in\phi}{}_2F_1\left(\begin{matrix}-n,,a+ix\\ 2a\end{matrix}\middle|1-e^{-2i\phi}\right). \tag{C10}$$

- Continuous Hahn polynomial $p_n(x;a_1,a_2,a_1',a_2')$:

$$p_n(x;a_1,a_2,a_1',a_2')\overset{\text{def}}{=}i^n\frac{(a_1+a_1')_n(a_1+a_2')_n}{n!}{}_3F_2\left(\begin{matrix}-n,n+a_1+a_2+a_1'+a_2'-1,a_1+ix\\ a_1+a_1',a_1+a_2'\end{matrix}\middle|1\right), \tag{C11}$$

which is symmetric under $a_1\leftrightarrow a_2$ and $a_1'\leftrightarrow a_2'$ separately.

- Continuous dual Hahn polynomial $S_n(x^2;a_1,a_2,a_3)$:

$$S_n(x^2;a_1,a_2,a_3)\overset{\text{def}}{=}(a_1+a_2)_n(a_1+a_3)_n{}_3F_2\left(\begin{matrix}-n,a_1+ix,a_1-ix\\ a_1+a_2,a_1+a_3\end{matrix}\middle|1\right), \tag{C12}$$

which is symmetric under the permutations of (a_1,a_2,a_3).

- Wilson polynomial $W_n(x^2;a_1,a_2,a_3,a_4)$:

$$\begin{aligned}W_n(x^2;a_1,a_2,a_3,a_4)\overset{\text{def}}{=}&(a_1+a_2)_n(a_1+a_3)_n(a_1+a_4)_n\\ &\times{}_4F_3\left(\begin{matrix}-n,n+\sum_{j=1}^4a_j-1,a_1+ix,a_1-ix\\ a_1+a_2,a_1+a_3,a_1+a_4\end{matrix}\middle|1\right),\end{aligned} \tag{C13}$$

which is symmetric under the permutations of (a_1,a_2,a_3,a_4).

- Askey-Wilson Hahn polynomial $p_n(\cos x;a_1,a_2,a_3,a_4|q)$:

$$\begin{aligned}p_n(\cos x;a_1,a_2,a_3,a_4|q)\overset{\text{def}}{=}&a_1^{-n}(a_1a_2,a_1a_3,a_1a_4;q)_n\\ &\times{}_4\phi_3\left(\begin{matrix}q^{-n},a_1a_2a_3a_4q^{n-1},a_1e^{ix},a_1e^{-ix}\\ a_1a_2,a_1a_3,a_1a_4\end{matrix}\middle|q;q\right),\end{aligned} \tag{C14}$$

which is symmetric under the permutations of (a_1,a_2,a_3,a_4).

(Received 4 August 2006; accepted 30 August 2006; published online 18 October 2006)

The quantum effects for a physical system can be described by the set $\mathcal{E}(\mathcal{H})$ of positive operators on a complex Hilbert space $\mathcal{H}$ that are bounded above by the identity operator I. The infimum problem of Hilbert space effects is to find under what condition the infimum $A\wedge B$ exists for two quantum effects A and $B\in\mathcal{E}(\mathcal{H})$. The problem has been studied in different contexts by Kadison, Gudder, Moreland, and Ando. In this Note, using the method of the spectral theory of operators, we give a affirmative answer of a conjecture of [S. Gudder, J. Math. Phys. **37**, 2637–2642 (1996)]. In addition, some properties of generalized infimum $A\sqcap B$ were considered. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2358392]

I. INTRODUCTION

Let $\mathcal{H}$ be a Hilbert space and $\mathcal{B}(\mathcal{H})$ the set of all bounded linear operators on $\mathcal{H}$. We use the notation

$$\mathcal{B}(\mathcal{H})^+=\{A\in\mathcal{B}(\mathcal{H}):0\leqslant A\},\quad \mathcal{E}(\mathcal{H})=\{A\in\mathcal{B}(\mathcal{H}):0\leqslant A\leqslant I\},$$

that is, $\mathcal{E}(\mathcal{H})$ is the set of quantum effects.[1–7,11] For operators $A,B\in\mathcal{B}(\mathcal{H})^+$ we denote by $A\wedge B$, the infimum, equivalently, the greatest lower bound, of A and B over the partially ordered set $(\mathcal{B}(\mathcal{H})^+,\geqslant)$, if it exists. To be more precise, $A\wedge B$ is an operator in $\mathcal{B}(\mathcal{H})^+$ uniquely determined by the following properties: $A\wedge B\leqslant A$, $A\wedge B\leqslant B$, and an operator $D\in\mathcal{B}^+(\mathcal{H})$ satisfies both $D\leqslant A$ and $D\leqslant B$ if and only if $D\leqslant A\wedge B$. As it is well known, in general, the infimum of two effects A and B may not exist. However, the infimum $A\wedge B$ always exists if A and B are comparable. Two positive operator A and B are said to be comparable if $A\geqslant B$ or $A\leqslant B$. The Hilbert space infimum question refers to the characterization of pairs of positive bounded operators that admit infimum over the cone of positive operators in a Hilbert space. The problem was earlier studied in different contexts by Kadison,[9] Ando,[1] Gudder[6,7] Moreland,[12] and Gheondea.[4] For example, Moreland and Gudder in Ref. 11 have proved that if A and $B\in\mathcal{E}(C^n)$ are injective positive definite matrices, then the infimum $A\wedge B$ exists if and only if A and B are comparable. If $A\in\mathcal{E}(\mathcal{H})$ and P is an orthogonal projection, then $P\wedge A$ exists. In Ref. 6, Gudder proposes the following conjecture: If $A,B\in\mathcal{E}(\mathcal{H})$ are invertible operators, then $A\wedge B$ exists if and only if A and B are comparable.

Before proving the main results in this paper, let us introduce some notations and terminology which are used later. For an operator $A\in\mathcal{B}(\mathcal{H})$, we shall denote by $N(A)$, $R(A)$, and $\sigma(A)$ the null space, the range, and the spectrum of A, respectively. An operator $A\in\mathcal{B}(\mathcal{H})$ is said to be injective if $N(A)=\{0\}$. The identity onto a Hilbert space $\mathcal{K}$ is denoted by $I_{\mathcal{K}}$ or I if there does not exist confusion. An operator $A\in\mathcal{B}(\mathcal{H})$ is said to be positive if $(Ax,x)\geqslant 0$ for all $x\in\mathcal{H}$. An operator $D\in\mathcal{B}(\mathcal{H})$ is said to be a contraction if $\|D\|\leqslant 1$. For self-adjoint operators $A$and B, $A\leqslant B$ means that $(Ax,x)\leqslant(Bx,x)$ for all $x\in\mathcal{H}$. For a self-adjoint operator $A\in\mathcal{B}(\mathcal{H})$, we define $|A|=(A^2)^{1/2}$, where $(A^2)^{1/2}$ is the unique positive square root of A^2. For self-adjoint operators A, $B\in\mathcal{B}(\mathcal{H})$, the generalized infimum $A\sqcap B$ is defined by

[a]Electronic mail: liyuan0401@yahoo.com.cn

$$A \sqcap B = \frac{1}{2}(A + B - |A - B|).$$

The generalized infimum has been studied in many works. It is easy to see that $A \sqcap B$ always exists. However, for $A, B \in \mathcal{E}(\mathcal{H})$, it is not necessarily true that $A \sqcap B \in \mathcal{E}(\mathcal{H})$, because $A \sqcap B$ may not be positive. Nevertheless, if A and B are comparable or if A and B commute, then $A \sqcap B \in \mathcal{E}(\mathcal{H})$.

In this Note, we first obtained that if $B \in \mathcal{B}(\mathcal{H})^+$, then $I \wedge B$ exists if and only if $\sigma(B) \subseteq \{0\} \cup [1, \|B\|]$ or $\sigma(B) \subseteq [0,1]$. As a corollary, we give a affirmative answer of Conjecture 4.2 of Ref. 6. In addition, we consider some properties of generalized infimum $A \sqcap B$.

II. $A \wedge B$

We begin with some lemmas.

First, we recall Douglas factorization theorem:

Lemma 2.1: Let $B, C \in \mathcal{B}(\mathcal{H})$. Then the following conditions are equivalent:

(1) $R(B) \subseteq R(C)$.
(2) There exists a positive number λ such that $BB^* \leqslant \lambda CC^*$.
(3) There exists $D \in \mathcal{B}(\mathcal{H})$ such that $B = CD$.

Lemma 2.2: Let $A \in \mathcal{B}(\mathcal{H})$ have the following operator matrix form:

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \tag{1}$$

according to the space decomposition $\mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2$. Then, $A \geqslant 0$ if and only if

(1) $A_{ii} \in \mathcal{B}(\mathcal{H}_i)$ and $A_{ii} \geqslant 0$, $i = 1, 2$;
(2) $A_{21} = A_{12}^*$;
(3) There exists a contraction D from $\mathcal{H}_2$ into $\mathcal{H}_1$ such that $A_{12} = A_{11}^{1/2} D A_{22}^{1/2}$, where $A_{ii}^{1/2}$ is the positive square root of A_{ii}, $i = 1, 2$.

Lemma 2.3: If $A \in \mathcal{B}(\mathcal{H})$ has the form

$$A = \begin{pmatrix} A_{11} & BA_{22}^{1/2} \\ A_{22}^{1/2} B^* & A_{22} \end{pmatrix}$$

with respect to the space decomposition $\mathcal{H} = \mathcal{H}_1 \oplus \mathcal{H}_2$, where $A_{22} \geqslant 0$ is a positive invertible operator on $\mathcal{H}_2$ and B is an operator from $\mathcal{H}_2$ into $\mathcal{H}_1$, then $A \geqslant 0$ if and only if $A_{11} - BB^* \geqslant 0$.

Proof: Since $A_{22} \geqslant 0$ is a positive invertible operator, then $A_{22}^{-1/2} \in \mathcal{B}(\mathcal{H})$. Let

$$C = \begin{pmatrix} I & -BA_{22}^{-1/2} \\ 0 & I \end{pmatrix}.$$

Since $CAC^* \geqslant 0$ if and only if $A \geqslant 0$, but

$$CAC^* = \begin{pmatrix} I & -BA_{22}^{-1/2} \\ 0 & I \end{pmatrix} \begin{pmatrix} A_{11} & BA_{22}^{1/2} \\ A_{22}^{1/2} B^* & A_{22} \end{pmatrix} \begin{pmatrix} I & 0 \\ -A_{22}^{-1/2} B^* & I \end{pmatrix} = \begin{pmatrix} A_{11} - BB^* & 0 \\ 0 & A_{22} \end{pmatrix}$$

and $A_{22} \geqslant 0$, these imply that $A \geqslant 0$ if and only if $A_{11} - BB^* \geqslant 0$.

Using Lemma 2.2, we can easily get the following result.

Lemma 2.4: Let $A \in \mathcal{B}(\mathcal{H})$ be a positive operator. If A has the operator matrix representation $A = (A_{ij})_{n \times n}$ with respect to the space decomposition $\mathcal{H} = \oplus_{i=1}^n \mathcal{H}_i$, then the following statements hold:

(1) A_{ii} as an operator on $\mathcal{H}_i$ is positive, $1 \leqslant i \leqslant n$.

(2) $A_{ij}=A_{ii}^{1/2}D_{ij}A_{jj}^{1/2}$ for some contraction $D_{ij}\in\mathcal{B}(\mathcal{H}_j,\mathcal{H}_i)$, $1\leqslant i,j\leqslant n$.

Lemma 2.5: Let $B\in\mathcal{B}(\mathcal{H})^+$ be injective. Then, $C=I\wedge B$ exists if and only if I and B are comparable.

Proof: Suppose that $I\wedge B$ exists. We show that I and B are comparable. It is clear that we need only to show that $\sigma(B)\subseteq[0,1]$ or $\sigma(B)\subseteq[1,\infty)$.

On the contrary, if $\sigma(B)\cap[0,1)\neq\emptyset$ and $\sigma(B)\cap(1,\infty)\neq\emptyset$, we will prove that $I\wedge B$ does not exist.

Since B is injective, 0 is an accumulation of $\sigma(B)$ or B is invertible. Thus, there exist $0<\mu<1$ and $1<\nu<\infty$ such that $[\frac{1}{2}\mu,\mu]\cap\sigma(B)\neq\emptyset$ and $[\nu,2\nu]\cap\sigma(B)\neq\emptyset$. Let $B=\int_0^{\|B\|}\lambda dE_\lambda$ be the spectral representation of B, we denote $\sigma_1=[0,1/2\mu)\cap\sigma(B)$, $\sigma_2=[\frac{1}{2}\mu,\mu]\cap\sigma(B)$, $\sigma_3=(\mu,1)\cap\sigma(B)$,$\sigma_4=[1,\nu)\cap\sigma(B)$, $\sigma_5=[\nu,2\nu]\cap\sigma(B)$, and $\sigma_6=(2\nu,\|B\|]\cap\sigma(B)$. Thus, B has the operator matrix form

$$B=\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{B}_4,\mathrm{B}_5,\mathrm{B}_6)$$

with respect to the space decomposition $\mathcal{H}=\oplus_{i=1}^6\mathcal{H}_i$, where $\mathcal{H}_1=E([0,\frac{1}{2}\mu))\mathcal{H}$, $\mathcal{H}_2=E([\frac{1}{2}\mu,\mu])\mathcal{H}$, $\mathcal{H}_3=E((\mu,1))\mathcal{H}$, $\mathcal{H}_4=E([1,\nu))\mathcal{H}$, $\mathcal{H}_5=E([\nu,2\nu])\mathcal{H}$, and $\mathcal{H}_6=E((2\nu,\|B\|])\mathcal{H}$. It is clear that $B_2(\leqslant I_{\mathcal{H}_2})$ and $B_5(\geqslant I_{\mathcal{H}_3})$ are invertible positive operators onto $\mathcal{H}_2$ and $\mathcal{H}_5$, respectively, and $\|B_2\|\leqslant\mu$ and $\|B_5^{-1}\|^{-1}\geqslant\nu$.

If $C=I\wedge B$ exists, then $C\leqslant I$ and C has the operator matrix form

$$C=(C_{ij})_{1\leqslant i,j\leqslant 6},$$

with respect to the space decomposition $\mathcal{H}=\oplus_{i=1}^6\mathcal{H}_i$. Note that

$$I\geqslant\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{I},\mathrm{I},\mathrm{I})$$

and

$$B=\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{B}_4,\mathrm{B}_5,\mathrm{B}_6)\geqslant\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{I},\mathrm{I},\mathrm{I});$$

then

$$\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{I},\mathrm{I},\mathrm{I})\leqslant(\mathrm{C}_{ij})_{1\leqslant i,j\leqslant 6}\leqslant\mathrm{I}$$

and

$$\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{I},\mathrm{I},\mathrm{I})\leqslant(\mathrm{C}_{ij})_{1\leqslant i,j\leqslant 6}\leqslant\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{B}_4,\mathrm{B}_5,\mathrm{B}_6).$$

Hence, by Lemma 2.4, $C_{11}=B_1$, $C_{22}=B_2$, $C_{33}=B_3$, $C_{44}=I_{\mathcal{H}_4}$, $C_{55}=I_{\mathcal{H}_5}$, $C_{66}=I_{\mathcal{H}_6}$, $C_{ij}=0$, $1\leqslant i,j\leqslant 6$, and $i\neq j$. This shows that

$$C=\mathrm{diag}(\mathrm{B}_1,\mathrm{B}_2,\mathrm{B}_3,\mathrm{I},\mathrm{I},\mathrm{I}).$$

Now take $\alpha=\frac{3}{4}$, $\beta=\frac{3}{4}$. Then, there exists a small positive number $1>\delta>0$ such that $\min\{(1-\alpha)(\nu-\beta),(\mu^{-1}-\alpha)(1-\beta)\}>(1+\delta)/16>(1-\alpha)(1-\beta)$. Set $\gamma^2=(1+\delta)/16$.

Define an operator $C_{\alpha\beta\gamma}$ by

$$C_{\alpha\beta\gamma}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \alpha B_2 & 0 & 0 & \gamma B_2^{\frac{1}{2}} D & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & \gamma D^* B_2^{\frac{1}{2}} & 0 & 0 & \beta I_{\mathcal{H}_5} & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix},$$

where D is a partial isometry from $\mathcal{H}_5$ into $\mathcal{H}_2$ with $D\neq 0$ and $I_{\mathcal{H}_2}-DD^*\neq 0$.

Note that $\alpha\beta=9/16>(1+\delta)/16=\gamma^2$. Since $\alpha\beta>\gamma^2$ implies that $\alpha\beta I_{\mathcal{H}_2}-\gamma^2 DD^*\geqslant 0$, then $\alpha\beta B_2-\gamma^2 B_2^{1/2}DD^*B_2^{1/2}=B_2^{1/2}(\alpha\beta I_{\mathcal{H}_2}-\gamma^2 DD^*)B_2^{1/2}\geqslant 0$, by Lemma 2.3, $C_{\alpha\beta\gamma}\geqslant 0$.

It follows from $B_5\geqslant \nu I_{\mathcal{H}_5}$ that $B_5-\beta I_{\mathcal{H}_5}\geqslant(\nu-\beta)I_{\mathcal{H}_5}$, then $(B_5-\beta I_{\mathcal{H}_5})^{-1}\leqslant[1/(\nu-\beta)]I_{\mathcal{H}_5}$. Thus,

$$\begin{aligned}(1-\alpha)B_2-\gamma^2 B_2^{1/2}D(B_5-\beta I_{\mathcal{H}_5})^{-1}D^*B_2^{1/2} &\geqslant B_2^{1/2}\left[(1-\alpha)I_{\mathcal{H}_2}-\gamma^2 D\frac{1}{\nu-\beta}I_{\mathcal{H}_5}D^*\right]B_2^{1/2}\geqslant B_2^{1/2}\Bigg\{(1-\alpha)\\ &\quad\times(I_{\mathcal{H}_2}-DD^*)+\frac{DD^*}{\nu-\beta}[(1-\alpha)(\nu-\beta)-\gamma^2]I_{\mathcal{H}_2}\Bigg\}B_2^{1/2}\\ &\geqslant 0,\end{aligned}$$

since $(1-\alpha)(\nu-\beta)-\gamma^2\geqslant 0$. By Lemma 2.3, $B-C_{\alpha\beta\gamma}\geqslant 0$.

Similarly, $B_2\leqslant\mu I_{\mathcal{H}_2}$ implies that

$$\begin{aligned}(1-\beta)(I_{\mathcal{H}_2}-\alpha B_2)-\gamma^2 B_2^{1/2}DD^*B_2^{1/2} &= (1-\beta)I_{\mathcal{H}_2}-B_2^{1/2}[(1-\beta)\alpha I_{\mathcal{H}_2}+\gamma^2 DD^*]B_2^{1/2}\\ &= B_2^{1/2}[(1-\beta)B_2^{-1}-(1-\beta)\alpha I_{\mathcal{H}_2}-\gamma^2 DD^*]B_2^{1/2}\\ &\geqslant B_2^{1/2}[(1-\beta)(\mu^{-1}-\alpha)I_{\mathcal{H}_2}-\gamma^2 DD^*]B_2^{12}\\ &= B_2^{1/2}[(1-\beta)(\mu^{-1}-\alpha)(I_{\mathcal{H}_2}-DD^*)]B_2^{1/2}\\ &\quad+B_2^{1/2}[(1-\beta)(\mu^{-1}-\alpha)-\gamma^2]DD^*B_2^{1/2}\geqslant 0,\end{aligned}$$

since $(1-\beta)(\mu^{-1}-\alpha)-\gamma^2\geqslant 0$. By Lemma 2.3, $I-C_{\alpha\beta\gamma}\geqslant 0$.

In a similar way, we obtain that $\gamma^2=(1+\delta)/16>1/16=(1-\alpha)(1-\beta)$ implies $C-C_{\alpha\beta\gamma}\not\geqslant 0$. It is a contradiction.

This shows that $I\wedge B$ does not exist when $\sigma(B)\cap(0,1)\neq\emptyset$ and $\sigma(B)\cap(1,\|B\|)\neq\emptyset$.

Conversely, it is clear that $I\wedge B$ exists if I and B are comparable.

Theorem 2.6: *Let* $B\in\mathcal{B}(\mathcal{H})^+$. *Then*, $I\wedge B$ *exists if and only if* $\sigma(B)\subseteq\{0\}\cup[1,\|B\|]$ *or* $\sigma(B)\subseteq[0,1]$.

Proof: Necessity. *Case 1*: B is injective, then by Lemma 2.5, I and B are comparable. Thus, $B\geqslant I$ or $B\leqslant I$, so $\sigma(B)\subseteq[1,\|B\|]$ or $\sigma(B)\subseteq[0,1]$.

Case 2: B is not injective, then

$$B=\begin{pmatrix} B_1 & 0 \\ 0 & 0 \end{pmatrix}: N(B)^\perp\oplus N(B)\to N(B)^\perp\oplus N(B),$$

where B_1 is injective from $N(B)^\perp$ into $N(B)^\perp$. It is clear that $\sigma(B)=\sigma(B_1)\cup\{0\}$. It follows from Case 1 that $\sigma(B)\subseteq\{0\}\cup[1,\|B\|]$ or $\sigma(B)\subseteq[0,1]$.

Sufficiency: If $\sigma(B)\subseteq[0,1]$, then $B\in\mathcal{B}(\mathcal{H})^+$ implies $B\leqslant I$, so $I\wedge B$ exists. Similarly, If $\sigma(B)\subseteq[1,\|B\|]$, then $B\in\mathcal{B}(\mathcal{H})^+$ implies $B\geqslant I$, so $I\wedge B$ exists. If $0\in\sigma(B)\subseteq\{0\}\cup[1,\|B\|]$, then 0 is an isolated point of $\sigma(B)$, so we have the Riesz idempotent

$$E_0 := \frac{1}{2\pi i}\int_{\partial D}(z-B)^{-1}\mathrm{d}z,$$

where $\{0\}\in D$ is an open disk which is far from the rest of $\sigma(B)$. Since $B\in\mathcal{B}(\mathcal{H})^+$, then it follows from Ref. 8, Theorem 2.5 that E_0 is a projection and $E_0\mathcal{H}=N(B)$. Thus, B can be decomposed as the form of

$$B=\begin{pmatrix} B_1 & 0 \\ 0 & 0 \end{pmatrix}: E_0^{\perp}\oplus E_0 \to E_0^{\perp}\oplus E_0,$$

where $\sigma(B_1)\subseteq[1,\|B\|]$ is an invertible operator. Similarly,

$$I=\begin{pmatrix} I_1 & 0 \\ 0 & I_2 \end{pmatrix}: E_0^{\perp}\oplus E_0 \to E_0^{\perp}\oplus E_0,$$

where I_1 and I_2 are identity operators on $E_0^{\perp}$ and E_0, respectively. Thus, $I_1\wedge B_1=I_1$, so

$$\begin{pmatrix} I_1 & 0 \\ 0 & 0 \end{pmatrix}\leqslant\begin{pmatrix} B_1 & 0 \\ 0 & 0 \end{pmatrix},\quad \begin{pmatrix} I_1 & 0 \\ 0 & I_2 \end{pmatrix}.$$

If

$$0\leqslant C=\begin{pmatrix} C_1 & C_2 \\ C_3 & C_4 \end{pmatrix}\leqslant\begin{pmatrix} B_1 & 0 \\ 0 & 0 \end{pmatrix},\quad \begin{pmatrix} I_1 & 0 \\ 0 & I_2 \end{pmatrix},$$

then it follows from Lemma 2.2 that $C_4=0$, so $C_2=0$ and $C_3=0$. Thus, $C\leqslant\begin{pmatrix} I_1 & 0 \\ 0 & 0 \end{pmatrix}$, we get $I\wedge B=\begin{pmatrix} I_1 & 0 \\ 0 & 0 \end{pmatrix}$.

Lemma 2.7: Suppose A, B, $C\in\mathcal{B}(\mathcal{H})^+$. If A is injective, then $B\wedge C$ exists if and only if $A^{1/2}BA^{1/2}\wedge A^{1/2}CA^{1/2}$ exists. In this case, $A^{1/2}(B\wedge C)A^{1/2}=A^{1/2}BA^{1/2}\wedge A^{1/2}CA^{1/2}$.

Proof: If $B\wedge C$ exists then it is clear that $A^{1/2}(B\wedge C)A^{1/2}\leqslant A^{1/2}BA^{1/2}$, $A^{1/2}CA^{1/2}$. Let $0\leqslant E\leqslant A^{1/2}CA^{1/2}$, $A^{1/2}BA^{1/2}$. By Lemma 2.1, $R(E^{1/2})\subseteq R(A^{1/2}C^{1/2})$, that is $E^{1/2}=A^{1/2}C^{1/2}D$, for some $D\in\mathcal{B}(\mathcal{H})$. Thus, $A^{1/2}C^{1/2}DD^*C^{1/2}A^{1/2}\leqslant A^{1/2}CA^{1/2}$. It follows from $\overline{R(A^{1/2})}=\mathcal{H}$ that $C^{1/2}DD^*C^{1/2}\leqslant C$. Similarly, $A^{1/2}C^{1/2}DD^*C^{1/2}A^{1/2}\leqslant A^{1/2}BA^{1/2}$implies $C^{1/2}DD^*C^{1/2}\leqslant B$, so $C^{1/2}DD^*C^{1/2}\leqslant B\wedge C$. Then, it easy to see that $E=A^{1/2}C^{1/2}DD^*C^{1/2}A^{1/2}\leqslant A^{1/2}(B\wedge C)A^{1/2}$, so $A^{1/2}(B\wedge C)A^{1/2}=A^{1/2}BA^{1/2}\wedge A^{1/2}CA^{1/2}$.

Conversely, assume that $F=A^{1/2}BA^{1/2}\wedge A^{1/2}CA^{1/2}$. By Lemma 2.1, $F\leqslant A^{1/2}BA^{1/2}$ implies $F^{1/2}=A^{1/2}F_1$, for some $F_1\in\mathcal{B}(\mathcal{H})$. Hence, $F=A^{1/2}F_1F_1^*A^{1/2}$. It follows from $\overline{R(A^{1/2})}=\mathcal{H}$ that $F_1F_1^*\leqslant C,B$. Let $0\leqslant G\leqslant B,C$. Then, $A^{1/2}GA^{1/2}\leqslant A^{1/2}BA^{1/2},A^{1/2}CA^{1/2}$, so $A^{1/2}GA^{1/2}\leqslant F=A^{1/2}F_1F_1^*A^{1/2}$. Hence, $G\leqslant F_1F_1^*$, since $\overline{R(A^{1/2})}=\mathcal{H}$. It follows $F_1F_1^*=B\wedge C$, so $A^{1/2}(B\wedge C)A^{1/2}=A^{1/2}BA^{1/2}\wedge A^{1/2}CA^{1/2}$.

The following is a extension of Conjecture 4.2 in Ref. 6.

Theorem 2.8: *Let $A\in\mathcal{B}(\mathcal{H})^+$ be an injective operator and $B\in\mathcal{B}(\mathcal{H})^+$ be an invertible operator. Then, there exists $A\wedge B$ if and only if A and B are comparable.*

Proof: Since $B\in\mathcal{B}(\mathcal{H})^+$ is an invertible operator, then $B^{-1/2}\in\mathcal{B}(\mathcal{H})^+$. It follows from Lemma 2.7 that $A\wedge B$ exists if and only if $B^{-1/2}AB^{-1/2}\wedge B^{-1/2}BB^{-1/2}$ exists if and only if $B^{-1/2}AB^{-1/2}\wedge I$ exists. Since $B^{-1/2}AB^{-1/2}\in\mathcal{B}(\mathcal{H})^+$ is an injective operator, by Lemma 2.5, $A\wedge B$ exists if and only if I and $B^{-1/2}AB^{-1/2}$ are comparable. Hence, $I\geqslant B^{-1/2}AB^{-1/2}$ or $I\geqq B^{-1/2}AB^{-1/2}$, so $A\geqslant B$ or $A\leqslant B$.

Corollary 2.9: (see Theorem 3.6 in Ref. 10) If A, $B\in\mathcal{E}(C^n)$ are incomparable and A, $B>0$, then $A\wedge B$ does not exist.

In general, for A, B, $C\in\mathcal{E}(\mathcal{H})$, the assertion that if $A\wedge B$ exists, then $(A+C)\wedge(B+C)$ exists is not true. we give a example as follows.

Example 2.10: Let A, B, $C\in\mathcal{E}(C^3)$,

$$A=\begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{4} \\ 0 & \frac{1}{4} & \frac{1}{2} \end{pmatrix}, \quad B=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad C=\begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \frac{1}{8} \end{pmatrix}.$$

Then

$$A+C=\begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{4} \\ 0 & \frac{1}{4} & \frac{5}{8} \end{pmatrix}, \quad B+C=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \frac{1}{8} \end{pmatrix}.$$

It is clear that $A+C$ and $B+C$ are invertible and that $A+C \geqslant B+C$ and $A+C \leqslant B+C$. By Corollary 2.9, $(A+C)\wedge(B+C)$ does not exist. But $A\wedge B$ exists, since B is a projection.

Proposition 2.11: Let $A \in \mathcal{E}(\mathcal{H})$. (1) If $2A\wedge I$ exists, then $A\wedge(I-A)$ exists.

(2) If $A\wedge(I-A)$ exists and $I-A$ is invertible, then $2A\wedge I$ exists.

Proof: (1) If $2A\wedge I=B$, then $A\leqslant B$, so $B-A\geqslant 0$. Clearly, $B-A\leqslant A$ and $B-A\leqslant I-A$. Let $0\leqslant C\leqslant A$ and $C\leqslant I-A$. Then it is clear that $C+A\leqslant B$, so $C\leqslant B-A$. Thus, $A\wedge(I-A)=B-A$.

(2) *Case 1*: $N(A)=\{0\}$. Since $A\wedge(I-A)$ exists and $I-A$ is invertible, by Theorem 2.8, $A\geqslant(I-A)$ or $A\leqslant(I-A)$, so $2A\wedge I$ exists.

Case 2: $N(A)\neq\{0\}$. It is clear that

$$A=\begin{pmatrix} A_1 & 0 \\ 0 & 0 \end{pmatrix}: N(A)^{\perp}\oplus N(A)\to N(A)^{\perp}\oplus N(A),$$

where A_1 is injective from $N(A)^{\perp}$ into $N(A)^{\perp}$. Then,

$$I=\begin{pmatrix} I_1 & 0 \\ 0 & I_2 \end{pmatrix}: N(A)^{\perp}\oplus N(A)\to N(A)^{\perp}\oplus N(A), \quad I-A=\begin{pmatrix} I_1-A_1 & 0 \\ 0 & I_2 \end{pmatrix}.$$

It is easy to show that $A\wedge(I-A)$ exists if and only if $A_1\wedge(I_1-A_1)$ exists and also that $2A\wedge I$ exists if and only if $2A_1\wedge I_1$ exists. It follows from Case 1 that $A_1\wedge(I_1-A_1)$ exists implies that $2A_1\wedge I_1$ exists.

Consequently, we obtain

Corollary 2.12: (see Ref. 4) Let $A\in\mathcal{E}(\mathcal{H})$. Then, the following assertions are equivalent:

(1) $A\wedge(I-A)$ exists;
(2) $\sigma(A)$ is contained either in $\{0\}\cup[\frac{1}{2},1]$ or in $[0,\frac{1}{2}]\cup\{1\}$;
(3) $A\wedge P_{A,I-A}$ and $(I-A)\wedge P_{A,I-A}$ are comparable, where $P_{A,B}$ is the orthogonal projection on the closure of $R(A^{1/2})\cap R(B^{1/2})$.

Proof: (1)⇒(2). Suppose that $A\wedge(I-A)$ exists. We assume that $I-A$ is invertible. By Proposition 2.11 (2), $2A\wedge I$ exists. It follows from Theorem 2.6 that $\sigma(2A)\subseteq\{0\}\cup[1,2]$ or $\sigma(2A)\subseteq[0,1]$. Thus, $\sigma(A)\backslash\{1\}\subseteq\{0\}\cup[\frac{1}{2},1]$ or $\sigma(A)\backslash\{1\}\subseteq[0,\frac{1}{2}]$. This shows that (2) holds.

(2)⇒(3). Denote $\mathcal{H}_0=(N(A)\oplus N(I-A))^{\perp}$. According to the space decomposition $\mathcal{H}=\mathcal{H}_0\oplus N(A)\oplus N(I-A)$, A and $I-A$ have the following operator matrix representations:

$$A=\begin{pmatrix} A_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & I \end{pmatrix} \quad \text{and } I-A=\begin{pmatrix} I-A_0 & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

respectively, where A_0 and $I-A_0$ are injective on $\mathcal{H}_0$. It is clear that

$$P_{A,I-A}=\begin{pmatrix} I & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad A\wedge P_{A,I-A}=\begin{pmatrix} A_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

and

$$(I-A)\wedge P_{A,I-A}=\begin{pmatrix} I-A_0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

If (2) holds, then $\sigma(A_0)\subseteq\sigma(A)\subseteq\{0\}\cup\left[\frac{1}{2},1\right]$ or $\sigma(A_0)\subseteq\left[0,\frac{1}{2}\right]\cup\{1\}$. Thus, $\sigma(A_0)\subseteq\left[\frac{1}{2},1\right]$ or $\sigma(I-A_0)\subseteq\left[\frac{1}{2},1\right]$, since A_0 and $I-A_0$ are injective. Thus, A_0 and $I-A_0$ are comparable, that is, $A\wedge P_{A,I-A}$ and $(I-A)\wedge P_{A,I-A}$ are comparable.

(3)⇒(1). If A has the operator matrix representation as above, then $A\wedge P_{A,I-A}$ and $(I-A)\wedge P_{A,I-A}$ are comparable, which implies that A_0 and $I-A_0$ are comparable. Thus, $A_0\wedge(I-A_0)$ exists. It is easily seen that

$$A\wedge(I-A)=\begin{pmatrix} A_0\wedge(I-A_0) & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Corollary 2.13: Let $A\in\mathcal{B}(\mathcal{H})^+$ and $B\in\mathcal{B}(\mathcal{H})^+$ be an invertible operator. Then, $A\wedge B=0$ if and only if $A=0$.

Proof: By Lemma 2.7, $A\wedge B=0$ if and only if $B^{-1/2}AB^{-1/2}\wedge I=0$. By the proof of Theorem 2.6, we have $B^{-1/2}AB^{-1/2}=0$, so $A=0$. See Refs. 11 and 12.

III. $A\sqcap B$

Gudder[7] has obtained the following result: For A, $B\in\mathcal{E}(\mathcal{H})$, If $A\sqcap B\in\mathcal{E}(\mathcal{H})$, then

(a) $A\sqcap B$ is a maximal lower bound for A and B in $\mathcal{E}(\mathcal{H})$.
(b) If $A\wedge B$ exists, then $A\wedge B=A\sqcap B$.

In Theorem 4.4 of Ref. 12, it is proved that the infimum $A\wedge P$ exists for any $A\in\mathcal{E}(\mathcal{H})$ and any projection $P\in\mathcal{E}(\mathcal{H})$. As a consequence, we may conjecture that $A\sqcap P\in\mathcal{E}(\mathcal{H})$. However this is not true.

Example 3.1: Let A, $P\in\mathcal{E}(C^3)$,

$$A=\begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & \frac{1}{4} \\ 0 & \frac{1}{4} & \frac{1}{2} \end{pmatrix}, \quad P=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Then

$$|A-P| = \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{\sqrt{5}}{4} & 0 \\ 0 & 0 & \frac{\sqrt{5}}{4} \end{pmatrix}, \quad A+P = \begin{pmatrix} \frac{3}{2} & 0 & 0 \\ 0 & \frac{3}{2} & \frac{1}{4} \\ 0 & \frac{1}{4} & \frac{1}{2} \end{pmatrix}.$$

It follows from $1/2-\sqrt{5}/4<0$ that $A+P \not\geqslant |A-P|$. Thus, $A \sqcap P \notin \mathcal{E}(\mathcal{H})$.

In Lemma 3.7 of Ref. 12, authors have obtained that $A \wedge B$ exists if and only if $(A \wedge P_{A,B}) \wedge (B \wedge P_{A,B})$ exists. For the generalized infimum $A \sqcap B$, we also get a similar result. we need following lemmas.

Lemma 3.2: (Ref. 7, Theorem 2.3 and Lemma 2.5) (a) If $A, B \in \mathcal{E}(\mathcal{H})$, then $(A-A \sqcap B)(B-A \sqcap B)=0$.

(b) For A, $B \in \mathcal{E}(\mathcal{H})$, $A \sqcap B=0$ if and only if $AB=0$.

Lemma 3.3: If $0 \leqslant A \leqslant B$, $0 \leqslant C \leqslant D$ and $BD=0$, then $AC=0$.

Proof: Since $BD=0=DB$, then $BD^{1/2}=D^{1/2}B$, so $D^{1/2}BD^{1/2}=DB=0$. It follows from $0 \leqslant D^{1/2}AD^{1/2} \leqslant D^{1/2}BD^{1/2}=0$ that $D^{1/2}AD^{1/2}=0$. Hence, $A^{1/2}D^{1/2}=0$. Similarly, $0 \leqslant A^{1/2}CA^{1/2} \leqslant A^{1/2}DA^{1/2}=0$, then $A^{1/2}C^{1/2}=0$. Thus $AC=0$.

Theorem 3.4: Let $A, B \in \mathcal{E}(\mathcal{H})$. If $A \sqcap B \in \mathcal{E}(\mathcal{H})$ then $(A \wedge P_{A,B}) \sqcap (B \wedge P_{A,B}) \in \mathcal{E}(\mathcal{H})$. In this case, $(A \wedge P_{A,B}) \sqcap (B \wedge P_{A,B})=A \sqcap B$.

Proof. Since $A \sqcap B \leqslant A$ and $A \sqcap B \leqslant B$, then $R(A \sqcap B) \subseteq R(A \sqcap B)^{1/2} \subseteq R(A^{1/2})$ and $R(A \sqcap B) \subseteq R(B^{1/2})$, by Lemma 2.1. Thus, $R(A \sqcap B) \subseteq R(A^{1/2}) \cap R(B^{1/2})$, so $A \sqcap B \leqslant P_{A,B}$. It follows that $A \sqcap B \leqslant A \wedge P_{A,B}$ and $A \sqcap B \leqslant B \wedge P_{A,B}$. By Lemma 3.2, $(A-A \sqcap B)(B-A \sqcap B)=0$. Since $A \wedge P_{A,B} \leqslant A$ and $B \wedge P_{A,B} \leqslant B$, by Lemma 3.3, we have $(A \wedge P_{A,B}-A \sqcap B)(B \wedge P_{A,B}-A \sqcap B)=0$. It follows from Lemma 3.2 again that

$$(A \wedge P_{A,B}-A \sqcap B) \sqcap (B \wedge P_{A,B}-A \sqcap B)=0,$$

so

$$(A \wedge P_{A,B}-A \sqcap B)+(B \wedge P_{A,B}-A \sqcap B)-|(A \wedge P_{A,B}-A \sqcap B)-(B \wedge P_{A,B}-A \sqcap B)|=0.$$

Thus

$$\tfrac{1}{2}[A \wedge P_{A,B}+B \wedge P_{A,B}-|A \wedge P_{A,B}-B \wedge P_{A,B}|]=A \sqcap B \geqslant 0.$$

Remark: The converse assertion of Theorem 3.4 does not hold, that is, there is $A, B \in \mathcal{E}(\mathcal{H})$ such that $A \sqcap B \notin \mathcal{E}(\mathcal{H})$ and $(A \wedge P_{A,B}) \sqcap (B \wedge P_{A,B}) \in \mathcal{E}(\mathcal{H})$.

Example 3.4: Let A, $B \in \mathcal{E}(C^3)$ and let $B=\frac{1}{2}P$, with A and P as above in Example 3.1. It is clear that

$$B \wedge P_{A,B} = \begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{1}{2} & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

From a direct calculation, we have

$$|A-B|=\begin{pmatrix} 0 & 0 & 0 \\ 0 & \frac{1}{4\sqrt{2}} & \frac{1}{4\sqrt{2}} \\ 0 & \frac{1}{4\sqrt{2}} & \frac{3}{4\sqrt{2}} \end{pmatrix}, \quad A+B=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & \frac{1}{4} \\ 0 & \frac{1}{4} & \frac{1}{2} \end{pmatrix}.$$

It follows from $(3/4\sqrt{2})-1/2>0$ that $A+B\not\geqslant|A-B|$, then $A\sqcap B\notin\mathcal{E}(\mathcal{H})$. It is easy to calculate that

$$A\wedge P_{A,B}=\begin{pmatrix} \frac{1}{2} & 0 & 0 \\ 0 & \frac{3}{8} & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

In fact, $\mathrm{diag}(\frac{1}{2},\frac{3}{8},0)\leqslant A$, $P_{A,B}$ is clear. Then, $A\wedge P_{A,B}\geqslant\mathrm{diag}(\frac{1}{2},\frac{3}{8},0)$. Therefore, by Lemma 2.3, $A\wedge P_{A,B}=\mathrm{diag}(\frac{1}{2},\frac{3}{8},0)$. Clearly, $(A\wedge P_{A,B})\sqcap(B\wedge P_{A,B})\in\mathcal{E}(\mathcal{H})$.

(Received 14 August 2006; accepted 12 September 2006; published online 23 October 2006)

In looking for *qualitative* differences between quaternionic and complex formulations of quantum physical theories, we provide a detailed discussion of the behavior of a wave packet in the presence of a quaternionic time-independent potential step. In this paper, we restrict our attention to diffusion phenomena. For the group velocity of the wave packet moving in the potential region and for the reflection and transmission times, the study shows a striking difference between the complex and quaternionic formulations which could be matter of further theoretical discussions and could represent the starting point for a possible experimental investigation. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2359577]

I. INTRODUCTION

Despite much research on quaternionic quantum mechanics, reviewed in its mathematical and physical aspects in the excellent book of Adler,[1] there have been few breakthroughs on the most natural question about the effect that quaternionic potentials play in the dynamics of elementary particles[2–5] and, as a consequence of it, about the possibility to look for an experimental proposal.[6–9] In this paper, by using the new mathematical tools developed in the analytic resolution of eigenvalue problems[10,11] and differential equations,[6,12–14] we analyze in detail the diffusion of a wave packet by a quaternionic potential step.

For the convenience of the reader and to facilitate access to the individual topics, this work is rendered as self-contained as possible. In Sec. II, we set up notation and terminology and proceed with the study of diffusion by quaternionic potentials. This section contains the (analytic) plane wave solution of the quaternionic Schrödinger equation in the presence of a potential step. This represents a fundamental mathematical tool in the discussion of the quaternionic stationary phase method (see Sec. III). We will touch only a few aspects of the theory of quaternionic integral transforms and restrict our attention to the diffusion of quaternionic wave packets with a peaked convolution function. The advantage of using the stationary phase method lies in the fact that, in the presence of a potential step, the motion of the wave packet can be correctly estimated by analyzing the phase derivative calculated at the maximum of the convolution function.[15–17] For a different shape of potentials, see, for example, the barrier, the stationary phase method, depending on the width of the potential and on the group velocity of the incoming particle, could break down. There is a rich number of articles leading with this problem in standard quantum mechanics.[18–23]

The results of this paper (a conclusion and outlooks are drawn in Sec. IV) shed some new light on the properties of quaternionic potentials. In particular, it is explicitly shown how the presence of a quaternionic perturbation modifies the momentum of the nonrelativistic incoming particle and its reflection (transmission) time. The study presented in this paper represents a starting point in view of a complete understanding of the behavior of wave packets impinging on quaternionic potentials. A detailed analysis of this topic could be fundamental in looking for experiments in which deviations from the complex quantum theory could be really seen. It is

worth pointing out that the question of finding the best experimental proposal to prove the existence of quaternionic potentials is, at present, far from being solved and in this paper we aim to contribute to this debate.

II. REFLECTION AND TRANSMISSION COEFFICIENTS

The quaternionic Schrödinger equation in the presence of a constant potential is given by

$$i\frac{\hbar}{2m}\Psi_{xx}(x,t)-\frac{iV_1+jV_2+kV_3}{\hbar}\Psi(x,t)=\Psi_t(x,t), \tag{1}$$

where $iV_1+jV_2+kV_3$ represents the quaternionic generalization of the anti-Hermitian complex potential iV_1. For a complete discussion, see Ref. 1. This partial differential equation, by the substitution

$$\Psi(x,t)=\Phi(x)\exp[-iEt/\hbar], \tag{2}$$

can be reduced to the following ordinary second order differential equation with constant quaternionic coefficients,

$$i\frac{\hbar^2}{2m}\Phi''(x)-\left(iV_1+jV_2+kV_3\right)\Phi(x)=-\Phi(x)Ei. \tag{3}$$

The solution of the Schrödinger equation in the presence of constant quaternionic potential has been matter of study in recent years.[4–6] New mathematical techniques, essentially based on the right eigenvalue problem for quaternionic operators,[10,12] allow us to obtain the solution without the need to translate the quaternionic problem in its complex counterpart.[2,3] In particular, in the presence of a potential step and for the diffusion case,

$$E>\sqrt{V_1^2+V_2^2+V_3^2},$$

the quaternionic plane wave solutions (for a detailed derivation, see Ref. 6) are as follows:

$$\text{(I) Free region } (x<0): \quad \Phi_I(x)=\exp[i\epsilon x]+r\exp[-i\epsilon x]+j\tilde{r}\exp[\epsilon x];$$

$$\text{(II) Potential region } (x>0): \quad \Phi_{II}(x)=(1+jw)t\exp[i\rho_- x]+(\overline{w}+j)\tilde{t}\exp[-\rho_+ x], \tag{4}$$

where

$$\epsilon=\sqrt{\frac{2m}{\hbar^2}E}, \quad \rho_\pm=\sqrt{\frac{2m}{\hbar^2}\left(\sqrt{E^2-V_2^2-V_3^2}\pm V_1\right)}, \quad w=-i\frac{V_2-iV_3}{E+\sqrt{E^2-V_2^2-V_3^2}},$$

and

$$t=\frac{2\epsilon}{\epsilon+\rho_-}\left[1-|w|^2\frac{\epsilon-i\rho_-}{\epsilon+\rho_-}\frac{\epsilon+i\rho_+}{\epsilon+\rho_+}\right]^{-1}, \quad \tilde{t}=\frac{i\rho_--\epsilon}{\epsilon+\rho_+}wt,$$

$$r=\frac{\epsilon-\rho_-}{2\epsilon}\left[1-|w|^2\frac{\epsilon-i\rho_-}{\epsilon-\rho_-}\frac{\epsilon-i\rho_+}{\epsilon+\rho_+}\right]t, \quad \tilde{r}=\frac{i\rho_-+\rho_+}{\epsilon+\rho_+}wt.$$

From the current conservation,

$$[\overline{\Psi}(x,t)\Psi(x,t)]_t=\frac{\hbar}{2m}[\overline{\Psi}(x,t)i\Psi_{xx}(x,t)+\text{h.c.}], \tag{5}$$

by recalling that we are considering stationary solutions of the Schrödinger equation, we obtain

$$\overline{\Phi}(x)i\Phi''(x) + \text{h.c.} = 0.$$

This implies that the current density,

$$J(x) = \overline{\Phi}(x)i\Phi'(x) + \text{h.c.}, \tag{6}$$

is a quantity independent of x. Due to the continuity of the wave function and its derivative, the current density has to satisfy the following constraint:

$$J_{\text{I}}(0) = J_{\text{II}}(0). \tag{7}$$

By using the explicit form of the plane wave solutions given in Eqs. (4), and the condition (7), a straightforward calculation conduces to

$$R + T = 1, \tag{8}$$

where

$$R = |r|^2 \quad \text{and} \quad T = \frac{\rho_-}{\epsilon}(1 - |w|^2)|t|^2.$$

Similar to the predictions of complex quantum mechanics, the incident particle has a nonzero probability of turning back. Nevertheless, we know that in standard quantum mechanics no phase is created by such reflection.[17] The situation drastically changes in the presence of a quaternionic perturbation. We shall come back to this point in Sec. III.

A. Reflection and transmission phases

From the stationary wave functions given in Eqs. (4), we shall construct, by linear superposition, wave packets and we shall study their time evolution (see Sec. III). In this spirit, it is convenient to rewrite the reflection and transmission coefficients in terms of their modulus and phases. By simple algebraic manipulations, we find

$$r = \sqrt{\frac{[(\epsilon-\rho_-)(\epsilon+\rho_+) - |w|^2(\epsilon^2-\rho_-\rho_+)]^2 + |w|^4\epsilon^2(\rho_-+\rho_+)^2}{[(\epsilon+\rho_-)(\epsilon+\rho_+) - |w|^2(\epsilon^2+\rho_-\rho_+)]^2 + |w|^4\epsilon^2(\rho_--\rho_+)^2}}\exp[i\theta_r],$$

$$t = \frac{2\epsilon(\epsilon+\rho_+)}{\sqrt{[(\epsilon+\rho_-)(\epsilon+\rho_+) - |w|^2(\epsilon^2+\rho_-\rho_+)]^2 + |w|^4\epsilon^2(\rho_--\rho_+)^2}}\exp[i\theta_t], \tag{9}$$

where

$$\theta_r = \arctan\left(\frac{\epsilon(\rho_++\rho_-)|w|^2}{(\epsilon-\rho_-)(\epsilon+\rho_+) - |w|^2(\epsilon^2-\rho_-\rho_+)}\right) + \theta_t,$$

$$\theta_t = \arctan\left(\frac{\epsilon(\rho_+-\rho_-)|w|^2}{(\epsilon+\rho_-)(\epsilon+\rho_+) - |w|^2(\epsilon^2+\rho_-\rho_+)}\right). \tag{10}$$

The important point to be noted here is the dependence on the energy, E, and the complex imaginary part of the potential, V_1, as expected from the standard quantum case, and the *new* dependence on the modulus of the pure quaternionic part of the potential, $|V_2+iV_3|$. This last result means that once fixed the modulus of the quaternionic perturbation any rotation in the plane (V_2, V_3) does not modify the reflection and transmission coefficients. The quaternionic rotation invariance is due to the choice of i as the imaginary unit in the anti-Hermitian momentum operator, $i\hbar\,\partial_{xx}/2m$, which appears in the quaternionic Scrhödinger equation (1).

B. The complex limit

The standard (complex) quantum results can be obtained by taking a simple limit case, i.e., $V_{2,3}\to 0$. In fact, by observing that

$$V_{2,3}\to 0 \Rightarrow \begin{cases} w \to 0, \\ \rho_- \to \sigma = \sqrt{\dfrac{2m}{\hbar^2}(E-V_1)}, \end{cases}$$

we find

$$R=|r|^2 \quad \text{and} \quad T=\frac{\sigma}{\epsilon}|t|^2,$$

where

$$r=\frac{\epsilon-\sigma}{\epsilon+\sigma} \quad \text{and} \quad t=\frac{2\epsilon}{\epsilon+\sigma}. \tag{11}$$

As expected, the reflection and transmission coefficients (r and t) are real ($\theta_r=\theta_t=0$), and this implies that there is no phase created by reflection or transmission.[17]

C. The pure quaternionic limit

It is interesting to consider a second limit, i.e., $V_1\to 0$. This represents the case of a *pure* quaternionic potential. Noting that

$$V_1\to 0 \Rightarrow \begin{cases} \rho_\pm \to \rho = \sqrt{\dfrac{2m}{\hbar^2}\sqrt{E^2-V_2^2-V_3^2}}, \\ |w|^2 \to \dfrac{\epsilon^2-\rho^2}{\epsilon^2+\rho^2}, \end{cases}$$

we obtain

$$R=|r|^2 \quad \text{and} \quad T=\frac{2\rho^3}{\epsilon(\epsilon^2+\rho^2)}|t|^2,$$

where

$$r=\frac{\epsilon-\rho}{\sqrt{\epsilon^2+\rho^2}}\exp\left[i\arctan\left(\frac{\epsilon}{\rho}\right)\right] \quad \text{and} \quad t=\frac{\epsilon}{\rho}. \tag{12}$$

In this limit, the symmetry between reflection and transmission times is broken down. For a pure quaternionic potential step, we find an instantaneous transmission but *not* an instantaneous reflection (we shall discuss in detail this point in Sec. III).

III. STATIONARY PHASE METHOD

Until now, we have been concerned only with plane waves. In this Section, we are going to study the time evolution of quaternionic wave packets and deducing from them several important properties. The principle of superposition guarantees that every *real* linear combination of the plane waves $\Phi_{\mathrm{I}}(x)\exp[-iEt/\hbar]$ and $\Phi_{\mathrm{II}}(x)\exp[-iEt/\hbar]$ will satisfy the Schrödinger equation in the presence of a quaternionic potential step.

Let $g(\epsilon)$ be a real convolution function with a maximum in ϵ_0. In the free region ($x<0$), the superposition can be written as follows:

$$\Omega_{\mathrm{I}}(x,t)=\int_{\epsilon_{\min}}^{\infty}\mathrm{d}\epsilon\, g(\epsilon)\{\exp[i\epsilon x]+r\exp[-i\epsilon x]+j\tilde{r}\exp[\epsilon x]\}\exp[-i\epsilon^2\hbar\, t/2m], \tag{13}$$

where

$$\epsilon_{\min}=\sqrt{\frac{2m}{\hbar^2}\sqrt{V_1^2+V_2^2+V_3^2}}.$$

The first term in Eq. (13) represents the incident wave, the second term the reflected wave and the third term an evanescent wave. The phases for the incoming and reflected waves are

$$\theta_{\mathrm{inc}}[\epsilon;x,t]=\epsilon x-\epsilon^2\frac{\hbar t}{2m},$$

$$\theta_{\mathrm{ref}}[\epsilon;x,t]=-\epsilon x-\epsilon^2\frac{\hbar t}{2m}+\theta_r. \tag{14}$$

The stationary phase condition (the derivative with respect to ϵ of the argument calculated in ϵ_0 equal to zero) enables us to calculate the position of the maximum of the incident and reflected wave packets:

$$x_{\mathrm{inc}}^{\max}(t)=\frac{\hbar\epsilon_0}{m}t,$$

$$x_{\mathrm{ref}}^{\max}(t)=-\frac{\hbar\epsilon_0}{m}t+\left[\frac{\mathrm{d}\theta_r}{\mathrm{d}\epsilon}\right]_0. \tag{15}$$

The maximum of the incident wave packet arrives at the step discontinuity at time $t=0$ (as it occurs in the complex case). During a certain interval of time, the wave packet is localized in the region $x\sim 0$. For large times the incident wave packet has practically disappeared and we only find the reflected wave packet. It is important to observe that contrary to the predictions of complex quantum mechanics ($\theta_r=0$), the maximum of the reflected wave packets is found at $x=0$ at time $t=(m/\hbar\epsilon_0)[\mathrm{d}\theta_r/\mathrm{d}\epsilon]_0$. This means that in the presence of a quaternionic perturbation we do *not* have an instantaneous reflection: for large times the maximum of the reflected wave packet is *not* at $-\hbar\epsilon_0 t/m$ but is shifted with respect to this value by a quantity equal to $[\mathrm{d}\theta_r/\mathrm{d}\epsilon]_0$.

An analogous discussion for the transmitted wave packet ($x>0$),

$$\Omega_{\mathrm{II}}(x,t)=\int\mathrm{d}\epsilon\, g(\epsilon)\{t\exp[i\rho_- x]+\tilde{wt}\exp[-\rho_+ x]\}\exp[-i\epsilon^2\hbar\, t/2m]+j\int\mathrm{d}\epsilon\, g(\epsilon)\{wt\exp[i\rho_- x]$$
$$+\tilde{t}\exp[-\rho_+ x]\}\exp[-i\epsilon^2\hbar\, t/2m], \tag{16}$$

where the phases to be considered are

$$\theta_{\mathrm{tra}}^{(1,i)}[\epsilon;x,t]=\rho_- x-\epsilon^2\frac{\hbar t}{2m}+\theta_t$$

$$\theta_{\mathrm{tra}}^{(j,k)}[\epsilon;x,t]=\rho_- x-\epsilon^2\frac{\hbar t}{2m}+\theta_t+\arctan\left[\frac{V_2}{V_3}\right], \tag{17}$$

leads to a similar conclusion for the transmitted time. Contrary to what happens in the standard (complex) quantum mechanics, where there is an instantaneous transmission, in the presence of a quaternionic potential step, the maximum of the transmitted wave packet,

$$x_{\mathrm{tra}}^{\max}(t)=\left\{\frac{\hbar\epsilon_0}{m}t-\left[\frac{\mathrm{d}\theta_t}{\mathrm{d}\epsilon}\right]_0\right\}\Bigg/\left[\frac{\mathrm{d}\rho_-}{\mathrm{d}\epsilon}\right]_0, \tag{18}$$

is found at $x=0$ at time $t=(m/\hbar\epsilon_0)[\mathrm{d}\theta_t/\mathrm{d}\epsilon]_0$. At first glance, it could appear a logical consequence of the result obtained for the reflection time. Nevertheless, it is important to note that $\theta_r\neq\theta_t$ and, consequently, the symmetry between reflection and transmission times is always broken down. For example, as it was explicitly shown in the previous section, instantaneous transmission does not necessarily imply instantaneous reflection.

In order to simplify the discussion about the results obtained in our study, let us introduce the following notation:

$$V_0=\sqrt{V_1^2+V_2^2+V_3^2},$$

and rewrite the maximum of the incident, reflected and transmitted wave packets in terms of E_0 (the maximum value of the energy spectrum of the incoming particles)

$$x_{\mathrm{inc}}^{\max}(t)=\sqrt{\frac{2E_0}{m}}t,$$

$$x_{\mathrm{ref}}^{\max}(t)=-\sqrt{\frac{2E_0}{m}}t+\frac{\hbar}{\sqrt{2mV_0}}\left[\frac{\mathrm{d}\theta_r}{\mathrm{d}\sqrt{\frac{E}{V_0}}}\right]_0,$$

$$x_{\mathrm{tra}}^{\max}(t)=\left\{\sqrt{\frac{2E_0}{m}}t-\frac{\hbar}{\sqrt{2mV_0}}\left[\frac{\mathrm{d}\theta_t}{\mathrm{d}\sqrt{\frac{E}{V_0}}}\right]_0\right\}\Bigg/\left[\frac{\mathrm{d}\rho_-}{\mathrm{d}\epsilon}\right]_0. \tag{19}$$

The incident and reflected wave packets propagate, respectively, with velocities of v_0 and $-v_0$,

$$v_0=\sqrt{2E_0/m}. \tag{20}$$

This is the standard result obtained in complex quantum mechanics. For the transmitted wave packet, the velocity is given by

$$v_{\mathrm{tra}}=v_0\Bigg/\left[\frac{\mathrm{d}\rho_-}{\mathrm{d}\epsilon}\right]_0. \tag{21}$$

Due to the fact that the quantity ρ_- has an additional dependence on $|V_2+iV_3|$ with respect to the standard dependence on V_1, the complex and quaternionic formulations give different predictions. For example, of particular interest, it is the comparison between the group velocity of the transmitted wave packet for the complex case, $V_0=V_1$,

$$v_{\mathrm{tra}}^{(i)}=v_0\Bigg/\left(\sqrt{\epsilon^2-\frac{2m}{\hbar^2}V_0}\right)_\epsilon=v_0\sqrt{1-\frac{V_0}{E_0}}, \tag{22}$$

and that one for the *pure* quaternionic case, $V_0=|V_2+iV_3|$,

$$v_{\mathrm{tra}}^{(j,k)}=v_0\Bigg/\left\{\left[\epsilon^4-\left(\frac{2m}{\hbar^2}V_0\right)^2\right]^{1/4}\right\}_\epsilon=v_0\left[1-\left(\frac{V_0}{E_0}\right)^2\right]^{3/4}. \tag{23}$$

A first *important* observation is that whereas $v_{\mathrm{tra}}^{(i)}$ is greater or smaller than v_0 depending on the sign of V_1, $v_{\mathrm{tra}}^{(j,k)}$ is always smaller than the group velocity in the fre region. For incident particles with an energy spectrum peaked in E_0, with $E_0\gg V_0$, the group velocities of the wave packet

traveling in the potential region, (22) and (23), can be approximated by taking the first terms in their Taylor expansions,

$$v_{\mathrm{tra}}^{(i)} = v_0\left[1 - \frac{1}{2}\frac{V_0}{E_0} - \frac{1}{8}\left(\frac{V_0}{E_0}\right)^2\right] + \mathcal{O}\left[\left(\frac{V_0}{E_0}\right)^3\right],$$

$$v_{\mathrm{tra}}^{(j,k)} = v_0\left[1 - \frac{3}{4}\left(\frac{V_0}{E_0}\right)^2\right] + \mathcal{O}\left[\left(\frac{V_0}{E_0}\right)^4\right].$$

This means that a clear difference between the complex and the (pure) quaternionic case is expected for the group velocity of a wave packet traveling in a region in which a small perturbation is turned on. In this spirit, it is also interesting to compare the reflection and transmission times,

$$\frac{\sqrt{2mV_0}}{\hbar}x_{\mathrm{ref}}^{\max}(0) = \left[\frac{\mathrm{d}\theta_r}{\mathrm{d}\sqrt{\frac{E}{V_0}}}\right]_0,$$

$$\frac{\sqrt{2mV_0}}{\hbar}x_{\mathrm{tra}}^{\max}(0) = -\left[\frac{\mathrm{d}\theta_t}{\mathrm{d}\sqrt{\frac{E}{V_0}}}\right]_0 \Bigg/ \left[\frac{\mathrm{d}\rho_-}{\mathrm{d}\epsilon}\right]_0. \tag{24}$$

Standard quantum mechanics predicts instantaneous reflection and transmission, i.e.,

$$x_{\mathrm{ref}}^{(i)\max}(0) = x_{\mathrm{tra}}^{(i)\max}(0) = 0.$$

For a pure quaternionic potential, the transmission, in analogy to the complex case, is instantaneous,

$$x_{\mathrm{tra}}^{(j,k)\max}(0) = 0,$$

but the reflection time is different from zero (breaking down the instantaneity),

$$\frac{\sqrt{2mV_0}}{\hbar}x_{\mathrm{ref}}^{(j,k)\max}(0) = -\left\{2\sqrt{\frac{E_0}{V_0}}\left[\frac{E_0}{V_0} + \sqrt{\left(\frac{E_0}{V_0}\right)^2 - 1}\right]\left[\left(\frac{E_0}{V_0}\right)^2 - 1\right]^{3/4}\right\}^{-1}.$$

This predicts, for large times, that the maximum of the reflected wave packet should be found at the left of the position predicted by standard quantum mechanics, i.e., $-\hbar\,\epsilon_0 t/m$. For $E_0 \gg V_0$, the difference between the complex and (pure) quaternionic case is *only* manifest at the third order in V_0/E_0,

$$\frac{\sqrt{2mV_0}}{\hbar}x_{\mathrm{ref}}^{\max}(0) = -\frac{1}{4}\left(\frac{V_0}{E_0}\right)^3 + \mathcal{O}\left[\left(\frac{V_0}{E_0}\right)^4\right],$$

and, consequently, for small perturbations, we practically find an instantaneous reflection. It is important to note that the shift in the position of the maximum of the reflected wave packet becomes important when E_0 approaches V_0, this implies $x_{\mathrm{ref}}^{(j,k)\max}(0) \to \infty$. Nevertheless, for incident wave packets peaked in $E_0 \sim V_0$, a more careful analysis is needed. In fact, in this limit new effects have to be considered and these effects cannot be obtained by simply using the stationary phase method.[19–21]

IV. CONCLUSIONS AND OUTLOOKS

The study presented in this paper, and based on the use of wave packets, represents, from our point of view, a first important attempt to discuss deviations from the standard (complex) quantum

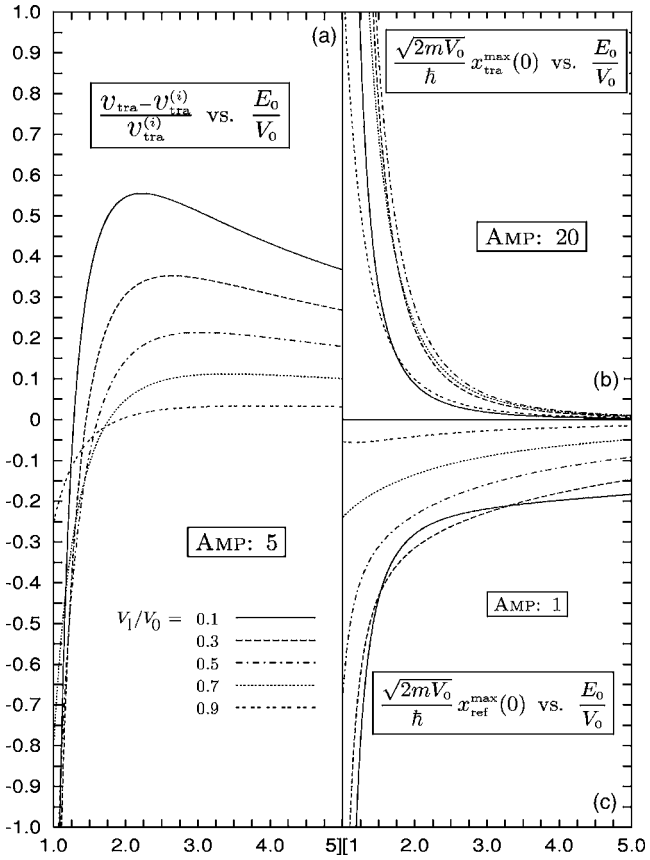

FIG. 1. Fixing the value of $V_0=|iV_1+jV_2+kV_3|$ and varying its complex component V_1, the group velocity of the transmitted wave packet (a) and the transmission/reflection times, (b) and (c) are plotted as a function of E_0/V_0, where E_0 is the maximum of the energy spectrum of the incident wave packet. The analysis is done for diffusion phenomena ($E_0>V_0$).

mechanics in the presence of quaternionic potentials. The wave packet formalism, with respect to the previous analysis, essentially based on the plane wave solutions, surely gives a more "physical" focus. For example, this formalism allows us to explicitly show the effect that quaternionic perturbations play in the momentum distribution of elementary particles and, in the particular case of a potential step, to calculate the new reflection and transmission times due to quaternionic interference phenomena. To emphasize the main differences between the complex and the quaternionic formulation of quantum mechanics for diffusion phenomena by a potential step, we have given, in the previous section, a detailed discussion based on the *analytic* study of the group velocities in the potential region and of the reflection time for complex and (pure) quaternionic potentials.

Now, let us return to the discussion for the general case, i.e., a complex potential in the presence of a quaternionic perturbation. In Fig. 1(a), fixing the value of V_0 and varying its complex component V_1, we draw

$$\frac{v_{\mathrm{tra}}-v_{\mathrm{tra}}^{(i)}}{v_{\mathrm{tra}}^{(i)}}, \tag{25}$$

as a function of E_0/V_0. The continuous line represents the case of a small complex component in the quaternionic potential, consequently such a curve approximates the case of a pure quaternionic potential,

$$\frac{v_{\mathrm{tra}}^{(j,k)}-v_{\mathrm{tra}}^{(i)}}{v_{\mathrm{tra}}^{(i)}}=\left(1-\frac{V_0}{E_0}\right)^{1/4}\left(1+\frac{V_0}{E_0}\right)^{3/4}-1\underset{E_0\gg V_0}{\longrightarrow}\frac{1}{2}\frac{V_0}{E_0}-\frac{3}{8}\left(\frac{V_0}{E_0}\right)^2+\mathcal{O}\left[\left(\frac{V_0}{E_0}\right)^3\right].$$

It is also interesting to observe that the maximum of $(v_{\mathrm{tra}}^{(j,k)}-v_{\mathrm{tra}}^{(i)})/v_{\mathrm{tra}}^{(i)}$ is found at $E_0=2V_0$.

The plots in Fig. 1(b) and Fig. 1(c), respectively, show the behavior of the transmission and reflection times as a function of E_0/V_0. Let us list some results coming out from our analysis. The quaternionic interefernce phenomena at the step discontinuity produce an new interesting effect in the reflected and transmitted wave packets: the maxima of such packets are found at $x=0$ before that the incident wave packet reaches the potential step discontinuity. The symmetry between reflection and transmission time is broken down [see the amplification if Fig. 1(b) and Fig. 1(c)].

Evidently, all the physical consequences of our analysis, regardless of whether we use a complex or a quaternionic potential in the Schrödinger equation deserve further investigation. Nevertheless, we think that the discussion presented in this paper and based on the use of the wave packet formalism represents the starting point for further theoretical studies and a fundamental tool in looking for possible experimental deviations from standard (complex) quantum mechanics.

Sjostrand and Zworski [J. Am. Math. Soc. **4**, 729–769 (1991)] proved a universal upper bound for the resonance counting function in black box scattering. Examples are presented which show that there is no corresponding general lower bound.
 [DOI: 10.1063/1.2356910]

I. INTRODUCTION

Consider the Schrödinger operator $-\Delta+V$ defined on R^n, where n is odd. We assume that V is bounded and compactly supported. The resolvent $(-\Delta+V-\lambda^2)^{-1}$ continues from $\mathrm{Im}\ \lambda>0$ to a meromorphic function on the complex λ plane. Its poles are known as resonances. Let $N(r)$ denote the number of resonances in a ball of radius r, i.e., $|\lambda|\leqslant r$. Zworski showed that $N(r)\leqslant c(r+1)^n$. In fact, Sjöstrand and Zworski showed that the same type of upper bound occurs much more generally as formalized in their theory of black box scattering.[1] The formalism of black box scattering allows a simultaneous treatment of potential, metric, and obstacle scattering, without entering into their particular features. It also allows completely abstract perturbations, some of which have geometric meaning, for instance scattering on manifolds with cusps. The situation for lower bounds is less well understood. For potential scattering, Sá Barreto[2] proved that $\limsup N(r)/r\geqslant c$, as $r\to\infty$. The lecture notes of Melrose[3] and the survey article of Zworski[4] contain more extensive references and foundational material. The lectures on resonances, available on the home page of Sjostrand, provide another source for background material. Christiansen and Hilsop[5] showed that for generic compactly supported potentials one has $\limsup \log N(r)/\log r = n$. Stefanov[6] discusses the optimality of constants appearing in the upper bounds for $N(r)$.

The purpose of this note is to provided some examples of compactly supported perturbations of $-\Delta$ where $N(r)\leqslant cr^{\beta}$, for any $1\leqslant\beta\leqslant n$. These examples satisfy the axioms of black box scattering. They are obtained by amalgamating collections of rotationally symmetric potentials. One applies estimates of Zworski[7] to verify that our examples satisfy the upper bound. Study of Zworski's paper about rotationally symmetric potentials lead to some ideas for simplifying his work. These ideas are outlined in the final section of this paper. The author thanks the referee for providing additional references and for suggestions concerning the exposition.

II. EXAMPLES OF BLACK BOX SCATTERING

Suppose that $V\in L^{\infty}(R^n)$ is compactly supported and rotationally symmetric. By separation of variables and renormalization of measures $-\Delta+V$ decomposes into a sum of one dimensional operators

$$\mathcal{D}_{\ell}\psi=-\psi''+\frac{\ell(\ell+1)}{s^2}\psi+V(s)\psi,\quad s\in R^{+}.$$

The parameter ℓ represents the order of the spherical harmonic using separation of variables (Ref. 7, p. 372).

[a)]Electronic mail: hgd@math.purdue.edu

The study of rotationally symmetric potentials suggests the definition of more general perturbations of $-\Delta$. In particular, for a real and non-negative, we set

$$\mathcal{D}_{\ell,\alpha}\psi = -\psi'' + \frac{\ell(\ell+1)}{s^2}\psi + \ell^{2\alpha}V(\ell^{\alpha}s)\psi.$$

The direct sum $\overline{\mathcal{D}}_{\alpha}=\Sigma_{\ell}\mathcal{D}_{\ell,\alpha}$ satisfies the axioms of black box scattering, as formulated in Ref. 1. If $N_{\alpha}(r)$ denotes the number of resonances, for the meromorphic continuation of the resolvent $(\overline{\mathcal{D}}_{\alpha}-\lambda^2)^{-1}$, in a ball of radius r, then the general result[1] for black box scattering yields $N_{\alpha}(r) \leqslant cr^n$.

To obtain a more precise upper bound, observe that by change of variables $x=\ell^{\alpha}s$, one has $N_{\alpha,\ell}(r)=N_{0,\ell}(r/\ell^{\alpha})$. Extending the argument of (Ref. 7, p. 385) gives, for large r,

$$N_{\alpha}(r) \leqslant c_1 \sum_{\ell} \ell^{n-2} N_{\alpha,\ell}(r) = c_1 \sum_{\ell} \ell^{n-2} N_{0,\ell}\left(\frac{r}{\ell^{\alpha}}\right).$$

If $\ell \geqslant c_2 r$, then $N_{0,\ell}(r)=0$, so that

$$N_{\alpha}(r) \leqslant c_1 \sum_{\ell \leqslant c_2 r \ell^{-\alpha}} \ell^{n-2} N_{0,\ell}\left(\frac{r}{\ell^{\alpha}}\right) \leqslant c_3 r \sum_{\ell \leqslant c_2 r \ell^{-\alpha}} \ell^{n-2-\alpha}.$$

When $\alpha > n-1$, this gives $N_{\alpha}(r) \leqslant c_4 r$. If $0 \leqslant \alpha < n-1, N_{\alpha}(r) \leqslant c_5 r^{n/(1+\alpha)}$. In particular, by suitable choice of α, we obtain $N_{\alpha}(r) \leqslant c_6 r^{\beta}$, for any given $1 \leqslant \beta \leqslant n$. These examples show that lower bounds in black box scattering do not have the same universality as upper bounds. To some extent this is already clear from consideration of the trivial case when V is identically zero.

For V satisfying a jump condition, i.e., $V \in C^2[0,a], V(a) \neq 0$, the method of (Ref. 7, p. 400) extends to give $N_{\alpha}(r) \sim cr^{\beta}$, for $1 \leqslant \beta \leqslant n$. Note that the linear case $N(r) \sim cr$ is easily obtained by taking the direct sum of $\widetilde{\mathcal{D}}_{\ell}$ where $\widetilde{\mathcal{D}}_{\ell} = -\psi'' + [\ell(\ell+1)/s^2]\psi$, except for finitely many values of ℓ, where $\widetilde{\mathcal{D}}_{\ell} = -\psi'' + [\ell(\ell+1)/s^2]\psi + V(s)\psi$.

Any axiomatic approach to lower bounds must exclude the $\overline{\mathcal{D}}_{\alpha}$, if one desires the conclusion $N(r) \geqslant cr^n$, i.e., the lower bound comparable to the upper bound. However, the $\overline{\mathcal{D}}_{\alpha}$ seem quite similar to potentials from the mathematical point of view. The author does not know whether or not they are physically reasonable.

III. ROTATIONALLY SYMMETRIC POTENTIALS

The purpose of this section is to outline some simplifications of Zworski's work[7] concerning the resonance counting function for rotationally symmetric potentials. The proofs presented in Ref. 7 are long and require intricate calculations. It is possible to handle some of the technical problems in a more elementary way.

Let $V(r)$ be bounded and compactly supported. The letter ℓ denotes the separation parameter corresponding to the order of the spherical harmonic on S^{n-1} and the letter λ corresponds to the resonance. After separation of variables the resolvent $-\Delta+V$ decomposes into a direct sum of one dimensional operators $R_V^{\ell}(\lambda)=\{(-d^2/dr^2)+[\ell(\ell+1)/r^2]+V(r)-\lambda^2\}^{-1}$. For each fixed choice of ℓ, the resonance counting function $N_{\ell}(|\lambda|) \sim c|\lambda|$ by standard results [Ref. 8, pp. 328–329], provided that $V(r)$ satisfies a jump condition. The problem is to obtain upper bounds and asymptotics for $N(|\lambda|)=\Sigma_{\ell}N_{\ell}(|\lambda|)$.

Clearly, for fixed $|\lambda|$ and ℓ sufficiently large, we have $N_{\ell}(|\lambda|)=0$. It is crucial to establish the more precise statement that $N_{\ell}(|\lambda|)=0$ for $\ell > c|\lambda|$. To see this observe that $R_V^{\ell}(\lambda)$ has no pole at λ if $I+R_0^{\ell}(\lambda)V$ is invertible, by the resolvent equation. Fredholm theory guarantees that $I+R_0^{\ell}(\lambda)V$ is invertible if $R_0^{\ell}(\lambda)V$ has no eigenvalue -1. If $\ell > c|\lambda|$, then $\|R_0^{\ell}(\lambda)\| \leqslant d\ell^{-2}$on the support of V. So if λ is sufficiently large, then $\||V|^{1/2}\mathrm{sgn}(V)R_0^{\ell}(\lambda)|V|^{1/2}\| < \epsilon$, and consequently neither this operator nor $R_0^{\ell}(\lambda)V$ has eigenvalue -1. Suppose that V is supported on $[0,b]$. Then

$R_V^\ell(\lambda)$ is holomorphic for $\ell > c|\lambda|$, where c can be made arbitrarily small by choosing a sufficiently small b. Scaling in the space variables reduces one to sufficiently small b.

Having quantified the existence of pole free regions, we need only consider $N_\ell(r)$ for $\ell < cr$. Let $\tilde{f}_0^\ell(x,\lambda)$ be the Bessel function satisfying the unperturbed equation $(-d^2\phi/dx^2)+[\ell(\ell+1)/(x^2)]\phi=\lambda^2\phi$ and having the asymptotics $\tilde{f}_0^\ell(x,\lambda)\sim e^{ix\lambda}$ as $x\to\infty$. Set $\phi(x)=\psi(\lambda x)=\psi(y)$, so that $(-d^2\psi/dy^2)+[\ell(\ell+1)/(y^2)]\psi=\psi$. If $|y|>c\ell$, elementary asymptotic formulas for Bessel functions[9] give $\tilde{f}_0^\ell(x,\lambda)\sim e^{ix\lambda}$ uniformly for $x>b/2$ and $|\lambda|>c\ell$, where c is sufficiently large. Consequently, the Bessel transform stabilizes uniformly to the Fourier transform when $|\lambda|>c\ell$. This means that the asymptotics of $N_\ell(r)$, for V satisfying a jump condition on its derivatives,[8] are uniformly $N_\ell(r)\sim cr$, for $r>c\ell$. Summing over $\ell<cr$ gives the asymptotics $N(r)=\Sigma_{\ell<cr}\ell^{n-2}N_\ell(r)=cr\Sigma_{\ell<cr}\ell^{n-2}+o(r^n)$. In the absence of the jump condition, the uniform stabilization of the Bessel transform suffices to give the upper bound $N_\ell(r)<cr$ and thus $N(r)<cr^n$. In particular, the entire function $\mathcal{M}^{(\ell)}(\lambda)$ defined by Zworski[7] is uniformly of order one, i.e., $\log|\mathcal{M}^\ell(\lambda)|\leqslant c_1|\lambda|+c_2$. The upper bound for $N(r)$ then follows from Jensen's formula.

Quantum invariants, modular forms, and lattice points II

Kazuhiro Hikami[a)]
Department of Physics, Graduate School of Science, University of Tokyo, Hongo 7-3-1, Bunkyo, Tokyo 113-0033, Japan

(Received 8 March 2006; accepted 15 August 2006; published online 10 October 2006)

We study the SU(2) Witten-Reshetikhin-Turaev (WRT) invariant for the Seifert fibered homology spheres with M-exceptional fibers. We show that the WRT invariant can be written in terms of (differential of) the Eichler integrals of modular forms with weight $1/2$ and $3/2$. By use of nearly modular property of the Eichler integrals we shall obtain asymptotic expansions of the WRT invariant in the large-N limit. We further reveal that the number of the gauge equivalent classes of flat connections, which dominate the asymptotics of the WRT invariant in $N\to\infty$, is related to the number of integral lattice points inside the M-dimensional tetrahedron. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2349484]

I. INTRODUCTION

The Witten invariant for the three-manifold $\mathcal{M}$ is defined by the Chern-Simons path integral as[1] (see also Ref. 2)

$$Z_k(\mathcal{M}) = \int \exp(2\pi i k \mathrm{CS}(A))\mathcal{D}A, \tag{1.1}$$

where $k \in \mathbb{Z}$, and $\mathrm{CS}(A)$ is the Chern-Simons functional

$$\mathrm{CS}(A) = \frac{1}{8\pi^2}\int_{\mathcal{M}} \mathrm{Tr}\left(A\wedge \mathrm{d}A + \frac{2}{3}A\wedge A\wedge A\right). \tag{1.2}$$

In a limit $k\to\infty$ of the Witten invariant $Z_k(\mathcal{M})$, we may apply the saddle point method. As the saddle point of the Chern-Simons functional (1.2) denotes the flat connection

$$\mathrm{d}A + A\wedge A = 0 \tag{1.3}$$

the asymptotics of the partition function becomes a sum of the Chern-Simons invariants, and it is expected to be[1–3]

$$Z_k(\mathcal{M}) \sim \frac{1}{2}e^{-(3/4)\pi \mathrm{i}(1+b^1)}\sum_{\alpha}(k+2)^{(\dim H^1 - \dim H^0)/2}\times \sqrt{T_\alpha}\mathrm{e}^{-2\pi \mathrm{i}(I_\alpha/4+\dim H^0/8)}\mathrm{e}^{2\pi \mathrm{i}(k+2)\mathrm{CS}(A_\alpha)}. \tag{1.4}$$

Here the sum of α denotes a gauge equivalent class of flat connections, and T_α and I_α, respectively, denote the Reidemeister torsion and the spectral flow. The first Betti number is b^1, and H^i is the cohomology space.

To study the asymptotic behavior of the Witten invariant rigorously, we need explicit expression of the invariant. Alternative and combinatorial definition of this quantum invariant was given by Reshetikhin and Turaev[4] (see also Ref. 5). We denote $\tau_N(\mathcal{M})$ as the Witten-Reshetikhin-Turaev (WRT) invariant, which is related to the Witten invariant $Z_k(\mathcal{M})$ by

a)Electronic mail: hikami@phys.s.u-tokyo.ac.jp

$$Z_k(\mathcal{M}) = \frac{\tau_{k+2}(\mathcal{M})}{\tau_{k+2}(S^2 \times S^1)} \tag{1.5}$$

and we have

$$\tau_N(S^3) = 1,$$

$$\tau_N(S^2 \times S^1) = \sqrt{\frac{N}{2}} \frac{1}{\sin(\pi/N)}.$$

Using this definition of the WRT invariant, asymptotic behavior of the WRT invariants for certain three-manifolds has been extensively studied.[6–13]

Several years ago, Lawrence and Zagier found a connection between the WRT invariant and modular form.[14] They showed that the WRT invariant $\tau_N(\mathcal{M})$ for the Poincaré homology sphere $\mathcal{M}=\Sigma(2,3,5)$ can be regarded as a limiting value of the Eichler integral of vector modular form with weight 3/2. Thanks to this correspondence, the exact asymptotic expansion of the WRT invariant in the large-N limit can be computed, and topological invariants such as the Chern-Simons invariant and the Reidemeister torsion can be interpreted from the viewpoint of modular forms. Meanwhile it has been established that this remarkable structure of the quantum invariants holds for the WRT invariants for three-manifolds such as the Brieskorn homology spheres,[15] four exceptional fibered Seifert homology spheres,[16] and the spherical Seifert manifolds.[17] Also established is a connection between the Eichler integrals of vector modular forms with weight 1/2 and the special values of the colored Jones polynomial for the torus knot $\mathcal{T}_{s,t}$ (Ref. 18 and see also Refs. 19–22) and the torus link $\mathcal{T}_{2,2m}$.[23]

One of the benefits of the quantum invariant/modular form correspondence is an observation that a limiting value of the Ramanujan mock theta functions[24] in $q \to e^{2\pi i/N}$ from outside a unit circle coincides with the WRT invariants for the spherical Seifert manifolds.[25] This fact opens up a new insight to modular forms and the Ramanujan mock theta functions, and we can expect that further studies on the quantum invariant/modular form correspondence should be fruitful.

In this article, as a continuation of Refs. 15 and 16, we study an exact asymptotic expansion of the WRT invariant $\tau_N(\mathcal{M})$ for the M-exceptional fibered Seifert integral homology sphere $\mathcal{M}=\Sigma(p_1,p_2,\ldots,p_M)$, where p_j are pairwise coprime positive integers. By use of modular forms with half-integral weight, we derive an asymptotic expansion in $N \to \infty$ number theoretically.

This article is organized as follows. In Sec. II we review the construction of the WRT invariant for the Seifert fibered homology spheres following Ref. 8. An explicit form of the WRT invariant is given. Also discussed is an integral expression of the invariant. In Sec. III we introduce a family of vector modular forms with half-integral weight. We define the Eichler integrals thereof, and study the nearly modular property of a limiting value of the Eichler integrals. By use of this quasimodular transformation property, we compute the asymptotic expansion of the WRT invariant in the large-N limit in Sec. IV. We shall see that the invariant is a limiting value of the holomorphic function.[26] We study a contribution of dominating terms in the large-N limit in detail, and reveal a relationship with the number of the integral lattice points inside the higher dimensional tetrahedron. Also given is an explicit relationship between the Casson invariant and the first nontrivial coefficient of the Ehrhart polynomial. In Sec. V we give some results based on numerical computations. We compare the exact value of the WRT invariant with our asymptotic formula. The last section is devoted to conclusion and discussions.

II. WRT INVARIANT FOR SEIFERT INTEGRAL HOMOLOGY SPHERE

Following Ref. 8, we compute the WRT invariant $\tau_N(\mathcal{M})$ for the Seifert fibered integral homology sphere with M-exceptional fibers $\mathcal{M}=\Sigma(\vec{p})=\Sigma(p_1,p_2,\ldots,p_M)$ where p_j are pairwise coprime positive integers. Hereafter we use $\vec{p}$ as M-tuple

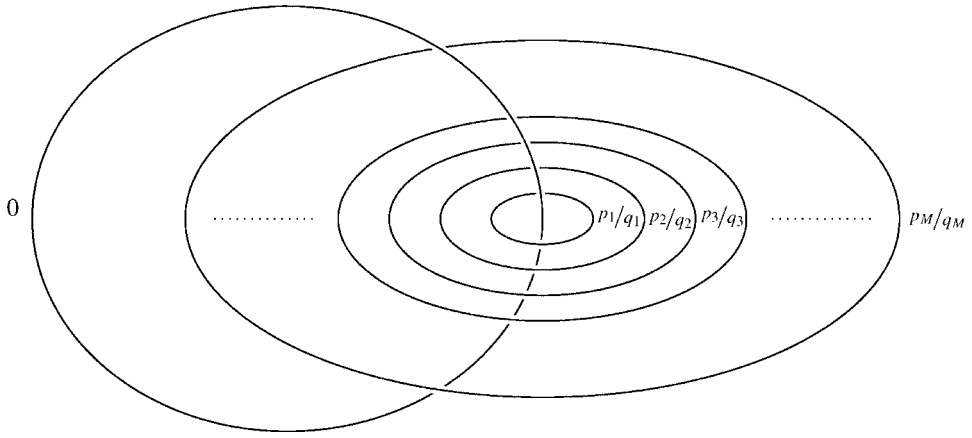

FIG. 1. Surgery description of the Seifert homology sphere $\Sigma(p_1,\ldots,p_M)$

$$\vec{p}=(p_1,p_2,\ldots,p_M).$$

The Seifert fibered integral homology sphere $\Sigma(\vec{p})$ has a rational surgery description as Fig. 1 (see, e.g., Refs. 27–29), and the fundamental group has a presentation

$$\pi_1(\Sigma(\vec{p}))=\left\langle x_1,x_2,\ldots,x_M,h \,\middle|\, \begin{array}{c} h \text{ is center} \\ x_j^{p_j}=h^{-q_j} \text{ for } 1\leqslant j\leqslant M \\ x_1x_2\cdots x_M=1 \end{array} \right\rangle. \tag{2.1}$$

Here $q_j\in\mathbb{Z}$ is coprime to p_j, and we have a constraint so that the fundamental group (2.1) gives the homology sphere;

$$P\sum_{j=1}^{M}\frac{q_j}{p_j}=1. \tag{2.2}$$

Here and hereafter we use

$$P=P(\vec{p})=\prod_{j=1}^{M}p_j. \tag{2.3}$$

When the three-manifold $\mathcal{M}$ is constructed by the rational surgeries p_j/q_j on the jth component of n-component link $\mathcal{L}$, it was shown[4,30] that the SU(2) WRT invariant $\tau_N(\mathcal{M})$ is given by

$$\tau_N(\mathcal{M})=e^{(\pi\mathrm{i}/4)[(N-2)/N](\Sigma_{j=1}^{n}\Phi(U^{(p_j,q_j)})-3\ \mathrm{sign}(\mathbf{L}))}\sum_{k_1,\ldots,k_n=1}^{N-1}J_{k_1,\ldots,k_n}(\mathcal{L})\prod_{j=1}^{n}\rho(U^{(p_j,q_j)})_{k_j,1}. \tag{2.4}$$

Here the surgery data p_j/q_j is encoded by an $\mathrm{SL}(2;\mathbb{Z})$ matrix

$$U^{(p_j,q_j)}=\begin{pmatrix} p_j & r_j \\ q_j & s_j \end{pmatrix}.$$

The Rademacher Φ function $\Phi(U)$ is defined by[31]

$$\Phi\left(\begin{pmatrix} p & r \\ q & s \end{pmatrix}\right) = \begin{cases} \dfrac{p+s}{q} - 12s(p,q) & \text{for } q \neq 0 \\ \dfrac{r}{s} & \text{for } q = 0 \end{cases} \tag{2.5}$$

where $s(b,a)$ denotes the Dedekind sum (A1). An $n \times n$ matrix $\mathbf{L}$ is a linking matrix

$$\mathbf{L}_{j,k} = \mathrm{lk}(j,k) + \frac{p_j}{q_j} \cdot \delta_{j,k} \tag{2.6}$$

where $1\mathrm{k}(j,k)$ denotes the linking number of the j- and kth components of link $\mathcal{L}$, and $\mathrm{sign}(\mathbf{L})$ denotes a signature of $\mathbf{L}$, i.e., the difference between the number of positive and negative eigenvalues of $\mathbf{L}$. The polynomial $J_{k_1,\ldots,k_n}(\mathcal{L})$ denotes the colored Jone polynomial for link $\mathcal{L}$ with color k_j for the jth component link, and $\rho(U^{(p,q)})$ is a representation ρ of $\mathrm{PSL}(2;\mathbb{Z})$ defined by

$$\rho(U^{(p,q)})_{a,b} = -\mathrm{i}\frac{\mathrm{sign}(q)}{\sqrt{2N|q|}} \mathrm{e}^{-(\pi\mathrm{i}/4)\Phi(U^{(p,q)})} \mathrm{e}^{(\pi\mathrm{i}/2Nq)sb^2} \sum_{\substack{\gamma \bmod 2Nq \\ \gamma = a \bmod 2N}} \mathrm{e}^{(\pi\mathrm{i}/2Nq)p\gamma^2} (\mathrm{e}^{(\pi\mathrm{i}/Nq)\gamma b} - \mathrm{e}^{-(\pi\mathrm{i}/Nq)\gamma b}) \tag{2.7}$$

for $1 \leqslant a,b \leqslant N-1$.[30] This representation is constructed from

$$\rho(S)_{a,b} = \sqrt{\frac{2}{N}} \sin\left(\frac{ab}{N}\pi\right),$$
$$\rho(T)_{a,b} = \mathrm{e}^{(\pi\mathrm{i}/2N)a^2 - (\pi\mathrm{i}/4)} \delta_{a,b} \tag{2.8}$$

with

$$S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad T = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \tag{2.9}$$

satisfying

$$S^2 = (ST)^3 = 1.$$

Based on the fact that the Seifert fibered manifold $\Sigma(\vec{p})$ has a surgery description as in Fig. 1, we have the following result.

Proposition 1 (Ref. 8): For the Seifert fibered integral homology sphere with M-exceptional fibers $\mathcal{M} = \Sigma(\vec{p})$, the WRT invariant is given by

$$\mathrm{e}^{(2\pi\mathrm{i}/N)(\phi(\vec{p})/4 - 1/2)} (\mathrm{e}^{2\pi\mathrm{i}/N} - 1) \tau_N(\mathcal{M}) = \frac{\mathrm{e}^{\pi\mathrm{i}/4}}{2\sqrt{2PN}} \sum_{\substack{n=0 \\ N \nmid n}}^{2PN-1} \mathrm{e}^{-(1/2PN)n^2\pi\mathrm{i}} \frac{\prod_{j=1}^{M} (\mathrm{e}^{(n/Np_j)\pi\mathrm{i}} - \mathrm{e}^{-(n/Np_j)\pi\mathrm{i}})}{(\mathrm{e}^{(n/N)\pi\mathrm{i}} - \mathrm{e}^{-(n/N)\pi\mathrm{i}})^{M-2}}. \tag{2.10}$$

Here $\phi(\vec{p})$ is defined by

$$\phi(\vec{p}) = 3 - \frac{1}{P} + 12\sum_{j=1}^{M} s\left(\frac{P}{p_j}, p_j\right), \tag{2.11}$$

where $s(b,a)$ denotes the Dedekind sum (A1).

Outline of Proof: We use the surgery formula (2.4), in which the colored Jones polynomial for a variant of Hopf link $\mathcal{L}$ depicted in Fig. 1 is given by

$$J_{k_0,k_1,\ldots,k_M}(\mathcal{L}) = \frac{1}{\sin(\pi/N)} \frac{\prod_{j=1}^{M} \sin\left(\frac{k_0 k_j}{N}\pi\right)}{\left[\sin\left(\frac{k_0}{N}\pi\right)\right]^{M-1}}.$$

Here k_0 is a color of component which has a linking number 1 with any other components of $\mathcal{L}$. After some computations using the Gauss sum reciprocity formula (A7), we get

$$\begin{aligned} e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{2\pi i/N}-1)\tau_N(\mathcal{M}) = {} & \frac{e^{\pi i/4}}{2\sqrt{2PN}} \sum_{k_0=1}^{N-1} \sum_{n_j \bmod p_j} \frac{1}{(e^{(k_0/N)\pi i} - e^{-(k_0/N)\pi i})^{M-2}} \\ & \times \prod_{j=1}^{M} e^{-(q_j/p_j)(k_0+2Nn_j)^2/2N} (e^{[(k_0+2Nn_j)/Np_j]\pi i} - e^{-[(k_0+2Nn_j)/Np_j]\pi i}). \end{aligned} \tag{2.12}$$

We see that the summand in (2.12) is invariant under

- $k_0 \to k_0+2N$ and $n_j \to n_j-1$ for all j,
- $n_j \to n_j+p_j$.

Using that p_j are pairwise coprime, we can then rewrite the multisum of (2.12) into a single sum of (2.10). □

The WRT invariant can be rewritten in the integral form as follows.

Proposition 2 (Ref. 8):

$$e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{2\pi i/N}-1)\tau_N(\mathcal{M}) = \frac{e^{\pi i/4}}{2\sqrt{2PN}} \left(-2\pi i \sum_{m=0}^{2P-1} \operatorname*{Res}_{z=mN} \frac{g(z)}{1-e^{-2\pi i z}} + \int_{\mathcal{C}} g(z)dz \right), \tag{2.13}$$

where

$$g(z) = e^{-(z^2/2PN)\pi i} \frac{\prod_{j=1}^{M} (e^{(z/Np_j)\pi i} - e^{-(z/Np_j)\pi i})}{(e^{(z/N)\pi i} - e^{-(z/N)\pi i})^{M-2}} \tag{2.14}$$

and the integration path $\mathcal{C}$ passes the origin from $(-1+i)\infty$ to $(1-i)\infty$.

Outline of proof: Key identity is

$$\Theta_M(x) = \Theta_M(x-N)e^{4\pi i P x} + 2\pi i \sum_{m=0}^{2P-1} \operatorname*{Res}_{z=mN} h_M(z,x) + \sum_{\substack{n=0 \\ N \nmid n}}^{2PN-1} f_M(n,x). \tag{2.15}$$

Here the function $\Theta_M(x)$ is defined by

$$\Theta_M(x) = \int_{\mathcal{C}} h_M(z,x)dz,$$

where

$$h_M(z,x) = e^{-(z^2/2PN)\pi i + 2x(z/N)\pi i} \frac{1}{(e^{(z/N)\pi i} - e^{-(z/N)\pi i})^{M-2}} \cdot \frac{1}{1-e^{-2\pi i z}} \equiv \frac{f_M(z,x)}{1-e^{-2\pi i z}}.$$

As the function $g(z)$ is a linear combination of $f_M(x,z)$, we obtain the expression (2.13). □

In view of (2.13), we can decompose the invariant as

$$\tau_N(\mathcal{M}) = \tau_N^{\rm res}(\mathcal{M}) + \tau_N^{\rm int}(\mathcal{M}) \tag{2.16}$$

where $\tau_N^{\rm res}(\mathcal{M})$ and $\tau_N^{\rm int}(\mathcal{M})$ respectively denote contributions from the residue terms and the integral term in (2.13). It was identified in Ref. 8 that the residue part $\tau_N^{\rm res}(\mathcal{M})$ is the contribution from irreducible flat connections while the integral term $\tau_N^{\rm int}(\mathcal{M})$ is the trivial connection contribution. The trivial connection contribution is related to the Ohtsuki series,[32] and we have as follows.

Proposition 3: In the limit $N\to\infty$, the trivial connection contribution has the asymptotic expansion as

$$e^{(2\pi i/N)(\phi(\vec{p})/4-1/2)}(e^{(2\pi i/N)}-1)\tau_N^{\rm int}(\mathcal{M}) \simeq \sum_{k=0}^{\infty} \frac{T_{\vec{p}}(k)}{k!}\left(\frac{\pi i}{2PN}\right)^k, \tag{2.17}$$

where the T series is given by

$$\frac{\prod_{j=1}^{M} \sinh\left(\frac{P}{p_j}x\right)}{[\sinh(Px)]^{M-2}} = \frac{1}{2}\sum_{k=0}^{\infty} \frac{T_{\vec{p}}(k)}{(2k)!}x^{2k}. \tag{2.18}$$

We will discuss later the relationship with the Ohtsuki series.

Similar integral with $\tau_N^{\rm int}(\mathcal{M})$ in the case of the three exceptional fibers $M=3$ appeared in studies[33,34] of the Ramanujan mock theta functions, which still remain to be mysterious and fascinating topics. This suggests the remarkable fact that the Ramanujan mock theta functions[24] are related to the WRT invariant for the Seifert fibered manifolds. See Refs. 17, 25, and 35 for detail.

The dominating term of the WRT invariant in a limit $N\to\infty$ follows from the irreducible flat connection contributions $\tau_N^{\rm res}(\mathcal{M})$ as was expected from the saddle point approximation (1.4). In terms of the Witten partition function $Z_k(\mathcal{M})$, the asymptotic expansion of the invariant is given by

$$Z_{k-2}(\mathcal{M}) \simeq \sum_{a=0}^{M-3} N^{M-3-a} Z_{N-2}^{(a)}(\mathcal{M}) + \text{trivial connection contribution}$$

and the dominating term $Z_{N-2}^{(0)}(\mathcal{M})$ in $N\to\infty$ can be computed as follows when we use an identity

$$\sin(\pi z) = \pi z \prod_{n=1}^{\infty}\left(1-\frac{z^2}{n^2}\right)$$

Proposition 4: In the large N limit, the Witten partition function $Z_N(\mathcal{M})$ for the M-exceptional fibered Seifert homology sphere $\mathcal{M}=\Sigma(\vec{p})$ is dominated by

$$Z_{N-2}(\mathcal{M}) \sim N^{M-3}\frac{2^{M-2}}{(M-2)!\sqrt{P}} e^{-(\phi(\vec{p})/2N)\pi i} e^{-[(2M-3)/4]\pi i} \times \sum_{m=0}^{2P-1} (-1)^{mM} B_{M-2}\left(\frac{m}{2P}\right) e^{-(m^2/2P)\pi i N}\left[\prod_{j=1}^{M} \sin\left(\frac{m}{p_j}\pi\right)\right], \tag{2.19}$$

*where $B_k(x)$ is the k*th *Bernoulli polynomial* (A8).

Among a sum of $2P$ terms on the right-hand side (r.h.s.) of (2.19), we can classify the summation by the Chern-Simons invariant, which corresponds to an exponential factor $-(m^2/4P)$ mod 1 as will be discussed later.

III. MODULAR FORMS AND EICHLER INTEGRAL

We introduce the vector modular forms with half-integral weight which play a crucial role in analysis of the WRT invariants for the Seifert fibered homology spheres.

A. Vector modular forms with half-integral weight

We set M-tuple

$$\vec{\ell} = (\ell_1, \ldots, \ell_M), \tag{3.1}$$

where ℓ_j are integers satisfying $0 < \ell_j < p_j$. As before we assume that p_j are pairwise coprime positive integers. For M-tuple $\vec{\ell}$, we define the periodic function $\chi_{2P}^{\vec{\ell}}(n)$ with modulus $2P$ by

$$\chi_{2P}^{\vec{\ell}}(n) = \begin{cases} -\prod_{j=1}^{M} \varepsilon_j & \text{if } n = P\left(1 + \sum_{j=1}^{M} \varepsilon_j \frac{\ell_j}{p_j}\right) \bmod 2P, \\ 0 & \text{otherwise} \end{cases} \tag{3.2}$$

where $\varepsilon_j = \pm 1$ for $\forall j$. We see that $\chi_{2P}^{\vec{\ell}}(n)$ is even (respectively odd) when M is even (respectively odd),

$$\chi_{2P}^{\vec{\ell}}(-n) = (-1)^M \chi_{2P}^{\vec{\ell}}(n) \tag{3.3}$$

and that it has a mean value zero,

$$\sum_{n=0}^{2P-1} \chi_{2P}^{\vec{\ell}}(n) = 0. \tag{3.4}$$

We define an involution σ_j on M-tuple $\vec{\ell}$ by

$$\sigma_j(\vec{\ell}) = (\ell_1, \ldots, \ell_{j-1}, p_j - \ell_j, \ell_{j+1}, \ldots, \ell_M) \tag{3.5}$$

for $1 \leqslant j \leqslant M$. As we have

$$\chi_{2P}^{\sigma_i \sigma_j(\vec{\ell})}(n) = \chi_{2P}^{\vec{\ell}}(n) \tag{3.6}$$

for $1 \leqslant i, j \leqslant M$, the number of the independent periodic functions $\chi_{2P}^{\vec{\ell}}(n)$ for given $\vec{p}$ is

$$D = D(\vec{p}) = \frac{1}{2^{M-1}} \prod_{j=1}^{M} (p_j - 1). \tag{3.7}$$

We note that

$$\chi_{2P}^{\vec{\ell}}(n+P) = -\chi_{2P}^{\sigma_j(\vec{\ell})}(n) \tag{3.8}$$

for $1 \leqslant j \leqslant M$.

We set

$$q = \exp(2\pi \mathrm{i} \tau), \tag{3.9}$$

where τ is in the upper half plane, $\tau \in \mathbb{H}$. By use of the periodic functions (3.2) we define the q series by

$$\Phi_{\vec{p}}^{\vec{\ell}}(\tau)=\frac{1}{2}\sum_{n\in\mathbb{Z}} n^{\mathrm{m}_2(M)}\chi_{2P}^{\vec{\ell}}(n)q^{n^2/4P}, \tag{3.10}$$

where we mean
