We choose $\xi_i = k_i + 2\nabla_i\phi$ and let $\Lambda = -2A_j\phi^{|j}$ and $\Lambda_i = 2B_{ji}\phi^{|j}$, where k_i is as yet arbitrary. With these choices the dilaton is completely eliminated from the flow equations for the metric and gauge fields,

$$\dot{g}_{ij} = -2\left(R_{ij} - \left(\epsilon_F F_i{}^k F_{jk} + \frac{\epsilon_H}{4} H_{ikl} H_j{}^{kl}\right)\right) + L_k g_{ij}, \tag{10}$$

$$\dot{A}_i = -\left(\nabla_j F_i{}^j + \frac{e\epsilon_F}{2}\eta_i{}^{jk} F_{jk}\right) + L_k A_i + \partial_i \lambda, \tag{11}$$

$$\dot{B}_{ij} = \nabla_k H^k{}_{ij} + L_k B_{ij} + \partial_i \lambda_j - \partial_j \lambda_i, \tag{12}$$

$$\dot{\phi} = -\chi + \Delta\phi - 2|\nabla\phi|^2 + \frac{\epsilon_F}{2}F^2 + \frac{\epsilon_H}{6}H^2 + L_k\phi. \tag{13}$$

The arbitrary vector k^i and gauge parameters λ, λ_i indicate that we are still free to add further De Turck and gauge terms to the equations. We will use this freedom later to simplify the equations that result from a particular *ansatz*.

IV. A PARTICULAR CASE WITH ONE KILLING VECTOR FIELD

Henceforth we set B_{ij} identically equal to 0, which is consistent with the flow equations. We also consider the case $e=0$ (no Chern-Simons term). We assume the metric to have a single Killing vector and to be manifestly hypersurface orthogonal (i.e., diagonal),

$$ds^2 = e^{\Phi}(dx^2 + dy^2) + e^{\sigma} dw^2. \tag{14}$$

We also choose the following *ansatz* for the vector potential:

$$A_i = [e^{\sigma/2}, 0, 0]. \tag{15}$$

Consistency of the above *ansatz* requires that the flow equations preserve the diagonal nature of the metric. It turns out that this can be accomplished by choosing the vector field k_i as

$$k_i = -\tfrac{1}{2}\partial_i\sigma, \tag{16}$$

With these choices the flow equations simplify to

$$\dot{g}_{xx} = e^{\Phi}\dot{\Phi} = \nabla^2\Phi + \tfrac{1}{2}(1+\epsilon_F)(\partial_x\sigma)^2,$$

$$\dot{g}_{yy} = e^{\Phi}\dot{\Phi} = \nabla^2\Phi + \tfrac{1}{2}(1+\epsilon_F)(\partial_y\sigma)^2,$$

$$\dot{g}_{xy} = 0 = \tfrac{1}{2}(1+\epsilon_F)\partial_x\sigma\partial_y\sigma, \tag{17}$$

$$\dot{A}_x = \dot{A}_y = 0,$$

$$\dot{A}_w = \epsilon_f\nabla^2 e^{\sigma/2} + (1+\epsilon_F)(\partial\sigma)^2. \tag{18}$$

In the above, ∇^2 denotes the flat space Laplacian.

We now fix $\epsilon_F = -1$, in which case the flow boils down to two simple partial differential equations. The first is

$$\partial_t e^{\Phi} = \nabla^2 \Phi, \tag{19}$$

which is the "continual Toda eqn" from Ref. 3. The other flow is the linearization of the continual Toda flow,

$$e^{\Phi} \partial_t e^{-\sigma/2} = -\nabla^2 e^{-\sigma/2}. \tag{20}$$

To the best of our knowledge, there is no simpler flow constructed from the Ricci-De Turck flow alone, without other fields, which can self-consistently flow the metric preserving the manifestly static form. Note that for any given solution Φ of (19), there exists a corresponding solution for σ,

$$e^{-\sigma/2} = \Phi(x,y,-t) + \chi(x,y), \tag{21}$$

where $\chi(x,y)$ is any harmonic function on the x,y subspace, i.e., satisfying, $\nabla^2 \chi = 0$.

V. EXACT SOLUTIONS OF THE FLOW

We first examine a nontrivial flow, namely the sausage solution of Bakas[3] (also called the Rossineau flow in the mathematical literature[8]). This is an exact solution of the continual Toda equation of the form

$$e^{\Phi} = \frac{2 \sinh[2\gamma t]}{\gamma(\cosh[2\gamma t] + \cosh(2y))}. \tag{22}$$

In this case,

$$e^{-\sigma/2} = \ln \left| \frac{2 \sinh[2\gamma t]}{\gamma(\cosh[2\gamma t] + \cosh(2y))} \right|, \tag{23}$$

where we have eliminated an imaginary term from $e^{-\sigma/2}$ by using the freedom to shift by a harmonic function.

In the limit as $t \to \infty$, $e^{\Phi} \to 2/\gamma$, and $e^{\sigma} \to \ln|2/\gamma|^{-2}$, so that the Ricci tensor goes to zero and in this limit, the geometry is flat. On the other hand, in the limit $t \to 0^+$, $e^{\Phi} \to 2t/\cosh^2 y$. In this limit, we find that the Ricci scalar $R \sim 1/t$. So, if we flow the highly curved nonhomogeneous metric with initial value at $t = \epsilon > 0$,

$$ds^2 = \left(\ln \frac{2\epsilon}{\cosh^2 y} \right)^{-2} dw^2 + \frac{2\epsilon}{\cosh^2(y)} (dx^2 + dy^2), \tag{24}$$

we end up at $t \to \infty$ with the flat metric. This is consistent with Thurston's conjecture.

The second type of solution is of the Liouville type. We set

$$e^{\Phi(x,y;t)} = T(t) e^{\psi(x,y)}. \tag{25}$$

Now for $t \geqslant 0$, we find that

$$\begin{aligned} T(t) &= \beta t, \\ \nabla^2 \psi - \beta e^{\psi} &= 0, \end{aligned} \tag{26}$$

where β is a separation constant. The second of the above equations is the Liouville equation, so the two-dimensional part of the metric, $e^{\Phi}(dx^2 + dy^2)$, has constant negative curvature (for $t \geqslant 0$).

Again we choose $e^{-\sigma/2} = \Phi$, so that

$$e^{\sigma} = [\ln \beta t + \psi(x,y)]^{-2}. \tag{27}$$

The separation constant $\ln \beta$ can be absorbed into ψ without loss of generality.

Hence the metric is

$$ds^2 = [\ln t + \psi(x,y)]^{-2}\, dw^2 + \beta t e^{\psi(x,y)}(dx^2 + dy^2). \tag{28}$$

The quantity $\psi(x,y)$ is a solution of the Liouville equation.

If $t \geqslant 0$, then the flow starts from some highly curved nonhomogeneous metric near $t=0$. As $t \to \infty$, we have

$$R_{AB} \sim -\frac{1}{2t} g_{AB},$$
$$R_{ww} \sim 0, \tag{29}$$

with $A, B, \cdots = x, y$. Hence, the geometry is asymptotically that of the homogeneous, but anisotropic geometry $H^2 \times E^1$.

Thus the flow is consistent with the Thurston conjecture.

VI. CONCLUSIONS

We have shown that the modified Ricci flow equations (9) for 3D metrics with at least one Killing vector can be integrated in precisely the same manner as the 2D equations, at least for the special case $\epsilon_F = -1$. In addition to extending this analysis to other values of the parameters in the action, and hence to other topologies, it is interesting to speculate whether these techniques could work for more general 3D metrics.

Consider, without loss of generality, a diagonal metric

$$ds^2 = e^{\Phi_1(x;t)}(dx^1)^2 + e^{\Phi_2(x;t)}(dx^2)^2 + e^{\Phi_3(x;t)}(dx^3)^2, \tag{30}$$

where the functions $\Phi_i(x;t)$ depend on all three coordinates x^i. The resulting bare Ricci flow is again not manifestly elliptic, and the equations have non-trivial off-diagonal terms on the right-hand side that make direct integration difficult. Since in three dimensions any metric can be made diagonal with a suitable coordinate transformation, it is reasonable to assume that there exists a modified flow that ensures that diagonal metrics evolve into diagonal metrics. We have as yet not succeeded in constructing this modified flow, but if it did exist, it is possible that the resulting three flow equations for each of the three scale factors would take a form similar to what we have found above, albeit with nontrivial coupling. It may therefore provide a basis for solving the 3D flow equations in a more general setting.

(Received 2 November 2005; accepted 20 January 2006; published online 9 March 2006)

We study the Casimir effect for free massless scalar fields propagating on a two-dimensional cylinder with a metric that admits a change of signature from Lorentzian to Euclidean. We obtain a nonzero pressure, on the hypersurfaces of signature change, which destabilizes the signature changing region and so alters the energy spectrum of scalar fields. The modified region and spectrum, themselves, back react on the pressure. Moreover, the central term of diffeomorphism algebra of corresponding infinite conserved charges changes correspondingly. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2174291]

I. INTRODUCTION

The Casimir effect is usually regarded as the most well-known manifestation of vacuum fluctuations in quantum field theory. In this effect, the presence of reflecting boundaries in the quantum vacuum alters the zero-point modes of the quantized fields, and results in the shifts of the vacuum expectation values of quantities such as energy densities and stresses. These shifts lead to vacuum forces which act on the reflecting boundaries. The particular features of these forces depend on the nature of the quantum field, the type of space-time manifold and its dimensionality, the boundary geometries and the specific boundary conditions imposed on the field. Since the original work by Casimir in 1948[1] many theoretical and experimental works have been done on this problem.[2–11] In general, there are several approaches to calculate the Casimir energy: mode summation,[2] Green's function method,[4] heat kernel method,[8] along with appropriate regularization schemes such as point separation,[12,13] dimensional regularization,[14] and zeta function regularization.[15–19] Recently, general new methods have been obtained to compute the renormalized one-loop quantum energies and energy densities.[20,21]

On the other hand, signature changing space-times have recently been of particular importance as the specific geometries with interesting physical effects. The original idea of signature change was due to Hartle, Hawking, and Sakharov.[22] This interesting idea would make it possible to have both Euclidean and Lorentzian metrics in path integral approach to quantum gravity. Later, it was shown that the signature change may happen in classical general relativity, as well.[23] There are two different approaches, continuous and discontinuous, to study the signature change in classical general relativity.[23,24] In the continuous approach, the signature of metric changes continuously in passing from Euclidean to Lorentzian region. Hence, the metric becomes degenerate at the border of these regions. In the discontinuous approach, however, the metric becomes nondegenerate everywhere and is discontinuous at the border of Euclidean and Lorentzian regions.

The issue of propagation of quantum fields on signature-changing space-times has also been of some interest.[24] For example, Dray *et al.* have shown that the phenomenon of particle production may happen for scalar particles propagating in a space-time with heterotic signature. They

[a]Author to whom correspondence should be addressed. Electronic mail: f.darabi@azaruniv.edu
[b]Electronic mail: rezakord@ipm.ir

have also obtained a rule for propagation of massless scalar fields on a two-dimensional space-time with signature change. Dynamical determination of the metric signature in space-time of nontrivial topology is another interesting issue which has been studied in Ref. 25

To the authors knowledge, no attempt has been done to study the Casimir effect within the geometries with signature change. A relevant work to the present paper is Ref. 26. In this work, a model of free massless scalar fields on a two-dimensional cylinder with a signature-changing strip has been studied and shown that the energy spectrum depends on the strip's width and differs from the ordinary bosonic spectrum, for low energies. Moreover, It was shown that the diffeomorphism algebra of the corresponding infinite conserved charges is different from "Virasoro" algebra and approaches it at higher energies.

In this paper, we study the Casimir effect for the free massless scalar field propagating on the above two-dimensional signature-changing cylinder. We will obtain a nonzero pressure on the hypersurfaces of signature change which leads to instability in the signature-changing region. Therefore, depending on situation, Euclidean or Lorentzian region will grow or shrink, and this will alter the energy spectrum and the diffeomorphism algebra discussed above.

Meanwhile, a lot of topics related to the Casimir effect have been explored in the context of string theory.[10,27] The above two-dimensional signature-changing cylinder is topologically similar to a closed string, with two Euclidean and Lorentzian parts, propagating in a distributional way in the two-dimensional target space, and the discontinuous nature of the model in classifying Euclidean and Lorentzian solutions with discrete symmetry motivates one to study it in the context of *orbifolds*.[26,28] On the other hand, a closed string with two Euclidean and Lorentzian parts may be of some importance in the context of *D*-branes and related conformal field theories. Therefore, taking into account this similarity, the study of Casimir effect in our model may have nontrivial impacts on closed strings or *D*-branes.

In general, we believe the idea of Casimir effect in signature-changing space-times is novel and interesting. In the present paper this effect is inevitably limited to two-dimensional space-time, which may be relevant to the study of closed bosonic strings with Euclidean and Lorentzian parts. But, further study of Casimir effect in $3+1$ dimensional signature changing space-times may have more important physical implications, especially at early universe.[29]

II. CASIMIR STRESS TENSOR IN SIGNATURE CHANGING SPACE-TIME

We consider a free massless scalar field ϕ which propagates on a two-dimensional manifold $M=R\times S^1$ (the circle S^1 represents *space* and the real line R represents *time*) with the following metric:

$$\mathrm{d}s^2 = -\,\mathrm{d}\tau^2 + g(\sigma)\mathrm{d}\sigma^2, \tag{1}$$

where τ is timelike coordinate and σ is a periodic spacelike coordinate with the period L (we assume L is the circumference of the circle with radius r), and $g(\sigma)$ is a periodic function of σ, which takes $+1$ for Lorentzian and -1 for Euclidean regions [notice that in this region the metric will be $g_{\alpha\beta}=\mathrm{diag}(-1,-1)$]

$$g(\sigma) = \begin{cases} -1 & 0 < \sigma < \sigma_0 + \mathrm{mod}\, L, \\ +1 & \sigma_0 < \sigma < L + \mathrm{mod}\, L, \end{cases} \tag{2}$$

where $\sigma=0$, L, and $\sigma=\sigma_0$ are the hypersurfaces of signature change. We assume the scalar field to satisfy specific junction conditions at these hypersurfaces. In the literature of signature change there are two kinds of junction conditions:

(i) ϕ and its derivatives are continuous across $\sigma=\sigma_0$, (Dray *et al.*),[24]
(ii) ϕ is continuous but its derivatives vanish across $\sigma=\sigma_0$, (Hayward).[23]

In this paper, we assume the first junction conditions as the appropriate boundary conditions at each region. We assume the continuity of ϕ as well as its derivatives at all times τ as

$$\phi^E|_{\Sigma,\Sigma'} = \phi^L|_{\Sigma,\Sigma'},$$
$$\partial_\sigma \phi^E|_{\Sigma,\Sigma'} = -\epsilon \partial_\sigma \phi^L|_{\Sigma,\Sigma'}, \tag{3}$$

where Σ, Σ' are the hypersurfaces of signature change, and $\epsilon = \epsilon^+/\epsilon^-$ takes the values ± 1 according to the orientation of the coordinates τ and σ in both regions of different signatures. Assuming $\epsilon^+ = +1$ and $\epsilon^- = +1$ for Euclidean and Lorentzian regions, respectively, the junction conditions (3) are written as[26]

$$\phi^E|_0 = \phi^L|_L, \quad \phi^E|_{\sigma_0} = \phi^L|_{\sigma_0},$$
$$\partial_\sigma \phi^E|_0 = -\partial_\sigma \phi^L|_L, \quad \partial_\sigma \phi^E|_{\sigma_0} = -\partial_\sigma \phi^L|_{\sigma_0}. \tag{4}$$

By solving the wave equations,

$$(\partial_\tau{}^2 + \partial_\sigma{}^2)\phi^E(\sigma,\tau) = 0,$$
$$(\partial_\tau{}^2 - \partial_\sigma{}^2)\phi^L(\sigma,\tau) = 0, \tag{5}$$

in both Euclidean and Lorentzian regions and imposing the junction conditions (4), we obtain nontrivial solutions for ϕ_ω, provided the continuous spectrum ω satisfies the following "quantization condition"[26]

$$\cosh \omega\sigma_0 \cos \omega(\sigma_0 - L) = 1. \tag{6}$$

[The spectrum ω in this model is obtained by solving the quantization condition which leads to real and σ_0-dependent values. It differs from ordinary spectrum (with pure Lorentzian signature) at low energies and coincides with the integer roots of $\cos \omega(L-\sigma_0)$, at high energies. Therefore, "sum over energies" approaches "sum over integers" at higher energies.[26]] It is shown in Ref. 26, that due to the same *time evolution* of the functions Φ^E_ω and Φ^L_ω one can construct a set of real *distributional* orthogonal and complete solutions on the arbitrary τ=const hypersurface as

$$\Phi_\omega(\sigma,\tau) = \Theta^+\Phi^E_\omega(\sigma,\tau) + \Theta^-\Phi^L_\omega(\sigma,\tau), \tag{7}$$

where $\Phi^E_\omega = (\phi^E_\omega + \phi^E_{-\omega})$, $\Phi^L_\omega = (\phi^L_\omega + \phi^L_{-\omega})$, and Θ^+, Θ^- are Heaviside distributions with support in Euclidean and Lorentzian regions, respectively. (Heaviside distributions have the property $d\Theta^\pm = \pm\delta$, where δ is the hypersurface Dirac distribution with support on the hypersurfaces of signature change.) The solutions Φ_ω are then expanded as normal mode expansions.[26]

One can also obtain the following expressions for the components of energy-momentum tensors associated with the scalar field $\Phi(\sigma,\tau)$ in both Euclidean and Lorentzian regions[26]

$$T^E_{00} = [(\partial_\tau \Phi^E)^2 - (\partial_\sigma \Phi^E)^2], \quad T^E_{01} = 2\partial_\tau \Phi^E \partial_\sigma \Phi^E,$$
$$T^L_{00} = [(\partial_\tau \Phi^L)^2 + (\partial_\sigma \Phi^L)^2], \quad T^L_{01} = 2\partial_\tau \Phi^L \partial_\sigma \Phi^L. \tag{8}$$

By introducing new coordinates σ^E_+, σ^E_- in the Euclidean region, and σ^L_+, σ^L_- in the Lorentzian one as

$$\sigma^E_+ = \tau + i\sigma, \quad \sigma^L_+ = \tau + \sigma,$$
$$\sigma^E_- = \tau - i\sigma, \quad \sigma^L_- = \tau - \sigma, \tag{9}$$

we obtain

$$T^E_{++} = (T^E_{00} - iT^E_{01})/2, \quad T^L_{++} = (T^L_{00} + T^L_{01})/2,$$

$$T^E_{--} = (T^E_{00} + iT^E_{01})/2, \quad T^L_{--} = (T^L_{00} - T^L_{01})/2, \tag{10}$$

$$T^E_{+-} = T^E_{-+} = 0, \quad T^L_{+-} = T^L_{-+} = 0.$$

Then by substituting the normal mode expansions of the solutions Φ_ω we obtain[26]

$$T^E_{++} = \tfrac{1}{2}[(\partial_\tau\Phi - i\partial_\sigma\Phi)]^2 = 2\sum_{\omega\omega'} \tilde{f}^E_\omega(+)\tilde{f}^E_{\omega'}(+)\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'},$$

$$T^E_{--} = \tfrac{1}{2}[(\partial_\tau\Phi + i\partial_\sigma\Phi)]^2 = 2\sum_{\omega\omega'} \tilde{f}^E_{-\omega}(-)\tilde{f}^E_{-\omega'}(-)\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'},$$

$$T^L_{++} = \tfrac{1}{2}[(\partial_\tau\Phi + \partial_\sigma\Phi)]^2 = 2\sum_{\omega\omega'} \tilde{f}^L_\omega(+)\tilde{f}^L_{\omega'}(+)\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'}, \tag{11}$$

$$T^L_{--} = \tfrac{1}{2}[(\partial_\tau\Phi - \partial_\sigma\Phi)]^2 = 2\sum_{\omega\omega'} \tilde{f}^L_{-\omega}(-)\tilde{f}^L_{-\omega'}(-)\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'},$$

where $\tilde{\alpha}^\dagger$ and $\tilde{\alpha}$ are the creation and annihilation operators, respectively, and (the scalar product $\langle\Phi_\omega, \Phi_\omega\rangle$ has been defined in Ref. 26)

$$\tilde{f}^E_\omega(\pm) = [(a/b)_\omega + 1]\exp(-i\omega\sigma^E_\pm)/\sqrt{4\pi\langle\Phi_\omega, \Phi_\omega\rangle},$$

$$\tilde{f}^L_\omega(\pm) = [(c/b)_\omega + (1/b)_{-\omega}]\exp(-i\omega\sigma^L_\pm)/\sqrt{4\pi\langle\Phi_\omega, \Phi_\omega\rangle}, \tag{12}$$

with $(a/b)_\omega$, $(c/b)_\omega$, $(1/b)_\omega$ given by[26]

$$(a/b)_\omega = \frac{\sin\omega(\sigma_0 - L)}{\cosh\omega\sigma_0 + \sinh\omega\sigma_0 - \cos\omega(\sigma_0 - L)},$$

$$(c/b)_\omega = \frac{(1+i)\exp(2\pi i\omega)(\sinh\omega\sigma_0 + \cosh\omega\sigma_0 - \exp(i\omega(\sigma_0 - L)))}{2(\cosh\omega\sigma_0 + \sinh\omega\sigma_0 - \cos\omega(\sigma_0 - L))}, \tag{13}$$

$$(1/b)_\omega = \frac{(1-i)\exp(-2\pi i\omega)(\sinh\omega\sigma_0 + \cosh\omega\sigma_0 - \exp(-i\omega(\sigma_0 - L)))}{2(\cosh\omega\sigma_0 + \sinh\omega\sigma_0 - \cos\omega(\sigma_0 - L))}.$$

Notice that in obtaining these results we have imposed the quantization condition (6).

Now, substituting the normal mode expansions (11) into Eqs. (10) leads to

$$T^E_{01} = i(T^E_{++} - T^E_{--}) = 2i\sum_{\omega\omega'} (\tilde{f}^E_\omega(+)\tilde{f}^E_{\omega'}(+) - \tilde{f}^E_{-\omega}(-)\tilde{f}^E_{-\omega'}(-))\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'},$$

$$T^L_{00} = T^L_{++} + T^L_{--} = 2\sum_{\omega\omega'} (\tilde{f}^L_\omega(+)\tilde{f}^L_{\omega'}(+) + \tilde{f}^L_{-\omega}(-)\tilde{f}^L_{-\omega'}(-))\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'}, \tag{14}$$

$$T^L_{01} = T^L_{++} - T^L_{--} = 2\sum_{\omega\omega'} (\tilde{f}^L_\omega(+)\tilde{f}^L_{\omega'}(+) - \tilde{f}^L_{-\omega}(-)\tilde{f}^L_{-\omega'}(-))\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'}.$$

III. VEV OF CASIMIR STRESS TENSOR

The poisson bracket structure for Φ and its conjugate momentum Π is given by equal time relations

$$\{\Phi(\sigma),\Pi(\sigma')\} = \delta(\sigma-\sigma'),$$
$$\{\Phi(\sigma),\Phi(\sigma')\} = \{\Pi(\sigma),\Pi(\sigma')\} = 0. \tag{15}$$

By substituting the normal mode expansions of Φ and Π together with the expansion of $\delta(\sigma-\sigma')$ we obtain[26]

$$[\tilde{\alpha}_\omega, \tilde{\alpha}^\dagger_{\omega'}] = \omega\delta_{\omega+\omega',0}. \tag{16}$$

If we assume $|0_L\rangle$ to be the vacuum state for the signature changing cylinder $R\times S^1$ with circumference L, then

$$\tilde{\alpha}_\omega|0_L\rangle = 0,$$
$$\langle 0_L|\tilde{\alpha}^\dagger_\omega = 0, \tag{17}$$
$$\langle 0_L|\tilde{\alpha}_\omega\tilde{\alpha}^\dagger_{\omega'}|0_L\rangle = \omega\delta_{\omega+\omega',0}$$

and we obtain the following vacuum expectation values for the components of energy momentum tensors:

$$\langle 0_L|T^E_{00}|0_L\rangle = 2\sum_{\omega\omega'}(\tilde{f}^E_\omega(+)\tilde{f}^E_{\omega'}(+)+\tilde{f}^E_{-\omega}(-)\tilde{f}^E_{-\omega'}(-))\omega\delta_{\omega+\omega',0},$$
$$\langle 0_L|T^E_{01}|0_L\rangle = 2i\sum_{\omega\omega'}(\tilde{f}^E_\omega(+)\tilde{f}^E_{\omega'}(+)-\tilde{f}^E_{-\omega}(-)\tilde{f}^E_{-\omega'}(-))\omega\delta_{\omega+\omega',0},$$
$$\langle 0_L|T^L_{00}|0_L\rangle = 2\sum_{\omega\omega'}(\tilde{f}^L_\omega(+)\tilde{f}^L_{\omega'}(+)+\tilde{f}^L_{-\omega}(-)\tilde{f}^L_{-\omega'}(-))\omega\delta_{\omega+\omega',0}, \tag{16}$$
$$\langle 0_L|T^L_{01}|0_L\rangle = 2\sum_{\omega\omega'}(\tilde{f}^L_\omega(+)\tilde{f}^L_{\omega'}(+)-\tilde{f}^L_{-\omega}(-)\tilde{f}^L_{-\omega'}(-))\omega\delta_{\omega+\omega',0},$$
$$\langle 0_L|T^E_{11}|0_L\rangle = -\langle 0_L|T^E_{00}|0_L\rangle,$$
$$\langle 0_L|T^L_{11}|0_L\rangle = \langle 0_L|T^L_{00}|0_L\rangle.$$

Now, by the following normalization,

$$4\pi\langle\Phi_\omega,\Phi_\omega\rangle = \tfrac{1}{2}(L-\sigma_0), \tag{19}$$

and inserting it into Eqs. (12) and then applying the delta function $\delta_{\omega+\omega',0}$ we obtain

$$\langle 0_L|T^E_{00}|0_L\rangle = \frac{2}{L-\sigma_0}\sum_{\omega=0}^{\infty}\left[\left(\frac{a}{b}\right)_\omega+1\right]\left[\left(\frac{a}{b}\right)_{-\omega}+1\right]\omega,$$
$$\langle 0_L|T^E_{01}|0_L\rangle = \langle 0_L|T^E_{10}|0_L\rangle = 0,$$

$$\langle 0_L|T^E_{11}|0_L\rangle = -\langle 0_L|T^E_{00}|0_L\rangle,$$
$$\langle 0_L|T^L_{00}|0_L\rangle = \frac{2}{L-\sigma_0}\sum_{\omega=0}^{\infty}\left[\left(\frac{c}{b}\right)_{\omega}+\left(\frac{1}{b}\right)_{-\omega}\right]\left[\left(\frac{c}{b}\right)_{\omega}+\left(\frac{1}{b}\right)_{-\omega}\right]^{*}\omega, \tag{20}$$
$$\langle 0_L|T^L_{01}|0_L\rangle = \langle 0_L|T^L_{10}|0_L\rangle = 0,$$
$$\langle 0_L|T^L_{11}|0_L\rangle = \langle 0_L|T^L_{00}|0_L\rangle.$$

By using the Heaviside distribution Θ^+, Θ^- we may write

$$\langle 0_L|T_{00}|0_L\rangle = \Theta^+\langle 0_L|T^E_{00}|0_L\rangle + \Theta^-\langle 0_L|T^L_{00}|0_L\rangle,$$
$$\langle 0_L|T_{11}|0_L\rangle = \Theta^+\langle 0_L|T^E_{11}|0_L\rangle + \Theta^-\langle 0_L|T^L_{11}|0_L\rangle. \tag{21}$$

The normal ordered expressions are then as follows:

$$\langle 0_L|:T_{00}:|0_L\rangle = \Theta^+\langle 0_L|:T^E_{00}:|0_L\rangle + \Theta^-\langle 0_L|:T^L_{00}:|0_L\rangle,$$
$$\langle 0_L|:T_{11}:|0_L\rangle = \Theta^+\langle 0_L|:T^E_{11}:|0_L\rangle + \Theta^-\langle 0_L|:T^L_{11}:|0_L\rangle, \tag{22}$$

such that

$$\langle 0_L|:T^E_{00}:|0_L\rangle = \langle 0_L|T^E_{00}|0_L\rangle - \lim_{L'\to\infty}\langle 0_{L'}|T^E_{00}|0_{L'}\rangle,$$
$$\langle 0_L|:T^L_{00}:|0_L\rangle = \langle 0_L|T^L_{00}|0_L\rangle - \lim_{L'\to\infty}\langle 0_{L'}|T^L_{00}|0_{L'}\rangle,$$
$$\langle 0_L|:T^E_{11}:|0_L\rangle = \langle 0_L|T^E_{11}|0_L\rangle - \lim_{L'\to\infty}\langle 0_{L'}|T^E_{11}|0_{L'}\rangle, \tag{23}$$
$$\langle 0_L|:T^L_{11}:|0_L\rangle = \langle 0_L|T^L_{11}|0_L\rangle - \lim_{L'\to\infty}\langle 0_{L'}|T^L_{11}|0_{L'}\rangle,$$

where the second terms are introduced to remove the ultraviolet divergences in the first terms.[2] Since we have Euclidean and Lorentzian quantities in the second terms, then the state $|0_{L'}\rangle$ should have the property: $|0_{L'}\rangle \to |0\rangle$ as $L' \to \infty$, such that $|0\rangle$ is the vacuum state of an $R\times R$ signature changing space-time. The Casimir energy is measured with respect to this state.

IV. REGULARIZATION OF VEV OF CASIMIR STRESS TENSOR

Because both terms on the right-hand side (rhs) of the above equations are individually divergent they must be subtracted by careful analysis. By introducing the cutoff to the sums in 00 components we obtain

$$\langle 0_L|T^E_{00}|0_L\rangle_{\text{cutoff}} = \frac{2}{L-\sigma_0}\sum_{\omega=0}^{\infty}\left[\left(\frac{a}{b}\right)_{\omega}+1\right]\left[\left(\frac{a}{b}\right)_{-\omega}+1\right]\omega e^{-\alpha\omega},$$
$$\langle 0_L|T^L_{00}|0_L\rangle_{\text{cutoff}} = \frac{2}{L-\sigma_0}\sum_{\omega=0}^{\infty}\left[\left(\frac{c}{b}\right)_{\omega}+\left(\frac{1}{b}\right)_{-\omega}\right]\left[\left(\frac{c}{b}\right)_{\omega}+\left(\frac{1}{b}\right)_{-\omega}\right]^{*}\omega e^{-\alpha\omega}. \tag{24}$$

The 11 components will be easily obtained in terms of 00 components through Eqs. (20). We now break down each sum into two separate sums,

$$\langle 0_L|T_{00}^E|0_L\rangle_{\text{cutoff}} = \frac{2}{L-\sigma_0}\sum_{\omega<N}\left[\left(\frac{a}{b}\right)_\omega + 1\right]\left[\left(\frac{a}{b}\right)_{-\omega} + 1\right]\omega e^{-\alpha\omega} + \frac{2}{L-\sigma_0}\sum_{\omega=N}^{\infty}\left[\left(\frac{a}{b}\right)_\omega + 1\right]\left[\left(\frac{a}{b}\right)_{-\omega} + 1\right]\omega e^{-\alpha\omega},$$

$$\langle 0_L|T_{00}^L|0_L\rangle_{\text{cutoff}} = \frac{2}{L-\sigma_0}\sum_{\omega<N}\left[\left(\frac{c}{b}\right)_\omega + \left(\frac{1}{b}\right)_{-\omega}\right]\left[\left(\frac{c}{b}\right)_\omega + \left(\frac{1}{b}\right)_{-\omega}\right]^*\omega e^{-\alpha\omega} + \frac{2}{L-\sigma_0}\sum_{\omega=N}^{\infty}\left[\left(\frac{c}{b}\right)_\omega + \left(\frac{1}{b}\right)_{-\omega}\right]\left[\left(\frac{c}{b}\right)_\omega + \left(\frac{1}{b}\right)_{-\omega}\right]^*\omega e^{-\alpha\omega}, \tag{25}$$

where N is the root of quantization condition so that for any $\omega \geqslant N$ the spectrum almost coincides with integer values. As is shown in Fig. 2 in Ref. 26, it is easily seen from quantization condition that whatever can σ_0 be, the real spectrum of ω approaches the integer one, generally at higher values of N. Hence, we assume N to be sufficiently large so that the first sums over $\omega<N$ be (finite) *sums over real values* and the second sums over $\omega \geqslant N$ be almost (infinite) *sums over integer values*. Thus, we may discard the cutoff $e^{-\alpha\omega}$ from the finite sums and keep them just for infinite sums.

Now, we consider the second sum in $\langle 0_L|T_{00}^E|0_L\rangle_{\text{cutoff}}$. Since each of the terms $[(a/b)_\omega+1]$ and $[(a/b)_{-\omega}+1]$ approaches 1 for large ω [because $(a/b)_{\pm\omega}$ almost vanish for large ω] then this sum goes like

$$\frac{2}{L-\sigma_0}\sum_{\omega=N}^{\infty}\omega e^{-\alpha\omega}. \tag{26}$$

In the same way for $\langle 0_L|T_{00}^L|0_L\rangle_{\text{cutoff}}$, it is easily shown that each of the terms $[(c/b)_\omega+(1/b)_{-\omega}]$ and $[(c/b)_\omega+(1/b)_{-\omega}]^*$ approaches 1 for large integerlike values $\omega \geqslant N$, and the second sum goes like

$$\frac{2}{L-\sigma_0}\sum_{\omega=N}^{\infty}\omega e^{-\alpha\omega}, \tag{27}$$

as well. Therefore, we calculate this sum for both regions. We know that $\omega \geqslant N$ denotes for integers, hence we redefine $\omega=N$ to (integer) $\Omega=0$. To this end, we note that $\omega \geqslant N$ indicates, by definition, the integer roots of $\cos\omega(L-\sigma_0)=0$ in the quantization condition, from which we obtain $\omega \geqslant (n+1/2)/(L-\sigma_0)\pi$ and $N=(n+1/2)/(L-\sigma_0)\pi$. This is equal to $n=[N(L-\sigma_0)/\pi]-\frac{1}{2}$ with integer n. Therefore, we may define $\Omega=n-[N(L-\sigma_0)/\pi]+\frac{1}{2}$, with $\Omega=0,1,2,\ldots$. We also obtain ω in terms of Ω as $\omega=N+[\pi\Omega/(L-\sigma_0)]$.

Therefore, the sum (26) or (27) in Euclidean and Lorentzian regions is written as

$$\frac{2}{L-\sigma_0}\sum_{\Omega=0}^{\infty}\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}},$$

which, after some calculations, leads to [we have used $\Sigma_{n=0}^{\infty} n e^{-2\pi\alpha n/L}=e^{2\pi\alpha/L}(e^{2\pi\alpha/L}-1)^{-2}$ (Ref. 2)]

$$\frac{2}{L-\sigma_0}\sum_{\Omega=0}^{\infty}\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}=\frac{2}{L-\sigma_0}e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}. \tag{28}$$

First, we focus on the Euclidean calculations. By using Eqs. (22) and (23) for the Euclidean region we find

$$\begin{aligned}\Theta^+\langle 0_L|:T^E_{00}:|0_L\rangle=\Theta^+\Bigg\{&\frac{2}{L-\sigma_0}\Bigg[\sum_{\omega=0}^{N-1}\left[\left(\frac{a}{b}\right)_{\omega}+1\right]\left[\left(\frac{a}{b}\right)_{-\omega}+1\right]\omega\\&+e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}\Bigg]\\&-\frac{2}{L-\sigma_0}\Bigg[\sum_{\omega=0}^{N-1}\omega+\lim_{L\to\infty}e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}\Bigg]\Bigg\},\end{aligned} \tag{29}$$

or

$$\begin{aligned}\Theta^+\Bigg\{&\frac{2}{L-\sigma_0}\Bigg[\sum_{\omega=0}^{N-1}\left[\left[\left(\frac{a}{b}\right)_{\omega}+1\right]\left[\left(\frac{a}{b}\right)_{-\omega}+1\right]-1\right]\omega\Bigg]\\&+\frac{2}{L-\sigma_0}\Bigg[e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}\\&-\lim_{L\to\infty}e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}\Bigg]\Bigg\},\end{aligned} \tag{30}$$

where the finite sum has appeared without cutoff. In obtaining $\Sigma_{\omega=0}^{N-1}\omega$ in the second line of (29), we have used $\lim_{L\to\infty}(a/b)_{\pm\omega}\equiv\lim_{\sigma_0\to\infty}(a/b)_{\pm\omega}=0$ in the finite sum. We now expand the

$$e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha(N+\pi\Omega/L-\sigma_0)}-1)^2}$$

terms in the second bracket of (30) about $\alpha=0$. After some calculation we obtain

$$\begin{aligned}&\frac{2}{L-\sigma_0}\left[e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}\right]\\&\quad=\frac{2}{\alpha^2\pi}-\left(\frac{\alpha^2N^2}{2}-\alpha N+1\right)\left[\frac{\pi}{6(L-\sigma_0)^2}+\frac{13}{6(L-\sigma_0)}N\right]-\frac{N^2}{\pi}(1-\alpha N).\end{aligned}$$

Substituting this result into the above bracket and taking $\alpha\to 0$ leads to

$$\frac{2}{L-\sigma_0}\left[e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}-\lim_{L\to\infty}e^{-\alpha N}\frac{\left(N+\frac{\pi\Omega}{L-\sigma_0}\right)e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-N}{(e^{-\alpha\{N+[\pi\Omega/(L-\sigma_0)]\}}-1)^2}\right]$$
$$=-\frac{\pi}{6(L-\sigma_0)^2}-\frac{13}{6(L-\sigma_0)}N.$$

Finally, we have the following expression for the Euclidean region:

$$\langle 0_L|:T^E_{00}:|0_L\rangle=\left\{\frac{2}{L-\sigma_0}\sum_{\omega=0}^{N-1}\left[\left[\left[\left(\frac{a}{b}\right)_\omega+1\right]\left[\left(\frac{a}{b}\right)_{-\omega}+1\right]-1\right]\omega-\frac{\pi}{6(L-\sigma_0)^2}-\frac{13}{6(L-\sigma_0)}N\right\}.\right. \tag{31}$$

In the same way, the calculations for the Lorentzian region lead to

$$\langle 0_L|:T^L_{00}:|0_L\rangle=\left\{\frac{2}{L-\sigma_0}\sum_{\omega=0}^{N-1}\left[\left[\left[\left(\frac{c}{b}\right)_\omega+\left(\frac{1}{b}\right)_{-\omega}\right]\left[\left(\frac{c}{b}\right)_\omega+\left(\frac{1}{b}\right)_{-\omega}\right]^*-1\right]\omega-\frac{\pi}{6(L-\sigma_0)^2}\right.\right.$$
$$\left.\left.-\frac{13}{6(L-\sigma_0)}N\right\}.\right. \tag{32}$$

Note that, since N is not uniquely determined, then the expectation values (31) and (32) are evaluated approximately. Therefore, for a given σ_0, replacing N by $N+1$ or $N-1$ leads to better or worse approximation, respectively. This is because, as we go to higher values of N the real spectrum coincides with integer one with better approximation.

V. FINITE ENERGY DENSITY AND PRESSURE IN EUCLIDEAN AND LORENTZIAN REGIONS

By using Eqs. (20) for the 11 components we have

$$\langle 0_L|:T^E_{11}:|0_L\rangle=-\langle 0_L|:T^E_{00}:|0_L\rangle,$$
$$\langle 0_L|:T^L_{11}:|0_L\rangle=\langle 0_L|:T^L_{00}:|0_L\rangle. \tag{33}$$

Therefore, the state $|0_L\rangle$ contains the finite energy density and pressure in the Euclidean and Lorentzian regions as follows:

$$\rho^E=\langle 0_L|:T^E_{00}:|0_L\rangle,$$
$$\rho^L=\langle 0_L|:T^L_{00}:|0_L\rangle, \tag{34}$$

$$p^E=\langle 0_L|:T^E_{11}:|0_L\rangle=-\rho^E,$$
$$p^L=\langle 0_L|:T^L_{11}:|0_L\rangle=\rho^L. \tag{35}$$

We then find that the total pressure acting on the signature-changing hypersurfaces $\sigma=0,L$ and $\sigma=\sigma_0$ is given by

$$p^T=p^L-p^E=\rho^L+\rho^E, \tag{36}$$

which is generally nonzero according to Eqs. (31), (32), and (34). This nonzero pressure causes instability in the location of σ_0 relative to $\sigma=0$. Depending on the initial location of σ_0, the corresponding value and sign of the pressure may lead one of the regions (L or E) to grow or shrink. It is very hard to judge about the exact behavior of the pressure from Eqs. (31) and (32),

because it depends on N, the location of σ_0, and the complicated functions $(a/b)_\omega$, $(c/b)_\omega$, $(1/b)_\omega$ in which the energy spectrum ω, itself, depends on σ_0 through the quantization condition (6).

Nevertheless, one may evaluate the situation in the two limits of σ_0. In the limit $\sigma_0 \to 0$, the term $\pi/6(L-\sigma_0)^2$ may be neglected in comparison with two other terms. Therefore, there is a competition between the first sums and third terms in Eqs. (31) and (32). And, upon this competition the pressure may cause the Euclidean region to grow or shrink. On the other hand, in the limit $\sigma_0 \to L$, the term $\pi/6(L-\sigma_0)^2$ may dominate the other two terms and the pressure $p^T=\rho^L+\rho^E$ becomes negative, $p^L<p^E$, which means the Euclidean region is growing (with increasing pressure) toward $\sigma_0=L$. Fortunately, in this case, there is no divergency problem at $\sigma_0=L$. This is because, once the circle is completely covered by Euclidean metric, the quantization condition and all subsequent calculations break down.

The nonzero pressure obtained above and the consequent change in the signature changing region will certainly change the energy spectrum of the scalar fields through the quantization condition

$$\cosh \omega\sigma_0 \cos \omega(\sigma_0 - L) = 1 .$$

The modified signature-changing region σ_0 and energy spectrum ω back react on the pressure through Eqs. (31) and (32). The central term of the algebra corresponding to infinite conserved charges[26]

$$[L_\omega, L_{\omega'}] = (\omega - \omega')L_{\omega+\omega'} + C(\omega, \omega')$$

is correspondingly changed through

$$C(\omega,\omega') = \delta_{\omega+\omega',0} f(\omega,\omega',\sigma_0) - 4 \sum_{\omega_1,\omega_2>0}^{N} {\omega_1}^2 {\omega_2}^2 C^{-\omega'}_{\omega_1,\omega_2} C^{\omega}_{\omega_1,\omega_2} + \sum_{\omega_1>0}^{N} {\omega_1}^2 (\omega-\omega_1)^2 C^{-\omega'}_{\omega_1,\omega-\omega_1},$$

where

$$f(\omega,\omega',\sigma_0) = 3 \sum_{l=-n}^{0} [-2(l+k)a - \omega - \omega'][2(l+k)a+\omega]^2 [|(2(l+k)a+\omega+\omega')(2(l+k)a)|]^{1/2}$$

and

$$N = (2k-1)a, \quad \omega = (2n-1)a, \quad a = \frac{\pi}{2(2\pi - \sigma_0)}$$

with k and n as integers.

It is seen that in the special case $N=0$ the first sums and the last terms vanish in (31) and (32) and these lead to the standard result $-\pi/6L^2$ for the pure Lorentzian metric $\sigma_0=0$ on the cylinder.[2] In fact, $N=0$ corresponds to $\omega=N=0$ which means ω is an integer starting from zero; a case which occurs only in the pure Lorentzian region.

VI. CONCLUSION

We have studied a two-dimensional model in which the space-time is a cylinder (circle $\times$ real number) with the circle representing *space* and the real line representing *time*. Moreover, we have assumed that this manifold admits a signature change of the type which had already been reported in Ref. 26.

We were interested in studying the Casimir effect for the real massless scalar fields propagating over this manifold. To this end, we have considered the expressions for the components of energy-momentum tensors associated with the real scalar field and calculated the corresponding vacuum expectation values. These expressions are found to be infinite, hence a regularization scheme is used to make them finite. By introducing a convenient cutoff and a regularization scheme, we obtain the finite expressions for the vacuum expectation values of the energy momen-

tum tensors. These provide us with the finite energy densities and pressures in both Euclidean and Lorentzian regions so that the net pressure on the signature changing hypersurfaces is obtained. This pressure causes instability in the signature changing region σ_0 and this instability alters the energy spectrum through the quantization condition. The modified σ_0 and spectrum ω themselves back react on the pressure through Eqs. (31) and (32). Moreover, the central term of diffeomorphism algebra of real massless scalar fields obtained in Ref. 26 is altered due to modifications in σ_0 and spectrum ω.

The action for free massless scalar field propagating on the signature-changing background

$$S=\frac{1}{2}\int \mathrm{d}t\int_{\text{Lorentzian}} \mathrm{d}\sigma\sqrt{|g|}g_L^{\mu\nu}\partial_\mu\phi_\omega^L\partial_\nu\phi_\omega^L+\frac{1}{2}\int \mathrm{d}t\int_{\text{Euclidean}} \mathrm{d}\sigma\sqrt{|g|}g_E^{\mu\nu}\partial_\mu\phi_\omega^E\partial_\nu\phi_\omega^E$$

may be rewritten in the form of string action

$$S\sim\frac{1}{2}\int \mathrm{d}t\int \mathrm{d}\sigma\sqrt{|g|}g^{\mu\nu}\partial_\mu\phi_\omega^a\partial_\nu\phi_\omega^b\eta_{ab}$$

with the distribution $g_{\mu\nu}=\Theta^+g_{\mu\nu}^E+\Theta^-g_{\mu\nu}^L$ and $\phi_\omega^a=(\phi_\omega^E,\phi_\omega^L)$ with $\eta_{ab}=\mathrm{diag}(\Theta^+,\Theta^-)$. In this way it looks like we have a closed string with Euclidean and Lorentzian parts propagating in a distributional way in the two-dimensional target space $(\phi_\omega^E,\phi_\omega^L)$.[26] The discontinuous nature of the model in classifying Euclidean and Lorentzian solutions $\Phi_\omega^E,\Phi_\omega^L$ with discrete symmetry under $\omega\leftrightarrow-\omega$ in each class motivates one to study it in the context of *orbifolds*. For example, if we suppose the target space M to be $\phi_\omega^a=(\phi_\omega^E,\phi_{-\omega}^E,\phi_\omega^L,\phi_{-\omega}^L)$ and assume a permutation of it $\pi=(\phi_\omega^E\phi_{-\omega}^E)\times(\phi_\omega^L\phi_{-\omega}^L)$, then regarding the definition of an orbifold as the object one obtains by dividing a manifold by the action of a discrete group, it seems to be possible to define an orbifold M/π which results in $\phi_\omega^a=(\phi_\omega^E,\phi_\omega^L)$. In this way, perhaps at a formal level, we may have *a string on an orbifold*.[26]

Therefore, the study of Casimir effect in the present model may provide important results relevant to the study of closed bosonic strings. It is also appealing to proceed with the idea of Casimir effect in different 3+1 dimensional signature-changing space-times to investigate what secondary effects may be produced by the Casimir effect.[29]

(Received 9 November 2005; accepted 30 January 2006; published online 14 March 2006)

We investigate the evolution equation of linear density perturbations in the Friedmann-Robertson-Walker universe with matter, radiation, and the cosmological constant. The concept of solvability by quadratures is defined and used to prove that there are no "closed form" solutions except for the known Chernin, Heath, Meszaros and simple degenerate ones. The analysis is performed applying Kovacic's algorithm. The possibility of the existence of other, more general solutions involving special functions is also investigated. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2178584]

I. INTRODUCTION

This paper is an attempt to apply the methods of differential algebra, and the differential Galois theory in particular, to a problem of cosmology. Although the considerations are mostly mathematical, the problem itself, and its solutions, are of rather practical interest. Linear perturbations of the Einstein equations in many forms are investigated due to their direct relation to such practical questions as the formation of galaxies or the CMB inhomogeneities. We, however, enter the physical domain only as the source of a theoretical problem, on which we concentrate.

The result itself is of negative nature, or, in other words, it makes any further investigation of this kind unnecessary. All the known solutions are given, together with the conditions for their validity. As no new ones can exist, this closes and completes the analysis of the given equation.

Of course, that is not to say that apart from those special cases nothing can be said about the behavior of the solution. It is only to some extent that differential algebra can make exact the intuitive concepts of "being possible to solve" or "expressible in a closed form." The definition of nonintegrability employed here is but one of many which were born as classical mechanics evolved. The Liouville's theorem implies that enough first integrals might yield a complete solution of a dynamical system, and accordingly many criteria regarding the existence of certain classes of first integrals were developed. The first achievements were those of Kovalevskaya and Lyapunov, greatly improved only recently by Ziglin, Morales, and Ramis. The Galois theory used here, can also be applied to prove nonexistence of meromorphic first integrals in more complex systems. Paradoxically here, we are presented with an equation simple enough not to allow for the application of those advanced methods. Thus, only a small part of the theory is put into practice and explained here. For a complete bibliography and exposition see, for example, Ref. 1.

The paper is organized as follows. In Sec. II we derive the equation in question in a nonstandard but intuitively clear way. The next two sections describe the concept of Liouvillian

[a]Electronic mail: toms@oa.uj.edu.pl
[b]Electronic mail: uoszydlo@cyf-kr.edu.pl
[c]Electronic mail: maciejka@astro.ia.uz.zgora.pl

solutions, integrability and give the basic criteria, which we proceed to use in Sec. V. We also investigate the possibility of solving the problem by a combination of some special and Liouvillian functions, and give the theorem which is the main result in Sec. VI. Finally, conclusions and finishing remarks are given in Sec. VII.

II. DENSITY PERTURBATION EQUATION

We will be considering the Friedmann-Robertson-Walker universe given by the metric

$$\mathrm{d}s^2 = c^2\,\mathrm{d}t^2 - a(t)^2\left[\frac{\mathrm{d}r^2}{1-Kr^2} + r^2\,\mathrm{d}\Omega^2\right], \tag{1}$$

where K is the curvature index, $\mathrm{d}\Omega^2$ is the distance element on a two-sphere. The universe will be filled with radiation and baryonic matter characterized by their pressures and densities p and ρ. A nonzero cosmological constant's effect will also be considered.

The Einstein equations for this model give

$$\left(\frac{\dot{a}}{a}\right)^2 = \frac{8\pi \boldsymbol{G}}{3}\rho + \frac{\Lambda}{3} - \frac{K}{a^2},$$
$$\frac{\ddot{a}}{a} = -\frac{4\pi \boldsymbol{G}}{3}(3p+\rho) + \frac{\Lambda}{3}, \tag{2}$$

where $\boldsymbol{G}$, and Λ are the gravitational and cosmological constants, respectively. The conservation equation reduces to

$$c^2\dot{\rho} = -3H(p+\rho c^2), \tag{3}$$

with the dot representing the time derivative. This can be expressed as the following transformation laws for matter and radiation, respectively:

$$p_m = 0 \Rightarrow \frac{\rho_m}{\rho_{m0}} = \left(\frac{a_0}{a}\right)^3,$$
$$p_r = \frac{1}{3}\rho_r \Rightarrow \frac{\rho_r}{\rho_{r0}} = \left(\frac{a_0}{a}\right)^4. \tag{4}$$

ρ_{m0} and ρ_{r0} are the values of the densities for the moment when $a=a_0$, which can be chosen as the present day.

The fluctuation is introduced by the means of the scale factor

$$a = \tilde{a}(1+y), \tag{5}$$

and $\tilde{a}$ is the solution of the original equations (2). As it is a matter perturbation only, we have

$$\rho_r = \tilde{\rho}_r,$$

$$\rho_m = \tilde{\rho}_m\left(\frac{a}{\tilde{a}}\right)^{-3} = \tilde{\rho}_m(1+y)^{-3} = \tilde{\rho}_m(1-3y),$$

where we use the scaling law (4) and linearize the problem. Substituting this into the second of Eqs. (2), we obtain

$$\ddot{\tilde{a}}(1+y)+2\dot{\tilde{a}}\dot{y}=-\frac{8\pi G}{3}\tilde{a}(1+y)\rho_r-\frac{4\pi G}{3}\tilde{a}(1+y)\tilde{\rho}_m(1-3y)+\frac{1}{3}\Lambda\tilde{a}(1+y), \tag{6}$$

which, after substituting the equation satisfied by the unperturbed $\tilde{a}$, simplifies to

$$\ddot{y}+2H\dot{y}-4\pi G\tilde{\rho}_m y=0, \tag{7}$$

with the Hubble "constant"

$$H:=\frac{\dot{\tilde{a}}}{\tilde{a}}. \tag{8}$$

This kind of perturbation is of the scalar type, i.e., constructed from a single function y. Here, we take it to depend on time only, although in general it could also involve spatial variables. This case could then be thought of as the zeroth order coefficient in the expansion of $y(t,r,\theta,\varphi)$ in terms of eigenfunctions of the spatial Laplace operator. Another generalization would be to consider the vector and tensor type perturbations (see Ref. 2 for details of the decomposition). As it turns out, vector perturbations also admit quite general exact solutions.[3]

In order to simplify Eq. (7) fully, that is, bring it to the linear form with rational coefficients, we choose new variables,

$$x:=\frac{\tilde{a}}{\tilde{a}_0},\quad u:=H_0 t, \tag{9}$$

and constant density parameters,

$$\Omega_{r0}:=\frac{8\pi G\rho_{r0}}{3H_0^2},\quad \Omega_{m0}:=\frac{8\pi G\rho_{m0}}{3H_0^2}, \tag{10}$$

$$\Omega_{K0}:=-\frac{c^2K}{\tilde{a}_0^2H_0^2},\quad \Omega_{\Lambda0}:=\frac{c^2\Lambda}{3H_0^2} \tag{11}$$

which allow us to rewrite the main equation as

$$\left(\frac{\mathrm{d}x}{\mathrm{d}u}\right)^2\frac{\mathrm{d}^2y}{\mathrm{d}x^2}+\left[\frac{\mathrm{d}^2x}{\mathrm{d}u^2}+\frac{2}{x}\left(\frac{\mathrm{d}x}{\mathrm{d}u}\right)^2\right]\frac{\mathrm{d}y}{\mathrm{d}x}-\frac{3}{2}\Omega_{m0}\frac{1}{x^3}y=0, \tag{12}$$

where the perturbation y is now considered as a function of x. Finally, using the first of Eqs. (2), which in the new variables reads

$$x^2\left(\frac{\mathrm{d}x}{\mathrm{d}u}\right)^2=\Omega_{\Lambda0}x^4+\Omega_{K0}x^2+\Omega_{m0}x+\Omega_{r0}=:W(x), \tag{13}$$

we can eliminate the derivatives with respect to u, and denoting the differentiation with respect to x with a prime, we get

$$x(\Omega_{\Lambda0}x^4+\Omega_{K0}x^2+\Omega_{m0}x+\Omega_{r0})y''+\left(3\Omega_{\Lambda0}x^4+2\Omega_{K0}x^2+\tfrac{3}{2}\Omega_{m0}x+\Omega_{r0}\right)y'-\tfrac{3}{2}\Omega_{m0}y=0. \tag{14}$$

As follows from the definitions, Ω_{K0} and $\Omega_{\Lambda0}$ are of arbitrary signs, while Ω_{r0} and Ω_{m0} are non-negative. We take Ω_{m0} to be strictly positive, though, because of the nature of the examined perturbations.

We also introduce the functions $p(x)$ and $q(x)$ related to the above equation in the following form:

$$y''(x) + p(x)y'(x) + q(x)y(x) = 0. \tag{15}$$

They are

$$p(x) = \frac{6\Omega_{\Lambda 0}x^4 + 4\Omega_{K0}x^2 + 3\Omega_{m0}x + 2\Omega_{r0}}{2x(\Omega_{\Lambda 0}x^4 + \Omega_{K0}x^2 + \Omega_{m0}x + \Omega_{r0})} \quad \text{and } q(x) = \frac{-3\Omega_{m0}}{2x(\Omega_{\Lambda 0}x^4 + \Omega_{K0}x^2 + \Omega_{m0}x + \Omega_{r0})}. \tag{16}$$

Having obtained the solutions as functions of x it is straightforward to express them as functions of the cosmological or conformal time, since $x(u)$ satisfies Eq. (13), and is therefore expressible in terms of the elliptic functions. The exact formulas can be found, for example, in Ref. 4.

III. LIOUVILLIAN SOLUTIONS

Equation (14) is, in general, a Fuchsian one, and the solutions can be found by means of series. In particular, in vicinities of the singular points

$$y_{\pm}(x) = (x - x_0)^{\alpha_{\pm}}\left(1 + \sum_{n=1}^{\infty} c_n(x - x_0)^n\right), \tag{17}$$

where $\alpha_{\pm}$ are the characteristic exponents at the point x_0. Such solutions are local, and the area of convergence around a given point is restricted by the remaining singular points. However, there are some special cases in which the solutions can be expressed by means of known special functions, and become global. It is then much easier to investigate and understand their behavior. Thus, we are lead to the natural question of existence of such "simple" solutions. In this section we give a short description of a class of functions, which could here be called closed-form solutions.

It is natural to start seeking for the solutions in a class of functions to which the given equation's coefficients belong, but such a set proves to be insufficient in most cases. As we are dealing with an equation whose coefficients are rational functions, the first choice is the field $\mathbb{C}(x)$—rational functions with complex numbers as the field of constants. Or, in the language of differential algebra, $(\mathbb{C}(x), \partial)$—the above field equipped with a suitable derivation operation, which, in this case, coincides with the usual, complex one, and will be denoted by a prime throughout this section.

This field is much too small, of course, and we are soon forced to extend it, introducing new elements. Just, as $\mathbb{C}(x)$ is an extension of $\mathbb{C}$ obtained by adjoining an indeterminate variable x, our new fields will be $\mathbb{C}(x)$ to which new functions are added. Naturally, the derivation on the extended field must coincide with the subfield's derivation when restricted to it (that is essentially what a differential extension is).

To keep the new functions relatively simple, so that the usual notion of "solvability by quadratures" could still be applied, the new elements are restricted to three classes.

Definition 1: For a differential field extension $F \subset G$, an element $a \in F$ is

primitive *over G if $a' \in G$,*

exponential *over G if $a'/a \in G$, or*

algebraic *over G if $P(a) = 0$ for some $P(x) \in G[x]$ — the ring of polynomials with coefficients in G.*

Definition 2: A field extension is called Liouvillian if it is a result of a finite number of extensions, each the adjunction of an algebraic, exponential, or primitive element.

Some examples of "new" functions appearing in this process are radicals (for algebraic elements), logarithms and inverse circular function (for primitives), and trigonometric functions (for exponentials). In short, the new elements are expressible as combinations of exponentials, integrals, and algebraic and elementary functions.

Finally, we are able to formulate what we mean by integrability.

Definition 3: A linear differential equation with coefficients in $\mathbb{C}(x)$ *is said to possess Liouvillian solutions, or be solvable by quadratures, if its solutions belong to a Liouvillian extension of* $\mathbb{C}(x)$.

IV. MONODROMY AND GALOIS GROUPS

In order to characterize a differential equation we can introduce two groups whose invariant properties are closely connected with those of the first integrals of the given equation.

The first, called the monodromy group $\mathcal{M}$ is associated with the continuation of the local solutions of a linear differential equation, along closed paths in the domain where the equation is defined. The group itself is an image of the fundamental group of that domain, and a subgroup of $\mathrm{GL}(n,\mathbb{C})$ for n the order of the equation. The only other fact, concerning $\mathcal{M}$, that we will need here is that $\mathcal{M}\subset\mathcal{G}$—the differential Galois group, which we proceed to describe.

$\mathcal{G}$ is directly connected with the extension of the base field $\mathbb{C}(x)$ to a bigger field F, which contains the solutions of the considered equation. $\mathcal{G}$ is defined as the group of automorphisms of F that leave $\mathbb{C}(x)$ elementwise fixed. Carrying this information regarding the equation, the Galois group enables to test for particular forms of solutions. One of the fundamental properties is as follows.

Lemma 1: Let $\mathcal{G}$ *be the differential Galois group of a linear differential equation* $w''(x)=r(x)w(x)$, $r(x)\in\mathbb{C}(x)$. *Then it is an algebraic subgroup of* $SL(2,\mathbb{C})$, *and one of the following cases can occur.*

(1) $\mathcal{G}$ *is triangulizable. There is a solution of the form* $\exp\int\omega$, *where* $\omega\in\mathbb{C}(x)$.

(2) $\mathcal{G}$ *is conjugate to a subgroup of*

$$D^{\dagger}=\left\{\begin{pmatrix}c_1 & 0\\ 0 & c_1^{-1}\end{pmatrix}\middle| c_1\in\mathbb{C}^*\right\}\cup\left\{\begin{pmatrix}0 & c_2\\ -c_2^{-1} & 0\end{pmatrix}\middle| c_2\in\mathbb{C}^*\right\},$$

where $\mathbb{C}^*=\mathbb{C}\backslash\{0\}$. *There is a solution of the form* $\exp\int\omega$, *with* ω *algebraic over* $\mathbb{C}(x)$ *of degree 2.*

(3) $\mathcal{G}$ *is finite. All the solutions are algebraic.*

(4) $\mathcal{G}=SL(2,\mathbb{C})$. *The equation has no Liouvillian solutions.*

V. NONINTEGRABILITY OF THE EQUATIONS

We now proceed to the direct analysis of the integrability of Eq. (14), based mainly on the Kovacic's algorithm.[5] First we consider the equation with $\Omega_{\Lambda 0}=0$, for which the calculation is not too cumbersome, and next, we outline the reasoning for the general case.

A. Models without the cosmological constant

In order to apply the algorithm, Eq. (15) is cast into a reduced form

$$v''(x)=r(x)v(x), \tag{18}$$

with

$$r(x)=-\frac{1}{4x^2}-\frac{3(2\kappa x+1)^2}{(\kappa x^2+x+\varrho)^2}+\frac{4\kappa x+7}{x(\kappa x^2+x+\varrho)}, \tag{19}$$

where we have introduced new parameters

$$\kappa := \frac{\Omega_{K0}}{\Omega_{m0}}, \quad \varrho := \frac{\Omega_{r0}}{\Omega_{m0}}.$$

The reduction itself is performed by means of the following change in the dependent variable:

$$y(x) = v(x)\exp\left[-\frac{1}{2}\int_{x_0}^{x} p(s)\mathrm{d}s\right], \tag{20}$$

where the constant x_0 is arbitrary. This transformation does not change the class of solutions we are interested in, as it uses the "admissible" operations only.

In the general case, there are two distinct roots of the polynomial $W(x)$ in Eq. (14) and they are both nonzero. The degenerate cases will be treated separately.

Looking for the local solutions around $x=0$, which is a regular singular point of the equation with both characteristic exponents equal to $\frac{1}{2}$, we find

$$\begin{aligned} v_1(x) &= x^{1/2}w_1(x), \\ v_2(x) &= \ln(x)v_1(x) + x^{1/2}w_2(x), \end{aligned} \tag{21}$$

and w_1 and w_2 are holomorphic at $x=0$. Using these, it is now possible to obtain an element of the monodromy group, by continuation of the fundamental solution matrix along a small closed path around $x=0$,

$$\begin{pmatrix} v_1 & v_2 \\ v_1' & v_2' \end{pmatrix} \to \begin{pmatrix} -1 & -2\pi i \\ 0 & -1 \end{pmatrix}\begin{pmatrix} v_1 & v_2 \\ v_1' & v_2' \end{pmatrix}. \tag{22}$$

Since $\mathcal{M} \subset \mathcal{G}$, the Galois group cannot be $D^{\dagger}$, as that group does not contain nondiagonalizable matrices. Also, a triangular, nondiagonal matrix cannot generate a finite group, so that $\mathcal{G}$ itself cannot be finite. We have thus excluded cases 2 and 3 of Lemma 1.

Case 1 can also be easily excluded applying the aforementioned algorithm. In order for the solution to be of the form

$$P(x)\exp\left[\int \omega(x)\mathrm{d}x\right], \tag{23}$$

with a monic $P(x) \in \mathbb{C}[x]$, and $\omega(x) \in \mathbb{C}(x)$, the following equation must be satisfied:

$$P''(x) + 2\omega(x)P'(x) + [\omega'(x) + \omega(x)^2 - r(x)]P(x) \equiv 0, \tag{24}$$

for $P(x)$ and $\omega(x)$ found according to the algorithm, as follows. First, we define a set of auxiliary quantities,

$$\alpha_c^{\pm} = \tfrac{1}{2} \pm \tfrac{1}{2}\sqrt{1+4b}, \tag{25}$$

where $c \in \Gamma \cup \{\infty\}$—the set of all the finite poles of $r(x)$ including infinity, and b is the coefficient of $(x-c)^{-2}$ in the Laurent expansion of $r(x)$ around a given point $x=c$. Next, for all possible combinations of signs $s(\infty), s(c)$ we compute the possible degrees of $P(x)$ as

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}, \tag{26}$$

and, for the same combinations of signs $s(c)$, the respective possible ω

$$\omega(x) = \sum_{c \in \Gamma} \frac{\alpha_c^{s(c)}}{x - c}. \tag{27}$$

Inserting the functions just obtained into Eq. (24) we are left with a system of linear equations determining the unknown coefficients of $P(x)$. In this particular case, the only non-negative value of d is 0, so that $P(x)=1$, and the system is reduced to

$$\frac{3}{2x(\kappa x^2 + x + \varrho)} \equiv 0, \tag{28}$$

which cannot hold. The first case of Lemma 1 is also excluded, which means that $\mathcal{G}$ is $\mathrm{SL}(2,\mathbb{C})$, and the equation has no Liouvillian solutions in the general case.

When we admit a double nonzero root of $W(x)$, or in other words, when

$$\Omega_{m0} = 2\sqrt{\Omega_{r0}}(1 - \sqrt{\Omega_{r0}}), \tag{29}$$

we have the well-known Chernin solution[6]

$$y(x) = {}_2F_1\left(-i\sqrt{3}, i\sqrt{3}, 1; \frac{x}{x + 2\Omega_{r0}}\right). \tag{30}$$

where ${}_2F_1$ is the Gauss hypergeometric function.

In the current notation it means that $4\varrho\kappa=1$, and that the root itself is $x_0=-2\varrho$. As Eq. (15) now has three regular singular points: 0, x_0, and ∞, it becomes a Riemann P-equation. The complete set of solutions is denoted by

$$y(x) = P\left\{\begin{matrix} 0 & -2\varrho & \infty & \\ 0 & -i\sqrt{3} & 0 & x \\ 0 & i\sqrt{3} & 1 & \end{matrix}\right\}. \tag{31}$$

Such a P-function is not Liouvillian either, as can be immediately checked using Kimura's theorem.[7]

Another degenerate subcase occurs when $\varrho=0$, and $\kappa\neq 0$, so that 0 becomes a root of $W(x)$ and there is another nonzero root $x=-1/\kappa$. Like before the solution is a P-function,

$$y(x) = P\left\{\begin{matrix} 0 & -\frac{1}{\kappa} & \infty & \\ -\frac{3}{2} & 0 & 0 & x \\ 1 & \frac{1}{2} & 1 & \end{matrix}\right\}. \tag{32}$$

This time however, it is a Liouvillian solution because we can express the above symbol as two base solutions,

$$\begin{aligned} y_1(x) &= x^{-3/2}\sqrt{\Omega_{m0} + \Omega_{K0}x}, \\ y_2(x) &= x\,{}_2F_1\left(1, 2, \frac{7}{2}; -\frac{\Omega_{K0}}{\Omega_{m0}}x\right), \end{aligned} \tag{33}$$

The next subcase is $\kappa=0$ and only two simple roots remain, 0 and $-\varrho$. We accordingly get

$$y(x) = P\begin{Bmatrix} 0 & -\varrho & \infty & \\ 0 & 0 & -1 & x \\ 0 & \frac{1}{2} & \frac{3}{2} & \end{Bmatrix}. \tag{34}$$

As before, this is a Liouvillian function, according to Kimura's theorem, and it can be rewritten as the following two independent solutions:

$$\begin{aligned} y_1(x) &= 1 + \frac{3\Omega_{m0}}{2\Omega_{r0}}x, \\ y_2(x) &= \sqrt{\Omega_{r0} + \Omega_{m0}}x_2F_1\left(2, -\frac{1}{2}, \frac{3}{2}; 1 + \frac{\Omega_{m0}}{\Omega_{r0}}x\right), \end{aligned} \tag{35}$$

which are the solutions discovered by Meszaros.[8]

The last possibility is that $\varrho=\kappa=0$ which implies $\Omega_{m0}=1$, and we simply obtain

$$\begin{aligned} y_1(x) &= x, \\ y_2(x) &= x^{3/2}. \end{aligned} \tag{36}$$

Taking into account that condition (29) makes it impossible for the physical cases ($\Omega_{m0}>0$) to have zero as a triple root, we conclude that the only Liouvillian solutions of Eq. (14) for $\Omega_{\Lambda 0}=0$, appear when at least one of the parameters Ω_{r0} or Ω_{K0} is equal to zero.

B. Models with the cosmological constant

The reasoning for $\Omega_{\Lambda 0}\neq 0$ is the same as in the preceding section, but since the leading coefficient now contains a polynomial of the fourth degree, the calculations are somewhat more laborious.

In general, when $W(x)$ has only simple roots, and they are all nonzero (which means $\Omega_{r0}\neq 0$), we obtain, as before, a triangular element of the monodromy group $\mathcal{M}$. This leaves us with only the first case of the Kovacic's algorithm to check, and the physical requirement of $\Omega_{m0}>0$ causes the equation to be nonintegrable.

In fact, even if the roots become multiple, but still nonzero, the local solutions in the vicinity of $x=0$ do not change and, again, we only need to consider the first case of the algorithm. We introduce the roots by the following formula:

$$W(x) = \Omega_{\Lambda 0}(x-e_1)(x-e_2)(x-e_3)(x-e_4).$$

Taking $e_2=e_4$, we could rewrite the polynomial as $W(x)=\Omega_{\Lambda 0}(x-e_1)(x+e1+2e_2)(x-e_2)^2$, because we must have $e_1+e_2+e_3+e_4=0$.

This time, the coefficients b, as defined in the preceding section, is not numeric, but depends on the roots. We now have

$$\alpha_{e_2}^{\pm} = \frac{1}{2} \pm \frac{1}{2}\sqrt{1 + 4\left(\frac{3}{4} + \frac{3e_1}{e_2 - e_1} - \frac{e_1}{e_1 + 3e_2}\right)} =: \frac{1 \pm n}{2}. \tag{37}$$

We see that n must be at least a positive integer, and that initially there are countably many possibilities to check. Since the relation between the roots and the densities Ω is known, we might obtain an important restriction of the form

$$\frac{\Omega_{r0}}{\Omega_{\Lambda 0}} = -\frac{3(n^2-4)}{n^2+12}e_2^4, \tag{38}$$

which means that $\Omega_{\Lambda 0}$ must be negative if $n>2$. One can readily check that $n=1,2$ give no solution. Further calculations with these restrictions on $\Omega_{\Lambda 0}$ and n, determining the coefficients of

the appropriate polynomial $P(x)$ require us to solve a system of n homogeneous, linear equations. Unfortunately we have been unable to do that for general n, but it is easy to check for the first 50 values that the determinant of the system is not zero, with its modulus monotonically increasing with n. Thus we conjecture that there are no values of n for which a solution exists.

When the double root becomes triple, it also becomes a pole of the third order of the function $r(x)$. This means that only the second case of Kovacic's algorithm needs to be considered, but it yields no Liouvillian solutions.

It is impossible for $W(x)$ to have two double roots or a quadruple root, because as we noted the sum of all roots must be zero, and that would lead to $\Omega_{m0}=0$.

Letting $\Omega_{r0}=0$ changes the multiplicity of $x=0$ as a singular point, and the monodromy argument no longer holds. We note also that no further increase in the multiplicity of that point is possible as $\Omega_{m0}\neq 0$.

Assuming first that there are no multiple roots of $W(x)$, the algorithm immediately yields the following fundamental solutions:

$$y_1(x) = x^{-3/2}\sqrt{\Omega_{\Lambda 0}x^3 + \Omega_{K0}x + \Omega_{m0}},$$
$$y_2(x) = y_1(x)\int \left(\frac{x}{\Omega_{\Lambda 0}x^3 + \Omega_{K0}x + \Omega_{m0}}\right)^{3/2} \mathrm{d}x, \tag{39}$$

which holds even if one of the roots becomes double. This solution is also known, and was found by Heath.[9]

As above, a triple root would mean $\Omega_{m0}=0$ and is thus not physical.

VI. ON MORE GENERAL SOLUTIONS

Although the concept of Liouvillian solutions gives us a simple and applicable formulation of solvability by quadratures, it is easily seen to be insufficient on itself as a mean to discard an equation as insolvable in general. The fact that the Bessel or hypergeometric functions (except for some special cases) are not Liouvillian is the best example of that.

Of course, there are no algorithms for finding more complex solutions, but it is possible to extend the considered class somewhat. Following the paper of Bronstein,[10] we try to find solutions in the form

$$y_1(x) = m(x)F_1[\xi(x)],$$
$$y_2(x) = m(x)F_2[\xi(x)], \tag{40}$$

where $F_1(\xi)$ and $F_2(\xi)$ are fundamental solutions of a given target equation

$$y''(\xi) = u(\xi)y(\xi), \tag{41}$$

and $m(x)$ and $\xi(x)$ are Liouvillian over $\mathbb{C}(x)$. The quoted paper presents an algorithmic approach for target equations which have an irregular singularity at infinity, and $\xi(x)\in\mathbb{C}(x)$. It also offers a check for a certain class of algebraic $\xi(x)$.

Upon substituting the form of solutions (40) into Eq. (18), and using the target equation (41), we are left with an expression containing only $F(\xi)$ and $F'(\xi)$. Making the coefficients equal to zero gives the fundamental equations to be solved

$$3\xi''(x)^2 - 2\xi'''(x)\xi'(x) + 4u[\xi(x)]\xi'(x)^4 - 4r(x)\xi'(x)^2 = 0, \tag{42}$$

$$m(x) = \frac{1}{\sqrt{\xi'(x)}}. \tag{43}$$

The main theorem of Ref. 10 makes it possible to find all rational solutions of Eq. (42), by bounding the degrees of the polynomials involved.

Theorem 1: *Let* $\Pi_i Q_i^i$ *be the square-free decomposition of the denominator of* $r \in \mathbb{C}(x)$. *If the order of* $u(x)$ *at infinity* $\nu_\infty(u) < 2$, *then any solution* $\xi \in \mathbb{C}(x)$ *of (42) can be written as* $\xi = P/Q$ *where*

$$Q = \prod_i Q^i_{(2-\nu_\infty(u))i+2} \in \mathbb{C}[x], \tag{44}$$

and $P \in C[x]$ *is such that either* $\deg(P) \leqslant \deg(Q)+1$ *or*

$$\deg(P) = \deg(Q) + \frac{2-\nu_\infty(r)}{2-\nu_\infty(u)}. \tag{45}$$

For the algebraic case, they also provide a possible (but not exhaustive) ansatz of the form

$$\xi(x) = P(x^{1/(2-\nu_\infty(u))}) \prod_{i>2} Q_i^{(i-2)(2-\nu_\infty(u))}, \tag{46}$$

and a bound for $\deg(P)$ of either

$$\deg(P) < (2-\nu_\infty(u))(\deg(Q)+2)$$

or

$$\deg(P) = (2-\nu_\infty(u))\deg(Q) + 2 - \nu_\infty(r).$$

Here, we choose to investigate the Bessel and Kummer functions, as the solutions of the target equation. The other classical classes of ${}_0F_1$ and ${}_1F_1$ functions, to which Theorem 1 is applicable, are equivalent to these two classes, rationally or algebraically.

In the general case of $\Omega_{\Lambda 0} \neq 0$, and no multiple roots of $W(x)$, the denominator of $r(x)$ is $16x^2W(x)^2$, and hence its square-free decomposition has only one term $Q_2 = xW(x)$. We take first the Bessel equation,

$$F''(\xi) = \left(\frac{4n^2-1}{4\xi^2} - \epsilon\right) F(\xi), \tag{47}$$

where ϵ is 1 for the Bessel and -1 for modified Bessel functions. We have $\nu_\infty(u) = 0$, and $\nu_\infty(r) = 2$, so

$$Q = \prod_i Q^i_{2i+2} = 1, \tag{48}$$

and $\deg(P) \leqslant 1$. Finally, substituting $\xi(x) = c_1 x + c_0$ into Eq. (42) yields no nonconstant solutions.

Proceeding in the same way, for Kummer functions, algebraic forms of $\xi(x)$, and possible cases of the roots of $W(x)$, we found no new solutions of this more general class.

Thus, we can finally formulate the main results as the following theorem.

Theorem 2: *If* $\Omega_{m0} > 0$, $\Omega_{r0} \geqslant 0$, $\Omega_{K0} \in \mathbb{R}$, *and* $\Omega_{\Lambda 0} \in \mathbb{R}$ [*unless* $W(x)$ *admits a double root, which requires the assumption of* $\Omega_{\Lambda 0} \geqslant 0$], *then the matter density perturbation equation (14) does not possess any solutions Liouvillian over* $\mathbb{C}(x)$, *or, in other words, is not solvable by quadratures, except for the following three cases*:

(1) *Heath's solution* ($\Omega_{r0} = 0$). *It is given by (39), for* $\Omega_{\Lambda 0} \neq 0$, *and by (33), when* $\Omega_{\Lambda 0} = 0$.
(2) *Meszaros's solution* ($\Omega_{K0} = 0$, $\Omega_{\Lambda 0} = 0$). *Given by (35).*
(3) *Matter only* ($\Omega_{\Lambda 0} = \Omega_{r0} = \Omega_{K0} = 0, \Omega_{m0} = 1$). *Given by (36).*

Moreover, there exist no solutions of the class $m(x)F[\xi(x)]$, *where* $F(\xi)$ *is a classical special function of the type* ${}_0F_1$ *or* ${}_1F_1$, $m(x)$ *is Liouvillian over* $\mathbb{C}(x)$, *and* $\xi(x) \in C(x)$ *or is algebraic of the form (46).*

However, when $\Omega_{\Lambda 0}=0$ *and* $W(x)$ *admits a double root, the non-Liouvillian solution of Chernin's, given by (30), applies.*

VII. CONCLUSIONS

The problem studied in this paper is a good example of a possible application of the differential Galois theory in practice. The known solution of the perturbation equation were originally discovered in different contexts and over the span of a few years, whereas here, one theory allows for full analysis.

Furthermore, the existence of other closed-form solutions has been ruled out. The one exception is the case of a double root of $W(x)$, when the cosmological constant is negative. Although Λ is usually assumed to be positive now, it still remains a viable mathematical possibility. However, we expect that case will not yield any new solutions, as the "manual" check for the first, simplest candidates failed.

Despite the fact that the analysis of perturbations can be performed numerically, without the need of explicit solutions, we feel that a more exact approach is always valuable—providing a better understanding of the complexity of the problem, revealing hidden, special solutions, or simply providing a more exact formula for numerical work. It also reflects, in some sense, the fact that general relativity, as the next step in the theory of gravitation, introduces nonintegrability into the basic equations. This can be seen clearly in a more advanced employment of the Galois theory applied to cosmological models themselves, for example, Refs. 1 and 11.

From the physical point of view, this model is a relatively simple one, and it is already known that the solutions found are not on themselves strong enough to explain the density fluctuations levels today. The main problem is the fact that they would need to be exponential, whereas they grow at most like a fixed power of the scale factor, and there is not enough time for the initial perturbations to increase sufficiently. One must also be aware that linear instability might be dumped when considered in the quadratic regime, so the least to be required of the linear equation's solutions is appropriate amplification. Nevertheless, these basic effects, being the first approximation, have physical meaning and should be taken into account when constructing more complicated models or explaining observational data.

We hope to investigate this field further in the future, as it does not limit the results to negative statements on integrability only, as we tried to demonstrate in this paper.

Analytical integrability and physical solutions of *d*-KdV equation

P. K. Karmakar[a] and C. B. Dwivedi
Centre of Plasma Physics, Tepesia, Sonapur, Guwahati-482 402, Assam, Bharat

(Received 10 November 2005; accepted 16 January 2006; published online 7 March 2006)

A new idea of electron inertia-induced ion sound wave excitation for *transonic plasma* equilibrium has already been reported. In such unstable plasma equilibrium, a linear source driven Korteweg-de Vries (*d*-KdV) equation describes the nonlinear ion sound wave propagation behavior. By numerical techniques, two distinct classes of solution (*soliton* and *oscillatory shocklike* structures) are obtained. Present contribution deals with the systematic methodological efforts to find out its (*d*-KdV) analytical solutions. As a first step, we apply the Painleve method to test whether the derived *d*-KdV equation is analytically integrable or not. We find that the derived *d*-KdV equation is indeed analytically integrable since it satisfies Painleve property. Hirota's bilinearization method and the modified *sine-Gordon* method (also termed as *sine-cosine* method) are used to derive the analytical results. Perturbative technique is also applied to find out quasistationary solutions. A few graphical plots are provided to offer a glimpse of the structural profiles obtained by different methods applied. It is conjectured that these solutions may open a new scope of *acoustic spectroscopy* in plasma hydrodynamics. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2173087]

I. INTRODUCTION

Recently, we have discovered an interesting property of a theoretically defined *transonic plasma* system, assumed to have hydrodynamic equilibrium configuration of physical interest.[1–3] Local normal mode theory defines the desired length of the theoretical transonic plasma system. The ion flow gradient is assumed to be weak enough so as to justify the uniform ion flow motion over the defined transonic plasma length. Of course, the equilibrium charge neutrality condition limits the range of allowed Mach number domain of plasma flows in transonic equilibrium. Self-similar plasma expansion[4] into vacuum may be a good example of transonic plasma flow under plasma approximation. Likewise, the solar wind plasmas are also of the category of self-similar plasma flow motion. The transonic plasma layer, in laboratory plasmas, exists near the Debye sheath edge created by plasma-boundary wall interaction processes. This is supposed to patch the Debye sheath layer on one end and the presheath layer on the other end.

According to our own proposed inertia-induced ion acoustic excitation theory, we argue that the large-scale plasma flow motion feeds the energy to the short scale fluctuations near the pre-sheath termination at sonic point. This is a kind of energy transfer process from large-scale flow energy to wave energy through short scale instability. In order to maintain the turbulence equilibrium there must be some source to feed large-scale flow and sink to arrest the infinite growth of the excited short waves. The growing wave energy could be used to remodify the global transonic equilibrium such that the transonic transition becomes a natural equilibrium with smooth change in flow motion from subsonic to supersonic. Of course, this is a quite involved problem to

[a]Electronic mail: pralaykarmakar@sify.com

handle the self-consistent turbulence theory of transonic plasma in terms of anomalous transport. Now the question arises, how to produce such boundary layer with sufficient size of the transonic plasma layer for laboratory experimentations?

This is an experimental challenge to design such experiments to produce extended length of the transonic zone to sufficient extent to resolve the desired unstable wave spectral components. Creation of a thick boundary layer of transonic flow dynamics is, no doubt, an important task. This zone lies between subsonic and supersonic domains and is bounded by low supersonic and high subsonic speeds. Mind it, here the sonic velocity corresponds to the phase velocity of the bulk plasma mode of the dispersionless ion acoustic wave. In case of sheath edge boundary, transonic layer could be probed by high-resolving diagnosis of the Debye length order. The desired experiments of spectral analysis of the unstable ion acoustic waves in *transonic plasma condition* may be quite useful to resolve the mystery of sheath edge singularity. Using *de-Lavel nozzle mechanism* of hydrodynamic flow motion, experiments could be designed to produce transonic transition layer of desired length.

Study of the ambient acoustic spectrum associated with plasma flow motion can be termed as the *acoustic spectroscopy* of equilibrium plasma flows. This may be useful for expanding background plasmas,[4] solar wind plasmas[5] and also in space plasmas through which the space vehicles' motion and aerodynamic motion[5] occur. Basic principles of the acoustic spectroscopy have concern to the linear and nonlinear ion acoustic wave turbulence theory and properties of the transonic plasma equilibrium.[4,6] These properties may be used to develop the required diagnostic tools to study and describe the hydrodynamic equilibrium states of plasma flows by suitable observations and analysis of the waves and instabilities they exhibit. In fact, the ambient turbulence-driven plasma flow is quite natural to occur in toroidal and poloidal directions of the magnetic confinement of tokamak device. Similar physical mechanism is supposed to be operative in the transonic transition behavior of equilibrium plasma flow motion. Thorough investigations of acoustic wave turbulence theory in transonic plasma condition will be needed.

Recently, there has been an outburst of interest in plasma states where the assumption of static equilibrium practically is violated. Great deals of research activities are now going on in transonic and supersonic magnetohydrodynamic flows in laboratory and astrophysical plasmas.[5] Similar activities are also important for understanding the designing of supersonic aerodynamics[7] having relevance in spacecraft-based laboratory experimentations of space plasma research as well. It is also argued that future tokamak reactors need the consideration of rotation of fusion plasma with high speeds that do not permit the assumption of static equilibrium to hold good. This may be brought about due to neutral beam heating and pumped divertor action for the extraction of heat and exhaust.

In astrophysics, the primary importance of plasma flows is revealed in such diverse situations as coronal flux tubes, stellar winds, rotating accretion disks, and jets emitted from radio galaxies. The main point is to argue that the basic understanding of the acoustic wave dynamics in transonic plasma system constitutes an important subject of future interdisciplinary research. This may be useful for development of the appropriate diagnostics for acoustic spectroscopy to measure and characterize the hydrodynamic equilibrium of transonic plasmas.

Consideration of the Boltzmannian electrons for ion acoustic wave description is no more practical in such plasma equilibrium. For example, it hides the unstable behavior of the ion acoustic wave fluctuations in transonic plasma equilibrium. For simple monoenergetic but uniform ion flow dynamics, it is predicted that the ion acoustic wave remains no more stable in transonic plasma condition. It suffers linear resonant growth[1] of explosive type due to linear process of resonance mode-mode coupling of positive and negative energy waves.[2] It is thus natural to argue that the acoustic wave turbulence should constitute the unique property of the transonic plasma system in the absence of magnetic and gravitational force fields. It is further argued that the conventional idea of Bohm condition for stable sheath formation requires a fresh review. Similar outlook is needed to understand the formation of other nonlinear localized structures of low frequency acoustic waves like solitons, double layers, etc.

The lowest order nonlinear wave theory of the ion acoustic wave dynamics predicts that the

usual KdV equation is not suitable to describe the kinetics of the nonlinear traveling ion acoustic waves in transonic plasma condition.[3] The *d*-KdV equation is prescribed as a more suitable nonlinear differential equation to describe the nonlinear traveling ion acoustic wave dynamics in transonic plasma condition. By mathematical structure of the derived *d*-KdV equation, it looks analytically nonintegrable and physically nonconservative dynamical system. Due to the linear source term, an additional class of nonlinear traveling wave solution of oscillatory shocklike nature is obtained. This is more prominent in the shorter scale domain of the unstable ion acoustic wave spectrum but within the validity limit of weak nonlinearity and weak dispersion. Researchers having interest in the subject are advised to read our earlier presentations for details.[1–3]

In this contribution, we make specific methodological attempts to analytically solve the *d*-KdV equation to reproduce our own predicted numerical results. We first apply the well-known Painleve method[8–14] of mathematical calculations to check the mathematical possibility of finding its analytical solutions. We find that it is indeed analytically integrable. In the process, Hirota's bilinear transformation[14,15] is obtained for analytical solutions. We then proceed further and apply the mathematical technique of *sine-cosine* method (also known as *modified sine-Gordon method*)[16,17] to derive the desired analytical solutions. Solution obtained by this method is akin to the linear superposition of two distinct nonlinear stationary waves. In the asymptotic limit of long wavelength of the driving source term, usual KdV soliton solution is recovered. For shorter wavelengths of the linear driving source, shock-dominated solution is found without any oscillatory character. But, due to limitations of the available mathematical tools, only approximate results are possible.

Quasistationary solutions with the well-known *perturbative technique*[18,19] are also derived. Physical significance of *quasistationarity* means that the amplitudes of the solutions are slowly varying and they are free from any secular terms in the asymptotic expansion of dynamical variables. In fact, as per required relative accuracy, the analytical results obtained by all these different mathematical methods are graphically compared. In all the cases a linear superposition of shock and soliton is obtained. Thus the numerical solutions[2] are partially verified with the help of obtained analytical findings. Absence of the oscillations in graphical representation of the shock-dominated solution may be attributed to the limitations of the applied mathematical tools. This provides further scope for suitable improvement of existing mathematical methods to produce the oscillatory shocklike solutions that comprise of oscillatory peaks in the shock-dominated solution. That means the well-defined (explicit) functional form of oscillatory shocklike solution is still unknown. This forms a good mathematical problem for future research work.

Contents of this research paper are organized as follows. Section II includes general physical discussions on integrability of the *d*-KdV equation. Section III highlights the methodology of analytical integration and derivation of the exact analytical (traveling wave) solutions. Section IV includes the results and discussions obtained thereof. Last, Sec. V contains a compact summary of the conclusions drawn from this present contribution.

II. INTEGRABILITY TEST OF *d*-KdV EQUATION

Actually, the concept of integrability is not well defined in mathematical sense. However, the question of integrable nonlinear dynamical equations could be associated with the following conceptual view of the unknown solutions. It is basically a mathematical property of the function of the unknown solutions of the given nonlinear dynamical equation. It is used to enhance the predictive ability of the given nonlinear equation to provide more and more quantitative and qualitative informations regarding the governing dynamical physical systems. There are two well-known broad notions as defined and discussed in mathematical literature.[8–14] We have used the notion of integrability in the complex time plane, which is now called the Painleve property. Fixed singularities occur at points where the coefficients of the equation are singular.[8–14] The ordinary differential system is said to possess the Painleve property when all the movable singularities are single valued (simple poles).

More briefly, a dynamical evolution equation is said to satisfy the Painleve property[9] when the solutions of the equation are single valued about the movable singularity manifold and the singu-

larity manifold is noncharacteristic. Theoretically speaking, a given dynamical evolution equation is said to have analytical integrability if it can have the reduced structures like mathematical forms of the Painleve transcendents[11] after proper mathematical transformations. The next section deals with the mathematical derivations of the Painleve property to predict integrable and conservative dynamical behavior of the *d*-KdV equation having self-consistent linear driving source term. This is to point out that this equation is an outcome of our own theoretical derivations[2,3] while describing the nonlinear ion acoustic wave dynamics in transonic plasma system.

A. Basic governing equations

For the sake of instant reference for readers of this paper, the self-consistently closed set of basic governing equations for fluid description of transonic plasma system in normalized form is given as follows.

Electron continuity equation

$$\frac{\partial \phi}{\partial t} + v_e \cdot \frac{\partial \phi}{\partial x} + \frac{\partial v_e}{\partial x} = 0. \tag{1}$$

Electron momentum equation

$$\frac{m_e}{m_i}\left(\frac{\partial v_e}{\partial t} + v_e \cdot \frac{\partial v_e}{\partial x}\right) = \frac{\partial \phi}{\partial x} - \frac{1}{n_e}\frac{\partial n_e}{\partial x}. \tag{2}$$

This is to remind the readers that this equation is obtained by substituting zero-order solution of Boltzmann electron density distribution into the normal electron continuity equation. In fact, in the asymptotic limit of $m_e/m_i \to 0$, electron continuity equation as such is redundant because the left-hand side (electron inertial effect) of (2) is ignorable. Equation (1) basically offers a scope to introduce the weak but finite role of electron to ion inertial mass ratio on the normal mode behavior of the ion acoustic wave.

Ion continuity equation

$$\frac{\partial n_i}{\partial t} + \frac{\partial}{\partial x}(n_i v_i) = 0. \tag{3}$$

Ion momentum equation

$$\frac{\mathrm{d}v_i}{\mathrm{d}t} = -\frac{\partial \phi}{\partial x}. \tag{4}$$

Poisson equation

$$\frac{\partial^2 \phi}{\partial x^2} = n_e - n_i. \tag{5}$$

Our previous theoretical calculations of linear ion acoustic wave analysis[1,2] provide a clear-cut idea of the possible existence of linear ion acoustic wave turbulence in transonic zone of plasma flows within fluid model approach. The following form of the derived *d*-KdV equation[3] obtained by reductive perturbation method then describes the nonlinear ion acoustic wave dynamics under transient limit:

$$K_0 \frac{\partial \phi}{\partial t} + M_0 \phi \frac{\partial \phi}{\partial x} + \frac{1}{2}\frac{\partial^3 \phi}{\partial x^3} = \gamma K_0 \phi. \tag{6}$$

Here the notations K_0 and M_0 termed as *complex response coefficients*[3] and the linear resonant growth rate (γ) of the ion acoustic wave appearing in Eq. (6) are defined as follows:

$$K_0 = [A^2 + B^2]^{1/2},$$

where

$$A = \left(\frac{M_r}{\varepsilon_m} + \frac{M_{Dr}^3 - 3M_{Dr}M_i^2}{(M_{Dr}^2 + M_i^2)^3} \right)$$

and

$$B = \left(\frac{M_i}{\varepsilon_m} + \frac{M_i^3 - 3M_{Dr}^2 M_i}{(M_{Dr}^2 + M_i^2)^3} \right),$$

$$M_0 = [C^2 + D^2]^{1/2},$$

where

$$C = \frac{1}{2}\left[\frac{3\{(M_{Dr}^2 - M_i^2)^2 - 4M_{Dr}^2 M_i^2\}}{(M_{Dr}^2 + M_i^2)^4} - \frac{(M_r^2 - M_i^2)^2 - 4M_r^2 M_i^2}{\varepsilon_m^2} - 1 \right]$$

and

$$D = -\frac{1}{2}\left\{ \frac{12(M_{Dr}^2 - M_i^2)M_{Dr}M_i}{(M_{Dr}^2 + M_i^2)^4} + \frac{4(M_r^2 - M_i^2)M_r M_i}{\varepsilon_m^2} \right\},$$

$$\gamma = \sqrt{2\left(\frac{m_i}{m_e}\right)} k\lambda_{De} |(1 - v_{i0})^{1/2}|.$$

Here the notation M_{Dr} represents for the real part of Doppler shifted ion sound wave Mach number and M_i represents for the imaginary part of the same and is correlated to the linear growth rate as discussed earlier.[3] The other notations like $k\lambda_{De}$ and v_{io} represent for the normalized acoustic wave number and equilibrium ion fluid flow velocity of the transonic plasma, respectively. Likewise, the notation defined as $\varepsilon_m = m_i/m_e$ denotes for the ion to electron mass ratio. Here it will be pertinent to comment that in our defined plasma system, the plasma ions are self-consistently drifting or streaming through a negative neutralizing background of hot electrons having relatively zero inertia. As such the time response of the electron fluid for ion sound wave description is normally ignored. As a result, the unique role of finite but weak electron inertia having an ability to destabilize the ion sound wave in transonic plasma equilibrium even within fluid model approach of normal mode description is masked.

Physical description of our proposed excitation theory of ion sound wave in transonic plasma equilibrium differs from those of the others (Refs. 20–24) to drive the same ion acoustic wave instability. Driving physics suggests that even a slight temporal delay of thermal electrons that offer instantaneous response to the ion sound wave potential fluctuations may cause a resonant explosive growth[1,2] if the ion flow velocity falls within the transonic domain of quasineutral plasma flow motion. In fact, an appropriate phase difference between the ion density and electron density perturbations are introduced so as to yield the growth. Contributions of other sources of ion sound wave instability driving may, however, be evaluated by the relative comparison of the growth rates and ion sound excitation thresholds.

B. Comments on derivation of *d*-KdV equation

In our earlier presentation,[3] the invariance property of stretched coordinates is assumed to hold good during transient time effect of the instability. This results into Eq. (6) with the stretched coordinate system defined by $\xi = \varepsilon^{1/2}(x - Mt)$ and $\tau = \varepsilon^{3/2}t$ where x and t are normalized forms. This can be justified as follows. Due to linear instability, Mach number M that defines the ratio of nonlinear phase velocity and ion sound speed becomes complex, i.e., $M = M_r + iM_i$. As a result,

$\xi_r=\varepsilon^{1/2}(x-M_r t)$ and $\xi_i=-\varepsilon^{1/2}M_i t$, where $\varepsilon=k^2\lambda_{De}^2$. If we define the transient time as $t=t_t\sim\varepsilon^{-1/2}\sim 1/k\lambda_{De}\sim X_\omega$, then $\xi_i=-M_i$ and the corresponding differential operators (under Galilean transformations) are transformed as follows: $\partial/\partial x\equiv\varepsilon^{1/2}\partial/\partial\xi_r$ and $\partial/\partial t\equiv -M_r\varepsilon^{1/2}\partial/\partial\xi_r+\varepsilon^{3/2}\partial/\partial\tau$. This implies that the differential operators remain invariant during transient effect of the instability on global structure of the nonlinear traveling wave solution.

Let us now consider the cyclic behavior of the space coordinate in Galilean frame of solitary wave and assume circular geometry to define $\xi=\xi_0 e^{i\alpha(t)}$ in time domain. Now for $M_i<1$, $\alpha(t)=\tan^{-1}(\xi_i/\xi_r)\sim(-M_i/X_\omega)=-M_i$ for $X_\omega\sim 1$, where $\varepsilon^{1/2}(x-M_r t)\sim X_\omega$ is the rescaled width of the solitary wave. The radius of the considered circular geometry is given by

$$\xi_0=\xi_r(1+\xi_i^2/\xi_r^2)^{1/2}\sim\varepsilon^{1/2}(x-M_r t)(1+\alpha^2)^{1/2}\sim\xi_r \quad \text{for } |\alpha|<1.$$

Thus under the defined circular geometry under the conditions $M_i<1$ and, one gets the following values of the phase angles β for K_0 and γ for M_0 as follows:

$$\beta=\tan^{-1}(B/A)=\tan^{-1}(-3M_i/1)\sim -3M_i,$$

$$\gamma=\tan^{-1}(D/C)=\tan^{-1}(-6M_i/1)\sim -6M_i.$$

These estimations of α, β, and γ are made for resonant conditions $M_{Dr}\sim 1$ for ion acoustic wave excitation. It is notable that $\alpha\sim\beta\sim\gamma<1$ within an order of magnitude. It is thus found that in the above limiting cases of the global phase transformation method (GPTM),[3] the compact form of the linear source driven KdV (d-KdV) equation is well verified and justified.

C. Painleve test of *d*-KdV equation

Now let us look into the details of the methodological description of the Painleve property of the derived d-KdV equation from these basic equations. Following the prescribed mathematical procedure, we will now prove that the d-KdV equation satisfies the Painleve property. The assumed Laurent's series expansion of the unknown solution of Eq. (6) around singularity (near singularity and not at singularity) as a function of singularity manifold $f(x,t)\neq 0$ is given as follows:

$$\phi=\sum_{j=0}^{\infty}\phi_j f^{j+\alpha}. \tag{7}$$

After substituting this expression into Eq. (6) and following the basic principle of homogeneity of leading order analysis (balancing the highest order contributions from the linear and nonlinear terms of the d-KdV equation), we get $\alpha=-2$ under the soliton formation condition of nonlinearity balanced by dispersion.

Now substituting the various differential terms obtained from (7) into Eq. (6) and collecting the coefficients of the power of f^{j-5} from each term, we get what is known as the *recurrence relation* (RR) and can be set in the more compact form as follows:

$$\begin{aligned}K_0\{\phi_{j-3,t}+\phi_{j-2}(j-4)f_t\}+M_0\left[\sum_{k=0}^{j}\phi_{j-k}\{f_{k-1,x}+(k-2)\phi_k f_x\}\right]+\frac{1}{2}[\phi_{j-3,xxx}+3\phi_{j-2,xx}(j-4)f_x\\ +3\phi_{j-1,x}(j-3)(j-4)f_x^2+3\phi_{j-2,x}(j-4)f_{xx}+3\phi_{j-1}(j-3)(j-4)f_x f_{xx}\\ +\phi_j(j-2)(j-3)(j-4)f_x^3+\phi_{j-2}(j-4)f_{xxx}]=\gamma K_0\phi_{j-3}.\end{aligned} \tag{8}$$

From this recurrence relation of general nature, one can generate order-by-order equations for different cases of j values.

Case (1): For $j=0$, we get from (8),

$$\phi_0 = -\left(\frac{6}{M_0}\right) f_x^2. \tag{9}$$

Case (2): For $j=1$, we get from (8),

$$\phi_1 = \left(\frac{6}{M_0}\right) \phi_{xx}. \tag{10}$$

Case (3): For $j=2$, we get from (8),

$$\frac{K_0}{M_0}(f_x f_t) + \frac{2}{M_0}(f_x f_{xxx}) - \frac{3}{2M_0} f_{xx}^2 + \phi_2 f_x^2 = 0. \tag{11}$$

Case (4): For $j=3$, we get from (8),

$$f_{xt} - \frac{M_0}{K_0}\phi_3 f_x^2 + \frac{1}{2K_0} f_{xxxx} + \frac{M_0}{K_0}\phi_2 f_{xx} = \gamma f_x. \tag{12}$$

Case 5: For $j=4$, we get from (8),

$$\frac{\partial}{\partial x}\left[f_{xt} - \frac{M_0}{K_0}\phi_3 f_x^2 + \frac{1}{2K_0} f_{xxxx} + \frac{M_0}{K_0}\phi_2 f_{xx} - \gamma f_x \right] = 0. \tag{13}$$

The arbitrary function is chosen such that $\phi_j = 0 \forall j \geqslant 3$ (closure property depending on the highest order of differentiation $j=3$ for d-KdV equation). It is noteworthy that the equation (13) with the help of condition (12) is known as the *compatibility condition* for d-KdV equation (6). This is also noted from the transcendental equations (11) and (12) that the recurrence relations for $j \geqslant 3$ are modified by an additional term proportional to linear growth rate (γ) of the ion acoustic wave instability in transonic plasma system.

Now collecting all the terms involving ϕ_j from (8), we determine the locations of the resonant terms (termed as the *resonances*) as follows:

$$M_0\phi_0\phi_j(j-4)f_x + \tfrac{1}{2}\{\phi_j(j-2)(j-3)(j-4)f_x^3\} = 0 \Rightarrow \tfrac{1}{2}(j+1)(j-4)(j-6)\phi_j f_x^3 = 0$$

$$\Rightarrow j = -1, 4, 6 (\text{resonances}). \tag{14}$$

This is to note that the resonances[8–14] at $j=-1,4,6$ are obtained by substituting the value of ϕ_0 in the above identity of Eq. (14). At these values of j the function ϕ_j is allowed to have arbitrary values. Now the solution can be shown to allow the Bäcklund transformation as given below,

$$\phi = \sum_{j=0}^{2} \phi_j f^{j-2} = \phi_0 f^{-2} + \phi_1 f^{-1} + \phi_2,$$

$$\phi = -\left(\frac{6}{M_0}\right)\frac{f_x^2}{f^2} + \frac{\phi_1}{f} + \phi_2,$$

$$\phi = \left(\frac{6}{M_0}\right)\frac{\partial^2}{\partial x^2}[(\ln(f))] + \phi_2. \tag{15}$$

It is now methodologically proved that the derived d-KdV equation of our concern satisfies the Painleve properties. That means that the assumed solutions are free from movable singularity and hence the d-KdV equation is, indeed, analytically integrable and solvable. Thus the equation (15) represents a form of analytical solution in terms of assumed singularity manifold. However, the

exact nature of the singularity manifold has been neither identified nor characterized analytically for explicit solutions.

D. Properties of *d*-KdV equation

One can now show that the deduced *d*-KdV equation derived for physical situation of *transonic plasma* system possesses the properties of integrable dynamical systems with sufficient number of conserved quantities.[14] The sufficiency of conserved quantities, however, depends on the order of the dynamical evolution equation describing the system. This is to remind the readers that for simplicity, the transonic plasma of infinite extension is assumed. Of course, realistic situation of laboratory produced transonic plasma will require nonlocal theory within fluid and Vlasov models. Moreover, detailed study will be required to develop an appropriate theory of saturation mechanism through turbulence production or otherwise. Other complexities like presence of external forces and collisions, etc., may be included to provide a wide range scanning of plasma and flow parameter domains to test the effect on the proposed excitation theory of ion sound wave.

1. Bäcklund transformations

A Bäcklund transformation (BT) is defined as a mathematical transformation that connects the same or distinct analytical solutions of two differential equations. If the transformation, however, connects two distinct solutions of the same differential equation, it is termed as the auto-Bäcklund transformation (*a*-BT). A BT[13] for the *d*-KdV equation (6) is obtained from the equation (15) with $\phi_2 \neq 0$ ($\phi_2=0$ for Hirota's bilinear transformation) as follows:

$$\phi = -\left(\frac{6}{M_0}\right)\frac{f_x^2}{f^2} + \frac{\phi_1}{f} + \phi_2. \tag{16}$$

It gives a mathematical idea of how the arbitrary function (f) enters the assumed solution of Eq. (6).

2. Lax pair

Now for our *d*-KdV equation (6), we can construct two canonically conjugate operators corresponding to the *invariance property* of usual KdV equation in absence of any driving source under Galilean transformations. These two operators (designated as L and B as given below) together form what is known as Lax pair and the connecting mathematical equation is termed as Lax equation of the *d*-KdV equation,

$$L = \frac{1}{2K_0}\frac{\partial^2}{\partial x^2} + \left(\frac{M_0}{K_0}\right)\phi I, \tag{17}$$

$$B = -\frac{2}{K_0}\frac{\partial^3}{\partial x^3} - \frac{M_0}{2K_0}\left(\phi\frac{\partial}{\partial x} + \frac{\partial}{\partial x}\phi\right), \tag{18}$$

$$\frac{\partial L}{\partial t} = [L,B]. \tag{19}$$

This equation (19) is known as the Lax equation[11,14] in terms of the Lax pair (Lax operators) L and B, which can be termed as the Lax equivalence of the derived *d*-KdV equation with I as an identity operator. In mathematical language, the existence of Lax pair is a decisive criterion for integrable systems. If L is time independent, one gets a commutator $[L,B]=0$ signifying a conservative and integrable dynamical system.

III. ANALYTICAL SOLUTIONS OF *d*-KdV EQUATION

Now it is clear that the *d*-KdV equation is integrable and hence one can, in principle, find out its analytical solutions. Analytical solution of a given dynamical equation means to derive the well-defined (explicit) functional form of the solution that satisfies the given equation. It is indeed difficult to analytically solve it in space and time domain as two-dimensional (2D) problem. To simplify the situation, we look for the steady state solution. For this we apply Galilean transformation to reduce 2D form of the nonlinear differential *d*-KdV equation into one-dimensional (1D) form of nonlinear differential equation. After that, we apply the sine-cosine method as discussed earlier[16,17] to derive analytical solutions of the steady state *d*-KdV.

A. Application of Hirota bilinear transformation method

The analytical transformation depicted by the equation (15) under the arbitrary condition of $\phi_2=0$ is known as Hirota's bilinear transformation.[14,15] The mathematical significance of bilinear is that the sum of the various powers of f in each term of the transformed differential equation (as follows) is equal to 2. After replacing the various differential terms of the equation (6) with the help of (15), we get the following transformed equation:

$$K_0\left[\frac{f_{xxt}}{f}-\frac{f_{xx}f_t}{f^2}-2\frac{f_xf_{xt}}{f^2}+2\frac{f_x^2f_t}{f^2}\right]+\frac{f_{xx}f_{xxx}}{f^2}-3\frac{f_xf_{xx}^2}{f^3}+4\frac{f_x^2f_{xxx}}{f^3}+\frac{1}{2}\frac{f_{xxxxx}}{f}-\frac{5}{2}\frac{f_xf_{xxxx}}{f^2}-48\frac{f_x^3f_{xx}}{f^4}$$
$$=\gamma K_0\frac{f_{xx}}{f}-\gamma K_0\frac{f_x^2}{f^2}. \tag{20}$$

Now, let us apply the reductive (nonlinear) perturbation technique about the vacuum in the form of harmonics in $\varepsilon(\ll 1)$ known as the dispersion strength representing the balancing between weak dispersion and weak nonlinearity, to expand the arbitrarily chosen singularity manifold function ϕ as $f=1+\varepsilon f^{(1)}+\varepsilon^2 f^{(2)}+\cdots$. By the first order analysis (with respect to ε) in the above mathematical method, we get the solution of the *d*-KdV equation (6) for one soliton system as follows:

$$\phi(x,t)=1.5\left(\frac{k^2}{M_0}\right)\sec h^2\left\{\frac{1}{2}(\eta_r+i\eta_i)\right\}. \tag{21}$$

Equation (21) represents analytical (traveling wave) solution of *d*-KdV equation propagating under transonic conditions, ignores to produce the analytical form of oscillatory shocklike structures. From a physical point of view, one may give a conclusion hereof that the argument $(\eta/2)$ of the soliton solution is getting self-consistently transformed into a complex one owing to the complex nature of the ion acoustic propagation vector (k) while passing through the unstable conditions of transonic plasmas. Complex nature of the argument in presence of a linear free energy source in transonic condition is itself a physical signature of the said instability. The real as well as imaginary parts of the complex argument of the KdV soliton are given as follows:

$$\eta_r=kx+\tfrac{1}{2}k^3t,$$

$$\eta_i=-\gamma K_0t.$$

Again, expanding Hirota solution as given by Eq. (21) by well-known expansion formulas of

circular and hyperbolic functions, this solution can be written in the following expanded form:

$$\phi(\eta_r,\eta_i)=1.5\left(\frac{k^2}{M_0}\right)\sec h^2\left\{\frac{1}{2}(\eta_r)\right\}\left[\frac{\cos(\eta_i)+\sin^2\left(\frac{1}{2}\eta_i\right)\sec h^2\left(\frac{1}{2}\eta_r\right)}{1-\sec h^2\left(\frac{1}{2}\eta_r\right)\sin^2\left(\frac{1}{2}\eta_i\right)}\right]-i1.5\left(\frac{k^2}{M_0}\right)\tanh\left\{\frac{1}{2}(\eta_r)\right\}$$
$$\times\left[\frac{\sin(\eta_i)\sec h^2\left(\frac{1}{2}\eta_r\right)}{1-\sec h^2\left(\frac{1}{2}\eta_r\right)\sin^2\left(\frac{1}{2}\eta_i\right)}\right]. \tag{22}$$

Now solution (22) can be simplified in the transient limit of $\eta_i<1$ into the following form:

$$\phi_r(\eta_r,\eta_i)=1.5\left(\frac{k^2}{M_0}\right)\sec h^2\left\{\frac{1}{2}(\eta_r)\right\}, \tag{23}$$

$$\phi_i(\eta_r,\eta_i)=1.5\left(\frac{k^2}{2M_0}\right)\eta_i\sinh(\eta_r)\sec h^4\left\{\frac{1}{2}\eta_r\right\}. \tag{24}$$

It is, however, noticed that the asymmetric structures represented by Eq. (24) fail to produce the expected nature of shocklike solutions. But, of course, the average qualitative features in transonic domains are reflected. And hence, it paves the way for further application of improved mathematical tools for more accurate results.

B. Application of sine-cosine method

Yan[15] developed *sine-cosine* method directly from the modified transformation of famous *sine-Gordon* equation. A new form of nonlinear mathematical transformation is obtained by suitable mathematical tailoring of the sine-Gordon equation. This was applied to solve the usual KdV equation and a new class of solutions was predicted for the usual KdV equation. The same is supposed to be true for other well studied nonlinear dynamical equations too. We apply this method to solve the *d*-KdV equation derived to describe the structural behaviors of nonlinear traveling ion acoustic wave in unique equilibrium condition of transonic plasma system.

This effort is primarily motivated by our own numerical results of the same *d*-KdV equation that predicts the possibility of oscillatory shocklike solution in addition to usual soliton solution. The main issue is to find out the explicit form of analytical solution for the oscillatory shocklike profile. As we will see later that even this method is incapable to yield the desired result. However, an explicit term of shock profile is analytically deduced. As per the mathematical procedure laid down for *sine-cosine* method to solve the usual KdV equation, we express the traveling wave solution of *d*-KdV equation as follows:

$$\phi(\eta)=A_0+\sum_{j=1}^{n}\tanh^{j-1}(\eta)[A_j\tanh(\eta)+B_j\sec h(\eta)], \tag{25}$$

where $\eta=x-t$ and the same is used to numerically solve the *d*-KdV equation to find out the steady state solution in our earlier work.[3] Accordingly, the nonlinear transformation derived from improved sine-Gordon equation (*sine-cosine* method) is given below,

$$\frac{d\omega}{d\eta}=\sin\omega. \tag{26}$$

After integration of Eq. (26), we arrive at the following transformations ($\omega\Leftrightarrow\eta$):

$$\sin(\omega) = \sec h(\eta),$$

$$\cos(\omega) = \tanh(\eta).$$

Now, the principle of homogeneous balancing used for evaluation of the upper limit of summation after equalizing the highest order contributions from the linear as well as nonlinear terms, yields $n=2$ for the equation (6). After using these transformations, the assumed solution (25) can be expressed in a new form as functions of the intermediate variable ω,

$$\phi(\omega) = A_0 + \sum_{j=1}^{n} \cos^{j-1}(\omega)[A_j \cos(\omega) + B_j \sin(\omega)]. \tag{27}$$

Substitution of this solution into the Galilean transformed form of Eq. (6) through the relation $\eta=x-t$ results into a trigonometric identity of algebraic shape. After collecting common terms, the coefficient of each term in the trigonometric identity must vanish. As a result, the following forms of algebraical relationships among the various unknown coefficients appearing in the transformed form of the d-KdV equation are derived by homogeneous equalization of various powers of $\sin^m \omega \cos^n \omega$ from both sides. It will be definitely noticed that there will be existence of some more terms with respect to the usual KdV equation because of the presence of an additional self-consistent source term involving γ in the d-KdV equation.

Constant:

$$A_1\left(1 - \frac{M_0}{K_0}A_0\right) + \frac{A_1}{K_0} - \gamma A_0 = 0.$$

$\sin \omega$:

$$B_2\left(1 - \frac{M_0}{K_0}A_0\right) - \frac{M_0}{K_0}A_1B_1 + \frac{5B_2}{2K_0} - \gamma B_1 = 0.$$

$\cos \omega$:

$$2A_2\left(1 - \frac{M_0}{K_0}A_0\right) - \frac{M_0}{K_0}(A_1^2 - B_1^2 + B_2^2) + \frac{8A_2}{K_0} - \gamma A_1 = 0.$$

$\cos^2 \omega$:

$$-A_1\left(1 - \frac{M_0}{K_0}A_0\right) - 3\frac{M_0}{K_0}\left(A_1A_2 - \frac{4}{3}B_1B_2\right) - \frac{4A_1}{K_0} - \gamma A_2 = 0.$$

$\cos^3 \omega$:

$$-2A_2\left(1 - \frac{M_0}{K_0}A_0\right) + \frac{M_0}{K_0}(A_1^2 - 2A_1^2 - B_1^2 + 3B_2^2) - \frac{20A_2}{K_0} = 0.$$

$\cos^4 \omega$:

$$A_1A_2 - B_1B_2 + \frac{A_1}{M_0} = 0.$$

$\cos^5$:

$$A_2^2 - B_2^2 + \frac{6A_2}{M_0} = 0.$$

$\sin \omega \cos \omega$:

$$-B_1\left(1-\frac{M_0}{K_0}A_0\right)-2\frac{M_0}{K_0}(A_1B_2+A_2B_1)-\frac{5}{2K_0}B_1-\gamma B_2=0.$$

$\sin\omega\cos^2\omega$:

$$-2B_2\left(1-\frac{M_0}{K_0}A_0\right)+\frac{M_0}{K_0}(2A_1B_1-3A_2B_2)-\frac{14}{K_0}B_2=0.$$

$\sin\omega\cos^3\omega$:

$$A_1B_2+A_2B_1+\frac{B_1}{M_0}=0.$$

$\sin\omega\cos^4\omega$:

$$A_2B_2+\frac{3}{M_0}B_2=0.$$

This is to note that a few additional terms in the above recursion equations are appearing due to linear resonant growth effect (γ) of the ion acoustic wave in transonic plasma equilibrium. Solving all these equations for an arbitrary choice of $B_1=0$ and $B_2=0$, we arrive at the following approximate values of the unknown coefficients:

$$A_0=\frac{K_0}{M_0}+\frac{4}{M_0},$$

$$A_1=-\frac{\gamma K_0}{M_0},$$

$$A_2=-\frac{6}{M_0}.$$

The above values of coefficients are calculated under weak dispersion and weak nonlinearity under ignorable resonant growth rate such that $\gamma\neq 0$ and $\gamma^p=0\,\forall\, p>1$. And, otherwise, all the recurrence relations could not be satisfied simultaneously. Last, the exact traveling wave analytical solutions of the *d*-KdV equation as an intermixed superposition of two distinct classes (shock and soliton) can be written as

$$\phi(\eta)=\left(\frac{K_0}{M_0}+\frac{4}{M_0}\right)+\left(-\frac{\gamma K_0}{M_0}\right)\tanh(\eta)+\left(-\frac{6}{M_0}\right)\tanh^2(\eta), \tag{28}$$

$$\phi(x-t)=\left(\frac{K_0}{M_0}-\frac{2}{M_0}\right)+\left[-\frac{\gamma K_0}{M_0}\tanh(x-t)+\frac{6}{M_0}\sec h^2(x-t)\right]. \tag{29}$$

After rescalings with $\phi\rightarrow(K_0/2)\phi$ and $\eta\rightarrow(K_0/2)^{-1/2}\eta$, the solution (29) can be written in the scaled out form as follows:

$$\phi_{SC}(\eta)=a_0\sec h^2\left(\sqrt{\frac{1}{2}K_0}\eta\right)+\left[a_2+a_3\tanh\left(\sqrt{\frac{1}{2}K_0}\eta\right)\right], \tag{30}$$

where $a_0=3K_0/M_0$, $a_1=K_0/2(K_0/M_0-2/M_0)$, and $a_2=-\gamma K_0^2/M_0$.

It is obviously clear from Eq. (30) that there is a linear superposition of both shock (tanh)-like and soliton (sech^2)-ic solutions over some dc background formed by the coherent self-coupling of identical spectral components of ion acoustic wave fluctuations in transonic plasma.

C. Application of perturbative method

New physical but analytically quasistationary solutions have already been obtained by perturbations over usual KdV solitons and solitary waves in a new frame of reference described by a set of fast and slow variables by Kodama *et al.*[18] We apply the same method to find out analytical solutions of the *d*-KdV equation of our concern. This method is actually believed to be motivated for newer and more satisfactory analytical results for a driven KdV system over others.

To apply the perturbative technique,[18,19] first of all, new transformations in terms of fast coordinate (η); and slow coordinates (τ) and (χ) are introduced for quasistationary solutions as follows: $\eta=x-t$, $\tau=\varepsilon t$, and $\chi=\varepsilon x$. These give $\partial\eta/\partial x=1$, $\partial\eta/\partial t=-1$, $\partial\tau/\partial t=\varepsilon$, and $\partial\chi/\partial x=\varepsilon$. Now, for quasistationary character, we assume that the usual potential function is of the form, $\phi=f(\eta,\tau,\varepsilon)=\phi_0+\varepsilon\phi_1+\cdots$, where ϕ_0 is the leading order solution (usual soliton) of the *d*-KdV in absence of the linear growth term, that is treated as perturbation. Then, these results on being substituted on the *d*-KdV equation, order-by-order analyses are performed and integrated to have the desired analytical results.

Now, as already reported in our earlier work,[3] $\varepsilon(\ll 1)$ is a smallness parameter specifying the strength of balancing between nonlinearity and dispersion of the plasma medium, we take $\gamma\equiv\varepsilon$ for the calculations by perturbative technique and substitute $\varepsilon\equiv\gamma$ back finally to get the desired analytical results. This is, of course, not going to change the physical properties of the plasma medium under the approximation of weak nonlinearity and weak dispersion during the lowest order nonlinear expansion of relevant physical variables with respect to leading order ones. With this background, our *d*-KdV equation (6) can now be written as

$$-\frac{\partial}{\partial\eta}(\phi_0+\varepsilon\phi_1+\cdots)+\frac{M_0}{K_0}(\phi_0+\varepsilon\phi_1+\cdots)\frac{\partial}{\partial\eta}(\phi_0+\varepsilon\phi_1+\cdots)+\frac{1}{2K_0}\frac{\partial^3}{\partial\eta^3}(\phi_0+\varepsilon\phi_1+\cdots)$$
$$=\varepsilon(\phi_0+\varepsilon\phi_1+\cdots)-\varepsilon\frac{\partial}{\partial\tau}(\phi_0+\varepsilon\phi_1+\cdots). \tag{31}$$

Now equating the coefficients of $\varepsilon^0,\varepsilon^1$, etc., to zero from both sides of Eq. (31), respectively, we get the following equations:

$$-\frac{\partial\phi_0}{\partial\eta}+\frac{M_0}{K_0}\phi_0\frac{\partial\phi_0}{\partial\eta}+\frac{1}{2K_0}\frac{\partial^3\phi_0}{\partial\eta^3}=0, \tag{32}$$

$$-\frac{\partial\phi_1}{\partial\eta}+\frac{M_0}{K_0}\left(\phi_0\frac{\partial}{\partial\eta}+\frac{\partial}{\partial\eta}\phi_0\right)\phi_1+\frac{1}{2K_0}\frac{\partial^3\phi_1}{\partial\eta^3}=\phi_0-\phi_{0\tau}. \tag{33}$$

The solution of Eq. (32) is the leading order unperturbed solution of Eq. (6), which is a usual soliton having amplitude-width relationship as $A\times w^2=6/M_0$. It is given by

$$\phi_0=3\left(\frac{K_0}{M_0}\right)\sec h^2\left(\sqrt{\frac{1}{2}K_0}\eta\right). \tag{34}$$

Now since we are interested in quasistationary solutions, a new slow variable $a=f(\tau)$ has been introduced for the description of slow amplitude variation such that $3K_0/M_0=4a^2$, that is, $a=\sqrt{3K_0/4M_0}$. Then from the equation (34), one gets

$$\phi_{0\tau}=\frac{a_\tau}{a}[2u_0+\eta u_{0\eta}]. \tag{35}$$

Under the assumption that equation (33) should be free from secular terms and for solutions quasistationary in nature, we equate the integration results of the right-hand side to zero to yield $a(\tau)=a_0\exp(2/3\tau)$. Now, in order to solve, the equation (33) on being substituted with $y=\tanh(a\eta)$ becomes

$$(1-y^2)\frac{d^2\phi_1}{dy^2}-2y\frac{d\phi_1}{dy}+\left[3(3+1)-\frac{4}{1-y^2}\right]\phi_1=\frac{2}{3}\sqrt{\frac{4M_0}{3K_0}}\frac{1}{1+y}+\frac{2}{3}\sqrt{\frac{4M_0}{3K_0}}\ln\left(\frac{1+y}{1-y}\right). \tag{36}$$

Applying the well-known *method of separation of variables*,[18,19] the solution of the equation (36) as a perturbation over usual soliton can be written as

$$\phi_1(\eta)=-\frac{1}{3}\sqrt{\frac{M_0}{3K_0}}[-1+\tanh\,\eta+2(1-\eta\tanh\,\eta)\sec h^2\eta+\eta(2-\eta\tanh\,\eta)\sec h^2\eta]. \tag{37}$$

Thus the total solution $\phi(\eta)=\phi_0(\eta)+\gamma\phi_1(\eta)+\cdots$ of the equation (6) as a superposition of the leading order solution and the perturbation over it obtained by perturbative technique as discussed above, can be written as

$$\phi(\eta)=3\left(\frac{K_0}{M_0}\right)\sec h^2\left(\sqrt{\frac{1}{2}K_0}\eta\right)-\frac{\gamma}{3}\sqrt{\frac{M_0}{3K_0}}[-1+\tanh\,\eta+2(1-\eta\tanh\,\eta)\sec h^2\eta+\eta(2-\eta\tanh\,\eta)\sec h^2\eta]. \tag{38}$$

The solution (38) can be set into a compact expression as follows:

$$\phi_{PT}(\eta)=a_0\sec h^2\left(\sqrt{\frac{1}{2}K_0}\eta\right)+[A(\eta)\sec h^2(\eta)+b_0(1-\tanh(\eta))], \tag{39}$$

where $a_0=3K_0/M_0$, $A(\eta)=-2b_0\{1+\eta(1-1.5\tanh\,\eta)\}$, $b_0=\gamma/3\sqrt{a_0}$.

It is again obvious from the equation (39), in conformity with the equation (30), that there is a linear superposition of both shock (tanh)-like and soliton (sech^2)-ic solutions over some preexisting dc background formed by the self-interaction of identical spectral components of ion acoustic wave fluctuations in transonic plasma. However, under the no-growth limit ($\gamma=0$), only solitonic structures exist and no shock at all. The analytically derived solutions represented by the equations (30) and (39) both, therefore, physically suffice to exhibit analogous characteristics.

IV. RESULTS AND DISCUSSIONS

Our mathematical calculations clearly demonstrate that the derived *d*-KdV is really analytically integrable. Solving it analytically, a solution as a linear superposition of two distinct modes of nonlinear traveling waves is generated. In mutual isolation, one corresponds to the usual *soliton* solution and the other corresponds to the *shock* solution. Of course, the oscillatory part with sinusoidal or nonsinusoidal peaks as depicted in numerically obtained profiles of the oscillatory shocklike solutions[3] does not appear there in our analytical solution. Furthermore, the depression and amplifications of solitons are feeble. This could be attributed to the limitation of the used mathematical techniques that seems to be blind to these oscillations. These two possible modes of nonlinear traveling ion acoustic wave should be observable in transonic plasma system if one allows the ion acoustic wave to propagate through it.

Required study of magnetohydrodynamic waves and instabilities of both laboratory and space plasmas has been carried out for many years under the assumption of static equilibrium. However, there are many practical situations as mentioned in the introduction where plasma flows are significantly large to violate the condition of static equilibrium. There are several efforts to conduct experiments in transonic and supersonic wind tunnels. Certain experimental facility like high frequency plasmatron is demonstrated to behave as ideal facility for MHD phenomena under real flight conditions of aircraft.

In the moving frame of space vehicles, which carry the payloads for exploring the properties of space plasma environment, background plasmas are always in motion. Its velocity can be approximately taken equal to the velocity of the vehicle itself but in opposite direction. The space

laboratory frame observations of the low frequency range in acoustic domain must have some signature of our results provided that the space vehicle is moving with near sonic or near supersonic speeds. We are not aware of any such particular observations of ion acoustic wave fluctuations in transonic condition of plasma flows.

Most of the plasma devices of industrial applications like dense plasma focus machine, plasma torches, etc., depend on the plasma flows that violate the static equilibrium.[4–6] In fusion plasmas of future generations too, the static approximation of the equilibrium plasma description may not be suitable to describe the wave behavior. In future course of fusion research, rotational motions of fusion plasmas in poloidal and toroidal directions may decide the equilibrium. This is important to state that in toroidal plasmas, the geodesic acoustic mode[20] becomes of fundamental importance in comparison to the ordinary sound modes. This may be more important when these rotational motions are in the defined range of the transonic limit. Simplicity is correlated to the local mode approximation of the acoustic wave description in the transonic limit of uniform and unidirectional plasma flow motion without magnetic field.

There are some indications that the magnetized plasma flow systems may emit nonlinear standing MHD waves. In plasmas only nonlinear wave modes like soliton, shock, etc., in general, can travel for long before suffering major modifications. Transonic plasma zone seems to act as an interesting site for rich varieties of linear and nonlinear ion acoustic wave activities. Like MHD spectroscopy, the coining of the idea of *acoustic spectroscopy*[5] in unmagnetized plasma flow motions may have far reaching impact to study the unique property of the transonic plasmas of laboratory or space productions for basic and applied research. The real key to open the mystery of the sheath edge singularity lies in thorough investigations of wave turbulence physics in transonic boundary layer, which is assumed to have diffuse nature of near quasineutral plasma potential distribution over a finite extension.

One can then speculate that the wave induced diffusion and transport phenomena may have gone into the evolutionary processes of the equilibrium formation of transonic plasma flows, wherever it exists. Logically speaking the residues of participating waves, even if a little, must have left behind a signature of turbulent state of transonic plasma in a self-consistent nonlinear hydrodynamic equilibrium. This can be verified if and only if one can observe and analyze the wide range acoustic spectrum, especially shorter scales, in defined transonic plasma zone. This is the logical basis to put forth our own hypothesis that the transonic plasma equilibrium should, in principle, look like a turbulent plasma medium maintained by anomalous diffusion processes. Here we expect that the collective scale energy exchange processes in between the ion acoustic wave energy and the ion flow energy occur predominantly in an adiabatic manner so that there is no violation of the law of conservation of energy. This, in fact, is the distinctive characteristic of any conservative dynamical system.

The driving source of energy transfers part of its amount to amplify the spectral components of the usual ion acoustic soliton. As a result, the usual global balancing between the nonlinearity and dispersion strength will be disturbed. If the dispersion strength of the source wavelength remains negligibly weaker to compete with soliton dispersion strength, the phase coordination among the spectral components of the soliton remains intact and only amplification or suppression of the soliton amplitude occurs. However, when the source dispersion strength becomes significant, the space-symmetry of the soliton potential distribution breaks down and a new steady state solution of oscillatory shocklike structure is obtained. Adiabatic process is supposed to govern the energy exchange process among different spectral acoustic components.

The nonlinear traveling wave solutions of the d-KdV equation as derived from Hirota's method, sine-cosine method as well as perturbative technique are graphically depicted in Figs. 1 and 2 for the characterization of the ion acoustic wave motion through transonic zone for some typical values[3] of resonance excitation threshold as deviation from sonic point $\delta=1-M_r$ and scale length $k\lambda_{De}$ of source perturbation. The graphical depictions are, however, in partial agreement with the predicted numerical results[3] in terms of average properties.

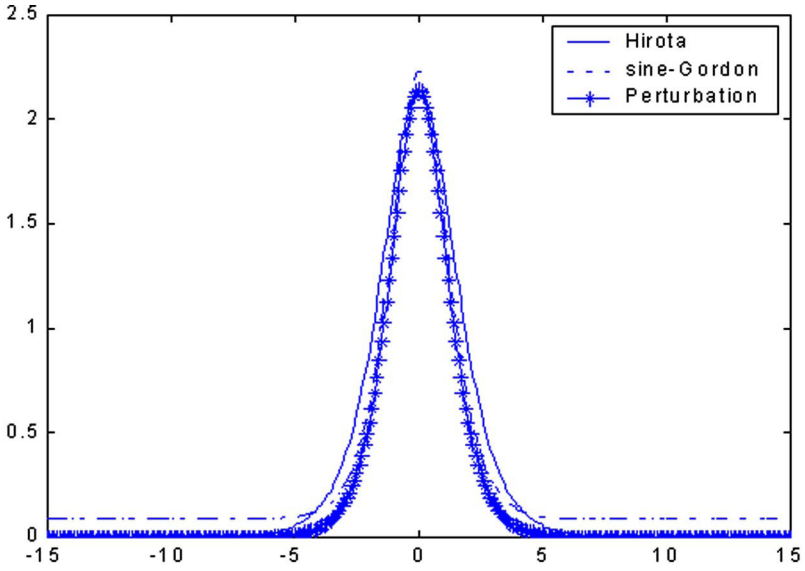

FIG. 1. (Color online) Solitonic symmetric structures obtained by Hirota, sine-Gordon, and perturbative techniques for $\delta=1.5\times10^{-8}$ and $k\lambda_{De}=1.5\times10^{-6}$.

V. CONCLUSIONS

In brief, we conclude that the present mathematical study of *d*-KdV equation offers a significant contribution of analytical supports to our numerical prediction of structural transformation of the traveling nonlinear ion acoustic waves in transonic plasma equilibrium of desired quality. It clearly shows that the actual solution of *d*-KdV equation is a resultant of linear mixing (superposition) of soliton and shock both.

Dominating features of the individual nonlinear modes is decided by an appropriate choice of the specific values of unstable wave number (or wavelength) for a given value of the ion flow Mach number. It is obvious to note that in zero growth limit of *d*-KdV equation, the shock-term disappears and only soliton remains. This limit is correlated with dc range of the chosen unstable wave number of quite weaker dispersion strength. As the dispersion strength becomes significant

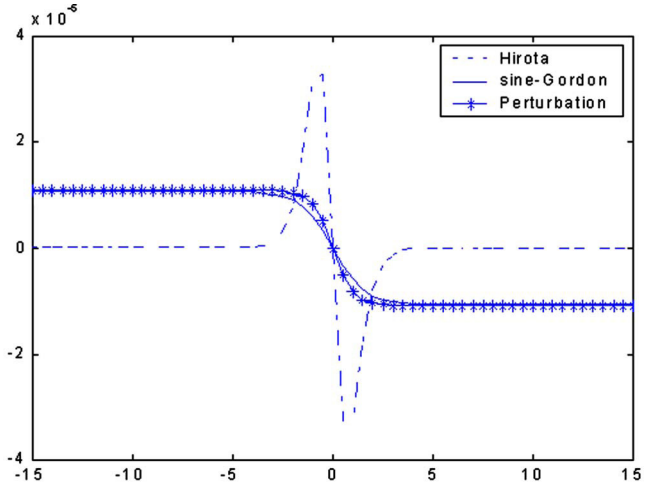

FIG. 2. (Color online) Shocklike asymmetric structures obtained by Hirota, sine-Gordon, and perturbative techniques for $\delta=2.5\times10^{-6}$ and $k\lambda_{De}=1.0\times10^{-4}$.

to influence the original soliton strength of weak nonlinearity and weak dispersion in the defined transonic plasma of finite extension, structural modification of the usual KdV soliton profile occurs.

We further argue that the linear and nonlinear normal mode behaviors of the ion acoustic waves in transonic plasma condition differ qualitatively from those derived for static and dynamic equilibriums without electron inertial correction. The finite but weak hydrodynamic tailoring of the electron fluid motion on ion acoustic space and time scales brings about this difference. It is then argued that the plasma flows in transonic equilibrium should exhibit rich spectrum of linear and nonlinear ion acoustic waves and oscillations. Of course, under Vlasov model the hot electrons with streaming velocity comparable to the phase speed of the ion sound wave may destabilize the ion sound mode through wave-particle resonance effect[21] too. However, our excitation mechanism of ion sound wave differs from the other known mechanisms[22–24] to excite the same ion sound wave on many grounds.[24]

This kind of theoretical scenario of *transonic plasmas* offers a unique scope of *acoustic spectroscopy* to describe the internal state of transonic equilibrium of plasma flows, if it exists at all. These calculations may have potential applications in thorough study of the ion acoustic wave turbulence related with aerodynamics, solar wind, and space plasmas, fusion plasmas of future generation, industrial plasmas, and plasma flows in astrophysical context, etc.

The aim of this work is to demonstrate a curious property of general periodic structures. It is well known that the corresponding homogenized matrix is positive definite. We calculate here the next order Burnett coefficients associated with such structures. We prove that these coefficients form a tensor which is negative semidefinite. We also provide some examples showing degeneracy in multidimension. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2179048]

I. INTRODUCTION

The aim of this paper is to demonstrate a curious property of general periodic structures. Let us consider acoustic wave propagation in a periodic medium with a small period denoted by ε. To first order, we can approximate this medium by the associated homogenized medium. It is well known that the acoustic wave propagation in the homogenized medium provides good approximation to the propagation of sufficiently long waves in the original periodic medium (Refs. 1 and 9).

Here, we are interested in higher order approximation. From our previous work,[2] it is known that the homogenized medium is described by the second order derivatives of the first Bloch eigenvalue $\lambda_1(\eta)$ at $\eta=0$ and the next order approximation to the periodic medium is provided by a fourth order tensor, namely the fourth derivatives of $\lambda_1(\eta)$ at $\eta=0$. In the physics literature such higher order derivatives are known as *Burnett coefficients* and they are of great interest (Refs. 14 and 8). It is known that the homogenized matrix is positive definite.[1] This work is devoted to the study of the next order approximation.

The approximation of the periodic medium comes about from the asymptotic expansion of $\lambda_1(\eta)$ near $\eta=0$,

$$\lambda_1(\eta) = \frac{1}{2!}\lambda_1''(0)\,\eta^2 + \frac{1}{4!}\lambda_1^{(4)}(0)\,\eta^4 + \cdots .$$

Substituting $\eta=\varepsilon\xi$, we get the asymptotic expansion of the first eigenvalue associated to the ε-periodic operator A^ε near $\eta=0$,

a)Electronic mail: cconca@dim.uchile.cl
b)Electronic mail: rafael.orive@uam.es
c)Electronic mail: vanni@mat.tifrbng.res.in

$$\lambda_1^\varepsilon(\xi) = \varepsilon^{-2}\lambda_1(\varepsilon\xi) = \frac{1}{2!}\lambda_1''(0)\xi^2 + \frac{1}{4!}\varepsilon^2\lambda_1^{(4)}(0)\xi^4 + \cdots.$$

It is already established that the Hessian matrix $\lambda_1''(0)/2$ coincides with the homogenized matrix denoted by $(q_{k\ell})$ (defined for instance in Ref. 1) and hence is positive definite. In this write-up, we show that

$$\frac{1}{4!}\lambda_1^{(4)}(0)\,\eta^4 \leqslant 0 \quad \forall\ \eta \in \mathbb{R}^N.$$

Further, we show that there can be directions $\eta \neq 0$ such that

$$\frac{1}{4!}\lambda_1^{(4)}(0)\,\eta^4 = 0.$$

However, in one dimension, as we show below, such a degeneracy cannot happen unless the medium is homogeneous.

Before starting our computations, let us interpret the above result in terms of acoustic wave propagation in the original ε-periodic medium. From the above expansion, it is clear that

$$\lambda_1^\varepsilon(\xi) \approx \frac{1}{2!}\lambda_1''(0)\xi^2 \quad \text{if } \varepsilon^2|\xi|^4 \text{ is small.}$$

This shows that the usual homogenized medium, as remarked above, provides a good description provided the waves are long. However, for short waves the above approximation is poor. Indeed if $\varepsilon^2|\xi|^4 = O(1)$ and $\varepsilon^4|\xi|^6 = o(1)$ then we have

$$\lambda_1^\varepsilon(\xi) \approx \frac{1}{2!}\lambda_1''(0)\xi^2 + \frac{1}{4!}\varepsilon^2\lambda_1^{(4)}(0)\xi^4.$$

The above picture shows that long waves experience hyperbolic effects while short waves in question undergo some dispersion too. This dispersive nature medium is described by the fourth order tensor $\lambda_1^{(4)}(0)$. However, the dispersion is not classical. It has a negative sign and we may then call it *negative dispersion*. Strictly speaking, the corresponding initial value problem modeling the propagation of such short waves is not well posed. We would like to bring to the attention of homogenization community that some curious materials (with negative refraction, negative reflection coefficients) are being conceived and produced (see Refs. 5, 10, 11, and 13). Viewed in this light, our result says that a fine periodic structure provides one such curious material as far as short wave propagation is concerned. At this point, we would like to emphasize other features of our result. It came as a surprise to us to see a definite sign for the fourth order derivative, as it was not expected. Though our computations follow a general pattern, it is not clear to us whether higher order derivatives too have a definite sign. The next remark is concerned with the level of generality at which we are working: we have no restriction whatsoever on the original periodic medium except the classical ones. In other words, the material components used in mixing are arbitrary, their proportions are arbitrary and the microgeometry of mixing is also arbitrary. This contrasts sharply with the current efforts in producing curious or smart materials using particular components and following a particular design, for example, photonic crystals (see Refs. 7, 6, and 12).

II. PRELIMINARIES

Let us now introduce the problem to be studied in this work. First, we remark that the summation with respect to the repeated indices is understood throughout this paper. We consider the operator

$$A \overset{\text{def}}{=} -\frac{\partial}{\partial y_k}\left(a_{k\ell}(y)\frac{\partial}{\partial y_\ell}\right), \quad y \in \mathbb{R}^N, \tag{2.1}$$

where the coefficients satisfy

$$\begin{aligned} &a_{k\ell} \in L^\infty_{\#}(Y) \quad \text{where } Y =]0,2\pi[^N, \text{ i.e., each } a_{k\ell} \text{ is a} \\ &Y\text{-periodic bounded measurable function defined on } \mathbb{R}^N, \text{ and} \\ &\exists\, \alpha > 0 \quad \text{such that } a_{k\ell}(y)\eta_k\eta_\ell \geqslant \alpha|\eta|^2 \quad \forall\, \eta \in \mathbb{R}^N, \quad y \in Y \text{ a.e.}, \\ &a_{k\ell} = a_{\ell k} \quad \forall\, k, \ell = 1, \ldots, N. \end{aligned} \tag{2.2}$$

For each $\varepsilon > 0$, we consider also the ε-periodic operator A^ε where

$$A^\varepsilon \overset{\text{def}}{=} -\frac{\partial}{\partial x_k}\left(a^\varepsilon_{k\ell}(x)\frac{\partial}{\partial x_\ell}\right) \quad \text{with } a^\varepsilon_{k\ell}(x) \overset{\text{def}}{=} a_{k\ell}\left(\frac{x}{\varepsilon}\right), \quad x \in \mathbb{R}^N. \tag{2.3}$$

In homogenization theory, it is usual to refer to x and y as the slow and the fast variables, respectively. They are related by $y = x/\varepsilon$.

Our results are based on Bloch waves ψ associated with the operator A which we define now. Let us consider the following spectral problem parametrized by $\eta \in \mathbb{R}^N$: find $\lambda = \lambda(\eta) \in \mathbb{R}$ and $\psi = \psi(y;\eta)$ (not zero) such that

$$\begin{aligned} &A\psi(\cdot;\eta) = \lambda(\eta)\psi(\cdot;\eta) \quad \text{in } \mathbb{R}^N, \quad \psi(\cdot;\eta) \text{ is } (\eta;Y)\text{-periodic, i.e.,} \\ &\psi(y + 2\pi m;\eta) = e^{2\pi i m\cdot\eta}\psi(y;\eta) \quad \forall\, m \in \mathbb{Z}^N, \quad y \in \mathbb{R}^N. \end{aligned} \tag{2.4}$$

Next, by the Floquet theory, we define $\phi(y;\eta) = e^{-iy\cdot\eta}\psi(y;\eta)$ and (2.4) can be rewritten in terms of ϕ as follows:

$$A(\eta)\phi = \lambda\phi \quad \text{in } \mathbb{R}^N, \quad \phi \quad \text{is} \quad Y\text{-periodic}. \tag{2.5}$$

Here, the operator $A(\eta)$ is called the translated operator and is defined by

$$A(\eta) = e^{-iy\cdot\eta}Ae^{iy\cdot\eta}.$$

It is well known (see Refs. 1 and 3) that for each $\eta \in Y' = [-1/2, 1/2[^N$, the above spectral problem (2.5) admits a discrete sequence of eigenvalues and their eigenfunctions (referred to as *Bloch waves*) introduced above enable us to describe the spectral resolution of A [an unbounded self-adjoint operator in $L^2(\mathbb{R}^N)$] in the orthogonal basis $\{e^{iy\cdot\eta}\phi_m(y;\eta)\,|\,m \geqslant 1, \eta \in Y'\}$.

To obtain the spectral resolution of A^ε, let us introduce Bloch waves at the ε-scale,

$$\lambda^\varepsilon_m(\xi) = \varepsilon^{-2}\lambda_m(\eta), \quad \phi^\varepsilon_m(x;\xi) = \phi_m(y;\eta), \quad \psi^\varepsilon_m(x;\xi) = \psi_m(y;\eta),$$

where the variables (x,ξ) and (y,η) are related by $y = x/\varepsilon$ and $\eta = \varepsilon\xi$. Observe that $\phi^\varepsilon_m(x;\xi)$ is εY-periodic (in x) and $\varepsilon^{-1}Y'$ periodic with respect to ξ. In the same manner, $\psi^\varepsilon_m(\cdot;\xi)$ is $(\varepsilon\xi;\varepsilon Y)$ periodic because of the relation $\psi^\varepsilon_m(x;\xi) = e^{ix\cdot\xi}\phi^\varepsilon_m(x;\xi)$. Note that the dual cell at ε-scale is $\varepsilon^{-1}Y'$ and hence we take ξ to vary in $\varepsilon^{-1}Y'$ in the sequel. With these notations, we have (see Ref. 1) the following.

Theorem 2.1: *Let $g \in L^2(\mathbb{R}^N)$. The m*th *Bloch coefficient of g at the ε-scale is defined as follows:*

$$(B^\varepsilon_m g)(\xi) = \int_{\mathbb{R}^N} g(x)e^{-ix\cdot\xi}\overline{\phi}^\varepsilon_m(x;\xi)\mathrm{d}x \quad \forall\, m \geqslant 1, \quad \xi \in \varepsilon^{-1}Y'.$$

Then the following inverse formula and Parseval's identity hold:

$$g(x) = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} (B_{m\delta}^{\varepsilon} g)(\xi) e^{ix\cdot\xi} \phi_m^{\varepsilon}(x;\xi) \mathrm{d}\xi,$$

$$\int_{\mathbb{R}^N} |g(x)|^2 \, \mathrm{d}x = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} |(B_m^{\varepsilon} g)(\xi)|^2 \, \mathrm{d}\xi.$$

Finally, for all g in the domain of A^{ε}, *we get*

$$A^{\varepsilon} g(x) = \int_{\varepsilon^{-1}Y'} \sum_{m=1}^{\infty} \lambda_m^{\varepsilon}(\xi)(B_{m\delta}^{\varepsilon} g)(\xi) e^{ix\cdot\xi} \phi_m^{\varepsilon}(x;\xi) \mathrm{d}\xi.$$

■

In the homogenization process, one can neglect all the modes for $m \geqslant 2$ (see Refs. 4 and 2). To this end, we consider a sequence of solutions u^{ε} of the equation

$$A^{\varepsilon} u^{\varepsilon} = f \quad \text{in } \mathbb{R}^N. \tag{2.6}$$

We can show that the component of u^{ε} in the higher Bloch modes are not significant. More precisely, let us consider v^{ε} defined by

$$v^{\varepsilon}(x) = \int_{\varepsilon^{-1}Y'} \sum_{m=2}^{\infty} (B_m^{\varepsilon} u^{\varepsilon})(\xi) e^{ix\cdot\xi} \phi_m^{\varepsilon}(x;\xi) \mathrm{d}\xi. \tag{2.7}$$

which is nothing but the projection of u^{ε} corresponding to all higher Bloch modes. Then the following estimates on v^{ε} are derived in Ref. 2.

Proposition 2.2: *Depending on the regularity of the source term f in* (2.6), *we have*

(i) *If* $f \in H^{-1}(\mathbb{R}^N)$: $\|v^{\varepsilon}\|_{L^2(\mathbb{R}^N)} \leqslant c\varepsilon \|f\|_{H^{-1}(\mathbb{R}^N)}$.
(ii) *If* $f \in L^2(\mathbb{R}^N)$: $\|v^{\varepsilon}\|_{L^2(\mathbb{R}^N)} \leqslant c\varepsilon^2 \|f\|_{L^2(\mathbb{R}^N)}$.
(iii) *If* $f \in L^2(\mathbb{R}^N)$: $|v^{\varepsilon}|_{H^1(\mathbb{R}^N)} \leqslant c\varepsilon \|f\|_{L^2(\mathbb{R}^N)}$.
(iv) *If* $f \in H^1(\mathbb{R}^N)$: $\|v^{\varepsilon}\|_{L^2(\mathbb{R}^N)} \leqslant c\varepsilon^3 |f|_{H^1(\mathbb{R}^N)}$.
(v) *If* $f \in H^1(\mathbb{R}^N)$: $|v^{\varepsilon}|_{H^1(\mathbb{R}^N)} \leqslant c\varepsilon^2 |f|_{H^1(\mathbb{R}^N)}$.

Here, we denote by $|\cdot|_{H^1(\mathbb{R}^N)}$ *the seminorm of* $H^1(\mathbb{R}^N)$. ■

The above result is at the basis of neglecting higher order Bloch eigenvalues $\{\lambda_m^{\varepsilon}(\xi)\}_{m\geqslant 2}$ in the context of our discussion in the Introduction.

III. FOURTH ORDER TENSOR $\lambda_1^{(4)}(0)$

In this section, we present the expression for the fourth order tensor $\lambda_1^{(4)}(0)$ and show that it is negative semidefinite. Recall that $\lambda_1(\eta)$ and $\phi_1(\cdot;\eta)$ depend analytically on η in a small neighborhood B_δ of $\eta=0$ (see Ref. 4).

A. Derivatives of the first Bloch eigenvalue and eigenvector

The purpose of this section is to present expressions for derivatives of the first Bloch eigenvalue $\lambda_1(\eta)$ and the first Bloch eigenvector $\phi_1(\cdot;\eta)$ at $\eta=0$ and indicate a systematic method to compute them. For details of these computations, the reader is referred to Ref. 2. Our approach exploits the connection between the Bloch space computation with the multiscale computation.

The derivatives of the first eigenvalue and eigenfunction in $\eta=0$ exist thanks to the regularity property established in Ref. 4. In fact, we know that there exists $\delta>0$ such that the first eigenvalue $\lambda_1(\eta)$ is an analytic function on $B_\delta=\{\eta \,|\, |\eta|<\delta\}$, and there is a choice of the first eigenvector $\phi_1(y;\eta)$ satisfying

$$\eta \to \phi_1(\cdot;\eta) \in H^1_{\#}(Y) \text{ is analytic on } B_\delta, \quad \phi_1(y;0) = |Y|^{-1/2} = \frac{1}{(2\pi)^{N/2}}.$$

Apart from the above result of regularity on the Bloch spectrum, the following proposition was also proved in Ref. 2.

Proposition 3.1: *We have the relations*

$$\lambda_1(0) = 0, \quad D_k\lambda_1(0) = \frac{\partial \lambda_1}{\partial \eta_k}(0) = 0 \quad \forall\, k = 1, \ldots, N,$$

$$\frac{1}{2} D^2_{k\ell}\lambda_1(0) = \frac{1}{2}\frac{\partial^2 \lambda_1}{\partial \eta_k\, \partial\, \eta_\ell}(0) = q_{k\ell} \quad \forall\, k, \ell = 1, \ldots, N,$$

where $q_{k\ell}$ *are the homogenized coefficients defined by*

$$q_{k\ell} = \mathcal{M}_Y\left(a_{k\ell} + a_{km}\frac{\partial \chi_\ell}{\partial y_m}\right) \overset{\text{def}}{=} \frac{1}{|Y|}\int_Y \left(a_{k\ell} + a_{km}\frac{\partial \chi_\ell}{\partial y_m}\right) \mathrm{d}y \quad \forall\, k, \ell = 1, \ldots, N, \tag{3.1}$$

with test function χ_k *defined by the following cell problem*:

$$A\chi_k = \frac{\partial a_{k\ell}}{\partial y_\ell} \quad \text{in } \mathbb{R}^N,$$

$$\chi_k \in H^1_{\#}(Y), \quad \mathcal{M}_Y(\chi_k) = 0. \tag{3.2}$$

Moreover, all odd order derivatives of λ_1 *at* $\eta = 0$ *vanish, i.e.*,

$$D^\beta \lambda_1(0) = 0 \quad \forall\, \beta \in \mathbb{Z}^N_+, \quad |\beta| \text{ odd}.$$

All even order derivatives of λ_1 *at* $\eta = 0$ *can be calculated in a systematic fashion. For instance, the fourth order derivatives have the following expressions: for all* $k, \ell, m, n = 1, \ldots, N$,

$$\begin{aligned}\frac{1}{4!} D^4_{k\ell mn}\lambda_1(0) = {} & \frac{1}{4}\frac{1}{|Y|}\int_Y \{C_n\chi_{k\ell m} + C_k\chi_{\ell mn} + C_\ell\chi_{mnk} + C_m\chi_{nk\ell}\}\mathrm{d}y \\ & - \frac{1}{3!}\frac{1}{|Y|}\int_Y \{(a_{k\ell} - q_{k\ell})\chi_{mn} + (a_{\ell m} - q_{\ell m})\chi_{nk} + (a_{mn} - q_{mn})\chi_{k\ell} \\ & + (a_{nk} - q_{nk})\chi_{\ell m} + (a_{km} - q_{km})\chi_{\ell n} + (a_{\ell n} - q_{\ell n})\chi_{km}\}\mathrm{d}y.\end{aligned}$$

Here, the operator C_k *is defined by*

$$C_k\phi \overset{\text{def}}{=} -a_{kj}(y)\frac{\partial \phi}{\partial y_j} - \frac{\partial}{\partial y_j}(a_{kj}(y)\phi) \tag{3.3}$$

(*is skew-adjoint*, $C^*_k = -C_k$), *and* $\chi_{k\ell}$, $\chi_{k\ell m}$ *are the test functions defined by the following cell problems*:

$$A\chi_{k\ell} = (a_{k\ell} - q_{k\ell}) - \tfrac{1}{2}(C_k\chi_\ell + C_\ell\chi_k) \quad \text{in } \mathbb{R}^N,$$

$$\chi_{k\ell} \in H^1_{\#}(Y), \quad \mathcal{M}_Y(\chi_{k\ell}) = 0, \tag{3.4}$$

$$A\chi_{k\ell m} = \tfrac{1}{3}[(a_{k\ell} - q_{k\ell})\chi_m + (a_{\ell m} - q_{\ell m})\chi_k + (a_{mk} - q_{mk})\chi_\ell]$$

$$- \tfrac{1}{3}[C_k\chi_{\ell m} + C_\ell\chi_{mk} + C_m\chi_{k\ell}] \quad \text{in } \mathbb{R}^N, \tag{3.5}$$

$$\chi_{k\ell m} \in H^1_{\#}(Y), \quad \mathcal{M}_Y(\chi_{k\ell m}) = 0.$$

■

The above expressions are obtained by differentiating the eigenvalue problem,

$$(A(\eta) - \lambda_1(\eta))\phi_1(\cdot\,;\eta) = 0,$$

and using that the branch $\eta \mapsto \phi_1(\cdot\,;\eta)$ can be so chosen that the following conditions are satisfied simultaneously:

$$\eta \in B_\delta \mapsto \phi_1(\cdot\,;\eta) \in H^1_{\#}(Y) \quad \text{is analytic},$$

$$\|\phi_1(\cdot\,;\eta)\|_{L^2(Y)} = 1 \quad \forall\ \eta \in B_\delta,$$

$$\mathrm{Im}\int_Y \phi_1(y;\eta)\mathrm{d}y = 0 \quad \forall\ \eta \in B_\delta.$$

B. $D^4\lambda_1(0)$ is negative semidefinite

First, we denote the fourth derivatives as

$$B_{k\ell mn} = \frac{1}{4!}D^4_{k\ell mn}\lambda_1(0).$$

Thus, by the Proposition 3.1, for any $\eta \in \mathbb{R}^N$ we get

$$\begin{aligned}
B_{k\ell mn}\eta_k\eta_\ell\eta_n\eta_m = {} & \frac{1}{4}\frac{1}{|Y|}\int_Y [(C_n\eta_n)(\chi_{k\ell m}\eta_k\eta_\ell\eta_m) + (C_k\eta_k)(\chi_{\ell mn}\eta_\ell\eta_m\eta_n)]\mathrm{d}y \\
& + \frac{1}{4}\frac{1}{|Y|}\int_Y [(C_\ell\eta_\ell)(\chi_{mnk}\eta_m\eta_n\eta_k) + (C_m\eta_m)(\chi_{nk\ell}\eta_k\eta_\ell\eta_n)]\mathrm{d}y \\
& - \frac{1}{3!}\frac{1}{|Y|}\int_Y [\eta_k\eta_\ell(a_{k\ell} - q_{k\ell})(\chi_{mn}\eta_m\eta_n) + \eta_\ell\eta_m(a_{\ell m} - q_{\ell m})(\chi_{nk}\eta_k\eta_n)]\mathrm{d}y \\
& - \frac{1}{3!}\frac{1}{|Y|}\int_Y [\eta_m\eta_n(a_{mn} - q_{mn})(\chi_{k\ell}\eta_k\eta_\ell) + \eta_k\eta_n(a_{nk} - q_{nk})(\chi_{\ell m}\eta_m\eta_\ell)]\mathrm{d}y \\
& - \frac{1}{3!}\frac{1}{|Y|}\int_Y [\eta_m\eta_k(a_{km} - q_{km})(\chi_{\ell n}\eta_\ell\eta_n) + \eta_\ell\eta_m(a_{\ell n} - q_{\ell n})(\chi_{km}\eta_m\eta_k)]\mathrm{d}y.
\end{aligned}$$

Now, we introduce the following notations:

$$C = \eta_n C_n, \quad \chi^{(1)} = \eta_k\chi_k, \quad \chi^{(2)} = \eta_k\eta_\ell\chi_{k\ell}, \quad \chi^{(3)} = \eta_k\eta_\ell\eta_m\chi_{k\ell m},$$

$$a = \eta_k\eta_m a_{km}, \quad q = \eta_k\eta_m q_{km}. \tag{3.6}$$

Then, by the summation, the above expression is simplified to the following:

$$B_{k\ell mn}\eta_k\eta_\ell\eta_m\eta_n = \frac{1}{|Y|}\int_Y C\chi^{(3)}\,\mathrm{d}y - \frac{1}{|Y|}\int_Y (a-q)\chi^{(2)}\,\mathrm{d}y. \tag{3.7}$$

Since the test function χ_k satisfies the cell problem (3.2), we have by the notations (3.6),

$$A\chi^{(1)} = \eta_k\frac{\partial a_{k\ell}}{\partial y_\ell}. \tag{3.8}$$

Analogously, by the cell problems (3.4) and (3.5), we have the following Y-periodic problems:

$$A\chi^{(2)} = (a-q) - C\chi^{(1)}, \tag{3.9}$$

$$A\chi^{(3)} = (a-q)\chi^{(1)} - C\chi^{(2)}. \tag{3.10}$$

By the notation (3.6), since C_k is defined in (3.3), we get

$$\frac{1}{|Y|}\int_Y C\chi^{(3)}\,\mathrm{d}y = -\frac{1}{|Y|}\int_Y \eta_k a_{k\ell}\frac{\partial\chi^{(3)}}{\partial y_\ell}\mathrm{d}y.$$

Using (3.8) and integrating by parts, we have

$$\frac{1}{|Y|}\int_Y C\chi^{(3)}\,\mathrm{d}y = \frac{1}{|Y|}\int_Y A\chi^{(1)}\chi^{(3)}\,\mathrm{d}y = \frac{1}{|Y|}\int_Y \chi^{(1)}A\chi^{(3)}\,\mathrm{d}y = \frac{1}{|Y|}\int_Y [(a-q)(\chi^{(1)})^2 - \chi^{(1)}C\chi^{(2)}]\mathrm{d}y,$$

by (3.10). Therefore, from (3.7), we obtain

$$B_{k\ell mn}\eta_k\eta_\ell\eta_m\eta_n = \frac{1}{|Y|}\int_Y (a-q)(\chi^{(1)})^2\,\mathrm{d}y - \frac{1}{|Y|}\int_Y \chi^{(1)}C\chi^{(2)}\,\mathrm{d}y - \frac{1}{|Y|}\int_Y (a-q)\chi^{(2)}\,\mathrm{d}y.$$

Again, by definition of C, we have $C^*=-C$ and hence

$$B_{k\ell mn}\eta_k\eta_\ell\eta_m\eta_n = \frac{1}{|Y|}\int_Y (a-q)(\chi^{(1)})^2\,\mathrm{d}y - \frac{1}{|Y|}\int_Y [(a-q) - C\chi^{(1)}]\chi^{(2)}\,\mathrm{d}y.$$

Using now (3.9), we get

$$B_{k\ell mn}\eta_k\eta_\ell\eta_n\eta_m = \frac{1}{|Y|}\int_Y (a-q)(\chi^{(1)})^2\,\mathrm{d}y - \frac{1}{|Y|}\int_Y A\chi^{(2)}\chi^{(2)}\,\mathrm{d}y.$$

Substituting,

$$a-q = A\chi^{(2)} + C\chi^{(1)},$$

we can rewrite the above expression as follows:

$$B_{k\ell mn}\eta_k\eta_\ell\eta_m\eta_n = -\frac{1}{|Y|}\int_Y A\left[\chi^{(2)} - \frac{1}{2}(\chi^{(1)})^2\right]\cdot\left[\chi^{(2)} - \frac{1}{2}(\chi^{(1)})^2\right]\mathrm{d}y + \frac{1}{4}\frac{1}{|Y|}\int_Y A(\chi^{(1)})^2\cdot(\chi^{(1)})^2\,\mathrm{d}y$$
$$+ \frac{1}{|Y|}\int_Y C\chi^{(1)}\cdot(\chi^{(1)})^2\,\mathrm{d}y. \tag{3.11}$$

We show now that the last two terms of the above expression add up to zero. More precisely, we prove

$$\frac{1}{4}\frac{1}{|Y|}\int_Y A(\chi^{(1)})^2\cdot(\chi^{(1)})^2\,dy+\frac{1}{|Y|}\int_Y C\chi^{(1)}\cdot(\chi^{(1)})^2\,dy=0. \tag{3.12}$$

To this end, let us first consider the last term. By definition of C,

$$\int_Y C\chi^{(1)}\cdot(\chi^{(1)})^2\,dy=-2\eta_k\int_Y a_{k\ell}\frac{\partial}{\partial y_\ell}\left(\frac{1}{3}(\chi^{(1)})^3\right)dy-\eta_k\int_Y\frac{\partial a_{k\ell}}{\partial y_\ell}(\chi^{(1)})^3\,dy.$$

Via a simple integration by parts, we obtain

$$\int_Y C\chi^{(1)}\cdot(\chi^{(1)})^2\,dy=-\frac{1}{3}\int_Y A\chi^{(1)}\cdot(\chi^{(1)})^3\,dy. \tag{3.13}$$

On the other hand, regarding the first term in (3.12), we can establish a more general relation,

$$\frac{1}{(p+1)^2}\int_Y A(\chi^{(1)})^{p+1}\cdot(\chi^{(1)})^{p+1}\,dy=\frac{1}{2p+1}\int_Y A\chi^{(1)}\cdot(\chi^{(1)})^{2p+1}\,dy\quad\forall\,p\in\mathbb{N}. \tag{3.14}$$

This proof is simply obtained by writing the expression

$$a_{k\ell}\frac{\partial\chi^{(1)}}{\partial y_\ell}\frac{\partial\chi^{(1)}}{\partial y_k}(\chi^{(1)})^{2p}$$

in two different ways, namely

$$a_{k\ell}\frac{\partial\chi^{(1)}}{\partial y_\ell}\frac{\partial}{\partial y_k}\left(\frac{1}{2p+1}(\chi^{(1)})^{2p+1}\right)\quad\text{and}\quad a_{k\ell}\frac{\partial}{\partial y_\ell}\left(\frac{1}{p+1}(\chi^{(1)})^{p+1}\right)\frac{\partial}{\partial y_k}\left(\frac{1}{p+1}(\chi^{(1)})^{p+1}\right).$$

A simple integration of these expressions leads us to the above relation (3.14). Finally, taking $p=1$ in (3.14) and using (3.13), we get (3.12). Thus, we conclude the proof of the following result.

Proposition 3.2: *The tensor of fourth derivatives of* λ_1 *in* 0 *is negative semidefinite. More precisely, for any* $\eta\in\mathbb{R}^N$, *we get*

$$\frac{1}{4!}D^4_{k\ell mn}\lambda_1(0)\,\eta_k\eta_\ell\eta_m\eta_n=-\frac{1}{|Y|}\int_Y A\left[\chi^{(2)}-\frac{1}{2}(\chi^{(1)})^2\right]\cdot\left[\chi^{(2)}-\frac{1}{2}(\chi^{(1)})^2\right]dy\leqslant 0. \tag{3.15}$$

■

C. One-dimensional case

In this case, we get a more simple formula for the form associated with the fourth order derivatives of λ_1. More exactly, we show that, for any $\eta\in\mathbb{R}$, we have

$$\frac{1}{4!}D^4\lambda_1(0)\,\eta^4=-\frac{q}{2\pi}\int_0^{2\pi}(\chi^{(1)})^2\,dy\leqslant 0. \tag{3.16}$$

Indeed, by (3.7) we know that

$$\frac{1}{4!}D^4\lambda_1(0)\,\eta^4=\frac{1}{2\pi}\int_0^{2\pi}(C\chi^{(3)}-(a-q)\chi^{(2)})dy.$$

Then, we prove (3.16) by showing that

$$\int_0^{2\pi}C\chi^{(3)}\,dy=\int_0^{2\pi}(-q(\chi^{(1)})^2+(a-q)\chi^{(2)})dy. \tag{3.17}$$

To prove the above result, we first establish some formulas where we use one-dimensional nature of the problem. Considering (3.8) and integrating, we get

$$a\frac{\mathrm{d}\chi^{(1)}}{\mathrm{d}y} = (q-a)\,\eta. \tag{3.18}$$

Now, considering (3.9) and integrating, we get

$$a\frac{\mathrm{d}\chi^{(2)}}{\mathrm{d}y} = -a\chi^{(1)}\eta + c,$$

where c is some constant. Dividing the above relation by a and integrating it over Y, we get $c=0$ and then the following relation results:

$$\frac{\mathrm{d}\chi^{(2)}}{\mathrm{d}y} = -\chi^{(1)}\eta. \tag{3.19}$$

Because of the above relations (3.18) and (3.19), there are simplifications in one dimension which can be exploited to establish (3.17). To this end, it is enough to use the equations satisfied by $\chi^{(1)}$ and $\chi^{(3)}$ and integration by parts.

Remark 3.3: An immediate consequence of (3.16) is

$$D^4\lambda_1(0) = 0 \;\Leftrightarrow\; a(y) \quad \textit{is constant}. \tag{3.20}$$

Indeed, if $D^4\lambda_1(0)=0$ *then* $\chi^{(1)}=0$ *and by (3.18), the coefficient* $a(y)$ *is constant.* ■

IV. DEGENERATE CASES

Unfortunately, in several space dimensions (3.20) need not be true. It can happen that the coefficients $\{a_{k\ell}\}$ are not constants and yet

$$D^4_{k\ell mn}\lambda_1(0)\,\eta_k\eta_\ell\eta_m\eta_n = 0 \quad \text{for some } \eta \neq 0. \tag{4.1}$$

In this section, we show some examples of such degenerates cases.

First, we propose to prove two equivalent expressions for (4.1).

Proposition 4.1: Let us pose

$$\beta^{(2)} = \beta^{(2)}_{k\ell}\eta_k\eta_\ell,$$

where the constants $\beta^{(2)}_{k\ell}$ *are defined by*

$$\beta^{(2)}_{k\ell} = \frac{1}{2!}\frac{1}{|Y|}\int_Y \chi_\ell\chi_k\,\mathrm{d}y. \tag{4.2}$$

Then, if there exists $\eta\in\mathbb{R}^N-\{0\}$ *satisfying (4.1), we get*

$$\chi^{(2)} = \tfrac{1}{2}(\chi^{(1)})^2 - \beta^{(2)}. \tag{4.3}$$

Also (4.1), is equivalent to the following Hamilton-Jacobi type equation for $\chi^{(1)}$*:*

$$a - q + 2\eta_k a_{k\ell}\frac{\partial\chi^{(1)}}{\partial y_\ell} + a_{k\ell}\frac{\partial\chi^{(1)}}{\partial y_k}\frac{\partial\chi^{(1)}}{\partial y_\ell} = 0. \tag{4.4}$$

■

Proof: From (3.15) and (4.1), we have immediately that $\chi^{(2)}-\frac{1}{2}(\chi^{(1)})^2=C$, for some constant C. Integrating this relation and using the definition of $\chi^{(1)}$ and $\chi^{(2)}$, we get

$$C|Y| = -\frac{1}{2}\eta_k \eta_\ell \int_Y \chi_k \chi_\ell \, \mathrm{d}y,$$

and by definition (4.2) of $\beta_{k\ell}^{(2)}$, we obtain (4.3).

Applying the operator A on the relation (4.3), we get

$$A\chi^{(2)} = A\left[\tfrac{1}{2}(\chi^{(1)})^2\right].$$

Since $\chi^{(1)}$ and $\chi^{(2)}$ are solutions of (3.8) and (3.9), respectively, we have

$$A\chi^{(2)} = a - q + 2\,\eta_k a_{k\ell} \frac{\partial \chi^{(1)}}{\partial y_\ell} + A\chi^{(1)} \cdot \chi^{(1)}$$

and

$$A\left[\frac{1}{2}(\chi^{(1)})^2\right] = A\chi^{(1)} \cdot \chi^{(1)} - a_{k\ell} \frac{\partial \chi^{(1)}}{\partial y_\ell} \frac{\partial \chi^{(1)}}{\partial y_k}.$$

We subtract the last two expressions and arrive at (4.4). Conversely, we can start from (4.4) and deduce (4.3). This completes the proof. ■

Next, we present some examples of degenerate cases in several space dimensions.

Case of laminates: We place ourselves in two dimensions. Consider the matrix of coefficients $(a_{k\ell}(y))$,

$$\begin{pmatrix} a_{11}(y_1) & 0 \\ 0 & a_{22} \end{pmatrix},$$

with a_{22} being a constant. Taking $\eta=(0,1)$, the following can be easily checked:

$$\chi_2 \equiv 0, \quad \chi^{(1)} \equiv 0, \quad q_{22} = a_{22}, \quad a = q = a_{22}.$$

[Recall that χ_2 is the solution of (3.2)]. Thus, the equation (4.4) and hence the property (4.1) are easily satisfied but $(a_{k\ell}(y))$ is not a constant matrix.

Irreducible tensor concomitants of an arbitrary complex antisymmetric second rank tensor, or bivector, in a Minkowski space-time are presented. These tensors are quadratic in the complex bivector and invariant under an overall multiplicative phase change of the bivector; in other words, they are sesquilinear-quadratic tensor concomitants of the complex bivector. The tensors are real and irreducible under the full real Lorentz group. Particular consideration is given to when the complex bivector is the electromagnetic field strength tensor (complex description is appropriate for radiation), and it is found that some of these irreducible tensors are novel electromagnetic observables not previously mentioned in the literature. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2173176]

I. INTRODUCTION

Quadratic concomitants of bivectors[12,8] (antisymmetric second rank tensors) are of fundamental importance in physics in general and in electromagnetism in particular. In electromagnetism, see Ref. 4, the electromagnetic field strength can be described by the real bivector

$$F^{\alpha\beta}=\begin{pmatrix} 0 & -E_1 & -E_2 & -E_3 \\ E_1 & 0 & -B_3 & B_2 \\ E_2 & B_3 & 0 & -B_1 \\ E_3 & -B_2 & B_1 & 0 \end{pmatrix}, \quad \alpha,\beta=0,1,2,3, \tag{1}$$

where (E_1,E_2,E_3) is the electric field and (B_1,B_2,B_3) is the magnetic field (Greek indices run over 0,1,2,3 where 0 is associated with a timelike coordinate and 1,2,3 with spacelike coordinates). $F^{\alpha\beta}$ has the following well-known bilinear concomitants: the two scalars.

$$C_+^{(r)}=\tfrac{1}{4}F^{\mu\nu}F_{\nu\mu}, \tag{2}$$

$$C_-^{(r)}=\tfrac{1}{8}F^{\mu\nu}F^{\alpha\beta}\epsilon_{\nu\mu\alpha\beta}, \tag{3}$$

where $\epsilon^{\alpha\beta\gamma\delta}$ is the Levi-Civita tensor in four dimensions (with $\epsilon^{0123}=-1$), and the second rank tensor

[a)]Electronic mail: T.Carozzi@sussex.ac.uk
[b)]Electronic mail: jb@irfu.se

$$T^{\alpha\beta}_{(r)} = F^{\alpha\mu}F_{\mu}{}^{\beta} - \tfrac{1}{4}C^{(r)}_{+}\eta^{\alpha\beta}, \tag{4}$$

where $\eta^{\alpha\beta}$ is the metric tensor of Minkowski space. $C^{(r)}_{+}$ is the Lagrangian density of the free electromagnetic field, $C^{(r)}_{-}$ is the electromagnetic pseudoscalar, and $T^{\alpha\beta}_{(r)}$ is the electromagnetic energy-momentum density tensor.

However, there are cases when we need to consider bivectors that are complex. For electromagnetic radiation, for instance, it is more convenient to use complex rather than real field quantities. From quantum theory of light it is known that the observables of an electromagnetic field are ultimately constructed from a complex field strength $F^{\alpha\beta}$, see Refs. 2 and 11. Of these observables, the simplest are sesquilinear-quadratic in $F^{\alpha\beta}$, that is, they are functions of the components of $F^{\alpha\beta}\bar{F}^{\gamma\delta}$, where $\bar{F}^{\gamma\delta}$ is the complex conjugate of $F^{\alpha\beta}$, see Ref. 5.

A question that has not yet been addressed fully, however, is which tensor valued observables can be constructed from an arbitrary complex $F^{\alpha\beta}$. At first glance this question seems pointless since one quickly realizes that an infinite number of sesquilinear-quadratic tensor concomitants of $F^{\alpha\beta}$ are possible. However, we will show that all sesquilinear-quadradric tensor concomitants of a complex $F^{\alpha\beta}$ can be constructed from a unique (up to duality transform) set of tensors. This is the set of tensor concomitants that are real irreducible under the full Lorentz group.[10]

The main objective of this paper is therefore to introduce this set of real irreducible tensors which are sesquilinear-quadratic concomitants of an arbitrary complex bivector. Although the results are of particular interest when the complex bivector is the electromagnetic field, we will keep the treatment general so it applies to any complex bivector. In Sec. II we provide the relevant definitions and criteria for the unique sesquilinear-quadratic concomitant which are then presented in Sec. III where we also show that any sesquilinear-quadratic concomitant of a complex bivector can be completely decomposed in terms of these tensors. Finally, we write these tensors explicitly in terms of electric and magnetic 3-vectors and find that some of them have not been previously discussed in the literature.

This work is related to Olofsson[7] which attempts to decompose rank-4 bilinear concomitants of complex bivectors. A paper using a spinor algebra approach, as opposed to the tensor algebra approach used here, is in preparation.[9]

II. CRITERIA FOR THE SESQUILINEAR-QUADRATIC TENSOR CONCOMITANTS

In what follows, we will be concerned with 4-tensors in a complex Minkowski space-time with the real metric tensor $g^{\alpha\beta}=\eta^{\alpha\beta}=\mathrm{diag}(+1,-1,-1,-1)$. Consider an arbitrary (in general not self-dual) complex bivector $F^{\alpha\beta}$. By definition it fulfills

$$F^{\alpha\beta} = -F^{\beta\alpha}, \quad \text{where } F^{\alpha\beta} \in \mathbb{C} \tag{5}$$

for all α,β. We will be interested in the tensor concomitants which are sesquilinear-quadratic in $F^{\alpha\beta}$. These are defined as follows.

Definition: A *sesquilinear-quadratic tensor concomitant* $H^{\mu_1\cdots\mu_m}_{\nu_1\cdots\nu_n}$ of a complex bivector $F^{\alpha\beta}$ is a tensor valued function $H^{\mu_1\cdots\mu_m}_{\nu_1\cdots\nu_n}(F^{\alpha\beta})$ of even rank $m+n$ that scales as $H^{\mu_1\cdots\mu_m}_{\nu_1\cdots\nu_n} \to |\lambda|^2 H^{\mu_1\cdots\mu_m}_{\nu_1\cdots\nu_n}$ under the change $F^{\alpha\beta}\to\lambda F^{\alpha\beta}$ where λ is an arbitrary complex scalar.

In practice, to construct sesquilinear-quadratic concomitants of a complex $F^{\alpha\beta}$, it is necessary to use the complex conjugate of the bivector which we denote $\bar{F}^{\alpha\beta}$ and define as

$$\bar{F}^{\alpha\beta} := \Re\{F^{\alpha\beta}\} - \mathrm{i}\Im\{F^{\alpha\beta}\}, \tag{6}$$

where $\Re\{\cdot\}$ and $\Im\{\cdot\}$ denote the real part and imaginary part, respectively, of its argument.

To be clear then, a sesquilinear-quadratic tensor concomitant of $F^{\alpha\beta}$ is any tensor constructed from the set $\{\bar{F}^{\alpha\beta}F^{\gamma\delta}, \eta^{\alpha\beta}, \epsilon^{\alpha\beta\gamma\delta}\}$, and their related covariant and mixed tensors, using the usual rules and operations of tensor algebra. Some examples of sesquilinear-quadratic tensor concomitants of $F^{\alpha\beta}$ are $\bar{F}_{\alpha\beta}F^{\gamma\mu}\epsilon_{\mu\delta\kappa\nu} - \bar{F}_{\alpha\mu}F^{\gamma\mu}\eta_{\beta\delta}\eta_{\kappa\nu}$ and $3\bar{F}_{\alpha\beta}F_{\mu\nu}\epsilon^{\mu\nu\gamma\delta}$.

We will show that out of the infinite number of possible sesquilinear-quadratic tensor concomitants of a complex bivector, there exists a unique (up to duality transform) finite set from which any sesquilinear-quadratic tensor concomitant can be constructed. The tensors in this set are the real irreducible tensors under the full real Lorentz group, $\mathcal{L}$. By real irreducible tensor under $\mathcal{L}$, we mean that the tensor cannot be written as a sum of tensors which transform independently of each other under a general transformation in $\mathcal{L}$, see Refs. 1 and 10.

Let us now stipulate some explicit criteria that the sesquilinear-quadratic tensor concomitants of a complex bivector should fulfill to be real irreducible under $\mathcal{L}$, and which we have used to find these tensors. Tensors of all ranks should be decomposed into proper tensors and pseudotensors; this because $\mathcal{L}$ includes improper transformations. Tensors of second rank should be traceless, that is, they should vanish when fully contracted with the metric tensor,

$$T_{\mu}{}^{\mu} = 0, \tag{7}$$

and they should be decomposed into symmetric and antisymmetric parts. Tensors of fourth rank should be traceless over all pairs of indices and in addition vanish when contracted over three or four indices of the Levi-Civita tensor; that is, for a fourth rank tensor concomitant $W^{\alpha\beta\gamma\delta}$ to be irreducible it must satisfy all of the following conditions:

$$W_{\mu}{}^{\mu\alpha\beta} = W_{\mu}{}^{\alpha\mu\beta} = W^{\alpha}{}_{\mu}{}^{\mu\beta} = W^{\alpha}{}_{\mu}{}^{\beta\mu} = W^{\alpha\beta}{}_{\mu}{}^{\mu} = W_{\mu}{}^{\alpha\beta\mu} = 0, \tag{8}$$

$$\epsilon_{\mu\nu\alpha\beta} W^{\mu\nu\alpha\beta} = 0, \tag{9}$$

$$\epsilon_{\alpha\mu\nu\gamma} W^{\beta\mu\nu\gamma} = \epsilon_{\alpha\mu\nu\gamma} W^{\mu\beta\nu\gamma} = \epsilon_{\alpha\mu\nu\gamma} W^{\mu\nu\beta\gamma} = \epsilon_{\alpha\mu\nu\gamma} W^{\mu\nu\gamma\beta} = 0. \tag{10}$$

These conditions ensure that a fourth rank tensor cannot be decomposed, for example, as $W^{\alpha\beta\gamma\delta} = X^{\alpha\beta\gamma\delta} + Y^{\alpha\delta}\eta^{\beta\gamma}$ or $W^{\alpha\beta\gamma\delta} = X^{\alpha\beta\gamma\delta} + c\epsilon^{\alpha\beta\gamma\delta}$ or $W^{\alpha\beta\gamma\delta} = X^{\alpha\beta\gamma\delta} + Y^{\alpha}{}_{\mu}\epsilon^{\mu\beta\gamma\delta}$, for some fourth rank tensor $X^{\alpha\beta\gamma\delta}$, second rank tensor $Y^{\alpha\delta}$, and scalar c. Tensors of ranks higher than four need not be considered as they can be constructed from the tensors of rank 0, 2, and 4 through multiplication with $\eta^{\alpha\beta}$ or $\epsilon^{\alpha\beta\gamma\delta}$. Finally, to be real[13] irreducible tensors we require that all the tensors be real (imaginary part is zero) for real representations of $\mathcal{L}$.

In conclusion the tensors in the irreducible tensorial set we wish to introduce must be

(1) Sesquilinear-quadratic concomitants of complex $F^{\alpha\beta}$,
(2) (all ranks) either proper tensors or pseudotensors,
(3) (second rank) symmetric or antisymmetric, and fulfill (7),
(4) (fourth rank) fulfill (8)–(10).

III. THE IRREDUCIBLE TENSORIAL SET

The irreducible tensorial set which fulfills the criteria enumerated in Sec. II are the six tensors

$$\mathcal{H} := \{C_+, C_-, Q^{\alpha\beta}, T^{\alpha\beta}, U^{\alpha\beta}, W^{\alpha\beta\gamma\delta}\} \tag{11}$$

defined as follows. The two scalars are the proper scalar

$$C_+ := (\bar{F}_{\mu\nu} F^{\nu\mu} - {}^*\bar{F}_{\mu\nu}{}^* F^{\nu\mu})/8 \tag{12}$$

and the pseudoscalar

$$C_- := (\bar{F}_{\mu\nu}{}^* F^{\nu\mu} + {}^*\bar{F}_{\mu\nu} F^{\nu\mu})/8, \tag{13}$$

where we have used the dual of $F^{\alpha\beta}$ defined as

$$^{*}F^{\alpha\beta} := \tfrac{1}{2}\epsilon^{\alpha\beta\mu\nu}F_{\mu\nu} = \tfrac{1}{2}\epsilon^{\alpha\beta}{}_{\mu\nu}F^{\mu\nu}. \tag{14}$$

The three second rank tensors are the antisymmetric pseudotensor

$$Q^{\alpha\beta} := \mathrm{i}(\bar{F}^{\alpha}{}_{\mu}F^{\mu\beta} - {}^{*}\bar{F}^{\alpha}{}_{\mu}{}^{*}F^{\mu\beta} - 2C_{+}\eta^{\alpha\beta})/2, \tag{15}$$

the symmetric proper tensor

$$T^{\alpha\beta} := (\bar{F}^{\alpha}{}_{\mu}F^{\mu\beta} + {}^{*}\bar{F}^{\alpha}{}_{\mu}{}^{*}F^{\mu\beta})/2, \tag{16}$$

and the symmetric pseudotensor

$$U^{\alpha\beta} := \mathrm{i}(\bar{F}^{\alpha}{}_{\mu}{}^{*}F^{\mu\beta} - {}^{*}\bar{F}^{\alpha}{}_{\mu}F^{\mu\beta})/2. \tag{17}$$

The fourth rank tensor is the proper tensor

$$W^{\alpha\beta\gamma\delta} := (\bar{F}^{\alpha\beta}F^{\gamma\delta} - {}^{*}\bar{F}^{\alpha\beta *}F^{\gamma\delta})/2 + 2\mathrm{i}Q^{[\alpha[\delta}\eta^{\gamma]\beta]} - \tfrac{2}{3}C_{+}\eta^{\alpha[\delta}\eta^{\gamma]\beta} - \tfrac{1}{3}C_{-}\epsilon^{\alpha\beta\gamma\delta}, \tag{18}$$

where the square brackets denotes antisymmetrization over the enclosed indices, e.g., $T^{\alpha[\delta}g^{\gamma]\beta} = \frac{1}{2}(T^{\alpha\delta}g^{\gamma\beta} - T^{\alpha\gamma}g^{\delta\beta})$, and nested brackets are not operated on by enclosing brackets, e.g., $T^{[\alpha[\delta}g^{\gamma]\beta]} = \frac{1}{4}(T^{\alpha\delta}g^{\gamma\beta} - T^{\alpha\gamma}g^{\delta\beta} - T^{\beta\delta}g^{\gamma\alpha} + T^{\beta\gamma}g^{\delta\alpha})$. It fulfills the symmetries $W^{\alpha\beta\gamma\delta} = -W^{\beta\alpha\gamma\delta} = -W^{\alpha\beta\delta\gamma} = W^{\gamma\delta\alpha\beta}$ and $W^{\alpha[\beta\gamma\delta]} = 0$.

Note that all the tensors in the set are either self-dual or anti-self-dual with respect to the duality transform: $F^{\alpha\beta} \mapsto {}^{*}F^{\alpha\beta}$ and ${}^{*}F^{\alpha\beta} \mapsto -F^{\alpha\beta}$ jointly. Note also that if $F^{\alpha\beta}$ is purely real, then $Q^{\alpha\beta}$ and $U^{\alpha\beta}$ vanish.

The importance of $\mathcal{H}$ is brought out in the following theorem.

Theorem: *Any sesquilinear-quadratic concomitant of a complex antisymmetric 4-tensor $F^{\mu\nu}$ can be completely decomposed in terms of the tensors in the set $\mathcal{H}$.*

Proof: As mentioned previously, any sesquilinear-quadratic tensor concomitant of $F^{\mu\nu}$ can be written exclusively as linear combinations of tensor terms of the form $\bar{F}^{\alpha\beta}F^{\gamma\delta}$ (possibly) multiplied and contracted over any of its indices by the tensors $\eta^{\mu\nu}$ and $\epsilon^{\mu\nu\iota\kappa}$.

Therefore it suffices to show that $\bar{F}^{\alpha\beta}F^{\gamma\delta}$ can be decomposed into the tensors in $\mathcal{H}$. Using straightforward tensor algebra, it is possible to show that

$$\begin{aligned}\bar{F}^{\alpha\beta}F^{\gamma\delta} = {} & T^{[\alpha[\delta}\eta^{\gamma]\beta]} - \tfrac{1}{8}\mathrm{i}(U^{\alpha\mu}\epsilon_{\mu}{}^{\beta\gamma\delta} - U^{\beta\mu}\epsilon_{\mu}{}^{\gamma\delta\alpha} - U^{\gamma\mu}\epsilon_{\mu}{}^{\delta\alpha\beta} + U^{\delta\mu}\epsilon_{\mu}{}^{\alpha\beta\gamma}) + W^{\alpha\beta\gamma\delta} \\ & - 2\mathrm{i}Q^{[\alpha[\delta}\eta^{\gamma]\beta]} + \tfrac{2}{3}C_{+}\eta^{\alpha[\delta}\eta^{\gamma]\beta} + \tfrac{1}{3}C_{-}\epsilon^{\alpha\beta\gamma\delta} + \tfrac{1}{2}\mathrm{i}\epsilon^{\gamma\delta}{}_{\mu\nu}U^{[\alpha[\nu}\eta^{\mu]\beta]} \\ & + \tfrac{1}{16}\epsilon^{\gamma\delta}{}_{\mu\nu}(T^{\alpha\kappa}\epsilon_{\kappa}{}^{\beta\mu\nu} - T^{\beta\kappa}\epsilon_{\kappa}{}^{\mu\nu\alpha} - T^{\mu\kappa}\epsilon_{\kappa}{}^{\nu\alpha\beta} + T^{\nu\kappa}\epsilon_{\kappa}{}^{\alpha\beta\mu}).\end{aligned}$$

It is clear from inspection of this expansion that the sesquilinear-quadratic dependency on F is completely contained in the six irreducible tensors: C_{+}, C_{-}, $Q^{\alpha\beta}$, $T^{\alpha\beta}$, $U^{\alpha\beta}$, and $W^{\alpha\beta\gamma\delta}$. ■

A further check of the above theorem is gained from the dimensionality of the space of sesquilinear-quadratic concomitants of a complex bivector. $F^{\alpha\beta}$ has 12 degrees of freedom counting both real and imaginary parts while $\bar{F}^{\alpha\beta}F^{\gamma\delta}$ has 36 degrees of freedom. The set $\mathcal{H}$ has, respectively, {1, 1, 6, 9, 9, 10} degrees of freedom, which in total gives 36 degrees of freedom. Thus, dimensionally $[\bar{6}]\otimes[6] = [1]\oplus[1]\oplus[6]\oplus[9]\oplus[9]\oplus[10]$, where a sesquilinear-quadratic product on a complex space is assumed on the left-hand side.

The set $\mathcal{H}$ is unique under the conditions enumerated in Sec. II up to a duality transform of either $Q^{\alpha\beta}$ or $W^{\alpha\beta\gamma\delta}$; that is,

$$^{*}Q^{\alpha\beta}, \tag{19}$$

$$^{*}W^{\alpha\beta\gamma\delta} := \tfrac{1}{2}\epsilon^{\alpha\beta}{}_{\mu\nu}W^{\mu\nu\gamma\delta} \tag{20}$$

are alternatives to either $Q^{\alpha\beta}$ or $W^{\alpha\beta\gamma\delta}$, respectively, as elements in the minimal set of real irreducible tensors.

IV. ELECTROMAGNETIC COMPONENTS OF THE IRREDUCIBLE TENSORS AND THEIR ASSOCIATION WITH KNOWN QUANTITIES

It is instructive to write out the components of the irreducible tensorial set, $\mathcal{H}$, in terms of complex electric and magnetic field 3-vectors. Any complex electromagnetic field strength 4-tensor can be written

$$F^{\alpha\beta} = \begin{pmatrix} 0 & -\mathbf{E}^{\mathsf{T}} \\ \mathbf{E} & \mathbf{B}\times \end{pmatrix}, \tag{21}$$

where

$$\mathbf{E} = (E_1, E_2, E_3)^{\mathsf{T}} \in \mathbb{C}^3, \tag{22}$$

$$\mathbf{B} = (B_1, B_2, B_3)^{\mathsf{T}} \in \mathbb{C}^3, \tag{23}$$

are the electric 3-vector and the magnetic 3-vector, respectively. Here T denotes the transpose operator, and the $\mathbf{B}\times := \epsilon_{ijk}B_j$ where ϵ_{ijk} is the Levi-Civita tensor in three dimensions (lower case italic letters $i,j,k=1,2,3$ represent Cartesian components in 3-space).

In terms of the **E** and **B** 3-vectors, the components of the irreducible tensors are as follows: The two scalars are

$$C_+ = (|\mathbf{E}|^2 - |\mathbf{B}|^2)/2, \tag{24}$$

$$C_- = -\Re\{\bar{\mathbf{E}}\cdot\mathbf{B}\}. \tag{25}$$

The three second rank tensors consists of the antisymmetric pseudotensor

$$Q^{00} = 0, \tag{26}$$

$$Q^{i0} = \Im\{\bar{\mathbf{E}}\times\mathbf{B}\}, \tag{27}$$

$$Q^{ij} = \Im\{\bar{\mathbf{E}}\otimes\mathbf{E} - \bar{\mathbf{B}}\otimes\mathbf{B}\} = \frac{\mathrm{i}}{2}(\bar{\mathbf{E}}\times\mathbf{E} - \bar{\mathbf{B}}\times\mathbf{B})\times, \tag{28}$$

$$Q^{ji} = -Q^{ij}, \tag{29}$$

and the symmetric proper tensor

$$T^{00} = (|\mathbf{E}|^2 + |\mathbf{B}|^2)/2, \tag{30}$$

$$T^{i0} = \Re\{\bar{\mathbf{E}}\times\mathbf{B}\}, \tag{31}$$

$$T^{ij} = -\Re\{\bar{\mathbf{E}}\otimes\mathbf{E} + \bar{\mathbf{B}}\otimes\mathbf{B}\} + T^{00}\mathbf{1}_3, \tag{32}$$

$$T^{ji} = T^{ij} \tag{33}$$

and the symmetric pseudotensor

$$U^{00} = \Im\{\bar{\mathbf{E}} \cdot \mathbf{B}\}, \tag{34}$$

$$U^{i0} = \frac{\mathrm{i}}{2}(\bar{\mathbf{E}} \times \mathbf{E} + \bar{\mathbf{B}} \times \mathbf{B}), \tag{35}$$

$$U^{ij} = -\Im\{\bar{\mathbf{E}} \otimes \mathbf{B} - \bar{\mathbf{B}} \otimes \mathbf{E}\} + U^{00}\mathbf{1}_3, \tag{36}$$

$$U^{ji} = U^{ij}, \tag{37}$$

where $\mathbf{1}_3$ is the identity matrix in three dimensions.

As for the last tensor in the set, the fourth rank proper tensor $W^{\alpha\beta\gamma\delta}$, it is more efficient to write its components out using a bivector indexing scheme, see Ref. 3. We will denote a bivector index with upper case italic letters, such as A or B, and let it run through the integers 1 through 6. F^A is used to represent the tensor component $F^{\alpha\beta}$ of an antisymmetric tensor according to the index mapping: $A \leftrightarrow [\alpha\beta]$, where $1 \leftrightarrow [10]$, $2 \leftrightarrow [20]$, $3 \leftrightarrow [30]$, $4 \leftrightarrow [32]$, $5 \leftrightarrow [13]$, $6 \leftrightarrow [21]$. Based on this scheme, the second rank antisymmetric tensor (21) can be written in terms of the 3-vectors $\mathbf{E}$ and $\mathbf{B}$ as

$$F^{\alpha\beta} = \begin{pmatrix} 0 & -\mathbf{E}^{\mathsf{T}} \\ \mathbf{E} & \mathbf{B}\times \end{pmatrix} \leftrightarrow \begin{pmatrix} \mathbf{E} \\ \mathbf{B} \end{pmatrix} = F^A \tag{38}$$

where the six-component vector on the right-hand side, F^A, is known as a sixtor, see Ref. 10. A fourth rank tensor can be written out in terms of its components using two bivector indices: the first and second 4-tensor indices map to the first bivector index, and the third and fourth 4-tensor indices map to the second bivector index. With this scheme we can write down the components of $W^{\alpha\beta\gamma\delta}$ accordingly

$$W^{\alpha\beta\gamma\delta} \leftrightarrow W^{AB} = \frac{1}{2}\begin{pmatrix} \Re\{\bar{\mathbf{E}} \otimes \mathbf{E} - \bar{\mathbf{B}} \otimes \mathbf{B}\} - \frac{2}{3}C_+\mathbf{1}_3 & \Re\{\bar{\mathbf{E}} \otimes \mathbf{B} + \bar{\mathbf{B}} \otimes \mathbf{E}\} - \frac{2}{3}C_-\mathbf{1}_3 \\ \Re\{\bar{\mathbf{E}} \otimes \mathbf{B} + \bar{\mathbf{B}} \otimes \mathbf{E}\} - \frac{2}{3}C_-\mathbf{1}_3 & -\Re\{\bar{\mathbf{E}} \otimes \mathbf{E} - \bar{\mathbf{B}} \otimes \mathbf{B}\} + \frac{2}{3}C_+\mathbf{1}_3 \end{pmatrix}. \tag{39}$$

From the above expressions of the irreducible tensors explicitly in terms of the complex electric and magnetic field components, it is possible to identify some quantities from electromagnetic theory. The tensors C_+, C_-, and $T^{\alpha\beta}$ are sesquilinear-quadratic generalizations of the well-known electromagnetic scalar-invariants and energy-momentum density tensor, respectively. Tensors closely related to $T^{\alpha\beta}$ and $U^{\alpha\beta}$ were introduced by Ref. 5. Also some of the 3-vectors are already known: Q^{i0} in Eq. (27) is the imaginary part of the complex Poynting vector, see Ref. 4, and the 3-vector U^{i0} in Eq. (35) is mentioned in Ref. 6. As far as the authors are aware the rest of the quantities, specifically the 4-tensors $Q^{\alpha\beta}$ and $W^{\alpha\beta\gamma\delta}$, are novel in the theory of electromagnetism.

V. CONCLUSION

We have shown that any sesquilinear-quadratic concomitant of a complex bivector can be completely decomposed into tensors in the set $\mathcal{H}$ as defined in Sec. III and summarized in Table I. The tensors in $\mathcal{H}$ are either proper tensors or pseudotensors and are real irreducible under the full real Lorentz group. This tensorial set is unique up to a duality transform of $Q^{\alpha\beta}$ or $W^{\alpha\beta\gamma\delta}$.

Of the tensors in set $\mathcal{H}$, the electromagnetic quantities related to C_+, C_-, and $T^{\alpha\beta}$ are all sesquilinear-quadratic generalizations of previously known quadratic tensor concomitants of real (electromagnetic) bivector fields; while Kujawski[5] introduced quantities closely related to $T^{\alpha\beta}$ and $U^{\alpha\beta}$. As far as the authors are aware the other tensors, $Q^{\alpha\beta}$ and $W^{\alpha\beta\gamma\delta}$, have not been previously considered in the literature.

TABLE I. Summary of the complete tensorial set $\mathcal{H}$. The + and − signs in column "Proper/Pseudo" correspond to whether the concomitant is a proper tensor or a pseudotensor, respectively. The heading "# comp" stands for "number of independent components." For the second rank the "*A*" and the "*S*" in the "Rank" column denote whether the tensor is antisymmetric or symmetric, respectively. $W^{\alpha\beta\gamma\delta}$ fulfills the same index symmetries as the Weyl tensor.

Concomitant	Rank	Proper/Pseudo	# comp
C_+	0	+	1
C_-	0	−	1
$Q^{\alpha\beta}$	2 (*A*)	−	6
$T^{\alpha\beta}$	2 (*S*)	+	9
$U^{\alpha\beta}$	2 (*S*)	−	9
$W^{\alpha\beta\gamma\delta}$	4	+	10

[12] By concomitant we mean here a 4-tensor constructed from the bivector, the metric tensor, and the Levi-Civita tensor using the laws of tensor algebra; see Ref. 8. By quadratic concomitant we mean that the concomitant is second order in the bivector, that is, it exclusively contains terms involving the bivector multiplied with itself.
[13] In this paper we choose to study real irreducible tensors as opposed to complex irreducible tensors because they correspond more closely to the well-known quadratic tensors of real bivectors in electromagnetism.

From Stäckel systems to integrable hierarchies of PDE's: Benenti class of separation relations

We propose a general scheme of constructing of soliton hierarchies from finite dimensional Stäckel systems and related separation relations. In particular, we concentrate on the simplest class of separation relations, called Benenti class, i.e., certain Stäckel systems with quadratic in momenta integrals of motion. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2176908]

I. INTRODUCTION

The theory of integrable nonlinear evolution equations has a long history as a part of many branches of theoretical physics and applied mathematics. Generally it can be divided in two parts: the theory of integrable nonlinear ordinary differential equations (ODE's) and the theory of integrable nonlinear partial differential equations (PDE's). Within the first class of equations (ODE's) we will consider finite dimensional Hamiltonian systems, integrable by the Hamilton-Jacobi method, called *Stäckel systems*, while within the second class (PDE's) we will consider $(1+1)$-dimensional field systems, having infinite hierarchy of commuting symmetries and called further for simplicity *soliton systems*. The solvability by quadratures of some class of finite dimensional systems by the Hamilton-Jacobi method, laid in the 19th century one of the fundaments of analytical mechanics of integrable systems, while the solvability by quadratures of some class of infinite dimensional field systems by the inverse scattering method, laid in the second half of the 20th century, one of the fundaments of the so-called soliton theory.

During the last few decades both theories have been developed very intensively using many common modern mathematical tools like Lax representation, r-matrix theory, multi-Hamiltonian theory, etc. In that time some links between both theories were investigated. It was found (Refs. 1–4, see also references in Ref. 5) that finite dimensional restrictions, invariant with respect to the action of a given soliton system, like stationary flows, restricted flows or constrained flows of Lax representation, are Liouville integrable Hamiltonian systems of Stäckel type. Moreover, analytical solutions of an appropriate finite dimensional systems are closely related to a special class of solutions of related soliton systems, like for example, so-called finite-gap solutions.[6,7]

In the present paper we are interested in passing in the opposite direction—building integrable hierarchies of PDE's from Stäckel systems.[8] In that sense we would like to initiate a unified approach to Stäckel ODE's and soliton PDE's. Our claim is the following: *both a wide class of Stäckel systems and a wide class of soliton systems can be constructed form common fundamental objects known as separation relations (or from separation curves).*

The paper is organized as follows. Section II is devoted to general description of the concept of separation relations. Section III explains the main ideas of relating soliton systems with separation curves that are quadratic in momenta. The idea is to apply to a set of Killing vector fields

[a)]Partially supported by KBN Research Project 1 P03B 111 27 and by Swedish Research Science Council Grant No. 2004-6920.

a set of invariants generated by Euler-Lagrange equations associated with appropriately chosen Lagrangian densities. This allows for elimination of some variables in our Killing systems which leads to dispersive soliton hierarchies. Section IV is a brief introduction to what can be called Benenti class of Stäckel systems. In Sec. V we describe the structure of our systems in Viète coordinates. In Sec. VI we explain the details of our elimination procedure which allows, in a systematic way, to construct soliton hierarchies. It is divided into two sections as the elimination procedure differs in case of "positive" and "negative" (see below) separable potentials. Section VII concludes the article with several examples.

II. SEPARATION RELATIONS

Let us consider a $2n$-dimensional manifold M equipped with a Poisson operator Π with some canonical (Darboux) coordinates labelled as $M \ni u=(\mu,\lambda)$, with $\mu=(\mu_1,\ldots,\mu_n)$ and $\lambda=(\lambda_1,\ldots,\lambda_n)$. The following definition introduces the basic object of our considerations.[9]

Definition 1: A set of n relations of the form

$$\varphi_i(\lambda_i,\mu_i,a_1,\ldots,a_n)=0, \quad i=1,\ldots,n, \quad a_i\in\mathbf{R} \tag{1}$$

(each involving only one pair λ_i,μ_i of canonical coordinates) are called separation relations provided that the dependence of φ on a is essential, i.e., that $\det(\partial\varphi_i/\partial a_j)\neq 0$.

The condition in (1) means that we can resolve the equations (1) with respect to a_i obtaining $a_i=H_i(\lambda,\mu)$, $i=1,\ldots,n$. This defines some new functions $H_i(\lambda,\mu)$ that in turn define the following Hamiltonian systems (evolutionary vector fields) on M,

$$u_{t_i}=\Pi\,\mathrm{d}H_i=X_{H_i}, \quad i=1,\ldots,n. \tag{2}$$

If the functions $W_i(\lambda_i,a)$ are solutions of a system of n decoupled ODE's obtained from (1) by substituting $\mu_i=\partial W_i(\lambda_i,a)/\partial\lambda_i$

$$\varphi_i\left(\lambda_i,\mu_i=\frac{\partial W_i(\lambda_i,a)}{\partial\lambda_i},a_1,\ldots,a_n\right)=0, \quad i=1,\ldots,n, \tag{3}$$

then the function $W(\lambda,a)=\sum_{i=1}^n W_i(\lambda_i,a)$ is an additively separable solution of *all* the equations (3) and *simultaneously* it is a solution of all Hamilton-Jacobi equations

$$a_i=H_i\left(\lambda,\mu=\frac{\partial W(\lambda,a)}{\partial\lambda}\right), \quad i=1,\ldots,n \tag{4}$$

related with the Hamiltonians H_i—simply because solving (1) to the form $a_i=H_i(\lambda,\mu)$ is a purely algebraic operation. Assume now that $\det(\partial^2 W/\partial\lambda_i\partial a_j)=\det(\partial^2 W_i/\partial\lambda_i\partial a_j)\neq 0$. Then the Hamiltonians H_i Poisson-commute since the constructed function $W(\lambda,a)$ is a generating function for the canonical transformation $(\lambda,\mu)\to(b,a)$ where

$$b_i=\frac{\partial W(\lambda,\alpha)}{\partial a_i}=t_i+\mathrm{const}_i, \quad i=1,\ldots,n. \tag{5}$$

Equations (5) are implicit solutions of (2) known as the *inversion Jacobi problem.* Thus, starting from a set of n separation relations we can create an n-dimensional separable Liouville system. All systems separable in the sense of Hamilton-Jacobi theory can be obtained in this way.

In an important case, when the functions φ_i in (1) do not depend on the index i, the separation relations (1) can be generated by taking n copies of a curve in λ-μ plane:

$$\varphi(\lambda,\mu,a_1,\ldots,a_n)=0, \quad a_i\in\mathbf{R} \tag{6}$$

called *separation curve*.

Restricting our considerations to a subclass of (1), when all separation relations are affine in $a_i=H_i$ with coefficients being monomials in λ and μ, we obtain

$$\sum_{k=1}^{n} H_k \mu_i^{\alpha_k} \lambda_i^{\beta_k} = \psi_i(\lambda_i, \mu_i), \quad i = 1, \ldots, n, \quad \alpha_k, \beta_k \in \mathbf{N}, \tag{7}$$

where ψ_i are arbitrary smooth functions of two arguments. Equations (7) are called generalized *Stäckel separation relations* and the related dynamic systems, generated by Hamiltonian functions H_i, are called the *Stäckel separable* ones. To recover explicit Stäckel form of Hamiltonians it is sufficient to solve the linear system (7) with respect to H_i. If additionally $\psi_i(\lambda_i, \mu_i) = \psi(\lambda_i, \mu_i)$ then the above separation conditions can be represented by n copies of the following separation curve:

$$\sum_{k=1}^{n} H_k \mu^{\alpha_k} \lambda^{\beta_k} = \psi(\lambda, \mu). \tag{8}$$

The separable systems that were most intensively studied in the last century were one-particle dynamical systems on Riemannian manifolds with flat or constant curvature metrics. All these systems can be obtained by choosing $\alpha_i = 0, \beta_i = n - i$, $i = 1, \ldots, n$ with ψ quadratic in momenta

$$\psi(\lambda, \mu) = \tfrac{1}{2} f(\lambda) \mu^2 + \gamma(\lambda). \tag{9}$$

This case will be considered in the next sections of this paper.

We can now shortly present—by a simple example—the possibility of passing from a separation curve to soliton systems.[10] Let us consider the separation curve (8) with $n = 2, \alpha_1 = \alpha_2 = 0, \beta_1 = 1, \beta_2 = 0$ and with ψ in the form of (9),

$$H_1 \lambda + H_2 = \tfrac{1}{2} \lambda \mu^2 + \lambda^4. \tag{10}$$

The related separation conditions (7) are

$$\begin{aligned} H_1 \lambda_1 + H_2 &= \tfrac{1}{2} \lambda_1 \mu_1^2 + \lambda_1^4, \\ H_1 \lambda_2 + H_2 &= \tfrac{1}{2} \lambda_2 \mu_2^2 + \lambda_2^4. \end{aligned} \tag{11}$$

Solving this linear system with respect to H_1 and H_2 one gets the Liouville integrable system (2) on four-dimensional phase space, written in separation coordinates (λ, μ). The explicit form of Hamiltonians H_i is

$$H_1 = \frac{1}{2} \frac{\lambda_1 \mu_1^2 - \lambda_2 \mu_2^2 + 2\lambda_1^4 - 2\lambda_2^4}{\lambda_1 - \lambda_2}, \quad H_2 = \frac{1}{2} \frac{\lambda_1 \lambda_2 (\mu_1^2 - \mu_2^2 + 2\lambda_1^3 - 2\lambda_2^3)}{\lambda_2 - \lambda_1}.$$

The canonical transformation of the form

$$q_1 = \lambda_1 + \lambda_2, \quad \tfrac{1}{4} q_2^2 = -\lambda_1 \lambda_2,$$

$$p_1 = \frac{\lambda_1 \mu_1}{\lambda_1 - \lambda_2} + \frac{\lambda_2 \mu_2}{\lambda_2 - \lambda_1}, \quad p_2 = \sqrt{-\lambda_1 \lambda_2} \left(\frac{\mu_1}{\lambda_1 - \lambda_2} + \frac{\mu_2}{\lambda_2 - \lambda_1} \right)$$

transforms the system to new coordinates (q, p), with

$$H_1 = \tfrac{1}{2} p_1^2 + \tfrac{1}{2} p_2^2 + q_1^3 + \tfrac{1}{2} q_1 q_2^2, \quad H_2 = \tfrac{1}{2} q_2 p_1 p_2 - \tfrac{1}{2} q_1 p_2^2 + \tfrac{1}{16} q_2^4 + \tfrac{1}{4} q_1^2 q_2^2.$$

The function $H_1(q, p)$ turns out to be the Hamiltonian function of the integrable case of the Henon-Heiles system, while $H_2(q, p)$ is the additional involutive first integral of this system. Let us now denote the evolution parameters t_1 and t_2 of the system by x and t, respectively. Then we obtain

$$q_{1,x} = \frac{\partial H_1}{\partial p_1} = p_1, \quad q_{2,x} = \frac{\partial H_1}{\partial p_2} = p_2,$$

$$q_{1,t} = \frac{\partial H_2}{\partial p_1} = \frac{1}{2} q_2 p_2, \quad q_{2,t} = \frac{\partial H_2}{\partial p_2} = \frac{1}{2} q_2 p_1 - q_1 p_2,$$

from which eliminating p_1 and p_2 we obtain a system of first order PDE's for $q_1(x,t)$ and $q_2(x,t)$,

$$q_{1,t} = \tfrac{1}{2} q_2 q_{2,x} = \tfrac{1}{4}(q_2^2)_x, \quad q_{2,t} = \tfrac{1}{2} q_2 q_{1,x} - q_1 q_{2,x}. \tag{12}$$

Finally, we can eliminate q_2 through

$$q_{1,xx} = p_{1,x} = -\frac{\partial H_1}{\partial q_1} = -3q_1^2 - \frac{1}{2} q_2^2$$

which yields $q_2^2 = -6q_1^2 - 2q_{1,xx}$ and then generate a higher order (in x-derivatives) PDE. The first equation in (12) turns then into the famous KdV soliton system

$$q_{1,t} + \tfrac{1}{2} q_{1,xxx} + 3q_1 q_{1,x} = 0, \tag{13}$$

while the second equation in (12) turns into a differential consequence of the first one. Obviously, just from the presented construction, there is no guarantee that Eq. (13) is integrable. We can only say that $q_1(x,t)$ calculated from the corresponding inversion Jacobi problem is a nontrivial particular solution (one-gap solution) for the field system (13). To prove the integrability of (13) one must construct some related infinite hierarchy of symmetries using some more regular procedure.

III. FROM SEPARATION CURVES TO CONSTRAINED DISPERSIONLESS SYSTEMS

In this paper we will concentrate on a special but important class of separation curves with the function $\psi(\lambda,\mu)$ in (8) being quadratic in momenta μ [more precisely, of the form (9)] and with multipliers of Hamiltonian functions being monomials with respect to λ,

$$H_1 \lambda^{\beta_1} + \cdots + H_n \lambda^{\beta_n} = \tfrac{1}{2} \lambda^m \mu^2 + \lambda^k, \tag{14}$$

where $\beta_1 > \cdots > \beta_{n-1} > \beta_n = 0$, $\beta_i \in \mathbf{N}, m, k \in \mathbf{Z}$ and $n \in \mathbf{N}$. Separable systems from this class describe one-particle dynamics on Riemannian manifolds and belong to classical Stäckel systems. Each class of these systems is labelled by a decreasing sequence $(\beta_1, \ldots, \beta_n)$ while members of a given class are numbered by pairs $(m,k) \in \mathbf{Z}^2$. Taking n copies of the curve (14) with variables (λ,μ) labelled within each copy as (λ_i, μ_i), we obtain a system of n separation relations in the form of n equations linear in the coefficients H_i. Solving it we obtain n functions $H_r^{(m,k)} = H_r^{(m,k)}(\lambda,\mu)$ of the form

$$H_r^{(m,k)} = \tfrac{1}{2} \mu^T K_r G^{(m)} \mu + V_r^{(k)}, \quad r = 1, \ldots, n, \quad m,k \in \mathbf{Z}, \tag{15}$$

where we denote $\lambda = (\lambda_1, \ldots, \lambda_n)^T$ and $\mu = (\mu_1, \ldots, \mu_n)^T$. The functions (15) can be interpreted as n Hamiltonians on the phase space $T^*\mathcal{Q}$ cotangent to a Riemannian manifold $\mathcal{Q}$ equipped with the contravariant metric tensor $G^{(m)}$. These Hamiltonians are in involution with respect to the canonical Poisson bracket on $T^*\mathcal{Q}$. Moreover, they are separable in the sense of Hamilton-Jacobi theory since they by the very definition satisfy Stäckel relations (14). The objects K_r in (15) can be interpreted as (1, 1)-type Killing tensors on $\mathcal{Q}$. The scalar functions $V_r^{(k)}$ are separable potentials. Further, all the metric tensors $G^{(m)}$ and all the Killing tensors K_r are diagonal in λ-variables so that

$$K_r = \operatorname{diag}(v_r^1, \ldots, v_r^n), \tag{16}$$

where v_r^i are eigenvalues of K_r. We will constantly assume that these eigenvalues are single.

The set (15) of n Hamiltonian functions leads to n Hamiltonian systems on $T^*\mathcal{Q}$ of the form

$$\lambda_{t_r} = \frac{\partial H_r^{(k,m)}}{\partial \mu}, \quad \mu_{t_r} = -\frac{\partial H_r^{(k,m)}}{\partial \lambda}, \quad r = 1, \ldots, n. \tag{17}$$

Let us now call the variable t_1 as x; $t_1 \equiv x$. Since all the Hamiltonians $H_r^{(k,m)}$ (for fixed k and m) commute, the equations (17) have a common set of solutions depending on all the evolution parameters t_i

$$\lambda_i = \lambda_i(t_1 = x, t_2, \ldots, t_n), \quad \mu_i = \mu_i(t_1 = x, t_2, \ldots, t_n).$$

We have, due to (17), that

$$\lambda_x \equiv \lambda_{t_1} = \frac{\partial H_1^{(k,m)}}{\partial \mu} = G^{(m)}\mu \quad \text{so that } \mu = g^{(m)}\lambda_x,$$

where the inverse of $G^{(m)}$ (i.e., respective covariant metric tensors) is denoted as $g^{(m)}$. Observe that the above relation does not depend on k. Using this to eliminate μ from the first part of (17) we obtain

$$\lambda_{t_r} = \frac{\partial H_r^{(k,m)}}{\partial \mu} = K_r G^{(m)}\mu,$$

or, according to the above

$$\lambda_{t_r} = K_r \lambda_x \equiv Z_r^n(\lambda, \lambda_x), \quad r = 1, \ldots, n. \tag{18}$$

This is a set of n autonomous systems of n coupled first order PDE's of evolutionary type, with the right-hand sides depending linearly on the derivatives λ_x.[11] More precisely, it is a set of n integrable dispersionless equations, belonging to the class of so-called weakly nonlinear semi-Hamiltonian systems,[12,13] where the variables λ_i are the Riemann invariants for (18). We will call them *Killing dispersionless system* as they are constructed directly from Killing tensors.

We will interpret the right-hand sides of (18) as vector fields on an infinite dimensional manifold $\mathcal{M}$ the points of which are vector functions of x of the form $u = (\lambda_1(x), \ldots, \lambda_n(x))$, where we assume that the functions $\lambda_i(x)$ are either periodic in x or they vanish together with all their derivatives when $x \to \pm\infty$. A vector field X is at a point $u \in \mathcal{M}$ given by an n-tuple of the form $X(u) = (f_1[\lambda], \ldots, f_n[\lambda])$ where $f_i[\lambda] = f_i(\lambda_1, \lambda_{1,x}, \ldots, \lambda_2, \lambda_{2,x}, \ldots, \lambda_n, \lambda_{n,x}, \ldots)$ are differential functions of λ. Similarly, a covector field α on $\mathcal{M}$ is in a point $u = (\lambda_1(x), \ldots, \lambda_n(x))$ given by $\alpha(u) = (g_1[\lambda], \ldots, g_n[\lambda])$. The dual map between $T_u\mathcal{M}$ and $T_u^*\mathcal{M}$ is given by

$$\langle \alpha, X \rangle(u) = \int_x \sum_{i=1}^{n} f_i[\lambda] g_i[\lambda] \mathrm{d}x.$$

Here and below the integration is performed over one period (in case of periodic boundary conditions) or over $\mathbf{R}$ in case of functions vanishing at $\pm\infty$. All functions and expressions are always assumed to be integrable. For any two given vector fields X and Y on $\mathcal{M}$ their commutator is defined in a usual way as $[X, Y] = X'[Y] - Y'[X]$ where $X'[Y]$ denotes the directional derivative of X in the direction of Y.

As was shown in Ref. 14, the vector fields Z_i^n pairwise commute,

$$[Z_i^n, Z_j^n] = 0, \quad i, j = 1, \ldots, n,$$

thus, (18) is a set of n commuting evolutionary dynamic systems (vector fields) on $\mathcal{M}$. We will need the superscript n to indicate the number of components (dimension) of these systems. Below we will introduce invariants on (18) that eventually turn these systems into hierarchies of soliton systems with lower number of fields. This is the main idea of this paper.

We begin by defining the following differential functions (currents, Lagrangians):

$$\mathcal{L}_r^{(n,m,k)} \overset{\text{def}}{=} \tfrac{1}{2}\lambda_x^T g^{(m)} K_r \lambda_x - V_r^{(k)}, \quad r=1,\dots,n. \tag{19}$$

In our further considerations we will especially need the first current $\mathcal{L}_1^{(n,m,k)}$, so we will denote it simply by $\mathcal{L}^{(n,m,k)}$,

$$\mathcal{L}^{(n,m,k)} \overset{\text{def}}{=} \mathcal{L}_1^{(n,m,k)}.$$

This current is a Legendre transform of $H_1^{(n,m,k)}$ (this is not true for $H_r^{(n,m,k)}$ with $r>1$). These differential functions yield the following functionals on $\mathcal{M}$:

$$I_r^{(n,m,k)}(u) \overset{\text{def}}{=} \int_x \mathcal{L}_r^{(n,m,k)}[\lambda]\mathrm{d}x,$$

where, as usual, $u=(\lambda_1(x),\dots,\lambda_n(x))$. We have, of course,

$$\frac{\mathrm{d}I_r^{(n,m,k)}}{\mathrm{d}t_s} = \left\langle \frac{\delta I_r^{(n,m,k)}}{\delta\lambda}, Z_s^n[\lambda] \right\rangle = \langle E(\mathcal{L}_r^{(n,m,k)}), Z_s^n[\lambda]\rangle,$$

where $E=(E_1,\dots,E_n)=(\delta/\delta\lambda_1,\dots,\delta/\delta\lambda_n)$ is the Euler-Lagrange operator on $\mathcal{M}$.

Lemma 2: In the notation as above,

$$\frac{\mathrm{d}I_1^{(n,m,k)}}{\mathrm{d}t_r} = 0, \quad r=1,\dots,n.$$

Proof: It suffices to prove that

$$\sum_{i=1}^n E_i(\mathcal{L}^{(n,m,k)})\lambda_{i,t_r} = \sum_{i=1}^n E_i(\mathcal{L}_r^{(n,m,k)})\lambda_{i,x} \tag{20}$$

since integrating of (20) yields,

$$\frac{\mathrm{d}I_1^{(n,m,k)}}{\mathrm{d}t_r} = \frac{\mathrm{d}I_r^{(n,m,k)}}{\mathrm{d}t_1}, \quad r=1,\dots,n$$

while

$$\frac{\mathrm{d}I_r^{(n,m,k)}}{\mathrm{d}t_1} = \int_x \sum_{i=1}^n E_i(\mathcal{L}_r^{(n,m,k)})\lambda_{i,x}\,\mathrm{d}x = \int_x \frac{d}{\mathrm{d}x}(\mathcal{L}_r^{(n,m,k)})\mathrm{d}x = 0$$

due to the appropriately chosen boundary conditions. The proof of (20) can be found in Appendix A. ■

Corollary 3: Lemma 2, due to theorem of Ref. 15 (see also Ref. 16) implies that the $2n$*-dimensional set* $\mathcal{E}\subset\mathcal{M}$ *defined as*

$$\mathcal{E} = \{u : E_i(\mathcal{L}^{(n,m,k)}) = 0 \text{ for all } i=1,\dots,n\}$$

is Z_r^n*-invariant for all* $r=1,\dots,n$.

Thus, if $u_0\in\mathcal{E}$ then the integral (Fröbenius) n-dimensional submanifold $\mathcal{S}_{u_0}$ of $\mathcal{M}$ spanned by the commuting vector fields Z_r^n and containing u_0 is a subset of $\mathcal{E}$. This means that the solution $\lambda(x,t_r)$ of the rth Killing system in (18) that starts at a point $u_0\in\mathcal{E}$, i.e., initially satisfying the set of Euler-Lagrange equations

$$E_i(\mathcal{L}^{(n,m,k)}) = 0, \quad i = 1, \ldots, n \tag{21}$$

remains in $\mathcal{E}$, i.e., always satisfy (21). This further means that we can use the set of equations (21) to eliminate some of the variables λ_i in (18). Such an operation does not alter (18), but reparametrizes it, leading to fewer equations of higher order, and the dispersion will occur. As we will see below, this operation of elimination of variables from (18) through the use of (21) will lead both to known and new soliton hierarchies in (1+1) dimensions.

IV. BENENTI CLASS OF STÄCKEL SYSTEMS

In the rest of this paper we consider the simplest class of separation curves (14) in the form

$$H_1\lambda^{n-1} + H_2\lambda^{n-2} + \cdots + H_n = \tfrac{1}{2}\lambda^m\mu^2 + \lambda^k \tag{22}$$

($\lambda, \mu \in \mathbf{R}$ for a moment), where $n \in \mathbf{N}$ while $m, k \in \mathbf{Z}$. This object contains a complete information about the so-called Benenti systems.[17–19] Hamiltonian functions calculated from the related system of separation relations take the form (15).[20] Due to a special form of (22) it turns out that the metric tensors $G^{(m)}$ are now

$$G^{(m)} = L^m G^{(0)}, \quad \text{with } G^{(0)} = \operatorname{diag}\left(\frac{1}{\Delta_1}, \ldots, \frac{1}{\Delta_n}\right), \quad m \in \mathbf{Z},$$

where $\Delta_i = \prod_{j\neq i}(\lambda_i - \lambda_j)$ and where $L = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$ is a (1, 1)-tensor on $\mathcal{Q}$ (it is a conformal Killing tensor with respect to all the metrics $G^{(m)}$). Moreover, Killing tensors K_r can now be obtained by the following recursion relation:

$$K_{r+1} = LK_r + q_r I, \quad K_1 = I, \quad K_{n+1} = 0, \quad r = 1, \ldots, n, \tag{23}$$

so that indeed they are diagonal (in λ-coordinates) in accordance with (16): $K_r = \operatorname{diag}(v_r^1, \ldots, v_r^n)$. The functions $q_r = q_r(\lambda)$ are coefficients of the characteristic polynomial of the tensor L, i.e., they are defined by

$$\det(\lambda I - L) = \sum_{i=0}^{n} q_i \lambda^{n-i}, \tag{24}$$

so that $q_0 = 1, q_1 = -\Sigma_{i=1}^n \lambda_i, \ldots, q_n = (-1)^n \Pi_{i=1}^n \lambda_i$ (q_i are Viète polynomials in the variables λ). Moreover, the potentials $V_r^{(k)}$ in Hamiltonians (15) can now be obtained from the following recursion relation:[20]

$$V_r^{(k)} = V_{r+1}^{(k-1)} - q_r V_1^{(k-1)}, \quad k \in \mathbf{Z} \tag{25}$$

(with the convention that $V_r^{(k)} \equiv 0$ for $r < 1$ or $r > n$) with the initial condition

$$V_r^{(0)} = \delta_{r,n}, \quad r = 1, \ldots, n. \tag{26}$$

This recursion can be reversed. The inverse recursion is given by

$$V_r^{(k)} = V_{r-1}^{(k+1)} - \frac{q_{r-1}}{q_n} V_n^{(k+1)}, \quad k \in \mathbf{Z}, \quad r = 1, \ldots, n. \tag{27}$$

The first potentials are rather trivial,

$$V_r^{(k)} = \delta_{r,n-k} \quad \text{for } k = 0, 1, \ldots, n-1, \quad V_r^{(n)} = -q_r, \quad V_r^{(-1)} = -\frac{q_{r-1}}{q_n}, \tag{28}$$

but for $r < -1$ or for $r > n$ the potentials become complicated polynomial (for $r > n$) or rational (for $r < -1$) functions of q.

From (25) we get

$$V_n^{(k)} = -q_n V_1^{(k-1)}, \quad k \in \mathbf{Z} \tag{29}$$

and

$$V_r^{(k)} = -q_r V_1^{(k-1)} - q_{r+1} V_1^{(k-2)} - \cdots - q_n V_1^{(k-n+r-1)}, \quad k \in \mathbf{Z} \tag{30}$$

while iteration of (27) leads to

$$V_r^{(k)} = -\frac{1}{q_n}(q_{r-1} V_n^{(k+1)} + \cdots + q_1 V_n^{(k+r-1)} + V_n^{(k+r)}) = q_{r-1} V_1^{(k)} + \cdots + q_1 V_1^{(k+r-2)} + V_1^{(k+r-1)}, \quad k \in \mathbf{Z}. \tag{31}$$

V. KILLING SYSTEMS AND RELATED INVARIANTS FOR THE BENENTI CLASS IN VIÈTE COORDINATES

The functions $q_r(\lambda)$ defined in (24) can serve as a new set of variables on $\mathcal{Q}$ (we will call them Viète coordinates). It turns out that these coordinates [that also reparametrize the infinite-dimensional manifold $\mathcal{M}$ so that $\mathcal{M} \ni u=(q_1(x), \ldots, q_n(x))$ now] are much more convenient for our further purposes. The above considerations, in particular Lemma 2 and the corollary that follows, remain true independently of coordinate system since the Euler-Lagrange equations are invariant with respect to point transformations. In this section we sort out the structure of (18) and (21) for the Benenti class in Viète coordinates as well as we prove many other important relations.

The tensors L, L^{-1}, $G^{(0)}$ and $g^{(0)}=(G^{(0)})^{-1}$ have in Viète coordinates (24) the form

$$L = \begin{pmatrix} -q_1 & 1 & & 0 \\ -q_2 & 0 & \ddots & \\ \vdots & & & 1 \\ -q_n & 0 & \cdots & 0 \end{pmatrix}, \quad L^{-1} = \begin{pmatrix} 0 & \cdots & 0 & -\dfrac{1}{q_n} \\ 1 & 0 & 0 & -\dfrac{q_1}{q_n} \\ & \ddots & 0 & \vdots \\ 0 & & 1 & -\dfrac{q_{n-1}}{q_n} \end{pmatrix}, \tag{32}$$

$$G^{(0)} = \begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & \cdots & \cdots & q_1 \\ 0 & 1 & \cdots & \vdots \\ 1 & q_1 & \cdots & q_{n-1} \end{pmatrix}, \quad g^{(0)} = \begin{pmatrix} V_1^{(2n-2)} & \cdots & -q_1 & 1 \\ \cdots & \cdots & \cdots & 0 \\ -q_1 & 1 & \cdots & \\ 1 & 0 & & 0 \end{pmatrix}, \tag{33}$$

so that $L_j^i = V_i^{(n-j+1)}$ and $g_{ij}^{(0)} = V_1^{(2n-i-j)}$. Moreover, for the Benenti class, the system (18) attains in Viète coordinates (24) the form $q_{t_r} = K_r(q) q_x$ or, explicitly

$$\frac{d}{dt_r} q_j = (q_{j+r-1})_x + \sum_{k=1}^{j-1} (q_k (q_{j+r-k-1})_x - q_{j+r-k-1}(q_k)_x) \equiv (Z_r^n[q])^j, \quad r,j = 1, \ldots, n, \tag{34}$$

where $q_\alpha = 0$ as soon as $\alpha > n$ and $(Z_r^n[q])^j$ denotes the jth component of the vector field $Z_r^n[q]$. One proves (34) by a direct calculation, using (32) and (23). Observe, that the following symmetry relation takes place: $(Z_i^n[q])^j = (Z_j^n[q])^i$, $i,j = 1, \ldots, n$.

We can, in accordance with the above, also define the *infinite Killing hierarchy* for the Benenti class

$$\frac{d}{dt_r}q_j = (q_{j+r-1})_x + \sum_{k=1}^{j-1}(q_k(q_{j+r-k-1})_x - q_{j+r-k-1}(q_k)_x) \equiv (Z_r^\infty[q])^j, \quad r,j = 1, \ldots, \infty \tag{35}$$

that is formally given by the same expression as (34) but where we now do not impose the restriction $q_\alpha = 0$ for $\alpha > n$. By comparing (34) and (35) one sees directly that for the nth Killing vector field $Z_r^n[q]$ from (34) its first $n+1-r$ components coincide with the corresponding components of the infinite vector field $Z_r^\infty[q]$,

$$(Z_r^n[q])^j = (Z_r^\infty[q])^j \quad \text{for } j + r - 1 \leqslant n. \tag{36}$$

Lemma 4: The infinite-component vector fields $Z_r^\infty[q]$ in (35) mutually commute:

$$[Z_i^\infty[q], Z_j^\infty[q]] = 0 \quad \textit{for all } i,j = 1, \ldots \infty.$$

Proof: This can be proved by using $[Z_i^n[q], Z_j^n[q]] = 0$ for all $i,j = 1, \ldots, n$ and (36). Indeed, from (36) and the relation

$$(Z_i^\infty[q])^j = (Z_i^\infty)^j[q_1, \ldots, q_{i+j-1}]$$

one finds that

$$([Z_i^\infty[q], Z_j^\infty[q]])^l = ([Z_i^{3(n-1)}[q], Z_j^{3(n-1)}[q]])^l, \quad i,j,l = 1, \ldots, n$$

for arbitrary $n \in \mathbf{N}$. ■

Let us point out that the infinite Killing hierarchy (35) is exactly the so-called universal hierarchy considered recently in Refs. 21 and 22 from the point of view of Lax representation.

Lemma 5: In Viète coordinates the following relations hold:

(1)

$$\frac{\partial V_1^{(k)}}{\partial q_i} = \frac{\partial V_1^{(k+\alpha)}}{\partial q_{i+\alpha}} \quad \text{for } i = 1, \ldots, n-\alpha, k \in \mathbf{Z}, \tag{37}$$

(2)

$$(L^k)_j^i = V_i^{(n+k-j)}, \quad k \in \mathbf{Z}, \tag{38}$$

(3)

$$g_{ij}^{(m)} = V_1^{(2n-m-i-j)}, \quad m \in \mathbf{Z}. \tag{39}$$

Proof: For relation (37) the proof is inductive with the help of formula (30). For relation (38) the proof is by induction with respect to k. By (32), $L_j^i = V_i^{(n-j+1)}$. By the induction assumption and due to the recursion (25),

$$(L^{k+1})_j^i = \sum_{r=1}^{n} L_r^i (L^k)_j^r = -q_i V_1^{(n+k-j)} + V_{i+1}^{(n+k-j)} = V_i^{(n+k-j+1)},$$

which concludes the inductive step up. Similarly, due to the recursion (27),

$$(L^{k-1})_j^i = \sum_{r=1}^{n} (L^{-1})_r^i (L^k)_j^r = V_{i-1}^{(n+k-j)} - \frac{q_{i-1}}{q_n} V_n^{(n+k-j)} = V_i^{(n+k-j-1)},$$

which concludes the inductive step down. Finally, for relation (39), according to (33), we have $g_{ij}^{(0)} = V_1^{(2n-i-j)}$. By induction

$$g_{ij}^{(m+1)} = \sum_{k=1}^{n} V_1^{(2n-m-i-k)} (L^{-1})_j^k.$$

Thus, due to (32) we have for $j<n$,

$$g_{ij}^{(m+1)} = g_{i,j+1}^{(m)} = V_1^{(2n-m-i-j-1)}$$

while for $j=n$ we have

$$g_{in}^{(m+1)} = -\frac{1}{q_n}(q_{n-1}V_1^{(n-m-i)} + \ldots + q_1 V_1^{(2n-m-2-i)} + V_1^{(2n-m-1-i)}) = -\frac{1}{q_n}V_n^{(n-m-i)} = V_1^{(n-m-i-1)},$$

which follows from (29) and (31). This concludes the inductive step up. The induction down (for $m<0$) is proved in a similar way. ■

The next theorem describes symmetry properties of functions (19). Observe that due to (28) the functions (19) are in the Benenti case geodesic (without the potential part) for $k=0,\ldots,n-1$.

Theorem 6: *For the Lagrangian densities*

$$\mathcal{L}^{n,m,k} = \frac{1}{2}\sum_{i,j=1}^{n} q_{i,x} g_{ij}^{(m)}(q) q_{j,x} - V_1^{(k)} = \frac{1}{2}\sum_{i,j=1}^{n} q_{i,x} V_1^{(2n-m-i-j)} q_{j,x} - V_1^{(k)}$$

the following relations hold:

(1) for $\alpha=1,\ldots,n-1$

$$E_i(\mathcal{L}^{n,m,k}) = E_{i-\alpha}(\mathcal{L}^{n,m+\alpha,k-\alpha}), \quad i=\alpha+1,\ldots,n, \tag{40}$$

that can also be written as

$$E_i(\mathcal{L}^{n,m,k}) = E_{i+\alpha}(\mathcal{L}^{n,m-\alpha,k+\alpha}), \quad i=1,\ldots,n-\alpha. \tag{41}$$

(2)

$$E_l(\mathcal{L}^{n,0,2n+\sigma}) = E_{l+1}(\mathcal{L}^{n+1,0,2n+\sigma+2}), \quad \sigma=1,\ldots,n-1, \quad l=\sigma+1,\ldots,n. \tag{42}$$

(3)

$$E_l(\mathcal{L}^{n,n-\sigma,0}) = E_l(\mathcal{L}^{n+1,n+1-\sigma,0}), \quad \sigma=1,\ldots,n-1, \quad l=1,\ldots,\sigma \tag{43}$$

$$E_{\sigma+l}(\mathcal{L}^{n,n-\sigma,-n})_{|q_j\to q_{j+1}} = E_l(\mathcal{L}^{n+1,n+1-\sigma,-n-1}), \quad l=1,\ldots,n-\sigma, \quad j=1,\ldots,n. \tag{44}$$

The proof of this theorem can be found in Appendix B. As it will be shown in the next section, Theorem 6 guarantees that the form of invariants survives the passage from n-component to $(n+1)$-component Killing system and hence it will be crucial for the construction of soliton hierarchies. The index σ will be related with the number of components of the obtained soliton systems.

VI. ELIMINATION PROCEDURE

Using the results of the preceding section we will now construct in a systematic way soliton hierarchies related to Benenti class of separation relations. These hierarchies will be generated by a procedure of elimination of variables in the set of dispersionless systems (34) with the help of Euler-Lagrange equations (21) (with suitable chosen parameters n, m, and k determining the metric tensor $g^{(m)}$ and the separable potential $V_1^{(k)}$). Actually, we present two separate elimination procedures, one for positive potentials (i.e., with $k>n$) and one for negative potentials (i.e., those with $k<0$), leading to different soliton hierarchies.

As we pointed out, the set $\mathcal{E}\subset\mathcal{M}$ of solutions of Euler-Lagrange equations (21) is invariant with respect to all the vector fields Z_r of Killing systems (18). The same must be true even in Viète coordinates: (21) written in Viète coordinates is also invariant with respect to (34). This means that we can use the set of equations (21) to eliminate some of the variables q_i in (34), since along the solutions of systems from (34) they are all the time mutually related by the relations (21).

A. Elimination for positive potentials

First, let us concentrate on the case with positive (polynomial) separable potentials. Our aim is to produce s ($s\in\mathbf{N}$) commuting σ-component ($\sigma\in\mathbf{N}$) vector fields (evolutionary systems) from (34) and (21). In order to do this we choose n as $n=s+\sigma-1$ and consider the set of systems (34) with this chosen n,

$$q_{t_r}=Z_r^{s+\sigma-1}[q_1,\ldots,q_{s+\sigma-1}],\quad r=1,\ldots,n=s+\sigma-1. \tag{45}$$

Notice that r can reach $r=s+\sigma-1$ but only up to $r=s$ the first σ components of (45) are complete in the sense of the infinite Killing hierarchy (35), i.e., coincide with the corresponding components of this hierarchy [see (36)]. We will now use (21) generated by $\mathcal{L}^{n,0,2n+\sigma}$ in order to perform the elimination. The structure of these equations is described in the lemma below.

Lemma 7: The last $n-\sigma$ invariant equations in (21) for $\mathcal{L}^{n,0,2n+\sigma}$, with $n=s+\sigma-1$ (so that $m=0$ and $k=2n+\sigma=2s+3\sigma-2$) have the form

$$\begin{aligned} w_{\sigma+1}^{(n,\sigma)}&\equiv -2q_n+\varphi_{\sigma+1}^{(n,\sigma)}[q_1,\ldots,q_{n-1}]=0,\\ &\cdots,\\ w_n^{(n,\sigma)}&\equiv -2q_{\sigma+1}+\varphi_n^{(n,\sigma)}[q_1,\ldots,q_\sigma]=0, \end{aligned} \tag{46}$$

where we denoted, to shorten the notation, $E_i(\mathcal{L}^{n,0,2n+\sigma})$ as $w_i^{(n,\sigma)}$.

Proof: From the recursion (25) it follows that

$$V_1^{(n+j)}=V_1^{(n+j)}(q_1,\ldots,q_{j+1}),\quad j=0,\ldots,n-1 \tag{47}$$

so that, again by (37) and (30),

$$\frac{\partial V_1^{(2n+\sigma)}}{\partial q_{n+1-j+\sigma}}=\frac{\partial V_1^{(n+j)}}{\partial q_1}=2q_j+f_j(q_1,\ldots,q_{j-1}),\quad j=2,\ldots,n,\quad \sigma=1,\ldots,n-1 \tag{48}$$

(for $j=1$ we would have $f_1\equiv 0$) where the first equality follows by inserting $i=1$, $k=n+j$ and $\alpha=n-j+\sigma$ in (37) and the second one from the fact that according to (28) and (30) $V_1^{(n+j)}=-q_{j+1}+2q_1q_j+\varphi_j(q_1,\ldots,q_{j-1})$ for $j=2,\ldots,n$. On the other hand, for the geodesic Lagrangian density

$$\mathcal{L}^{n,0,0}=\frac{1}{2}\sum_{i,j=1}^{n}V_1^{(2n-i-j)}q_{i,x}q_{j,x}$$

from (B2), as $V_1^{(k)}\neq 0$ for $k\geqslant n-1$ and $\partial V_1^{(k)}/\partial q_1\neq 0$ for $k\geqslant n$, we find that

$$E_l(\mathcal{L}^{n,0,0})=F_l[q_1,\ldots,q_{n-l+1}],\quad l=1,\ldots,n.$$

Since $\mathcal{L}_1^{n,0,2n+\sigma}=\mathcal{L}_1^{n,0,0}-V_1^{(2n+\sigma)}$, we obtain [setting $j=n+1-i+\sigma$ in (48)]

$$E_i(\mathcal{L}^{n,0,2n+\sigma})=-2q_{\sigma+n-i+1}+\varphi_i^{(n,\sigma)}[q_1,\ldots,q_{\sigma+n-i}],\quad i=1,\ldots,n,$$

(where as usual we denote $q_\alpha=0$ for $\alpha>n$) where

$$\varphi_i^{(n,\sigma)}[q_1,\ldots,q_{\sigma+n-i}] = F_i[q_1,\ldots,q_{n-i+1}] + f_{\sigma+n-i+1}(q_1,\ldots,q_{\sigma+n-i}).$$

■

Due to their structure, Eqs. (46) make it possible to successively express (eliminate) the variables $q_{\sigma+1},\ldots,q_{s+\sigma-1}\equiv q_n$ as differential functions of $q_1,\ldots,q_\sigma$,

$$\begin{aligned} q_{\sigma+1} &= f^n_{\sigma+1}[q_1,\ldots,q_\sigma],\\ q_{\sigma+2} &= f^n_{\sigma+2}[q_1,\ldots,q_\sigma],\\ &\cdots,\\ q_n &= f^n_n[q_1,\ldots,q_\sigma]. \end{aligned} \tag{49}$$

Let us first observe that performing the elimination (49) in the systems (45) must lead to σ-component systems of the form $\bar{q}_{t_r}=\bar{Z}^\sigma_r[q_1,\ldots,q_\sigma]$, while for each system in (45) the last $s-1$ components turn into some system of differential consequences of $w_1^{(n,\sigma)},\ldots,w_\sigma^{(n,\sigma)}$ (and are zero on $\mathcal{S}_{u_0}$, i.e., they are satisfied along any solutions of $\bar{q}_{t_r}=\bar{Z}^\sigma_r$). Therefore, after this elimination we obtain

$$\begin{aligned} \bar{q}_{t_r} &= \bar{Z}^\sigma_r[q_1,\ldots,q_\sigma], \quad r=1,\ldots,n,\\ 0 &= \varphi^i_r[w_1,\ldots,w_\sigma], \quad i=\sigma+1,\ldots,n, \end{aligned} \tag{50}$$

with $\bar{q}=(q_1,\ldots,q_\sigma)^T$ and $\varphi^i_r\equiv q_{i,t_r}-(Z^n_r)^i$.

Lemma 8: The first s vector fields $\bar{Z}^\sigma_r$ in (50) commute:

$$[\bar{Z}^\sigma_i,\bar{Z}^\sigma_j]=0, \quad i,j=1,\ldots,s.$$

Proof: Obviously, in general, for $i,j=1,\ldots,n$,

$$[\bar{Z}^\sigma_i,\bar{Z}^\sigma_j] = V_{ij}[w_1^{(n,\sigma)},\ldots,w_\sigma^{(n,\sigma)}]$$

for some vector fields V_{ij} that vanish on $\mathcal{E}\subset\mathcal{M}$ only. Assume for a moment that for $n=s+\sigma-1$ and for some $i,j\leqslant s$ we have $V_{ij}[w_1^{(n,\sigma)},\ldots,w_\sigma^{(n,\sigma)}]\neq 0$. As the vector fields $\bar{Z}^\sigma_i,\bar{Z}^\sigma_j$ were obtained by the reduction of the complete (in the sense of the infinite hierarchy) components of Z^n_i,Z^n_j, thus by increasing $n\to n+\beta$, we do not change the form of V_{ij}, which now must be expressed by a higher dimension invariants $w_j^{(n+\beta,\sigma)}$: $V_{ij}=V_{ij}[w_1^{(n+\beta,\sigma)},\ldots,w_\sigma^{(n+\beta,\sigma)}]$. But $w_j^{(n+\beta,\sigma)}=w_j^{(n+\beta,\sigma)}[q_1,\ldots,q_{n+\beta}]$ and lower dimensional invariants $w_j^{(n,\sigma)}$ are nonexpressible by the higher dimensional invariants $w_i^{(n+\beta,\sigma)}$, so we get a contradiction. ■

We will now show that this procedure leads in fact to an infinite hierarchy of commuting flows. In order to do this, we will for a moment introduce a new index so that the vector fields in (50) will be denoted $\bar{Z}^{n,\sigma}_r$ as being obtained by reducing the n-component Killing systems (45).

Lemma 9: In the above notation

$$\bar{Z}^{n+1,\sigma}_r = \bar{Z}^{n,\sigma}_r \quad \text{for } r=1,\ldots,s.$$

Proof: According to (42) we have

$$w^{(n+1,\sigma)}_{\sigma+i+1} = w^{(n,\sigma)}_{\sigma+i} \quad \text{for } i=1,\ldots,n-\sigma.$$

Thus, increasing s to $s+1$ and keeping σ unaltered (so that n changes to $n+1$) the $n-\sigma$ equations (49) change to $n-\sigma+1$ equations

$$q_{\sigma+i} = f^{n+1}_{\sigma+i}[q_1, \ldots, q_\sigma] = f^{n}_{\sigma+i}[q_1, \ldots, q_\sigma], \quad i = 1, \ldots, n-\sigma,$$

$$q_{n+1} = f^{n+1}_{n+1}[q_1, \ldots, q_\sigma],$$

so that the variables $q_{\sigma+1}, \ldots, q_n$ are expressed by the same functions of $q_1, \ldots, q_\sigma$ and a new elimination equation for q_{n+1} appears. Moreover, $(Z^{n+1}_r[q])^j = (Z^n_r[q])^j$ for $j = 1, \ldots, \sigma$ and $r = 1, \ldots, s$. Thus, replacing $q_{\sigma+i}$ by $f^n_{\sigma+i}[q_1, \ldots, q_\sigma]$ in $(Z^{n+1}_r[q])^j$ and in $(Z^n_r[q])^j$ yields for $j = 1, \ldots, \sigma$ and $r = 1, \ldots, s$ the same expression. But the first operation leads to the reduced vector field $\bar{Z}^{n+1,\sigma}_r$ while the second to $\bar{Z}^{n,\sigma}_r$. ■

Let us now take $s+1$ instead of s (so that $n \to n+1$) in (45) and (49) and perform the reduction. According to the above lemma we obtain the following sequence of $s+1$ reduced systems:

$$\bar{q}_{t_r} = \bar{Z}^{n+1,\sigma}_r = \bar{Z}^{n,\sigma}_r \quad \text{for } r = 1, \ldots, s \text{ and } \bar{q}_{t_{n+1}} = \bar{Z}^{n+1,\sigma}_{n+1},$$

i.e., we obtain the same sequence of s systems as before plus an additional system at the end of the sequence. Therefore, we see that this procedure leads to infinite hierarchies of commuting systems, since we can always increase n as much as we please without altering the already obtained systems generated in previous steps.

The procedure described above can be generalized by using only some part of the equations in (46) in order to perform the elimination, since all of these equations are invariant along the flows of our Killing systems. Namely, we can skip the last α (with $0 \leqslant \alpha \leqslant n-\sigma-1 = s-2$) equations in (46) and use only the remaining equations (i.e., $w^{(n,\sigma)}_{\sigma+1} = 0, w^{(n,\sigma)}_{\sigma+2} = 0, \ldots, w^{(n,\sigma)}_{n-\alpha} = 0$) to eliminate $q_{\sigma+\alpha+1}, \ldots, q_n$ in the Killing systems with $n = s+\sigma+\alpha-1$,

$$q_{t_r} = Z^{s+\sigma+\alpha-1}_r[q_1, \ldots, q_{s+\sigma+\alpha-1}], \quad r = 1, \ldots, n = s+\sigma+\alpha-1. \tag{51}$$

Thus, the index α indicates how many of the last equations in (46) we "forget" about. It turns out that the elimination that follows leads also to hierarchies of commuting equations. To see that, let us first observe, that this elimination can formally be obtained by performing the above described procedure with the help of the Lagrangian density $\mathcal{L}^{n,-\alpha,2n+\sigma+\alpha}$, since according to Theorem 6 we have

$$E_i(\mathcal{L}^{n,-\alpha,2n+\sigma+\alpha}) = E_{i-\alpha}(\mathcal{L}^{n,0,2n+\sigma}) \equiv w^{(n,\sigma)}_{i-\alpha} \quad \text{for } i = \alpha+1, \ldots, n. \tag{52}$$

Denoting $E_i(\mathcal{L}^{n,m,2n+k})$ as $w^{(n,m,k)}_i$, where now $w^{(n,0,k)}_i \equiv w^{(n,k)}_i$ [in the notation of (46)], the last $n-\sigma-\alpha$ Euler-Lagrange equations (invariants), associated with $\mathcal{L}^{n,-\alpha,2n+\sigma+\alpha}_1$, have therefore the form

$$\begin{gathered} w^{(n,-\alpha,\sigma+\alpha)}_{\sigma+\alpha} = w^{(n,\sigma)}_{\sigma} = w^{(n,\sigma)}_{\sigma}[q_1, \ldots, q_n] = 0, \\ w^{(n,-\alpha,\sigma+\alpha)}_{\sigma+1+\alpha} = w^{(n,\sigma)}_{\sigma+1} = -2q_n + \varphi^{(n,\sigma)}_{\sigma+1}[q_1, \ldots, q_{n-1}] = 0, \\ \cdots, \\ w^{(n,-\alpha,\sigma+\alpha)}_{n} = w^{(n,\sigma)}_{n-\alpha} = -2q_{\sigma+\alpha+1} + \varphi^{(n,\sigma)}_{n-\alpha}[q_1, \ldots, q_{\sigma+\alpha}] = 0. \end{gathered} \tag{53}$$

These equations make it possible to successively express (eliminate) the variables $q_{\sigma+\alpha+1}, \ldots, q_n$ as differential functions of $q_1, \ldots, q_{\sigma+\alpha}$, which yields

$$q_{\sigma+\alpha+1} = q_{\sigma+\alpha+1}[q_1, \dots, q_{\sigma+\alpha}],$$

$$\cdots, \tag{54}$$

$$q_n = q_n[q_1, \dots, q_{\sigma+\alpha}].$$

Therefore, after this elimination the Killing equations (51) take the form

$$\begin{gathered} \bar{q}_{t_r} = \bar{Z}_r^{\sigma+\alpha}[\bar{q}], \\ 0 = \varphi_r^i[w_1^{(n,-\alpha,\sigma+\alpha)}, \dots, w_{\sigma+\alpha}^{(n,-\alpha,\sigma+\alpha)}], \quad i = \sigma+\alpha+1, \dots, n \end{gathered} \tag{55}$$

for $r=1,\dots,n=s+\sigma+\alpha-1$ and with $\bar{q}=(q_1,\dots,q_{\sigma+\alpha})^T$ and $\varphi_r^i \equiv q_{i,t_r} - (Z_r^n)^i$ (so that the reduced systems will have $N=\sigma+\alpha$ components). Similarly as before, in Killing equations (51), only up to $r=s$ the first $\sigma+\alpha$ components are complete in the sense of the infinite Killing hierarchy (35). As before, it stems from the fact that the first s vector fields $\bar{Z}_r^{\sigma+\alpha}$ commute to zero,

$$[\bar{Z}_i^{\sigma+\alpha}, \bar{Z}_j^{\sigma+\alpha}] = 0, \quad i,j = 1, \dots, s,$$

the proof of which is analogous as in the case $\alpha=0$ but now we must take $n=s+\sigma+\alpha-1$. As previously, we can repeat the elimination procedure taking $s+1$ instead of s [so that n increases to $n+1$ and $k=2n+\sigma+\alpha$ increases to $2(n+1)+\sigma+\alpha=k+2$ while σ and α are kept unaltered]. By the same argument as before, this new procedure (with $n+1$ instead of n) will lead to a sequence of $s+1$ autonomous $(\sigma+\alpha)$-component systems in which the first s systems will coincide with the corresponding systems obtained from the original procedure (with n). Thus, again we will obtain infinite hierarchies of soliton systems.

B. Elimination for negative potentials

We now present the second possibility of elimination—with the use of negative (rational) separable potentials. Again, our aim is to produce s ($s \in \mathbf{N}$) commuting σ-component ($\sigma \in \mathbf{N}$) vector fields (evolutionary systems) from (34) and (21). This time however we have to choose $n=s+2\sigma-1$ and the Lagrangian density $\mathcal{L}^{n,n-\sigma,-n}$ in order to create an infinite hierarchy of commuting flows.

Lemma 10: The first $n-\sigma$ invariant equations (21) with $\mathcal{L}^{n,n-\sigma,-n}$, i.e., with $m=n-\sigma$ and $k=-n$, have the form

$$\begin{gathered} v_1^{(n,\sigma)} \equiv -\frac{1}{q_n^2} + \gamma_1^{(n,\sigma)}[q_1, \dots, q_\sigma] = 0, \\ v_i^{(n,\sigma)} \equiv \frac{2q_{n-i+1}}{q_n^3} + \gamma_i^{(n,\sigma)}[q_1, \dots, q_{\sigma-i+1}, q_{n-i+2}, \dots, q_n] = 0, \quad i = 2, \dots, n-\sigma, \end{gathered} \tag{56}$$

where we denote, to shorten the notation, $E_i(\mathcal{L}^{n,n-\sigma,-n})$ as $v_i^{(n,\sigma)}$ and $q_\alpha=0$ when $\alpha<1$.

Proof: From the recursion (27) it follows that

$$V_1^{(-j)} = V_1^{(-j)}(q_{n-j+1}, \dots, q_n), \quad j = 1 \dots, n. \tag{57}$$

From this and from (B5), (47), and (B7), we have

$$E_i(\mathcal{L}^{n,n-\sigma,0}) = G_i[q_1, \ldots, q_{\sigma-i+1}], \quad i = 1, \ldots, \sigma,$$
$$E_i(\mathcal{L}^{n,n-\sigma,0}) = G_i[q_{n-i+1+\sigma}, \ldots, q_n], \quad i = \sigma+1, \ldots, n-\sigma. \tag{58}$$

Moreover, by using Lemma 5 we find

$$\frac{\partial V_1^{(-n+1-i)}}{\partial q_1} = -\frac{2q_{n-i+1}}{q_n^3} + g_i(q_{n-i+2}, \ldots, q_n), \quad i = 2, \ldots, n-\sigma$$

and

$$\frac{\partial V_1^{(-n+\sigma)}}{\partial q_{\sigma+1}} = \frac{\partial V_1^{(-n)}}{\partial q_1} = \frac{1}{q_n^2}.$$

Plugging all this into $E_i(\mathcal{L}^{n,n-\sigma,-n}), i=1,\ldots,n-\sigma$, we obtain (56) where $\gamma_i^{(n,\sigma)}[q]=G_i[q]-g_i(q)$. ■

Let us now consider the following Killing systems:

$$q_{t_r} = Z_r^n[q], \quad r = \sigma+1, \ldots, \sigma+s, \quad \text{with } n = s+2\sigma-1. \tag{59}$$

We can use the $n-\sigma$ equations (56) to successively express (eliminate) the variables $q_{\sigma+1}, \ldots, q_n$ as differential functions of $q_1, \ldots, q_\sigma$. This leads to the elimination relations of the form

$$q_{\sigma+i} = f_{\sigma+i}^n[q_1, \ldots, q_\sigma], \quad i = 1, \ldots, n-\sigma. \tag{60}$$

Performing the elimination (60) in (59) we obtain an autonomous sequence of s evolution equations

$$\bar{q}_{t_r} = \bar{Z}_r^\sigma[q_1, \ldots, q_\sigma], \quad r = \sigma+1, \ldots, \sigma+s \tag{61}$$

such that the vector fields $\bar{Z}_r^\sigma$ mutually commute to zero. One proves this by the same arguments as in the positive case, since the first σ components of all the vector fields in (59) are complete in the sense of infinite hierarchy (35).

Analogously to the positive case, we will now show that this procedure leads to an infinite hierarchy. As in the positive case, we will for a moment introduce a new index so that the vector fields in (61) will be denoted $\bar{Z}_r^{n,\sigma}$ as being obtained by reducing the n-component Killing systems (59).

Lemma 11: In the notation as above

$$\bar{Z}_{r+1}^{n+1,\sigma} = \bar{Z}_r^{n,\sigma} \quad \textit{for } r = \sigma+1, \ldots, \sigma+s.$$

Proof: Let us observe that, according to results (41), (43), (44), and (B9),

$$v_i^{(n+1,\sigma)} = v_i^{(n,\sigma)}\big|_{q_j \to q_{j+1}, j=n-i+1,\ldots,n} \quad \text{for } i = 1, \ldots, n-\sigma. \tag{62}$$

Thus, increasing s to $s+1$ and keeping σ unaltered (so that n changes to $n+1$) the $n-\sigma$ equations (60) change to $n-\sigma+1$ equations

$$q_{\sigma+1} = f_{\sigma+1}^{n+1}[q_1, \ldots, q_\sigma], \quad q_{\sigma+i+1} = f_{\sigma+i+1}^{n+1}[q_1, \ldots, q_\sigma] = f_{\sigma+i}^n[q_1, \ldots, q_\sigma], \quad i = 1, \ldots, n-\sigma. \tag{63}$$

Observe that the last $n-\sigma$ equations (60) express now $q_{\sigma+i+1}$ (instead of $q_{\sigma+i}$) as $f_{\sigma+i}^n[q_1, \ldots, q_\sigma]$. On the other hand, due to (34), by changing $q_i \to q_{i+1}$ for all $i > \sigma$ in the sequence $q_{t_r} = Z_r^{n+1}[q]$ we transform it so that $(Z_r^{n+1}[q])^j \to (Z_{r+1}^{n+1}[q])^j$ for $j = 1, \ldots, \sigma$ and $r = \sigma+1, \ldots, \sigma+s$. Thus, inserting

$f^n_{\sigma+i}[q_1,\dots,q_\sigma]$ instead of $q_{\sigma+i+1}$ in $(Z^{n+1}_{r+1}[q])^j$ (for $j=1,\dots,\sigma$ and $r=\sigma+1,\dots,\sigma+s$) yields the same expression as inserting the same function $f^n_{\sigma+i}[q_1,\dots,q_\sigma]$ instead of $q_{\sigma+i}$ in $(Z^{n+1}_r[q])^j$. But the first operation leads to the reduced vector field $\bar{Z}^{n+1,\sigma}_{r+1}$ while the second—to $\bar{Z}^{n,\sigma}_r$. ■

Let us now take $s+1$ instead of s (so that $n\to n+1$) in (59) and (60) and perform the reduction. According to Lemma 11 we obtain the following sequence of $s+1$ reduced systems:

$$\bar{q}_{t_{\sigma+1}}=\bar{Z}^{n+1,\sigma}_{\sigma+1},\quad \bar{q}_{t_{r+1}}=\bar{Z}^{n+1,\sigma}_{r+1}=\bar{Z}^{n,\sigma}_r \quad \text{for } r=\sigma+1,\dots,\sigma+s,$$

i.e., we obtain the same sequence of s systems as before but shifted and an additional system in the beginning of the sequence. This first system can therefore be treated as a next system in some infinite, commuting hierarchy of vector fields.

Let us also observe that we could use (60) to eliminate variables in Killing systems of the form (45) and this would lead to a system of s commuting evolutionary systems. However, this choice does not lead to any hierarchy: by increasing s to $s+1$ we obtain a different sequence of systems.

As before, this procedure can be generalized: we can use the first $n-\sigma-\alpha$ equations ($0\leqslant\alpha<n-\sigma-1$) in (56) to eliminate $q_{\sigma+\alpha+1},\dots,q_n$ from the following sequence of s Killing systems:

$$q_{t_r}=Z^n_r[q],\quad r=\sigma+\alpha+1,\dots,\sigma+\alpha+s \text{ with } n=s+2(\sigma+\alpha)-1. \tag{64}$$

This elimination leads—similarly as above—to s commuting to zero $N=\sigma+\alpha$-component systems $\bar{q}_{t_r}=\bar{Z}^{\sigma+\alpha}_r[q_1,\dots,q_{\sigma+\alpha}]$ and by increasing s by 1 we always obtain a new system of the hierarchy at the beginning of the sequence.

Next section contains some examples of the above described elimination procedures.

VII. EXAMPLES

A. Elimination with positive potentials

Below we will present some examples performed with the help of the (generalized) procedure described in the preceding section. Soliton hierarchies are now classified by pairs (σ,α), $\sigma=1,2,\dots,\alpha=0,1,\dots$, where $N=\sigma+\alpha$ is a number of components in the systems of a given hierarchy. Assume we would like to construct first s members of the hierarchy. We have then to fix $n=s+\sigma+\alpha-1$ and take first s Killing equations in (51). Then, we have to eliminate coordinates $q_{\sigma+\alpha+1},\dots,q_{\sigma+\alpha+s-1}=q_n$ using invariants $w^{(n,\sigma)}_{\sigma+1}=0,\dots,w^{(n,\sigma)}_{n-\alpha}=0$. According to (52), these invariants can be generated, for example, from $\mathcal{L}^{n,0,2n+\sigma}$ by taking the equations $E_i(\mathcal{L}^{n,0,2n+\sigma})=0$, $i=\sigma+1,\dots,n-\alpha$. After the elimination procedure, soliton equations are represented by first $N=\sigma+\alpha$ components of first s reduced Killing equations. Observe, that in this procedure the first soliton equation has always the trivial form $\bar{q}_{t_1}=\bar{q}_x$, $\bar{q}=(q_1,\dots,q_{\sigma+\alpha})^T$.

Let us start with a one-field hierarchy: $N=\sigma+\alpha=1$. There is only one possibility here: $\sigma=1$, $\alpha=0$. We present how to produce first $s=3$ flows which will be recognized as the first members of the KdV hierarchy. We have therefore to take $n=3$ and $k=7$. Killing systems (34) have the form

$$\frac{d}{dt_1}\begin{pmatrix}q_1\\q_2\\q_3\end{pmatrix}=\begin{pmatrix}q_{1,x}\\q_{2,x}\\q_{3,x}\end{pmatrix}=Z^3_1,$$

$$\frac{d}{dt_2}\begin{pmatrix}q_1\\q_2\\q_3\end{pmatrix}=\begin{pmatrix}q_{2,x}\\q_{3,x}+q_1q_{2,x}-q_2q_{1,x}\\q_1q_{3,x}-q_3q_{1,x}\end{pmatrix}=Z^3_2,$$

$$\frac{d}{\mathrm{d}t_3}\begin{pmatrix} q_1 \\ q_2 \\ q_3 \end{pmatrix} = \begin{pmatrix} q_{3,x} \\ q_1 q_{3,x} - q_3 q_{1,x} \\ q_2 q_{3,x} - q_3 q_{2,x} \end{pmatrix} = Z_3^3 \tag{65}$$

while the Lagrangian $\mathcal{L}^{3,0,7}$ is

$$\mathcal{L}^{3,0,7} = \tfrac{1}{2}q_1^2 q_{1,x}^2 - \tfrac{1}{2}q_2 q_{1,x}^2 - q_1 q_{1,x} q_{2x} + q_{1,x} q_{3,x} + \tfrac{1}{2}q_{2,x}^2 - 2q_2 q_3 + 3q_1^2 q_3 + 3q_1 q_2^2 - 4q_1^3 q_2 + q_1^5$$

and the Euler-Lagrange equations (46) for the above Lagrangian attain the form

$$w_2^{(3,1)} \equiv -2q_3 + 6q_1 q_2 - 4q_1^3 + \tfrac{1}{2}q_{1,x}^2 + q_1 q_{1,xx} - q_{2,xx} = 0,$$

$$w_3^{(3,1)} \equiv -2q_2 + 3q_1^2 - q_{1,xx} = 0.$$

These equations can be solved with respect to q_2, q_3 yielding (49) of the form

$$q_2 = -\tfrac{1}{2}q_{1,xx} + \tfrac{3}{2}q_1^2, \quad q_3 = \tfrac{1}{4}q_{1,xxxx} - \tfrac{5}{2}q_1 q_{1,xx} - \tfrac{5}{4}q_{1,x}^2 + \tfrac{5}{2}q_1^3. \tag{66}$$

Substituting it to the above Killing systems gives (50) that read now explicitly as

$$\begin{cases} q_{1,t_1} = q_{1,x} = \bar{Z}_1^1, \\ 0 = 0, \\ 0 = 0, \end{cases}$$

$$\begin{cases} q_{1,t_2} = -\tfrac{1}{2}q_{1,xxx} + 3q_1 q_{1,x} = \bar{Z}_2^1, \\ 0 = 0, \\ 0 = \tfrac{1}{2}w_{1,x}, \end{cases}$$

$$\begin{cases} q_{1,t_3} = \tfrac{1}{4}q_{1,xxxxx} - 5q_{1,x}q_{1,xx} - \tfrac{5}{2}q_1 q_{1,xxx} + \tfrac{15}{2}q_1^2 q_{1,x} = \bar{Z}_3^1, \\ 0 = \tfrac{1}{2}w_{1,x}, \\ 0 = -\tfrac{1}{4}w_{1,xxx} + \tfrac{3}{2}q_1 w_{1,x} \end{cases}$$

so that the first components $q_{1,t_i} = \bar{Z}_i^1[q_1]$ are the first three flows of the KdV hierarchy while the remaining equations are just differential consequences of w_1, which of course vanish on any $\mathcal{S}_{u_0}$. By taking larger s we can produce an arbitrary number of flows from the KdV hierarchy.

Next, let us consider two-field systems: $N=\sigma+\alpha=2$. There are two possibilities: $(\sigma,\alpha)=(2,0)$ and $(\sigma,\alpha)=(1,1)$. Therefore, as a second example we consider the case $(\sigma,\alpha)=(2,0)$, and $s=3$. We have now to take $n=s+\sigma+\alpha-1=4$ and $k=2n+\sigma=10$. The Euler-Lagrange equations $E_4(\mathcal{L}^{4,0,10})=w_4^{(4,2)}=0$ and $E_3(\mathcal{L}^{4,0,10})=w_3^{(4,2)}=0$ can be solved with respect to q_3, q_4 yielding (49) of the form

$$q_3 = -\tfrac{1}{2}q_{1,xx} + 3q_1 q_2 - 2q_1^3,$$

$$q_4 = \tfrac{1}{4}q_{1,x}^2 - \tfrac{1}{2}q_{2,xx} - q_1 q_{1,xx} - \tfrac{7}{2}q_1^4 + 3q_1^2 q_2 + \tfrac{3}{2}q_2^2.$$

Substituting it to two first components of Killing equations $Z_2^4[q]$, $Z_3^4[q]$ yields two first nontrivial members of another two-field soliton hierarchy,

$$q_{1,t_2} = q_{2,x},$$
$$q_{2,t_2} = -\tfrac{1}{2}q_{1,xxx} + 4q_1q_{2,x} + 2q_2q_{1,x} - 6q_1^2q_{1,x}, \tag{67}$$

and

$$q_{1,t_3} = -\tfrac{1}{2}q_{1,xxx} + 3q_1q_{2,x} + 3q_2q_{1,x} - 6q_1^2q_{1,x},$$

$$q_{2,t_3} = -\tfrac{1}{2}q_{2,xxx} - \tfrac{3}{2}q_1q_{1,xxx} + 3q_2q_{2,x} + 6q_1q_2q_{1,x} + 6q_1^2q_{2,x} - 18q_1^3q_{1,x}.$$

In the second two-field case $(\sigma,\alpha)=(1,1)$, if we keep $s=3$ unchanged, we have to take $n=s+\sigma+\alpha-1=4$ and $k=2n+\sigma=9$. From the Euler-Lagrange equations (46) for $\mathcal{L}^{4,0,9}$,

$$E_3(\mathcal{L}^{4,0,9}) = w_3^{(4,1)} = 0, \quad E_2(\mathcal{L}^{4,0,9}) = w_2^{(4,1)} = 0$$

we can eliminate q_3 and q_4, which yields (54). Explicitly, we obtain

$$q_3 = \tfrac{1}{4}q_{1,xxxx} - \tfrac{5}{2}q_1q_{1,xx} - \tfrac{5}{4}q_{1,x}^2 + \tfrac{5}{2}q_1^3,$$

$$q_4 = \tfrac{1}{4}q_{2,xxxx} - \tfrac{1}{4}q_1q_{1,xxxx} - \tfrac{3}{4}q_{1,x}q_{1,xxx} - \tfrac{1}{2}q_{1,xx}^2 - q_2q_{1,xx} - \tfrac{5}{2}q_{1,x}q_{2,x} + 4q_1^2q_{1,xx} - \tfrac{5}{2}q_1q_{2,xx} + \tfrac{25}{4}q_1q_{1,x}^2 + 3q_1^2q_2 - \tfrac{7}{2}q_1^4 + \tfrac{3}{2}q_2^2.$$

Then, two first components of the Killing equations $q_{t_2}=Z_2^4[q]$, $q_{t_3}=Z_3^4[q]$ turn into

$$q_{1,t_2} = q_{2,x},$$

$$q_{2,t_2} = -\tfrac{1}{2}q_{2,xxx} + \tfrac{1}{2}q_1q_{1,xxx} + q_{1,x}q_{1,xx} + 4q_1q_{2,x} + 2q_2q_{1,x} - 6q_1^2q_{1,x},$$

and

$$q_{1,t_3} = -\tfrac{1}{2}q_{2,xxx} + \tfrac{1}{2}q_1q_{1,xxx} + q_{1,x}q_{1,xx} + 3q_1q_{2,x} + 3q_2q_{1,x} - 6q_1^2q_{1,x},$$

$$q_{2,t_3} = \tfrac{1}{4}q_{2,xxxxx} - \tfrac{1}{4}q_1q_{1,xxxxx} - q_{1,x}q_{1,xxxx} - \tfrac{7}{4}q_{1,xx}q_{1,xxx} - q_2q_{1,xxx} - \tfrac{7}{2}q_{2,x}q_{1,xx} + \tfrac{9}{2}q_1^2q_{1,xxx} - 3q_1q_{2,xxx} - \tfrac{9}{2}q_{1,x}q_{2,xx} + 21q_1q_{1,x}q_{1,xx} + 6q_1q_2q_{1,x} + 3q_2q_{2,x} + 6q_1^2q_{2,x} + 6q_{1,x}^2 - 18q_1^3q_{1,x}.$$

Finally, we shortly mention the three-field case: $N=\sigma+\alpha=3$. There are three different hierarchies with the following first nontrivial member of each hierarchy: for $(\sigma,\alpha)=(3,0)$,

$$q_{1,t_2} = q_{2,x},$$

$$q_{2,t_2} = q_{3,x} + q_1q_{2,x} - q_2q_{1,x},$$

$$q_{3,t_2} = -\tfrac{1}{2}q_{2,xxx} - 12q_1q_2q_{1,x} - 6q_1^2q_{2,x} + 3q_2q_{2,x} + 2q_3q_{1,x} + 4q_1q_{3,x} + 10q_1^3q_{1,x};$$

for $(\sigma,\alpha)=(2,1)$,

$$q_{1,t_2} = q_{2,x},$$

$$q_{2,t_2} = q_{3,x} + q_1q_{2,x} - q_2q_{1,x},$$

$$q_{3,t_2} = -\tfrac{1}{2}q_{2,xxx} + \tfrac{1}{2}q_1 q_{1,xxx} + q_{1,x}q_{1,xx} - 12q_1 q_2 q_{1,x} - 6q_1^2 q_{2,x} + 3q_2 q_{2,x} + 2q_3 q_{1,x} + 4q_1 q_{3,x} + 10q_1^3 q_{1,x};$$

and for $(\sigma,\alpha)=(1,2)$,

$$q_{1,t_2} = q_{2,x},$$

$$q_{2,t_2} = q_{3,x} + q_1 q_{2,x} - q_2 q_{1,x},$$

$$q_{3,t_2} = -\tfrac{1}{2}q_{3,xxx} + \tfrac{1}{2}q_1 q_{2,xxx} + \tfrac{1}{2}q_2 q_{1,xxx} - \tfrac{1}{2}q_1^2 q_{1,xxx} - 2q_1 q_{1,x} q_{1,xx} + q_{1,x}q_{2,xx} + q_{2,x}q_{1,xx} - \tfrac{1}{2}q_{1,x}^3 + 2q_3 q_{1,x} + 4q_1 q_{3,x} - 12q_1 q_2 q_{1,x} - 6q_1^2 q_{2,x} + 3q_2 q_{2,x} + 10q_1^3 q_{1,x}.$$

In general, for a fixed $N=\sigma+\alpha$, this procedure leads to N different N-component hierarchies of soliton systems. As the field representation of constructed hierarchies is nonstandard, it is not easy to recognize which hierarchies are known and which are new. We immediately recognized the KdV hierarchy. We also found that two-field hierarchy starting from (67) turns after the transformation

$$u_1 = -3q_1^2 + 2q_2, \quad u_2 = 2q_1, \quad x \to \sqrt{2}ix, \quad t \to \sqrt{2}it$$

into the 2-component coupled KdV hierarchy in the representation of Fordy and Antonowicz.[23] For example, the first flow of this hierarchy (67) turns into

$$u_{1,t_1} = \tfrac{1}{4}u_{2,xxx} + \tfrac{1}{2}u_2 u_{1,x} + u_1 u_{2,x},$$

$$u_{2,t_1} = u_{1,x} + \tfrac{3}{2}u_2 u_{2,x}$$

[yielding (3.18) in Ref. 23].

B. Elimination with negative potentials

We start by presenting the first two ($s=2$) flows of the only $N=1$-component hierarchy that can be obtained within our scheme by using the negative separable potentials. Since $N=1=\alpha+\sigma$, the only choice is to set $\sigma=1$, $\alpha=0$, which yields $n=s+2(\sigma+\alpha)-1=3$. The Euler-Lagrange equations (56) for

$$\mathcal{L}^{n,n-\sigma,-n} = \mathcal{L}^{3,2,-3} = \frac{1}{2}q_{1,x}^2 - \frac{q_{2,x}q_{3,x}}{q_3} + \frac{q_{3,x}^2 q_2}{2q_3} - \frac{q_1}{q_3^2} + \frac{q_2^2}{q_3^3}$$

attain the form

$$-1 - q_3^2 q_{1,xx} = 0, \quad 4q_2 + 2q_3^2 q_{3,xx} - q_3 q_{3,x}^2 = 0 \tag{68}$$

which allows for expressing q_2 and q_3 as differential functions of q_1,

$$q_3 = q_3[q_1] = (-q_{1,xx})^{-1/2},$$

$$q_2 = q_2[q_1] = -\tfrac{1}{16}(5q_{1,xxx}^2 - 4q_{1,xx}q_{1,xxxx})(-q_{1,xx})^{-7/2}$$

(here and in what follows we only consider the positive solution for q_n, otherwise we can change $t \to -t$). Substituting these expressions to the Killing systems (64) and performing the necessary derivations we obtain the following two commuting flows:

$$q_{1,t_2} = (q_2[q_1])_x, \quad q_{1,t_3} = (q_3[q_1])_x$$

with the differential functions $q_2[q_1]$ and $q_3[q_1]$ given as above. After substitution $u=-q_{1,xx}$ the second equation turns into the well known Harry Dym equation while the first one becomes the second member of the hierarchy. If we want to produce a next member of this hierarchy we have to take $s=3$. According to the general remarks in the previous section this new system will appear as the first system in our sequence of systems.

Let us now consider two-field systems: $N=\sigma+\alpha=2$. As before, we have now two choices: $(\sigma,\alpha)=(1,1)$ and $(\sigma,\alpha)=(2,0)$. We start with $(\sigma,\alpha)=(2,0)$. We have now $n=s+2\sigma-1=5$ and thus we consider the Lagrangian $\mathcal{L}^{n,n-\sigma,-n}=\mathcal{L}^{5,3,-5}$. The associated Euler-Lagrange equations (56) can be written as

$$q_5^2(q_{1,x}^2 + 2q_{1,xx}q_1 - 2q_{2,xx}) - 2 = 0, \quad 2q_4 - q_5^3 q_{1,xx} = 0,$$

$$4q_3q_5 - q_{5,x}^2 q_5^2 - 6q_4^2 + 2q_5^3 q_{5,xx} = 0$$

and they can be solved to

$$q_5 = f_5^5[q_1,q_2] = 2w^{-1/2},$$

$$q_4 = f_4^5[q_1,q_2] = 4q_{1,xx}w^{-3/2},$$

$$q_3 = f_3^5[q_1,q_2] = \left(-\tfrac{5}{2}w_x^2 + 12q_{1,xx}^2 w + 2ww_{xx}\right)w^{-7/2},$$

where $w=2q_{1,x}^2+4q_{1,xx}q_1-4q_{2,xx}$. Substituting it into (64) we arrive at the following two commuting two-component systems:

$$q_{1,t_3} = (f_3^5[q_1,q_2])_x,$$

$$q_{2,t_3} = q_1(f_3^5[q_1,q_2])_x - (f_3^5[q_1,q_2])q_{1,x} + (f_4^5[q_1,q_2])_x$$

and

$$\begin{aligned} q_{1,t_4} &= (f_4^5[q_1,q_2])_x, \\ q_{2,t_4} &= q_1(f_4^5[q_1,q_2])_x - (f_4^5[q_1,q_2])q_{1,x} + (f_5^5[q_1,q_2])_x. \end{aligned} \tag{69}$$

The system (69) can be written more explicitly as

$$q_{1,t_4} = 2(2q_{1,xxx}w - 3q_{1,xx}w_x)w^{-5/2},$$

$$q_{2,t_4} = (4q_1q_{1,xxx}w - 6q_1q_{1,xx}w_x - 4q_{1,x}q_{1,xx}w - ww_x)w^{-5/2}.$$

Finally, let us consider the case $(\sigma,\alpha)=(1,1)$. Again, we have $n=5$, but this time we consider the Lagrangian $\mathcal{L}^{n,n-\sigma-\alpha,-n+\alpha}=\mathcal{L}^{5,3,-4}$. Its first $n-\sigma-\alpha=3$ Euler-Lagrange equations

$$0 = -q_5^2 q_{1,xx} - 1,$$

$$0 = 4q_4 + 2q_5^2 q_{5,xx} - q_5 q_{5,x}^2,$$

$$0 = 2q_3q_5 - q_5^2 q_{4,x}q_{5,x} + q_4q_5q_{5,x}^2 - 3q_4^2 + q_5^3 q_{4,xx} - q_5^2 q_4 q_{5,xx}$$

yield the following elimination equations:

$$q_5 = f_5^5[q_1] = (-q_{1,xx})^{-1/2},$$

$$q_4 = f_4^5[q_1] = -\frac{1}{2^4}(5q_{1,xxx}^2 - 4q_{1,xx}q_{1,xxxx})(-q_{1,xx})^{-7/2}, \tag{70}$$

$$q_3 = f_3^5[q_1] = \frac{1}{2^9}P[q_1](-q_{1,xx})^{-13/2},$$

where $P[q_1]$ is some complicated differential polynomial of q_1 (homogeneous of degree 4 and of order 6) with integer coefficients. Substituting (70) into the Killing systems (64) we arrive at the following two commuting two-component flows:

$$q_{1,t_3} = (f_3^5[q_1])_x,$$

$$q_{2,t_3} = q_1(f_3^5[q_1])_x - f_3^5[q_1]q_{1,x} + (f_4^5[q_1])_x$$

and

$$q_{1,t_4} = (f_4^5[q_1])_x,$$

$$q_{2,t_4} = q_1(f_4^5[q_1])_x - f_4^5[q_1]q_{1,x} + (f_5^5[q_1])_x.$$

The last vector field can be written more explicitly as

$$q_{1,t_4} = \frac{1}{2^5}(-40ww_xw_{xx} + 35w_x^3 + 8w^2w_{xxx})w^{-9/2},$$

$$q_{2,t_4} = \frac{1}{2^5}(10q_{1,x}ww_x^2 - 8q_{1,x}w^2w_{xx} - 40q_1ww_xw_{xx} + 35q_1w_x^3 + 8q_1w^2w_{xxx})w^{-9/2},$$

where $w=-q_{1,xx}$. Let us notice that in this case we obtain a hierarchy of systems such that every system is driven by its first equation which is a consecutive equation of Harry Dym hierarchy. One can see that, contrary to the positive case, if $\alpha>0$ the obtained systems are always driven by its first σ components that coincide with the corresponding systems from $\alpha=0$ hierarchy.

VIII. CONCLUSIONS

In this paper we developed a method of unified constructing of Stäckel systems and soliton hierarchies from the same common denominator in the form of separation relations (7). We developed our theory starting from separation relations generated by separation curves of the form

$$H_1\lambda^{\beta_1} + \ldots + H_n\lambda^{\beta_n} = \tfrac{1}{2}\lambda^m\mu^2 + \lambda^k, \quad \beta_i, n \in \mathbf{N}, \quad m,k \in \mathbf{Z}. \tag{71}$$

We performed a detailed, systematic construction of soliton hierarchies for the Benenti class of separation relations, given by the particular form of (71), namely

$$H_1\lambda^{n-1} + H_2\lambda^{n-2} + \cdots + H_n = \tfrac{1}{2}\lambda^m\mu^2 + \lambda^k.$$

The results we obtained are hopefully only a first step of a new research program. The next step of this program would be finding out a way for systematic constructing of other soliton hierarchies from different classes of separation curves (71), when the sequence $(\beta_1,\ldots,\beta_n)$ differs from $(n-1,\ldots,0)$. The next-nontrivial-step would be to extend the theory to the case of polynomial separation curves (8) with $(\alpha_1,\ldots,\alpha_n)\neq(0,\ldots,0)$. We expect by presented procedure to generate not only the majority of known soliton systems but also to construct in a systematic way a vast

number of new integrable hierarchies. One should also investigate the possibility of "prolongation" of standard integrable structures of separable systems (such as integrals of motion, bi-Hamiltonian structure) onto the corresponding evolutionary hierarchies of PDE's.

APPENDIX A

The involutivity of $H_1^{(m,k)}$ and $H_r^{(m,k)}$ (15) leads to the following relations imposed on $g_{kk}^{(m)}(\lambda), v_r^k(\lambda), V_1^{(k)}(\lambda)$ and $V_r^{(k)}(\lambda)$:[14]

$$\frac{\partial v_r^i}{\partial \lambda_i} = 0, \quad i = 1, \ldots, n, \tag{A1}$$

$$\frac{\partial}{\partial \lambda_i} \ln g_{kk}^{(m)} = \frac{\dfrac{\partial v_r^k}{\partial \lambda_i}}{v_r^k - v_r^i}, \quad i \neq k, \quad \text{all } m, r \tag{A2}$$

$$\frac{\partial V_r^{(k)}}{\partial \lambda_i} = v_r^i \frac{\partial V_1^{(k)}}{\partial \lambda_i} \quad \text{for all } i, r, \text{ and } k. \tag{A3}$$

We will prove here the relation (20), i.e.,

$$\sum_{i=1}^{n} E_i(\mathcal{L}^{(n,m,k)})\lambda_{i,t_r} - \sum_{i=1}^{n} E_i(\mathcal{L}_r^{(n,m,k)})\lambda_{i,x} = 0. \tag{A4}$$

First, let us consider the geodesic case. Due to (18) we have $\lambda_{i,t_r} = v_r^i \lambda_{i,x}$ where v_r^i are eigenvalues of K_r [see (16)]. For the geodesic Hamiltonians,

$$\mathcal{L}^{(n,m,0)} = \frac{1}{2}\sum_{i=1}^{n} g_{ii}^{(m)} \lambda_{i,x}^2 \quad \text{and} \quad \mathcal{L}_r^{(n,m,0)} = \frac{1}{2}\sum_{i=1}^{n} g_{ii}^{(m)} v_r^i \lambda_{i,x}^2$$

so that in this case the left-hand side of (A4) attains the form

$$\begin{aligned}
&\sum_{i=1}^{n} E_i(\mathcal{L}^{(n,m,0)})\lambda_{i,t_r} - \sum_{i=1}^{n} E_i(\mathcal{L}_r^{(n,m,0)})\lambda_{i,x} \\
&\quad = \left(\frac{1}{2}\sum_{i,k=1}^{n} \frac{\partial g_{kk}^{(m)}}{\partial \lambda_i} (\lambda_{k,x})^2 v_r^i \lambda_{i,x} - \sum_{i=1}^{n} \frac{d}{dx}(g_{ii}^{(m)} \lambda_{i,x}) v_r^i \lambda_i^x \right) \\
&\qquad - \left(\frac{1}{2}\sum_{i,k=1}^{n} \frac{\partial g_{kk}^{(m)}}{\partial \lambda_i} (\lambda_{k,x})^2 v_r^k \lambda_{i,x} + \frac{1}{2}\sum_{i,k=1}^{n} g_{kk}^{(m)} \frac{\partial v_r^k}{\partial \lambda_i} (\lambda_{k,x})^2 \lambda_{i,x} \right. \\
&\qquad \left. - \sum_{i=1}^{n} \frac{d}{dx}(g_{ii}^{(m)} \lambda_{i,x}) v_r^i \lambda_{i.x} - \sum_{i=1}^{n} g_{ii}^{(m)} \lambda_{i,x}^2 \frac{dv_r^i}{dx} \right) \\
&\quad = \frac{1}{2}\sum_{i,k=1}^{n} \frac{\partial g_{kk}^{(m)}}{\partial \lambda_i} (\lambda_{k,x})^2 (v_r^i - v_r^k) \lambda_{i,x} - \left(\frac{1}{2}\sum_{i,k=1}^{n} g_{kk}^{(m)} \frac{\partial v_r^k}{\partial \lambda_i} (\lambda_{k,x})^2 \lambda_{i,x} - \sum_{i=1}^{n} g_{ii}^{(m)} \lambda_{i,x}^2 \frac{dv_r^i}{dx} \right) = 0
\end{aligned}$$

since the expression in the last parentheses equals to

$$\frac{1}{2}\sum_{i,k=1}^{n} g_{kk}^{(m)}\frac{\partial v_r^k}{\partial \lambda_i}(\lambda_{k,x})^2\lambda_{i,x} - \sum_{i,k=1}^{n} g_{ii}^{(m)}\lambda_{i,x}^2\frac{\partial v_r^i}{\partial \lambda_k}\lambda_{k,x} = -\frac{1}{2}\sum_{i,k=1}^{n} g_{kk}^{(m)}\frac{\partial v_r^k}{\partial \lambda_i}(\lambda_{k,x})^2\lambda_{i,x}$$

$$= +\frac{1}{2}\sum_{i,k=1}^{n}\frac{\partial g_{kk}^{(m)}}{\partial \lambda_i}(\lambda_{k,x})^2(v_r^i - v_r^k)\lambda_{i,x},$$

where the last equality follows from formula (A2) which can be written in equivalent form

$$g_{kk}^{(m)}\frac{\partial v_r^k}{\partial \lambda_i} = \frac{\partial g_{kk}^{(m)}}{\partial \lambda_i}(v_r^k - v_r^i)$$

(that is in fact also valid for $k=i$). Thus, the statement has been proved for geodesic densities. For the potential parts,

$$\sum_{i=1}^{n} E_i(V_1^{(k)})\lambda_{i,t_r} - \sum_{i=1}^{n} E_i(V_r^{(k)})\lambda_{i,x} = \sum_{i=1}^{n}\left(\frac{\partial V_1^{(k)}}{\partial \lambda_i}v_r^i - \frac{\partial V_r^{(k)}}{\partial \lambda_i}\right)\lambda_{i,x} = 0$$

due to (A3). This concludes the proof.

APPENDIX B

We will prove here Theorem 6. The relation (40) is a consequence of (37) and (39) of Lemma 5. Indeed, by (39),

$$E_l(\mathcal{L}^{n,m,k}) = \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial V_1^{(2n-m-i-j)}}{\partial q_l}(q_i)_x(q_j)_x - \frac{\partial V_1^{(k)}}{\partial q_l} - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{(2n-m-i-l)}(q_i)_x\right),$$

and

$$E_{l-\alpha}(\mathcal{L}^{n,m+\alpha,k-\alpha}) = \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial V_1^{(2n-m-\alpha-i-j)}}{\partial q_{l-\alpha}}(q_i)_x(q_j)_x - \frac{\partial V_1^{(k-\alpha)}}{\partial q_{l-\alpha}} - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{(2n-m-\alpha-i-l+\alpha)}(q_i)_x\right)$$

$$\overset{\text{lemma 5}}{=} E_l(\mathcal{L}^{n,m,k}).$$

The relation (41) is just a rewritten form of (40).

Since in what follows we will compare separable potentials with different n, in the rest of the proof we will use temporary extended notation for potentials in the form $V_1^{n,(k)}$. From (28) and (47) it follows that

$$V_1^{n,(n+k)} = V_1^{n+1,(n+1+k)}, \quad k = -n, \ldots, n-1. \tag{B1}$$

We prove now (42). Using the relation (37) for $r=1$ we obtain

$$E_l(\mathcal{L}^{n,0,0}) = \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial V_1^{n,(2n-i-j)}}{\partial q_l}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{n,(2n-i-l)}(q_i)_x\right)$$

$$= \frac{1}{2}\sum_{i,j=1}^{n}\frac{\partial V_1^{n,(2n-i-j-l+1)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{n,(2n-i-l)}(q_i)_x\right). \tag{B2}$$

and in a similar way we have

$$E_{l+1}(\mathcal{L}^{n+1,0,0}) = \frac{1}{2}\sum_{i,j=1}^{n+1} \frac{\partial V_1^{n+1,(2n+2-i-j-l)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{\mathrm{d}x}\left(\sum_{i=1}^{n+1} V_1^{n+1,(2n-i-l+1)}(q_i)_x\right)$$
$$\overset{(*)}{=} \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n+1,(2n-i-j-l+2)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{\mathrm{d}x}\left(\sum_{i=1}^{n} V_1^{n+1,(2n-i-l+1)}(q_i)_x\right)$$
$$\overset{(B1)}{=} \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n,(2n-i-j-l+1)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{\mathrm{d}x}\left(\sum_{i=1}^{n} V_1^{n,(2n-i-l)}(q_i)_x\right).$$

The equality $(*)$ is due to the fact that $V_1^{n+1,(2n-i-l+1)}=0$ for $i=n+1$ and similarly $V_1^{n+1,(2n-i-j-l+2)}$ does not depend on q_1 for $i=n+1$ or $j=n+1$ [this follows from (42) and (57)]. Thus

$$E_l(\mathcal{L}^{n,0,0}) = E_{l+1}(\mathcal{L}^{n+1,0,0}), \quad l=1,\ldots,n. \tag{B3}$$

Moreover, from (30) it follows that

$$V_1^{n,(2n+\sigma)} = -q_1 V_1^{n,(2n+\sigma-1)} - \cdots - q_n V_1^{n,(n+\sigma)},$$

hence, for $l>\sigma$

$$\frac{\partial V_1^{n,(2n+\sigma)}}{\partial q_l} = -q_1\frac{\partial V_1^{n,(2n+\sigma-1)}}{\partial q_l} - \cdots - q_n\frac{\partial V_1^{n,(n+\sigma)}}{\partial q_l} - V_1^{n,(2n+\sigma-l)}$$
$$= -q_1\frac{\partial V_1^{n,(2n+\sigma-l)}}{\partial q_1} - \cdots - q_n\frac{\partial V_1^{n,(n+\sigma-l+1)}}{\partial q_1} - V_1^{n,(2n+\sigma-l)}.$$

On the other hand, we have

$$V_1^{n+1,(2n+\sigma+2)} = -q_1 V_1^{n+1,(2n+\sigma+1)} - \cdots - q_n V_1^{n+1,(n+\sigma+2)} - q_{n+1} V_1^{n+1,(n+\sigma+1)},$$

hence, for $l>\sigma$ and according to (B1) and (47)

$$\frac{\partial V_1^{n+1,(2n+\sigma+2)}}{\partial q_{l+1}} = -q_1\frac{\partial V_1^{n+1,(2n+\sigma+1)}}{\partial q_{l+1}} - \cdots - q_n\frac{\partial V_1^{n+1,(n+\sigma+2)}}{\partial q_{l+1}} - V_1^{n+1,(2n+\sigma-l+1)}$$
$$= -q_1\frac{\partial V_1^{n+1,(2n+\sigma+1-l)}}{\partial q_1} - \cdots - q_n\frac{\partial V_1^{n+1,(n+\sigma+2-l)}}{\partial q_1} - V_1^{n+1,(2n+\sigma-l+1)}$$
$$= -q_1\frac{\partial V_1^{n,(2n+\sigma-l)}}{\partial q_1} - \cdots - q_n\frac{\partial V_1^{n,(n+\sigma+1-l)}}{\partial q_1} - V_1^{n,(2n+\sigma-l)} = \frac{\partial V_1^{n,(2n+\sigma)}}{\partial q_l}, \tag{B4}$$

and from (37) it follows that

$$\frac{\partial V_1^{n,(n+s)}}{\partial q_l} = \frac{\partial V_1^{n+1,(n+s+2)}}{\partial q_{l+1}}, \quad 0 \leqslant s-l+1 \leqslant n.$$

So, from (B3) and (B4) for $\sigma<l\leqslant n$ equation (42) is fulfilled.

Now, we pass to the proof of relations (43). First, we have

$$E_l(\mathcal{L}^{n,n-\sigma,0}) = \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n,(n+\sigma-i-j)}}{\partial q_l}(q_i)_x(q_j)_x - \frac{d}{\mathrm{d}x}\left(\sum_{i=1}^{n} V_1^{n,(n+\sigma-i-l)}(q_i)_x\right)$$
$$= \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n,(n+\sigma-i-j-l+1)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{\mathrm{d}x}\left(\sum_{i=1}^{n} V_1^{n,(n+\sigma-i-l)}(q_i)_x\right). \tag{B5}$$

On the other hand,

$$E_l(\mathcal{L}^{n+1,n+1-\sigma,0}) = \frac{1}{2}\sum_{i,j=1}^{n+1} \frac{\partial V_1^{n+1,(n+\sigma-i-j-l+2)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n+1} V_1^{n+1,(n+\sigma-i-l+1)}(q_i)_x\right).$$

By (42) and (57), for $l \leqslant \sigma$ the last term in both sums does not contribute. Moreover, according to (B1) and the fact that $V_1^{n,(2n)} - q_{n+1} = V_1^{n+1,(2n+1)}$, we have

$$\frac{\partial V_1^{n,(n+k)}}{\partial q_1} = \frac{\partial V_1^{n+1,(n+k+1)}}{\partial q_1}, \quad k = -n, \ldots, n,$$

hence

$$E_l(\mathcal{L}^{n+1,n+1-\sigma,0}) = \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n,(n+\sigma-i-j-l+1)}}{\partial q_1}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{n,(n+\sigma-i-l)}(q_i)_x\right) = E_l(\mathcal{L}^{n,n-\sigma,0}).$$

Finally, we prove the relation (44). From the negative recursion (27), we have

$$V_1^{n,(-k)}(q_{n-k+1}, \ldots, q_n)\big|_{q_i \to q_{i+1}, i=n-k+1,\ldots,n} = V_1^{n+1,(-k)}(q_{n-k+2}, \ldots, q_{n+1}), \quad k = 1, \ldots, n. \tag{B6}$$

Then

$$\begin{aligned} E_{\sigma+l}(\mathcal{L}^{n,n-\sigma,0}) &= \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n,(n-i-j+1-\sigma)}}{\partial q_{l+\sigma}}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{n,(n-i-l)}(q_i)_x\right) \\ &= \frac{1}{2}\sum_{i,j=1}^{n} \frac{\partial V_1^{n,(2n-i-j-l+1)}}{\partial q_n}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n} V_1^{n,(n-i-l)}(q_i)_x\right) \end{aligned} \tag{B7}$$

and

$$E_{\sigma+l}(\mathcal{L}^{n+1,n+1-\sigma,0}) = \frac{1}{2}\sum_{i,j=1}^{n+1} \frac{\partial V_1^{n+1,(n-i-j+2-\sigma)}}{\partial q_{l+\sigma}}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n+1} V_1^{n+1,(n-i-l+1)}(q_i)_x\right)$$

$$\frac{1}{2}\sum_{i,j=1}^{n+1} \frac{\partial V_1^{n+1,(2n-i-j-l+3)}}{\partial q_{n+1}}(q_i)_x(q_j)_x - \frac{d}{dx}\left(\sum_{i=1}^{n+1} V_1^{n+1,(n-i-l+1)}(q_i)_x\right)$$

$$\frac{1}{2}\sum_{i,j=0}^{n} \frac{\partial V_1^{n+1,(2n-i-j-l+1)}}{\partial q_{n+1}}(q_{i+1})_x(q_{j+1})_x - \frac{d}{dx}\left(\sum_{i=0}^{n} V_1^{n+1,(n-i-l)}(q_{i+1})_x\right).$$

As for $i,j=0$ there is no contribution to the sum, so according to (B6) we have

$$E_{\sigma+l}(\mathcal{L}^{n,n-\sigma,0})_{|q_j \to q_{j+1}} = E_{\sigma+l}(\mathcal{L}^{n+1,n+1-\sigma,0}), \quad l = 1, \ldots, n-\sigma, \quad j = 1, \ldots, n. \tag{B8}$$

From (37) and (B6) we have

$$\left.\frac{\partial V_1^{n,(-n)}}{\partial q_i}\right|_{q_j \to q_{j+1}, j=1,\ldots,n} = \frac{\partial V_1^{n+1,(-n)}}{\partial q_{i+1}} = \frac{\partial V_1^{n+1,(-n-1)}}{\partial q_i}, \quad i = 1, \ldots, n \tag{B9}$$

that together with (B8) proves the relation (44).

(Received 26 January 2006; accepted 27 January 2006; published online 21 March 2006)

We consider a scalar field action for which the Lagrangian density is a power of the massless Klein-Gordon Lagrangian. The coupling of gravity to this matter action is considered. In this case, we show the existence of nontrivial scalar field configurations with vanishing energy-momentum tensor on any static, spherically symmetric vacuum solutions of the Einstein equations. These configurations in spite of being coupled to gravity do not affect the curvature of space-time. The properties of this particular matter action are also analyzed. For a particular value of the exponent, the extended Klein-Gordon action is shown to exhibit a conformal invariance without requiring the introduction of a nonminimal coupling. We also establish a correspondence between this action and a nonrelativistic isentropic fluid in one fewer dimension. This fluid can be identified with the (generalized) Chaplygin gas for a particular value of the power. It is also shown that the nonrelativistic fluid admits, apart from the Galileo symmetry, an additional symmetry whose action is a rescaling of the time. © *2006 American Institute of Physics.*

I. INTRODUCTION

The fundamental tenet of general relativity is the manifestation of the curvature of space-time produced by the presence of matter. This phenomena is encoded through the Einstein equations that relate the Einstein tensor (with or without a cosmological constant) to the energy-momentum tensor of the matter,

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = \kappa T_{\mu\nu}. \tag{1}$$

Since the energy-momentum tensor depends explicitly on the metric, both sides of the equations must be solved simultaneously.

In the first part of this paper, we address the following question: for a fixed geometry solving the vacuum Einstein equations, is it possible to find a matter source coupled to this space-time without affecting it. Concretely, this problem consists of examining a particular solution of the Einstein equations (1) for which both sides of the equations vanish, i.e.,

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = 0 = \kappa T_{\mu\nu}. \tag{2}$$

In three dimensions, such gravitationally undetectable solutions have been obtained in the context of scalar fields nonminimally coupled to gravity with a negative cosmological constant.[1] Recently, the same problem has been considered in higher dimensions but with a flat geometry.[2]

In our case, we show that for any static, spherically symmetric vacuum solutions of the Einstein equations (eventually with a cosmological constant), a particular matter source action can

[a)]Electronic mail: hassaine@inst-mat.utalca.cl

be coupled to this geometry yielding to nontrivial solutions of the equations (2). This matter source is described in $(D,1)$ dimensions by an extended Klein-Gordon action,

$$S_\alpha = \int d^D\vec{x}\, dt \sqrt{-g}(g^{\mu\nu}\nabla_\mu\theta\nabla_\nu\theta)^\alpha, \tag{3}$$

where θ is the dynamical field and α is a real parameter whose range will be fixed later. For $\alpha=1$, this action reduces to the well-known massless Klein-Gordon action.

The derivation of solutions of the equations (2) is shown to be equivalent of finding a null vector field k^μ (for the vacuum metric $g_{\mu\nu}$) which derives from the scalar field θ. For a static, spherically symmetric space-time, the derivation of vector fields satisfying these conditions is always possible. In this case, the potential θ can be expressed as a general smooth function that depends only on a null coordinate.

The existence of these gravitationally undetectable solutions is essentially due to the particular form of the matter action (3). For this reason, we investigate some properties of this matter action in the second part of this paper. In particular, the symmetries of the extended Klein-Gordon action (3) are analyzed. It is shown that for the particular value $\alpha=(D+1)/2$, this action exhibits a conformal invariance for which the conformal weight of the scalar field θ is zero. In contrast with the massless Klein-Gordon action, this conformal symmetry is achieved without requiring the introduction of a nonminimal coupling. Finally, we establish a correspondence between the relativistic action (3) and a nonrelativistic isentropic fluid defined in one fewer dimension. The clue of this correspondence lies in the fact that the nonrelativistic space-time can be viewed as the quotient of a higher-dimensional Lorentz manifold by the integral curves of a covariantly, lightlike vector field.[3] For $\alpha=1/2$, this nonrelativistic fluid is identified with the Chaplygin gas while for $0<\alpha<1/2$, the model corresponds to the generalized Chaplygin gas. Note that the Chaplygin cosmology provides an interesting setup to explain that the expansion of the universe is accelerating.[4–6] The Chaplygin gas has also raised a growing attention because of its connection with the Nambu-Goto action,[7] its rich symmetrical structure[8] and its supersymmetric extension.[9] For a general review on this topics see Ref. 10 and works on supersymmetric fluid models are reported in Ref. 11. The features of the Chaplygin gas can also be understood in a Kaluza-Klein-type framework.[12] The symmetries of the nonrelativistic fluid are also investigated and it is shown the existence, apart from the Galileo symmetry, of an additional symmetry whose action is a time rescaling.

The paper is organized as follows. We first derive solutions of the equations (2) for the energy-momentum tensor associated to the extended Klein-Gordon action (3). In the remaining sections, we discuss some general features of the matter action. In particular, we explain the origin of the conformal invariance of the extended Klein-Gordon action for the particular value $\alpha=(D+1)/2$. The last part of the paper is devoted to the correspondence between the relativistic matter action and a nonrelativistic isentropic and polytropic fluid in one fewer dimension. The symmetries of this nonrelativistic fluid are also analyzed.

II. STEALTH SOLUTIONS

We consider the action of $(D+1)$-dimensional gravity coupled to a scalar field θ with dynamics described by the extended Klein-Gordon action (3),

$$I = \int d^D\vec{x}\, \mathrm{d}t \sqrt{-g}\left[\frac{1}{2\kappa}(R-2\Lambda) - \frac{1}{2}(g^{\mu\nu}\nabla_\mu\theta\nabla_\nu\theta)^\alpha\right], \tag{4}$$

where R is the scalar curvature and κ is the gravitational constant. The field equations obtained by varying the metric and the scalar field read, respectively,

$$G_{\mu\nu} + \Lambda g_{\mu\nu} = \kappa T_{\mu\nu}, \tag{5a}$$

$$\nabla_\mu(\sqrt{-g}g^{\mu\nu}\nabla_\nu\theta(\nabla_\sigma\theta\nabla^\sigma\theta)^{\alpha-1}) = 0, \tag{5b}$$

where the energy-momentum tensor is given by

$$T_{\mu\nu} = 2\alpha\nabla_\mu\theta\nabla_\nu\theta(\nabla_\sigma\theta\nabla^\sigma\theta)^{\alpha-1} - g_{\mu\nu}(\nabla_\sigma\theta\nabla^\sigma\theta)^\alpha. \tag{6}$$

We look for a particular solution of the Einstein equations (5a) for which both sides of the equations vanish (2). We first show that the equation $T_{\mu\nu}=0$ implies some restrictions on the scalar field θ and on the real parameter α. Indeed, independently of the background metric, the vanishing of the energy-momentum tensor is possible only if the scalar field satisfies $\nabla_\sigma\theta\nabla^\sigma\theta=0$, otherwise the metric would be proportional to

$$g_{\mu\nu} \propto \frac{\nabla_\mu\theta\nabla_\nu\theta}{\nabla_\sigma\theta\nabla^\sigma\theta},$$

and, hence its determinant would vanish. Consequently, the condition $T_{\mu\nu}=0$ can be consistently achieved only for a scalar field satisfying $\nabla_\sigma\theta\nabla^\sigma\theta=0$ and for $\alpha>1$ because of the form of the energy-momentum tensor (6). It is interesting to note that under these conditions, the extended Klein-Gordon equation (5b) is automatically satisfied.

In sum, the system described by the particular Einstein equations (2) together with the extended wave equation (5b) is equivalent of finding a vacuum metric and a null vector field that derives from θ,

$$g_{\mu\nu}k^\mu k^\nu = 0, \quad k_\mu = \partial_\mu\theta. \tag{7}$$

We now show that a static and spherically symmetric space-time geometry always admits such vector field (7). Indeed, let us consider such geometry which in addition is supposed to solve the vacuum Einstein equations. The line element is given by

$$\mathrm{d}s^2 = -f(r)h(r)\mathrm{d}t^2 + \frac{\mathrm{d}r^2}{f(r)} + r^2\,\mathrm{d}\Sigma_{D-1}^2, \tag{8}$$

where $\mathrm{d}\Sigma_{D-1}^2$ is the line element of the $(D-1)$-dimensional sphere. It is simple to see that the vector field defined by

$$k^\mu = \mp\frac{1}{\sqrt{h(r)}}\delta_r^\mu - \frac{1}{f(r)h(r)}\delta_t^\mu \tag{9}$$

is null and derived from the potential

$$t \mp \int^r \frac{\mathrm{d}\tilde{r}}{f(\tilde{r})\sqrt{h(\tilde{r})}}. \tag{10}$$

Hence, any smooth function of this potential (10)

$$\theta = F\left(t \mp \int^r \frac{\mathrm{d}\tilde{r}}{f(\tilde{r})\sqrt{h(\tilde{r})}}\right), \tag{11}$$

is a solution on the vacuum space-time metric of the constraint

$$g^{\mu\nu}\nabla_\mu\theta\nabla_\nu\theta = 0. \tag{12}$$

This result is not surprising and can be explained as follows. The null coordinates u and v associated to the space-time (8) can be defined as

$$u = t - \int^{r} \frac{\mathrm{d}\tilde{r}}{f(\tilde{r})\sqrt{h(\tilde{r})}}, \tag{13a}$$

$$v = t + \int^{r} \frac{\mathrm{d}\tilde{r}}{f(\tilde{r})\sqrt{h(\tilde{r})}}, \tag{13b}$$

and, in these coordinates, the metric (8) takes the following form:

$$\mathrm{d}s^2 = -f(r)h(r)\mathrm{d}u\,\mathrm{d}v + r^2\,\mathrm{d}\Sigma_{D-1}^2. \tag{14}$$

Consequently, any smooth function F of one of the null coordinate, i.e., $F(u)$ or $F(v)$, will provide a nontrivial solution to the equation (12). In the original coordinates (8), this solution becomes precisely (11).

Thus, we have shown that the curvature of vacuum space-time (8) may not react to the presence of matter source described by the action (3) provided the scalar field is given by the expression (11). The existence of such configurations is a direct consequence of the particular form of the matter action. In what follows, we analyze some properties of this action.

III. PROPERTIES OF THE EXTENDED KLEIN-GORDON ACTION

We first show that the matter action (3) can be derived from the action of a massive complex scalar field with Lagrangian given by

$$\mathcal{L} = \tfrac{1}{2}g^{\mu\nu}(\partial_\mu\Phi)(\partial_\nu\Phi^\star) + V(|\Phi|^2), \tag{15}$$

where V denotes a potential that depends only on the module of the scalar field. Decomposing the scalar field as

$$\Phi = \frac{f}{m}e^{-im\theta}, \tag{16}$$

where m represents the mass of the complex scalar field, the Lagrangian density (15) becomes

$$\mathcal{L} = \frac{1}{2m^2}g^{\mu\nu}\partial_\mu f\partial_\nu f + \frac{1}{2}f^2 g^{\mu\nu}\partial_\mu\theta\partial_\nu\theta + V(f^2/m^2). \tag{17}$$

As shown below, this expression reduces to the extended Klein-Gordon Lagrangian (3) provided the first term in (17) is neglected or eliminated and also for a particular election of the potential. One possibility to eliminate the first term is to consider an effective potential that depends also on the derivatives of the scalar field,

$$V_{\mathrm{eff}}(|\Phi|,\partial_\mu|\Phi|) = V(|\Phi|) - \tfrac{1}{2}g^{\mu\nu}(\partial_\mu|\Phi|)(\partial_\nu|\Phi|).$$

In this case the starting Lagrangian (15) with this potential reduces to

$$\mathcal{L} = \tfrac{1}{2}f^2 g^{\mu\nu}\partial_\mu\theta\partial_\nu\theta + V(f^2/m^2). \tag{18}$$

One can also reach this expression (18) by neglecting the first term of (17) by considering the scale of the inhomogeneities as corresponding to the space-time variations of f on scales greater than m^{-1}, i.e., $\partial_\mu f \ll mf$. This has been considered in the context of cosmology to show that the generalized Chaplygin gas can be described by a generalized Born-Infeld Lagrangian.[5]

The field equations resulting from the variation of the Lagrangian (18) read

$$\tfrac{1}{2}g^{\mu\nu}(\partial_\mu\theta)(\partial_\nu\theta) = -V'(f^2), \tag{19a}$$

$$\nabla_\mu(f\sqrt{-g}g^{\mu\nu}\nabla_\nu\theta)=0. \tag{19b}$$

where we have set the mass to unity for simplicity. We consider a self-interacting potential V given by

$$V(|\Phi|)=\lambda(\Phi\Phi^\star)^{\alpha/(\alpha-1)}, \tag{20}$$

where λ is a constant. In this case, the action (18) becomes

$$S=\int_M d^D\vec{x}\,\mathrm{d}t\sqrt{-g}\left[\frac{1}{2}f^2(\partial_\mu\theta)(\partial^\mu\theta)+\lambda f^{2\alpha/(\alpha-1)}\right], \tag{21}$$

and the function f can be eliminated in favor of the phase θ through the equation of motion (19a),

$$f^2\propto(\partial_\sigma\theta\partial_\sigma\theta)^{\alpha-1}.$$

Finally, the substitution of this last expression into the Lagrangian (21) yields the extended Klein-Gordon action (3).

A. Conformal symmetry

In $(D+1)$ dimensions, the extended Klein-Gordon action (3) possesses the conformal invariance for a value of the parameter α given by

$$\alpha=\frac{D+1}{2}. \tag{22}$$

Indeed, it is simple to see that the trace of the energy-momentum tensor (6) vanishes for this value,

$$g^{\mu\nu}T_{\mu\nu}=[2\alpha-(D+1)](\partial_\sigma\theta\partial^\sigma\theta)^\alpha.$$

The implementation of this symmetry on the scalar field θ is with a zero conformal weight,

$$g_{\mu\nu}\to\Omega^2 g_{\mu\nu},\quad \theta\to\theta. \tag{23}$$

Various comments can be made with respect to this conformal symmetry. First, in contrast with the standard Klein-Gordon action this conformal symmetry is achieved without the introduction of the nonminimal coupling. Moreover, it is interesting to note that the scalar field action (3) remains unchanged against the transformations (23), i.e.,

$$S_{(D+1)/2}(\Omega^2 g_{\mu\nu},\theta)=S_{(D+1)/2}(g_{\mu\nu},\theta).$$

Finally, the origin of this conformal invariance can be explained as follows. It is well known that in $(D+1)$ dimension with $D>1$, the following generalized Klein-Gordon Lagrangian density:

$$\mathcal{L}_{(D,1)}=\frac{1}{2}g^{\mu\nu}(\partial_\mu\Phi)(\partial_\nu\Phi^\star)+\frac{(D-1)}{8D}R\Phi\Phi^\star+\lambda(\Phi\Phi^\star)^{(D+1)/(D-1)} \tag{24}$$

is conformally invariant. Here R represents the scalar curvature of the metric and the last term in (24) is the unique potential that preserves the conformal invariance. For convenience, we rewrite this action in terms of the module and the phase, $\Phi=fe^{i\theta}$,

$$\mathcal{L}_{(D,1)}=\frac{1}{2}\partial_\mu f\partial^\mu f+\frac{1}{2}f^2\partial_\mu\theta\partial^\mu\theta+\frac{(D-1)}{8D}Rf^2+\lambda f^{2(D+1)/(D-1)}, \tag{25}$$

and the implementation of the conformal symmetry on the dynamical fields is given by

$$g_{\mu\nu} \to \Omega^2 g_{\mu\nu}, \quad f \to \Omega^{(1-D)/2} f, \quad \theta \to \theta. \tag{26}$$

A simple but tedious computation shows that the term proportional to Rf^2 is precisely introduced to cancel the variation of the term $\partial_\mu f \partial^\mu f$ under the conformal transformation (26). Consequently, if one drops this kinetic term (as we did in the previous derivation), the following Lagrangian

$$\mathcal{L}_{(D,1)} = \frac{1}{2} f^2 g^{\mu\nu} \partial_\mu \theta \partial_\nu \theta + \lambda f^{2(D+1)/(D-1)} \tag{27}$$

also exhibits the conformal invariance. This expression corresponds precisely to the Lagrangian (21) for the conformal value of the parameter α given by (22).

B. Nonrelativistic fluid

We now establish a correspondence between the relativistic action (3) defined in $(D,1)$ dimensions and a nonrelativistic fluid in $(D-1,1)$ dimensions through a Kaluza-Klein-type framework. The clue of this correspondence lies in the fact that the quotient of a Lorentz $(D,1)$ manifold by the integral curves of a covariantly constant and lightlike vector field ξ is a $(D-1,1)$ manifold which carries the geometric structure of nonrelativistic space-time.[3]

We first illustrate this framework with a simple example. On the Lorentz manifold we consider a coordinate system given by $(t,\vec{x},z)$ where $(t,\vec{x})$ are the coordinates on the nonrelativistic space-time and z represents the additional coordinate. Let Φ be a complex scalar field satisfying the wave equation in $(D,1)$ dimensions together with an equivariance condition

$$\Box \Phi = 0, \tag{28a}$$

$$\xi^\mu \partial_\mu \Phi = i\Phi. \tag{28b}$$

This system of equations (28) has been shown to be strictly equivalent to the free Schrödinger equation in $(D-1,1)$ dimensions on a general Newton-Cartan space-time.[3]

In our case, we consider the action defined in (21) which has been shown to be equivalent to the extended Klein-Gordon action (3). The field equations associated to (21) read

$$\frac{1}{2} g^{\mu\nu} (\partial_\mu \theta)(\partial_\nu \theta) = -\frac{\lambda \alpha}{\alpha - 1} \rho^{1/(\alpha-1)}, \tag{29a}$$

$$\partial_\mu (\rho \sqrt{-g} g^{\mu\nu} \partial_\nu \theta) = 0, \tag{29b}$$

where for convenience we have substituted f^2 by ρ. In order to fix the set up of the Kaluza-Klein-type framework, we consider the Minkowski metric written in the light-cone coordinates

$$\mathrm{d}s^2 = 2\, \mathrm{d}t\, \mathrm{d}z + \mathrm{d}\vec{x}^2, \tag{30}$$

for which the lightlike vector field ξ can be chosen to be $\xi^\mu \partial_\mu = \partial_z$. Since ρ is the module and θ the phase of the complex scalar field (16), the analogue of the equivariance condition (28) is given by

$$\xi^\mu \partial_\mu \rho = 0 \Rightarrow \rho = \rho(t,\vec{x}), \tag{31a}$$

$$\xi^\mu \partial_\mu \theta = 1 \Rightarrow \theta(t,\vec{x},z) = \Theta(t,\vec{x}) + z. \tag{31b}$$

It is easy to see that on the flat background (30) and for fields ρ and θ satisfying the conditions (31), the relativistic field equations (29) project onto the following $(D-1,1)$-dimensional nonrelativistic equations:

$$\partial_t \rho + \vec{\nabla} \cdot (\rho \vec{\nabla} \Theta) = 0, \tag{32a}$$

$$\partial_t\Theta + \frac{1}{2}|\vec{\nabla}\Theta|^2 = -\frac{\lambda\alpha}{\alpha-1}\rho^{1/(\alpha-1)}. \tag{32b}$$

These equations turn out to be the nonrelativistic equations of an isentropic, irrotational and polytropic fluid. Indeed, identifying Θ as the potential velocity, i.e., $\vec{v}=\vec{\nabla}\Theta$ and ρ as the density, the first equation (32a) is a continuity relation while the gradient of the second equation (32b) yields a Euler equation of an isentropic fluid with pressure given by

$$p = \frac{\lambda}{\alpha-1}\rho^{\alpha/(\alpha-1)}. \tag{33}$$

For a potential strength $\lambda>0$ and for $\alpha=1/2$ (respectively, for $0<\alpha<1/2$), the relation (33) represents the state equation of the Chaplygin gas (respectively, the generalized Chaplygin gas). Finally, we remark that the field equations (32) can be derived from the following action principle:

$$S(\rho,\Theta) = \int d^{D-1}\vec{x}\,\mathrm{d}t\left[\rho\left(\partial_t\Theta + \frac{1}{2}|\vec{\nabla}\Theta|^2\right) + \lambda\rho^{\alpha/(\alpha-1)}\right]. \tag{34}$$

In what follows, we study the symmetries of the nonrelativistic fluid model whose dynamics is described by the equations (32).

Nonrelativistic symmetries: We analyze the dynamical symmetries of the nonrelativistic isentropic fluid described by the equations (32). This model being nonrelativistic possesses the appropriate symmetry, namely the Galileo symmetry. The action of this symmetry on the coordinates is given by

$$t \to T = t + \epsilon,$$

$$\vec{x} \to \vec{X} = \mathcal{R}\vec{x} + \vec{\delta} - \vec{\beta}t,$$

where $\mathcal{R}\in \mathrm{SO}(D-1)$, ϵ, $\vec{\delta}$, and $\vec{\beta}$ are the parameters associated to the rotations, the time translations, the space translations and the Galileo boosts, respectively. The implementation of the Galileo symmetry on the dynamical fields reads

$$\rho \to \tilde{\rho}(t,\vec{x}) = \rho(T,\vec{X})$$

and

$$\Theta \to \tilde{\Theta}(t,\vec{x}) = \Theta(T,\vec{X}) + \vec{\beta}\cdot\vec{x} - \tfrac{1}{2}|\vec{\beta}|^2 t.$$

The application of the Noether theorem yields to the following constants of motion:

$$H = \int d^{D-1}\vec{x}\mathcal{H} = \int\left[\frac{1}{2}\rho|\vec{\nabla}\Theta|^2 + \lambda\rho^{\alpha/(\alpha-1)}\right] \tag{35a}$$

$$\vec{P} = \int d^{D-1}\vec{x}\vec{\mathcal{P}} = \int d^{D-1}\vec{x}(\rho\vec{\nabla}\Theta), \tag{35b}$$

$$M_{ij} = \int d^{D-1}\vec{x}(x_i\mathcal{P}_j - x_j\mathcal{P}_i), \tag{35c}$$

$$\vec{G} = t\vec{P} - \int d^{D-1}\vec{x}(\vec{x}\rho), \tag{35d}$$

which corresponds to the energy ϵ, the momentum $\vec{\delta}$, the rotations $\mathcal{R}$ and the Galileo boosts $\vec{\beta}$, respectively. The equations are also invariant under a shift of the velocity potential by constant, $\Theta \to \Theta + \text{constant}$, and the associated conserved charge is given by

$$N = \int d^{D-1}\vec{x}\rho. \tag{36}$$

The corresponding Lie algebra generated by H, $\vec{P}$, M_{ij}, $\vec{G}$, and N is the Galileo algebra with a central extension given by (36) and corresponds to the Galileo 2-cocycle.

(i) For a generic value of the parameter α, there exists an additional symmetry which does not belong to the Galileo group. This symmetry acts on the coordinates by rescaling only the time

$$t \to T = e^{\omega}t,$$

$$\vec{x} \to \vec{X} = \vec{x}, \tag{37}$$

while its action on the dynamical fields is given by

$$\rho \to \tilde{\rho}(t,\vec{x}) = e^{2(\alpha-1)\omega}\rho(T,\vec{X}),$$

$$\Theta \to \tilde{\Theta}(t,\vec{x}) = e^{\omega}\Theta(T,\vec{X}), \tag{38}$$

or infinitesimally

$$\delta\rho = 2(\alpha-1)\rho(t,\vec{x}) + t\partial_t\rho(t,\vec{x}),$$

$$\delta\Theta = \Theta(t,\vec{x}) + t\partial_t\Theta(t,\vec{x}). \tag{39}$$

The associated conserved quantity reads

$$B_\alpha = tH - \frac{(3-2\alpha)}{2\alpha+1}\int d^{D-1}\vec{x}(\rho\Theta) - \frac{(2\alpha-1)}{2\alpha+1}\int d^{D-1}\vec{x}(\vec{x}\cdot\vec{\nabla}\Theta)\rho. \tag{40}$$

This expression is clearly not defined for $\alpha=-1/2$ in spite of the fact that this value is not singular at the level of the transformations (37) and (38). In fact, a careful application of the Noether procedure shows that for $\alpha=-1/2$ the associated conserved quantity does not involve the energy density and instead is given by

$$B_{-1/2} = \int d^{D-1}\vec{x}\left[\rho\Theta - \frac{1}{2}(\vec{x}\cdot\vec{\nabla}\Theta)\rho\right]. \tag{41}$$

In the case of the Chaplygin gas, $\alpha=1/2$, the last piece of the expression (40) vanishes and the Noether charge corresponds to the one derived in Ref. 8. Interestingly, for $\alpha \neq 1/2$, the two conserved charges (40) and (41) involve a piece proportional to the space coordinate $\vec{x}$. This fact is intriguing since the transformations (37) only affect the time and not the space coordinate. This can be explained by the fact that, under the infinitesimal changes of the dynamical fields (39), the variation of the action (34) becomes

$$\Delta S = S(\rho + \delta\rho, \Theta + \delta\Theta) - S(\rho, \Theta) = (2\alpha - 1)S(\rho, \Theta) + \int \partial_t[\rho\partial_t(t\Theta) - \rho\Theta + t\mathcal{H}], \tag{42}$$

where $\mathcal{H}$ represents the density energy (35a). For $\alpha = 1/2$, this variation (42) reduces to a surface term and, hence a direct application of the Noether theorem yields to the conserved charge (40). For $\alpha \neq 1/2$, the reason for which the transformation (37) still acts as a symmetry is due to the fact that the original action can also be written as a surface term. Indeed, using the equations of motion (32), the action (34) can be expressed on-shell as

$$S(\rho, \Theta) = \frac{1}{2\alpha + 1} \int d^{D-1}\vec{x}\, \mathrm{d}t\, \partial_t(2\rho\Theta - \rho\vec{x} \cdot \vec{\nabla}\Theta). \tag{43}$$

As a consequence, for $\alpha \neq 1/2$, the variation ΔS of the action (42) under the time dilatation transformation (37) is also a surface term. This proves that these transformations act as a symmetry for the action and also the reason for which the conserved quantities (40) and (41) involve the space coordinate $\vec{x}$.

For a generic value of the parameter α, the group structure of the symmetries is given by the semidirect sum of the Galileo group with central extension $\mathcal{G}$ with the generator associated to this extra symmetry (40),

$$G = \mathcal{G} \times \mathcal{B}. \tag{44}$$

There exist two particular values of the parameter α for which the symmetry group can be larger than the one discussed before (44).

(ii) For the value $\alpha = 1/2$, which corresponds to the Chaplygin gas, it has been shown that, apart from the time dilation (37), there exists an extra symmetry whose action is field dependent, i.e.,

$$t \to T = t + \tfrac{1}{2}\vec{\omega} \cdot (\vec{x} + \vec{X}),$$

$$\vec{x} \to \vec{X} = \vec{x} + \vec{\omega}\Theta(T, \vec{X}), \tag{45}$$

and

$$\rho \to \tilde{\rho}(t, \vec{x}) = \rho(T, \vec{X})\frac{1}{|J|},$$

$$\Theta \to \tilde{\Theta}(t, \vec{x}) = \Theta(T, \vec{X}), \tag{46}$$

where $|J|$ is the Jacobian of the transformation, $J = \det(\partial X^\mu / \partial x^\sigma)$.[8] The Noether conserved quantity is given by

$$\vec{D} = \int d^{D-1}\vec{x}\, \mathrm{d}t(\vec{x}\mathcal{H} - \Theta\vec{\mathcal{P}}), \tag{47}$$

and the group structure generated by the quantities (35), (40), and (47) is the Poincaré group in one higher dimension, namely in $(D, 1)$ dimensions. The existence of this symmetry is due to the fact that for $\alpha = 1/2$, the action expressed in terms of Θ can be written as a square root,

$$S = \int d^{D-1}\vec{x}\, \mathrm{d}t \sqrt{\partial_t\Theta + \frac{1}{2}|\vec{\nabla}\Theta|^2},$$

and this later can be seen to descend from a Nambu-Goto action in one higher dimension in the light cone parametrization.[7] This explains the arising of the Poincaré symmetry only for $\alpha = 1/2$

since for the other values of α, the action is not a square root and hence it is not longer parametrization invariant.

(iii) In $(D-1,1)$ dimensions and for a value of α given by $(D+1)/2$, the polytropic fluid exhibits a Schrödinger symmetry for which the group structure is the semidirect sum of the static Galileo group with $\mathrm{SL}(2,\mathbb{R})$, (see Refs. 13 and 14 and for an extension to discontinuous flows see Ref. 15). The arising of this symmetry is a consequence of the conformal symmetry of the relativistic model in one higher dimension.

IV. DISCUSSION

Here, we have considered the Einstein equations with a matter source scalar field. The dynamics of the scalar field is described by an extended Klein-Gordon action that depends on a real parameter α. We have restricted ourselves to a particular class of solutions for which both sides of the Einstein equations vanish. In this case, we have shown that for any static, spherically symmetric vacuum solutions of the Einstein equations, a nontrivial scalar field with zero energy-momentum on-shell can be derived. This means that this matter source in spite of being coupled to gravity does not affect the curvature of the space-time. An interesting work will consist to see whether scalar field with a nonzero energy momentum tensor can be coupled to black hole geometry. The existence of these undetectable solutions is essentially due to the form of the matter action. For this reason, some properties of this action have been analyzed. In particular, we have shown that the extended Klein-Gordon action possesses a conformal invariance for a particular value of the exponent α. This invariance does not require the introduction of the nonminimal coupling as it is the case for the standard Klein-Gordon action. We have also established a correspondence between this extended Klein-Gordon dynamics and a nonrelativistic isentropic fluid in one fewer dimension. This gas can be identified with the (generalized) Chaplygin gas for specific values of the parameter α. The nonrelativistic model corresponds to an irrotational, isentropic, and polytropic fluid. This fluid admits, apart from the Galileo symmetry, an additional symmetry. The action of this extra symmetry on the coordinate consists of a rescaling of the time only. An interesting work will consist of finding solutions of this nonrelativistic fluid and to make use of this extra symmetry to generate nontrivial solutions.

(Received 17 October 2005; accepted 17 January 2006; published online 8 March 2006)

We consider a self-adjoint, purely absolutely continuous operator M. Let P be a rank one operator $Pu=\langle\varphi,u\rangle\varphi$ such that for β_0 $H_{\beta_0}:=M+\beta_0 P$ has a simple eigenvalue E_0 embedded in its absolutely continuous spectrum, with corresponding eigenvector ψ. Let H_ω be a rank one perturbation of the operator H_{β_0}, namely, $H_\omega=M+(\beta_0+\omega)P$. Under suitable conditions, the operator H_ω has no point spectrum in a neighborhood of E_0, for ω small. Here, we study the evolution of the state ψ under the Hamiltonian H_ω, in particular, we obtain explicit estimates for its sojourn time $\tau_\omega(\psi)=\int_{-\infty}^{\infty}|\langle\psi,e^{-iH_\omega t}\psi\rangle|^2\,dt$. By perturbation theory, we prove that $\tau_\omega(\psi)$ is finite for $\omega\neq 0$, and that for ω small it is of order ω^{-2}. Finally, by using an analytic deformation technique, we estimate the sojourn time for the Friedrichs model in $\mathbb{R}^n$. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2174236]

I. INTRODUCTION

A rank one perturbation of an operator H_0 may drastically change the nature of its spectrum. See for instance Refs. 2 and 16. Here we study a class of perturbations for a self-adjoint operator H_0 having a simple eigenvalue E_0 embedded in its absolutely continuous spectrum. We impose general conditions on the rank one perturbation P, $Pu=\langle\varphi,u\rangle\varphi$, which guarantee that the operator $H_\omega=H_0+\omega P$ is purely absolutely continuous. Moreover if H_0 has a normalized eigenvector ψ_0 with corresponding eigenvalue E_0 then we explicitly estimate the sojourn time $\tau_\omega(\psi_0)$, precisely,

$$\tau_\omega(\psi_0) \sim \frac{1}{\pi}\frac{1}{\omega^2}\frac{1}{|\langle P\psi_0,\psi_0\rangle|^2\mu'_{\psi_0}(E_0)}$$

under conditions which guarantee in particular suitable regularity of the spectral measure μ_{ψ_0} of M.

In the case where M is the multiplication operator by x and φ is analytic (in the sense of Sec. V) we can use the analytic translation technique to prove that

$$\tau_\omega(\psi_0) = \frac{1}{2|\Gamma|} + O\left(\frac{1}{|\omega|}\right),$$

where $1/2\Gamma$ is the Fermi golden rule term,

$$\frac{1}{2}\Gamma = \omega^2 \operatorname{Im}\langle P\psi_0, S(E_0+i0)P\psi_0\rangle.$$

Here, $S(E_0+i0)$ is the reduced resolvent of H_{β_0} at E_0 (Ref. 8, Chap. III, Sec. 6.5, for the definition of the reduced resolvent).

There are numerous works which describe resonances by analyzing the behavior of the survival amplitude, i.e., the function $\mathbb{R} \ni t \mapsto \langle e^{-itH}\psi_0, \psi_0\rangle$, which, in many cases, include explicit exponential decay laws for this quantity. We mention, Refs. 1, 3, 4, 6, 10, 11, 17, 19, 18, and 20, for example. On the other hand, as it was suggested in Ref. 10, the study of the sojourn time seems to be an approach to resonances more general than analytic continuation techniques. (See Refs. 7, 13, and 15.)

The present work is also an attempt to give a dynamical characterization of quantum resonances, by estimating directly the sojourn time, that is, the L^2 norm of this survival amplitude, which measures the total amount of time that well chosen states remain on itself. We expect that this direct approach of the sojourn time will allow less regular Hamiltonian than the ones considered with the survival amplitude method. For example, in the concrete Friedrichs model, see Sec. IV A, we need only that our perturbation P is twice differentiable with respect to the x variable, which seems to be a rather weak condition in view of the above quoted papers. This hope must be tested with a genuine potential perturbation. Also, contrary to what is usually done, we have not localized ψ_0 within an ad hoc spectral subspace of H_ω, i.e., $g(H_\omega)\psi_0$, where g is a function localized around the embedded eigenvalue E_0; this is mainly because our assumptions on M do not allow neither thresholds nor other eigenvalues than E_0.

This paper has the following structure: in the first two sections we establish some technical facts. The following section contains our main result, the asymptotics of the sojourn time. In the last section we use the analytic translation technique to establish the connection with resonance theory.

II. RANK ONE PERTURBATIONS OF SELF-ADJOINT OPERATORS

Although the content of this section is classical, we include it for the reader's convenience. Let M be a self-adjoint operator on a Hilbert space $\mathcal{H}$. We consider rank one perturbations of M,

$$H_\beta = M + \beta P, \tag{2.1}$$

where $\beta \in \mathbb{R}$ and $P = |\varphi\rangle\langle\varphi|$ denotes the orthogonal projection $Pu = \langle\varphi, u\rangle\varphi$ and $\|\varphi\| = 1$.

Let E_x^M be the resolution of the identity associated to M, that is $M = \int_{-\infty}^{\infty} x\, \mathrm{d}E_x^M$ and let $\mu_\varphi(x) := \langle\varphi, E_x^M\varphi\rangle$. For $z \in \mathbb{C}$ with $\operatorname{Im} z > 0$ we consider the Borel transform of the measure μ_φ, that is

$$F_\varphi(z) = \langle\varphi, (M-z)^{-1}\varphi\rangle. \tag{2.2}$$

Lemma 2.1: Assume E_0 is not an eigenvalue of M. Given $\beta \neq 0$, the real number E_0 is an eigenvalue of H_β if and only if $\lim_{\epsilon\to 0}(M - E_0 - i\epsilon)^{-1}\varphi$ exists in $\mathcal{H}$ and $F_\varphi(E_0+i0) = -1/\beta$.

Proof: If $H_\beta\psi_0=E_0\psi_0$, ψ_0 normalized, then,

$$M\psi_0+\beta\langle\varphi,\psi_0\rangle\varphi=E_0\psi_0. \tag{2.3}$$

Since E_0 is not an eigenvalue of M, we have that $\langle\psi_0,\varphi\rangle\neq 0$ and φ belongs to the range of $M-E_0$.

On the other hand,

$$(M-E_0)(M-E_0-i\epsilon)^{-1}\psi_0=-\beta\langle\varphi,\psi_0\rangle(M-E_0-i\epsilon)^{-1}\varphi.$$

But $(M-E_0)(M-E_0-i\epsilon)^{-1}$ is a bounded operator which is strongly convergent to the identity as ϵ approaches 0. By computing such limit we have that $\psi:=\lim_{\epsilon\to 0}(M-E_0-i\epsilon)^{-1}\varphi$ exists and it satisfies $\psi_0+\beta\langle\varphi,\psi_0\rangle\psi=0$. It follows that,

$$F_\varphi(E_0+i0)=\langle\varphi,\psi\rangle=-\frac{1}{\beta}.$$

Conversely, if both conditions hold, then $\psi:=\lim_{\epsilon\to 0}(M-E_0-i\epsilon)^{-1}\varphi$ satisfies $\langle\varphi,\psi\rangle=-1/\beta$. Consider $\psi(\epsilon)=(M-E_0-i\epsilon)^{-1}\varphi$. Then,

$$(M-E_0)\psi(\epsilon)=(M-E_0)(M-E_0-i\epsilon)^{-1}\varphi,$$

converges to φ, when ϵ approaches 0. Since M is a closed operator, we obtain that ψ belongs to the domain of M and $(M-E_0)\psi=\varphi$.

Hence, $M\psi-\varphi=E_0\psi$. The eigenvalue equation (2.3) follows from the identity $-1=\beta\langle\varphi,\psi\rangle$.

□

Corollary 2.1: Let E_0 be an eigenvalue of H_β. Then E_0 is simple with eigenvector $\psi=\lim_{\epsilon\to 0}(M-E_0-i\epsilon)^{-1}\varphi$. Also,

$$\|\psi\|^2=\int_{-\infty}^{\infty}\frac{d\mu_\varphi}{(x-E_0)^2}\quad \textit{and}\ \langle\psi,\varphi\rangle=\int_{-\infty}^{\infty}\frac{d\mu_\varphi}{x-E_0}. \tag{2.4}$$

Proof: The first part of the corollary follows from the proof of the Lemma 2.1. To prove formula (2.4), we note that since $\|\psi\|^2=\lim_{\epsilon\to 0}\|(M-E_0-i\epsilon)^{-1}\varphi\|^2$ exists, by the monotone convergence theorem,

$$\int_{\mathbb{R}}\frac{d\mu_\varphi}{(x-E_0)^2}=\lim_{\epsilon\to 0}\int_{\mathbb{R}}\frac{d\mu_\varphi}{(x-E_0)^2+\epsilon^2}=\|\psi\|^2.$$

So the integrals $\int_{\mathbb{R}}[d\mu_\varphi/(x-E_0)^2]$ and $\int_{\mathbb{R}}(d\mu_\varphi/|x-E_0|)$ are finite. The Lebesgue theorem then implies

$$\langle\psi,\varphi\rangle=\lim_{\epsilon\to 0}\int_{\mathbb{R}}\frac{d\mu_\varphi}{(x-E_0)+i\epsilon}+\int_{\mathbb{R}}\frac{d\mu_\varphi}{x-E_0}.$$

□

We now consider a family of rank one perturbations of the operator $H_{\beta_0}=M+\beta_0 P$ on $\mathcal{H}$, explicitly,

$$H_\beta=M+\beta|\varphi\rangle\langle\varphi|, \tag{2.5}$$

where $\varphi\in\mathcal{H}$ is a fixed unit vector. We are mainly interested on studying the time behavior of possible bound states of H_{β_0}, under the Hamiltonian H_β, for β near β_0.

Let us assume that $H_{\beta_0}=M+\beta_0|\varphi\rangle\langle\varphi|$ has an eigenvalue E_0 with corresponding eigenvector ψ. Because of Lemma 2.1 and Corollary 2.1, this means that $1+\beta_0\lim_{\epsilon\to 0}F_\varphi(E_0+i\epsilon)=0$ and

$$\int_{-\infty}^{\infty} \frac{\mathrm{d}\mu_\varphi}{(x-E_0)^2} < \infty.$$

Our goal is to study the time evolution of ψ under the perturbed Hamiltonian H_β for the parameter ω close to zero.

For this purpose, we study the function

$$\mathbb{R} \ni t \mapsto |\langle \psi, e^{-iH\beta t}\psi\rangle|^2$$

which represents the probability of finding at time t the system in its initial state ψ, and

$$\tau_\omega(\psi) = \int_{-\infty}^{\infty} |\langle \psi, e^{-iH\beta t}\psi\rangle|^2 \,\mathrm{d}t, \quad \omega = \beta - \beta_0 \tag{2.6}$$

which measures the total amount of time the state remains in its initial subspace $\{s\psi : s \in \mathbb{C}\}$. We observe that $|\langle \psi, e^{-iH_{\beta_0}t}\psi\rangle|^2 = 1$ for all t and so $\tau_0(\psi)$ is infinite.

We shall prove that for $\omega \neq 0$ and small, the sojourn time $\tau_\omega(\psi)$ is finite and of order ω^{-2}, when the operator H_β has no bound states [see assumption (H3)].

III. FINITENESS OF THE SOJOURN TIME OF ψ

Let H be a self-adjoint operator on a complex Hilbert space $\mathcal{H}$. For any vector ϕ in the absolutely continuous subspace $\mathcal{H}_{\mathrm{ac}}(H)$ associated to H, we know that

$$\langle \phi, e^{-iHt}\phi\rangle = \sqrt{\frac{2}{\pi}} \int_{-\infty}^{\infty} e^{-i\lambda t}\, \mathrm{Im}\langle \phi, (H - \lambda - i0)^{-1}\phi\rangle \mathrm{d}\lambda.$$

This allows us to express the sojourn time in terms of resolvent operators, explicitly,

$$\tau(\psi) = \frac{1}{2\pi} \int_{-\infty}^{\infty} |\mathrm{Im}\langle \psi, (H - \lambda - i0)^{-1}\psi\rangle|^2 \,\mathrm{d}\lambda. \tag{3.1}$$

It is known that (2.6) and (3.1) are both valid expressions for the sojourn time, as soon as the survival amplitude $\mathbb{R} \ni t \mapsto (e^{-itH}\varphi, \varphi)$ is in $L^2(\mathbb{R})$, see Ref. 12.

In all what follows, we assume the following hypothesis.

(H0): *M is a purely absolutely continuous operator acting on the Hilbert space $\mathcal{H}$, $\varphi \neq 0$ a normalized element of $\mathcal{H}$, $P := |\varphi\rangle\langle\varphi|$ and $H_\beta := M + \beta P$.*

(H1): *There exists $\beta_0 \neq 0$, such that H_{β_0} has a unique eigenvalue E_0, $H_{\beta_0}\psi = E_0\psi$.* Notice that, by Lemma 2.1, this implies in particular that $\psi := (M - E_0 \pm i0)^{-1}\varphi$ exists in $\mathcal{H}$ and $\langle \varphi, \varphi\rangle = -\beta_0^{-1}$.

(H2): *The function $\lambda \in \mathbb{R} \mapsto \langle \varphi, (M - \lambda - i0)^{-1}\varphi\rangle \in \mathbb{C}$ is continuous. We assume moreover that*

$$\lim_{|\lambda| \to \infty} \langle \varphi, (M - \lambda - i0)^{-1}\varphi\rangle = 0.$$

Notice that, by the first resolvent equation, this implies in particular that

$$\mathbb{R} \setminus \{E_0\} \ni \lambda \mapsto \langle \psi, (M - \lambda - i0)^{-1}\psi\rangle \in \mathbb{C}$$

exists as a continuous function.

(H3): *There exists $\omega_0 > 0$ such that for all $0 < |\omega| \leqslant \omega_0$, the function*

$$D(\lambda, \omega) := 1 + (\beta_0 + \omega)\langle \varphi, (M - \lambda - i0)^{-1}\varphi\rangle$$

does not vanish, for any $\lambda \in \sigma(M)$. Clearly, for such ω, the operator $H_{\beta_{0+\omega}}$ has no eigenvalues.

(H4): *The function $\lambda \mapsto \langle \psi, (M - \lambda - i0)^{-1}\psi\rangle \in \mathbb{C}$ is of class C^1 in a neighborhood of E_0, that is,*

$$g(\lambda) := \mathrm{Re}\langle \psi, (M - \lambda - i0)^{-1}\psi\rangle,$$

$$\mu'_\varphi(\lambda) := \frac{1}{\pi}\,\mathrm{Im}\langle\psi,(M-\lambda-i0)^{-1}\psi\rangle$$

exist and they are C^1 *functions in a neighborhood of* E_0.
(H5): *The function* μ'_ψ *belongs to* $L^2(\mathbb{R})$.
(H6): $\mu'_\psi(E_0)>0$.
Concerning the resolvent operators, we use the following notation:

$$R_\omega(z)=(H_\beta-z)^{-1},\quad R_0(z)=(H_{\beta_0}-z)^{-1},\quad R(z)=(M-z)^{-1},$$

where $\omega=\beta-\beta_0$. The Aronszjan-Krein formula[9,16] expresses the resolvent $R_\omega(z)$ in terms of $R_0(z)$ for any $z=\lambda+i\epsilon\in\mathbb{C}$, with $\epsilon\neq 0$. This formula gives

$$R_\omega = R_0 - \frac{\omega}{1+\omega\langle\varphi,R_0\varphi\rangle}R_0PR_0. \tag{3.2}$$

Similarly,

$$R_0 = R - \frac{\beta_0}{1+\beta_0\langle\varphi,R\varphi\rangle}RPR. \tag{3.3}$$

Again, we use the Borel transform $F_\varphi(z)=\langle\varphi,(M-z)^{-1}\varphi\rangle$, which, because of (3.3) gives

$$\langle\varphi,R_0(z)\varphi\rangle=\frac{F_\varphi(z)}{1+\beta_0F_\varphi(z)}.$$

Thus, by replacing in (3.2),

$$R_\omega = R_0 - \omega\frac{1+\beta_0F_\varphi}{1+(\beta_0+\omega)F_\varphi}R_0|\varphi\rangle\langle\varphi|R_0. \tag{3.4}$$

Since, $\mu_\varphi(\lambda)=\langle\varphi,E^M_\lambda\varphi\rangle$, for any positive ϵ we have that

$$F_\varphi(z)=\int_{-\infty}^{\infty}\frac{x-\lambda}{(x-\lambda)^2+\varepsilon^2}\mathrm{d}\mu_\varphi(x)+i\int_{-\infty}^{\infty}\frac{\varepsilon}{(x-\lambda)^2+\varepsilon^2}\mathrm{d}\mu_\varphi(x). \tag{3.5}$$

By our hypothesis, we have that $\mathrm{d}\mu_\varphi(\lambda)=\mu'_\varphi(\lambda)\mathrm{d}\lambda=(1/\pi)\mathrm{Im}\,F_\varphi(\lambda+i0)\mathrm{d}\lambda$, where μ'_φ denotes the Radon-Nikodym derivative of the measure μ_φ relative to the Lebesgue measure. So the limit when $\varepsilon\to 0$ in (3.5) exists thanks to (H6) and gives

$$F_\varphi(\lambda+i0)=PV\int_{-\infty}^{\infty}\frac{\mu'_\varphi(x)}{x-\lambda}\mathrm{d}x+i\pi\mu'_\varphi(\lambda), \tag{3.6}$$

where the first term on the right-hand side of (3.6) is the Cauchy principal value.

Lemma 3.1: Suppose that (H0), (H1), (H2), (H3), and (H5) hold. Then, for all $0<|\omega|\leqslant\omega_0$ *is finite and*

$$\tau_\omega(\psi)=\frac{2\pi\omega^4}{\beta_0^4}\int_{\mathbb{R}}\frac{|\mu'_\psi(\lambda)|^2}{|D(\omega,\lambda)|^4}\mathrm{d}\lambda, \tag{3.7}$$

where

$$D(\lambda,\omega):=1+(\beta_0+\omega)F_\varphi(\lambda+i0). \tag{3.8}$$

Proof: From the formula (3.1), we only need to compute $\mathrm{Im}\langle\psi,R_\omega(\lambda+i0)\psi\rangle$ for $\lambda\neq E_0$.

Since $H_{\beta_0}\psi=E_0\psi$ and $\psi=(M-E_0-i0)^{-1}\varphi$, we have that $\beta_0\langle\psi,\varphi\rangle=-1$. Hence, the identity (3.4) gives

$$\langle \psi, R_\omega(z)\psi\rangle = \frac{1}{E_0 - z}\|\psi\|^2 - \omega\frac{1+\beta_0 F_\varphi(z)}{1+(\beta_0+\omega)F_\varphi(z)}\frac{1}{\beta_0^2(E_0-z)^2}.$$

Consider $z=\lambda+i\epsilon$ with $\epsilon>0$. Hypothesis (H2) allows us to compute the limit as $\varepsilon\to 0$ to obtain that

$$\langle \psi, R_\omega(\lambda+i0)\psi\rangle = \frac{1}{(E_0-\lambda)}\|\psi\|^2 - \frac{\omega}{\beta_0^2(E_0-\lambda)^2}\lim_{\varepsilon\to 0}\frac{1+\beta_0 F_\varphi(\lambda+i\epsilon)}{1+(\beta_0+\omega)F_\varphi(\lambda+i\epsilon)}.$$

By taking the imaginary part, it follows immediately that

$$\mathrm{Im}\langle \psi, R_\omega(\lambda+i0)\psi\rangle = -\frac{\omega}{\beta_0^2(E_0-\lambda)^2}\lim_{\varepsilon\to 0}\mathrm{Im}\frac{1+\beta_0 F_\varphi(z)}{1+(\beta_0+\omega)F_\varphi(z)}.$$

Now,

$$\mathrm{Im}\frac{1+\beta_0 F_\varphi(z)}{1+(\beta_0+\omega)F_\varphi(z)} = \frac{\omega\,\mathrm{Im}\,\overline{F_\varphi}(z)}{|1+(\beta_0+\omega)F_\varphi(z)|^2}.$$

Hence, by using that $[1/(E_0-\lambda)^2]\mu_\varphi'(\lambda)=\mu_\psi'(\lambda)$ we conclude that

$$\mathrm{Im}\langle \psi, R_\omega(\lambda+i0)\psi\rangle = -\frac{\omega^2}{\beta_0^2(E_0-\lambda)^2}\lim_{\varepsilon\to 0}\frac{\mathrm{Im}\,\overline{F_\varphi}(\lambda+i\epsilon)}{|1+(\beta_0+\omega)F_\varphi(\lambda+i\epsilon)|^2} = \frac{\omega^2}{\beta_0^2}\frac{\pi\mu_\psi'(\lambda)}{|D(\lambda,\omega)|^2}$$

for any $\lambda\neq E_0$, thus ending the proof. The integral of (3.7) makes sense, i.e., is finite, thanks to (H2), (H3), and (H5). □

IV. EXACT ASYMPTOTICS FOR τ_ω

In this section we prove the explicit asymptotics for the sojourn time in a general context and we will apply it to some concrete examples.

Theorem 4.1: *Assume that* (H0)–(H6) *holds. Then the sojourn time* $\tau_\omega(\psi)$ *has the following behavior:*

$$\lim_{\omega\to 0}\omega^2\tau_\omega(\psi) = \frac{1}{\pi}\frac{\beta_0^2\|\psi\|^{10}}{\mu_\varphi'(E_0)}.$$

Proof: By using the first resolvent equation and (H1), we can rewrite $D(\lambda,\omega)$ as

$$D(\lambda,\omega) = 1+\beta\langle\varphi, R(\lambda+i0)\varphi\rangle = 1-\frac{\beta}{\beta_0}+\beta(\lambda-E_0)\langle\psi, R(\lambda+i0)\varphi\rangle.$$

By (H4) and applying the resolvent equation twice, we obtain that

$$D(\lambda,\omega) = -\frac{\omega}{\beta_0}+\beta(\lambda-E_0)q(\lambda)+i\pi\beta(\lambda-E_0)^2\mu_\psi'(\lambda)$$

with

$$q(\lambda) := \|\psi\|^2+(\lambda-E_0)g(\lambda).$$

By Lemma 3.1 we known that $\tau_\omega(\psi)$ is finite and it is represented by (3.7).

Consider the interval $I_\delta := \{\lambda\in\mathbb{R}, |\lambda-E_0|\leq\delta\}$ for some $\delta>0$. Let us split the integral in two parts,

$$A_\delta := \frac{2\pi\omega^6}{\beta_0^4}\int_{I_\delta}\frac{|\mu_\psi'(\lambda)|^2}{|D(\lambda,\omega)|^4}\mathrm{d}\lambda, \quad B_\delta := \frac{2\pi\omega^6}{\beta_0^4}\int_{\mathbb{R}\setminus I_\delta}\frac{|\mu_\psi'(\lambda)|^2}{|D(\lambda,\omega)|^4}\mathrm{d}\lambda.$$

We will prove first that $B_\delta \to 0$ as $\omega \to 0$ and second that A_δ tends to the desired limit using the Lebesgue dominated convergence theorem.

We get at once that $B_\delta = \mathcal{O}(\omega^6)$ since $|D(\lambda,\omega)| \geqslant c_\delta > 0$ on $\mathbb{R}\setminus I_\delta$, and μ_ψ' belongs to $L^2(\mathbb{R})$ by assumption (H5).

For $\omega \neq 0$ one defines

$$s_\omega(\lambda) := \omega^{-2}(-\omega\beta_0^{-1} + \beta(\lambda - E_0)q(\lambda)).$$

Thanks to (H4) we know that $g(\lambda)$ is a C^1 function in a neighborhood I_{δ_g} of E_0. Then s is a C^1 function with derivative

$$s_\omega'(\lambda) = \frac{\beta(q(\lambda) + (\lambda - E_0)q'(\lambda))}{\omega^2}$$

in I_{δ_g} and $s_\omega'(E_0) = \omega^{-2}\beta\|\psi\|^2$.

We choose $\omega_0 \leqslant |\beta_0|/2$ so that β does not vanish and therefore E_0 is not a critical point of s_ω. By the inverse mapping theorem we know that s_ω is locally in E_0 a C^1 diffeomorphism, i.e., we can choose $\delta_s > 0$ small enough so that the restriction of s_ω to I_{δ_s} is such a C^1-diffeomorphism. In view of the explicit dependence of s_ω with respect to ω one can choose this δ_s independently of ω. We continue to denote δ_s by δ. We note that

$$s \in \widetilde{I}_\delta \Leftrightarrow \left| s + \frac{1}{\omega\beta_0}\right| < \delta\frac{|\beta q(\lambda(s))|}{\omega^2}.$$

Let $\widetilde{I}_\delta \ni s \mapsto \lambda_\omega(s) \in I_\delta$ be the inverse of the previous change of variable. The quantities D and A_δ can now be written as

$$D(\lambda_\omega(s),\omega) = \omega^2 s + \frac{i\pi}{\beta}\left(\frac{\omega^2 s + \omega\beta_0^{-1}}{q(\lambda_\omega(s))}\right)^2 \mu_\psi'(\lambda_\omega(s)) =: \omega^2\widetilde{D}(s,\omega)$$

with

$$\widetilde{D}(s,\omega) = s + \frac{i\pi}{\beta}\left(\frac{\omega s + \beta_0^{-1}}{q(\lambda_\omega(s))}\right)^2 \mu_\psi'(\lambda_\omega(s))$$

and

$$\begin{aligned} A_\delta &= \frac{2\pi\omega^6}{\beta_0^4}\int_{\widetilde{I}_\delta}\frac{|\mu_\psi'(\lambda_\omega(s))|^2}{\omega^8|\widetilde{D}(s,\omega)|^4}\frac{\omega^2}{\beta(q(\lambda_\omega(s)) + (\lambda_\omega(s) - E_0)q'(\lambda_\omega(s)))}\mathrm{d}s \\ &= \frac{2\pi}{\beta\beta_0^4}\int_{\mathbb{R}} 1_{\widetilde{I}_\delta}\frac{|\mu_\psi'(\lambda_\omega(s))|^2}{|\widetilde{D}(s,\omega)|^4}\frac{1}{q(\lambda_\omega(s)) + (\lambda_\omega(s) - E_0)q'(\lambda_\omega(s))}\mathrm{d}s, \end{aligned}$$

where $1_{\widetilde{I}_\delta}$ denotes the characteristic function of I_δ.

We know that $q(\lambda) = \|\psi\|^2 + (\lambda - E_0)g(\lambda)$ and g is assumed to be C^1 on I_{δ_g} so g is bounded there. Therefore we can choose $0 < \delta_q < \min\{\delta_g, \delta_s\}$ small enough such that $q(\lambda) \geqslant \frac{1}{2}\|\psi\|^2$ on I_{δ_q}. In view of

$$\forall s \in I_{\delta_s}, \quad \omega^2 s + \omega\beta_0^{-1} = \beta(\lambda(s) - E_0)q(\lambda(s))$$

we see at once that $\lim_{\omega\to 0}\lambda_\omega(s) = E_0$. Then, by assumption (H4),

$$\lim_{\omega\to 0}\mu'_\psi(s)=\mu'_\psi(E_0),\quad \lim_{\omega\to 0}\tilde{D}(s,\omega)=s+\frac{i\pi}{\beta_0^3\|\psi\|^4}\mu'_\psi(E_0)$$

and

$$\lim_{\omega\to 0}\frac{1}{(q(\lambda_\omega(s))+(\lambda_\omega(s)-E_0)q'(\lambda_\omega(s)))}=\frac{1}{\|\psi\|^2}.$$

Therefore,

$$\lim_{\omega\to 0}(\text{integrand})=\frac{2\pi}{\beta_0^5}\frac{|\mu'_\psi(E_0)|^2}{\left|s^2+\frac{\pi^2|\mu'_\psi(E_0)|^2}{\beta_0^6\|\psi\|^8}\right|^2}=\frac{1}{\|\psi\|^2}.$$

By formal integration one arrives at

$$\frac{2\pi}{\beta_0^5}\frac{|\mu'_\psi(E_0)|^2}{\|\psi\|^2}\int_{\mathbb{R}}\frac{1}{\left|s^2+\frac{|\pi\mu'_\psi(E_0)|^2}{\beta_0^6\|\psi\|^8}\right|^2}\mathrm{d}s=\frac{2\pi}{\beta_0^5}\frac{|\mu'_\psi(E_0)|^2}{\|\psi\|^2}\frac{\pi}{2\left(\frac{\pi|\mu'_\psi(E_0)|}{\beta_0^3\|\psi\|^4}\right)^3}=\frac{\beta_0^4}{\pi}\frac{\|\psi\|^{10}}{|\mu'_\psi(E_0)|}.$$

Then, it remains to justify the interchange of the limit with the integral.

First we have

$$|\tilde{D}(s,\omega)|^2=s^2+\frac{\pi^2}{\beta^2}\left(\frac{\omega s+\beta_0^{-1}}{q(\lambda_\omega(s))}\right)^4(\mu'_\psi(\lambda_\omega(s)))^2.$$

Due to assumptions (H4), (H6) we know that there exists a neighborhood of E_0 on which $\mu'_\psi>0$. Let K be a compact interval which contains 0 in its interior, the image of K in the λ variable is a compact interval which contains E_0 and shrinks as $\omega\to 0$. So for $|\omega|$ small enough we are sure that $\mu'_\psi(\lambda_\omega(s))^2\geqslant c>0$ with c independent of ω. Since we can also easily make that the quantity $(1/\beta^2)(\omega s+\beta_0^{-1}/q(\lambda_\omega(s)))^4$ is also bounded below uniformly with respect to ω we get that

$$\exists\,\omega_0>0,\quad \forall\, s\in K,\quad \forall\,|\omega|\leqslant\omega_0,\quad |\tilde{D}(s,\omega)|^2\geqslant c>0.$$

It follows that

$$\forall\, s\in\tilde{I}_\delta,\quad |\tilde{D}(s,\omega)|^2\geqslant\max\{s^2,c\}.$$

Then since g is C^1 on I_{δ_g} one has that $\lambda\mapsto q(\lambda)-(\lambda-E_0)q'(\lambda)$ is C^0 on I_{δ_g} and since $q(E_0)=\|\psi\|^2>0$ one can choose $\delta:=\delta_g$ small enough so that

$$\forall\, s\in\tilde{I}_\delta,\quad q(\lambda_\omega(s))+(\lambda_\omega(s)-E_0)q'(\lambda_\omega(s))\geqslant c>0.$$

Finally thanks to (H4) we can choose δ small enough so that $|\mu'_\psi|\leqslant c_1$ on I_δ. In conclusion we have obtained

$$\exists\,\delta>0,\quad \exists\,\omega_0>0,\quad \forall\, s\in\tilde{I}_\delta,\quad \forall\,|\omega|\leqslant\omega_0,\quad 0\leqslant\text{integrand}\leqslant\frac{4\pi}{\beta_0^5}\frac{c_1^2}{\max\{s^4,c^2\}c}$$

and since outside $\tilde{I}_\delta$ the integrand vanishes this bound is valid on $\mathbb{R}$. □

A. The Friedrichs model

The Friedrichs model corresponds to a very simple choice of the operator M, namely, the multiplication operator $M\varphi(x)=x\varphi(x)$ acting in $\mathcal{H}:=L^2(\mathbb{R})$. The operator M with domain $D(M)=\{\varphi: x\varphi\in L^2(\mathbb{R})\}$ is purely absolutely continuous with spectrum $\sigma(M)=\mathbb{R}$. Moreover, its spectral measure is given by $\mu'_\varphi(x)=\langle\varphi, E_x^M\varphi\rangle=|\varphi(x)|^2$.

We consider the rank one perturbation $H_\beta=M+\beta|\varphi\rangle\langle\varphi|$. In order to verify our hypothesis, we impose on the vector φ the following conditions.

(F0): φ is normalized in $\mathcal{H}$.

(F1): φ belongs to the Sobolev space $\mathcal{H}^2(\mathbb{R})$.

(F2): φ has a unique zero at $x=E_0$.

(F3): $\beta_0\neq 0$ and φ satisfy the relation

$$1+\beta_0\int_{-\infty}^{\infty}\frac{|\varphi(x)|^2}{x-E_0}\mathrm{d}x=0.$$

(F4): $\varphi'(E_0)\neq 0$, and $\varphi\in C^2$ in a neighborhood of E_0.

Clearly (H0) holds. On the other hand, conditions (F1)–(F3) imply hypothesis (H1)–H(5). Also, (F4) guarantees condition (H6). By Theorem 4.1 we deduce the following result.

Theorem 4.2 (Friedrichs model): *Assume that* (F1)–(F4) *holds. Then the sojourn time* $\tau_\omega(\psi)$ *has the following behavior:*

$$\lim_{\omega\to 0}\omega^2\tau_\omega(\psi)=\frac{1}{\pi}\frac{\beta_0^4\|\psi\|^{10}}{|\psi(E_0)|^2},$$

or else if $\psi_0:=\psi\|\psi\|^{-1}$ *denotes the normalized eigenvector then*

$$\tau_\omega(\psi_0)\overset{\omega\to 0}{\sim}\frac{1}{\pi}\frac{1}{\omega^2}\frac{1}{|\langle P\psi_0,\psi_0\rangle\psi_0(E_0)|^2}.$$

Actually conditions (F1)–(F4) can be relaxed by asking local properties, around E_0, for the vector φ.

B. Model $M=X^2$

Another choice of the operator M is the multiplication by x^2 in $\mathcal{H}:=L^2(\mathbb{R})$, which it is purely absolutely continuous with spectrum $\sigma(M)=[0,\infty)$. Its spectral measure is just

$$\mu'_\phi(\lambda)=\begin{cases}0 & \text{if } \lambda<0,\\ \dfrac{|\phi(\sqrt{\lambda})|^2+|\phi(-\sqrt{\lambda})|^2)}{2\sqrt{\lambda}} & \text{if } \lambda>0.\end{cases}$$

Again, we consider rank one perturbations $H_\beta=M+\beta|\varphi\rangle\langle\varphi|$. As we mentioned in the Introduction, in order to apply our results we must choose φ as $g(M)$ times an adequate function, where g is a suitable cutoff function. It is easy to verify that if we just take $g(x)=x^2$ and φ_0 satisfies

(1) φ_0 is in the Schwartz' class and $\varphi_0(x)>0$, for all $x\in\mathbb{R}$,
(2) $\int_{-\infty}^{\infty}(x^2-E_0)x^4|\varphi_0|^2=-1/\beta_0$,
(3) $\int_{-\infty}^{\infty}(x^2-E_0)x^4|\varphi_0|^2\neq\int_{-\infty}^{\infty}(x^2-E_0)^2x^2|\varphi_0|^2$, and
(4) $\int_{-\infty}^{\infty}(x^2-E_0)^2x^4|\varphi_0|^2=1$.

then, with E_0 positive and $\varphi(x)=g(M)(x^2-E_0)\varphi_0(x)=x^2(x^2-E_0)\varphi_0(x)$ all the hypothesis (H0)–(H6) are satisfied.

V. SOJOURN TIME AND RESONANCES DEFINED BY ANALYTIC TRANSLATION

This section is concerned with the connection between the sojourn time and the resonance width which can be shown for the Friedrichs model in $L^2(\mathbb{R}^n)$, $n \geqslant 1$. We first recall its definition.

Let $\mathbf{e}=(e_1,e_2,\ldots,e_n)$ be a unit vector in $\mathbb{R}^n$ and consider the multiplication operator by the function $\mathbf{e}\cdot x=\sum_{i=1}^n e_i x_i$, i.e., the operator

$$(M\phi)(x) = \mathbf{e}\cdot x\phi(x). \tag{5.1}$$

We denote by $\mathcal{D}$ its natural domain. Let now $\varphi \in L^2(\mathbb{R}^n)$, $\|\varphi\|=1$ and denote by P the projector on the vector φ. Then the Friedrichs operators,

$$H(\beta) = M + \beta P, \quad \beta \in \mathbb{R} \tag{5.2}$$

with domain $\mathcal{D}$ are well defined in $L^2(\mathbb{R}^n)$ as self-adjoint operators. We are interested in the study of the sojourn time associated to the dynamics defined from the family of Hamiltonians $\{H_\beta, \beta \in \mathbb{R}\}$ for a dense subset of vectors of $L^2(\mathbb{R}^n)$ (Ref. 12, p. 88). We shall estimate the time evolution under $H(\beta)$ and the sojourn time, following a method developed by Herbst in the context of Stark effect see, e.g., Refs. 3 and 4. From now we use the notation $H := H(\beta)$.

For $\theta \in \mathbb{R}$, define the following family of unitary transformations:

$$\forall\, \phi \in L^2(\mathbb{R}^n), \quad (U_\theta\phi)(x) := \phi(x - \theta\mathbf{e}). \tag{5.3}$$

Then, U_θ; $\theta \in \mathbb{R}$ is a strongly continuous one-parameter unitary group and

$$H_\theta := U_\theta H U_\theta^{-1} = M_\theta + \beta P_\theta, \quad M_\theta = \mathbf{e}\cdot x - \theta, \tag{5.4}$$

where P_θ is the projector on the span generated by the vector $\varphi_\theta := U_\theta\varphi$.

Our general assumption is the following.

(HA): There exists some $a>0$ such that the vector valued function, $\mathbb{R} \ni \theta \to \varphi_\theta \in L^2(\mathbb{R}^n)$ has an analytic extension in the strip $\mathcal{S}_a := \{z \in \mathbb{C}, |\mathrm{Im}\, z| < a\}$.

We denote by $\mathcal{D}_a$ the set of vectors satisfying the assumption (HA). This set is a dense subset of $L^2(\mathbb{R}^n)$.[5]

We extend P_θ, for $\theta \in S_a$ by

$$\forall\, \phi \in L^2(\mathbb{R}^n), \quad P_\theta\phi := \langle \varphi_{\bar\theta}, \phi\rangle \varphi_\theta$$

which is an analytic family of rank one operators. Then $\{H_\theta; \theta \in \mathcal{S}_a\}$ is a self-adjoint analytic family of type A operators.[8] Moreover, due to the Weyl theorem,[14] we have that $\sigma_{\mathrm{ess}}(H_\theta) = \sigma_{\mathrm{ess}}(H_{0,\theta}) = \mathbb{R} - i\,\mathrm{Im}\,\theta$. Our first technical result is the following.

Lemma 5.1: Suppose that (HA) *is satisfied. Then for* $a > \mathrm{Im}\,\theta > 0$ *and* $0 < \epsilon \leqslant 1$, *there exists a positive energy e such that*

$$\sup\{\|(H_\theta - z)^{-1}\|;\ z \in \mathbb{C},\ |\mathrm{Re}\, z| \geqslant e,\ \mathrm{Im}\, z \geqslant -\mathrm{Im}\,\theta(1-\epsilon)\} < \infty. \tag{5.5}$$

Lemma 5.1, together with the discreteness of the spectrum in $\{z \in \mathbb{C}, \mathrm{Im}\, z > -\mathrm{Im}\,\theta\}$ imply that for $a > \mathrm{Im}\,\theta \geqslant 0$, the operators H_θ have only a finite number of eigenvalues localized in the compact set $\{z \in \mathbb{C}, 0 \geqslant \mathrm{Im}\, z \geqslant -\mathrm{Im}\,\theta(1-\epsilon), |\mathrm{Re}\, z| \leqslant e\}$, $0 < \epsilon \leqslant 1$. Some of them can be real, in that case they correspond to embedded eigenvalues for the self-adjoint operator H while the nonreal eigenvalues correspond to resonances for the pair (M,H) (see, e.g., Refs. 14 and 4). Notice that the upper bound on the number of eigenvalues given by the proof below diverges when a tends to 0.

Proof: Because of the unitary property for real θ, it is sufficient to choose $\theta = i\eta$, $a > \eta > 0$. Then for $z \in \mathbb{C}$, $\mathrm{Im}\, z > -\eta$ we have

$$\|(M_{i\eta} - z)^{-1}\| \leqslant (\eta + \mathrm{Im}\, z)^{-1}. \tag{5.6}$$

Recall that by the Aronszjan-Krein formula we get

$$(H_{i\eta}-z)^{-1}=(M_{i\eta}-z)^{-1}-\beta\frac{(M_{i\eta}-z)^{-1}P_{i\eta}(M_{i\eta}-z)^{-1}}{1+\beta\langle\varphi_{-i\eta},(M_{i\eta}-z)^{-1}\varphi_{i\eta}\rangle}. \tag{5.7}$$

Hence the lemma is proven if we show that the denominator on the right-handside (rhs) of (5.7) is uniformly bounded below by a strictly positive constant. Then consider the following integral:

$$I=\int_{\mathbb{R}^n}\mathrm{d}x\frac{|\varphi_{i\eta}(x)|^2}{(|\mathbf{e}\cdot x-\mathrm{Re}\,z|^2+|\eta+\mathrm{Im}\,z|^2)^{1/2}}. \tag{5.8}$$

For $\delta>0$ let $\Omega_\delta:=\{x\in\mathbb{R}^n,|\mathbf{e}\cdot x-\mathrm{Re}\,z|\geqslant\delta\}$ and Ω_δ^c its complement, accordingly let

$$I_\delta=\int_{\Omega_\delta}\mathrm{d}x\frac{|\varphi_{i\eta}(x)|^2}{(|\mathbf{e}\cdot x-\mathrm{Re}\,z|^2+|\eta+\mathrm{Im}\,z|^2)^{1/2}}$$

and $I_\delta^c=I-I_\delta$. Since obviously

$$I_\delta\leqslant\frac{\|\varphi_{i\eta}\|^2}{\delta}$$

we can choose $\delta>0$ such that $I_\delta\leqslant 1/4$. On the other hand,

$$I_\delta^c\leqslant\frac{1}{|\eta+\mathrm{Im}\,z|}\int_{\Omega_\delta^c}|\varphi_{i\eta}(x)|^2\,\mathrm{d}x$$

but the rhs of this last inequality goes to zero as $|\mathrm{Re}\,z|$ goes to infinity, uniformly in $\mathrm{Im}\,z\geqslant-\eta(1-\epsilon)$. Hence there exists a positive energy e such that for $z\in\mathbb{C}$, $|\mathrm{Re}\,z|\geqslant e$, $\mathrm{Im}\,z\geqslant-\eta(1-\epsilon)$, $I_\delta^c\leqslant 1/4$ and then $1+|\langle\varphi_{-i\eta},(M_{i\eta}-z)^{-1}\varphi_{i\eta}\rangle|\geqslant 1/2$ which finishes to prove the lemma. □

We turn now on the dynamics defined by the operators (5.2). Let $\{E_j\}_{j=1,\ldots,N}$ be the real eigenvalues of H and $\{\Pi_j\}_{j=1,\ldots,N}$ the associated orthogonal eigenprojectors. We know from Refs. 14 and 4 that for $j=1,\ldots,N$, $\{\Pi_j(\theta),\theta\in\mathcal{S}_a\}$ are analytic families of projectors and that for $\mathrm{Im}\,\theta\neq 0$ they coincide with

$$\Pi_j(\theta)=-\frac{1}{2\pi i}\int_{|z-E_j|=\rho}(H_\theta-z)^{-1}\,\mathrm{d}z,\quad \rho>0 \text{ and small enough}. \tag{5.9}$$

Fix $\mathrm{Re}\,\theta=0$, $\mathrm{Im}\,\theta=\eta$, $0<\eta<a$ and denote by $\{Z_j\}_{j=1,\ldots,M}$ the set of complex eigenvalues of $H_{i\eta}$ and by $\{\tilde{\Pi}_j(i\eta)\}_{j=1,\ldots,M}$, the associated eigenprojectors defined through the Cauchy integral formula as in (5.9). We have the following.

Theorem 5.1: *Assume* (HA). *Let* $0<\eta<a$ *as above and* $\phi\in\mathcal{D}_a$, *then there exist* $0<\epsilon<1$ *such that for all* $t\geqslant 0$,

$$\langle\phi,e^{-itH}\phi\rangle\overset{t\to\infty}{=}\sum_{j=1..N}e^{-itE_j}\langle\phi,\Pi_j\phi\rangle+\sum_{j=1..M}e^{-itZ_j}\langle\tilde{\phi}_{-i\eta},\tilde{\Pi}_j(i\eta)\tilde{\phi}_{i\eta}\rangle+O_{\phi,\eta}(e^{-(\eta(1-\epsilon))t}). \tag{5.10}$$

Here $\tilde{\phi}_{\pm i\eta}:=(1-\Pi(i\eta))\phi_{\pm i\eta}$ *and* $\Pi:=\Sigma_{j=1\ldots N}\Pi_j$. *If* H *has no eigenvalue take* $\Pi=0$ *on the rhs of (5.10) and similarly for the complex eigenvalues* Z_j *of* $H_{i\eta}$.

It is worth to notice, in particular to well understand (5.18), that due to the analyticity and unitary properties, the coefficients $\{\langle\tilde{\phi}_{-i\eta},\tilde{\Pi}_j(i\eta)\tilde{\phi}_{i\eta}\rangle\}_{j=1,\ldots,M}$ are η independent.

Proof: By using the spectral theorem and since H has no singular continuous spectrum (H is a rank one perturbation of the purely ac operator M, see Ref. 8), for every $\phi\in\mathcal{D}_a$, we have

$$\langle \phi, e^{-itH}\phi\rangle = \sum_{j=1..N} e^{-itE_j}\langle \phi, \Pi_j \phi\rangle + \int_{\mathbb{R}} \mathrm{d}\lambda\, Q_\phi(\lambda) e^{-it\lambda}. \tag{5.11}$$

Here

$$Q_\phi(\lambda) = \frac{1}{2i\pi}(G_{\tilde{\phi}}(\lambda + i0) - G_{\tilde{\phi}}(\lambda - i0)), \tag{5.12}$$

where

$$G_\phi(z) := \langle \phi, (H-z)^{-1}\phi\rangle. \tag{5.13}$$

From our previous discussion, it is clear that $\{G_{\tilde{\phi}}(z), \mathrm{Im}\, z > 0\}$ has a meromorphic extension in $\{\mathrm{Im}\, z > -\eta\}$ given by

$$G_{\tilde{\phi}}(z) = \langle \tilde{\phi}_{-i\eta}, (H_{i\eta} - z)^{-1}\tilde{\phi}_{i\eta}\rangle.$$

Similarly $\{G_{\tilde{\phi}}(z), \mathrm{Im}\, z < 0\}$ has a meromorphic extension in $\mathrm{Im}\, z < \eta$ with the expression

$$G_{\tilde{\phi}}(z) = \langle \tilde{\phi}_{i\eta}, (H_{-i\eta} - z)^{-1}\tilde{\phi}_{-i\eta}\rangle.$$

Moreover by using the formula

$$(H-z)^{-1} = -\frac{1}{z} - \frac{1}{z^2}H + \frac{1}{z^2}H(H-z)^{-1}H$$

and the analyticity properties evoked above, we have for $0 > \mathrm{Im}\, z > -\eta$, $|\mathrm{Re}\, z| \geqslant e$,

$$Q_\phi(z) = \frac{1}{2i\pi z^2}(\langle H_{-i\eta}\tilde{\phi}_{-i\eta}, (H_{i\eta} - z)^{-1}H_{i\eta}\tilde{\phi}_{i\eta}\rangle - \langle H\tilde{\phi}, (H-z)^{-1}H\tilde{\phi}\rangle) \tag{5.14}$$

which together with Lemma 5.1 immediately implies

$$|Q_\phi(z)| = Q_{\phi,\eta}\left(\frac{1}{|z|^2}\right) \tag{5.15}$$

if $0 > \mathrm{Im}\, z > -\eta(1-\epsilon)$, $0 < \epsilon \leqslant 1$, and $|\mathrm{Re}\, z|$ large enough. Then the integral on the rhs of (5.11) can be computed by using the Cauchy theorem,

$$\int_{\mathbb{R}} \mathrm{d}\lambda\, Q_\phi(\lambda) e^{-it\lambda} = \sum_{j=1..M} e^{-itZ_j}\, \mathrm{Res}\, G_{\tilde{\phi}}(z)\big|_{z=Z_j} + e^{-(\eta(1-\epsilon))t}\int_{\mathbb{R}} \mathrm{d}\lambda\, Q_\phi(\lambda - i(\eta(1-\epsilon))\; e^{-it\lambda}. \tag{5.16}$$

The parameter ϵ, $0 < \epsilon < 1$ is chosen such that the operator $H_{i\eta}$ has no complex eigenvalues on the line $\{\lambda - i(\eta - \epsilon); \lambda \in \mathbb{R}\}$. Standard arguments show that the first term of the rhs of (5.16) gives the second term of the rhs of (5.10). By using the estimate (5.15) we get that the second term of the rhs of (5.16) is $O_{\phi,\eta}(e^{-\eta(1-\epsilon)t})$ so that (5.16) implies the theorem. □

Theorem 5.1 provides a general framework to study sojourn times associated to the family of operators $\{H(\beta), \beta > 0\}$ given in (5.2), for the dense set of analytic vectors associated to the one parameter unitary group $\{U_\theta, \theta \in \mathbb{R}\}$.

According to the general context of this paper we consider the following situation. Suppose that $H(\beta_0)$ has only one real eigenvalue E_0 for some β_0. Lemma 2.1 gives a necessary and sufficient condition for this property to take place and Corollary 2.1 asserts that E_0 is simple. Let $\Pi := |\psi_0\rangle\langle\psi_0|$ be the orthogonal projector onto the corresponding eigenvector. We know that E_0 remains a simple eigenvalue of $H_{i\eta}(\beta_0)$ for $a > \eta > 0$. Denote by $\{Z_j\}_{j=1,\ldots,M}$ the (eventual) complex eigenvalues of $H_{i\eta}(\beta_0)$.

We also assume that, for β near β_0 and $\beta \neq \beta_0$, the operator $H(\beta)$ has only continuous spectrum. Then, $H_{i\eta}(\beta)$ has no real eigenvalues and therefore, by the usual perturbation theory, the operator $H_{i\eta}(\beta)$ has an eigenvalue $E(\beta)$ near E_0 with $\operatorname{Im} E(\beta) \neq 0$ and eigenvalues $\{Z_j(\beta)\}_{j=1,\ldots,M}$ near $\{Z_j\}_{j=1,\ldots,M}$.

Using the classical formulas of regular perturbation theory, see Ref. 8, Chap. 2, one gets with $\omega := \beta - \beta_0$,

$$E(\beta) \overset{\omega\to 0}{=} E_0 + \omega\langle \psi_{0,-i\eta}, P_{i\eta}\psi_{0,i\eta}\rangle - \omega^2\langle \psi_{0,-i\eta}, P_{i\eta}S_{i\eta}(E_0)P_{i\eta}\psi_{0,i\eta}\rangle + \mathcal{O}_\eta(\omega^3)$$
$$\overset{\omega\to 0}{=} E_0 + \omega\langle \psi_0, P\psi_0\rangle - \omega^2\langle P\psi_0, S(E_0+i0)P\psi_0\rangle + \mathcal{O}_\eta(\omega^3),$$

where $S_{i\eta}(E_0)$ denotes the reduced resolvent of $H_{i\eta}(\beta_0)$ at E_0, see Ref. 8, Chap. III, Sec. 6.5 for the definition of the reduced resolvent. Let

$$\Gamma := 2\omega^2 \operatorname{Im}\langle P\psi_0, S(E_0+i0)P\psi_0\rangle, \tag{5.17}$$

be the resonance width of $E(\beta)$; one has $\operatorname{Im} E(\beta) = -\frac{1}{2}\Gamma + \mathcal{O}(\omega^3)$. One also obtains that $|Z_j(\beta) - Z_j| = \mathcal{O}(\omega)$ and therefore $|\operatorname{Im} Z_j(\beta)|$ remains uniformly away from zero for ω small enough. Finally the perturbation theory gives the expansion of the eigenprojector associated to $E(\beta)$,

$$\Pi(i\eta,\beta) \overset{\omega\to 0}{=} \Pi(i\eta,\beta_0) + \mathcal{O}_\eta(\omega) \quad \text{with } \Pi(i\eta,\beta_0) = |\psi_{0,i\eta}\rangle\langle\psi_{0,-i\eta}|.$$

Define now $\tau_\omega^\pm$ (the sojourn time in the future, respectively, in the past)

$$\tau_\omega^\pm(\phi) := \int_{\mathbb{R}_\pm} |\langle \phi, e^{-itH(\beta_0+\omega)}\phi\rangle|^2 \, \mathrm{d}t.$$

By using Theorem 5.1 one gets integrating (5.10) over $\mathbb{R}_+$ (notice that here $\tilde{\phi} = \phi$),

$$\tau_\omega^+(\phi) \overset{\omega\to 0}{=} \frac{|\langle \phi_{-\eta}, \Pi(i\eta,\beta)\phi_{i\eta}\rangle|^2}{-2\operatorname{Im} E(\beta)} + \mathcal{O}_{\phi,\eta}(1) \overset{\omega\to 0}{=} \frac{|\langle \phi, \psi_0\rangle|^4}{\Gamma} + \mathcal{O}_{\phi,\eta}(\omega^{-1}).$$

Since clearly $\tau_\omega^- = \tau_\omega^+$ we have proven the following.

Theorem 5.2: *In the conditions stated above let $\phi \in \mathcal{D}_a$ and assume in addition that Γ defined in (5.17) does not vanish. Then for $\beta = \beta_0 + \omega$,*

$$\tau_\omega(\phi) \overset{\omega\to 0}{=} \frac{|\langle \phi_{-i\eta}, \Pi(i\eta,\beta)\phi_{i\eta}\rangle|^2}{-\operatorname{Im} E(\beta)} + \mathcal{O}_{\phi,\eta}(1) \tag{5.18}$$

$$= 2\frac{|\langle \phi, \psi_0\rangle|^4}{\Gamma} + \mathcal{O}_\phi(\omega^{-1}), \tag{5.19}$$

where ψ_0 denotes the normalized eigenvector associated to the eigenvalue E_0 of $H(\beta_0)$.

Remark 5.1: (a) Let us illustrate this result in the one dimensional case. Again with the Aronszjan-Krein formula

$$S(E_0+i0) = R_0(E_0+i0) + (R_0(E_0+i0)\psi_0,\psi_0)\Pi - (R_0(E_0+i0)\Pi + \Pi R_0(E_0+i0))$$

so that

$$\frac{1}{2}\Gamma = \omega^2 \operatorname{Im}\langle P\psi_0, S(E_0+i0)P\psi_0\rangle = \omega^2|(\varphi,\psi_0)|^4 \operatorname{Im}(R(E_0+i0)\psi_0,\psi_0) = \pi\omega^2|\langle\psi_0, P\psi_0\rangle|^2|\psi_0(E_0)|^2$$
$$= \frac{\pi\omega^2|\psi(E_0)|^2}{\beta_0^4\|\psi\|^6} = \frac{\pi\omega^2|\varphi'(E_0)|^2}{\beta_0^4\|\psi\|^6}.$$

First we see that the assumption $\varphi'(E_0) \neq 0$ *guarantees that* $\Gamma \neq 0$. *Then* $\omega^2 \tau_\omega(\psi_0) = \langle \psi_0, P\psi_0 \rangle|^{-2} |\psi_0(E_0)|^{-2} + \mathcal{O}(\omega)$ *which indeed is what we found in Theorem 4.1 with a more precise estimate here on the rate of decay of the remainder.*

(b) Instead of requiring that $H(\beta)$ *has no real eigenvalue for* β *near* β_0 *we could equivalently demand that the resonance width* Γ *is not zero since as we have seen above* $E(\beta_0 + \omega) = E_0 + \omega \langle \psi_0, P\psi_0 \rangle - \frac{1}{2}\Gamma + \mathcal{O}(\omega^3)$.

(Received 31 August 2005; accepted 20 January 2006; published online 8 March 2006)

We show that second-order superintegrable systems in two-dimensional and three-dimensional Euclidean space generate both exactly solvable (ES) and quasiexactly solvable (QES) problems in quantum mechanics via separation of variables, and demonstrate the increased insight into the structure of such problems provided by superintegrability. A principal advantage of our analysis using nondegenerate superintegrable systems is that they are multiseparable. Most past separation of variables treatments of QES problems via partial differential equations have only incorporated separability, not multiseparability. Also, we propose another definition of ES and QES. The quantum mechanical problem is called ES if the solution of Schrödinger equation can be expressed in terms of hypergeometric functions ${}_mF_n$ and is QES if the Schrödinger equation admits polynomial solutions with coefficients necessarily satisfying a three-term or higher order of recurrence relations. In three dimensions we give an example of a system that is QES in one set of separable coordinates, but is not ES in any other separable coordinates. This example encompasses Ushveridze's tenth-order polynomial QES problem in one set of separable coordinates and also leads to a fourth-order polynomial QES problem in another separable coordinate set. © *2006 American Institute of Physics.*

I. INTRODUCTION

It is well known that N-dimensional nonrelativistic quantum systems described by the Hamiltonian

$$\mathcal{H} = -\frac{1}{2}\sum_{i=1}^{N}\frac{\partial^2}{\partial x_i^2} + V(x_1, x_2, \ldots, x_N) \tag{1}$$

are integrable if there exist N linearly independent and global differential operators $\mathcal{I}_\ell$, $\ell = 0, 1, \ldots, N-1$ and $\mathcal{I}_0 = \mathcal{H}$, commuting with the Hamiltonian (1) and with each other

$$[\mathcal{I}_\ell, \mathcal{H}] = 0, \quad [\mathcal{I}_\ell, \mathcal{I}_j] = 0, \quad \ell, j = 1, 2, \ldots, N-1. \tag{2}$$

This particular class of integrable systems is called (maximally) superintegrable (this term was introduced first by Rauch-Wojciechowski in Ref. 1) if it is integrable and, also, possesses $2N-1$

functionally independent differential operators (integrals of motion). The additional $N-1$ integrals $\mathcal{L}_k$, commute with the Hamiltonian

$$[\mathcal{L}_k,\mathcal{H}]=0, \quad k=1,2,\ldots,N-1, \tag{3}$$

but not necessarily with each other. (These definitions have obvious classical analogs for the classical Hamiltonian.) Three examples of this kind have been well known for a long time, viz. the Kepler-Coulomb problem, the isotropic harmonic oscillator, and the nonisotropic oscillator with commensurable frequencies.

The existence of additional quantum integrals of motion for these systems leads to many interesting properties not shared by integrable systems. In classical mechanics the corresponding additional integrals of motion have the consequence that in the case of superintegrable systems in two dimensions and maximally superintegrable systems in three dimensions all finite trajectories are found to be periodic.

One of the most important properties for many superintegrable systems (particularly second-order systems where there are $2N-1$ functionally independent quadratic constants of the motion) is multiseparability, i.e., the separation of variables for the Hamilton-Jacobi and Schrödinger equations in more than one orthogonal coordinate system.[2–8] (Each separable coordinate system is associated with N commuting second-order constants of the motion.) For instance, the isotropic harmonic oscillator in three dimensions is separable in eight coordinate systems, namely in Cartesian, spherical, circular polar, circular elliptic, conical, oblate spheroidal, prolate spheroidal, and ellipsoidal coordinates. The Kepler-Coulomb potential is separable in four coordinate systems, namely in conical, spherical parabolic, and prolate spheroidal coordinates.

A systematic search for such systems in two- and three-dimensional Euclidean space was started in the pioneering work of Smorodinsky and Winternitz with collaborators in Refs. 9–11 and was continued in Ref. 12. Particularly, in Ref. 10 it was shown that in two-dimensional real Euclidean space there exist four superintegrable potentials, three of which could be considered as the singular generalization of Kepler-Coulomb, circular oscillator and anisotropic oscillator systems. These results were extended for two- and three-dimensional spaces with constant curvature (both positive and negative),[13] and on the complex two-dimensional sphere and Euclidean space.[14–18] The program is continuing for various conformally flat space spaces.[19–30,5–7]

In the last 15 years superintegrable systems have become a subject of investigation from many points of view: in Refs. 13, 18, 31, and 32 via the path integral approach, in Refs. 19, 21, and 22 by solving the Schrödinger equation with the help of the Niven ansatz,[33] in Refs. 34–39 from the purely algebraic approach, and generally in Ref. 40. As has been shown by a number of authors, many superintegrable systems generate an algebraic structure which may be considered as a nonlinear extension of the Lie algebra (in classical mechanics Poisson algebras), namely a quadratic algebra. The general form of quadratic algebras, which are encountered in the case of two-dimensional quantum superintegrable systems has been investigated.[39,5,6]

Particularly useful is the exact solvability of many superintegrable systems. Essentially, this means that after any separation of variables each of the separated ordinary differential equations admits an exact solution. However, the term exact solvability is defined differently by different authors. In Refs. 41 and 42 [see also the recent paper (Ref. 43)] we read that "an exactly solvable quantum mechanical system can be characterized by the fact that in its solution space one can indicate explicitly an infinite flag of functional linear spaces, which is preserved by the Hamiltonian" or the "Hamiltonian is exactly solvable if its spectrum can be calculated algebraically." Indeed, in spite of an "intuitive" understanding of the term exactly solvable, no universal definition exists up to now.

On the other hand, there are limiting cases of well-known one-dimensional exactly solvable systems, namely the harmonic oscillator and Coulomb problems with γ/x^2 $(\gamma>-1/4)$ interaction, Morse potential, trigonometric and modified Pöschl-Teller potentials, trigonometric and hyperbolic Manning-Rosen potentials,[44,45] and the Natanson potential.[46] All these potentials have the general property that the Schrödinger spectral problem has an explicit formula for the *whole* energy spectrum including the continuous spectrum, and the eigenfunctions (up to the asymptotic

ansatz or gauge transformations[41,42]) are of hypergeometric type ${}_1F_1$, ${}_2F_1$. For the bound states we have solutions in terms of classical polynomials[47] whereas for continuous states just infinite series. Moreover, hypergeometric functions describe both the continuous quantum systems as well as the finite systems and appear also as solutions of related difference equations, for instance, the finite one- and two-dimensional oscillator expressed in terms of discrete variables polynomials, Krawchuk, Meixner, and Hahn.[48] The standard definitions of exact solvability do not include many of these systems.

Thus, we propose another definition of exact solvability: a *quantum mechanical system is called exactly solvable if the solutions of the Schrödinger equation can be expressed in terms of hypergeometric functions* ${}_mF_n$. (Basically, we are requiring that the coefficients in power series expansions of the solutions satisfy two-term recurrence relations, rather than recurrence relations of higher order.) It is obvious that an N-dimensional Schrödinger equation is exactly solvable if it is separable in some coordinate systems and each of the separated equations is exactly solvable. Further, *we say that a superintegrable system is exactly solvable if it is exactly solvable in at least one system of coordinates*.

At first sight, such a definition of exactly solvable problems may seem too narrow, but it leads us to distinguish two kinds of models: (1) those which it is possible to study analytically and (2) those which can be solved numerically via the solution of algebraic equations.

The process of separation of variables in the N-dimensional Schrödinger equation leads to ordinary differential equations having as solutions many of the special functions of mathematical physics. A complication of the separated equations involves the N separation constants. In general we have a multiparameter eigenvalue problem.[49] It is possible to distinguish three different cases, namely when there is complete, partial or nonseparability of the separation constants. It is obvious that in the case of complete separability (of separation constants) the initial N-dimensional Schrödinger equation splits into N independent second-order differential equations, each involving a single separation parameter. This situation occurs, for instance, in the case of separation of variables in the Helmholtz (free Schrödinger equation, which is also superintegrable) or the Schrödinger equation for the harmonic oscillator in Cartesian coordinates. The second "extremal" case, when complete nonseparability exists, is realized, in separation of variables for the same problems but in ellipsoidal coordinates. In the last case each separated second-order differential equation contains simultaneously all separation constants (usually depending on dimensional or nondimensional parameters),[3,4] for which the simultaneous quantization becomes nontrivial.

The standard method of solution of a second-order ordinary differential equation, obtained after separation of variables in N-dimensional Schrödinger equations, involves (after taking into account the asymptotic ansatz) expansions around one of the singular points of the differential equation (the standard power series method,[50] or the so-called Hill-determinant method[51]). The problem reduces to the solution of the recurrence relations for the expansion coefficients. If one can express the equation in a form such that the coefficients obey a two-term recurrence relation, then the corresponding solution can be written in closed or analytic form or in terms of hypergeometric functions and we have an exactly solvable problem. Such situations occur when separation of variables for superintegrable systems is possible in subgroup type coordinate (spherical, cylindrical, and Cartesian)[52] and often in parabolic type coordinates. This method is also powerful when separation of variables is possible in nonsubgroup systems of coordinates such as spheroidal or elliptic types. In this case we arrive at high-order recurrence relations, the subsequent analysis of which allows us to investigate the behavior of the solution and to determine if polynomial solutions exist.

There is another general approach for solving the Schrödinger equation by exploring the Niven-type ansatz,[33] based on the existence of polynomial solutions. According to this method the complete solution can be constructed without direct separation of variables and computed in terms of the zeros of the corresponding polynomial. This method has been used in Refs. 19, 21, and 22 for the investigation of two- and three-dimensional superintegrable systems in Euclidean and curved spaces. We illustrate the difference between systems that are merely separable and those

that are superintegrable. Consider the problem of motion in the plane for a charged particle with two fixed Coulomb centers with coordinates $(\pm D/2,0)$ (the so-called plane two center problem)

$$V(x,y) = -\frac{\alpha_1}{\sqrt{y^2+(x+D/2)^2}} - \frac{\alpha_2}{\sqrt{y^2+(x-D/2)^2}}. \tag{4}$$

This system is not superintegrable and separation of variables is possible only in two-dimensional elliptic coordinates [see Eq. (70)]. Upon the substitution $\psi(\nu,\mu;D^2)=X(\nu;D^2)Y(\mu;D^2)$ and the separation constant $A(D)$, the Schrödinger equation splits into a system of two ordinary differential equations

$$\frac{d^2X}{d\nu^2} + \left[\frac{D^2E}{2}\cosh^2\nu + D(\alpha_1+\alpha_2)\cosh\nu + A(D)\right]X = 0, \tag{5}$$

$$\frac{d^2Y}{d\mu^2} - \left[\frac{D^2E}{2}\cos^2\mu + D(\alpha_1-\alpha_2)\cos\mu + A(D)\right]Y = 0. \tag{6}$$

Both Eqs. (5) and (6) belong to the class of nonexactly solvable problems. In general polynomial solutions do not exist even for the case of discrete spectrum $E<0$ (to be completely correct let us note that polynomial solutions exist only for special values of parameters α_1,α_2, and R), and each of the wave functions $X(\nu;D^2)$ and $Y(\mu;D^2)$ is expressed as an infinite series with a three-term recurrence relation.

Let us now set $\alpha_2=0$. Then the potential (4) transforms to the ordinary two-dimensional (2D) hydrogen atom problem, which is well known as a superintegrable system[53–55] with dynamical symmetry group SO(3), and admits separation of variables in three systems of coordinates: polar, parabolic, and elliptic. In this case we can see that the separation equations (5) and (6), namely

$$\frac{d^2X}{d\nu^2} + \left[\frac{D^2E}{2}\cosh^2\nu + D\alpha_1\cosh\nu + A(D)\right]X = 0, \tag{7}$$

$$\frac{d^2Y}{d\mu^2} - \left[\frac{D^2E}{2}\cos^2\mu + D\alpha_1\cos\mu + A(D)\right]Y = 0 \tag{8}$$

transform into each other by the change $\mu\leftrightarrow i\nu$. Thus separation of variables in elliptic coordinates for the 2D hydrogen atom gives two functionally identical one-dimensional Schrödinger type equations with two parameters: coupling constant E and energy $A(D)$ (correspondingly energy and separation constant for 2D), but one defined on the real and the other on the imaginary axis. In other words, instead of the systems of differential equations (7) and (8), the problem reduces to solving only one of the equations (7) or (8) for which the "domain of definition" is the complex plane. The requirement of finiteness for the wave functions in the complex plane permits only polynomial solutions (see for details Ref. 56). As a result we obtain *simultaneous* quantization of the energy spectrum

$$E_n = -\frac{\alpha_1^2}{2(n+1/2)^2}, \quad n=0,1,2,\ldots \tag{9}$$

and the elliptic separation constant $A_s(D)$ where $s=0,1,2,\ldots,n$ (as a solution of an nth-degree algebraic equation). The polynomial solution is defined by a finite series with three-term recurrence relations for the coefficients. They cannot be considered as exactly solvable and can be investigated only numerically. A similar situation occurs, for instance, in the case of the two-center problem in three-dimensional Euclidean space (the so-called prolate spheroidal radial and angular Coulomb wave functions)[57] and three-dimensional sphere (Heun wave functions),[58] where after eliminating one of the Coulomb centers the problems reduce to superintegrable systems admitting only polynomial solutions. These (and many other) examples suggest a deep connection of the

notion of superintegrability and existence of polynomial solutions of the corresponding Schrödinger equation.

We note that each of equations (7) or (8) has the form of a one-dimensional Schrödinger equation with the parameter E and eigenvalue $A(D)$, and could be separately considered in the regions $\mu \in [0, 2\pi]$ or $\nu \in [0, \infty)$, correspondingly. Then for arbitrary values of constant E [for example when $E_n = 0$ $(n \to \infty)$ the equations (7) and (8) transform to periodic and modified Mathieu equations, which are nonexactly solvable] the solutions of Eqs. (7) or (8) expressed via infinite series and only on the "energy surface" of the 2D hydrogen atom (9), split into polynomial and nonpolynomial sectors (each of these sectors is noncomplete) and for fixed number n, only *some* of the eigenvalues $A_s(D)$ $(s = 0, 1, 2, \ldots, n)$ can be calculated from an nth-degree algebraic equation. We can say that Eqs. (7) and (8) "remember" their polynomial solutions. It is obvious that the spectrum of $A_s(D)$, $(s = 0, 1, 2 \ldots, n)$ and occurrence of polynomial solutions of each of the equations (7) and (8) coincides with the eigenvalues of separation constants and the wave function after the reduction to one of the regions $\mu \in [0, 2\pi]$ or $\nu \in [0, \infty)]$ for the 2D hydrogen atom.

These phenomena have been intensively discussed in the literature in the late 1980s and called *quasiexact solvability* (this term was first introduced by Turbiner and Ushveridze in Ref. 59) and models of this type called *quasiexactly solvable* systems[60–62] (see also Ref. 63 and references therein). The crucial example that stimulated the investigation of quasiexactly solvable systems is the Hamiltonian (1) with anharmonic potential

$$V(x) = \frac{1}{2}\omega^2 x^6 + 2\beta\omega^2 x^4 + (2\beta^2\omega^2 - 2\delta\omega - \lambda)x^2 + 2\frac{\left(\delta - \frac{1}{4}\right)\left(\delta - \frac{3}{4}\right)}{x^2}, \tag{10}$$

where ω, β, $\delta > 1/2$ and λ are constants. As noticed by many authors,[64–66] this system admits polynomial solutions only for special values of constant $\lambda = \omega(2n+1)$ $(n = 0, 1, 2 \ldots)$

$$\Psi(x) \approx x^{2\delta - 1/2} e^{-(\omega/4)x^4 - \beta\omega x^2} P_n(x^2). \tag{11}$$

There are different approaches to the investigation of quasiexactly solvable systems. In the algebraic approach formulated by Turbiner in Ref. 60 quasiexact solvability is explained in terms of a "hidden symmetry algebra" $\mathrm{sl}(2, R)$. [This is not a hidden dynamical symmetry in the usual sense because the Hamiltonian (12) belongs to the enveloping algebra but is not a Casimir operator.] More precisely this means the following: The one-dimensional Hamiltonian (1) after suitable changes of variable $z = \xi(x)$ and "gauge transformation" $H = e^{-\alpha(z)}\mathcal{H}e^{\alpha(z)}$ can be written in the form

$$H = \sum_{a,b=0,\pm} C_{ab} J_a J_b + \sum_{a=0,\pm} C_a J_a, \tag{12}$$

where the first-order differential operators $\{J_\pm, J_0\}$ satisfy the commutation relations for $\mathrm{sl}(2, R)$.[60]

The above mentioned analysis for the 2D hydrogen atom shows that, despite the elegance of the algebraic approach, the phenomena of quasiexactly solvability has deeper roots than can be explained via the "one-dimensional" model (12). Other examples are the hydrogen atom and oscillator problems on two- and three-dimensional spheres[19,67] and two-dimensional hyperboloids,[22] which generate not only hyperbolic and trigonometric but elliptic quasiexactly solvable systems (see also Refs. 68, 56, 69, and 70). We should also mention Lamé polynomials. They come from separation of variables for the Helmholtz (also superintegrable!) or Schrödinger equation in elliptic coordinates on the two-dimensional sphere. As also determined in Ref. 37 (without showing the mechanism of this phenomena) some of the quasiexactly solvable systems can be obtained through dimensional reduction from two- and three-dimensional superintegrable models with quadratic invariants (second-order superintegrability).

A second approach, known as analytic, was formulated by Ushveridze (see, for example, Refs. 61–63) and represents a one-dimensional reduction of the Niven-Stieltjes method for solving multiparameter spectral problems such as the generalized Lamé equation (or ellipsoidal equation).[33] The solution in this method is determined by the zeros of polynomials $P_n(x^2)$. Then the wave function (11) can be rewritten in the form

$$\Psi(x) \approx x^{2\delta-1/2} e^{-(\omega/4)x^4-\beta\omega x^2} \prod_{i=0}^{n} (x^2 - \xi_i), \tag{13}$$

where the numbers $(\xi_1, \xi_2, \ldots, \xi_n)$ satisfy a system of n algebraic equations (see Sec. II C). According to the oscillation theorem, the number of zeros in the physical interval $\xi_i \in [0, \infty)$ enumerates the ground state and first n excitations, described in terms of all zeros (complete solutions of the systems of algebraic equations and including nonphysical section $\xi_i \in (-\infty, 0]$) as

$$E = 4\delta \left[\beta\omega + \sum_{i=1}^{n} \frac{1}{\xi_i} \right]. \tag{14}$$

Two natural questions occur in this approach: what is the physical meaning of the negative zeros ξ_i, and why in the correct formula for the energy spectrum (14) do n zeros of the polynomial $P_n(x^2)$ appear?

With this paper we begin an investigation of second-order superintegrable systems on constant curvature spaces (Euclidean, sphere, hyperboloid and pseudo-Euclidean) based on the superintegrability and direct solutions of the Schrödinger equation. We pay special attention to nonsubgroup type coordinates and prove the existence of polynomial solutions for several of these systems. We demonstrate that quasiexact solvability is directly related with multiseparability of second-order superintegrable systems, on one hand, and with the presence of polynomial solutions for these systems on the other.

The first part of this paper is devoted to two (singular anisotropic and singular circular oscillators) from the four possible superintegrable systems in two-dimensional real Euclidean space (see, for example, Ref. 19). The other two systems may be transformed (only for the discrete spectrum) to the singular circular oscillator (for V_3) or ordinary shifted oscillator (for V_4) systems by the help of the Levi-Civita mapping,[71] so are less fundamental for our purposes. In the second part of the paper we give some examples of superintegrable systems in three dimensions that reinforce our definitions of exact and quasiexact solvability. In particular we exhibit a quasiexactly solvable superintegrable system which is not at the same time exactly solvable in any separable set of coordinates. In one set of separable coordinates this provides deeper insight into an example of Ushveridze,[63] p. 155 (the tenth-order polynomial QES problem) and also leads to a fourth-order polynomial QES problem in another separable coordinate set. In addition we indicate precisely how the eigenvalues of the symmetry operators which describe separation can be calculated from a determinant condition. For these examples we will work with complex superintegrable systems and not address the relatively simple issue of determining the distinct real restrictions of the complex spaces. These examples greatly clarify the concepts and show how the extension to N dimensions can be achieved.

II. THE SINGULAR ANISOTROPIC OSCILLATOR

Let us first consider the potential $(k_2 > 0)$

$$V_1(x,y) = \frac{1}{2}\omega^2(4x^2 + y^2) + k_1 x + \frac{k_2^2 - \frac{1}{4}}{2y^2} \tag{15}$$

the *singular anisotropic oscillator*. The Schrödinger equation has the form

$$\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} \right)\Psi + \left[2E - \omega^2(4x^2 + y^2) - 2k_1 x - \frac{k_2^2 - \frac{1}{4}}{y^2} \right]\Psi = 0. \tag{16}$$

For $k_2 > 1/2$ the singular term at $y=0$ is repulsive and the motion takes place only on one of the half planes $(-\infty < x < \infty, y > 0)$ or $(-\infty < x < \infty, y < 0)$, whereas for $0 < k_2 < 1/2$ in whole plane (x,y). The Schrödinger equation separates in two systems: *Cartesian and parabolic coordinates.*

A. Cartesian bases

Separation of variables for Eq. (16) in Cartesian coordinates leads to the two *independent* one-dimensional Schrödinger equations

$$\frac{d^2\psi_1}{dx^2} + (2\lambda_1 - 4\omega^2 x^2 - 2k_1 x)\psi_1 = 0, \tag{17}$$

$$\frac{d^2\psi_2}{dy^2} + \left(2\lambda_2 - \omega^2 y^2 - \frac{k_2^2 - \frac{1}{4}}{y^2}\right)\psi_2 = 0, \tag{18}$$

where

$$\Psi(x,y;k_1, \pm k_2) = \psi_1(x;k_1)\psi_2(y; \pm k_2) \tag{19}$$

and λ_1, λ_2 are *Cartesian separation constants* with $\lambda_1+\lambda_2=E$.

Equation (18) represents the well-known linear singular oscillator system (see for instance Refs. 72 and 73 and Refs. 10, 20, and 74). It is an exactly solvable problem and has been used in many applications, for example, as a model in N-body problems,[75] or fractional statistics and anyons.[76,77] The complete set of orthonormalized eigenfunctions, (on $1/2$) in the interval $0<y<\infty$ of Eq. (18), can be expressed in terms of finite confluent hypergeometric series or Laguerre polynomials

$$\psi_{n_2}(y; \pm k_2) = \sqrt{\frac{2\omega^{(1\pm k_2)} n_2!}{\Gamma(n_2 \pm k_2 + 1)}} y^{1/2\pm k_2} e^{-1/2\omega y^2} L_{n_2}^{\pm k_2}(\omega y^2), \tag{20}$$

where $\lambda_2=\omega(2n_2+1\pm k_2)$. We assume that the positive sign at the k_2 must be taken if $k_2>\frac{1}{2}$ and both the positive and the negative sign must be taken if $0<k_2<\frac{1}{2}$, so that the polynomials have finite norm. Let us also note that unlike the potential (15) the wave function is not invariant under the replacement $k_2\rightarrow -k_2$ and splits into two families of solutions that transform to one another under this change.

The second equation (17) easily transforms to the ordinary one-dimensional oscillator problem. In terms of Hermite polynomials the orthonormal solutions (in region $-\infty<x<\infty$) are

$$\psi_{n_1}(x;k_1) = \left(\frac{2\omega}{\pi}\right)^{1/4} \frac{e^{-\omega z^2}}{\sqrt{2^{n_1} n_1!}} H_{n_1}(\sqrt{2\omega} z), \quad z = x + \frac{k_1}{4\omega^2}, \tag{21}$$

where $\lambda_1=\omega(2n_1+1)-(k_1^2/8\omega^2)$. Thus the complete energy spectrum is

$$E = \lambda_1 + \lambda_2 = \omega[2n + 2 \pm k_2] - \frac{k_1^2}{8\omega^2}, \quad n = n_1 + n_2 = 0,1,2,\ldots \tag{22}$$

and the degree of degeneracy for fixed principal quantum number n is $(n+1)$. Finally note that the separation of variables in Cartesian coordinates leads to two exactly solvable one-dimensional Schrödinger equations and the complete wave function may be constructed with the help of formulas (20), (21), and (19).

B. Parabolic bases

1. Separation of variables

Parabolic coordinates ξ and η are connected with the Cartesian x and y by

$$x = \tfrac{1}{2}(\xi^2 - \eta^2), \quad y = \xi\eta, \quad \xi \in \mathbf{R}, \quad \eta > 0. \tag{23}$$

The Laplacian and the two-dimensional volume element are given by

$$\Delta = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{1}{\xi^2 + \eta^2}\left(\frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \eta^2}\right), \quad \mathrm{d}v = \mathrm{d}x\,\mathrm{d}y = (\xi^2 + \eta^2)\mathrm{d}\xi\,\mathrm{d}\eta. \tag{24}$$

The Schrödinger equation in parabolic coordinates (23) is

$$\frac{1}{\xi^2 + \eta^2}\left(\frac{\partial^2 \Psi}{\partial \xi^2} + \frac{\partial^2 \Psi}{\partial \eta^2}\right) + \left[2E - \omega^2(\xi^4 - \xi^2\eta^2 + \eta^4) - k_1(\xi^2 - \eta^2) - \frac{k_2^2 - \frac{1}{4}}{\xi^2 \eta^2}\right]\Psi = 0. \tag{25}$$

Upon substituting

$$\Psi(\xi, \eta) = X(\xi)Y(\eta)$$

and introducing the parabolic separation constant λ, the equation (25) splits into two ordinary differential equations,

$$\frac{d^2X}{\mathrm{d}\xi^2} + \left(2E\xi^2 - \omega^2\xi^6 - k_1\xi^4 - \frac{k_2^2 - \frac{1}{4}}{\xi^2}\right)X = -\lambda X, \tag{26}$$

$$\frac{d^2Y}{\mathrm{d}\eta^2} + \left(2E\eta^2 - \omega^2\eta^6 + k_1\eta^4 - \frac{k_2^2 - \frac{1}{4}}{\eta^2}\right)Y = +\lambda Y. \tag{27}$$

Equations (26) and (27) are transformed into one another by change $\xi \leftrightarrow i\eta$. We have

$$\Psi(\xi, \eta; E, \lambda) = C(E, \lambda)Z(\xi; E, \lambda)Z(i\eta; E, \lambda), \tag{28}$$

where $C(E, \lambda)$ is the normalization constant determined by the condition

$$\int_0^\infty \mathrm{d}\eta \int_{-\infty}^{\infty} \mathrm{d}\xi(\xi^2 + \eta^2)|\Psi(\xi, \eta; E, \lambda)|^2 = 1 \tag{29}$$

and the function $Z(\mu; E, \lambda)$ is a solution of the equation

$$\left[-\frac{d^2}{\mathrm{d}\mu^2} + \left(\omega^2\mu^6 + k_1\mu^4 - 2E\mu^2 + \frac{k_2^2 - \frac{1}{4}}{\mu^2}\right)\right]Z(\mu; E, \lambda) = \lambda Z(\mu; E, \lambda). \tag{30}$$

Thus, at $\mu \in (-\infty, \infty)$ we have Eq. (26) and at $\mu \in [0, i\infty)$—Eq. (27). Note that in the complex μ domain the "physical" region is just the two lines Im $\mu = 0$ and Re $\mu = 0$, Im $\mu > 0$. Our task is to find the solutions of Eq. (30) that are regular and decreasing as $\mu \to \pm\infty$ and $\mu \to i\infty$.

2. Recurrence relations

Consider now the equation (30). To solve it we make the substitution

$$Z(\mu; E, \lambda) = \exp\left(-\frac{\omega}{4}\mu^4 - \frac{k_1}{4\omega}\mu^2\right)\mu^{\frac{1}{2} \pm k_2}\psi(\mu; E, \lambda), \tag{31}$$

and obtain the differential equation

$$\frac{d^2\psi}{\mathrm{d}\mu^2} + \left[\frac{2\left(\frac{1}{2} \pm k_2\right)}{\mu} - 2\omega\mu\left(\mu^2 + \frac{k_1}{2\omega^2}\right)\right]\frac{\mathrm{d}\psi}{\mathrm{d}\mu} + [2\tilde{E}\mu^2 + \tilde{\lambda}]\psi = 0, \tag{32}$$

where

$$\tilde{E} = E + \frac{k_1^2}{8\omega^2} - \omega(2 \pm k_2), \quad \tilde{\lambda} = \lambda - \frac{k_1}{\omega}(1 \pm k_2). \tag{33}$$

Passing to a new variable $z = \mu^2$ in Eq. (32), we have

$$z\frac{d^2\psi}{dz^2}+\left[(1\pm k_2)-\omega z\left(z+\frac{k_1}{2\omega^2}\right)\right]\frac{d\psi}{dz}+\left[\frac{1}{2}\tilde{E}z+\frac{1}{4}\tilde{\lambda}\right]\psi=0. \tag{34}$$

We express the wave function $\psi(z)$ in the form

$$\psi(z;E,\lambda)=\sum_{s=0}^{\infty}A_s(E,\lambda)z^s. \tag{35}$$

The substitution (35) in Eq. (34) leads to the following three-term recurrence relation for the expansion coefficients $A_s\equiv A_s(E,\lambda)$,

$$(s+1)(s+1\pm k_2)A_{s+1}+\frac{1}{4}\left[\lambda-\frac{k_1}{\omega}(2s+1\pm k_2)\right]A_s+\frac{1}{2}\left[E+\frac{k_1}{8\omega^2}-\omega(2s\pm k_2)\right]A_{s-1}=0, \tag{36}$$

with the initial conditions $A_{-1}=0$ and $A_0=1$.

As shown in the Appendix, the asymptotic behavior of the expansion coefficients $A_s\equiv A_s(E,\lambda)$ for large s is $A_s\sim\sqrt{\xi_\pm}\sqrt{\omega^s/s!}$, depending on whether s is even or odd, and

$$\psi(z)\sim\sum\frac{\sqrt{\xi_\pm}(\sqrt{\omega}z)^s}{\sqrt{s!}}. \tag{37}$$

Then we have for $z>0$ [the case of Eq. (26)],

$$\sum\frac{\sqrt{\xi_\pm}(\sqrt{\omega}z)^s}{\sqrt{s!}}>\sqrt{\sum\frac{\xi_\pm(\omega z^2)^s}{s!}}=\xi_\pm\cosh\left(\frac{\omega}{2}z^2\right)+\xi_\mp\sinh\left(\frac{\omega}{2}z^2\right). \tag{38}$$

This function does not belong to the Hilbert space. If $k_1>0$ then we must make the replacements $b_s\to -b_s$ and $\xi_s\to-\xi_s$. This has the effect of replacing z by $-z$ in (37). Now the asymptotic solution is oscillatory. However, for $z<0$ [the case of Eq. (27)] the solution does not belong to the Hilbert space. The solution we have found is the minimal solution of the three-term recurrence relations. There is a linearly independent solution, but the coefficients grow more rapidly than the minimal solution coefficients.

3. Energy spectrum and separation constant

The function $Z(\mu)$ cannot converge simultaneously at large μ for real and imaginary μ and therefore the series (35) should be truncated in order to obtain convergence. The condition for series (35) to be truncated results in the energy spectrum (22) where now the coefficients $A_s\equiv A_s^{nq}(k_1,\pm k_2)$ satisfy the relation

$$(s+1)(s+1\pm k_2)A_{s+1}+\beta_sA_s+\omega(n+1-s)A_{s-1}=0,\quad \beta_s=\frac{\lambda}{4}-\frac{k_1}{4\omega}(2s+1\pm k_2). \tag{39}$$

The three-term recurrence relations (39) represent a homogeneous system of $n+1$ algebraic equations for $n+1$ coefficients $\{A_0,A_1,A_2,\ldots,A_n\}$. The requirement for the existence of a nontrivial solution leads to a vanishing of the determinant

$$D_n(\lambda)=\begin{vmatrix}\beta_0 & 1\pm k_2 & & & \\ \omega n & \beta_1 & 2(2\pm k_2) & & \\ & & & & \\ & & & 2\omega & \beta_{n-1} & n(n\pm k_2)\\ & & & & \omega & \beta_n\end{vmatrix}=0. \tag{40}$$

The roots of the corresponding algebraic equation give us the $(n+1)$ eigenvalues of the parabolic separation constant $\lambda_n(k_1,\pm k_2)$. It is known that all roots for such determinants are real and

distinct.[78] Thus all values of the separation constant are real and can be enumerated with the help of the integer q, namely the values are $\lambda_n(k_1,\pm k_2)\to\lambda_{nq}(k_1,\pm k_2)$, where $0\leqslant q\leqslant n$. The degeneracy for the n-energy state, as in the Cartesian case, equals $n+1$.

Note that Eq. (40) is invariant under the simultaneous transformation $k_1\to -k_1$ and $\lambda\to-\lambda$. Thus if one of the $\lambda=\lambda_n(k_1,\pm k_2)$ is a root of Eq. (40), then $\lambda=-\lambda_n(-k_1,\pm k_2)$ is also a root of the same equation. We see that for the odd energy state (n-odd) the range of $\lambda_{nq}(k_1,\pm k_2)$ splits into two subsets $\lambda_{nq}^{(1)}$ and $\lambda_{nq}^{(2)}$ connected by the relation $\lambda_{nq}^{(1)}(k_1,\pm k_2)\leftrightarrow-\lambda_{nq'}^{(2)}(-k_1,\pm k_2)$. For n-even, there exists the additional root $\lambda_{nq}(k_1,\pm k_2)=-\lambda_{nq}(-k_1,\pm k_2)$, which equals zero when $k_1=0$.

4. Wave functions

We will term the polynomial solutions of Eq. (34), or Eq. (32), as $Mk_{nq}(z;k_1,\pm k_2)$, and the function (31) as $Ta_{nq}(z;k_1,\pm k_2)$. [The notation Ta is in memory of Professor V. Ter-Antonyan (1942–2003).] Then the physical admissible solutions of Eq. (34) have the form

$$Mk_{nq}(z;k_1,\pm k_2)\equiv\psi(z;E,\lambda)=\sum_{s=0}^{n}A_s^{nq}(k_1,\pm k_2)z^s, \tag{41}$$

and the corresponding solution of Eq. (31) is

$$Ta_{nq}(\mu;k_1,\pm k_2)=\exp\left(-\frac{\omega}{4}\mu^4-\frac{k_1}{4\omega}\mu^2\right)\mu^{\frac{1}{2}\pm k_2}Mk_{nq}(\mu^2;k_1,\pm k_2). \tag{42}$$

Observe that parabolic wave functions (and also Cartesian wave functions) split into two classes and transform to each other via $k_2\to-k_2$. In the case $k_2=0$ (when the centrifugal term disappears), the solution (42) becomes an even and odd parity wave function under the exchange $\mu\to-\mu$.

It is known that there exists a direct connection between the quantum numbers q and numbers of zeros of the polynomial (41) and, therefore, the eigenvalues of the separation constant $\lambda_{nq}(k_1,\pm k_2)$ may be ordered by the numbers of nodes of the wave function $Ta_{nq}(\mu;k_1,\pm k_2)$. Indeed we will see that these are orthogonal polynomials, hence,[50] all the n zeros of the $Mk_{nq}(z;k_1,\pm k_2)$ are situated on the real axis $-\infty<z<\infty$, and all zeros have multiplicity one. Assume that the separation constants $\lambda_{nq}(k_1,\pm k_2)$ are enumerated in ascending order, i.e.,

$$\lambda_{n0}(k_1,\pm k_2)<\lambda_{n1}(k_1,\pm k_2)<\cdots<\lambda_{n,n-1}(k_1,\pm k_2)<\lambda_{n,n}(k_1,\pm k_2). \tag{43}$$

Then according to the oscillation theorem,[79] the quantum number q also enumerates the zeros of polynomials $Mk_{nq}(z;k_1,\pm k_2)$ in the region $z>0$, or the real axis of μ. Let us now introduce two quantum numbers q_1 and q_2, which determine the zeros of polynomials $Mk_{nq}(z;k_1,\pm k_2)$ for $z>0$ and $z<0$, correspondingly. Then $q_1+q_2=n$, and

$$\lambda_{nq_1}(k_1,\pm k_2)=-\lambda_{nq_2}(-k_1,\pm k_2). \tag{44}$$

For $\mu=\xi$ the function (42) gives the solution of Eq. (26), and for $\mu=i\eta$ the solution of Eq. (27). Thus the parabolic wave function (28) can be written in the following way:

$$\Psi_{nq_1q_2}(\xi,\eta;k_1,\pm k_2)=C_{nq_1q_2}(k_1,\pm k_2)Ta_{nq_1}(\xi;k_1,\pm k_2)Ta_{nq_2}(i\eta;k_1,\pm k_2). \tag{45}$$

5. Orthogonality relations and normalization constant

The wave functions (45) as eigenfunctions of Hamiltonians are orthogonal for quantum number n, or for $n\neq n'$,

$$\int_0^\infty d\eta \int_{-\infty}^\infty d\xi(\xi^2+\eta^2)\Psi^*_{n'q_1q_2}(\xi,\eta;k_1,\pm k_2)\Psi^*_{nq_1q_2}(\xi,\eta;k_1,\pm k_2)=0. \tag{46}$$

Because the energy spectrum is degenerate there exist additional orthogonality relations for quantum number q. Using the equations (26) and (27) it is easy to prove that for $q_1 \neq q_1'$ and $q_2 \neq q_2'$,

$$\int_{-\infty}^\infty d\xi\, Ta^*_{nq_1'}(\xi;k_1,\pm k_2)Ta_{nq_1}(\xi;k_1,\pm k_2)=\int_0^\infty d\eta\, Ta^*_{nq_2'}(i\eta;k_1,\pm k_2)Ta_{nq_2}(i\eta;k_1,\pm k_2)=0. \tag{47}$$

Thus we have for $q \neq q'$,

$$\int_0^\infty d\eta \int_{-\infty}^\infty d\xi(\xi^2+\eta^2)\Psi^*_{nq_1'q_2'}(\xi,\eta;k_1,\pm k_2)\Psi_{nq_1q_2}(\xi,\eta;k_1,\pm k_2)=0. \tag{48}$$

Let us now calculate the normalization constant $C_{nq_1q_2}(k_1,\pm k_2)$. From the explicit form of the wave function $\Psi^*_{nq_1q_2}(\xi,\eta;k_1,\pm k_2)$ and the normalization condition (29), it follows that

$$\frac{1}{8}|C_{nq_1q_2}(k_1,\pm k_2)|^2 \sum_{s,s',t,t'=0}^{n}(-1)^{t+t'}A^n_s(k_1,\pm k_2)A^n_{s'}(k_1,\pm k_2)A^n_t(k_1,\pm k_2)A^n_{t'}(k_1,\pm k_2)\{F^{-1/4}_{t,t'}F^{+1/4}_{s,s'} + F^{+1/4}_{t,t'}F^{-1/4}_{s,s'}\}=1, \tag{49}$$

where

$$F^{\pm 1/4}_{t,t'}=\sum_{m=0}^{\infty}\frac{\Gamma\left(\frac{m+t+t'\pm k_2+1}{2}+\frac{1}{4}\pm\frac{1}{4}\right)}{m!}\left(\frac{k_1}{2\omega}\right)^m. \tag{50}$$

C. Niven approach

Let us express solutions of the Schrödinger equation (16) in the following form:[19]

$$\Psi(x,y)=e^{-\omega[x+(k_1/4\omega^2)]^2-\frac{1}{2}\omega y^2}y^{\frac{1}{2}\pm k_2}\Phi(x,y). \tag{51}$$

From Eqs. (20), (21), and (31) follows that the function $\Phi(x,y)$ is a polynomial (product of two polynomials) in terms of the variables (x,y^2) in Cartesian coordinates and (ξ^2,η^2) for parabolic ones. It satisfies the equation

$$\mathcal{R}\Phi(x,y)=-2E\Phi(x,y), \tag{52}$$

where the operator $\mathcal{R}$ is

$$\mathcal{R}=\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+\left[\frac{(1\pm 2k_2)}{y}-2\omega y\right]\frac{\partial}{\partial y}-4\omega\left[x+\frac{k_1}{4\omega^2}\right]\frac{\partial}{\partial x}-\omega(2\pm k_2)+\frac{k_1^2}{8\omega^2}. \tag{53}$$

Taking into account that

$$Mk_{nq}(z;k_1,\pm k_2)=\sum_{s=0}^{n}A^{nq}_s(k_1,\pm k_2)z^s=\Pi^n_{\ell=1}(z-\alpha_\ell), \tag{54}$$

where α_ℓ, $\ell=1,2,\ldots,n$ are zeros of polynomials $Mk_{nq}(z)$ on the real axis $-\infty<z<\infty$, and that in parabolic coordinates

$$\frac{y^2}{\alpha}+2x-\alpha=\frac{(\xi^2-\alpha)(\eta^2+\alpha)}{\alpha}, \tag{55}$$

we can choose a solution of Eq. (52) in the form

$$\Phi(x,y)=Mk_{nq_1}(\xi^2;k_1,\pm k_2)Mk_{nq_2}(-\eta^2;k_1,\pm k_2)\cong\Pi_{\ell=1}^{n}\left(\frac{y^2}{\alpha_\ell}+2x-\alpha_\ell\right). \tag{56}$$

Then from (52) it follows that the zeros α_ℓ must satisfy the systems of n algebraic equations

$$\sum_{m\neq\ell}^{n}\frac{2}{\alpha_\ell-\alpha_m}+\frac{(1\pm k_2)}{\alpha_\ell}-\omega\alpha_\ell=\frac{k_1}{2\omega},\quad \ell=1,2,\ldots,n, \tag{57}$$

and for the energy spectrum we again have a formula (22). The system of algebraic equations (57) contains n sets of solutions (zeros) $(\alpha_1^{(q)},\alpha_2^{(q)},\ldots,\alpha_n^{(q)})$, $q=1,2,\ldots,n$ and all zeros are real. The positive zeros $\alpha_\ell>0$ define the nodes of wave functions for Eq. (26), whereas negative zeros $\alpha_\ell<0$ define the nodes of wave functions for Eq. (27).

The eigenvalues of the parabolic separation constant can be calculated in the same way via the operator equation $\Lambda\Phi(x,y)=\lambda\Phi(x,y)$ (see for details Ref. 19). A more elegant way is to use directly the differential equation (34).[63] We first rewrite Eq. (34) in the form

$$\left\{4z\frac{d^2}{dz^2}+4\left[(1\pm k_2)-\omega z\left(z+\frac{k_1}{2\omega^2}\right)\right]\frac{d}{dz}+\left[4n\omega z-\frac{k_1}{\omega}(1\pm k_2)\right]\right\}Mk_{nq}(z;k_1,\pm k_2)$$
$$=\lambda Mk_{nq}(z;k_1,\pm k_2). \tag{58}$$

Setting the wave function $Mk_{nq}(z;k_1,\pm k_2)$ in the form of (54), we arrive at the following result:

$$\lambda_{nq}(k_1,\pm k_2)=4(1\pm k_2)\left[\frac{k_1}{4\omega}+\sum_{\ell=1}^{n}\frac{1}{\alpha_\ell^{(q)}}\right], \tag{59}$$

(in case of $n=0$ the sum must be eliminated) where the quantum number $q=1,2,\ldots,n$ labels the eigenvalue of the parabolic separation constant.

III. THE SINGULAR CIRCULAR OSCILLATOR

The potential of the singular circular oscillator is $(k_1,k_2>0)$

$$V_2(x,y)=\frac{1}{2}\omega^2(x^2+y^2)+\frac{1}{2}\left(\frac{k_1^2-\frac{1}{4}}{x^2}+\frac{k_2^2-\frac{1}{4}}{y^2}\right). \tag{60}$$

The corresponding Schrödinger equation separates in three different orthogonal coordinate systems: **Cartesian, polar, and elliptical coordinates**.

A. Cartesian bases

From the asymptotic ansatz,

$$\Psi(x,y)=x^{\frac{1}{2}\pm k_1}y^{\frac{1}{2}\pm k_2}\exp[-\omega(x^2+y^2)]X(x)X(y) \tag{61}$$

we obtain two independent and identical separation equations

$$\left[\frac{\partial^2}{\partial z_i^2}+\left(-2\omega+\frac{1\pm 2k_i}{x_i^2}\right)x\frac{\partial}{\partial x_i}-(1\pm 2k_i)\omega\right]X(x_i)=2\lambda_i X(x_i),\quad i=1,2, \tag{62}$$

where $x_1=x$, $x_2=y$, and $\lambda_1+\lambda_2=-E$. As in the case of the singular anisotropic oscillator we assume that the positive sign of k_i must be taken if $k_i>\frac{1}{2}$ and both the positive and the negative sign must be taken if $0<k_i<\frac{1}{2}$.

The last equation is just that for confluent hypergeometric functions. The quantization rule gives

$$\lambda_i=-\omega(2n_i\pm k_i+1),\quad n_i=0,1,2,\ldots \tag{63}$$

and the solution of Eq. (62) in terms of Laguerre polynomials is $X(x_i)=L_{n_i}^{\pm k_i}(\omega x_i^2)$. Thus the corresponding set of orthonormal eigenfunctions which are normalized in quadrant $x>0, y>0$ (on 1/4) is

$$\Psi_{n_1,n_2}^{(\pm k_1,\pm k_2)}(x,y)=C_{n_1,n_2}^{(\pm k_1,\pm k_2)}(x)^{\frac{1}{2}\pm k_1}(y)^{\frac{1}{2}\pm k_2}e^{-(\omega/2)(x^2+y^2)}L_{n_1}^{\pm k_1}(\omega x^2)L_{n_2}^{\pm k_2}(\omega y^2), \tag{64}$$

where

$$C_{n_1,n_2}^{(\pm k_1,\pm k_2)}=\sqrt{\frac{\omega^{2\pm k_1\pm k_2}n_1!\,n_2!}{\Gamma(n_1\pm k_1+1)\Gamma(n_2\pm k_2+1)}}. \tag{65}$$

From (63) we have

$$E_n=\omega(2n+2\pm k_1\pm k_2), \tag{66}$$

where $n=n_1+n_2=0,1,2,\ldots$ is the principal quantum number and the degree of degeneracy is $n+1$.

B. Polar bases

Separation of variables in the Schrödinger equation for the potential (61) in polar coordinates

$$x=r\cos\phi,\quad y=r\sin\phi,\quad 0\leqslant r<\infty,\quad 0\leqslant\phi<2\pi \tag{67}$$

gives us the orthonormal solution in polynomial form

$$\Psi_{n_r,m}^{(\pm k_1,\pm k_2)}(r,\phi)=\sqrt{\frac{2\omega n_r!}{\Gamma(n_r+2m\pm k_1\pm k_2+2)}}(\sqrt{\omega}r)^{(2m\pm k_1\pm k_2+1)}e^{-\omega r^2/2}L_{n_r}^{2q\pm k_1\pm k_2+1}(\omega r^2)\Phi_m^{(\pm k_1,\pm k_2)}(\phi),$$
$$n_r,m=0,1,2,\ldots, \tag{68}$$

$$\Phi_m^{(\pm k_1,\pm k_2)}(\phi)=\sqrt{\frac{(2m\pm k_1\pm k_2+1)q!\,\Gamma(q\pm k_1\pm k_2+1)}{2\Gamma(m\pm k_2+1)\Gamma(m\pm k_1+1)}}(\cos\phi)^{1/2\pm k_1}(\sin\phi)^{1/2\pm k_2}P_m^{(\pm k_2,\pm k_1)}$$
$$\times(\cos 2\phi), \tag{69}$$

where $P_m^{(\alpha,\beta)}(x)$ is a Jacobi polynomial and $E=\omega(2n\pm k_1\pm k_2+2)$, with $n=n_r+m$ and with the same degree of degeneracy $(n+1)$.

Thus the quantum system (60) is exactly solvable in the Cartesian and polar systems of coordinates.

C. Elliptic bases

1. Separation of variables

Elliptic coordinates (ν,μ) connect with Cartesian ones by $(0\leqslant\nu<\infty, 0\leqslant\mu<2\pi)$

$$x = \frac{D}{2}\cosh\nu\cos\mu, \quad y = \frac{D}{2}\sinh\nu\sin\mu, \tag{70}$$

where D is the interfocal distance. The Laplacian and volume element are

$$\Delta = \frac{8}{D^2(\cosh 2\nu - \cos 2\mu)}\left(\frac{\partial^2}{\partial\nu^2} + \frac{\partial^2}{\partial\mu^2}\right), \quad \mathrm{d}V = \frac{D^2}{8}(\cosh 2\nu - \cos 2\mu)\mathrm{d}\nu\,\mathrm{d}\mu. \tag{71}$$

The Schrödinger equation with (60) can be rewritten as

$$\frac{\partial^2\psi}{\partial\nu^2} + \frac{\partial^2\psi}{\partial\mu^2} + \left\{\frac{D^2E}{4}(\cosh 2\nu - \cos 2\mu) - \frac{D^4\omega^2}{64}(\cosh^2 2\nu - \cos^2 2\mu) - \left[\frac{\left(k_1^2 - \frac{1}{4}\right)}{\cos^2\mu} + \frac{\left(k_2^2 - \frac{1}{4}\right)}{\sin^2\mu}\right] - \left[\frac{\left(k_1^2 - \frac{1}{4}\right)}{\sinh^2\nu} - \frac{\left(k_2^2 - \frac{1}{4}\right)}{\cosh^2\nu}\right]\right\}\psi = 0, \tag{72}$$

and after the separation ansatz

$$\psi(\nu,\mu;D^2) = X(\nu;D^2)Y(\mu;D^2) \tag{73}$$

transforms to two ordinary differential equations

$$\frac{d^2X}{\mathrm{d}\nu^2} + \left[\frac{D^2E}{4}\cosh 2\nu - \frac{D^4\omega^2}{64}\cosh^2 2\nu - \frac{k_2^2 - \frac{1}{4}}{\sinh^2\nu} + \frac{k_1^2 - \frac{1}{4}}{\cosh^2\nu}\right]X = -\lambda(D^2)X, \tag{74}$$

$$\frac{d^2Y}{\mathrm{d}\mu^2} - \left[\frac{D^2E}{4}\cos 2\mu - \frac{D^4\omega^2}{64}\cos^2 2\mu + \frac{k_1^2 - \frac{1}{4}}{\cos^2\mu} + \frac{k_2^2 - \frac{1}{4}}{\sin^2\mu}\right]Y = +\lambda(D^2)Y, \tag{75}$$

where λ is the elliptic separation constant. These equations can be written in the unit form

$$\frac{d^2Z(\zeta)}{\mathrm{d}\zeta^2} + \left[\frac{D^4\omega^2}{64}\cos^2 2\zeta - \frac{D^2E}{4}\cos 2\zeta - \frac{k_1^2 - \frac{1}{4}}{\cos^2\zeta} - \frac{k_2^2 - \frac{1}{4}}{\sin^2\zeta}\right]Z(\zeta) = \lambda(D^2)Z(\zeta), \tag{76}$$

where at $\zeta \in [0, 2\pi]$ we have the equation (75) but at $\zeta \in [0, i\infty)$—Eq. (74). In other words, in the complex ζ plane the "physical regions" are only the shaded domains on the two lines Im $\zeta = 0$ and Re $\zeta = 0$.

For $k_{1,2} > \frac{1}{2}$ the centrifugal barrier is repulsive and motion takes place in only one of the quadrants, as $\zeta \in [0, \pi/2]$, whereas for $0 < k_{1,2} < \frac{1}{2}$ it takes place in the whole region $\zeta \in [0, 2\pi]$. For the particular case $k_1 = k_2 = \frac{1}{2}$ the equation (76) transforms to the problem of the ordinary two-dimensional oscillator and has been investigated in detail in Ref. 69. In this paper we have shown that the solution of Eq. (76) (for $k_1 = k_2 = 1/2$) is described by Ince polynomials.[80]

In the case where k_1 and k_2 are integers, Eqs. (74) and (75) coincide with those that have been found via separation of variables in the Schrödinger equation for the four-dimensional isotropic oscillator in spheroidal coordinates.[70]

2. Recurrence relations

Let us now consider the equation (76). First, introducing the function $W(\zeta;D^2)$ according to

$$Z(\zeta;D^2) = \exp\left[-\frac{D^2\omega}{16}\cos 2\zeta\right]W(\zeta;D^2), \tag{77}$$

we have the equation

$$\frac{d^2W}{d\zeta^2}+\frac{D^2\omega}{4}\sin 2\zeta\frac{dW}{d\zeta}+\left[\frac{D^2\omega}{4}\cos 2\zeta-\frac{D^2E}{2}\cos^2\zeta-\frac{k_1^2-\frac{1}{4}}{\cos^2\zeta}-\frac{k_2^2-\frac{1}{4}}{\sin^2\zeta}-\lambda\right]W=0. \tag{78}$$

For $k_1=k_2=1/2$ this is the Ince equation.[50]

Next the substitution

$$W(\zeta;D^2)=(\sin\zeta)^{\frac{1}{2}\pm k_2}(\cos\zeta)^{\frac{1}{2}\pm k_1}U(\zeta;D^2) \tag{79}$$

yields the equation

$$\frac{d^2U}{d\zeta^2}+\left[(1\pm 2k_2)\cot\zeta-(1\pm 2k_1)\tan\zeta+\frac{D^2\omega}{4}\sin 2\zeta\right]\frac{dU}{d\zeta}+[p\cos^2\zeta-\tilde{\lambda}]U=0, \tag{80}$$

where

$$p=\frac{D^2}{2}[\omega(2\pm k_1\pm k_2)-E],\quad \tilde{\lambda}=\lambda+\frac{D^2\omega}{2}(1\pm k_1)+(1\pm k_1\pm k_2)^2-\frac{D^2E}{4}-\frac{D^4\omega^2}{64}. \tag{81}$$

Passing to a new variable $t=\cos^2\zeta$ we find

$$t(1-t)\frac{d^2U}{dt^2}+\left\{(1\pm k_1)(1-t)-(1\pm k_2)t+\frac{D^2\omega}{4}t(t-1)\right\}\frac{dU}{dt}+\frac{1}{4}[pt-\tilde{\lambda}]U=0. \tag{82}$$

Finally, looking for the solution of the last equation in the form

$$U(t;D^2)=\sum_{s=0}^{\infty}A_s(D^2)t^s, \tag{83}$$

for coefficients $A_s(D^2)$ we have the three-term recurrence relation

$$(s+1)(s+1\pm k_1)A_{s+1}-\left[s(s+1\pm k_1\pm k_2)+\frac{D^2\omega}{4}s+\frac{\tilde{\lambda}}{4}\right]A_s+\frac{1}{4}[p+D^2\omega(s-1)]A_{s-1}=0, \tag{84}$$

with $A_{-1}=0$ and initial condition $A_0=1$.

3. Energy spectrum and separation constant

In analogy with our asymptotic solution of the recurrence relation for the singular anisotropic operator in the parabolic basis we use continued fractions. For the minimal solution of the recurrence relations we find for $s^{-1}\ll 1$,

$$\frac{A_{s+1}}{A_s}\sim\frac{D^2\omega}{4s}\left(1+O\left(\frac{1}{\sqrt{s}}\right)\right). \tag{85}$$

Thus we have

$$A_s\sim\frac{\left(\frac{D^2\omega}{4}\right)^s}{s!},$$

and

$$U(\cos\zeta) \sim \sum \frac{\left(\frac{D^2\omega}{4}\right)^k}{k!} \cos^{2k}\zeta \sim \exp\left(\frac{D^2\omega}{8}\cos 2\zeta\right). \tag{86}$$

Therefore we see that for this case the function $Z(\cos\zeta;D^2)$ as $\zeta\to i\infty$ is not normalizable. There is a linearly independent solution of the recurrence relations, but the coefficients grow even faster. Hence it follows that the series (83) should be truncated. The condition that the series (83) be truncated gives us well-known formulas for the energy spectrum (66) and reduces the solution to polynomials,

$$U_n^{(\pm k_1,\pm k_2)}(t;D^2) = \sum_{s=0}^{n} A_s^{(\pm k_1,\pm k_2)}(D^2)t^s, \tag{87}$$

where now the coefficients $A_s \equiv A_s^{(\pm k_1,\pm k_2)}(D^2)$ satisfy the following three-term recurrent relations:

$$(s+1)(s+1\pm k_1)A_{s+1} + \beta_s A_s - \frac{D^2\omega}{4}(n-s+1)A_{s-1} = 0, \quad s = 0,1,\ldots,n \tag{88}$$

with

$$\beta_s = -\frac{1}{4}\left[(2s+1\pm k_1\pm k_2)^2 + \frac{D^2\omega}{2}(2s-n+4\pm 4k_1) - \frac{D^2\omega}{4}(2\pm k_1\pm k_2) - \frac{D^4\omega^2}{64} + \lambda(D^2)\right] \tag{89}$$

and $A_{-1}=A_{n+1}=0$.

The recurrence relations (88) become a system of $(n+1)$ linear homogeneous equations for the coefficients A_s. Equating the corresponding determinant to zero,

$$D_n(\lambda) = \begin{vmatrix} \beta_0 & (1\pm k_1) & & & \\ -\frac{D^2\omega}{4}n & \beta_1 & 2(2\pm k_1) & & \\ & & & -\frac{D^2\omega}{2} & \beta_{n-1} \quad n(n\pm k_1) \\ & & & & -\frac{D^2\omega}{4} \quad \beta_n \end{vmatrix} = 0 \tag{90}$$

leads to the algebraic equation of degree $(n+1)$ which determines the eigenvalues of the elliptic separation constant $\lambda_{nq}^{(\pm k_1,\pm k_2)}(D^2)$. The quantum number $q=0,1,2,\ldots,n$ labels the $(n+1)$ roots of Eq. (90) and therefore the degree of degeneracy, as in the polar and Cartesian cases, for the nth energy state is $n+1$. It is also known that the corresponding enumeration of the quantum number q defines the numbers of zeros of the polynomial (87), which has exactly n zeros situated in the open interval $0<t<\infty$, and therefore, the elliptic separation constant $\lambda_{nq}^{(\pm k_1,\pm k_2)}(D^2)$ may be ordered also by the numbers of the nodes of the eigenfunction of Eq. (76).

4. Wave functions

The condition of finiteness of the solution of Eq. (78) allows the following polynomials:

$$\mathcal{I}_{nq}^{(\pm k_1,\pm k_2)}(\zeta;D^2) = (\sin\zeta)^{\frac{1}{2}\pm k_2}(\cos\zeta)^{\frac{1}{2}\pm k_1}\sum_{s=0}^{n} A_s^{(\pm k_1,\pm k_2)}(D^2)(\cos\zeta)^{2s}, \tag{91}$$

while the corresponding solution of Eq. (76) is

$$\mathcal{Z}_{nq}^{(\pm k_1,\pm k_2)}(\zeta;D^2) = e^{-(D^2\omega/16)\cos 2\zeta}\mathcal{I}_{nq}^{(\pm k_1,\pm k_2)}(\zeta;D^2). \tag{92}$$

We will denote the polynomials $\mathcal{I}_{nq}^{(\pm k_1,\pm k_2)}(\zeta;D^2)$ as *associated Ince polynomials*. In the case of $k_1=k_2=1/2$ these polynomials transform to the four types of ordinary *Ince polynomials*, which are even or odd with respect to the changes $\zeta\to-\zeta$ and $\zeta\to\zeta+\pi$.[80,69]

At $\zeta=\mu$ the wave functions (92) give us the solution of the angular equation (75), and for $\zeta=i\nu$ the solution of the radial equation (74). For each of the wave functions, radial or angular, there corresponds a definite number of zeros which can be represented by two quantum numbers q_1 and q_2, obeying the condition $q_1+q_2=n$. Then the complete elliptic wave function (73) may be written as

$$\Psi_{nq_1q_2}^{(\pm k_1,\pm k_2)}(\nu,\mu;D^2)=C_{nq_1q_2}(\pm k_1,\pm k_2;D^2)\mathcal{Z}_{nq_1}^{(\pm k_1,\pm k_2)}(\mu;D^2)\mathcal{Z}_{nq_2}^{(\pm k_1,\pm k_2)}(i\nu;D^2), \tag{93}$$

where $C_{nq_1q_2}(\pm k_1,\pm k_2;D^2)$ is the normalization constant. It could be calculated from the condition

$$\frac{D^2}{4}\int_0^\infty \mathrm{d}\nu\int_0^{\pi/2}\mathrm{d}\mu(\cosh^2\nu-\cos^2\mu)\Psi_{nq_1q_2}^{(\pm k_1,\pm k_2)*}(\nu,\mu;D^2)\Psi_{nq_1q_2}^{(\pm k_1,\pm k_2)}(\nu,\mu;D^2)=\frac{1}{4}. \tag{94}$$

5. Orthogonality relations

The wave functions (93) as eigenfunctions of the Hamiltonians are orthogonal $n\neq n'$,

$$\int_0^\infty\int_0^{\pi/2}\Psi_{n'q_1q_2}^{(\pm k_1,\pm k_2)*}(\nu,\mu;D^2)\Psi_{nq_1q_2}^{(\pm k_1,\pm k_2)}(\nu,\mu;D^2)\mathrm{d}V=0. \tag{95}$$

Equations (74) and (75) enable one to prove the property of *double orthogonality* for wave functions $\mathcal{Z}_{nq}^{(\pm k_1,\pm k_2)}(\zeta;D^2)$, namely

$$\int_0^\infty \mathcal{Z}_{nq_2'}^{(\pm k_1,\pm k_2)*}(i\nu;D^2)\mathcal{Z}_{nq_2}^{(\pm k_1,\pm k_2)}(i\nu;D^2)\mathrm{d}\nu=0, \tag{96}$$

$$\int_0^{\pi/2}\mathcal{Z}_{nq_1'}^{(\pm k_1,\pm k_2)*}(\mu;D^2)\mathcal{Z}_{nq_1}^{(\pm k_1,\pm k_2)}(\mu;D^2)\mathrm{d}\mu=0 \tag{97}$$

for $q_1\neq q_1'$ and $q_2\neq q_2'$, and therefore when $q\neq q'$,

$$\int_0^\infty \mathrm{d}\nu\int_0^{\pi/2}\mathrm{d}\mu(\cosh^2\nu-\cos^2\mu)\Psi_{nq_1'q_2'}^{(\pm k_1,\pm k_2)*}(\nu,\mu;D^2)\Psi_{nq_1q_2}^{(\pm k_1,\pm k_2)}(\nu,\mu;D^2)=0. \tag{98}$$

IV. THREE-DIMENSIONAL SPACE

So far we have considered only superintegrable systems in two dimensions. To make clearer our approach and how it extends to all dimensions, we consider some three-dimensional (3D) examples.

A. The harmonic oscillator

As is very well known, the Schrödinger equation for the 3D harmonic oscillator (a superintegrable system) is exactly solvable in Cartesian coordinates. We consider it in elliptic coordinates where the separation equations are QES. We will show explicitly that the polynomial solutions of the uncoupled 3D problem can be found directly and that the results greatly simplify the determination of the polynomial solutions of the separated QES equations. In elliptic coordinates the Schrödinger equation has the form

$$H=\frac{1}{(u-v)(u-w)}\left[4\sqrt{P(u)}\frac{\partial}{\partial u}\left(\sqrt{P(u)}\frac{\partial}{\partial u}\right)-\omega^2(u^3-E_1u^2)\right]$$
$$+\frac{1}{(v-u)(v-w)}\left[4\sqrt{P(v)}\frac{\partial}{\partial v}\left(\sqrt{P(v)}\frac{\partial}{\partial v}\right)-\omega^2(v^3-E_1v^2)\right]$$
$$+\frac{1}{(v-w)(v-u)}\left[4\sqrt{P(w)}\frac{\partial}{\partial w}\left(\sqrt{P(w)}\frac{\partial}{\partial w}\right)-\omega^2(w^3-E_1w^2)\right],$$

where

$$E_1=e_1+e_2+e_3,\quad P(\lambda)=(\lambda-e_1)(\lambda-e_2)(\lambda-e_3).$$

Here the elliptic coordinates are given by

$$x^2=\frac{(u-e_1)(v-e_1)(w-e_1)}{(e_1-e_2)(e_1-e_3)},\quad y^2=\frac{(u-e_2)(v-e_2)(w-e_2)}{(e_2-e_1)(e_2-e_3)},$$

$$z^2=\frac{(u-e_3)(v-e_3)(w-e_3)}{(e_3-e_2)(e_3-e_1)}.$$

The separation equations that describe the solutions of $H\Psi=E\Psi$ are

$$\left[4\sqrt{P(\lambda)}\frac{\partial}{\partial\lambda}\left(\sqrt{P(\lambda)}\frac{\partial}{\partial\lambda}\right)-\omega^2(\lambda^3+(-E_1+E)\lambda^2)+L_1\lambda-L_2\right]\Lambda(\lambda)=0$$

for $\lambda=u,v,w$. The operators that describe the separation constants are

$$L_1=\frac{vw}{(u-v)(u-w)}\left[4\sqrt{P(u)}\frac{\partial}{\partial u}\left(\sqrt{P(u)}\frac{\partial}{\partial u}\right)-\omega^2(u^3-E_1u^2)\right]$$
$$+\frac{uw}{(v-u)(v-w)}\left[4\sqrt{P(v)}\frac{\partial}{\partial v}\left(\sqrt{P(v)}\frac{\partial}{\partial v}\right)-\omega^2(v^3-E_1v^2)\right]$$
$$+\frac{uv}{(w-u)(w-v)}\left[4\sqrt{P(w)}\frac{\partial}{\partial w}\left(\sqrt{P(w)}\frac{\partial}{\partial w}\right)-\omega^2(w^3-E_1w^2)\right],$$

and

$$L_2=\frac{v+w}{(u-v)(u-w)}\left[4\sqrt{P(u)}\frac{\partial}{\partial u}\left(\sqrt{P(u)}\frac{\partial}{\partial u}\right)-\omega^2(u^3-E_1u^2)\right]$$
$$+\frac{u+w}{(v-u)(v-w)}\left[4\sqrt{P(v)}\frac{\partial}{\partial v}\left(\sqrt{P(v)}\frac{\partial}{\partial v}\right)-\omega^2(v^3-E_1v^2)\right]$$
$$+\frac{u+v}{(w-u)(w-v)}\left[4\sqrt{P(w)}\frac{\partial}{\partial w}\left(\sqrt{P(w)}\frac{\partial}{\partial w}\right)-\omega^2(w^3-E_1w^2)\right].$$

In order to find square integrable solutions to this problem it is natural to remove an exponential factor according to

$$\Psi(u,v,w)=\exp\left(-\frac{\omega}{2}(u+v+w)\right)\Phi(u,v,w).$$

Then there are polynomial solutions for $\Phi(u,v,w)$ of the form

$$\Phi(u,v,w) = \prod_{j=1}^{r}(u-\theta_j)(v-\theta_j)(w-\theta_j).$$

The zeros of the polynomials satisfy the relations

$$-4\omega + \sum_{i\neq j}\frac{4}{\theta_i-\theta_j} + \sum_{s=1}^{3}\frac{1}{\theta_j-e_s} = 0.$$

It follows that the eigenvalues E and ℓ_1, ℓ_2 of the operators L_1 and L_2 can be expressed in the form

$$\ell_1 = -4r^2E_1 + 2(3+4r)\sum_{j=1}^{r}\theta_j + \left[-(1+4r)E_2 + 4E_1\sum_{j=1}^{r}\theta_j - \sum_{j=1}^{r}\theta_j^2\right]\omega - E_3\omega^2,$$

$$\ell_2 = -2r(2r+1) - 2(2r+1)E_1\omega + 4\omega\sum_{j=1}^{r}\theta_i - E_2\omega^2,$$

where $E_2=e_1e_2+e_2e_3+e_1e_3$ and $E_3=e_1e_2e_3$. Because of the relations among the zeros θ_j there are also alternative expressions available for these eigenvalues. We now turn our attention to calculating the eigenvalues. Let us first consider the special case $r=1$. If we choose a basis of functions of u, v, and w $F_0=1, F_1=u+v+w, F_2=uv+uw+vw$, and $F_3=uvw$ then we can find solutions

$$\Phi(u,v,w) = a_0F_0 + a_1F_1 + a_2F_2 + a_3F_3.$$

If we look for eigenfunctions for the operator L_1 that correspond to this form we obtain the conditions

$$(2E_3\omega^2 + 5E_2\omega + 4E_1 + \ell_1)a_3 + (4E_1\omega + 6)a_2 + 4\omega a_1 = 0,$$

$$(-2E_2 - 4E_3\omega)a_3 + (\ell_1 + \omega E_2 + \omega^2E_3)a_2 = 0,$$

$$(-2E_2 - 4E_3\omega)a_2 + (\ell_1 + \omega E_2 + \omega^2E_3)a_1 = 0, \quad (-2E_2 - 4E_3\omega)a_1 + (\ell_1 + \omega E_2 + \omega^2E_3)a_0 = 0.$$

For these equations to have a nontrivial solution the corresponding determanental condition must hold viz.

$$\begin{aligned}(\ell_1 + \omega E_2 + \omega^2E_3)(\ell_1^3 + (4E_1 + 7E_2\omega + 3E_3\omega^2)\ell_1^2 + (14E_3E_2\omega^3 + (24E_1E_3 + 11E_2^2)\omega^2 \\ + (16E_1E_2 + 24E_3)\omega + 12E_2)\ell_1 + E_3(20E_1E_3 + 11E_2^2)\omega^4 + (5E_2^3 + 188E_3^2 + 32E_1E_2E_3)\omega^3 \\ + 4E_2(6E_1E_2 - 14E_3)\omega^2 + 28E_2\omega) = 0.\end{aligned}$$

For the operator L_2 the corresponding relations among the a_i are

$$(6 + \ell_2 + E_2\omega^2 + 6\omega E_1)a_3 + 4\omega a_2 = 0, \quad (6 + \ell_2 + E_1\omega + E_2\omega^2)a_2 + 4\omega a_3 = 0,$$

$$-(2E_2 - 4E_3\omega)a_3 + (-4E_2\omega + 4E_1)a_2 + (E_2\omega^2 + 2\omega E_1 + \ell_2)a_1 = 0,$$

$$-(2E_2 - 4E_3\omega)a_2 + (-4E_1 + 4E_2\omega)a_1 + (\ell_2 + 2E_1\omega + E_2\omega^2)a_0 = 0,$$

with the determinant condition

$$(\ell_2 + 2\omega E_1 + \omega^2 E_2)(\ell_2^3 + (14\omega E_1 + 3\omega^2 E_2)\ell_2^2 + (3\omega^4 E_2^2 + 28\omega^3 E_1 E_2 + \omega^2(60E_1^2 + 40E_2) + 112\omega E_1 + 36)\ell_2 + \omega^6 E_2^3 + 14\omega^5 E_1 E_2^2 + 4\omega^4 E_2(15E_1^2 + 7E_2) + \omega^3(72E_1^3 + 208E_1 E_2 - 343E_3) + \omega^2(240E_1^2 + 100E_2) + 168\omega E_1) = 0.$$

This illustrates clearly that our method gives the eigenvalues of L_1 and L_2 as solutions of polynomial equations. If we substitute in this way into the Schrödinger equation itself then we obtain the conditions

$$(E + 7\omega)a_j = 0, \quad j = 1,2,3,$$

$$(2E_2 + 4E_3\omega)a_3 + 4(E_1 + \omega E_2)a_2 + 2(3 + 2\omega E_1)a_1 - (E + 3\omega)a_0 = 0$$

yielding the two eigenvalues -7ω *and* -3ω for E. This method has obvious extensions to $r = 2, \ldots$.

Note that if we look for polynomial solution of the separation equations then we obtain different equations. In particular if we look for solutions of the form $\Lambda(\lambda) = \exp[-(\omega/2)\lambda](\lambda - c)$ in the separation equation

$$\sqrt{P(\lambda)}\frac{\partial}{\partial\lambda}\left(\sqrt{P(\lambda)}\frac{\partial}{\partial\lambda}\Lambda(\lambda)\right) + (\omega^2(-\lambda^3 + (E_1 - E)\lambda^2) + \ell_2\lambda - \ell_1)\Lambda(\lambda) = 0$$

we obtain the relations

$$\ell_2^2 + \ell_2(6 + 8\omega E_1 + 2\omega^2 E_2) + 4\omega\ell_1 + \omega^4 E_2^2 + \omega^3(8E_1 E_2 + 4E_3) + \omega^2(12E_1^2 + 26E_2) + 28\omega = 0,$$

$$\ell_1\ell_2 + \omega(E_2 + E_3\omega)\ell_2 + \omega(6E_1 + \omega E_2)\ell_1 + E_2 E_3\omega^4 + \omega^3(6E_1 E_3 + E_2^2) + \omega^2(6E_1 E_2 + 22E_3) + 14E_2\omega = 0,$$

where

$$c = ((12 + 2\ell_2) + 6\omega E_1 + \omega^2 E_2)/4\omega.$$

If we were to pursue this approach further then we would obtain more complicated relations among the ℓ_1 and ℓ_2 which could be uncoupled to produce the individual equations for ℓ_1 and ℓ_2, respectively. This example shows clearly how study of the full 3D superintegrable system yields results for solutions of the separation equations that could not easily be obtained from a direct study of the separation equations themselves.

B. Ushveridze's separation of variables example

A critical further example is that studied by Ushveridze on p. 115 of Ref. 63. He takes two copies of an ordinary differential QES problem (polynomial potential of order 10) and combines them to form a single 2D partial differential equation from which the original ordinary differential equations can be obtained by separation of variables. However, the partial differential equation that he obtains is merely separable, not multiseparable. In particular it is not superintegrable. Here we show the increased insight and greater simplicity obtained by using three copies of the QES problem to form a 3D superintegrable system. We proceed as follows. Consider the Schrödinger equation $H\Psi = E\Psi$ where

$$H = \frac{1}{(u^2-v^2)(u^2-w^2)}\left[\frac{\partial^2}{\partial u^2} - 36k_1^2u^{10} - 48k_1k_2u^8 - 8(2k_2^2+3k_1k_3)u^6 + \frac{p(1-p)}{u^2}\right]$$
$$+ \frac{1}{(v^2-u^2)(v^2-w^2)}\left[\frac{\partial^2}{\partial v^2} - 36k_1^2v^{10} - 48k_1k_2v^8 - 8(2k_2^2+3k_1k_3)v^6 + \frac{p(1-p)}{v^2}\right]$$
$$+ \frac{1}{(w^2-v^2)(w^2-u^2)}\left[\frac{\partial^2}{\partial w^2} - 36k_1^2w^{10} - 48k_1k_2w^8 - 8(2k_2^2+3k_1k_3)w^6 + \frac{p(1-p)}{w^2}\right].$$

This equation is clearly separable in the u,v,w coordinates. Passing to Cartesian coordinates $z = iuvw$ and

$$x+iy = \tfrac{1}{2}(u^2v^2+u^2w^2+v^2w^2) - \tfrac{1}{4}(u^4+v^4+w^4), \quad x-iy = \tfrac{1}{2}(u^2+v^2+w^2),$$

we can recognize the Hamiltonian operator in the form

$$H = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} + 36k_1^2(2(x-iy)^3 - 4(x^2+y^2) - z^2) + 48k_1k_2(3(x-iy)^2 - (x+iy))$$
$$- 16(2k_2^2+3k_1k_3)(x+iy) - \frac{p(p-1)}{z^2}. \tag{99}$$

This in turn can be recognized as essentially the complex Euclidean space superintegrable system with nondegenerate potential

$$V = \alpha(z^2 - 2(x-iy)^3 + 4(x^2+y^2)) + \beta(2(x+iy) - 3(x-iy)^2 2) + \gamma(x+iy) + \frac{\delta}{z^2}, \tag{100}$$

in which the six basis second-order symmetry operators can be taken in the form

$$H = \partial_x^2 + \partial_y^2 + \partial_z^2 + V,$$

$$S_1 = (\partial_x - i\partial_y)2 + f_1, \quad S_2 = \partial_z^2 + f_2, \quad S_3 = \{\partial_z, J_2 + iJ_1\} + f_3, \tag{101}$$

$$S_4 = \frac{1}{2}\{J_3, \partial_x - i\partial_y\} - \frac{i}{4}(\partial_x + i\partial_y)^2 + f_4, \quad S_5 = (J_2+iJ_1)^2 + 2i\{\partial_z, J_1\} + f_5,$$

where $\{A,B\}=AB+BA$, the J_i are the angular momentum operators, e.g., $J_3=x\partial_y - y\partial_x$, and the f_i are appropriate functions. There is a quadratic algebra generated by these symmetries. This is a direct consequence of the observation that this potential is an example of a nondegenerate potential in three dimensions.[7,8]

The separation equations for the Schrödinger equation have the form

$$\left[\frac{\partial^2}{\partial \lambda^2} - 36k_1^2\lambda^{10} - 48k_1k_2\lambda^8 - 8(2k_2^2+3k_1k_3)\lambda^6 + \frac{p(1-p)}{\lambda^2} + E\lambda^4 + \ell_2\lambda^2 + \ell_3\right]\Lambda(\lambda) = 0,$$

essentially, Ushveridze's 1D QES problem. The operators with the separation constants as eigenvalues are

$$L_2 = \frac{v^2+w^2}{(u^2-v^2)(u^2-w^2)}\left[\frac{\partial^2}{\partial u^2} - 36k_1^2u^{10} - 48k_1k_2u^8 - 8(2k_2^2+3k_1k_3)u^6 + \frac{p(1-p)}{u^2}\right]$$
$$+ \frac{u^2+w^2}{(v^2-u^2)(v^2-w^2)}\left[\frac{\partial^2}{\partial v^2} - 36k_1^2v^{10} - 48k_1k_2v^8 - 8(2k_2^2+3k_1k_3)v^6 + \frac{p(1-p)}{v^2}\right]$$
$$+ \frac{u^2+v^2}{(w^2-v^2)(w^2-u^2)}\left[\frac{\partial^2}{\partial w^2} - 36k_1^2w^{10} - 48k_1k_2w^8 - 8(2k_2^2+3k_1k_3)w^6 + \frac{p(1-p)}{w^2}\right] \tag{102}$$

and

$$L_3 = \frac{v^2w^2}{(u^2-v^2)(u^2-w^2)}\left[\frac{\partial^2}{\partial u^2} - 36k_1^2u^{10} - 48k_1k_2u^8 - 8(2k_2^2+3k_1k_3)u^6 + \frac{p(1-p)}{u^2}\right]$$
$$+ \frac{u^2w^2}{(v^2-u^2)(v^2-w^2)}\left[\frac{\partial^2}{\partial v^2} - 36k_1^2v^{10} - 48k_1k_2v^8 - 8(2k_2^2+3k_1k_3)v^6 + \frac{p(1-p)}{v^2}\right]$$
$$+ \frac{u^2v^2}{(w^2-v^2)(w^2-u^2)}\left[\frac{\partial^2}{\partial w^2} - 36k_1^2w^{10} - 48k_1k_2w^8 - 8(2k_2^2+3k_1k_3)w^6 + \frac{p(1-p)}{w^2}\right]. \tag{103}$$

In searching for finite solutions of $H\Psi = E\Psi$ we write

$$\Psi(u,v,w) = \exp(k_1(u^6+v^6+w^6) + k_2(u^4+v^4+w^4) + k_3(u^2+v^2+w^2))(uvw)^p\Phi(u,v,w),$$

where

$$\Phi(u,v,w) = \prod_{j=1}^{r}(u^2-\theta_j)(v^2-\theta_j)(w^2-\theta_j).$$

The zeros of the polynomials satisfy the relations

$$\frac{2r+1}{2\theta_i} - 12k_1\theta_i^2 - 4k_2\theta_i - k_3 + \sum_{j\neq i}\frac{1}{\theta_i-\theta_j} = 0.$$

Solving these equations we see that the eigenvalues of the operators H, L_2, and L_3 have the form

$$E = -(30+24r+12p)k_1 - 16k_2k_3, \quad \ell_2 = -4k_3^2 - (12+16r)k_2 - 24k_1\sum_{j=1}^{r}\theta_j,$$

$$\ell_3 = -(2+8r+4p)k_3 - 16k_2\sum_{j=1}^{r}\theta_j - 24k_1\sum_{j=1}^{r}\theta_j^2.$$

Because of the relations among the zeros there are many other expressions for these eigenvalues. If we look for solutions of the form

$$\Phi(u,v,w) = a_0G_0 + a_1G_1 + a_2G_2 + a_3G_3,$$

where $G_0=1$, $G_1=u^2+v^2+w^2$, $G_2=u^2v^2+u^2w^2+v^2w^2$, and $G_3=u^2v^2w^2$, i.e., second-order polynomial solutions, and substitute this expression into the eigenvalue equations, we obtain the following polynomial equations for the eigenvalues:

$$(E+k_1(54+12p))^3(E+k_1(30+12p)) = 0,$$

$$(\ell_2 + 2k_2(4p+1) + 4k_3^2)(\ell_2^3 + (12k_3^2 + (68+24p)k_2)\ell_2^2$$

$$+ (192k_1k_3 + 16(2p+7)(6p+13)k_2^2 + 32k_3^2k_2(6p+17) + 48k_3^4)\ell_2$$

$$+ 64(17+6p)k_2k_3^4 + 768k_1k_3^3 + 64(2p+7)(6p+13)k_2^2k_3^2 + 768(2p+7)k_1k_2k_3$$

$$+ 64(2p+3)(2p+7)^2k_3^2 - 1152(2p+1)k_1^2 = 0,$$

$$(\ell_3 + 2k_3(p+1))(\ell_3^3 + 2(6p+7)k_3\ell_3^2 + 4(6p+11)(1+2p)k_3^2\ell_3 + 8(1+2p)^2(12k_1 + 2pk_3^2 + 5k_3^3)) = 0.$$

On the other hand, if we study the separation equations individually and look for a solution of the form

$$\Lambda(\lambda) = \exp(k_1\lambda^6 + k_2\lambda^4 + k_3\lambda^2)\lambda^p(\lambda - c)$$

in the above separation equation then we obtain different relations

$$\ell_2^2 + (4k_2(10+4p) + 8k_3^2)\ell_2 + 24k_1\ell_3 + 16k_3^4 + 8(4k_2k_3^2 + 6k_1k_3)(5+2p) + 16k_2^2(2p+7)(2p+3) = 0,$$

$$\ell_2\ell_3 + 2(2p+1)\ell_2 + (4k_2(2p+7) + 4k_3^2)\ell_3 + 48k_1(1+2p) + 8k_2k_3(2p+7)(2p+1) + 8(1+2p)k_3^3 = 0,$$

where

$$c = -\frac{1}{24k_1}(4k_2(p+7) + 4k_3^3 + \ell_2).$$

The above computation extends in an obvious manner to the computation of polynomial solutions of any order. There is a clear relationship with Ushveridze's equation on p. 115 of Ref. 63 through the correspondence $a=6k_1$, $b=4k_2$, $c=2k_3$, and $s=(2p+1)/4$.

We now look for solutions determined by other second-order constants of the motion and corresponding (possibly separable) coordinate systems. First consider our basic equation $H\Psi = E\Psi$ written in terms of different coordinates $\xi=x+iy$, $\eta=x-iy$, z. We can find nonseparable solutions in these coordinates of the form

$$\Psi = \exp\Bigg(2\sqrt{[\lambda + (k_2+3k_1\xi)^2]}\,\eta \times \int\left[-\frac{3k_1(k_2+3k_1\xi)}{[\lambda+(k_2+3k_1\xi)^2]} + \frac{\xi(-9k_1^2\xi^2 + 9k_1k_2\xi + 6k_1k_2 + 4k_2^2) + E}{\sqrt{(\lambda+(k_2+3k_1\xi)^2)}}\right]d\xi\Bigg) \times \exp(-3k_1z^2)z^pL_n^{p+\frac{1}{2}}(6k_1z^2),$$

where

$$E = E - 6k_1(4n+2p+1)$$

and $L_m^{\alpha}(t)$ is a Laguerre polynomial. It is clear that the above ξ integral can be calculated in terms of elementary functions but we prefer the form given as it is more compact. This possibility for an explicit solution comes about from the existence of a symmetry of the form $p_\eta^2 + f$.

If we choose new separable coordinates u, v, z defined by

$$x+iy=-\tfrac{1}{2}(u-v)^2,\quad x-iy=u+v$$

then the Schrödinger equation has the separable form

$$H\Psi=\left[\frac{1}{u-v}\left[\left(\frac{\partial}{\partial u^2}-144k_1^2u^4-96k_1k_2u^3+16(2k_2^2+3k_1k_3)u^2\right)\right.\right.$$
$$\left.\left.-\left(\frac{\partial}{\partial v^2}-144k_1^2v^4-96k_1k_2v^3+16(2k_2^2+3k_1k_3)v^2\right)\right]+\frac{\partial^2}{\partial z^2}-36k_1^2z^2+\frac{p(1-p)}{z^2}\right]\Psi=E\Psi. \tag{104}$$

The symmetry operator L associated with separation in these coordinates is of the form

$$L\Psi=\left[\frac{1}{u-v}\left[v\left(\frac{\partial}{\partial u^2}-144k_1^2u^4-96k_1k_2u^3+16(2k_2^2+3k_1k_3)u^2\right)\right.\right.$$
$$\left.\left.-u\left(\frac{\partial}{\partial v^2}-144k_1^2v^4-96k_1k_2v^3+16(2k_2^2+3k_1k_3)v^2\right)\right]\Psi.$$

Searching for finite solutions using these coordinates, we see that they can be taken in the form

$$\Psi=\exp\left(4k_1(u^3+v^3)+2k_2(u^2+v^2)-2\left(\frac{k_2^2}{k_1}+k_3\right)(u+v)\right)\Pi_{i=0}^{r}[(u-\theta_i)(v-\theta_i)]$$
$$\times\exp(-3k_1z^2)z^pL_n^{p+\frac{1}{2}}(6k_1z^2).$$

For solutions of this kind these zeros satisfy

$$-2k_1k_3-2k_2^2+4k_1k_2\sum_{i=1}^{r}\theta_i+12k_1^2\sum_{i=1}^{r}\theta_i^2+\sum_{j\neq i}\frac{k_1}{\theta_i-\theta_j}=0.$$

The eigenvalues of L and H' have the form

$$\lambda_r=-4\frac{k_2^4}{k_1^2}-8\frac{k_2^2k_3}{k_1}-4k_3^2-4(1+2r)k_2-24\sum_{i=1}^{r}\theta_i,\quad E_r=16k_2k_3+16\frac{k_2^3}{k_1}-24(r+1)k_1,$$

and $E=E_r+6k_1(4n+2p+1)$.

It is clear that we can find solutions of the form given above but with a choice of polynomial, say $c_1uv+c_2(u+v)+c_3$ for illustration. The resulting polynomial equation for the eigenvalues of L is

$$(\lambda k_1^2+4k_1^2k_3^2+4k_2k_1^2+4k_2^4+8k_1k_3k_2^2)(k_1^4\lambda^2+8k_1^2(2k_2k_1^2+k_3^2k_1^2+2k_1k_3k_1^2+k_2^4)\lambda)$$

$$-96k_3k_1^5-48k_2^2k_1^4+64k_3^2k_1^4k_2+16k_3^4k_1^4+128k_2^3k_3k_1^3+64k_3^3k_1^3k_2^2+64k_2^5k_1^2+96k_1^2k_2^4k_3^2$$

$$+64k_2^6k_1k_3+16k_2^8=0.$$

These are finite solutions, clearly different from those given previously. The above analysis can be extended in an obvious manner to yield polynomial solutions of any order.

Note that for this last coordinate system we have given an example of a QES problem with a quartic potential, something hitherto not known to be possible (as mentioned in Ushveridze's book). Indeed the separation equations have the form

$$\left(\frac{\partial^2}{\partial \ell^2} - 144k_1^2\ell^4 - 96k_1k_2\ell^3 + 16(2k_2^2 + 3k_1k_3)\right)\ell^2$$
$$-\left\{16k_2k_3 + 16\frac{k_3^2}{k_1} + 6k_1(4n - 4r + 2p - 3)\ \ell\ + \lambda_r\right\}\Lambda(\ell) = 0,$$

where $\Lambda = U, V$ and $\ell = u, v$. There are typically $r+1$ solutions

$$\Lambda(\ell) = \exp\left(4k_1\ell^3 + 2k_2\ell^2 - 2\left(\frac{k_2^2}{k_1} + k_3\right)\ \ell\ \right)\Pi_{i=0}^{r}(\ell - \theta_i)$$

of this equation, with corresponding eigenvalues $\lambda_r^{(s)}, s = 1, \ldots, r+1$. It is clear from our definition of QES that if we look for series solutions then the recurrence relations involved will contain more than three terms. The analysis then proceeds in analogy with what has been demonstrated for the case of three terms and the requirement of polynomial solutions (to within a factor) is a consequence of the solutions generated in this manner being well behaved at the regular singular points.

It is clear that in higher dimensions there are many examples which generalize the examples occurring in Ref. 63. The utility of the use of partial differential operators, rather than ordinary differential operators, is evident. Finally, we note in the superintegrable example presented here, though our system is multiseparable there are no separable coordinates in which the separated equations are each exactly solvable.

V. CONCLUSIONS AND SUMMARY

We have demonstrated that solutions of the Schrödinger equation for the potential V_1 may be constructed via separation of variables in two different ways. Using Cartesian coordinates we arrive at two independent exactly solvable equations (17) and (18), each of them representing a one-dimensional *nonparametric* spectral problem where the Cartesian separation constants λ_i play the role of energy. To obtain solutions in the form of Laguerre and Hermite polynomials, both separation constants are quantized and as a result the energy spectrum for the two-dimensional Schrödinger equation is obtained. For the second separable system which uses parabolic coordinates the solution method is more complex. We have shown that the separation procedure reduces to an ordinary differential equation for real and imaginary variables. It has been proven that the requirement of convergence for solutions of Eq. (30) at the singular points $\mu = \pm\infty$ and $\mu = i\infty$ leads to only polynomial solutions (42) with the restriction for the energy spectrum E in the form (22) and for a fixed energy (or quantum number n) gives the spectrum of the separation constant as the root of an nth-degree polynomial equation. In contrast to the solution in Cartesian coordinates the coefficients of the polynomial solutions satisfy three-term recurrence relations and cannot be written in explicit form in general. For this reason we refer to the equation (30) as quasiexactly solvable.

On the other hand, the substitution of the formula for the energy spectrum into Eq. (30) gives rise to the equation

$$\left[-\frac{d^2}{d\mu^2} + \left(\omega^2\mu^6 + k_1\mu^4 + \left[\frac{k_1^2}{4\omega^2} - \omega(4n + 4 \pm 2k_2)\right]\mu^2 + \frac{k_2^2 - \frac{1}{4}}{\mu^2}\right)\right]Z_n(\mu) = \lambda Z_n(\mu), \tag{105}$$

which on the real axis completely coincides for $k_1 = 4\beta\omega^2$ and $1 \pm k_2 = 2\delta$, with the one-dimensional spectral problem (10), and is called a quasiexactly solvable problem. Now it is easy to understand the origins of the occurrence of quasiexactly solvable systems. The requirement of convergence just in real space (which is possible to determine following Ref. 37 as the dimensional reduction) in the vicinity of singular points $\mu = \pm\infty$ requires that there are polynomial solutions of the form (41). We also can shed light on the mystery of the zeros of the polynomial $P_n(x^2)$. Indeed, the substitution of the wave function (11) into the Schrödinger equation with potential (10) leads to

the differential equation for polynomial $P_n(x^2)$ in the same form as Eq. (58) (in variable $x^2=z$), but with the difference that the physical region of Eq. (58) is the whole real axis $z \in (-\infty, \infty)$, and therefore all zeros (for positive and negative x^2) of $P_n(x^2)$ correspond to the zeros of two-dimensional eigenfunction of singular anisotropic oscillator in parabolic coordinates.

The situation is repeated in the case of the second potential (60). We have determined that the separation of variables in two-dimensional elliptic coordinates leads to a Schrödinger type equation (76) in the complex plane and the requirement of convergence at the point $\zeta=0,2\pi$ and $\zeta=i\infty$ requires polynomial solutions and defines the energy spectrum (66). As a consequence trigonometric and hyperbolic quasiexactly solvable systems (see potentials 5 and 8 in Ref. 61) are generated in the form

$$\frac{d^2X}{d\nu^2} + \left[\left(\frac{\alpha^2}{4} + \alpha(2n+2\pm k_1 \pm k_2)\right)\cosh^2\nu - \frac{\alpha^2}{4}\cosh^4\nu - \frac{k_1^2-\frac{1}{4}}{\sinh^2\nu} + \frac{k_2^2-\frac{1}{4}}{\cosh^2\nu} + \lambda\right]X = 0,$$

$$\frac{d^2Y}{d\mu^2} - \left[\left(\frac{\alpha^2}{4} + \alpha(2n+2\pm k_1 \pm k_2)\right)\cos^2\mu - \frac{\alpha^2}{4}\cos^4\mu + \frac{k_1^2-\frac{1}{4}}{\cos^2\mu} + \frac{k_2^2-\frac{1}{4}}{\sin^2\mu} + \lambda\right]Y = 0,$$

where $\alpha=D^2\omega/2$. Thus we have established that an integral part of the notion of quasiexact solvability is the reduction of superintegrable systems to one-dimensional problems.

Indeed, we can express our observation in the form of the following hypothesis: All quantum-mechanical problems which are expressible as one-dimensional quasiexactly solvable systems can be determined via separation of variables in an N-dimensional Schrödinger equation for superintegrable systems.

This analogy prompts us to use the term quasiexact solvability for the equations of type (30) or (76), defined in the complex plane and which are not exactly solvable but which admit polynomial solutions. Thus we suggest calling quantum mechanical systems first-order quasiexactly solvable if the polynomial solution of the one-parametric differential equation of the kind of Schrödinger equation or N-dimensional equation after separation of variables is defined through recurrence relations which must always contain three terms or more and the discrete eigenvalues can be calculated as the solutions of algebraic equations. According to this definition systems (30) and (76) are first order quasiexactly solvable.

In three dimensions we have provided even more striking examples of 1D QES problems obtained as restrictions from superintegrable systems. We exhibited a quasiexactly solvable superintegrable system which is not at the same time exactly solvable in any separable set of coordinates. In one set of separable coordinates we obtain Ushveridze's tenth-order polynomial QES problem and in another set a fourth-order polynomial QES problem. We have shown how the eigenvalues of the symmetry operators which describe separation can be calculated from a determinant condition. These examples, and more to come on other manifolds and in higher dimensional spaces, indicate that our modified definition of QES systems can be extended to N-dimensional spaces and fine tuned to distinguish between the number of parameters in the systems. These matters will be taken up in other papers in this series.

APPENDIX: ASYMPTOTIC BEHAVIOR OF COEFFICIENTS

To understand the behavior of the solutions of relations (36) for large s we use continued fractions theory.[81] Setting

$$\frac{A_s}{A_{s-1}} = \xi_s f(s),$$
$$f(s) = \sqrt{\frac{\omega}{2}} \frac{\Gamma\left(\frac{s}{2}+\frac{1}{2}\right)\Gamma\left(\pm\frac{k_2}{2}+\frac{s}{2}+\frac{1}{2}\right)\Gamma\left(\frac{\alpha}{2\omega}\pm\frac{k_2}{2}+\frac{s}{2}+1\right)}{\Gamma\left(\frac{s}{2}+1\right)\Gamma\left(\pm\frac{k_2}{2}+\frac{s}{2}+1\right)\Gamma\left(\frac{\alpha}{2\omega}\pm\frac{k_2}{2}+\frac{s}{2}+\frac{1}{2}\right)}, \tag{A1}$$

where $\Gamma(z)$ is the gamma function, we can write the recurrence relation (36) in the standard form

$$\xi_s = \frac{1}{b_s + \xi_{s+1}},$$
$$b_s = \sqrt{\frac{2}{\omega}} \frac{\Gamma\left(\frac{s}{2}+\frac{1}{2}\right)\Gamma\left(\pm\frac{k_2}{2}+\frac{s}{2}+\frac{1}{2}\right)\Gamma\left(\frac{\alpha}{2\omega}\pm\frac{k_2}{2}+\frac{s}{2}+1\right)\left[-\lambda+\frac{k_1}{\omega}(2s+1\pm k_2)\right]}{\Gamma\left(\frac{s}{2}+1\right)\Gamma\left(\pm\frac{k_2}{2}+\frac{s}{2}+1\right)\Gamma\left(\frac{\alpha}{2\omega}\pm\frac{k_2}{2}+\frac{s}{2}+\frac{3}{2}\right)2^3}, \tag{A2}$$

where $\alpha=-(E+k_1/(8\omega^2))/2$. Note that

$$f(s+1)f(s) = \omega \frac{\left(\frac{\alpha}{\omega}\pm k_2+s+1\right)}{(s+1)(\pm k_2+s+1)}.$$

Stirling's formula for the gamma function $\Gamma(z)=z^{z-1/2}e^{-z}\sqrt{2\pi}(1+O(1/z))$ as $|z|\to\infty$ with $|\arg z|<\pi$, gives $f(s)=-\sqrt{\omega}/s(1+O(1/s))$ and $b_s=\pm(k_2/2\omega\sqrt{s\omega})(1+O(1/s))$. In the following we take $k_1\leqslant 0$, k_2,λ,E real and $\omega>0$. Without loss of generality we can assume b_s is positive for sufficiently large s since, otherwise, we could make the replacements $b_s\to -b_s$, $\xi_s\to-\xi_s$.

Since $\Sigma b_s=\infty$, it is a consequence of the Seidel-Stern theorem that the formal continued fraction expressions for the ξ_s converge,

$$\xi_s = \frac{1}{b_s} + \frac{1}{b_{s+1}} + \cdots + \frac{1}{b_{s+k}} + \cdots .$$

Moreover, standard continued fraction theory tells us that

$$\xi_s = \lim_{n\to\infty} \frac{A_n^{(s)}}{B_n^{(s)}}, \tag{A3}$$

where

$$\begin{pmatrix} A_{-1}^{(s)} \\ B_{-1}^{(s)} \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad \begin{pmatrix} A_0^{(s)} \\ B_0^{(s)} \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \tag{A4}$$

and

$$\begin{pmatrix} A_n^{(s)} \\ B_n^{(s)} \end{pmatrix} = b_{n+s}\begin{pmatrix} A_{n-1}^{(s)} \\ B_{n-1}^{(s)} \end{pmatrix} + \begin{pmatrix} A_{n-2}^{(s)} \\ B_{n-2}^{(s)} \end{pmatrix}, \quad n \geqslant 1.$$

Furthermore the relation $A_n^{(s)}B_{n-1}^{(s)}-A_{n-1}^{(s)}B_n^{(s)}=(-1)^{n-1}$ holds for all $n\geqslant 0$, which implies

$$\frac{A_n^{(s)}}{B_n^{(s)}} - \frac{A_{n-1}^{(s)}}{B_{n-1}^{(s)}} = \frac{(-1)^{n-1}}{B_{n-1}^{(s)} B_n^{(s)}}.$$

This result in turn implies that the sequence $A_{2n}^{(s)}/B_{2n}^{(s)}$ is, for large s and n, monotone increasing in n and goes to ξ_s in the limit, whereas $A_{2n+1}^{(s)}/B_{2n+1}^{(s)}$ is monotone decreasing in n and goes to ξ_s in the limit. For example,

$$\frac{A_{2n+2}^{(s)}}{B_{2n+2}^{(s)}} - \frac{A_{2n}^{(s)}}{B_{2n}^{(s)}} = \frac{b_{2n+2+s}}{B_{2n}^{(s)} B_{2n+2}^{(s)}}. \tag{A5}$$

It follows from (A3), (A5) that

$$\xi_s = \frac{A_0^{(s)}}{B_0^{(s)}} + \sum_{n=1}^{\infty} \frac{b_{2n+2+s}}{B_{2n}^{(s)} B_{2n+2}^{(s)}}. \tag{A6}$$

Simple estimates using the recurrence relations (A4) give

$$B_{2n}^{(s)} > 1 + b_{s+1} \sum_{m=1}^{n} b_{2m+s}, \quad B_{2n+1}^{(s)} > \sum_{m=0}^{n} b_{2m+1+s}.$$

Substituting these results into the identities

$$B_{2n}^{(s)} = \sum_{m=1}^{n} b_{2m+s} B_{2m-1}^{(s)}, \quad B_{2n+1}^{(s)} = \sum_{m=0}^{n} b_{2m+s+1} B_{2m}^{(s)}$$

we get refined upper bounds for $B_{2n}^{(s)}, B_{2n+2}^{(s)}$. We can approximate the sum $\Sigma_{m=s}^{n} 1/\sqrt{m}$ by the integral $\int_s^n (1/\sqrt{x})\mathrm{d}x$ and use similar approximations to get an upper bound for the series (A6),

$$|\xi_s| < \kappa_1 \int_0^{\infty} \frac{\mathrm{d}y}{\sqrt{y+s}(y^2+1)} + \kappa_2$$

for positive constants κ_j independent of s. This shows that $|\xi_s|$ is uniformly bounded in s. Since $\xi_{s+1} = -b_s + 1/\xi_s$ and $b_s \to 0$ as $s \to \infty$ it is also true that $|1/\xi_s|$ is uniformly bounded in s.

It follows from (A2) that

$$\xi_{s+1} - \xi_{s-1} = \frac{\xi_{s-1} - (b_s + \xi_{s-1})(1 - b_{s-1}\xi_{s-1})}{1 - b_{s-1}\xi_{s-1}}.$$

Now choose s_0 so large that $b_{s+1} < b_s$ and $b_s \xi_s < 1$ for all $s \geqslant s_0$. Note from this identity that if $\xi_{s_1-1} > 1$ for some $s_1 > s_0$ then $\xi_{s_1+1} > \xi_{s_1-1} > 1$. Thus the sequence ξ_{s_1+2k-1} is monotonically increasing for all $k \geqslant 0$. Since $|\xi_s|$ is bounded, it follows that in this case $\lim_{k\to\infty} \xi_{s_1+2k-1} = \xi_+$ exists, and $\xi_+ > 1$. Since $\xi_{s+1} = -b_s + 1/\xi_s$, $b_s \to 0$ as $s \to \infty$ and $|1/\xi_s|$ is uniformly bounded in s, then the sequence ξ_{s_1+2k} is also convergent, $\lim_{k\to\infty} \xi_{s_1+2k} = \xi_-$ where $0 < \xi_- < 1$.

The other possibility is that $\xi \leqslant 1$ for all $s \geqslant s_0$. Since $1/\xi_s - \xi_{s+1} = b_s \to 0$ as $s \to \infty$, and $1/\xi_s \geqslant 1$, $\xi_{s+1} \leqslant 1$ for all $s \geqslant s_0$ it follows that $\lim_{k\to\infty} \xi_k = \xi_+ = \xi_- = 1$. Thus in all cases the sequences ξ_{2k} and ξ_{2k+1} converge.

We conclude that

$$\frac{A_{s+1}}{A_s} = f(s+1)\xi_s = \sqrt{\frac{\omega \xi_\pm}{s}}(1 + O(1/s)), \quad \xi_+ \xi_- = 1,$$

depending on whether s is even or odd.

Intrinsic spectral geometry of the Kerr-Newman event horizon

Martin Engman[a)] and Ricardo Cordero-Soto
Departamento de Cencias y Tecnología, Universidad Metropolitana, San Juan, PR 00928, Puerto Rico

(Received 1 November 2005; accepted 18 January 2006; published online 9 March 2006)

We uniquely and explicitly reconstruct the instantaneous intrinsic metric of the Kerr-Newman event horizon from the spectrum of its Laplacian. In the process we find that the angular momentum parameter, radius, area; and in the uncharged case, mass, can be written in terms of these eigenvalues. In the uncharged case this immediately leads to the unique and explicit determination of the Kerr metric in terms of the spectrum of the event horizon. Robinson's "no hair" theorem now yields the corollary: One can "hear the shape" of noncharged stationary axially symmetric black hole space-times by listening to the vibrational frequencies of its event horizon only. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2174290]

I. INTRODUCTION

Although in general the spectrum of the Laplacian on a manifold determines, via the heat kernel, a sequence of invariants which restrict the geometry, it is a rare occasion indeed that the metric is uniquely determined by the eigenvalues (see, for example, Ref. 6). In fact one of the few uniqueness results of this kind was proved by Brüning and Heintze:[1] An S^1 invariant two-dimensional surface diffeomorphic to the sphere, which has, in addition, a mirror symmetry about its equator is uniquely determined by its spectrum. This has been generalized by Zelditch,[16] but the Brüning and Heintze result is the appropriate setting for our purposes since this is exactly the class of metrics which include Kerr-Newman event horizons.

In 1973 Smarr[11] studied the metric of the horizon in terms of a scale parameter and a distortion parameter and in a particularly convenient coordinate system for calculating, for example, the curvature. More recently, the first author of the present paper has used a similar coordinate system to study the spectrum of S^1 invariant surfaces. As it turns out, Smarr's form of the horizon metric is a scaled version of a special case of our form of the metric.

S^1 invariant metrics on S^2 can be described in terms of a single function $f(x)$. One can show that the sum of the reciprocals of the nonzero, S^1 invariant eigenvalues (i.e., the trace of the S^1 invariant Greens operator) is given by an integral involving the function $f(x)$. The key to the results we obtain here is that, in the case of the Kerr-Newman event horizon, the function $f(x)$ is a simple rational function and the above-mentioned integral can be calculated explicitly. Together with a similar equivariant trace formula, one can now write Smarr's parameters in terms of these traces and hence explictly display the metric in terms of it's spectrum. As far as we know, this is the only nontrivial example of this phenomonen (the Brüning and Heintze result is not constructive in this sense).

An interesting byproduct of our results (in the uncharged case), together with Robinson's uniqueness theorem, is the unique reconstruction of space-time in terms of these eigenvalues. We conclude the paper with a discussion of possible physical interpretations of these results.

II. SMARR'S FORM OF THE METRIC

The *Kerr-Newman metric* describing the geometry of a rotating charged black hole written in Kerr ingoing coordinates (v,r,θ,ϕ) is

$$ds^2 = -\left(1-\frac{2mr-e^2}{\Sigma}\right)dv^2 + 2\,dr\,dv - \frac{(2mr-e^2)2a\sin^2\theta}{\Sigma}dv\,d\phi - 2a\sin^2\theta\,dr\,d\phi + \Sigma\,d\theta^2 + \left(\frac{(r^2+a^2)^2-\delta a^2\sin^2\theta}{\Sigma}\right)\sin^2\theta\,d\phi^2, \tag{1}$$

in which (m,a,e) represent, respectively, the total mass, angular momentum per unit mass, and the charge. Also $\Sigma=r^2+a^2\cos^2\theta$ and $\delta=r^2-2mr+a^2+e^2$ (we use the lower case letter here, instead of the traditional upper case, to avoid confusion with the equally traditional use of Δ for the Laplacian). The uncharged $(e=0)$ case is the *Kerr metric*.

This family of metrics is quite general. To quote Wald[15] "… the Kerr-Newman family of solutions completely describes all the stationary black holes which can possibly occur in general relativity." This fact is due to the famous uniquess theorems of Israel,[7] Carter and Robinson,[10] and Mazur,[8] for example.

For the Kerr-Newman metric the surface of the event horizon can be thought of as a spacelike slice through the null hypersurface defined by the largest root, r_+, of $\delta=0$, i.e., $r_+=m+\sqrt{m^2-a^2-e^2}$. The intrinsic instantaneous metric on the event horizon is obtained by setting $r=r_+$, so that $dr=0$, and also setting $dv=0$ to get

$$ds^2_{eh} = (r_+^2+a^2\cos^2\theta)d\theta^2 + \left(\frac{(r_+^2+a^2)^2}{r_+^2+a^2\cos^2\theta}\right)\sin^2\theta\,d\phi^2. \tag{2}$$

In Ref. 11, Smarr defines *the scale parameter* by $\eta=\sqrt{r_+^2+a^2}$ and *the distortion parameter* by $\beta=a/\sqrt{r_+^2+a^2}$ and introducing a new variable $x=\cos\theta$ one finds that the event horizon metric is

$$ds^2_{eh} = \eta^2\left(\frac{1}{f(x)}dx^2 + f(x)d\phi^2\right), \tag{3}$$

where $(x,\phi)\in(-1,1)\times[0,2\pi)$ and

$$f(x) = \frac{1-x^2}{1-\beta^2(1-x^2)}. \tag{4}$$

It is well known that the Gauss curvature of a metric in this form is simply $K(x)=-1/(2\eta^2)f''(x)$ so that in this case

$$K(x) = \frac{1}{\eta^2}\left(\frac{1-\beta^2(1+3x^2)}{(1-\beta^2(1-x^2))^3}\right), \tag{5}$$

and the surface area of the metric is $A=4\pi\eta^2$. We point out that in case $a=0$ $(\beta=0)$, $e=0$ (1) gives the Schwarzschild black hole and (3) is the metric of the constant Gauss curvature$=1/\eta^2$ metric on S^2.

III. SPECTRUM OF S^1 INVARIANT METRICS

For any Riemannian manifold with metric g_{ij} *the Laplacian* is given by

$$\Delta_g = -\frac{1}{\sqrt{g}}\frac{\partial}{\partial x^i}\left(\sqrt{g}g^{ij}\frac{\partial}{\partial x^j}\right).$$

This is the Riemannian version of the *Klein-Gordon*, or *D'Alembertian*, or *wave* operator usually denoted by $\Box$.

In this section we outline some previous work on the spectrum of the Laplacian on S^1 invariant metrics on S^2. The interested reader may consult Refs. 2–4 for further details.

To simplify the discussion the area of the metric is normalized to $A=4\pi$ for this section only. The metrics we study have the form

$$\mathrm{d}l^2 = \frac{1}{f(x)}\mathrm{d}x^2 + f(x)\mathrm{d}\phi^2, \tag{6}$$

where $(x,\phi)\in(-1,1)\times[0,2\pi)$ and $f(x)$ satisfies $f(-1)=0=f(1)$ and $f'(-1)=2=-f'(1)$. In this form, it is easy to see that the Gauss curvature of this metric is given by $K(x)=(-1/2)f''(x)$. The canonical (i.e., constant curvature) metric is obtained by taking $f(x)=1-x^2$ and the metric (3) is a homothety (scaling) of a particular example of the general form (6).

The Laplacian for the metric (6) is

$$\Delta_{\mathrm{d}l^2} = -\frac{\partial}{\partial x}\left(f(x)\frac{\partial}{\partial x}\right) - \frac{1}{f(x)}\frac{\partial^2}{\partial\phi^2}.$$

Let λ be any eigenvalue of $-\Delta$. We will use the symbols E_λ and $\dim E_\lambda$ to denote the eigenspace for λ and it's multiplicity (degeneracy), respectively. In this paper the symbol λ_m will always mean the mth *distinct* eigenvalue. We adopt the convention $\lambda_0=0$. Since S^1 (parametrized here by $0\leqslant\phi<2\pi$) acts on (M,g) by isometries we can separate variables and because $\dim E_{\lambda_m}\leqslant 2m+1$ (see Ref. 4 for the proof), the orthogonal decomposition of E_{λ_m} has the special form

$$E_{\lambda_m} = \bigoplus_{k=-m}^{k=m} e^{ik\theta}W_k$$

in which $W_k(=W_{-k})$ is the "eigenspace" (it might contain only 0) of the ordinary differential operator

$$L_k = -\frac{\mathrm{d}}{\mathrm{d}x}\left(f(x)\frac{\mathrm{d}}{\mathrm{d}x}\right) + \frac{k^2}{f(x)}$$

with suitable boundary conditions. It should be observed that $\dim W_k\leqslant 1$, a value of zero for this dimension occurring when λ_m is not in the spectrum of L_k.

The set of positive eigenvalues is given by $\mathrm{Spec}(\mathrm{d}l^2)=\cup_{k\in Z}\mathrm{Spec}\,L_k$ and consequently the nonzero part of the spectrum of $-\Delta$ can be studied via the spectra $\mathrm{Spec}\,L_k=\{0<\lambda_k^1<\lambda_k^2<\cdots<\lambda_k^j<\cdots\}\,\forall\,k\in\mathbb{Z}$. The eigenvalues λ_0^j in the case $k=0$ above are called the S^1 *invariant eigenvalues* since their eigenfunctions are invariant under the action of the S^1 isometry group. If $k\neq 0$ the eigenvalues are called k *equivariant* or simply *of type* $k\neq 0$. Each L_k has a Green's operator, $\Gamma_k:(H^0(M))^\perp\to L^2(M)$, whose spectrum is $\{1/\lambda_k^j\}_{j=1}^\infty$, and whose trace is defined by

$$\gamma_k \equiv \sum_{j=1}^{\infty}\frac{1}{\lambda_k^j}. \tag{7}$$

The formulas of present interest were derived in Refs. 2 and 3 and are given by

$$\gamma_0 = \frac{1}{2}\int_{-1}^{1}\frac{1-x^2}{f(x)}\mathrm{d}x \tag{8}$$

and

$$\gamma_k = \frac{1}{|k|} \quad \text{if } k\neq 0. \tag{9}$$

Remark: One must be careful with the definition of γ_0 since $\lambda_0^0=0$ is an S^1 invariant eigen-

value of $-\Delta$. To avoid this difficulty we studied the S^1 invariant spectrum of the Laplacian on 1-forms in Ref. 3 and then observed that the nonzero eigenvalues are the same for functions and 1-forms.

IV. SPECTRAL DETERMINATION OF THE EVENT HORIZON

In case $f(x)$ is given by (4) the metric (3) is related to (6) via the homothety $ds^2_{eh}=\eta^2\, dl^2$, and it is well known that

$$\lambda \in \mathrm{Spec}(dl^2) \quad \text{if and only if } \frac{\lambda}{\eta^2} \in \mathrm{Spec}(\eta^2\, dl^2)$$

so that, after an elementary integration, the trace formulas for the event horizon are

$$\gamma_0 = \eta^2\left(1-\frac{2\beta^2}{3}\right) \tag{10}$$

and

$$\gamma_k = \frac{\eta^2}{|k|} \quad \forall\, k \neq 0. \tag{11}$$

For the $k=1$ case, for example, one can invert the resulting pair of equations to get

$$\beta^2 = \frac{3}{2}\left(1-\frac{\gamma_0}{\gamma_1}\right) \tag{12}$$

and

$$\eta^2 = \gamma_1, \tag{13}$$

and thereby write the event horizon metric explicitly and uniquely in terms of the spectrum as follows.

Proposition: With γ_0 *and* γ_1 *defined as in* (7) *the instantaneous intrinsic metric of the Kerr-Newman event horizon is given by*

$$ds^2_{eh} = \gamma_1\left(\frac{1-\frac{3}{2}\left(1-\frac{\gamma_0}{\gamma_1}\right)(1-x^2)}{1-x^2}dx^2 + \frac{1-x^2}{1-\frac{3}{2}\left(1-\frac{\gamma_0}{\gamma_1}\right)(1-x^2)}d\phi^2\right). \tag{14}$$

An immediate consequence of (11) is that the area of the metric has a representation for each $k \in \mathbb{N}$ given by

$$A = 4\pi k \gamma_k. \tag{15}$$

Remarks: (i) One might view Eqs. (10) and (11) as nothing more than definitions of new parameters in terms of the old. On the other hand, the quantities γ_k are fundamental and naturally defined quantities coming from the discrete set of vibrational wave frequencies on the surface. Alternatively, one can think of each trace, γ_k as the sum of the squares of all wavelengths of given quantum number k.

(ii) One can use γ_0 together with γ_k for any k to reconstruct the metric. In some sense one can "construct the metric in $\aleph_0$ ways."

(iii) Brüning and Heintze proved that for S^1 invariant metrics symmetric about the equator the S^1 invariant spectrum determines the metric. Their result requires the prescription of all of the eigenvalues of the $k=0$ spectrum to uniquely determine the surface of revolution. In the example of the present paper the metric is, therefore, uniquely determined once we have knowledge of the

entire list of S^1 invariant eigenvalues. For the explicit construction one exchanges complete knowledge of the $k=0$ spectrum for partial spectral data, namely the traces of the Greens operators for $k=0$ and any $k\neq 0$.

All the physical parameters can also be written in terms of the spectra as follows:

$$a^2 = \tfrac{3}{2}(\gamma_1 - \gamma_0), \tag{16}$$

$$r_+^2 = \frac{3\gamma_0 - \gamma_1}{2}, \tag{17}$$

$$m^2 = \frac{(\gamma_1 + e^2)^2}{6\gamma_0 - 2\gamma_1}, \tag{18}$$

as well as the angular velocity and surface gravity. We observe, however, that the mass depends on the charge e as well as the spectrum so that the mass is uniquely determined by the spectrum only in the Kerr ($e=0$) case.

We set together Remark (iii) with (16) and (18) (with $e=0$), (1), and Robinson's uniqueness theorem[10] to observe.

Theorem: *A noncharged stationary axially symmetric asymptotically flat vacuum space-time with a regular event-horizon is uniquely determined by the S^1 invariant spectrum of the intrinsically defined Laplacian on its event horizon. The space-time is explicitly constructed from the S^1 invariant trace together with any $k\neq 0$ trace of the associated Green's operator on the event horizon.*

V. DISCUSSION

It is well known (see Refs. 5, 13, and 9, among many others) that the quasinormal mode frequencies for scalar, electromagnetic, and gravitational radiation of black holes are related to the separation constants arising from separating variables in the Teukolsky master equation. These "characteristic sounds" of the black hole are considered to be observable in an astrophysical sense. The angular operator (and, respectively, its separation constants) coming from the separation of variables is closely related to the Laplacian (and, respectively, its eigenvalues) on the event horizon in the sense that, for scalar fields, they both reduce to the Laplacian (and corresponding eigenvalues) on the constant curvature S^2 for the Schwarzschild ($a=0$) case. There is also some evidence (this is a work in progress) that the $a>0$ Teukolsky angular equation can be viewed, after a change of variables, as a Laplace eigenvalue equation for a fourth order Taylor polynomial approximation of the horizon metric function. We hope to pursue these matters in our future work.

On a more philosophical note, the reader may have noticed that the main result of this paper is consistent with the holographic principle (Refs. 12 and 14) in as much as the structure of the (3+1 dimensional) Kerr-Newman space-time is encoded in the intrinsic spectral data of the (two-dimensional) event horizon surface.

These phenomena suggest that the spectrum of the Laplacian on event horizons is playing an important, if rather subtle and not well understood, role in the physics of the space-time manifold.

Flow equations for uplifting half-flat to Spin(7) manifolds

In this supplement to the paper by Franzen *et al.* [Fortschr. Phys. (to be published)], we discuss the uplift of half-flat sixfolds to Spin(7) eightfolds by fibration of the former over a product of two intervals. We show that the same can be done in two ways—one, such that the required Spin(7) eightfold is a double G_2 sevenfold fibration over an interval, the G_2 sevenfold itself being the half-flat sixfold fibered over the other interval, and second, by simply considering the fibration of the half-flat sixfold over a product of two intervals. The flow equations one gets are an obvious generalization of the Hitchin's flow equations [to obtain sevenfolds of G_2 holonomy from half-flat sixfolds [Hitchin (2001)]]. We explicitly show the uplift of the Iwasawa using both methods, thereby proposing the form of new Spin(7) metrics. We give a plausibility argument ruling out the uplift of the Iwasawa manifold to a Spin(7) eightfold at the "edge," using the second method. For Spin(7) eightfolds of the type $X_7 \times S^1$, X_7 being a sevenfold of SU(3) structure, we motivate the possibility of including elliptic functions into the "shape deformation" functions of sevenfolds of SU(3) structure of Franzen *et al.* via some connections between elliptic functions, the Heisenberg group, theta functions, the already known $D7$-brane metric [Greene *et al.*, Nucl. Phys. B 337, 1 (1990)], and hyper-Kähler metrics obtained in twistor spaces by deformations of Atiyah-Hitchin manifolds by a Legendre transform [Chalmers, Phys. Rev. D 58, 125011 (1998)]. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2178156]

INTRODUCTION

It is known that manifolds with G_2 and Spin(7) holonomies, are very useful in getting minimal amount of supersymmetry after compactification of seven and eight dimensions, respectively, in string/M-theory.[1] In the past few years, half-flat manifolds have been shown to be relevant to flux compactifications in string theory (see Refs. 2 and 3 and references therein). In Ref. 4, using the results of Ref. 5, we explicitly showed how to uplift the Iwasawa manifold, an example of a half-flat manifold, to sevenfolds of either G_2-holonomy or SU(3) structure. In this short note, we show how to uplift half-flat manifolds to Spin(7) eightfolds. We will be following the notations of Ref. 4. We also give plausibility arguments in favor of inclusion of the Weierstrass elliptic function in Spin(7)-metrics of the type $X_7 \times S^1$, X_7 being sevenfolds of SU(3) structure.

Spin(7) folds are characterized by a self-dual closed (and hence co-closed) Cayley four-form (with the additional constraint that the $\hat{A}$-genus of the eightfold equals unity[6]). We will begin with the construction of a Spin(7) eightfold as a double G_2-fibration over an interval. We then go on to constructing a Spin(7) eightfold as a fibration of a half-flat over the product of two intervals.

SPIN(7) AS A DOUBLE G_2-FIBRATION OVER AN INTERVAL

Let us begin with the following construction of a Spin(7) eightfold $X_8^{\mathrm{Spin}(7)}$ (see diagram 1 below):

$$
\begin{array}{ccccc}
I_{t_1} & & & & \\
\uparrow & & & & \\
| & X_7^{G_2}(t_2) & \longrightarrow & I_{t_2} & \\
| & & & M_6 & \\
| & & & & \\
X_8^{\mathrm{Spin}(7)} & \longrightarrow & I_{t_2} & & \\
 & & X_7^{G_2}(t_1) & & \\
 & & | & & \\
 & & \downarrow M_6 & & \\
 & & I_{t_1} & &
\end{array}
$$

In other words, one has a "double" G_2-fibration structure in the sense that the Spin(7) eightfold is a fibration of a $G_2(t_1)$-manifold over an interval $I(t_2)$ *as well as* a $G_2(t_2)$-manifold over an interval $I(t_1)$, where the $G_2(t_i)$-manifold is itself a fibration of a half-flat sixfold over an interval $I(t_i)$ (via the Hitchin's construction[7]). Given a half-flat manifold $M_6(\Omega, J)$, the Hitchin's construction involves (with respect to seven dimensions) a closed and co-closed three-form $\phi_3 = J \wedge \mathrm{d}t + \Omega_+(t)$, $\Omega_+ \equiv \mathrm{Re}(\Omega)$, one can write down the following Cayley four-form ϕ_4:

$$\phi_4 = \alpha_1 * {}_7\phi_3^1 + \alpha_2 * {}_7\phi_3^2 + \tilde{\alpha}_1 \phi^1 \wedge \mathrm{d}t_2 + \tilde{\alpha}_2 \phi_3^2 \wedge \mathrm{d}t_1$$

$$+ \beta_1 \Omega_+ \wedge \mathrm{d}t_1 + \beta_2 \Omega_+ \wedge \mathrm{d}t_2 + \gamma_1 \Omega_- \wedge \mathrm{d}t_1 + \gamma_2 \Omega_- \wedge \mathrm{d}t_2 + \delta J \wedge J + \epsilon J \wedge \mathrm{d}t_1 \wedge \mathrm{d}t_2. \tag{1}$$

The self-duality condition would thus imply

$$\alpha_1 (J \wedge \mathrm{d}t_1 \wedge \mathrm{d}t_2 + \Omega_+ \wedge \mathrm{d}t_2) + \alpha_2 (J \wedge \mathrm{d}t_1 \wedge \mathrm{d}t_2 - \Omega_+ \wedge \mathrm{d}t_1)$$

$$+ \tilde{\alpha}_1 \left(\frac{1}{2} J \wedge J + \Omega_- \wedge \mathrm{d}t_1 \right) + \tilde{\alpha}_2 \left(- \frac{1}{2} J \wedge J - \Omega_- \wedge \mathrm{d}t_2 \right)$$

$$- \beta_1 \Omega_- \wedge \mathrm{d}t_2 + \beta_2 \Omega_- \wedge \mathrm{d}t_1 + \gamma_1 \Omega_+ \wedge \mathrm{d}t_2 - \gamma_2 \Omega_+ \wedge \mathrm{d}t_1$$

$$+ 2\delta J \wedge \mathrm{d}t_1 \wedge \mathrm{d}t_2 + \frac{\epsilon}{2} J \wedge J$$

$$= \alpha_1 \left(\frac{1}{2} J \wedge J + \Omega_- \wedge \mathrm{d}t_1 \right) + \alpha_2 \left(\frac{1}{2} J \wedge J + \Omega_- \wedge \mathrm{d}t_2 \right)$$

$$+ \tilde{\alpha}_1 (J \wedge \mathrm{d}t_1 \wedge \mathrm{d}t_2 + \Omega_+ \wedge \mathrm{d}t_2) + \tilde{\alpha}_2 (- J \wedge \mathrm{d}t_1 \wedge \mathrm{d}t_2 + \Omega_+ \wedge \mathrm{d}t_1)$$

$$+\beta_1\Omega_+\wedge \mathrm{d}t_1+\beta_2\Omega_+\wedge \mathrm{d}t_2+\gamma_1\Omega_-\wedge \mathrm{d}t_1+\gamma_2\Omega_-\wedge \mathrm{d}t_2$$

$$\delta J\wedge J+\epsilon J\wedge \mathrm{d}t_1\wedge \mathrm{d}t_2, \tag{2}$$

implying

$$\alpha_1+\alpha_2+2\delta=\tilde{\alpha}_1-\tilde{\alpha}_2+\epsilon,$$

$$\alpha_1+\gamma_1=\tilde{\alpha}_1+\beta_2,\quad -\alpha_2-\gamma_2=\tilde{\alpha}_2+\beta_1. \tag{3}$$

Hence, the following is the form of the self-dual four-form:

$$\begin{aligned}\phi_4=\alpha_1 *_7\phi_3^1+\alpha_2 *_7\phi_3^2+\tilde{\alpha}_1\phi^1\wedge \mathrm{d}t_2+\tilde{\alpha}_2\phi_3^2\wedge \mathrm{d}t_1+\beta_1\Omega_+\wedge \mathrm{d}t_1+\beta_2\Omega_+\wedge \mathrm{d}t_2+(\tilde{\alpha}_1+\beta_2\\ -\alpha_1)\Omega_-\wedge \mathrm{d}t_1-(\alpha 2+\tilde{\alpha}_2+\beta_1)\Omega_-\wedge \mathrm{d}t_2+\delta J\wedge J+(\alpha_1+\alpha_2+2\delta+\tilde{\alpha}_2-\tilde{\alpha}_1)J\wedge \mathrm{d}t_1\wedge \mathrm{d}t_2.\end{aligned} \tag{4}$$

For (4) to be a Cayley four-form, it must satisfy the condition that it is closed, which on using

$$d *_7\phi_3^1=\left(\hat{d}+\mathrm{d}t_1\wedge\frac{\partial}{\partial t_1}+\mathrm{d}t_2\wedge\frac{\partial}{\partial t_2}\right)*_7\phi_3^1=\mathrm{d}t_2\wedge\frac{\partial *_7\phi_3^1}{\partial t_2},$$

$$d *_7\phi_3^2=\left(\hat{d}+\mathrm{d}t_1\wedge\frac{\partial}{\partial t_1}+\mathrm{d}t_2\wedge\frac{\partial}{\partial t_2}\right)*_7\phi_3^2=\mathrm{d}t_1\wedge\frac{\partial *_7\phi_3^2}{\partial t_2},$$

$$\mathrm{d}\phi_3^1=\mathrm{d}t_2\wedge\frac{\partial\phi_3^1}{\partial t_2},\quad \mathrm{d}\phi_3^2=\mathrm{d}t_2\wedge\frac{\partial\phi_3^2}{\partial t_1}, \tag{5}$$

implies

$$\begin{aligned}\mathrm{d}\phi_4\Big|_{\hat{\mathrm{d}}J\wedge J=\hat{\mathrm{d}}\Omega_+=0}=\alpha_1\left(\mathrm{d}t_2\wedge\frac{\partial J}{\partial t_2}\wedge J+\mathrm{d}t_2\wedge\frac{\partial\Omega_-}{\partial t_2}\wedge \mathrm{d}t_1\right)+\alpha_2\left(\mathrm{d}t_1\wedge\frac{\partial J}{\partial t_1}\wedge J+\mathrm{d}t_1\wedge\frac{\partial\Omega_-}{\partial t_1}\wedge \mathrm{d}t_1\right)\\ +\beta_1\left(\mathrm{d}t_2\wedge\frac{\partial\Omega_+}{\partial t_2}\wedge \mathrm{d}t_1\right)+\beta_2\left(\mathrm{d}t_1\wedge\frac{\partial\Omega_+}{\partial t_1}\wedge \mathrm{d}t_2\right)+(\tilde{\alpha}_1+\beta_2-\alpha_1)\left(\hat{\mathrm{d}}\Omega_1\wedge \mathrm{d}t_1\right.\\ \left.+\mathrm{d}t_2\wedge\frac{\partial\Omega_-}{\partial t_2}\wedge \mathrm{d}t_1\right)-(\alpha_2+\tilde{\alpha}_2+\beta_1)\left(\hat{\mathrm{d}}\Omega_1\wedge \mathrm{d}t_2+\mathrm{d}t_1\wedge\frac{\partial\Omega_-}{\partial t_1}\wedge \mathrm{d}t_2\right)\\ +2\delta\left(\mathrm{d}t_1\wedge\frac{\partial J}{\partial t_1}\wedge J+\mathrm{d}t_2\wedge\frac{\partial J}{\partial t_2}\wedge J\right)+(\alpha_1+\alpha_2+2\delta+\tilde{\alpha}_2-\tilde{\alpha}_1)\hat{\mathrm{d}}J\wedge \mathrm{d}t_1\wedge \mathrm{d}t_2=0.\end{aligned} \tag{6}$$

One thus gets the following flow equations:

$$(\alpha_1+2\delta)\frac{\partial J}{\partial t_2}\wedge J=(\alpha_2+\tilde{\alpha}_2+\beta_1)\hat{\mathrm{d}}\Omega_-,$$

$$(2\delta+\alpha_2)\frac{\partial J}{\partial t_1}\wedge J=(\alpha_1-\beta_2+\tilde{\alpha}_1)\hat{\mathrm{d}}\Omega_-,$$

$$(\tilde{\alpha}_1+\tilde{\beta}_2)\frac{\partial\Omega_-}{\partial t_2}+(\tilde{\alpha}_2+\beta_1)\frac{\partial\Omega_-}{\partial t_1}+\beta_1\frac{\partial\Omega_+}{\partial t_2}-\beta_2\frac{\partial\Omega_+}{\partial t_1}+(\alpha_1+\alpha_2+2\delta+\tilde{\alpha}_2-\tilde{\alpha}_1)\hat{\mathrm{d}}J=0. \tag{7}$$

Let us use the flow equations of (7) to explicitly uplift the Iwasawa manifold to a Spin(7) eightfold, working with the standard complex structure limit of the Iwasawa, and consider its deformation of the type

$$J(t_1,t_2)=e^{a(t_1,t_2)}e^{12}+e^{b(t_1,t_2)}e^{34}+e^{c(t_1,t_2)}e^{56} \tag{8}$$

and

$$\Omega(t_1,t_2)=e^{(a+b+c)(t_1,t_2)/2}(e^1+ie^2)\wedge(e^3+ie^4)\wedge(e^5+ie^6). \tag{9}$$

Then the flow equations (7) imply

$$\frac{\partial a}{\partial t_1}=\frac{\partial b}{\partial t_1}=-\frac{\partial c}{\partial t_1},\quad 2\frac{\partial a}{\partial t_1}e^{a+b}=4\xi_1 e^{(a+b+c)/2}, \tag{10}$$

where $\xi_1\equiv(\alpha_1-\beta_2+\tilde{\alpha}_1)/(2\delta+\alpha_2)$, which could be satisfied by equality of $a,b,-c$, and

$$a(t_1,t_2)=\frac{2}{3}\ln(3\xi_1 e^{\lambda_1}t_1+f_2(t_2)), \tag{11}$$

λ_1 being a linear combination of the integration constants that would appear in the integration of the first set of equations in (10); similarly,

$$a(t_1,t_2)=\tfrac{2}{3}\ln(3\xi_2 e^{\lambda_1}t_2+f_1(t_1)), \tag{12}$$

where $\xi_2\equiv(\alpha_2+\tilde{\alpha}_2+\beta_1)/(\alpha_1+2\delta)$,

$$\frac{(\tilde{\alpha}_1+\beta_2)}{2}\frac{\partial a}{\partial t_2}+\frac{(\tilde{\alpha}_2+\beta_1)}{2}\frac{\partial a}{\partial t_1}=0,$$

$$\Leftrightarrow(\tilde{\alpha}_1+\beta)\xi_2+(\tilde{\alpha}_2+\beta_1)\xi_1=0,$$

$$e^{(a+b+c)/2}\left(\frac{\beta_1}{2}\frac{\partial a}{\partial t_2}-\frac{\beta_2}{2}\frac{\partial a}{\partial t_1}\right)=(\alpha_1+\alpha_2+2\delta+\tilde{\alpha}_2-\tilde{\alpha}_1)e^c, \tag{13}$$

$$\Leftrightarrow(\beta_1\xi_2-\beta_2\xi_1)e^{-(3a/2)+\lambda_1}=(\alpha_1+\alpha_2+2\delta+\tilde{\alpha}_2-\tilde{\alpha}_1)e^{-a+\lambda_3},$$

$$\Rightarrow\beta_1\xi_2-\beta_2\xi_1=\alpha_1+\alpha_2+2\delta+\tilde{\alpha}_2-\tilde{\alpha}_1.$$

Hence, the metric corresponding to the Spin(7) eightfold obtained by uplifting the Iwasawa manifold via the flow equations of (7) such that the eightfold is a double G_2-fibration over an interval, is given by the following solutions to (10)–(13):

$$ds_8^2 = ds_{I\times I}^2(t_1,t_2) + (1+\xi_1 t_1 + \xi_2 t_2)^{\frac{2}{3}}(|dz|^2 + |dv|^2) + \frac{1}{d(1+\xi_2 t_1 + \xi_2 t_2)^{\frac{2}{3}}}|du - z dv|^2, \quad (14)$$

with the constraints

$$\beta_1\xi_2 - \beta_2\xi_1 = \alpha_1 + \alpha_2 + 2\delta + \tilde{\alpha}_2 - \tilde{\alpha}_1,$$

$$\frac{\xi_1}{\xi_2} = -\frac{\tilde{\alpha}_1 + \beta_2}{\tilde{\alpha}_2 + \beta_1}, \quad \text{or } \tilde{\alpha}_1 = -\beta_2,\ \tilde{\alpha}_2 = -\beta_1. \quad (15)$$

Notice that (14) has the required double G_2-fibration structure of diagram 1 by noting that (14) is made up of

$$ds_7^2(t_1, \text{given } t_2) = dt_1^2 + (\xi_1' + \xi_1 t_1)^{\frac{2}{3}}(|dz|^2 + |dv|^2) + \frac{1}{(\xi_1' + \xi_1 t_1)^{\frac{2}{3}}}|du - z\, dv|^2 \quad (16)$$

and

$$ds_7^2(t_2, \text{given } t_1) = dt_2^2 + (\xi_2' + \xi_2 t_2)^{\frac{2}{3}}(|dz|^2 + |dv|^2) + \frac{1}{(\xi_2' + \xi_2 t_2)^{\frac{2}{3}}}|du - z\, dv|^2, \quad (17)$$

which are the two-parameter G_2-metrics of Ref. 4. (In Ref. 4, however, one had set $\xi_i' = 1$.) The metric of (14) also thus has G_2-holonomy. (The authors thank J. Maldacena for pointing this out.)

SPIN(7) AS A FIBRATION OF A HALF-FLAT OVER $I\times I$

Let us now consider the following fibration structure:

$$\begin{array}{ccc} X_8^{\text{Spin(7)}} & \longrightarrow & I_{t_1} \times I_{t_2} \\ & & M_6 \end{array} \quad (18)$$

Let us assume that the Cayley four-form is given by

$$\phi_4 = a_1\Omega_- \wedge dt_1 + a_2\Omega_- \wedge dt_2 + b_1\Omega_+ \wedge dt_1 + b_2\Omega_+ \wedge dt_2 + cJ \wedge J + fJ \wedge dt_1 \wedge dt_2. \quad (19)$$

One then gets

$$*_8\phi_4 = a_1\Omega_+ \wedge dt_2 - a_2\Omega_+ \wedge dt_1 - b_1\Omega_- \wedge dt_2 + b_2\Omega_- \wedge dt_1 + 2cJ \wedge dt_1 \wedge dt_2 + \frac{f}{2}J \wedge J, \quad (20)$$

implying that for $\phi_4 = *_8\phi_4$,

$$a_1 = b_1, \quad a_2 = -b_1, \quad c = \frac{d}{2}. \quad (21)$$

The required Cayley four-form is

$$\phi_4 = a_1\Omega_- \wedge dt_1 + a_2\Omega_- \wedge dt_2 - a_2\Omega_+ \wedge dt_1 + a_1\Omega_+ \wedge dt_2 + \frac{f}{2}J \wedge J + fJ \wedge dt_1 \wedge dt_2. \quad (22)$$

Finally, the condition that ϕ_4 of (22) is closed gives

$$
\begin{aligned}
\mathrm{d}\phi_4 = a_1\left(\hat{\mathrm{d}}\Omega_- \wedge \mathrm{d}t_1 + \mathrm{d}t_2 \wedge \frac{\partial \Omega_-}{\partial t_2} \wedge \mathrm{d}t_1\right) + a_2\left(\hat{\mathrm{d}}\Omega_- \wedge \mathrm{d}t_2 + \mathrm{d}t_1 \wedge \frac{\partial \Omega_-}{\partial t_1} \wedge \mathrm{d}t_2\right) \\
+ a_1\left(\hat{\mathrm{d}}\Omega_+ \wedge \mathrm{d}t_2 + \mathrm{d}t_1 \wedge \frac{\partial \Omega_+}{\partial t_1} \wedge \mathrm{d}t_2\right) - a_2\left(\hat{\mathrm{d}}\Omega_+ \wedge \mathrm{d}t_1 + \mathrm{d}t_2 \wedge \frac{\partial \Omega_-}{\partial t_2} \wedge \mathrm{d}t_1\right) \\
+ f\left(\hat{\mathrm{d}}J \wedge J + \mathrm{d}t_1 \wedge \frac{\partial J}{\partial t_1} \wedge J + \mathrm{d}t_2 \wedge \frac{\partial J}{\partial t_2} \wedge J\right) = 0. \qquad (23)
\end{aligned}
$$

Using that for half-flat manifolds, $\hat{\mathrm{d}}J \wedge J = \hat{\mathrm{d}}\Omega_+ = 0$, one thus gets the following flow equations:

$$
a_1\,\hat{\mathrm{d}}\Omega_- = -f\frac{\partial J}{\partial t_1} \wedge J,
$$

$$
a_2\,\hat{\mathrm{d}}\Omega_- = -f\frac{\partial J}{\partial t_2} \wedge J,
$$

$$
-a_1\frac{\partial \Omega_+}{\partial t_2} + a_2\frac{\partial \Omega_-}{\partial t_1} + a_2\frac{\partial \Omega_+}{\partial t_2} + a_1\frac{\partial \Omega_+}{\partial t_2} = f\,\hat{\mathrm{d}}J. \qquad (24)
$$

One can again show that one can explicitly uplift the Iwasawa manifold to a Spin(7) eightfold at standard complex structure limit of the Iwasawa and consider its deformation of the type as given in (8) and (9). The set of equations that one gets from (24), are

$$
\frac{\partial a}{\partial t_i} = \frac{\partial b}{\partial t_i} = -\frac{\partial c}{\partial t_i},
$$

$$
\frac{\partial a}{\partial t_1} = -\frac{2a_1}{f}e^{-(3a/2)+\lambda_1}, \quad \frac{\partial a}{\partial t_2} = -\frac{2a_2}{f}e^{-(3a/2)+\lambda_1}, \qquad (25)
$$

$$
\left(\frac{a_1}{2}\frac{\partial a}{\partial t_2} - a_2\frac{\partial a}{\partial t_1}\right)e^{(a+b+c)/2} = 0, \quad \left(-\frac{a_2}{2}\frac{\partial a}{\partial t_2} - \frac{a_1}{2}\frac{\partial a}{\partial t_1}\right)e^{(a+b+c)/2} = fe^c,
$$

which are satisfied by

$$
a(t_1,t_2) = \frac{2}{3}\ln\left(1 + 3\frac{a_1e^{\lambda_1}}{f}t_1 + 3\frac{a_2e^{\lambda_2}}{f}t_2\right),
$$

$$
\text{with } a_1^2 + a_2^2 = f^2. \qquad (26)
$$

Thus, the metric for the Spin(7) eightfold is

$$
\begin{aligned}
\mathrm{d}s_8^2 = \mathrm{d}s_{I\times I}^2(t_1,t_2) + \left(1 + \frac{a_1}{\sqrt{a_1^2+a_2^2}}t_1 + \frac{a_2}{\sqrt{a_1^2+a_2^2}}t_2\right)^{\frac{2}{3}}(|\mathrm{d}z|^2 + |\mathrm{d}v|^2) \\
+ \left(1 + \frac{a_1}{\sqrt{a_1^2+a_2^2}}t_1 + \frac{a_2}{\sqrt{a_1^2+a_2^2}}t_2\right)^{-\frac{2}{3}}|\mathrm{d}u - z\,\mathrm{d}v|^2. \qquad (27)
\end{aligned}
$$

Again, the metric also has G_2-holonomy.

However, it is unlikely to be able to uplift the Iwasawa to a Spin(7) eightfold at the "edge." One notes that at the edge (see Ref. 2 and references therein), the one-forms, incorporating $t_{1,2}$-dependent deformations, are $\alpha = -e^{\mathcal{A}(t_1,t_2)}f^1$, $\beta = e^{\mathcal{B}(t_1,t_2)}(f^3 + if^4)$, $\gamma = e^{\mathcal{C}(t_1,t_2)}(e^5 + ie^6)$, and J

$=(i/2)$ $(\alpha\wedge\overline{\alpha}+\beta\wedge\overline{\beta}+\gamma\wedge\overline{\gamma}$and $\Omega=\alpha\wedge\beta\wedge\gamma)$. The one-forms $f^i, i=1,\ldots,4$ are defined via $f^i=P^i_j e^j$, where $P\in \mathrm{SO}(4)$ matrix, and one writes it as$\left(\begin{smallmatrix} X & 0 \\ 0 & Y \end{smallmatrix}\right)$, where $X,Y\in \mathrm{SU}(2)$, i.e.,

$$\begin{pmatrix} P^1_1 & P^1_2 & 0 & 0 \\ P^2_1 & P^2_2 & 0 & 0 \\ 0 & 0 & P^3_3 & P^3_4 \\ 0 & 0 & P^4_3 & P^4_4 \end{pmatrix},$$

where $P^1_1P^2_2-P^1_2P^2_1=P^3_3P^4_4-P^3_4P^4_3=1$. The flow equations $\hat{\mathrm{d}}\Omega_-=-\partial J/\partial t_1\wedge J=-\partial J/\partial t_2\wedge J$ implies $\mathcal{A}$ gives the same result after differentiation with respect to t_1 or t_2. Unlike the standard complex structure limit, there are common components to Ω_+ and Ω_- in the edge. One can show that the other flow equation

$$a_1\frac{\partial\Omega_-}{\partial t_2}-a_2\frac{\partial\Omega_-}{\partial t_1}-a_2\frac{\partial\Omega_+}{\partial t_2}-a_1\frac{\partial\Omega_+}{\partial t_1}+f\hat{\mathrm{d}}J=0$$

becomes

$$\begin{aligned} e^{\mathcal{A}+\mathcal{B}+\mathcal{C}}\Big[&\big(\mathcal{D}_-(P^1_1P^3_3+P^2_1P^4_3)-\mathcal{D}_+(P^2_1P^3_3-P^1_1P^4_3)\big)e^{136}+\big(\mathcal{D}_-(P^1_1P^3_4+P^2_1P^4_4)-\mathcal{D}_+(P^2_1P^3_4-P^1_1P^4_4)\big)e^{146}\\ &+\big(\mathcal{D}_-(P^1_2P^3_3+P^2_2P^4_3)-\mathcal{D}_+(P^2_2P^3_3-P^1_2P^4_3)\big)e^{236}\\ &+\big(\mathcal{D}_-(P^1_2P^3_4+P^2_2P^4_4)-\mathcal{D}_+(P^2_2P^3_4-P^1_2P^4_4)\big)e^{246}\\ &+\big(\mathcal{D}_-(-P^1_1P^4_3+P^2_1P^3_3)-\mathcal{D}_+(-P^1_1P^3_3-P^2_1P^4_3)\big)e^{135}\\ &+\big(\mathcal{D}_-(-P^1_1P^4_4+P^2_1P^3_4)-\mathcal{D}_+(-P^1_1P^3_4-P^2_1P^4_4)\big)e^{145}\\ &+\big(\mathcal{D}_-(-P^1_2P^4_3+P62_2P^3_3)-\mathcal{D}_+(-P^1_2P^3_3-P^2_2P^4_3)\big)e^{235}\\ &+\big(\mathcal{D}_-(-P^1_2P^4_4+P^2_2P^3_4)-\mathcal{D}_+(-P^1_2P^3_4-P^2_2P^4_4)\big)e^{246}\\ &=-e^{2\mathcal{C}}(e^{135}+e^{425}-e^{614}-e^{623}), \end{aligned} \tag{28}$$

(where $\mathcal{D}_+\equiv[a_2(\partial/\partial t_2)+a_1(\partial/\partial t_1)]\,\mathcal{ABC}$ and $\mathcal{D}_-\equiv[a_1(\partial/\partial t_2)-a_2(\partial/\partial t_1)]\mathcal{ABC}$), which implies that one will overconstrain the matrix P [from the first set of flow equations, one sees that $\mathcal{D}_-=0$, and hence one gets from (28), eight equations in the six parameters P^i_j]. Hence, the uplift of the edge to a Spin(7) is quite likely to be impossible.

POSSIBILITY OF INTRODUCING WEIERSTRASS ELLIPTIC FUNCTIONS IN SPIN(7) EIGHTFOLDS INCLUDING AN S^1

We now give some very compelling evidence in support of the possibility of inclusion of Weierstrass elliptic functions in those Spin(7) eightfolds which are of the type $X_7\times S^1$, X_7 being a sevenfold of SU(3) structure.

Seven-dimensional manifolds of G_2-holonomy or SU(3) structure are required for getting $\mathcal{N}=1$ supersymmetry in four dimensions from the 11-dimensional M-theory. Similarly, Spin(7) eightfolds are required for getting $\mathcal{N}=1$ supersymmetry in three dimensions from (the 11 dimensional) M-theory. One could explore the option of getting compact Spin(7) uplifts using S^1's instead of intervals by using the same flow equations as derived in this paper, but further demanding periodicity with respect to t_1 and t_2, of the solutions.

Assuming the existence of Spin(7) eightfolds of the type $X_7 \times S^1$, one could first argue the existence of a G_2-structure by noting the existence of a singlet in the decomposition under $G_2 \subset \mathrm{Spin}(7)$ of the **8** in the fundamental spinorial representation ($\mathbf{8} \to \mathbf{7}+\mathbf{1}$). Further, assuming that Majorana-Weyl spinors ($\xi = \xi^+ \oplus \xi^-$, the $\pm$ signs referring to the chiralities) on the Spin(7) eightfold are nowhere vanishing, there is a further reduction of the structure group to $G_{2+} \cap G_{2-} = \mathrm{SU}(3)$, the two G_2's corresponding to the two chiralities of $\xi^{\pm}$.

Having established the connection between (the use of) Spin(7) eightfolds and sevenfolds with SU(3)-structure, let us now move to the main theme of this section—the possibility of inclusion of Weierstrass elliptic functions in sevenfolds with SU(3) structure and thereby Spin(7) eightfolds of the type $X_7 \times S^1$.

Using the results of Ref. 5, explicit metrics for sevenfolds with SU(3) structure were obtained. The "shape" deformation functions "$A(z, \overline{z}; v, \overline{v})$" and "$B(z, \overline{z}; v, \overline{v})$," as indicated in Ref. 4, could also be related to elliptic functions—the seven-dimensional SU(3) structure does not impose too many constraints if one allows wrapped $M5$-branes in the analysis. The following are some interesting connections between some concepts, thereby motivating further the idea of having singular uplifts to seven dimensions of the Iwasawa manifold, involving elliptic functions.

(i) The $D7$-brane metric (relevant to "cosmic strings" in Ref. 8) is given by

$$\mathrm{d}s_{10}^2 = \mathrm{d}s_8^2 + \tau_2(z)\,|\eta(\tau(z))|^4 |z|^{-N/6} |\mathrm{d}z|^2, \tag{29}$$

where $\tau_2 \equiv \mathrm{Im}\,\tau$, $\tau = a + ie^{-\phi}$, $a \equiv$ axion and $\phi \equiv$ dilaton, $\eta \equiv$ Dedekind eta function (see below), $N \equiv$ the number of $D7$-branes, and z is the complex coordinate transverse to the $D7$-brane. Hence, one has one explicit example of a metric involving η, which is related to theta functions, as indicated below.

(ii) The Jacobi theta function[9] defined for two complex variables z and τ where $\mathrm{Im}\,\tau > 0$, $\vartheta(z:\tau) = \Sigma_{-\infty}^{\infty} e^{i\pi n^2 \tau + 2\pi i n z}$. The theta function is related to the Dedekind eta function via $\vartheta(0;\tau) = \eta^2[(\tau+1)/2]/\eta(\tau+1)$.

(iii) The Weierstrass elliptic function[9] is a doubly periodic function with periods $2\omega_1$ and $2\omega_2$ such that $\omega_1 \omega_2$ is not real,

$$\mathcal{P}(z;\omega_1,\omega_2) = \frac{1}{z^2} + \sum_{m,n \in \mathbf{Z}\setminus(0,0)} \left(\frac{1}{(z - 2m\omega_1 - 2n\omega_2)^2} - \frac{1}{(2m\omega_1 + 2n\omega_2)^2} \right).$$

$\mathcal{P}$ satisfies the following cubic equation:

$$\left(\frac{\mathrm{d}\mathcal{P}(z;\tau)}{\mathrm{d}z} \right)^2 = \mathcal{P}^3(z;\tau) - g_2 \mathcal{P} - g_3,$$

where $g_2 = 60\Sigma_{m,n \in \mathbf{Z}\setminus(0,0)}[1/(2m\omega_1 + 2n\omega_2)^4]$, $g_3 = 140\Sigma_{m,n \in \mathbf{Z}\setminus(0,0)}[1/(2m\omega_1 + 2n\omega_2)^6]$. This is an equation of a torus, which could be related to the Riemann surface that is referred to in Ref. 5. The torus degenerates, i.e., becomes singular along the discriminant locus given by $\Delta = g_2^3 - 27 g_3^2 = 0$. There is the following relation between the discriminant locus and the Dedekind eta function: $\Delta = (2\pi)^{12} \eta^{24}$. The following relations are true: $\mathcal{P}(z;\omega_1 = 1, \omega_2 = \tau) = -(d^2/\mathrm{d}z^2)\vartheta_{11}(z;\tau) + \text{constant} = \pi^2 \vartheta^2(0;\tau)\vartheta_{10}^2(0;\tau)[\vartheta_{10}^2(z;\tau)/\vartheta_{11}^2(z;\tau)] + e_2(\tau)$, where e_2 is one of the three roots $e_{i=1,2,3}$, of the cubic equation $4t^3 - g_2 t - g_3 = 0$, and $\mathcal{P}(\omega_1) = e_1$, $\mathcal{P}(\omega_2) = e_2$, $\mathcal{P}(-\omega_1 - \omega_2) = e_3$. [The e_i's are given by $e_1(\tau) = (\pi^2/3)(\vartheta^4(0;\tau) + \vartheta_{01}^4(0;\tau))$, $e_2(\tau) = -(\pi^2/3) \times (\vartheta^4(0;\tau) + \vartheta^4(0;\tau))$ $e_3(\tau) = (\pi^2/3)(\vartheta_{10}^4(0;\tau) - \vartheta^4(0;\tau))$, where the three other theta functions are defined as $\vartheta_{01}(z;\tau) = \vartheta\left(z + \frac{1}{2};\tau\right)$ $\vartheta_{10}(z;\tau) = e^{i(\pi/4) + i\pi z}\vartheta(z + (\tau/2);\tau)$ $\vartheta_{11}(z;\tau) = e^{i(\pi/4) + i\pi\left(z + \frac{1}{2}\right)}\vartheta(z + [(\tau+1)/2];\tau)$.]

(iv) Consider a holomorphic function $f(z)$ and $a, b \in \mathbf{R}$. Define two operators S_a and T_b as follows: $(S_a f)(z) = f(z+a)$, $(T_b f)(z) = e^{i\pi b^2 \tau + 2i\pi b z} f(z + b\tau)$. Then S, T and a phase factor form the generators of the nilpotent Heisenberg group central to the group-theoretic way of understanding the Iwasawa manifold. If $U(\lambda \in \mathbf{C}, a, b) \in H \equiv$ Heisenberg group, then

$$U(\lambda,a,b)f(z)=\lambda(S_a\circ T_b f)(z)=\lambda e^{i\pi b^2\tau+2i\pi bz}f(z+b\tau+a),$$

and U is referred to as the theta representation of the Heisenberg group.[10]

(v) (Inverse) Elliptic functions, as shown in Ref. 11, naturally figure in the hyper-Kähler metrics in twistor spaces obtained by deformations of Atiyah-Hitchin spaces and Legendre transform. Lets elaborate upon this a little.

Deformations of Atiyah-Hitchin manifolds (written as hypersurface in $\mathbf{C}^3$: $x^2+y^2z=1$) of the type $x^2z+(yz+a)^2=z^2+a^2$ have been considered. The twistor threefolds are obtained as holomorphic sections $\Gamma(\mathcal{O}_{\mathbf{CP}^1}(4))$ with the following similar equation: $x^2(\zeta)\eta(\zeta)+(y(\zeta)\eta(\zeta)+p(\zeta))^2=\eta(\zeta)+p^2(\zeta)$, where η is $\Gamma(\mathcal{O}_{\mathbf{CP}^1}(4))$ and the deformation p is $\Gamma(\mathcal{O}_{\mathbf{CP}^1}(2))$, and ζ is a $\mathbf{CP}^1$-valued coordinate. The reality involution: $\overline{\eta^{(2m)}}(\zeta)=(-)^m(\overline{\zeta})^{(2m)}(-1/\overline{\zeta})$,where $\eta^{(2m)}(\zeta)$ is $\Gamma(\mathcal{O}_{\mathbf{CP}^1}(2m))$, implies that $\eta(\zeta)$ has five independent parameters, i.e., $\eta(\zeta)=z+v\zeta+w\zeta^2-\overline{v}\overline{\zeta}^3+\overline{z}\overline{\zeta}^4$ $(z,v\in\mathbf{C}$ and $w\in\mathbf{R})$ and the deformation $p(\zeta)=a+b\zeta-\overline{a}\overline{\zeta}^2, a\in\mathbf{C}, b\in\mathbf{R}$. An $\mathrm{SL}(2,\mathbf{C})$ transformation: $\zeta\rightarrow(a\zeta+b)/(-b\zeta+\overline{a})$, $|a|^2+|b|^2=1$ can be used to restrict $p(\zeta)=\tilde{b}\zeta$. For genericvalues of the five real parameters in $\eta(\zeta)$, one gets eight points on an elliptic curve, $\gamma^2=\eta(z\zeta)$, corresponding to the roots of $\eta(\zeta)+p^2(\zeta)=0$—the divisor for four of these eight should correspond to $\Gamma(L^m)$, where L^m are holomorphic line bundles over $T\mathbf{CP}^1$ with $e^{-m\xi/\zeta}$ (ξ being a fiber coordinate) the transition functions. The splitting of the eight roots into two groups of four each is determined by the following condition: $(\int_\alpha^\infty+\int_\beta^\infty-\int_{-1/\overline{\alpha}}^\infty-\int_{-1/\overline{\beta}}^\infty)[\mathrm{d}\zeta/\sqrt{\eta(\zeta)}]=2$; the roots of $\eta(\zeta)+p^2(\zeta)=0$ are $\alpha,\beta,-1/\overline{\alpha},-1/\overline{\beta}$.Now, if x_1,x_2 are roots of $\eta(\zeta)+\tilde{b}\zeta=0$ *after* the $\mathrm{SL}(2,\mathbf{C})$ transformation,

$$\begin{pmatrix}\eta(\zeta)\\ p(\zeta)\end{pmatrix}\overset{\zeta\rightarrow\frac{a\zeta+b}{-b\zeta+a}}{\rightarrow}\begin{pmatrix}\dfrac{r_1\zeta^3-r_2\zeta^2-r_1\zeta}{(-\overline{b}\zeta+\overline{a})^4}\\ \dfrac{\tilde{b}(a\zeta+b)}{(-\overline{b}\zeta+\overline{a})}\end{pmatrix},$$

$r_1,r_2\in\mathbf{R}$, then the aforementioned constraint can be rewritten in terms of inverse elliptic functions,

$$\mathcal{P}^{-1}\left(x_1-\frac{r_2}{3r_1}\right)+\mathcal{P}^{-1}\left(x_2-\frac{r_2}{3r_1}\right)-\mathcal{P}^{-1}\left(-\frac{1}{\overline{x_1}}-\frac{r_2}{3r_1}\right)-\mathcal{P}^{-1}\left(-\frac{1}{\overline{x_2}}-\frac{r_2}{3r_1}\right)=\frac{m\sqrt{r_1}}{2},$$

where the inverse elliptic function $\mathcal{P}^{-1}(z)\equiv\int_\infty^z(\mathrm{d}\zeta/\sqrt{4\zeta^3-g_2\zeta-g_3})$. The constraint is also equivalent to $\partial F/\partial w=0$ for a suitable constraint function F defined in terms of appropriate contour integrals. The Kähler potential is then given in terms of the Legendre transform of $F:K(z,\overline{z};\partial F/\partial v,\partial\overline{F}/\partial\overline{v})=F(z,\overline{z};v,\overline{v};w)-v(\partial F/\partial v)-\overline{v}(\partial\overline{F}/\partial\overline{v})$ evaluated at the constraint, $\partial F/\partial w=0$.

Thus, one sees the existence of (inverse) elliptic functions in the hyper-Kähler metrics in twistor spaces obtained using deformations of Atiyah-Hitchin spaces and Legendre transforms.

To summarize, we have obtained the relevant flow equations for uplifting half-flat manifolds to Spin(7) eightfolds by two methods—first, by considering a double G_2 (constructed from the half-flat) fibration over an interval, and the second, by considering a fibration of the half-flat over the product of two intervals. We were able to explicitly uplift the Iwasawa at the standard complex structure limit in the moduli space of almost complex structures on the Iwasawa. We gave a plausibility argument against the same for the second method, at the "edge." We also gave motivating reasons for considering singular uplifts involving doubly periodic functions—the physical interpretation of the same is not yet clear.

(Received 25 November 2005; accepted 25 January 2006; published online 15 March 2006)

We provide a simple method for the calculation of the terms c_n in the Zassenhaus product $e^{a+b}=e^a\cdot e^b\cdot\Pi_{n=2}^{\infty}e^{c_n}$ for noncommuting a and b. This method has been implemented in a computer program. Furthermore, we formulate a conjecture on how to translate these results into nested commutators. This conjecture was checked up to order $n=17$ using a computer. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2178586]

I. INTRODUCTION

The product of the exponentials of two noncommuting variables x and y may be expressed in terms of the Baker-Campbell-Hausdorff (BCH) series

$$e^x e^y = e^{x+y+\Sigma_{n=2}^{\infty} z_n}. \tag{1}$$

The terms z_n of the sum may be written as linear combinations of words W of length n consisting of letters x and y,

$$z_n = \sum_{W(s_1,\ldots,s_n)} z(W) W(s_1,\ldots,s_n), \tag{2}$$

where each word $W(s_1,\ldots,s_n)$ is a product of n factors $s_i=x$ or $s_i=y$. The sum in Eq. (2) is over all possible different words, i.e., the sum over W has in principle 2^n terms. Some of these terms vanish, because the corresponding coefficient $z(W)$ equals zero. The coefficients $z(W)$ may be determined in various ways. A simple method to determine these coefficients has been suggested recently by Reinsch.[1] His method is easily implemented in a computer program.[1,2] Another method was presented by Goldberg,[3] and his method was implemented in a program by Newman and Thompson.[4]

The terms z_n of the BCH series may be expressed as linear combinations of nested commutators of x and y. This was originally shown by Baker, Campbell, and Hausdorff.[5] However, explicit determination of the coefficients was difficult for general n. Dynkin[6,7] showed that the coefficients are in fact easily obtained, so that the z_n can be represented as

$$z_n = \frac{1}{n} \sum_{W(s_1,\ldots,s_n)} z(W)[[\cdots[[s_1,s_2],s_3],\ldots],s_n], \tag{3}$$

where $[[\cdots[[s_1,s_2],s_3],\ldots],s_n]$ is a direct translation of the word W into a left normal nested commutator, i.e., the order of the letters in the commutator and the word are the same. The representation of the z_n in terms of commutators is not unique due to the Jacobi identity

a)Electronic mail: mehr-davon@gmx.de
b)Electronic mail: michael.weyrauch@ptb.de

$[[x,y],z]+[[y,z],x]+[[z,x],y]=0$ and similar identities for higher order commutators. Some of them are discussed by Oteo.[8] Oteo also formulates a conjecture concerning another translation of the BCH terms into a linear combination of commutators. This translation consists of fewer terms than Dynkin's translation, but a general proof of its validity is not known to us. We have checked the validity of Oteo's conjecture up to order $n=17$ on a computer.

It was first shown by Zassenhaus[9] that there exists a formula analogous to the BCH formula for the exponential of the sum of two noncommuting variables a and b,

$$\mathrm{e}^{a+b} = \mathrm{e}^{a} \cdot \mathrm{e}^{b} \cdot \prod_{n=2}^{\infty} \mathrm{e}^{c_n}, \tag{4}$$

which is known as the Zassenhaus product formula. The individual terms c_n will be called the Zassenhaus exponents in the following. They may also be written in terms of words of length n consisting of the letters a and b, i.e.,

$$c_n = \sum_{W(t_1,\ldots,t_n)} c(W) W(t_1, \ldots, t_n) \tag{5}$$

with $t_i=a$ or $t_i=b$. It is the goal of this paper to provide a simple method for the calculation of the coefficients $c(W)$ as well as to propose a suitable computer implementation. Our method has been developed in analogy to the procedure proposed by Reinsch[1] for the BCH terms.

The Zassenhaus exponents may also be obtained in terms of nested commutators as shown, e.g., in Refs. 9 and 10. Dynkin's theorem[6] provides a (generally valid) translation of words into nested commutators, if such a translation exists. Therefore, it is possible to directly translate the expressions for the Zassenhaus exponents (5) into a linear combination of left normal nested commutators as in Eq. (3). In analogy to the conjecture by Oteo[8] for the BCH terms, we formulate here a conjecture concerning another translation of words into left normal nested commutators for the Zassenhaus exponents involving fewer terms than Dynkin's translation. Using a computer, we found this conjecture to be valid for the Zassenhaus exponents up to order $n=17$, but at this time we cannot provide a general proof.

II. THE ZASSENHAUS EXPONENTS

In this section we state a corollary which allows a recursive determination of the Zassenhaus exponents.

Let $\tau_1, \ldots, \tau_n$ be commuting variables. In terms of these variables we define three upper triangular $(n+1)\times(n+1)$ matrices H, K, and L with matrix elements given by

$$H_{ij} = \frac{1}{(j-i)!} \cdot \prod_{k=i}^{j-1} (1+\tau_k), \quad K_{ij} = \frac{(-1)^{i+j}}{(j-i)!}, \tag{6}$$

$$L_{ij} = \frac{(-1)^{i+j}}{(j-i)!} \cdot \prod_{k=i}^{j-1} \tau_k, \tag{7}$$

for $1 \leqslant i \leqslant j \leqslant n+1$ and zero otherwise. These matrices may be expressed as exponentials of the $(n+1)\times(n+1)$ matrices P and Q defined by

$$P_{ij} = \delta_{i+1,j}, \quad Q_{ij} = \delta_{i+1,j}\tau_i, \tag{8}$$

where δ_{ij} is the Kronecker symbol,

$$H = \exp(P+Q), \quad K = \exp(-P), \quad L = \exp(-Q). \tag{9}$$

Furthermore, we define an operator U which operates on products p of the variables τ_i,

$$p = \tau_1^{\mu_1}\tau_2^{\mu_2}\tau_3^{\mu_3}\cdots\tau_n^{\mu_n}$$

with $\mu_i \in \{0,1\}$ for $i=1,\ldots,n$. The operator U "translates" such a product p into a word consisting of letters a and b according to the following rule: If $\mu_i=0$, $\tau_i^{\mu_i}$ is replaced by an a, and if $\mu_i=1$, $\tau_i^{\mu_i}$ is replaced by a b. The index i determines the position of the letter in the word. For example, for $n=6$ the product $p=\tau_1^1\tau_2^0\tau_3^1\tau_4^1\tau_5^0\tau_6^0=\tau_1\tau_3\tau_4$ is translated as follows:

$$U(p) = U(\tau_1^1\tau_2^0\tau_3^1\tau_4^1\tau_5^0\tau_6^0) = U(\tau_1\tau_3 u_4) = babbaa.$$

The operator U is a vector-space isomorphism mapping the space of polynomials in the τ variables (with $\mu_i=0$ or $\mu_i=1$) into the space of words of length n.

Corollary 1: The Zassenhaus exponent c_2 defined in Eq. (4) is obtained in terms of the 3×3 *matrices L, K, H as $c_2=U(L\cdot K\cdot H)_{1,3}$. For $n>2$, the Zassenhaus exponents c_n are given in terms of the corresponding $(n+1)\times(n+1)$ matrices as*

$$c_n = U((\mathrm{e}^{-\mathcal{C}_{n-1}}\cdot\ \cdots\ \cdot\mathrm{e}^{-\mathcal{C}_2}\cdot L\cdot K\cdot H)_{1,n+1}). \tag{10}$$

Here, $\mathcal{C}_m$ $(1<m<n)$ are the Zassenhaus exponents written in terms of the $(n+1)\times(n+1)$ matrices P and Q, and the index $1,n+1$ indicates the upper right element of a matrix.

This corollary permits a recursive determination of the Zassenhaus exponents. In fact, due to the special structure of the matrices P and Q all exponentials in Eq. (10) are obtained as finite sums, and the whole calculation can be done in a finite amount of steps either by hand or on a computer. A suitable computer implementation will be presented in Sec. IV.

Examples: Before proving Corollary 1 we work out a number of examples.

For $n=2$ we need to use the 3×3 matrices given by

$$L=\begin{pmatrix} 1 & -\tau_1 & \frac{1}{2}\tau_1\tau_2 \\ 0 & 1 & -\tau_2 \\ 0 & 0 & 1 \end{pmatrix}, \quad K=\begin{pmatrix} 1 & -1 & \frac{1}{2} \\ 0 & 1 & -1 \\ 0 & 0 & 1 \end{pmatrix},$$

$$H=\begin{pmatrix} 1 & (1+\tau_1) & \frac{1}{2}(1+\tau_1)(1+\tau_2) \\ 0 & 1 & (1+\tau_2) \\ 0 & 0 & 1 \end{pmatrix}.$$

Then,

$$L\cdot K\cdot H=\begin{pmatrix} 1 & 0 & \frac{1}{2}\tau_1-\frac{1}{2}\tau_2 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

and the second Zassenhaus exponent takes the form

$$c_2 = U(L\cdot K\cdot H)_{1,n+1} = U\left(\tfrac{1}{2}\tau_1-\tfrac{1}{2}\tau_2\right) = \tfrac{1}{2}U(\tau_1^1\tau_2^0-\tau_1^0\tau_2^1) = \tfrac{1}{2}(ba-ab). \tag{11}$$

For $n=3$ we need to use the 4×4 matrices,

$$L=\begin{pmatrix} 1 & -\tau_1 & \frac{1}{2}\tau_1\tau_2 & -\frac{1}{6}\tau_1\tau_2\tau_3 \\ 0 & 1 & -\tau_2 & \frac{1}{2}\tau_2\tau_3 \\ 0 & 0 & 1 & -\tau_3 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

$$K=\begin{pmatrix} 1 & -1 & \frac{1}{2} & -\frac{1}{6} \\ 0 & 1 & -1 & \frac{1}{2} \\ 0 & 0 & 1 & -1 \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

$$H=\begin{pmatrix} 1 & (1+\tau_1) & \frac{1}{2}(1+\tau_1)(1+\tau_2) & \frac{1}{6}\sum_{i=1}^{3}(1+\tau_i) \\ 0 & 1 & (1+\tau_2) & \frac{1}{2}\sum_{i=2}^{3}(1+\tau_i) \\ 0 & 0 & 1 & (1+\tau_3) \\ 0 & 0 & 0 & 1 \end{pmatrix},$$

and the matrices P and Q defined in Eq. (8),

$$P=\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad \text{and } Q=\begin{pmatrix} 0 & \tau_1 & 0 & 0 \\ 0 & 0 & \tau_2 & 0 \\ 0 & 0 & 0 & \tau_3 \\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

It follows from Eq. (11) that

$$e^{-C_2}=\exp\left(-\frac{1}{2}(Q\cdot P-P\cdot Q)\right)=\begin{pmatrix} 1 & 0 & \frac{1}{2}(\tau_2-\tau_1) & 0 \\ 0 & 1 & 0 & \frac{1}{2}(\tau_3-\tau_2) \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

Therefore, the third Zassenhaus exponent takes the form

$$\begin{aligned} c_3 &= U(e^{-C_2}\cdot L\cdot K\cdot H)_{1,n+1} \\ &= U\left(\tfrac{2}{3}\tau_1\tau_3-\tfrac{1}{3}\tau_2-\tfrac{1}{3}\tau_2\tau_3-\tfrac{1}{3}\tau_1\tau_2+\tfrac{1}{6}\tau_1+\tfrac{1}{6}\tau_3\right) \\ &= \tfrac{2}{3}bab-\tfrac{1}{3}aba-\tfrac{1}{3}abb-\tfrac{1}{3}bba+\tfrac{1}{6}baa+\tfrac{1}{6}aab. \end{aligned}$$

In an analogous way one obtains for c_4,

$$\begin{aligned} c_4 = &-\tfrac{1}{24}aaab+\tfrac{1}{8}aaba+\tfrac{1}{8}aabb-\tfrac{1}{8}abaa-\tfrac{1}{4}abab-\tfrac{1}{8}abbb+\tfrac{1}{24}baaa+\tfrac{1}{4}baba+\tfrac{3}{8}babb-\tfrac{1}{8}bbaa \\ &-\tfrac{3}{8}bbab+\tfrac{1}{8}bbba. \end{aligned}$$

These results all agree with the standard results given in the literature, see, e.g., Ref. 11.

III. PROOF OF COROLLARY 1

The $(n+1)\times(n+1)$ matrices P and Q have nonzero elements only in their first superdiagonal. A product of m factors P or Q is a $(n+1)\times(n+1)$ matrix which contains nonzero elements only in the mth superdiagonal. In particular, a product of n factors P or Q has only one nonzero element in its upper right corner. A product of k factors P or Q with $k>n$ is a null matrix.

Each Zassenhaus exponent c_n is a linear combination of words of length n. As a consequence, $\mathcal{C}_n$ is a $(n+1)\times(n+1)$ matrix, which has a nonzero entry only in its upper right-hand corner, and for each $n\in\mathbb{N}$,

$$e^{P+Q} = e^{P} \cdot e^{Q} \cdot \prod_{i=1}^{n} e^{\mathcal{C}_i} \tag{12}$$

is obtained in terms of a finite product with n factors. Therefore, one obtains

$$e^{\mathcal{C}_n} = e^{-\mathcal{C}_{n-1}} \cdot \cdots \cdot e^{-\mathcal{C}_2} \cdot e^{-Q} \cdot e^{-P} \cdot e^{P+Q}. \tag{13}$$

The exponentials can be calculated from a finite sum.

Since $\mathcal{C}_n$ only has one nonzero element in its upper right-hand corner, it holds that $\mathbf{e}^{\mathcal{C}_n} = I + \mathcal{C}_n$, and we find

$$(\mathcal{C}_n)_{1,n+1} = \left(\sum c(A_1 \cdots A_n) A_1 \cdots A_n\right)_{1,n+1} = (e^{\mathcal{C}_n})_{1,n+1} = (e^{-\mathcal{C}_{n-1}} \cdot \cdots \cdot e^{-\mathcal{C}_2} \cdot e^{-Q} \cdot e^{-P} \cdot e^{P+Q})_{1,n+1}, \tag{14}$$

where $A_i = P$ or $A_i = Q$, and the sum runs over all different matrix products $A_1 \cdots A_n$. The next step is to show that the upper-right element of a product matrix $A_1 \cdots A_n$ is given by a product of τ_i, and that the indices on the τ_i variables determine the positions of the Q's in the matrix product $A_1 \cdots A_n$. This has been shown in Ref. 1 and is not repeated here. Applying the operator U on this product of τ_i then transforms the result Eq. (14) into a linear combination of words in terms of the letters a and b. This proves Corollary 1.

IV. COMPUTER IMPLEMENTATION

The following *Mathematica* program implements Corollary 1. Calling it will return the Zassenhaus exponent c_n in terms of the variables a and b.

The program consists of three parts: First the matrices L, K, H, P, and Q are defined. Then the product of exponentials as required by Corollary 1 is calculated (starting from $n=2$), and finally the translation U is implemented. The program works with strings in order to prevent *Mathematica* from sorting the words alphabetically.

```
ZH[n_,a_,b_]:=Module[{C,L,K,H,P,Q,m,t,r,i,j,k,u,z},
C[2]=(t[1]^2 t[2])/2-(t[1] t[2]^2)/2;
For [m=2, m<=n, m++,
L=Table[(-1)^(i+j)/(j-i)! Product[t[k],{k,i,j-1}], {i,m+1},
  {j,m+1}];
K=Table[(-1)^(i+j)/(j-i)!, {i,m+1}, {j,m+1}];
H=Table[1/(j-i)! Product[(1+t[k]), {k,i,j-1}], {i,m+1}, {j,m+1}];
P=Table[KroneckerDelta [i+1,j], {i,m+1}, {j,m+1}];
Q=Table[KroneckerDelta [i+1,j] t[i], {i,m+1}, {j,m+1}];
C[m]=Expand[
     ((Dot @@ Table[MatrixExp[-Sum[
     r=(List @@ C[m-u][[z]]) /. {t[i_]→P, t[i_]^2→Q};
     r[[1]] (Dot @@ Take [r,-Length[r]+1]),
     {z,Length[C[m-u]]}]],
     {u,1,m-2}]) .L.K.H) [[1, m+1]] Product [t[j], {j,m}]]];
Sum[r=(List @@ C[n][[k]])
    /. {t[i_]→ToString[a], t[i_]^2 → ToString[b]};
    r[[1]] (StringJoin @@ Take [r,-n]), {k, Length [C[n]]}]];
```

More elegant but less readable *Mathematica* implementations than the one given above are possible, e.g., using NestList instead of a For loop. Since the Zassenhaus exponents for larger n are rather lengthy expressions, the computer needs a significant amount of memory for this calculation. On a standard personal computer with 2 GB of memory we could obtain the Zassenhaus exponents up to $n=17$ within about one hour of computer time.

V. EXPRESSION IN TERMS OF COMMUTATORS

In the introduction we briefly discussed Dynkin's translation[6,7] of words into commutators, which is applicable, whenever such a translation exists. Since it is known that a representation in terms of commutators exists for the Zassenhaus exponents,[9,10] we may directly use Dynkin's prescription in order to obtain an explicit representation of the Zassenhaus exponents in terms of commutators. We checked the validity of this procedure using a computer up to order $n=17$. A translation for the BCH terms into commutators involving fewer terms than Dynkin's prescription was proposed by Oteo.[8] To our knowledge the validity of this translation has never been proved in general. Oteo showed it to be valid up to order $n=10$, and we checked this conjecture up to order $n=17$ on a computer.

In analogy to Oteo's prescription for the BCH terms, we now write down an expression for the Zassenhaus exponents

$$c_n = \sum_{W(t_1,\ldots,t_n)} c(W) W(t_1,\ldots,t_n) \tag{15}$$

in terms of commutators. The words W consist of letters a and b; $n_a(W)$ counts the number of a's in that word. Analogously, $n_b(W)=n-n_a(W)$ counts the number of b's in the word W. We conjecture that the Zassenhaus exponent c_n may be expressed in terms of the left normal commutator as follows:

$$c_n = \sum_{\substack{W(t_1,\ldots,t_n)\\ t_1=b,t_2=a}} \frac{c(W)}{n_b(W)} [[\cdots[[t_1,t_2],t_3],\ldots],t_n]. \tag{16}$$

Here we only sum over words starting with the letters ba. Similarly, one may write

$$c_n = \sum_{\substack{W(t_1,\ldots,t_n)\\ t_1=a,t_2=b}} \frac{c(W)}{n_a(W)} [[\cdots[[t_1,t_2],t_3],\ldots],t_n] \tag{17}$$

and only sum over words starting with the letters ab.

We checked this conjecture up to order $n=17$ using *Mathematica* and compared results up to order $n=6$ with expressions given in the literature, e.g., in Ref. 11.

Example: For $n=4$ one finds the following representation of the Zassenhaus exponent in terms of words

$$c_4 = -\tfrac{1}{24}aaab + \tfrac{1}{8}aaba + \tfrac{1}{8}aabb - \tfrac{1}{8}abaa - \tfrac{1}{4}abab - \tfrac{1}{8}abbb + \tfrac{1}{24}baaa + \tfrac{1}{4}baba + \tfrac{3}{8}babb - \tfrac{1}{8}bbaa - \tfrac{3}{8}bbab + \tfrac{1}{8}bbba.$$

According to our conjecture this may be translated into nested commutators as

$$\begin{aligned} c_4 &= \tfrac{1}{24}[[[b,a],a],a] + \tfrac{1}{8}[[[b,a],b],a] + \tfrac{1}{8}[[[b,a],b],b] \\ &= -\tfrac{1}{24}[[[a,b],a],a] - \tfrac{1}{8}[[[a,b],a],b] - \tfrac{1}{8}[[[a,b],b],b]. \end{aligned}$$

This result agrees with results given in the literature (e.g., in Ref. 10).

VI. CONCLUSION

We developed a method for the calculation of the Zassenhaus exponents c_n in the Zassenhaus product formula $e^{a+b}=e^a\cdot e^b\cdot\prod_{n=2}^{\infty}e^{c_n}$ for noncommuting a and b. The method is given in Corollary 1, from which we obtain the Zassenhaus exponents in terms of words. It appears that our method is simpler and faster than previous methods (see, e.g., Ref. 10). We provide a suitable computer implementation.

We would like to mention that the method presented here can be easily generalized to the Zassenhaus product formula for q-deformed exponentials. (The Zassenhaus formula for q-deformed exponentials is discussed, e.g., in Ref. 11 and references therein.)

Furthermore, we formulated a conjecture on how to translate the Zassenhaus exponents given in terms of words into a form in terms of left normal nested commutators. This representation involves fewer terms than a translation based on Dynkin's theorem[7] and has been found to be valid for Zassenhaus exponents up to order $n=17$ using a computer. We expect a proof of our conjecture to be possible along the lines of Dynkin's proof for his representation of the BCH formula in terms of commutators. This proof shows essentially by direct calculation that the conjectured commutator representation is equivalent to the representation in terms of words. We will address this issue in a forthcoming paper.

On the Birman-Schwinger principle applied to $\sqrt{-\Delta+m^2}-m$

M. Maceda
Mathematisches Institut, Ludwig-Maximilians Universität, 80333 Munich, Germany

(Received 8 December 2005; accepted 30 January 2006; published online 16 March 2006)

The condition for $E=0$ to be an eigenvalue of the operator $\sqrt{-\Delta+m^2}-m+\lambda V$ is obtained through the use of the Birman-Schwinger principle (Theorem 3.2). By setting $E=-\alpha^2$ and using the analyticity of the corresponding Birman-Schwinger kernel (Theorem 3.1), the series development of λ^{-1} is obtained up to second order on α (Theorem 4.1). © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2179049]

I. INTRODUCTION

The Birman-Schwinger principle[2,24] has been extensively used in several branches of physics and mathematics. The original motivation for its implementation was the possibility of having eigenvalue counting functions for the Schrödinger equation. In this approach, the potential term is taken to be of the form λV with λ being a constant and V a potential satisfying a certain number of properties (e. g., V is nonpositive). The eigenvalue counting functions thus obtained will depend on λ, and in general, for a given operator $\mathcal{O}$, they can be defined by the following expression:

$$N(\lambda)=\{\text{number of } \mu_j \in \text{Spec}(\mathcal{O}), \mu_j < \lambda\}.$$

Research on this class of functions was actually initiated by Weyl for the Laplace operator Δ,[27,28] with an emphasis in the following years on the asymptotic expression for $N(\lambda)$ when $\lambda \to \infty$.[5,20,26] More recently, the use of microlocal analysis has indeed allowed a more detailed study of asymptotics with some proposals to replace eigenvalue counting functions by spectral shift functions.[10]

Generalizations of the method itself have also been proposed to deal with certain physical situations arising in quantum mechanics[6] and modified versions have been formulated, for example, in phonon physics where perturbations on acoustic and electromagnetic waves can be described through the presence of exponentially localized eigenmodes of their corresponding operators,[8,9] and where an analogy with the appearance of bound states for the Schrödinger equation can also be established.

In Ref. 15 the eigenvalue equation

$$(-\Delta+\lambda V)\psi=E\psi \tag{1}$$

was studied through the use of the Birman-Schwinger principle and some conditions expressing the fact that the solutions to the Schrödinger equation are in $\mathcal{L}^2(\mathbb{R}^3)$ were obtained. A related study was also done for the Dirac operator in Ref. 14. In both cases the potential V were assumed to satisfy a certain set of properties. In this work we shall apply the same techniques to the case of the pseudodifferential operator $\sqrt{-\Delta+m^2}-m$, which was studied by Herbst in the presence of a Coulomb potential.[12] This operator had also been used in other contexts such as hadronic physics.[25,7,18] For a discussion of several aspects of this relativistic operator and its relation to the Dirac operator we refer to Refs. 16, 11, 18, and 17.

In the next section we mention some basic facts regarding the Birman-Schwinger principle. Section III deals with the analyticity of the Birman-Schwinger kernel for $\sqrt{\Delta+m^2}-m$ (Theorem 3.1). In this section we also state a theorem (Theorem 3.2) providing the condition under which $E=0$ is an eigenvalue of $\sqrt{\Delta+m^2}-m+\lambda V$, with V a nonpositive potential with compact support. The series expansion of λ^{-1} up to second order on α is discussed in Sec. IV and the corresponding

expressions for the coefficients are given (Theorem 4.1). Several expressions used in the main text are derived in Appendix A and Appendix B. Appendix C contains a simple estimate on $|(\sqrt{-\Delta+m^2}-E)^{-1}(x)|$.

II. THE BIRMAN-SCHWINGER PRINCIPLE

For convenience we recall the steps leading to the Birman-Schwinger principle and how it can be used in order to extract some information about eigenvalues. One begins from a general eigenvalue equation of the form

$$H\psi=(H_0+\lambda V)\psi=E\psi \tag{2}$$

with H_0 an operator representing the kinetic energy. We shall suppose in the following that the potential $V\in C_0^\infty(\mathbb{R}^3)$ and takes negative values. The above equation then can be recast in the form

$$\psi=\lambda(H_0-E)^{-1}|V|\psi.$$

By multiplying this equation by $|V|^{1/2}$ and defining $\phi:=|V|^{1/2}\psi$ one obtains

$$\lambda K\phi=\phi,\quad K=|V|^{1/2}(H_0-E)^{-1}|V|^{1/2}. \tag{3}$$

The physical meaning behind this rewriting is that the operator K has an eigenvalue λ_0^{-1} if and only if H has an eigenvalue $E=E_0$ for $\lambda=\lambda_0$, the multiplicity in both cases being the same. One can think of this in some sense as transformation which preserves the multiplicity among the eigenvalues of these two different operators.

It is clear that the main feature of the method is to interchange the role played by the constant λ and the energy E: the usual approach in quantum mechanics when dealing with an equation as Eq. (1) is to consider the potential term as being a perturbation and under suitable assumptions, the techniques of perturbation theory can then be employed to obtain a (convergent) solution for the eigenfunctions ψ and the eigenvalues E in terms of the perturbation parameter λ. The Birman-Schwinger principle on the other hand allows one to consider the energy E as a free parameter on which a series expansion for λ can be obtained. In fact, for most practical reasons it is useful to set $E=-\alpha^2$ and consider a series development on powers of the parameter α (which is identified with the fine structure constant) as

$$(\lambda(\alpha))^{-1}=\lambda_0^{-1}+a\alpha+b\alpha^2+\cdots. \tag{4}$$

After this is done, the question is to know if one can solve the above relation for α in terms of λ and if the resulting series obtained in this way is analytic. As outlined in Ref. 15, most of the steps leading to Eq. (4) pose no difficulties on this regard but a careful analysis must be done for the second part.

III. KERNEL IN COORDINATE SPACE

In this section we study some properties of the Birman-Schwinger kernel for the operator $\sqrt{-\Delta+m^2}-m$. The integral kernel is given by Eqs. (1) and (2) in Appendix A, namely

$$K(x,y)=|V(x)|^{1/2}\frac{m}{4\pi|x-y|}\left[\left(1-\frac{\mu^2}{m^2}\right)^{1/2}e^{-\mu|x-y|}+\frac{2}{\pi}F(m|x-y|;\mu)\right]|V(y)|^{1/2}. \tag{5}$$

The potential V is assumed to be nonpositive and with compact support Ω. The parameter μ is determined from $\mu^2=m^2-(m+E)^2=-2mE-E^2$. By setting $E=-\alpha^2$, one has $\mu^2=2m\alpha^2-\alpha^4$; this parametrization will be used at the end of this section and in Sec. IV.

In order to use perturbation theory on this operator, it is necessary to prove that it depends analytically on the parameter μ. For convenience we shall set $m=1$ in the following. First, if one considers the case of real μ, it is more or less clear that Eq. (5) makes only sense as long as $0<\mu<1$, and thus one can try to look for analyticity inside the disc $|\mu|<1$ in the complex plane

(we shall see that this is not an arbitrary choice for the problem). Let us then consider (f,Kg) for $f,g\in\mathcal{L}^2$. There are four different integrals over $\mathbb{R}^3\times\mathbb{R}^3$ to be considered:

$$\text{(i)}\quad (1-\mu^2)^{1/2}\left(f,|V|^{1/2}\frac{e^{-\mu|\cdot|}}{|\cdot|}|V|^{1/2}g\right),$$

$$\text{(ii)}\quad \left(f,|V|^{1/2}\frac{K_1(|\cdot|)}{|\cdot|}|V|^{1/2}g\right),$$

$$\text{(iii)}\quad (1-\mu^2)\left(f,|V|^{1/2}e^{-\mu|\cdot|}\int_0^{|\cdot|}\cosh(\mu z)K_0(z)\mathrm{d}z\ \ V|^{1/2}g\right),$$

$$\text{(iv)}\quad (1-\mu^2)\left(f,|V|^{1/2}\sinh(\mu|\cdot|)\int_{|\cdot|}^{\infty}e^{-\mu z}K_0(z)\mathrm{d}z|V|^{1/2}g\right).$$

To deal with them we shall argue in the same way as in Ref. 14 for the Dirac operator. The argument is based on writing (f,Kg) as a sum of integrals of the form

$$c(\mu)\int\int f(x)\frac{h(x,y)}{|x-y|^2}e^{-\mu|x-y|}g(y)d^3xd^3y$$

with $h(x,y)$ a function in $\mathcal{L}^\infty(\mathbb{R}^3\times\mathbb{R}^3)$ having compact support and $c(\mu)$ an analytic function of μ. By using Sobolev's inequality one then finds that $f(x)[h(x,y)/|x-y|^2]g(y)\in\mathcal{L}^1(\mathbb{R}^3\times\mathbb{R}^3)$. The fact that K as an operator can be bounded by operators with compact support in $\mathcal{L}^2$ means that one is dealing with a meaningful object. In this way the whole problem of an analytic extension on μ is contained in the expression of the coefficients $c(\mu)$ and the exponential $e^{-\mu|x|}$.

For the first integral one immediately has $c(\mu)=(1-\mu^2)^{1/2}$ and $h(x,y)=|V(x)|^{1/2}|x-y||V(y)|^{1/2}$. In the second case obviously there is no dependence on μ and it suffices to note that with the function $h(x,y)=|V(x)|^{1/2}|x-y|K_1(|x-y|)|V(y)|^{1/2}$, which has compact support and is in $\mathcal{L}^\infty(\mathbb{R}^3\times\mathbb{R}^3)$, one has $f(x)[h(x,y)/|x-y|^2]g(y)\in\mathcal{L}^1(\mathbb{R}^3\times\mathbb{R}^3)$.

The third and fourth integral require more care: first, for the third integral one must consider $c(\mu)=(1-\mu^2)$, which is analytical on μ, and a function

$$h_\mu(x,y)=|V(x)|^{1/2}|x-y|\int_0^{|x-y|}\cosh(\mu z)K_0(z)\mathrm{d}z|V(y)|^{1/2}.$$

However, it is clear that $h_\mu(x,y)<F_1(\mu)|V(x)|^{1/2}|x-y||V(y)|^{1/2}$ where

$$F_1(\mu)=\int_0^\infty\cosh(\mu z)K_0(z)\mathrm{d}z=\frac{\pi}{2\sqrt{1-\mu^2}}$$

as an elementary calculation shows. This also points to the necessity of considering $|\mu|\neq 1$. One can now apply Sobolev inequality to the product $|V(x)|^{1/2}|x-y||V(y)|^{1/2}$, obtaining thus that $f(x)[h_\mu(x,y)/|x-y|^2]g(y)\in\mathcal{L}^1(\mathbb{R}^3\times\mathbb{R}^3)$. Furthermore, by writing $\cosh(\mu z)$ in terms of exponentials functions, it is clear that $h_\mu(x,y)$ is analytical on μ.

Consider now the fourth integral: one has as before $c(\mu)=(1-\mu^2)$ and

$$h_\mu(x,y)=|V(x)|^{1/2}|x-y|\sinh(\mu|x-y|)\int_{|x-y|}^\infty e^{-\mu z}K_0(z)\mathrm{d}z|V(y)|^{1/2}.$$

One can now see that $h_\mu(x,y)<\frac{1}{2}c|V(x)|^{1/2}|x-y||V(y)|^{1/2}$, where $c=\int_0^\infty K_0(z)\mathrm{d}z=\pi/2$, using the fact that $e^{-\mu z}\leqslant e^{-\mu a}$ for $z\in[a,\infty)$ and that $\int_a^\infty K_0(z)\mathrm{d}z\leqslant\int_0^\infty K_0(z)\mathrm{d}z$ for $a\geqslant 0$. Sobolev's inequality then

leads as in the previous case to $f(x)[h_\mu(x,y)/|x-y|^2]g(y) \in \mathcal{L}^1(\mathbb{R}^3 \times \mathbb{R}^3)$. As before, the function h_μ is analytical on μ since it involves in a simple way analytical functions of μ in its definition.

From the previous considerations we have the following.

Theorem 3.1: *Let $f,g \in \mathcal{L}^2(\mathbb{R}^3)$ then (f,Kg) where the kernel $K(x,y)$ is given by Eq. (5) is analytical in the sense of norm.*

Proof: Since we already know that (f,Kg) is analytical on μ, Theorem 3.12 in Ref. 13 can be used to deduce that K is indeed analytic in the sense of norm. □

One should notice that the fact that one is considering a potential V with compact support Ω is fundamental for this argument to work. Let us now proceed to finding under which conditions is 0 an eigenvalue of Eq. (2). On general grounds one can argue in the following way: given an operator $\mathcal{O}$ with inverse $\mathcal{O}^{-1}$, consider a function ϕ solution to the equation

$$l_0\phi = \mu_0\phi, \tag{6}$$

where $l_0 = |V|^{1/2}\mathcal{O}^{-1}|V|^{1/2}$. This equation is similar in structure to Eq. (3). Let us now define a function u through the relation

$$u = \mathcal{O}^{-1}|V|^{1/2}\phi.$$

This function satisfies the integral equation

$$u = \mathcal{O}^{-1}|V|^{1/2}\phi = \mu_0^{-1}\mathcal{O}^{-1}|V|^{1/2}|V|^{1/2}\mathcal{O}^{-1}|V|^{1/2}\phi = \mu_0^{-1}\mathcal{O}^{-1}|V|u,$$

namely

$$u(x) = \mu_0^{-1}\int_{\text{supp } V} \mathcal{O}^{-1}(x,y)|V(y)|u(y)d^3y. \tag{7}$$

In the case of a potential V with compact support, let us say Ω, one obtains a development in series for large $|x|$ of the previous expression as

$$u(x) = \mu_0^{-1}|x|^{-1}\int_\Omega c_1(y)|V(y)|u(y)d^3y + \mu_0^{-1}|x|^{-2}\int_\Omega c_2(y)|V(y)|u(y)d^3y + \cdots \tag{8}$$

and therefore

$$\int_\Omega c_1(y)|V(y)|u(y)d^3y = \mu_0\int_\Omega c_1(y)|V(y)|^{1/2}\phi(y)d^3y = 0 \tag{9}$$

must be imposed in order to have $u \in \mathcal{L}^2(\mathbb{R}^3)$. In the above the functions $c_1(y)$ and $c_2(y)$ are determined from the series development of $\mathcal{O}^{-1}(x,y)$ in powers of $1/|x|$ for large $|x|$. We have assumed that the negative powers of $|x|$ appearing in this series development are integers, which is clearly seen from Eq. (8). This might be not necessarily the most general scenario, but as long as the first term has a factor $|x|^{-\gamma}$ with $\gamma \leqslant 3/2$, as in the case we are considering, Eq. (9) will be obtained.

Along the precedent lines we can state the following theorem.

Theorem 3.2: *Let V be a nonpositive potential with compact support $\Omega \in \mathbb{R}^3$. Then $E=0$ is an eigenvalue of $\sqrt{-\Delta+m^2}-m+\lambda V$ if and only if $\int_\Omega |V(y)|u(y)d^3y = 0$, where u is the corresponding eigenfunction assumed to be in $\mathcal{L}^2(\mathbb{R}^3)$.*

Proof: According to the previous discussion, let us consider $\mathcal{O} = \sqrt{-\Delta+m^2}-m$. We have then that the operator $l_0 = |V|^{1/2}\mathcal{O}^{-1}|V|^{1/2}$ is given by

$$l_0 = |V(x)|^{1/2}\frac{m}{4\pi|x-y|}\left[1 + \frac{2}{\pi}K_1(m|x-y|) + \frac{2}{\pi}\int_0^{m|x-y|} K_0(y)\mathrm{d}y\right]|V(y)|^{1/2}$$

and that u defined as $u = \mathcal{O}^{-1}|V|^{1/2}\phi$, with $l_0\phi = \mu_0\phi$, satisfies

$$u(x)=\mu_0^{-1}(\mathcal{O}^{-1}|V|u)(x)=\frac{m}{4\pi\mu_0}\int_\Omega\frac{1}{|x-y|}\left[1+\frac{2}{\pi}K_1(m|x-y|)+\frac{2}{\pi}\int_0^{m|x-y|}K_0(y)\mathrm{d}y\right]u(y)d^3y. \tag{10}$$

Using this expression one obtains for large values of $|x|$,

$$u(x)=\frac{m}{2\pi\mu_0}\frac{1}{|x|}\int_\Omega|V(y)|u(y)d^3y+\cdots, \tag{11}$$

since $\int_0^\infty K_0(y)\mathrm{d}y=\pi/2$ and $K_1(z)\sim\sqrt{\pi/2z}e^{-z}$ for large z. It is clear that Eq. (11) corresponds to having $c_1(y)=m/2\pi$ in Eq. (8). It is then clear that if $u\in\mathcal{L}^2(\mathbb{R}^3)$ then the coefficient of $|x|^{-1}$ in Eq. (11) should vanish, leading to the condition $\int_\Omega|V(y)|u(y)d^3y=0$. On the other hand, from the Birman-Schwinger principle one knows that $u=\mu_0^{-1}\mathcal{O}^{-1}|V|u$ iff $(\mathcal{O}+\mu_0^{-1}V)u=0$, this last equation being understood in the sense of distributions. Therefore, the constraint $\int_\Omega|V(y)|u(y)d^3y=0$ is a necessary and sufficient condition for $E=0$ to be an eigenvalue of $\sqrt{-\Delta+m^2}-m+\mu_0^{-1}V$. □

One should notice that a similar condition exists for the Schrödinger operator. This can be understood on the grounds of the nonlocal behavior associated to $\sqrt{-\Delta+m^2}-m$: nonlocality is contained in the Bessel function $K_1(z)$ appearing in the function $F(m|x|;\mu=0)$ in Eq. (6) and for large distances (at least greater than m^{-1}) it becomes highly suppressed. In this situation the main contribution arises from a Schrödinger-type term [first term in Eq. (5)].

One can also try to see what happens for small values of $|x|$. In this case there are two terms to lowest order to be considered,

$$A_1=\int_\Omega\frac{1}{|y|}|V(y)|u(y)d^3y \tag{12}$$

and

$$A_2=\int_\Omega\frac{1}{|y|}|V(y)|u(y)\int_{|y|}^\infty\frac{K_1(z)}{z}\mathrm{d}z\,d^3y. \tag{13}$$

Both terms are constants, independent of $|x|$. If supp $V=\Omega$ contains the origin, then for a nondivergent value of $u(|x|=0)$ to exist, these constants should have finite values. The constant A_1 also appears when one considers a similar situation for the kernel of the Schrödinger operator. If the product $|V(y)|u(y)$ behaves like $y^{-\beta}$ with $\beta\leqslant 2$ near 0 then it is well defined (strict inequality means $A_1=0$). On the other hand, A_2 is more singular due to the presence of the integral involving the Bessel function K_1. The first integral (from $|y|$ to infinity) diverges as $1/y$ near the origin. This means that finite values are possible in this case when the product $|V(y)|u(y)$ behaves like $y^{-\beta}$ with $\beta\leqslant 1$ (again, strict inequality means a vanishing value for A_2).

IV. PERTURBATION THEORY AND FOURIER TRANSFORM

In what follows we shall consider perturbation theory for Eq. (5). From this kernel we can immediately write for α small the series development $K=L_0+(2m)^{1/2}\alpha A+2m\alpha^2B+\cdots$ where

$$L_0(x,y)=|V(x)|^{1/2}\frac{m}{4\pi|x-y}\left[2+\frac{2}{\pi}\int_{m|x-y|}^\infty\frac{K_1(z)}{z}\mathrm{d}z\right]|V(y)|^{1/2}, \tag{14}$$

$$A(x,y)=-\frac{m}{2\pi}|V(x)|^{1/2}|V(y)|^{1/2}, \tag{15}$$

and

$$B(x,y)=|V(x)|^{1/2}\frac{1}{|x-y|}\left\{\frac{1}{2}\left(|x-y|^2-\frac{1}{m^2}\right)+\frac{1}{\pi}\left(|x-y|^2-\frac{2}{m^2}\right)\int_0^{m|x-y|}K_0(z)\mathrm{d}z\right.$$
$$\left.+\frac{2|x-y|}{\pi m}\int_{m|x-y|}^{\infty}K_0(z)z\,\mathrm{d}z+\frac{1}{\pi m^2}\int_0^{m|x-y|}K_0(z)z^2\,\mathrm{d}z\right\}|V(y)|^{1/2}. \tag{16}$$

As mentioned before, the presence of the second term inside the brackets in Eq. (14) is an indication of the nonlocality of the Herbst operator. Furthermore, by going into Fourier space, one can see that the kernel of L_0 is not positive definite, and for large values of k it can take arbitrary positive and negatives values. This is due to the strong divergence produced by the integral of the quotient $K_1(z)/z$, which when coupled with the factor $1/|x-y|$ is of order 3.

Let us now find an expression for $\lambda^{-1}=(\phi,K\phi)$ [see Eq. (3)] where ϕ satisfies $L_0\phi=\mu_0\phi$ and $\|\phi\|_2=1$. We have

$$(\lambda(\alpha))^{-1}=(\phi,L_0\phi)+(2m)^{1/2}\alpha(\phi,A\phi)+2m\alpha^2(\phi,B\phi)+\cdots$$
$$=\mu_0-\frac{\alpha m^{3/2}}{\sqrt{2}\pi}\left(\int_\Omega|V(y)|^{1/2}\phi(y)d^3y\right)^2+b\alpha^2+\cdots. \tag{17}$$

The expression for the coefficient b is rather cumbersome as can be deduced from Eq. (16) and no definite statement on the sign of this coefficient can readily be established. But before with the analysis of it, let us review the general procedure used to write the energy E as a function of the parameter λ. Assuming $\mu_0\neq 0$, one deduces from the expression

$$(\lambda(\alpha))^{-1}=\mu_0+a\alpha+b\alpha^2+\cdots$$

the relation

$$\lambda_0^{-1}\lambda(\alpha)=1-\lambda_0 a\alpha+\lambda_0(\lambda_0 a^2-b)\alpha^2+\cdots,\quad \lambda_0:=\mu_0^{-1},$$

for α small. The next step is to invert this relation and to find α as a function of λ; it is here where care should be taken. If a does not vanish then one has

$$\alpha(\lambda)=-\frac{1}{\lambda_0^2 a}(\lambda-\lambda_0)+\frac{\lambda_0 a^2-b}{\lambda_0^4 a^3}(\lambda-\lambda_0)^2+\cdots$$

and therefore

$$E(\lambda)=-\alpha(\lambda)^2=-\frac{1}{(\lambda_0^2 a)^2}(\lambda-\lambda_0)^2+\cdots.$$

On the other hand, if a vanishes then

$$\lambda_0^{-1}\lambda(\alpha)=1-\lambda_0 b\alpha^2+c\alpha^3+\cdots$$

and it follows that there are two different expressions for α,

$$\alpha_\pm(\lambda)=\tilde{n}\left[\frac{1}{\lambda_0^2(-b)}(\lambda-\lambda_0)-\frac{c}{\lambda_0^3(-b)^{3/2}}(\lambda-\lambda_0)^{3/2}+\cdots\right]^{1/2}.$$

One obtains then

$$E_\pm(\lambda)=-\alpha_\pm(\lambda)^2=-\frac{1}{\lambda_0^2(-b)}(\lambda-\lambda_0)+\cdots$$

and moreover, the series development is done in powers of $(\lambda-\lambda_0)^{1/2}$. For $\mathcal{O}=\sqrt{-\Delta+m^2}-m$, the coefficient a is proportional to $(\int_\Omega|V(y)|^{1/2}\phi(y)d^3y)^2$ according to Eq. (17) and then it suffices to

recall the discussion leading to Eq. (11) to conclude that the (first) second series development corresponds to $E=0$ (not) being an eigenvalue. For the first series, when $a\neq 0$, it is possible to appeal to the implicit theorem function to deduce analyticity of $\alpha(\lambda)$ at the point λ_0 and thus of $E(\lambda)$. When $a=0$, analyticity does not hold in the Schrödinger case[15] because of an argument making use of the fact that $-\Delta+\lambda V$ only admits nonpositive eigenvalues for all $\lambda>0$ [Theorem XIII.11 in Ref. 21 applied to $V\in\mathcal{C}_0^\infty(\mathbb{R}^3)$]. Unfortunately we have not been able to find a similar result for the Herbst operator in the three-dimensional case.

We also remark that in the case when $a=0$, if λ approaches λ_0 from above by real values then b should necessarily be negative for $\alpha_\pm(\lambda)$ to be well defined. In the case of the Schrödinger equation it is known through an argument involving Fourier transform that b takes negative values when a vanishes,[15] in consequence the energy approaches a value $E_0=0$ from below as $\lambda\to\lambda_0^+$. For the Herbst operator one can proceed in the same way, i.e., one can write

$$B(x,y)=|V(x)|^{1/2}\mathcal{B}(x,y)|V(y)|^{1/2}$$

and therefore

$$b=2m^2(\phi,B\phi)=2m^2(\phi,|V|^{1/2}\mathcal{B}|V|^{1/2}\phi)=2m^2(f,\mathcal{B}f)=2m^2\int\hat{\mathcal{B}}(k)|\hat{f}(k)|^2d^3k \tag{18}$$

with $f=|V|^{1/2}\phi$. The sign of b is then related to the behavior of the Fourier transform $\hat{\mathcal{B}}$. We should also note that the fact that $a=0$ guarantees that the expression in momentum space on the right-hand side of Eq. (18) is defined as $k\to 0$.

As seen from Eq. (16) not all functions appearing in that expression have norm in $\mathcal{L}^2(\mathbb{R}^3)$, and it is then necessary to use Fourier transform in the sense of distributions to find the Fourier transform $\hat{\mathcal{B}}(k)$. The details of this are given in Appendix B, here we only write the final result of the calculations which reads as

$$\begin{aligned}b&=2m^2\int\hat{\mathcal{B}}(k)|\hat{f}(k)|^2d^3k=2m\int(m^4\hat{\mathcal{B}}(m\sigma))|\hat{f}(m\sigma)|^2d^3\sigma\\&=2m\int\left[-\frac{1}{2\pi\sigma^2}-\frac{1}{4\pi^3\sigma^4}-\frac{1}{\pi}\left[\frac{1}{8\pi^2\sigma^4}\frac{6w^4+5w^2+2}{(1+w^2)^{5/2}}+\frac{1}{\sigma^2}\frac{1}{(1+w^2)^{1/2}}\right]\right.\\&\quad\left.+\frac{3}{2\pi^2\sigma^3}\frac{w^3}{(1+w^2)^{5/2}}-\frac{1}{2\pi\sigma^2}\frac{2w^2-1}{(1+w^2)^{5/2}}\right]|\hat{f}(m\sigma)|^2d^3\sigma,\end{aligned} \tag{19}$$

where $\vec{\sigma}=\vec{k}/m$, $\sigma=|\vec{\sigma}|\in[0,\infty)$, and $w=2\pi\sigma$. Even though a positive term is present in this expression, its contribution is dominated by similar negative terms as one can easily verify from Eq. (19). Therefore one concludes that b is (conditionally) negative and that $E\to 0^-$ when $\lambda\to\lambda_0^+$. Moreover, it also follows from this expression that in the nonrelativistic case ($k=m\sigma\to 0$) the leading order contribution is given by $-\pi^{-1}\sigma^{-2}-(2\pi^3)^{-1}\sigma^{-4}$, an analogous result to the Schrödinger case.

We can resume the previous calculations in the following theorem.

Theorem 4.1: *Consider the series development of* $\lambda^{-1}=(\phi,K\phi)=\lambda_0^{-1}+a\alpha+b\alpha^2+\cdots$ *in powers of* α, *then*

(i) $a=-(m^{3/2}/\sqrt{2}\pi)(\int_\Omega|V(y)|^{1/2}\phi(y)d^3y)^2$,

(ii) *if* $a=0$ *then* $b=2m^2(f,\mathcal{B}f)$ *with* $f=|V|^{1/2}\phi$, *is conditionally negative and the Fourier transform* $\hat{\mathcal{B}}(k)$ *of the kernel* $\mathcal{B}(x,y)$ *can be read out from Eq. (19).*

V. CONCLUSIONS

It has been shown that having wave functions of the operator $\sqrt{-\Delta+m^2}-m$ in $\mathcal{L}^2(\mathbb{R}^3)$ is closely related to the vanishing of the first order coefficient a in the series development given by

Eq. (4), perturbation theory being permitted due to the analyticity of the corresponding Birman-Schwinger kernel (Theorem 3.1). The coefficient a has the same form as in the Schödinger case as seen from Eq. (17) and its vanishing can be recast as a statement on the fact that $E=0$ is an eigenvalue of the equation $(\sqrt{-\Delta+m^2}-m+\lambda V)\phi=E\phi$ (Theorem 3.2). Moreover, the second order coefficient b in Eq. (4) can be shown to consist of a Schrödinger-type part and more involved contributions due to the nonlocal nature of the operator under study. Fourier analysis however can be used to show that b is conditionally negative (Theorem 4.1). The physical consequence of these facts is similar to the Schrödinger case, namely, the phenomenon of "coupling constant threshold."

When considering the Schrödinger operator with a spherically symmetric potential V, the above characterization can be explicitly formulated as a condition for the presence of s-waves as solutions of the equation $(-\Delta+V)\Psi=0$ and indeed, it is only the behavior of Ψ at infinity, where the potential V vanishes, which should be considered to obtain this result.[15]

In the case of the Herbst operator a similar criteria should be also possible, however there is a simple feature that is present in one case and not in the other: the answer for the Schrödinger operator can readily be given because one knows precisely the expression for the operator Δ in spherical coordinates meanwhile for the Herbst operator one should study instead an integral equation. The following auxiliary problem then arises: is it possible to write an appropriate integral equation for $\Delta\Psi=0$ from which one can recover the well known radial dependence r^l and r^{-l-1}, $l=0,1,\ldots$, of the spherically symmetric solutions? The answer is yes. The next natural step is to see if the same process can be applied to the integral equation obtained from $(\sqrt{-\Delta+m^2}-m)\Psi=0$. This is a subject that we hope to discuss in a future work.

Morozov for several discussions along this work. It is also recognized the financial support received through a grant from the Quantum and Analysis network, Contract No. HPRN-CT-2002-00277.

APPENDIX A: INVERSE FOURIER TRANSFORM

In this section we would like to derive the expression for $(\sqrt{-\Delta+m^2}-E)^{-1}$ in coordinate space. Since one is lead to deal with tempered function, the Fourier transform in the generalized sense should be considered. Several ways exist to calculate the Fourier transform of tempered functions, such as the ϵ-prescription, where it is customary to consider after the calculations only those terms with no dependence on ϵ in the limit $\epsilon\to 0$. This method was widely used in the evaluation of propagators in the early days of QED. The Hankel transform[3] is the other method introduced to deal with tempered functions. It is known that the ϵ-prescription, the same being the case with the Hankel transform, is related to the notion of finite part, *Pf.* of a distributional pseudofunction (Ref. 22, pp. 20) acting on Schwartz's space $\mathcal{S}$ of infinitely differentiable and rapidly vanishing functions, together with its derivatives, at infinity. We shall also use the fact that for a distribution f, the relations $\langle\mathcal{F}(f),\phi\rangle=\langle f,\mathcal{F}(\phi)\rangle$ and $\langle\mathcal{F}^{-1}(f),\phi\rangle=\langle f,\mathcal{F}^{-1}(\phi)\rangle$ where $\phi\in\mathcal{S}$ hold.[4]

Accordingly one can write

$$\int_{\mathbb{R}^3}\frac{1}{\sqrt{4\pi^2p^2+m^2}-E}\phi(p)d^3p=E\int_{\mathbb{R}^3}\frac{1}{4\pi^2p^2+m^2-E^2}\phi(p)d^3p+\int_{\mathbb{R}^3}\frac{\sqrt{4\pi^2p^2+m^2}}{4\pi^2p^2+m^2-E^2}\phi(p)d^3p$$

$$=E\int_{\mathbb{R}^3}\frac{1}{4\pi^2p^2+m^2-E^2}\phi(p)d^3p$$

$$+(-\Delta+m^2)\int_{\mathbb{R}^3}\frac{1}{\sqrt{4\pi^2p^2+m^2}[4\pi^2p^2+\mu^2]}\phi(p)d^3p$$

$$= E\int_{\mathbb{R}^3} \frac{1}{4\pi^2p^2+\mu^2}\phi(p)d^3p$$
$$+ (-\Delta+\mu^2)\int_{\mathbb{R}^3} \frac{1}{\sqrt{4\pi^2p^2+m^2}[4\pi^2p^2+\mu^2]}\phi(p)d^3p$$
$$+ (m^2-\mu^2)\int_{\mathbb{R}^3} \frac{1}{\sqrt{4\pi^2p^2+m^2}[4\pi^2p^2+\mu^2]}\phi(p)d^3p,$$

where we have set $\mu^2=m^2-E^2$. Therefore, from $<\mathcal{F}(f),\phi>=<f,\mathcal{F}(\phi)>=<\mathcal{F}^{-1}(\mathcal{F}(f)),\phi>$, one has in the sense of distributions acting on $\mathcal{S}$,

$$\mathcal{F}^{-1}\left[\frac{1}{\sqrt{4\pi^2p^2+m^2}-E}\right](x) = E\mathcal{F}^{-1}\left[\frac{1}{4\pi^2p^2+\mu^2}\right](x)$$
$$+ (-\Delta+\mu^2)\mathcal{F}^{-1}\left[\frac{1}{\sqrt{4\pi^2p^2+m^2}[4\pi^2p^2+\mu^2]}\right](x)$$
$$+ (m^2-\mu^2)\mathcal{F}^{-1}\left[\frac{1}{\sqrt{4\pi^2p^2+m^2}[4\pi^2p^2+\mu^2]}\right](x).$$

The first term is a standard example in textbooks on Fourier transforms or potential theory and can be easily found:

$$\int_{\mathbb{R}^3}\frac{1}{4\pi^2p^2+\mu^2}\phi(p)d^3p = \int_{\mathbb{R}^3}\int_0^\infty e^{-(4\pi^2p^2+\mu^2)t}\,\mathrm{d}t\;\phi(p)d^3p$$
$$= \int_{\mathbb{R}^3}\int_0^\infty\int_{\mathbb{R}^3} e^{-4\pi^2p^2t+2\pi p\cdot x}d^3p e^{-\mu^2t}\mathcal{F}(\phi)(x)d^3x$$
$$= \int_{\mathbb{R}^3}\int_0^\infty \frac{1}{(4\pi t)^{3/2}}\exp[-|x|^2/4t-\mu^2t]dt\mathcal{F}(\phi)(x)d^3x$$
$$= \frac{\mu}{(4\pi)^{3/2}}2\sqrt{\frac{2}{\mu|x|}}\int_{\mathbb{R}^3}K_{1/2}(m|x|)\mathcal{F}(\phi)(x)d^3x = \int_{\mathbb{R}^3}\frac{e^{-\mu|x|}}{4\pi|x|}\mathcal{F}(\phi)(x)d^3x$$

with $\phi\in\mathcal{S}$. In the above we have use Fubini's theorem and an integral representation of the Bessel functions $K_\nu(z)$. For the second and third term one should calculate the inverse Fourier transform

$$\mathcal{F}^{-1}\left[\frac{1}{\sqrt{4\pi^2p^2+m^2}[4\pi^2p^2+\mu^2]}\right](x).$$

Using the fact that the usual properties of convolution of the (inverse) Fourier transform remain valid for distributions,[4] then the problem reduces to the convolution of $\mathcal{F}^{-1}[1/(4\pi^2p^2+\mu^2)](x)$ with $\mathcal{F}^{-1}[1/\sqrt{4\pi^2p^2+m^2}](x)$. This latter inverse Fourier transform can be found in the same way as done before with the result

$$\int_{\mathbb{R}^3}\frac{1}{\sqrt{4\pi^2p^2+m^2}}\phi(p)d^3p = \frac{m}{2\pi^2}\int_{\mathbb{R}^3}\frac{K_1(m|x|)}{|x|}\mathcal{F}(\phi)(x)d^3x.$$

Therefore, in distributional sense, one has the following expression:

$$\mathcal{F}^{-1}\left[\frac{1}{\sqrt{4\pi^2p^2+m^2}-E}\right](x)=\frac{E}{4\pi|x|}e^{-\mu|x|}+(-\Delta+\mu^2)\left[\frac{e^{-\mu|\cdot|}}{4\pi|\cdot|}*\frac{m}{2\pi^2}\frac{K_1(m|\cdot|)}{|\cdot|}\right](x)$$
$$+\frac{m(m^2-\mu^2)}{8\pi^3}\left[\frac{e^{-\mu|\cdot|}}{|\cdot|}*\frac{K_1(m|\cdot|)}{|\cdot|}\right](x)$$
$$=\frac{E}{4\pi|x|}e^{-\mu|x|}+\frac{m}{2\pi^2}\frac{K_1(m|x|)}{|x|}+\frac{m(m^2-\mu^2)}{8\pi^3}\left[\frac{e^{-\mu|\cdot|}}{|\cdot|}*\frac{K_1(m|\cdot|)}{|\cdot|}\right](x).$$

It is clear from the above that this expression might be treated indeed as an ordinary function if the convolution in the last line makes sense. In fact, using the expansion[1]

$$\frac{e^{-\lambda R}}{\lambda R}=\frac{2}{\pi}\sum_{l=0}^{\infty}(2l+1)\left[\sqrt{\frac{\pi}{2\lambda r_1}}I_{l+1/2}(\lambda r_1)\right]\left[\sqrt{\frac{\pi}{2\lambda r_2}}K_{l+1/2}(\lambda r_2)\right]P_l(\cos\gamma),$$

where $R=[r^2+\rho^2-2r\rho\cos(\gamma)]^{1/2}, r_1=\min(r,\rho), r_2=\max(r,\rho)$, only the term with $l=0$ is seen to give a nonvanishing contribution for the convolution after performing the integral over the angular variables. Therefore, one obtains

$$\left[\frac{e^{-\mu|\cdot|}}{|\cdot|}*\frac{K_1(m|\cdot|)}{|\cdot|}\right](x)=\frac{4\pi}{m^2}\frac{2\mu}{\pi}\sqrt{\frac{\pi}{2\mu|x|}}K_{1/2}(\mu|x|)\int_0^{m|x|}\sqrt{\frac{m\pi}{2\mu y}}I_{1/2}\left(\frac{\mu y}{m}\right)K_1(y)y\,dy$$
$$+\frac{4\pi}{m^2}\frac{2\mu}{\pi}\sqrt{\frac{\pi}{2\mu|x|}}I_{1/2}(\mu|x|)\int_{m|x|}^{\infty}\sqrt{\frac{m\pi}{2\mu y}}K_{1/2}\left(\frac{\mu y}{m}\right)K_1(y)y\,dy$$
$$=\frac{4\pi}{m^2|x|}e^{-\mu|x|}\int_0^{m|x|}\frac{m}{\mu y}\sinh\left(\frac{\mu y}{m}\right)K_1(y)y\,dy$$
$$+\frac{4\pi}{m}\frac{\sinh(\mu|x|)}{\mu|x|}\int_{m|x|}^{\infty}e^{-\mu y/m}K_1(y)dy.$$

The explicit expressions of the Bessel functions $I_{1/2}(x)$ and $K_{1/2}(x)$ have been used in order to write the above relation. The final outcome of the previous calculations is then

$$\mathcal{F}^{-1}\left[\frac{1}{\sqrt{4\pi^2p^2+m^2}-E}\right](x)=\frac{m}{4\pi|x|}\left[\frac{E}{m}e^{-\mu|x|}+\frac{2}{\pi}F(m|x|;\mu)\right]$$
$$=\frac{m}{4\pi|x|}\left[\left(1-\frac{\mu^2}{m^2}\right)^{1/2}e^{-\mu|x|}+\frac{2}{\pi}F(m|x|;\mu)\right] \tag{A1}$$

with

$$F(m|x|;\mu)=K_1(m|x|)+\frac{m^2-\mu^2}{4\pi}|x|\left[\frac{e^{-\mu|\cdot|}}{|\cdot|}*\frac{K_1(m|\cdot|)}{|\cdot|}\right](x)=K_1(m|x|)+\left(1-\frac{\mu^2}{m^2}\right)$$
$$\times\left[e^{-\mu|x|}\int_0^{m|x|}\left[\frac{m}{\mu y}\right]\sinh\left(\frac{\mu y}{m}\right)K_1(y)y\,dy+\frac{m}{\mu}\sinh(\mu|x|)\int_{m|x|}^{\infty}e^{-\mu y/m}K_1(y)dy\right]$$
$$=K_1(m|x|)+\left(1-\frac{\mu^2}{m^2}\right)\left[e^{-\mu|x|}\int_0^{m|x|}\cosh\left(\frac{\mu y}{m}\right)K_0(y)dy-\sinh(\mu|x|)\int_{m|x|}^{\infty}e^{-\mu y/m}K_0(y)dy\right]. \tag{A2}$$

In the above we have used some relations among integrals involving Bessel and exponentials functions[19,1] in order to write the last expression.

APPENDIX B: FOURIER TRANSFORM OF $\mathcal{B}(x,y)$

For convenience we present here the calculations leading to Eq. (19) in the text. In the expression for $\mathcal{B}$, several tempered functions in the sense of distributions appear and their Fourier transforms, which will be also tempered functions, can be found in this context.

In the following we shall apply the Hankel transform to a well-behaved function suited to the problem (strictly speaking the Hankel transform refers to the one-dimensional case) and then argue its validity for more general cases.

To begin with we shall use the formula (Ref. 3, Sec. 43)

$$\mathcal{F}(f,k)=\frac{2\pi}{k^{(n-2)/2}}\int_0^{+\infty}\mathrm{d}r\, f(r)r^{n/2}J_{(n-2)/2}(2\pi kr).$$

Here n is the dimension of the space under consideration. Let us apply this to the function $f(x)=|x|^{-\alpha}\int_0^{m|x|}g(z)\mathrm{d}z$ with $0<\alpha$, we have

$$\begin{aligned}\mathcal{F}(f,r)&=\frac{2\pi}{r^{(n-2)/2}}\int_0^{\infty}\mathrm{d}r\, r^{-\alpha}\int_0^{mr}\mathrm{d}z\, g(z)r^{n/2}J_{(n-2)/2}(2\pi kr)\\&=\frac{2\pi}{r^{(n-2)/2}}\int_0^{\infty}\mathrm{d}r\, r^{n/2-\alpha}J_{(n-2)/2}(2\pi kr)\int_0^{mr}\mathrm{d}z\, g(z)\\&=\frac{2\pi}{k^{(n-2)/2}}\frac{1}{(2\pi k)^{n/2-\alpha+1}}\int_0^{\infty}\mathrm{d}z\, g(z)\int_{z/m}^{\infty}\mathrm{d}u\, u^{n/2-\alpha}J_{(n-2)/2}(u)\\&=\frac{1}{(2\pi)^{n/2-\alpha}}\frac{1}{k^{n-\alpha}}\left[\int_0^{\infty}\mathrm{d}z\, g(z)\int_0^{\infty}\mathrm{d}u\, u^{n/2-\alpha}J_{(n-2)/2}(u)-\int_0^{\infty}\mathrm{d}z\, g(z)\int_0^{wz}\mathrm{d}u\, u^{n/2-\alpha}J_{(n-2)/2}(u)\right].\end{aligned}$$

In the above we have defined a dimensionless parameter $w=2\pi k/m$ and assumed that the function $g(z)$ is well behaved so that Fubini's theorem can be used. For our function $g(z)$ we shall take indeed $g(z)=z^{\beta}K_0(z), 0\leqslant\beta$. The previous expression is justified as long as $n/2<\alpha<n$ since the integrals involving the Bessel function $J_\nu(u)$ are then well defined. After using the relations

$$\int_0^{\infty}s^{\mu}J_{\nu}(s)\mathrm{d}s=2^{\mu}\Gamma\left(\frac{\nu+\mu+1}{2}\right)\Big/\Gamma\left(\frac{\nu-\mu+1}{2}\right),$$

$$\int_0^{\infty}s^{\mu}K_{\nu}(s)\mathrm{d}s=2^{\mu-1}\Gamma\left(\frac{\mu+\nu+1}{2}\right)\Gamma\left(\frac{\mu-\nu+1}{2}\right),$$

and

$$\int_0^{x}s^{\mu}J_{\nu}(s)\mathrm{d}s=x^{\mu+1}\sum_{k=0}^{\infty}\frac{(-1)^k(x/2)^{\nu+2k}}{k!(\mu+\nu+2k+1)\Gamma(\nu+k+1)},$$

one arrives to

$$\mathcal{F}(f,r)=\frac{1}{(2\pi)^{n/2-\alpha}}\frac{1}{k^{n-\alpha}}\left[2^{\beta+n/2-\alpha-1}\Gamma\left(\frac{\beta+1}{2}\right)^2\frac{\Gamma\left(\frac{n-\alpha}{2}\right)}{\Gamma\left(\frac{\alpha}{2}\right)}\right.$$
$$\left.-w^{n-\alpha}2^{\beta+n/2-\alpha-1}\sum_{m=0}^{\infty}\frac{(-w^2)^m}{m!\left(m+\frac{n-\alpha}{2}\right)}\frac{\Gamma\left(m+\frac{\beta+n-\alpha+1}{2}\right)^2}{\Gamma\left(m+\frac{n}{2}\right)}\right].$$

The sum inside the brackets is just a hypergeometric function; the final result then reads as

$$\mathcal{F}(f,r)=\frac{1}{(2\pi)^{n/2-\alpha}}\frac{1}{k^{n-\alpha}}\left[2^{\beta+n/2-\alpha-1}\Gamma\left(\frac{\beta+1}{2}\right)^2\frac{\Gamma\left(\frac{n-\alpha}{2}\right)}{\Gamma\left(\frac{\alpha}{2}\right)}-w^{n-\alpha}2^{\beta+n/2-\alpha}\frac{\Gamma\left(\frac{\beta+n-\alpha+1}{2}\right)^2}{(n-\alpha)\Gamma\left(\frac{n}{2}\right)}\right.$$
$$\left.\times\,{}_3F_2\left(\frac{n-\alpha}{2},\frac{\beta+n-\alpha+1}{2},\frac{\beta+n-\alpha+1}{2};\frac{n}{2},1+\frac{n-\alpha}{2};-w^2\right)\right]. \tag{B1}$$

Using a reasoning due to Schwartz (Ref. 23, p. 113), this expression can be seen to hold also for other values of α, in particular for $\alpha<0$, if one keeps in mind that the function f should be then understood as a tempered function as well as its Fourier transform. More care should be taken when $n-\alpha=-2h$, $\alpha=-2h$, or $\beta+n-\alpha+1=-2h$, h being a positive integer, where poles appear in the Γ function, but the appropriate modification to be used for those cases has also been pointed out by Schwartz. This modification will not concern us however because of the values of α (±1 or 0) appearing in Eq. (16) and of the dimension $n=3$. As a particular case then one can consider $\alpha=1,\beta=0,n=3$,

$$\mathcal{F}(f,r)=\frac{1}{(2\pi)^{1/2}}\frac{1}{k^2}\left[\frac{\pi^{1/2}}{2^{1/2}}-\frac{w^2}{2^{1/2}}\Gamma(3/2)\,{}_3F_2(1,3/2,3/2;3/2,2;-w^2)\right]=\frac{1}{2k^2}\frac{1}{(1+w^2)^{1/2}}.$$

This corresponds, taking into account a factor $-2/(\pi m^2)$ and replacement $k=m\sigma$, to the second term inside the brackets in Eq. (19).

It is also straightforward from the previous computation to identify the Fourier transform of $f(x)=|x|^{-\alpha}\int_{m|x|}^{\infty}g(z)\mathrm{d}z, 0<\alpha$, this is given by the second term in Eq. (B1), namely

$$\mathcal{F}(f,r)=\frac{1}{(2\pi)^{n/2-\alpha}}\frac{1}{k^{n-\alpha}}w^{n-\alpha}2^{\beta+n/2-\alpha}\frac{\Gamma\left(\frac{\beta+n-\alpha+1}{2}\right)^2}{(n-\alpha)\Gamma\left(\frac{n}{2}\right)}$$
$$\left.\times\,{}_3F_2\left(\frac{n-\alpha}{2},\frac{\beta+n-\alpha+1}{2},\frac{\beta+n-\alpha+1}{2};\frac{n}{2},1+\frac{n-\alpha}{2};-w^2\right)\right]. \tag{B2}$$

This formula can also be generalized to other values of α than those in the interval $(n/2,n)$, with care needed only to be taken in more detail at the points mentioned in a previous paragraph. Taking this into account, if we now calculate the case $\alpha=0,\beta=1,n=3$, the following expression is obtained:

$$\mathcal{F}(f,r)=\frac{1}{(2\pi)^{3/2}}\frac{1}{k^3}w^3 2^{5/2}\frac{\Gamma(5/2)^2}{3\Gamma(3/2)}{}_3F_2(3/2,5/2,5/2;3/2,5/2;-w^2)=\frac{3}{4\pi}\frac{1}{k^3}w^3 2^{3/2}\frac{1}{(1+w^2)^{5/2}}$$

corresponding, times a factor $2/(\pi m)$ and replacement $k=m\sigma$, to the positive term in Eq. (19).

APPENDIX C: AN ESTIMATE

We rewrite Eq. (1) as

$$(\sqrt{-\Delta+m^2}-E)^{-1}(|x|)=\frac{m}{4\pi|x|^2}\left[\left(1-\frac{\mu^2}{m^2}\right)^{1/2}|x|e^{-\mu|x|}+\frac{2}{\pi}|x|F(m|x|;\mu)\right].$$

We would like to show that for a fixed value of μ, each term inside the brackets is bounded as function of $|x|$. This is obviously true for $h_0(|x|)=|x|e^{-\mu|x|}(\leqslant\mu^{-1})$ and also for the first term coming from the product $|x|F(m|x|;\mu)$, namely $h_1(|x|)=|x|K_1(m|x|)(\leqslant 1)$. The next two terms to consider are

$$h_2(|x|)=|x|e^{-\mu|x|}\int_0^{m|x|}\cosh\left(\frac{\mu y}{m}\right)K_0(y)\mathrm{d}y$$

and

$$h_3(|x|)=|x|\sinh(\mu|x|)\int_{m|x|}^{\infty}e^{-\mu y/m}K_0(y)\mathrm{d}y.$$

h_2 can be seen to be bounded as follows:

$$\begin{aligned}h_2(|x|)&\leqslant\mu^{-1}\int_0^{\infty}\cosh\left(\frac{\mu y}{m}\right)K_0(y)\mathrm{d}y=\frac{1}{2\mu}\int_0^{\infty}\cosh\left(\frac{\mu y}{m}\right)\int_0^{\infty}\exp\left[-\frac{1}{u}-\frac{uy^2}{4}\right]\frac{\mathrm{d}u}{u}\mathrm{d}y\\&=\frac{1}{4\mu}\int_0^{\infty}\int_{-\infty}^{\infty}\exp\left[-\frac{uy^2}{4}+\frac{\mu y}{m}\right]\mathrm{d}y\,e^{-1/u}\frac{\mathrm{d}u}{u}=\frac{\pi^{1/2}}{2\mu}\int_0^{\infty}\exp\left[-\frac{1}{u}\left(1-\frac{\mu^2}{m^2}\right)\right]\frac{\mathrm{d}u}{u^{3/2}}\\&=\frac{\pi}{2\mu}\left(1-\frac{\mu^2}{m^2}\right)^{-1/2}.\end{aligned}$$

Let us turn now to h_3, one has

$$h_3(|x|)\leqslant|x|e^{\mu|x|}\int_{m|x|}^{\infty}K_0(y)e^{-\mu y/m}\,\mathrm{d}y\leqslant|x|\int_{m|x|}^{\infty}K_0(y)\mathrm{d}y\leqslant m|x_0|^2K_0(m|x_0|),$$

where $m|x_0|$ satisfies the transcendental equation $\int_z^{\infty}K_0(y)\mathrm{d}y=zK_0(z)$ with solution $z=0.745\,1315$. From this follows also that $m|x_0|K_0(m|x_0|)<\pi/2$ and hence

$$h_3(|x|)<\pi|x_0|/2\leqslant c\pi/2m,\quad c\in[0.745\,1315,\infty).$$

Collecting all the previous results we have the following estimate:

$$\begin{aligned}|(\sqrt{-\Delta+m^2}-E)^{-1}(|x|)|&\leqslant\frac{m}{4\pi|x|^2}\left[\left(1-\frac{\mu^2}{m^2}\right)^{1/2}\frac{1}{\mu}+\frac{2}{\pi}\left[1+\left(1-\frac{\mu^2}{m^2}\right)\left[\frac{\pi}{2\mu}\left(1-\frac{\mu^2}{m^2}\right)^{-1/2}+\frac{c\pi}{2m}\right]\right]\right]\\&\leqslant\frac{m}{4\pi|x|^2}\left[1+\frac{2}{\mu}+\frac{c}{m}\right].\end{aligned}\tag{C1}$$

The multitime correlation functions, free white noise, and the generalized Poisson statistics in the low density limit

A. N. Pechen[a)]
Department of Chemistry, Frick Laboratory, Princeton University, Princeton, New Jersey 08544-1009

(Received 1 April 2005; accepted 26 January 2006; published online 22 March 2006)

In the present paper the low density limit of the nonchronological multitime correlation functions of boson number type operators is investigated. We prove that the limiting truncated nonchronological correlation functions can be computed using only a subclass of diagrams associated to noncrossing pair partitions and thus coincide with nontruncated correlation functions of suitable free number operators. The independent in the limit subalgebras are found and the limiting statistics is investigated. In particular, it is found that the cumulants of certain elements coincide in the limit with the cumulants of the Poisson distribution. An explicit representation of the limiting correlation functions and thus of the limiting algebra is constructed in a special case through suitably defined quantum white noise operators. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2178154]

I. INTRODUCTION

The reduced dynamics of a quantum open system interacting with a reservoir in certain physical regimes is approximated by Markovian master equations. These regimes include the weak system-reservoir interactions and dilute reservoirs and in the theoretical framework they are described by certain limits. For a weakly interacting system one considers the limit as the coupling constant goes to zero (weak coupling limit, WCL) whereas for a dilute reservoir one considers the limit as the density of the reservoir goes to zero (low density limit, LDL) and an appropriate time rescaling should be performed in order to get a nontrivial limit. The Markovian reduced dynamics in these limits is considered in the review papers by Spohn and Lebowitz.[1,2] The reduced dynamics in the LDL was considered in details later by Dümcke[3] using the method based on the quantum Bogoliubov-Born-Green-Kirkwood-Yvon hierarchy.

The total dynamics in these limits is governed by various quantum stochastic equations. There is a unique up to now approach, called the *stochastic limit method*, which allows an efficient derivation of the stochastic equations in the WCL. This approach is based on the quantum white noise technique and was developed by Accardi, Lu, and Volovich.[4]

The convergence of the evolution operator of the total system in the LDL to a solution of a quantum stochastic equation was proved by Accardi and Lu[5] and by Rudnicki, Alicki, and Sadowski.[6] Recently the low density limit was investigated with the quantum white noise technique.[7,8] This technique, well developed for the WCL, was nontrivially modified to include the LDL and for this case was called *the stochastic golden rule for the low density limit*. This technique was applied to the derivation of the quantum stochastic equations in the LDL. An advantage of the obtained equations is that they, in contrast with the exact Schrödinger equation, are explicitly solvable. At the same time they provide a good approximation of the exact dynamics.

[a)]Electronic mail: apechen@princeton.edu

The approach of Refs. 7 and 8 uses the so-called Fock–anti-Fock representation for the canonical commutation relations (CCR) algebra (this representation is unitary equivalent to the Gel'fand-Naimark-Segal representation). The difficulty with this approach is that the creation and annihilation operators in the Fock–anti-Fock Hilbert space do not describe creation and annihilation of physical particles and thus do not have direct physical meaning. To avoid this difficulty the investigation of the LDL directly in terms of the physical fields was performed.[9] Using this approach the chronological correlation functions in the LDL were found and the corresponding stochastic equations derived.

In the present paper we investigate the low density limit of the nonchronologically ordered correlation functions of boson number type operators. The investigation is related with *ab initio* derivations of quantum stochastic equations describing quantum dynamics of a test particle interacting with a dilute gas. We find the limiting truncated correlation functions of the number type operators and show that they can be computed by representing the number operators through creation and annihilation operators and then considering only a subclass of diagrams associated to noncrossing pair partitions. This fact allows to represent the limiting truncated correlation functions as the nontruncated correlation functions of number operators of a free quantum white noise thus making a connection with the Voiculescu free probability theory. We find the limiting statistics and show that the cumulants of certain elements coincide in the limit with the cumulants of the Poisson distribution.

The free probability theory was developed by Voiculescu around 1985 as a way to deal with von Neumann algebras of free groups. Then the theory was separated from this special context and began to develop as an independent field. In particular, applications of the free independence theory to random matrices were found. The details of free probability theory and its applications to random matrices could be found, for example, in Refs. 10 and 11.

Expectations of free random variables are characterized by diagrams associated to noncrossing pair partitions. The vanishing of crossing diagrams in the stochastic weak coupling limit for nonrelativistic QED and for the Anderson model was found in Refs. 4 and 12, respectively, thus making a connection between the WCL and free probability. The WCL is typically described by the quantum Boltzmann statistics.[4] In Ref. 13 a generalized version of Boltzmann commutation relations, the so-called entangled commutation relations, was found in the weak coupling limit for nonlinear interactions and possible applications to photon splitting cascades were discussed.

The investigation of the multitime nonchronologically ordered correlation functions could have a connection with the behavior of fluctuations in certain asymptotic regimes. The latter is described in the review paper by Andries, Benatti, De Cock, and Fannes.[14] In that approach the limiting statistics is defined in terms of ground state distribution determined by nontrivial pair partitions. The authors conjecture the appearance of exotic statistics in certain asymptotic regimes. The asymptotic fluctuations are the limiting correlation functions of appropriate centered elements and thus the results of the present paper could be applied to study the fluctuations in the low density limit.

In Sec. II the truncated nonchronologically ordered correlation functions are defined and their low density limit is established (Theorem 1). In Sec. III the irreducible diagrams (pair partitions) which contribute to the limiting correlation functions are found (Theorem 2). In Sec. IV the limiting truncated correlation functions are represented as correlation functions of a suitable free white noise. In Sec. V we identify the independent in the limit subalgebras (Theorem 4) and calculate the limiting cumulants which for some elements coincide with the cumulants of the Poisson distribution (Theorem 5). In Sec. VI an explicit representation of the limiting correlation functions and thus of the limiting algebra is constructed for a special case by using suitable quantum white noise operators.

II. THE CORRELATION FUNCTIONS IN THE LDL

We begin this section with construction of a general class of noncommutative probability spaces relevant for the investigation of the low density limit. The framework of a *-probability space is used. A relation between the objects defined in this section and the model of a test particle interacting with a dilute gas is given in Appendix A.

Definition 1: A *-probability space *is a pair* $(\mathcal{A},\omega)$, *where* $\mathcal{A}$ *is a unital* *-*algebra over* $\mathbb{C}$ *and* $\omega:\mathcal{A}\to\mathbb{C}$ *is a state, i.e., a linear normalized,* $\omega(1_{\mathcal{A}})=1$, *and strictly positive functional.*

Let $\mathcal{H}$ be a Hilbert space with inner product denoted by $\langle\cdot,\cdot\rangle$ (called as one particle Hilbert space), $\{S_t\}_{t\in\mathbb{R}}$ a one parameter unitary group in $\mathcal{H}$ (a one particle free evolution), $\hat{n}$ a bounded positive operator in $\mathcal{H}$ (density operator) such that $\forall t\in\mathbb{R}, S_{-t}\hat{n}S_t=\hat{n}$, and B a countable set of real numbers.

Let $\Gamma(\mathcal{H})$ be the symmetric Fock space over $\mathcal{H}$. For any trace class self-adjoint operator T acting in $\mathcal{H}$ we denote by $N(T)\equiv \mathrm{d}\Gamma(T)$ its second quantization operator in $\Gamma(\mathcal{H})$ and extend this definition by complex linearity to the set of all trace class operators $\mathcal{T}(\mathcal{H})$. For any $T\in\mathcal{T}(\mathcal{H}), \omega\in B$, and a positive number $\epsilon>0$ we define the following operator in $\Gamma(\mathcal{H})$:

$$N_{T,\omega,\epsilon}(t) := \frac{e^{-it\omega/\epsilon}}{\epsilon} N(S_{t/\epsilon}TS_{-t/\epsilon}). \tag{1}$$

Let $L(\mathbb{R})=\cap_{p\in\mathbb{N}}L^p(\mathbb{R})$, where $L^p(\mathbb{R})$ is the space of p-power integrable functions over $\mathbb{R}$. For any open subset $\Lambda\subseteq\mathbb{R}$ let $L(\Lambda)$ be the set of functions from $L(\mathbb{R})$ with support in Λ. We denote by $\mathcal{A}_{\Lambda,\epsilon}$ the *-algebra generated by operators $N_{T,\omega,\epsilon}(\varphi) := \int \mathrm{d}t\, \varphi(t)N_{T,\omega,\epsilon}(t)$ with $T\in\mathcal{T}(\mathcal{H})$, $\omega\in B$, $\varphi\in L(\Lambda)$ and denote $\mathcal{A}_{\epsilon} := \mathcal{A}_{\mathbb{R},\epsilon}$.

Let $A^{\pm}(g)$, $g\in\mathcal{H}$ be the creation and annihilation operators in $\Gamma(\mathcal{H})$ [we denote in the sequel $A^{-}(g)\equiv A(g)$] with the canonical commutation relations $[A(f),A^{+}(g)]=\langle f,g\rangle$ and let $\mathcal{A}_{\mathrm{CCR}}$ be the algebra of polynomials in $A^{\pm}(\cdot)$. Any operator $N(T)$ can be represented in terms of the creation and annihilation operators. For example, if $T=|f\rangle\langle g|$, where we use Dirac's notations for elements $f,g\in\mathcal{H}$, then $N(T)=A^{+}(f)A(g)$. An arbitrary operator $N(T)$ can be expressed in terms of $A^{\pm}$ using the fact that any trace class operator T is a limit of finite rank operators. Thus the algebra $\mathcal{A}_{\epsilon}$ is a subalgebra of $\mathcal{A}_{\mathrm{CCR}}$.

Let $\omega_{\hat{n}}$ be a Gaussian gauge-invariant mean-zero state on $\mathcal{A}_{\mathrm{CCR}}$ with the two point correlation function $\omega_{\hat{n}}(A^{+}(f)A(g)) := \langle g,\hat{n}f\rangle$ [thus $\omega_{\hat{n}}(N(T))=\mathrm{Tr}(\hat{n}T)$ and here we use the assumption for T being trace class]. Denoting by the same symbol its restriction to $\mathcal{A}_{\Lambda,\epsilon}$, we finally have for any $\epsilon>0$ and for any open subset $\Lambda\subseteq\mathbb{R}$ the *-probability space $(\mathcal{A}_{\Lambda,\epsilon},\omega_{\epsilon\hat{n}})$.

Remark 1: The condition $\forall t: S_{-t}\hat{n}S_t=\hat{n}$ *leads to the invariance of the state* $\omega_{\hat{n}}$ *under the free evolution generated by* S_t.

With the notations above we define the nonchronologically ordered multitime correlation functions as

$$W_{\epsilon,\hat{n},T_1,\omega_1,\ldots,T_n,\omega_n}(t_1,\ldots,t_n) := \omega_{\epsilon\hat{n}}(N_{T_1,\omega_1,\epsilon}(t_1)\cdots N_{T_n,\omega_n,\epsilon}(t_n)), \tag{2}$$

$$W_{\epsilon,\hat{n},T_1,\omega_1,\ldots,T_n,\omega_n}(\varphi_1,\ldots,\varphi_n) := \omega_{\epsilon\hat{n}}(N_{T_1,\omega_1,\epsilon}(\varphi_1)\cdots N_{T_n,\omega_n,\epsilon}(\varphi_n)). \tag{3}$$

We will use for the correlation functions (2) and (3) also the shorter notations $W_{\epsilon}(t_1,\ldots,t_n)$ and $W_{\epsilon}(\varphi_1,\ldots,\varphi_n)$. The reason for introducing the averaged operators $N_{T,\omega,\epsilon}(\varphi)$ and the averaged correlation functions (3) is that, as we will show below, the nonaveraged operators $N_{T,\omega,\epsilon}(t)$ and the correlation functions (2) in the limit as $\epsilon\to 0$ become singular distributions. Clearly, one has the relation

$$W_{\epsilon}(\varphi_1,\ldots,\varphi_n)=\int \mathrm{d}t_1\cdots\mathrm{d}t_n\, W_{\epsilon}(t_1,\ldots,t_n)\varphi_1(t_1)\cdots\varphi_n(t_n).$$

Definition 2: The truncated correlation functions $W^{\mathrm{T}}_{\epsilon}(t_1,\ldots,t_n)$ *are defined for* $n=1$ *by*

$W^{\mathrm{T}}_{\epsilon}(t_1) := W_{\epsilon}(t_1)$ *and for* $n>1$ *by induction through the relation:*

$$W_{\epsilon}(t_1,\ldots,t_n) = W^{\mathrm{T}}_{\epsilon}(t_1,\ldots,t_n) + \sum_{l=2}^{n}\sum_{n}{}' W^{\mathrm{T}}_{\epsilon}(t_{i_1},\ldots,t_{i_{k_1}}) \times W^{\mathrm{T}}_{\epsilon}(t_{i_{k_1+1}},\ldots,t_{i_{k_2}})\cdots W^{\mathrm{T}}_{\epsilon}(t_{i_{k_l}},\ldots,t_{i_n}),$$

where Σ'_n *is the sum over* $i_1<i_2<\cdots i_{k_1}$, $i_{k_1+1}<\cdots<i_{k_2},\ldots,<i_{k_l+1}<\cdots<i_n$.

The truncated correlation functions are often used in quantum field theory and in quantum kinetic theory.[15] They entirely determine the corresponding nonchronological correlation functions. Thus the investigation of the limit of the nonchronological correlation functions can be reduced to the investigation of the limit of the truncated correlation functions.

We define the "projection" $P_E := (2\pi)^{-1}\int \mathrm{d}t\, S_t e^{-itE}$ [it has the property $P_E P_{E'} = \delta(E-E')P_E$] and for any $k=1,2,\ldots,n$ denote $\tilde{\omega}_k = \omega_n+\cdots+\omega_k$. The following theorem states the low density limit of the truncated correlation functions.

Theorem 1: One has the limit in the sense of distributions in variables $t_1,\ldots,t_n$,

$$\lim_{\epsilon\to 0} W^{\mathrm{T}}_{\epsilon,\hat{n},T_1,\omega_1,\ldots,T_n,\omega_n}(t_1,\ldots,t_n) = (2\pi)^{n-1}\delta(t_2-t_1)\cdots\delta(t_n-t_{n-1}) \times \delta_{\tilde{\omega}_1,0}\int \mathrm{d}E\,\mathrm{Tr}[\hat{n}P_{E+\tilde{\omega}_1}T_1 P_{E+\tilde{\omega}_2}T_2\cdots P_{E+\tilde{\omega}_n}T_n], \tag{4}$$

where Tr *denotes trace and* $\delta_{\tilde{\omega}_1,0}$ *is the Kronecker delta symbol.*

The theorem is a corollary of Theorem 2 from Sec. III.

III. THE NONTRIVIAL DIAGRAMS

In the present section we investigate the low density limit of the nonchronologically ordered correlation functions for the particular case of operators of the form $T_l = |f_l\rangle\langle g_l|$ and find the diagrams which are nontrivial in the low density limit.

In order to simplify the notations we will use the following energy representation for the creation and annihilation operators:

$$A^+_l := \frac{e^{-it_l E_l/\epsilon}}{\sqrt{\epsilon}} A^+(P_{E_l} f_l), \quad A_l := \frac{1}{\sqrt{\epsilon}} A(S_{t_l/\epsilon} g_l)$$

(a slightly different version of the energy representation was introduced in Ref. 7). One has $N_{T_l,\omega_l,\epsilon}(t_l) = e^{-it_l\omega_l/\epsilon}\int \mathrm{d}E_l\, A^+_l A_l$. Notice that the operator A^+_l is not the adjoint of A_l. The symbols A_l, A^+_l are used only to simplify the notations below.

A multitime correlation function can be expressed using Gaussianity of the state $\omega_{\hat{n}}$ and the energy representation for the creation and annihilation operators as

$$W_{\epsilon,\hat{n},T_1,\omega_1,\ldots,T_n,\omega_n}(t_1,\ldots,t_n) = \exp\left(-i\sum_{l=1}^{n}\omega_l t_l/\epsilon\right)\sum{}' \int \mathrm{d}E_1\cdots\mathrm{d}E_n\, \omega_{\epsilon\hat{n}}(A^+_{i_1}A_{j_1})\cdots \times \omega_{\epsilon\hat{n}}(A^+_{i_k}A_{j_k})\omega_{\epsilon\hat{n}}(A_{j_{k+1}}A^+_{i_{k+1}})\cdots\omega_{\epsilon\hat{n}}(A_{j_n}A^+_{i_n}), \tag{5}$$

where Σ' is the sum over $k=1,\ldots,n$, $1=i_1<i_2<\cdots<i_k, j_{k+1}<\cdots<j_n$, $i_l \leqslant j_l$ for $l=1,\ldots,k$ and $j_l<i_l$ for $l=k+1,\ldots,n$. The sum contains terms of the form

$$\omega_{\epsilon\hat{n}}(A^+_{i_1}A_{j_1})\cdots\omega_{\epsilon\hat{n}}(A^+_{i_k}A_{j_k})\omega_{\epsilon\hat{n}}(A_{j_{k+1}}A^+_{i_{k+1}})\cdots\omega_{\epsilon\hat{n}}(A_{j_n}A^+_{i_n}). \tag{6}$$

To each such term we associate a diagram by pairing in the string $A^+_1A_1A^+_2A_2\cdots A^+_nA_n$ the operators $A^+_{i_l}$ and A_{j_l} for $l=1,2,\ldots,n$.

Definition 3: We say that the expression (6) *corresponds to a reducible diagram if there exists*

a nonempty subset $I \subset \{1,\ldots,n\}$ *(strict inclusion) such that* $i_l \in I \Leftrightarrow j_l \in I$. *Otherwise we say that the expression* (6) *corresponds to an irreducible diagram.*

An important property of the truncated correlation functions (Definition 2) is that they keep only all irreducible diagrams. The following are the examples of irreducible (first) and reducible (second) diagrams for $n=2$:

$$A_1^+ A_1 A_2^+ A_2 \qquad\qquad A_1^+ A_1 A_2^+ A_2 \tag{7}$$

Given a reducible diagram, one can represent the set $\{1,\ldots,n\}$ as a union of several disjoint subsets $I_1,\ldots,I_l$ such that the diagram contains only pairings between operators with indices from the same subsets. In this sense a general reducible diagram can be represented as a union of mutually disjoint irreducible diagrams. Examples of the truncated correlation functions, the corresponding irreducible diagrams, and their limits as $\epsilon \to 0$ for $n=1,2,3$ are given below.

Example 1: $n=1$. The invariance of the state under the free evolution leads to the identity $W_\epsilon^{\mathrm{T}}(t) = W_\epsilon(t) = W_\epsilon(0) = \langle g_1, \hat{n} f_1 \rangle$.

Example 2: $n=2$. One has

$$W_\epsilon^{\mathrm{T}}(t_1,t_2) = W_\epsilon(t_1,t_2) - W_\epsilon(t_1)W_\epsilon(t_2) = \int \mathrm{d}E_1\, \mathrm{d}E_2\, \omega_{\epsilon\hat{n}}(A_1^+ A_2)\omega_{\epsilon\hat{n}}(A_1 A_2^+)$$

$$= \int \mathrm{d}E_1\, \mathrm{d}E_2 \frac{e^{i(t_2-t_1)(E_2-E_1)/\epsilon}}{\epsilon} \langle g_2, P_{E_2}\hat{n} f_1\rangle \langle g_1, (1+\epsilon\hat{n}) P_{E_2} f_2\rangle. \tag{8}$$

This expression corresponds to the first (irreducible) diagram in (7) which is nonzero in the limit. Application of Lemma 1 (see Appendix B) to the right-hand side (rhs) of (8) gives

$$\lim_{\epsilon\to 0} W_\epsilon^{\mathrm{T}}(t_1,t_2) = 2\pi\delta(t_2-t_1) \int \mathrm{d}E \langle g_2, P_E \hat{n} f_1\rangle \langle g_1, P_E f_2\rangle.$$

Example 3: $n=3$. One has

$$W_\epsilon^{\mathrm{T}}(t_1,t_2,t_3) = \int \mathrm{d}E_1\, \mathrm{d}E_2\, \mathrm{d}E_3 [\omega_{\epsilon\hat{n}}(A_1^+ A_3)\omega_{\epsilon\hat{n}}(A_1 A_2^+)\omega_{\epsilon\hat{n}}(A_2 A_3^+) + \omega_{\epsilon\hat{n}}(A_1^+ A_2)\omega_{\epsilon\hat{n}}(A_1 A_3^+)\omega_{\epsilon\hat{n}}(A_2^+ A_3)].$$

This expression corresponds to the sum of the two irreducible diagrams:

$$A_1^+ A_1 A_2^+ A_2 A_3^+ A_3 + A_1^+ A_1 A_2^+ A_2 A_3^+ A_3$$

In this case only the first diagram is non-zero in the limit and Lemma 1 gives

$$\lim_{\epsilon\to 0} W_\epsilon^{\mathrm{T}}(t_1,t_2,t_3) = (2\pi)^2 \delta(t_3-t_2)\delta(t_2-t_1) \int \mathrm{d}E \langle g_3, P_E \hat{n} f_1\rangle \langle g_1, P_E f_2\rangle \langle g_2, P_E f_3\rangle.$$

The case of arbitrary n is described by the following theorem.

Theorem 2: Let $T_l = |f_l\rangle\langle g_l|$, *where* $f_l, g_l \in \mathcal{H}$ *for* $l=1,2,\ldots,n$. *One has the limit in the sense of distributions in variables* $t_1,\ldots,t_n$,

$$\lim_{\epsilon\to 0} W^{\mathrm{T}}_{\epsilon,\hat{n},T_1,\omega_1,\ldots,T_n,\omega_n}(t_1,\ldots,t_n) = (2\pi)^{n-1}\delta(t_2-t_1)\cdots\delta(t_n-t_{n-1})\delta_{\tilde{\omega}_1,0} \int \mathrm{d}E \langle g_n, P_E \hat{n} f_1\rangle$$

$$\times \langle g_1, P_{E+\tilde{\omega}_2} f_2\rangle \cdots \langle g_{n-1}, P_{E+\tilde{\omega}_n} f_n\rangle. \tag{9}$$

For each n only the following irreducible diagram is non zero as $\epsilon \to 0$:

$$A_1^+ A_1 A_2^+ A_2 A_3^+ A_3 A_4^+ \ldots A_{n-1} A_n^+ A_n \tag{10}$$

Proof: Case (a): $\omega_1 = \omega_2 = \cdots = \omega_n = 0$. Using the correlation functions

$$\omega_{\epsilon\hat{n}}(A_{i_\alpha}^+ A_{j_\alpha}) = e^{i(t_{i\alpha} - t_{j_\alpha})E_{i_\alpha}/\epsilon} \langle g_{j_\alpha}, \hat{n} f_{i_\alpha} \rangle,$$

$$\omega_{\epsilon\hat{n}}(A_{j_\beta} A_{i_\beta}^+) = \frac{e^{i(t_{i\beta} - t_{j_\beta})E_{i_\beta}/\epsilon}}{\epsilon} \langle g_{j_\beta}, (1 + \epsilon\hat{n}) f_{i_\beta} \rangle,$$

one can write (6) as

$$\frac{1}{\epsilon^n} \exp\{i[(t_1 - t_{j_1})E_1 + \cdots + (t_{i_n} - t_{j_n})E_{i_n}]/\epsilon\}(\epsilon^k F(E) + O(\epsilon^{k+1})), \tag{11}$$

where

$$F(E) = \prod_{l=1}^{k} \langle g_{j_l}, P_{E_l} \hat{n} f_{i_l} \rangle \prod_{l=k+1}^{n} \langle g_{j_l}, P_{E_{il}} f_{i_l} \rangle.$$

Define the permutations p_i and p_j of the set $(1, \ldots, n)$ by $p_i(l) = i_l$ and $p_j(l) = j_l$ for $l = 1, \ldots, n$ and let $p_\alpha = p_i p_j^{-1}$. Consider the expression in the square brackets in the exponent in (11). The term proportional to t_l in this expression has the form $t_l(E_l - E_{\alpha_l})$, where $\alpha_l = p_\alpha(l)$. Thus (11) can be written as

$$\frac{1}{\epsilon^n} \exp\{i[t_n(E_n - E_{\alpha_n}) + \cdots + t_1(E_1 - E_{\alpha_1})]/\epsilon\}(\epsilon^k F(E) + O(\epsilon^{k+1}))$$

and with the notations $\Omega_l(E) = E_n + \cdots + E_l - E_{\alpha_n} - \cdots - E_{\alpha_l}$ for $l = 2, \ldots, n$ as

$$\frac{e^{i(t_n - t_{n-1})\Omega_n(E)/\epsilon}}{\epsilon} \cdots \frac{e^{i(t_2 - t_1)\Omega_2(E)/\epsilon}}{\epsilon} (\epsilon^{k-1} F(E) + O(\epsilon^k)). \tag{12}$$

If the expression (6) corresponds to an irreducible diagram then the functions $\Omega_l(E)$ are linearly independent and, since they are linear in their arguments, the convolution $\delta(\Omega_2(E)) \cdots \delta(\Omega_n(E))$ is well defined.

In the case $k > 1$, since for any $l = 2, \ldots, n$ (see Lemma 1),

$$\lim_{\epsilon \to 0} \frac{e^{i(t_l - t_{l-1})\Omega_l(E)/\epsilon}}{\epsilon} = 2\pi \delta(t_l - t_{l-1}) \delta(\Omega_l(E)) \tag{13}$$

and $k - 1 > 0$, the limit of (12) equals zero.

In the case $k = 1$ the expression (6) corresponds to the diagram (10) and one has

$$\omega_{\epsilon\hat{n}}(A_1^+ A_n) \omega_{\epsilon\hat{n}}(A_1 A_2^+) \cdots \omega_{\epsilon\hat{n}}(A_{n-1} A_n^+)$$

$$= \frac{e^{i(t_n - t_{n-1})\Omega_n(E)/\epsilon}}{\epsilon} \cdots \frac{e^{i(t_2 - t_1)\Omega_2(E)/\epsilon}}{\epsilon} (F(E) + O(\epsilon)), \tag{14}$$

where $\Omega_l(E) = E_l - E_1$. Using (13) one finds that the limit of the rhs of (14) is

$$(2\pi)^{n-1} \delta(t_2 - t_1) \cdots \delta(t_n - t_{n-1}) \delta(E_2 - E_1) \cdots \delta(E_n - E_1)$$

$$\times\langle g_n, P_{E_1}\hat{n}f_1\rangle\langle g_1, P_{E_2}f_2\rangle\cdots\langle g_{n-1}, P_{E_n}f_n\rangle.$$

Integration over $E_1\cdots E_n$ gives the equality (9) in the case (a).

Case (b): arbitrary $\omega_1,\ldots,\omega_n$. In this case the expression (14) in the decomposition (5) is multiplied by the factor $\exp(-i\Sigma_l\omega_l t_l/\epsilon)$. The product can be written as

$$\frac{e^{i(t_n-t_{n-1})(\Omega_n(E)-\tilde{\omega}_n)/\epsilon}}{\epsilon}\cdots\frac{e^{i(t_2-t_1)(\Omega_2(E)-\tilde{\omega}_2)/\epsilon}}{\epsilon}e^{-it_1\tilde{\omega}_1/\epsilon}(F(E)+O(\epsilon)).$$

If $\tilde{\omega}_1=0$ then the statement of the theorem follows by the same arguments as in the case (a). If $\tilde{\omega}_1\neq 0$ then the limit of this term equals to zero by Riemann-Lebesgue lemma due to the presence of the rapidly oscillating factor $\exp(-it_1\tilde{\omega}_1/\epsilon)$. □

IV. THE FREE WHITE NOISE NUMBER OPERATORS

In the present section we show that the limiting truncated correlation functions coincide with the complete (i.e., nontruncated) correlation functions of the free white noise number operators.

Definition 4: Free white noise operators $N_T(t)$ *are the operators satisfying the multiplication rule*

$$N_T(t)N_{T'}(t') = \delta(t-t')N_{T*T'}(t), \tag{15}$$

*where the *-product of operators T and T' is defined by* $T*T' := 2\pi\int \mathrm{d}E\, P_E T P_E T'$.

Remark 2: *We call the operators $N_T(t)$ as* free (or Boltzmann) number operators *since they can be constructed using the creation and annihilation operators $B_f^{\pm}(t)$ satisfying the free relations $B_f^-(t)B_g^+(t')=2\pi\delta(t-t')\langle f,g\rangle$. In fact, define $N_{|f\rangle\langle g|}(t) := \int \mathrm{d}E\, B^+_{P_{Ef}}(t)B^-_{P_{Eg}}(t)$ and extend this definition by linearity to any T. Then such defined operators satisfy the relation* (15).

Let $\mathcal{A}$ be the algebra generated by the free white noise operators $N_T(t)$ and let $\phi_{\hat{n}}$ be the state on $\mathcal{A}$ characterized by $\phi_{\hat{n}}(N_T(t))=Tr(\hat{n}T)$.

Theorem 3: *One has the equality*

$$\lim_{\epsilon\to 0} W^{\mathrm{T}}_{\epsilon,\hat{n},T_1,0,\ldots,T_n,0}(t_1,\ldots,t_n) = \phi_{\hat{n}}(N_{T_1}(t_1)\cdots N_{T_n}(t_n)). \tag{16}$$

Proof: By direct calculations using the Eq. (4) and the relation (15).

The existence of the representation of the limiting truncated correlation functions by the free white noise number operators is related to the fact that only a subclass of the noncrossing irreducible diagrams survives in the low density limit. We emphasize however, that the left-hand side (lhs) of Eq. (16) is the limit of a truncated correlation function whereas the rhs contains the complete correlation function.

V. INDEPENDENCE AND THE GENERALIZED POISSON STATISTICS IN THE LDL

The fact that the limiting truncated correlation functions are the distributions in variables $t_1,\ldots,t_n$ with support at $t_1=\cdots=t_n$ leads to the appearance of independent subalgebras in the low density limit. In the beginning of this section we remind the basic notions of independent subalgebras and of cumulants. Then we find the asymptotically independent subalgebras of $\mathcal{A}_\epsilon$ and discuss the limiting statistics. We show that the cumulants and the moments of certain elements in the algebra $\mathcal{A}_\epsilon$ in the low density limit coincide with the cumulants and the moments of the Poisson distribution.

Definition 5: *Let $(\mathcal{A},\omega)$ be a *-probability space. A family of unital *-subalgebras $\{\mathcal{A}_i\}_{i\in I}$, $\mathcal{A}_i\subset\mathcal{A}$, is called* independent *if $\omega(a_1\cdots a_n)=0$ whenever $a_l\in\mathcal{A}_{i_l}, \omega(a_l)=0$, and $k\neq l$ implies $i_k\neq i_l$.*

Definition 6: *Let $(\mathcal{A},\omega)$ be a *-probability space*. Cumulants *of the space $(\mathcal{A},\omega)$ are the multilinear functionals $\kappa_n:\mathcal{A}^n\to\mathbb{C}, n\geq 1$, uniquely determined by $\kappa_1(a):=\omega(a), a\in\mathcal{A}$, and for $n>1$ by induction through the relation*

$$\omega(a_1 \cdots a_n) = \sum_{\pi,\pi=:\{A_1,\ldots,A_k\}} \kappa_{|A_j|}((a_1,\ldots,a_n)|A_j),$$

where the sum is over all partitions π *of the set* $\{1,\ldots,n\}$ *and* "$(a_1,\ldots,a_n)|A$" *designates the set of* a_i *with* $i \in A$.

Remark 3: The cumulants $\kappa_n^{(\epsilon)}$ *for a *-probability space* $(\mathcal{A}_\epsilon, \omega_{\epsilon\hat{n}})$ *are directly related to the truncated correlation functions. Namely, if* $a_1 = N_{T_1,\omega_1,\epsilon}(\varphi_1), \ldots, a_n = N_{T_n,\omega_n,\epsilon}(\varphi_n)$, *then* $\kappa_n^{\epsilon}(a_1,\ldots,a_n) = W^{\mathrm{T}}_{\epsilon,\hat{n},T_1,\omega_1,\ldots,T_n,\omega_n}(\varphi_1,\ldots,\varphi_n)$.

For the analysis of independence in the low density limit we introduce the notion of asymptotically independent subalgebras for a *-probability space $(\mathcal{A}_\epsilon, \omega_{\epsilon\hat{n}})$.

Definition 7: Let $(\mathcal{A}_\epsilon, \omega_{\epsilon\hat{n}})$ *be a *-probability space for the LDL. We say that a family of subalgebras* $\mathcal{A}_{1,\epsilon},\ldots,\mathcal{A}_{l,\epsilon}$ *of* $\mathcal{A}_\epsilon$ *is* asymptotically independent *if*

$$\lim_{\epsilon\to 0} \omega_{\epsilon\hat{n}}(a_1,\ldots,a_n) = 0$$

whenever $a_l \in \mathcal{A}_{i_l,\epsilon}, \omega_{\epsilon\hat{n}}(a_l) = 0$, *and* $k \neq l$ *implies* $i_k \neq i_l$.

The next theorem identifies asymptotically independent subalgebras of $\mathcal{A}_\epsilon$.

Theorem 4: *Let* $\Lambda_1,\ldots,\Lambda_l$ *be a family of disjoint open subsets in* $\mathbb{R}$. *Then the family of subalgebras* $\mathcal{A}_{\Lambda_1,\epsilon},\ldots,\mathcal{A}_{\Lambda_l,\epsilon}$ *is asymptotically independent*.

The proof follows from the fact that the truncated correlation functions become in the limit as $\epsilon \to 0$ distributions in variables $t_1,\ldots,t_n$ with support at $t_1 = t_2 = \cdots = t_n$. □

Now let us analyze the statistics which appears in the low density limit. From Theorem 1 and the relation between the cumulants and the truncated correlation functions it follows that lth cumulant for the element $a = N_{T,\omega,\epsilon}(\varphi)$ in the limit has the form

$$\kappa_l(a,\ldots,a) := \lim_{\epsilon\to 0} W^{\mathrm{T}}_{\epsilon,\hat{n},T,\omega,\ldots,T,\omega}(\varphi,\ldots,\varphi) = \frac{1}{2\pi}\delta_{\omega,0}\int \mathrm{d}t\,\mathrm{d}E\,\mathrm{Tr}\,\hat{n}[2\pi\varphi(t)P_E T]^l. \tag{17}$$

We specify the further consideration to the case $\mathcal{H} = L^2(\mathbb{R}^3)$. Consider $\hat{n} = 1$ (identity operator) and $S_t = e^{itH_1}$ where H_1 is the multiplication operator by the function $\omega(\mathbf{k}) = |\mathbf{k}|^2$, $\mathbf{k} \in \mathbb{R}^3$. Let T_λ be the integral operator in $\mathcal{H}$ with the kernel $T_\lambda(\mathbf{k},\mathbf{k}') = (2\pi\sqrt{|\mathbf{k}||\mathbf{k}'|})^{-1}\chi_{[0,\sqrt{\lambda}]}(|\mathbf{k}|)\chi_{[0,\sqrt{\lambda}]}(|\mathbf{k}'|)$, where λ is a positive number and $\chi_{[0,\sqrt{\lambda}]}$ is the characteristic function of the interval $[0,\sqrt{\lambda}]$. Let $\varphi_0(t) = (2\pi)^{-1}\chi_{[0,2\pi]}(t)$.

Theorem 5: *Let* $a_\lambda = N_{T_\lambda,\omega,\epsilon}(\varphi_0)$, *where* T_λ *and* φ_0 *are defined as above. Then for any* $l \in \mathbb{N}$ *one has*

$$\kappa_l(a_\lambda,\ldots,a_\lambda) = \lambda\,\delta_{\omega,0}.$$

Thus, the cumulants of the element a_λ *in the case* $\omega = 0$ *coincide in the low density limit with the cumulants of the Poisson distribution with expectation equal to* λ.

Proof: The proof of the theorem is based on the direct calculation of the cumulants using Eq. (17). One has

$$\frac{1}{2\pi}\int \mathrm{d}t[2\pi\varphi_0(t)]^l = 1.$$

One also has

$$\int \mathrm{d}E\,\mathrm{Tr}\,\hat{n}[P_E T_\lambda]^l = \int \mathrm{d}E \int \mathrm{d}\mathbf{k}_1\cdots\mathrm{d}\mathbf{k}_l\,\delta(|\mathbf{k}_1|^2 - E)T_\lambda(\mathbf{k}_1,\mathbf{k}_2)$$

$$\times\,\delta(|\mathbf{k}_2|^2 - E)T_\lambda(\mathbf{k}_2,\mathbf{k}_3)\cdots\delta(|\mathbf{k}_l|^2 - E)T_\lambda(\mathbf{k}_l,\mathbf{k}_1)$$

$$= \int \mathrm{d}E \left[T_\lambda(\sqrt{E}, \sqrt{E}) \int \mathrm{d}\mathbf{k}\ \delta(|\mathbf{k}|^2 - E) \right]^l = \int \mathrm{d}E\ \chi_{[0,\sqrt{\lambda}]}(\sqrt{E}) = \lambda .$$

Thus the rhs of Eq. (17) equals $\lambda \delta_{\omega,0}$. This proves the theorem. □

Moments of the element a_λ in the case $\omega=0$ in the low density limit are equal to the sum over all partitions of the limiting cumulants and given by Touchard polynomials,

$$\lim_{\epsilon \to 0} \omega_{\epsilon \hat{n}}(a_\lambda^n) = \sum_{k=1}^{n} S(n,k) \lambda^k,$$

where $S(n,k)$ is a Stirling number of the second kind, i.e., the number of partitions of a set of size n into k disjoint nonempty subsets. The limiting moments coincide with the moments of the Poisson distribution with expectation equal to λ. For a_1 one has

$$\lim_{\epsilon \to 0} \omega_{\epsilon \hat{n}}(a_1^n) = B_n,$$

where B_n is the nth Bell number, i.e., the number of partitions of a set of size n. The Bell numbers are the moments of the Poisson distribution with expectation equal to 1.

VI. AN OPERATOR REPRESENTATION OF THE LIMITING CORRELATION FUNCTIONS

In the present section we explicitly realize the limiting correlation functions as correlation functions of certain operators acting in a suitable Hilbert space. Presence of delta functions in the limiting correlation functions suggests that they can be represented as correlation functions of certain white noise operators. Here such a representation is constructed in the special case using the results of Ref. 7.

Let $g_0, g_1 \in \mathcal{H}$ satisfy the condition $\langle g_0, S_t g_1 \rangle = 0$ for any $t \in \mathbb{R}$. Define for $n,m=0,1$ the Hilbert space $\mathcal{K}_{nm} := L^2(\mathrm{Spec}\, H_1, \mathrm{d}\mu_{nm})$, where $\mathrm{Spec}\, H_1 \subset \mathbb{R}$ is the spectrum of H_1 and $\mathrm{d}\mu_{nm} := \langle g_n, P_E g_n \rangle \langle g_m, P_E \hat{n} g_m \rangle \mathrm{d}E$. Let $\mathcal{K} := \oplus_{n,m=0,1} \mathcal{K}_{nm}$ and let $\mathcal{H}_{\mathrm{WN}} := \Gamma(L^2(\mathbb{R}, \mathcal{K}))$ be the symmetric Fock space over the Hilbert space of square integrable $\mathcal{K}$-valued functions on $\mathbb{R}$ (abbreviation WN here stands for white noise). Using the natural decomposition $\mathcal{H}_{\mathrm{WN}} = \oplus_{n,m=0,1} \Gamma(L^2(\mathbb{R}, \mathcal{K}_{nm}))$ one can define the creation and annihilation operator valued distributions $B^{\pm}_{m,n}(E,t)$ acting in $\mathcal{H}_{\mathrm{WN}}$ and satisfying the canonical commutation relations

$$[B^-_{m,n}(E,t), B^+_{m',n'}(E',t')] = 2\pi \delta(t'-t) \delta(E'-E) \langle g_m, P_E g_{m'} \rangle \langle g_{n'}, P_E \hat{n} g_n \rangle. \tag{18}$$

The operator valued distributions $B^{\pm}_{m,n}(E,t)$ are called time-energy quantum white noise due to the presence of $\delta(t'-t)\delta(E-E')$ in (18). Let us define the number operators,

$$\tilde{N}_{m,n}(E,t) := \sum_{n'=0,1} \frac{1}{\langle g_{n'}, P_E \hat{n} g_{n'} \rangle} B^+_{m,n'}(E,t) B^-_{n,n'}(E,t)$$

and denote $N_{g_m, g_n}(t) := \int \mathrm{d}E [\tilde{N}_{m,n}(E,t) + B^-_{n,m}(E,t) + B^+_{m,n}(E,t)]$. Let $\Omega \in \mathcal{H}_{\mathrm{WN}}$ be the vacuum vector.

Theorem 6: *Let* $T_1 = |g_{m_1}\rangle\langle g_{n_1}|, \ldots, T_k = |g_{m_k}\rangle\langle g_{n_k}|$, *where* $m_1, n_1, \ldots, m_k, n_k \in \{0,1\}$. *One has the equality*

$$\lim_{\epsilon \to 0} W_{\epsilon, \hat{n}, T_1, 0, \ldots, T_k, 0}(t_1, \ldots, t_k) = \langle \Omega, N_{g_{m_1}, g_{n_1}}(t_1) \cdots N_{g_{m_k}, g_{n_k}}(t_k) \Omega \rangle. \tag{19}$$

Proof. The right-hand side of (19) has the form

$$\langle \Omega, N_{g_{m_1},g_{n_1}}(t_1)\cdots N_{g_{m_k},g_{n_k}}(t_k)\Omega\rangle = \int \mathrm{d}E_1\cdots \mathrm{d}E_k \langle \Omega, [\tilde{N}_{m_1,n_1}(E_1,t_1) + B^-_{m_1,n_1}(E_1,t_1) + B^+_{m_1,n_1}(E_1,t_1)]\cdots [\tilde{N}_{m_k,n_k}(E_k,t_k) + B^-_{n_k,m_k}(E_k,t_k) + B^+_{m_k,n_k}(E_k,t_k)]\Omega\rangle$$

Let us denote $\tilde{N}_{m,n}(t) := \int \mathrm{d}E\, \tilde{N}_{m,n}(E,t)$. The truncated correlation function corresponds to the term

$$\int \mathrm{d}E\, \mathrm{d}E' \langle \Omega, B^-_{n_1,m_1}(E,t_1)\tilde{N}_{m_2,n_2}(t_2)\tilde{N}_{m_3,n_3}(t_3)\cdots \tilde{N}_{m_{k-1},n_{k-1}}(t_{k-1})B^+_{m_k,n_k}(E',t_k)\Omega\rangle. \tag{20}$$

Notice that $\tilde{N}_{m,n}(t)\Omega = 0$. Therefore (20) equals

$$\int \mathrm{d}E\, \mathrm{d}E' \langle \Omega, [\cdots [[B^-_{n_1,m_1}(E,t_1), \tilde{N}_{m_2,n_2}(t_2)], \tilde{N}_{m_3,n_3}(t_3)]\cdots \tilde{N}_{m_{k-1},n_{k-1}}(t_{k-1})]B^+_{m_k,n_k}(E',t_k)\Omega\rangle.$$

The commutators can be calculated by induction using the canonical commutation relations (18). The result is

$$(2\pi)^{k-2}\delta(t_2-t_1)\cdots\delta(t_{k-1}-t_{k-2})\int \mathrm{d}E\, \mathrm{d}E' \langle g_{n_1}, P_E g_{m_2}\rangle\cdots\langle g_{n_{k-2}}, P_E g_{m_{k-1}}\rangle \times \langle \Omega, B^-_{n_{k-1},m_1}(E,t_{k-1})B^+_{m_k,n_k}(E',t_k)\Omega\rangle. \tag{21}$$

The last two-point correlation function can be calculated using the commutation relations (18). This gives for (21) the expression

$$(2\pi)^{k-1}\delta(t_2-t_1)\cdots\delta(t_k-t_{k-1})\int \mathrm{d}E \langle g_{n_1}, P_E g_{m_2}\rangle\cdots\langle g_{n_{k-1}}, P_E g_{m_1}\rangle\langle g_{n_k}, P_E \hat{n} g_{m_1}\rangle$$

which coincides with the rhs of (9) in the case $\omega_1 = \cdots = \omega_k = 0$.

Remark 4: The limiting correlation functions could be represented as expectations of certain quantum white noise operators in the general case if one could construct a Hilbert space $\mathcal{H}_{\mathrm{WN}}$, *a vector* $\Omega \in \mathcal{H}_{\mathrm{WN}}$, *and operator valued distributions* $B^{\pm}_{f,g}(E,t)$ *and* $\tilde{N}_{f,g}(E,t)$ *in* $\mathcal{H}_{\mathrm{WN}}$ *with the property* $B^-_{f,g}(E,t)\Omega = \tilde{N}_{f,g}(E,t)\Omega = 0$ *and satisfying the commutation relations*

$$[B^-_{f,g}(E,t), B^+_{f',g'}(E',t')] = 2\pi\delta(t'-t)\delta(E'-E)\langle f, P_E f'\rangle\langle g', P_E \hat{n} g\rangle, \tag{22}$$

$$[B^-_{f,g}(E,t), \tilde{N}_{f',g'}(E',t')] = 2\pi\delta(t'-t)\delta(E-E')\langle f, P_E f'\rangle B^-_{g',g}(E,t), \tag{23}$$

$$[\tilde{N}_{f,g}(E,t), \tilde{N}_{f',g'}(E',t')] = 2\pi\delta(t'-t)\delta(E'-E)[\langle g, P_E f'\rangle N_{f,g'}(E,t) - \langle g', P_E f\rangle N_{f',g}(E,t)]. \tag{24}$$

Suppose there exist such operators. Define $N_{f,g}(t) := \int \mathrm{d}E[\tilde{N}_{f,g}(E,t) + B^-_{g,f}(E,t) + B^+_{f,g}(E,t)]$. *Then one can prove exactly in the same way as in Theorem 6 that*

$$\lim_{\epsilon\to 0} W_{\epsilon,\hat{n}|f_1\rangle\langle g_1|,0,\ldots,|f_n\rangle\langle g_n|,0}(t_1,\ldots,t_n) = \langle \Omega, N_{f_1,g_1}(t_1)\cdots N_{f_n,g_n}(t_n)\Omega\rangle.$$

APPENDIX A

Here we make a connection between the objects defined in Sec. II and the model of a test particle interacting with a dilute Bose gas (see Ref. 9 for details).

The one particle Hilbert space for this model has the form $\mathcal{H}\equiv L^2(\mathbb{R}^3)$, where $\mathbb{R}^3$ is the three-dimensional coordinate or momentum space. The one particle free evolution is a unitary group $S_t\equiv e^{itH_1}$ whose generator H_1 in the momentum representation is the multiplication operator by the function $\omega(\mathbf{k})=|\mathbf{k}|^2/2m$, where m is the mass of a gas particle. The test particle is characterized by its Hilbert space $\mathcal{H}_S$ and its free Hamiltonian H_S acting in $\mathcal{H}_S$ which is assumed to have a discrete spectrum. The discrete set B is the set of all transition frequencies of the test particle, or equivalently, the spectrum of its free Liouvillean $-i[H_S,\cdot]$.

The dynamics of a test particle interacting with a gas is described by an evolution operator $U(t)$ acting in $\mathcal{H}_S\otimes\Gamma(\mathcal{H})$ and satisfying in the interaction picture, after the time rescaling $t\rightarrow t/\epsilon$, the following Schrödinger equation:

$$\frac{\mathrm{d}U(t/\epsilon)}{\mathrm{d}t}=-i\left[\sum_{l,\omega}Q_{l,\omega}\otimes N_{T_l,\omega,\epsilon}(t)\right]U(t/\epsilon). \tag{A1}$$

Here $Q_{l,\omega}$ are certain operators in $\mathcal{H}_S$ such that $[H_S,Q_{l,\omega}]=-\omega Q_{l,\omega}$ and T_l are certain operators in $\mathcal{H}$. The explicit form of these operators is determined by the details of the microscopic interaction between the test particle and particles of the gas. Equation (A1) is the place where the operators $N_{T,\omega,\epsilon}(t)$ appear.

The condition $S_{-t}\hat{n}S_t=\hat{n}$ and positivity of $\hat{n}$ imply that for this model $\hat{n}$ is a multiplication operator by a function $n:\mathbb{R}^3\rightarrow[0,\infty)$. The value $n(\mathbf{k})$ has the meaning of the density of gas particles at momentum $\mathbf{k}$. If the state of the gas is $\omega_{\epsilon\hat{n}}$ then the density of gas particles and the rate of collisions between the test particle and the gas are of order ϵ. Thus the limit $\epsilon\rightarrow 0$ is the low density limit. The limit is nontrivial since the dynamics is studied on the kinetic time scale of order $1/\epsilon$.

APPENDIX B

Let $S(\mathbb{R})$ be the Schwartz space over $\mathbb{R}$ and let $S'(\mathbb{R})$ be the dual space of distributions. We reproduce the following lemma from Ref. 4.

Lemma 1: One has the limit in $S'(\mathbb{R})\times S'(\mathbb{R})$,

$$\lim_{\epsilon\rightarrow 0}\frac{e^{itx/\epsilon}}{\epsilon}=2\pi\delta(t)\delta(x),$$

Proof: Let $f,\phi\in S(\mathbb{R})$ and let $\tilde{f}$ be Fourier transform of f, $\tilde{f}(\tau)=\int\mathrm{d}x\,e^{i\tau x}f(x)$. One has the identifies

$$I:=\lim_{\epsilon\rightarrow 0}\int\mathrm{d}t\,\mathrm{d}x\frac{e^{itx/\epsilon}}{\epsilon}f(x)\phi(t)=\lim_{\epsilon\rightarrow 0}\int\mathrm{d}\tau\,\phi(\epsilon\tau)\int\mathrm{d}x\,e^{i\tau x}f(x)=\lim_{\epsilon\rightarrow 0}\int\mathrm{d}\tau\,\phi(\epsilon\tau)\tilde{f}(\tau).$$

Since $\tilde{f}\in S(\mathbb{R})$, the function $\phi(\epsilon\tau)\tilde{f}(\tau)$ satisfies the conditions of the Lebesgue lemma which allows to exchange the limit and integration in the last expression. Thus

$$I=\phi(0)\int\mathrm{d}\tau\,\tilde{f}(\tau)=2\pi\phi(0)f(0).$$

Relativistic and nonrelativistic anyons are described in a unified formalism by means of the coadjoint orbits of the symmetry groups in the free case as well as when there is an interaction with a constant electromagnetic field. To deal with interactions we introduce the extended Poincaré and Galilei Maxwell groups.
 [DOI: 10.1063/1.2168399]

I. INTRODUCTION

The first works, of a rather theoretical character, devoted to particles with an arbitrary spin and statistics in (2+1) dimensions go back to 1977,[1] but the real interest in physics behind the anyons started some years later when the fractional quantum Hall effect was explained just in terms of anyons.[2]

In the last years some works analyzing the role of the Galilei and Poincaré groups in (2+1) dimensions in the theory of anyons have appeared in the literature.[3–10] Although the usual group theoretical considerations fit well when the anyons are free, this is not the case when the action of an external electromagnetic field is considered.[11] However, recently[12,13] we have introduced two noncentral extensions of the Poincaré and Galilei groups by homogeneous and constant electromagnetic fields, called Maxwell groups[14,15] that seem to provide an appropriate group theoretical framework for anyons in the presence of constant fields. Our intention here is to adopt this viewpoint to present a unified approach for these kinds of interacting systems in 2-space +1-time dimensions which can also involve noncommuting coordinates. In this context we mention a recent work[16] where the authors also obtain, in a different way, the extended Galilei-Maxwell group (called by them "enlarged Galilei group").

The paper has been organized as follows. In the first two sections we revise the Poincaré and Galilei groups to recover the main features of the free relativistic and nonrelativistic anyons and fix the notation. As in all the cases presented along this paper, we have made a systematic use of the coadjoint orbit method that supply us with a canonical setup of classical systems bearing enough symmetry in terms of the corresponding symmetry group; in particular, for the Galilei group we have taken into account its double central extension. In the next two sections we deal with interacting anyons and constant electromagnetic fields. First, in Sec. IV within a relativistic frame, while the nonrelativistic situation is considered in the following section, where we also discuss how to perform the nonrelativistic limit. As we mentioned before the groups involved in our analysis are certain noncentral extensions of the Galilei and Poincaré groups where the key point is that electromagnetic fields take part as dynamical objects. Some conclusions and comments on the main differences with other approaches end the paper.

[c]Electronic mail: tosiek@p.lodz.pl

We have also added two Appendixes for the sake of completness. In the first Appendix we give a brief review about the symplectic structures associated to a Lie group. In the second Appendix we supply a classification of orbits for the space $\mathcal{GM}^*(2+1)$ dual to the Lie algebra of the Galilei-Maxwell group.

II. ANYONS AND THE POINCARÉ GROUP

The Poincaré group $P(2+1)$, is a six-dimensional (6D) Lie group of transformations of the $(2+1)$-D Minkowski space-time provided with the metric tensor $g_{ij}=\mathrm{diag}(1,-1,-1)$. Two spatial Cartesian axes will be denoted by X_1 and X_2.

Our $(2+1)$-D system may be seen as embedded in the $(3+1)$-D Minkowski space-time equipped with the metric tensor $g_{ij}=\mathrm{diag}(1,-1,-1,-1)$. Then, the third spatial axis perpendicular to the X_1X_2 plane will be denoted by X_3. We will make use of this embedding; for example, a rotation on the plane X_1X_2 may be considered as the rotation around X_3. In that case vectors on the spatial plane are thought to be three-dimensional (3D) objects.

Each element of $P(2+1)$ is parametrized by a pair (a,Λ), where $a=(b,a_1,a_2)$ represents a time (b) and space (a_1,a_2) translation, and Λ a Lorentz transformation. The element Λ can be factorized as $\Lambda=\Lambda(\chi,\vec{n})\Lambda(R_\phi)$, with $\Lambda(\chi,\vec{n})$ being a boost of rapidity χ in the direction of the unit planar vector $\vec{n}$ and $\Lambda(R_\phi)$ denoting a rotation of angle ϕ around the axis X_3.

The Lie algebra $\mathcal{P}(2+1)$ of the Poincaré group $P(2+1)$ is spanned by the basis $\{P_0\equiv H,P_1,P_2,K_1,K_2,J\}$, which are the infinitesimal generators of time and space translations, boosts transformations along axes X_1, X_2, and X_3 rotations, respectively. The nonvanishing commutators are

$$[H,K_i]=-P_i,\quad [P_i,K_i]=-H,\quad [P_i,J]=-\varepsilon_{ij}P_j,$$

$$[K_i,K_j]=-\varepsilon_{ij}J,\quad [K_i,J]=-\varepsilon_{ij}K_j,\quad i,j=1,2, \tag{2.1}$$

where ε_{ij} denotes the 2D completely skew-symmetric tensor.

A. Coadjoint orbits

Let (h,p_1,p_2,k_1,k_2,j) be the coordinates of an arbitrary point of $\mathcal{P}^*(2+1)$, the dual space of $\mathcal{P}(2+1)$, in a basis dual to $\{H,P_1,P_2,K_1,K_2,J\}$. The coadjoint action of $P(2+1)$ on $\mathcal{P}^*(2+1)$ is given by[17]

$$g:(h,p_1,p_2,k_1,k_2,j)\to(h',p_1',p_2',k_1',k_2',j'),\quad g=(b,a_1,a_2,\Lambda(\chi,\vec{n}),\Lambda(R_\phi)),$$

$$h'=\cosh\chi h-\sinh\chi\vec{n}\cdot\vec{p}^{\,\phi},$$

$$\vec{p}\,'=\vec{p}^{\,\phi}-\sinh\chi h\vec{n}+(\cosh\chi-1)(\vec{n}\cdot\vec{p}^{\,\phi})\vec{n},$$

$$\begin{aligned}\vec{k}'=&\vec{k}^{\,\phi}+\sinh\chi\vec{j}\times\vec{n}^{\pi/2}-(\cosh\chi-1)(\vec{n}^{\pi/2}\cdot\vec{k}^{\,\phi})\vec{n}^{\pi/2}\\&+b[\vec{p}^{\,\phi}-\sinh\chi h\vec{n}+(\cosh\chi-1)(\vec{n}\cdot\vec{p}^{\,\phi})\vec{n}]+\vec{a}[\cosh\chi h-\sinh\chi\vec{n}\cdot\vec{p}^{\,\phi}],\end{aligned}$$

$$\vec{j}\,'=\cosh\chi\vec{j}+\sinh\chi\vec{n}\times\vec{k}^{\,\phi}+\vec{a}\times[\vec{p}^{\,\phi}-\sinh\chi h\vec{n}+(\cosh\chi-1)(\vec{n}\cdot\vec{p}^{\,\phi})\vec{n}], \tag{2.2}$$

where we have used the following notation:

$$\vec{n}=(n_1,n_2,0),\quad \vec{p}=(p_1,p_2,0),\quad \vec{k}=(k_1,k_2,0),\quad \vec{a}=(a_1,a_2,0),\quad \vec{j}=(0,0,j), \tag{2.3}$$

and $\vec{x}^{\,\phi}$ stands for the rotation of a vector $\vec{x}$ around the axis X_3 by an angle ϕ.

The invariants of the coadjoint action (2.2) are

$$C_1 = \rho^2 = g^{\mu\nu}\rho_\mu\rho_\nu = h^2 - p_1^2 - p_2^2, \quad C_2 = h\vec{j} + \vec{p} \times \vec{k}, \tag{2.4}$$

where $\rho=(h,p_1,p_2)$ and $g_{\mu\nu}=\mathrm{diag}(1,-1,-1)$.

The invariant C_2 is in fact a 3D vector, but its only nonzero component is the third one, equal to $hj+p_1k_2-k_1p_2$. It is a lower dimensional version of the Pauli-Lubanski four-vector. Recall that in (3+1)-D Minkowski space-time the Pauli-Lubanski vector w takes the form

$$w = (w^0, \mathbf{w}) = (\mathbf{j}\cdot\mathbf{p}, h\mathbf{j} + \mathbf{p}\times\mathbf{k}), \tag{2.5}$$

where now the involved vectors are generic 3D. The scalar w^2 is invariant under the (3+1)-Poincaré group action. In (2+1) dimensions the Pauli-Lubanski vector reduces to the expression (2.4) of C_2.

The classification of the coadjoint orbits was published in Refs. 17 and 18. There are orbits of dimension 4, 2, and 0 (points). The four-dimensional (4D) orbits are divided in three classes,

(i) $C_1>0$ relativistic particles of a mass $\sqrt{C_1}$,
(ii) $C_1<0$ tachyons,
(iii) $C_1=0$, $\vec{p}\neq 0$ massless particles.

We will consider the strata of orbits with $C_1>0$. Rewriting $C_1=m^2$, where m is the rest mass of the particle, the invariant C_1 leads to the equation of a hyperboloid of two sheets $h^2-p_1^2-p_2^2-m^2=0$. We will restrict to that one of positive energy $h>0$, denoted H_m^+, as usual. For the second invariant, we rewrite $C_2=m\vec{s}$, where

$$\vec{s} = \frac{h\vec{j} + \vec{p}\times\vec{k}}{\sqrt{h^2 - p_1^2 - p_2^2}}. \tag{2.6}$$

The nontrivial component of $\vec{s}$ is the spin s of the system.

B. Symplectic structure

The two independent invariants m and s fix, in the way presented above, a coadjoint orbit $\mathcal{O}_{m,s}^+$ that constitutes a 4D differentiable submanifold of $\mathcal{P}^*(2+1)$. Moreover, we can cover $\mathcal{O}_{m,s}^+$ with one chart $(\mathcal{O}_{m,s}^+,\varphi)$ using as coordinates (p_1,p_2,k_1,k_2). Indeed, the Jacobian of the transformation

$$(h,p_1,p_2,k_1,k_2,j) \to (C_1,C_2,p_1,p_2,k_1,k_2)$$

being $(2h^2)^{-1}$, it is always positive on the sheet H_m^+. On the orbits $\mathcal{O}_{m,s}^+$ there is a natural Poisson structure (A5)—see Appendix A—given by

$$\Lambda = h\frac{\partial}{\partial k_i} \wedge \frac{\partial}{\partial p_i} - j\frac{\partial}{\partial k_1} \wedge \frac{\partial}{\partial k_2}. \tag{2.7}$$

The symplectic form related with the tensor Λ is

$$\omega = -\frac{1}{h}\mathrm{d}k_i \wedge \mathrm{d}p_i - \frac{j}{h^2}\mathrm{d}k_1 \wedge \mathrm{d}k_2, \tag{2.8}$$

where, according to (2.4),

$$h = +\sqrt{\vec{p}^2 + m^2}, \quad j = \frac{ms - p_1k_2 + p_2k_1}{\sqrt{\vec{p}^2 + m^2}}. \tag{2.9}$$

The coordinates, p_i, k_i, $i=1,2$ are not canonical since their Poisson brackets are

$$\{k_1,k_2\}=-j,\quad \{p_1,p_2\}=0,\quad \{k_i,p_j\}=h\delta_{ij}. \tag{2.10}$$

The equations of the time evolution obtained from the law of motion (A6) with the Hamiltonian (2.9) are

$$\dot{p}_i=0,\quad \dot{k}_i=p_i,\quad i=1,2. \tag{2.11}$$

They look like the equations of motion of a nonrelativistic free particle.

We find a set of canonical coordinates $\{\vec{p},\vec{q}\}$, where

$$\vec{q}=\frac{\vec{k}}{h}-\frac{\vec{p}\times\vec{s}}{h(m+h)} \tag{2.12}$$

and the expression for the angular momentum becomes

$$j=\frac{ms}{h}+\vec{q}\times\vec{p}+\frac{ms}{h(m+h)}\vec{p}^2. \tag{2.13}$$

Now, if we identify q_i as position coordinates, the equations of motion are the well-known relations

$$\dot{p}_i=0,\quad \dot{q}_i=\frac{p_i}{h},\quad i=1,2. \tag{2.14}$$

A detailed analysis of the different coordinate systems for anyons can be found in Ref. 19.

C. Irreducible unitary representations

In quantum mechanics the coadjoint orbits of a Lie group allow us to define the irreducible unitary representations (IUR) associated to quantum elementary physical systems having such a symmetry group. Thus, the IUR's of $P(2+1)$ associated to the stratum of orbits $\mathcal{O}^+_{m,s}$ are

$$[U_{m,s}(a,\Lambda)]\psi(p)=e^{ip\cdot a}e^{is\theta(p,\Lambda)}\psi(\Lambda^{-1}p), \tag{2.15}$$

where s is the quantum number labelling a representation of SO(2) and $\theta(p,\Lambda)$ is the Wigner angle, which is determined by the little group of a point of the orbit. More explicitly, choosing the point $p_m=(m,0,0)$, whose isotropy group is SO(2), and the boost elements $\Lambda_{p\to p'}\in \mathrm{SO}(2,1)$ transforming the point p into p', then

$$\theta(p,\Lambda)=\Lambda^{-1}_{p_m\to\Lambda(p)}\Lambda\Lambda_{p_m\to p}. \tag{2.16}$$

The functions $\psi(p)$ belong to the Hilbert space $\mathcal{H}=\mathcal{L}^2(H^+_m,\mathrm{d}\mu(p))$, being $\mathrm{d}\mu(p)$ the SO(2,1)-invariant measure in H^+_m.

The differential realization of the generators for this representation is

$$\hat{H}=h,\quad \hat{P}_i=p_i,\quad \hat{K}_j=i(h\partial_{p_j}+p_j\partial_h)+\frac{\varepsilon^{jk}p_k}{2m}s,\quad \hat{J}=i(p_2\partial_{p_1}-p_1\partial_{p_2})+\frac{h}{m}s. \tag{2.17}$$

The two Casimirs corresponding to the invariants (2.4), $C_1=\hat{P}^2$ and $C_2=\hat{H}\cdot\hat{J}+\hat{\vec{P}}\times\hat{\vec{K}}$, give the following equations:

$$(p^2-m^2)\psi(p)=0,\quad (h\hat{J}+\hat{\vec{P}}\times\hat{\vec{K}}-ms)\psi(p)=0. \tag{2.18}$$

The first one corresponds to the mass shell condition which gives rise to the Klein-Gordon equation. The second one is the Pauli-Lubanski equation describing the spin of the particle. In two dimensions the unitarity of the realizations does not impose restrictions on the values of s, thus allowing for the existence of anyons. In this way we easily recover results of Ref. 4.

III. NONRELATIVISTIC ANYONS AND THE GALILEI GROUP

In the nonrelativistic case we must deal with the Galilei group $G(2+1)$ in $(2+1)$-D, which can be seen as a contraction of the Poincaré group $P(2+1)$. The commutation rules of its Lie algebra $\mathcal{G}(2+1)$ are those of Poincaré (2.1) except that now

$$[K_1,K_2]=0, \quad [K_i,P_j]=0, \quad i,j=1,2. \tag{3.1}$$

The algebra $\mathcal{G}(2+1)$ admits a 2D central extension $\bar{\mathcal{G}}(2+1)$ characterized by the new commutators[20,21]

$$[P_i,K_j]=-\delta_{ij}M, \quad [K_1,K_2]=\mathcal{K}, \tag{3.2}$$

where M and $\mathcal{K}$ are central generators, i.e., $[M,\cdot]=[\mathcal{K},\cdot]=0$ for any element of $\mathcal{G}(2+1)$.

Both extensions can also be obtained by a contraction from the Poincaré group.[21,22] It is enough to consider the direct product $\tilde{P}(2+1)=\mathbb{R}^2\otimes P(2+1)$. Obviously, at the level of the Lie algebra we have $\tilde{\mathcal{P}}(2+1)=\mathbb{R}^2\oplus\mathcal{P}(2+1)$. Hence, a basis is constituted by the generators of $\mathbb{R}^2$ $(M,\mathcal{K})$ plus the known generators of the Poincaré algebra (H,P_1,P_2,K_1,K_2,J). Let us consider a new basis given by

$$M'=M, \quad \mathcal{K}'=\mathcal{K}, \quad H'=H-M, \quad P_i'=P_i, \quad K_i'=K_i, \quad J'=J+\mathcal{K}, \quad i=1,2. \tag{3.3}$$

The nonvanishing commutators of $\tilde{\mathcal{P}}(2+1)$ in this new basis are

$$[H',K_i']=-P_i', \quad [P_i',K_i']=-H'-M', \quad [P_i',J']=-\varepsilon_{ij}P_j',$$

$$[K_i',K_j']=-\varepsilon_{ij}(J'-\mathcal{K}'), \quad [K_i',J']=-\varepsilon_{ij}K_j', \quad i,j=1,2. \tag{3.4}$$

Now in order to perform the contraction we define an appropriate rescaled basis

$$M''=\epsilon^2M', \quad \mathcal{K}''=\epsilon^2\mathcal{K}', \quad H''=H', \quad P_i''=\epsilon P_i', \quad K_i''=\epsilon K_i', \quad J''=J', \tag{3.5}$$

where ϵ is a fixed real positive number. The nonvanishing Lie commutators are now

$$[H'',K_i'']=-P_i'', \quad [P_i',K_i']=-\epsilon^2\left(H''+\frac{1}{\epsilon^2}M''\right), \quad [P_i'',J'']=-\varepsilon_{ij}P_j'',$$

$$[K_i'',K_j'']=-\varepsilon_{ij}\epsilon^2\left(J''-\frac{1}{\epsilon^2}\mathcal{K}''\right), \quad [K_i'',J'']=-\varepsilon_{ij}K_j'', \quad i,j=1,2.$$

In the limit $\epsilon\to 0$ we recover the Lie commutators of the extended algebra $\bar{\mathcal{G}}(2+1)$.

To give a physical interpretation of the contraction procedure we identify the contraction parameter ϵ with the inverse of the light speed $(\epsilon=1/c)$. From a cohomological point of view a change of the basis defined by relations (3.3)–(3.5) corresponds to introducing a trivial two-cocycle on the Poincaré group. After the contraction $\epsilon\to 0$ this trivial two-cocyle becomes a nontrivial one of the Galilei group.[23]

A. Coadjoint orbits

By $\bar{\mathcal{G}}^*(2+1)$ we will denote the space dual to the algebra $\bar{\mathcal{G}}(2+1)$. Each vector belonging to $\bar{\mathcal{G}}^*(2+1)$ is characterized by eight components $(m,\kappa,h,p_1,p_2,k_1,k_2,j)$ in the basis dual to $(M,\mathcal{K},H,P_1,P_2,K_1,K_2,J)$ of $\bar{\mathcal{G}}(2+1)$.

Let us denote by $g=(\theta,\eta,b,\vec{a},\vec{v},R_\phi)$ the elements of $\bar{G}(2+1)$, with a convention similar to that of Poincaré $\mathcal{P}(2+1)$ except that $\vec{v}$ stands for the Galilean boosts, and (θ,η) parametrize the group elements generated by $(M,\mathcal{K})$. The coadjoint action of $g\in\bar{G}(2+1)$ on the dual space $\bar{\mathcal{G}}^*(2+1)$ is given by[21]

$$m'=m,$$

$$\kappa'=\kappa,$$

$$h'=h-\vec{v}\cdot\vec{p}^{\phi}+\tfrac{1}{2}m\vec{v}^2,$$

$$\vec{p}'=\vec{p}^{\phi}-m\vec{v},$$

$$\vec{k}'=\vec{k}^{\phi}+b\vec{p}^{\phi}+m(\vec{a}-b\vec{v})+\vec{v}\times\vec{\kappa},$$

$$\vec{j}'=\vec{j}+\vec{a}\times\vec{p}^{\phi}+\vec{v}\times\vec{k}^{\phi}-\tfrac{1}{2}\kappa\vec{v}^2-m\vec{a}\times\vec{v}, \tag{3.6}$$

where we have also used the notation

$$\vec{p}=(p_1,p_2,0),\quad \vec{v}=(v_1,v_2,0),\quad \vec{k}=(k_1,k_2,0),\quad \vec{a}=(a_1,a_2,0),\quad \vec{\kappa}=(0,0,\kappa),\quad \vec{j}=(0,0,j).$$

The invariants of the coadjoint action (3.6), besides m and κ, are

$$C_1=\vec{p}^2-2mh,\quad C_2=m\vec{j}-\vec{\kappa}h+\vec{p}\times\vec{k}. \tag{3.7}$$

Note that the first one can be written as $U=-C_1/2m$ and is interpreted as the internal energy of the physical system. As in the relativistic case we denote $C_2=m\vec{s}$, but now

$$\vec{s}=\vec{j}-\frac{\vec{\kappa}h}{m}+\frac{\vec{p}\times\vec{k}}{m}. \tag{3.8}$$

It is easy to derive the expressions (3.7) from their relativistic counterparts (2.4) following the contraction procedure outlined above (see also Ref. 22). Obviously, expression (3.8) is the nonrelativistic limit of (2.6).

The classification of the coadjoint orbits (4D, 2D, and 0D) was presented in Ref. 21. The relevant 4D orbits characterized by the values $\{m\neq 0,\kappa,U,s\}$ are denoted by $\mathcal{O}^{\kappa,U}_{m,s}$. In the following we will assume $\kappa\neq 0$, since the results for $\kappa=0$ can be obtained directly.

B. Symplectic structure

A set of coordinates adapted to the orbit $\mathcal{O}^{\kappa,U}_{m,s}$ are $(m,\kappa,U,s,p_1,p_2,x_1,x_2)$, where $x_i=k_i/m$. Since the transformation

$$(m,\kappa,h,p_1,p_2,k_1,k_2,j)\rightarrow(m,\kappa,U,s,p_1,p_2,x_1=k_1/m,x_2=k_2/m)$$

has a nonzero Jacobian (as long as $m\neq 0$!), we can cover the whole orbit $\mathcal{O}^{\kappa,U}_{m,s}$ with one chart $(\mathcal{O}^{\kappa,U}_{m,s},\varphi)$ using coordinates (p_1,p_2,x_1,x_2). The induced Poisson tensor Λ on the orbit $\mathcal{O}^{\kappa,U}_{m,s}$ takes the form

$$\Lambda=\frac{\partial}{\partial x_i}\wedge\frac{\partial}{\partial p_i}+\frac{\kappa}{m^2}\frac{\partial}{\partial x_1}\wedge\frac{\partial}{\partial x_2},\quad i=1,2. \tag{3.9}$$

The inverse of Λ gives the symplectic form ω on $\mathcal{O}^{\kappa,U}_{m,s}$,

$$\omega = \mathrm{d}x_i \wedge \mathrm{d}p_i + \frac{\kappa}{m^2}\mathrm{d}x_1 \wedge \mathrm{d}x_2, \quad i = 1,2. \tag{3.10}$$

The coordinates $(\vec{p},\vec{x})$ are not canonical since their Poisson brackets are

$$\{x_1,x_2\} = \frac{\kappa}{m^2}, \quad \{p_1,p_2\} = 0, \quad \{x_i,p_j\} = \delta_{ij}. \tag{3.11}$$

Nevertheless, the Hamiltonian

$$h = \frac{\vec{p}^2}{2m} + U \tag{3.12}$$

has the usual form of a free nonrelativistic particle, leading to the motion equations

$$\dot{\vec{p}} = 0, \quad \dot{\vec{x}} = \frac{\vec{p}}{m}. \tag{3.13}$$

We see that the dynamics of the particle is independent of the parameter κ because the Hamiltonian function (3.12) does not contain any function of $\vec{x}$. Equations (3.13) are consistent with (3.6) if we assume that the parameter b represents the time and the coadjoint action gives the relation between the coordinates in two different inertial frames. Indeed, let the laboratory frame Σ' and the (instantaneous) rest frame Σ of the particle be related by the element $g=(t,\vec{a},-\vec{v},0) \in G(2+1)$. Then, Eqs. (3.6) can be read as

$$\vec{p}_{\Sigma'} = m\vec{v}, \quad \vec{x}_{\Sigma'} = t\frac{\vec{p}_{\Sigma'}}{m} - \frac{\vec{p}_{\Sigma'}}{m^2} \times \vec{\kappa} + \vec{a}. \tag{3.14}$$

The angular momentum is given by

$$j = \vec{x} \times \vec{p} + \frac{\vec{\kappa}}{m}\left(\frac{\vec{p}^2}{2m} + U\right) + s \tag{3.15}$$

which is the nonrelativistic limit of (2.13).

A set of canonical coordinates $(\vec{p},\vec{q})$ can be straightforwardly obtained from $(\vec{p},\vec{k})$ by

$$q_i = x_i + \frac{\varepsilon_{ij}\kappa p_j}{2m^2}. \tag{3.16}$$

It is worth to consider (3.16) as the nonrelativistic limit of the corresponding ones (2.12) for Poincaré. The coadjoint action of the Galilei group $G(2+1)$ in these coordinates is expressed by formulas

$$\vec{p}\,' = \vec{p}^{\,\phi} - m\vec{v},$$

$$\vec{q}\,' = \vec{q}^{\,\phi} + \frac{b}{m}\vec{p}^{\,\phi} + (\vec{a} - b\vec{v}) + \frac{1}{2m}\vec{v} \times \vec{\kappa}. \tag{3.17}$$

Although κ does not affect the dynamics, it gives the contribution $(1/2m)\vec{v}\times\vec{\kappa}$ to $\vec{q}$. The time evolution of canonical variables is given by [cf. (3.13)]

$$\dot{p}_i = 0, \quad \dot{q}_i = p_i, \quad i = 1,2. \tag{3.18}$$

Note that in the coordinates $(\vec{p},\vec{q})$ the angular momentum takes the form

$$\vec{j} = \vec{q} \times \vec{p} + \frac{\vec{\kappa} U}{m} + s, \tag{3.19}$$

where κ gives rise to an extra term. Similarly to (3.14) equations (3.17) give now

$$\vec{p} = m\vec{v}, \quad \vec{q} = t\frac{\vec{p}}{m} - \frac{\vec{p}}{2m^2} \times \vec{\kappa} + a. \tag{3.20}$$

The κ term is the only one that remains without a clear physical interpretation in the free case.[21,24]

C. Irreducible unitary representations

The IUR of $G(2+1)$ associated to this stratum of orbits are[21]

$$[U^{\kappa,U}_{m,s}(g)]\psi(\vec{p}) = e^{i([(1/2m)\vec{p}^2+U]b-\vec{p}\cdot\vec{a})} e^{i\kappa[(1//2m)\vec{v}\times\vec{p}]} e^{i[s+\kappa(U/m)]\phi} \psi(R^{-1}(\phi)(\vec{p}-m\vec{v})), \tag{3.21}$$

where $R(\phi)$ is a rotation of angle ϕ. The carrier space of the representation is the Hilbert space $\mathcal{H}=\mathcal{L}^2(\mathbb{R}^2)$. Note that the differential realization of the generators in this representation is

$$\hat{P}_j = p_j, \quad \hat{K}_j = im\partial_{p_j} - \frac{\kappa}{2m}\varepsilon^{jk}p_k, \quad \hat{H} = \frac{1}{2m}\vec{p}^2 + U, \quad \hat{J} = i(p_2\partial_{p_1} - p_1\partial_{p_2}) + s + \kappa U. \tag{3.22}$$

After a global change of phase, $U'(g)=\lambda(g)U(g)$, the IUR $U^{\kappa,U}_{m,s}$ is shown to be equivalent to $U^{\kappa,0}_{m,0}$.

It is worth mentioning that we can consider massless particles in the Galilean framework. In this case their 4D coadjoint orbits are characterized by $(m=0, \kappa\neq 0)$ and the invariants $C_1=\vec{p}^2 \neq 0$ and $C_2=\vec{p}\times\vec{k}-\kappa h$. If we compare C_2 with the relativistic Pauli-Lubanski operator for $m=0$ in (2.18), $(h\hat{J}+\hat{\vec{P}}\times\hat{\vec{K}}-C_2)\psi(p)=0$, we see that C_2 gives the helicity of our system, while J is now replaced by κ. We remark that this case is not equivalent to that of the orbit $(m=0, \kappa=0)$, and that in the present context the Hamiltonian becomes linear in $\vec{p}$. However, one must be careful about the interpretation since the coordinates $(\vec{k},\vec{p})$ are not canonical (see also Ref. 4).

The IUR associated to the null-mass orbits are

$$[U^{\kappa}_{C_1,C_2}(g)]\psi(\vec{w},\theta) = e^{i\kappa\left(\frac{1}{2}\vec{w}\times\vec{y}\right)} e^{i\vec{p}\cdot(\vec{a}-b\vec{y})} e^{-i(C_2/2\kappa)b} \psi(\vec{y}-\vec{w},\theta-\phi), \tag{3.23}$$

where $\vec{p}=\sqrt{C_1}(\cos\theta,\sin\theta)$ and $\psi\in\mathcal{L}^2(\mathbb{R}^2\times S^1)$.

IV. RELATIVISTIC ANYONS IN AN EXTERNAL ELECTROMAGNETIC FIELD

Once revisited the description of free anyons, in the next sections we will analyze the more interesting case when charged particles move in a constant electromagnetic field. The presence of external forces modifies the symmetry group of the system. This is the reason why instead of the Poincaré $P(2+1)$ and Galilei $G(2+1)$ groups, we will consider the so-called Poincaré-Maxwell PM$(2+1)$ and Galilei-Maxwell GM$(2+1)$ groups.[14,15]

Let us start with the relativistic case. The Poincaré-Maxwell group PM$(2+1)$ is a nine-dimensional (9D) Lie group with six infinitesimal generators $\{H,P_1,P_2,K_1,K_2,J\}$, corresponding to $P(2+1)$, plus three new elements $\{B,E_1,E_2\}$ related to the electromagnetic field.[14] It can be considered as a 3D noncentral extension of the Poincaré group. The nonvanishing commutators for its Lie algebra, $\mathcal{PM}(2+1)$, are

$$[B,K_i]=\varepsilon_{ij}E_j, \quad [E_i,K_j]=-\varepsilon_{ij}B, \quad [E_i,J]=-\varepsilon_{ij}E_j,$$

$$[H,P_i]=E_i,\quad [H,K_i]=-P_i,\quad [P_i,P_j]=-\varepsilon_{ij}B,$$

$$[P_i,K_j]=-\delta_{ij}H,\quad [P_i,J]=-\varepsilon_{ij}P_j,\quad [K_i,K_j]=-\varepsilon_{ij}J,$$

$$[K_i,J]=-\varepsilon_{ij}K_j,\quad i,j=1,2. \tag{4.1}$$

A. Coadjoint orbits

We will denote by $(\beta,\epsilon_1,\epsilon_2,h,p_1,p_2,k_1,k_2,j)$ the coordinates fixing a point on $\mathcal{PM}^*(2+1)$ by means of the dual basis of $(B,E_1,E_2,H,P_1,P_2,K_1,K_2,J)$. The general formula expressing the coadjoint action of a group element $g=(c,\vec{d},b,\vec{a},\Lambda(\chi,\vec{n})\Lambda(R_\phi))\in PM(2+1)$ on $\mathcal{PM}^*(2+1)$ is given by

$$\vec{\beta}'=(\cosh\chi)\vec{\beta}+(\sinh\chi)(\vec{n}\cdot\vec{\epsilon}^{\phi})\vec{n}^{\pi/2},$$

$$\vec{\epsilon}'=\vec{\epsilon}-(\sinh\chi)(\vec{\beta}\times\vec{n}^{\pi/2})+(\cosh\chi-1)(\vec{n}^{\pi/2}\cdot\vec{\epsilon}^{\phi})\vec{n}^{\pi/2},$$

$$h'=(\cosh\chi)h-(\sinh\chi)(\vec{n}\cdot\vec{p}^{\phi})-\vec{a}\cdot\vec{\epsilon}',$$

$$\vec{p}'=\vec{p}^{\phi}-(\sinh\chi)h\vec{n}+(\cosh\chi-1)(\vec{n}\cdot\vec{p}^{\phi})\vec{n}+b\vec{\epsilon}'-\vec{\beta}'\times\vec{a},$$

$$\vec{k}'=\vec{k}^{\phi}-(\sinh\chi)\vec{j}\times\vec{n}^{\pi/2}+(\cosh\chi-1)(\vec{n}^{\pi/2}\times\vec{k}^{\phi})\vec{n}^{\pi/2}$$
$$+b\vec{p}'-\tfrac{1}{2}b^2\vec{\epsilon}'+h'\vec{a}+\tfrac{1}{2}\vec{a}^2\vec{\epsilon}'-\vec{\beta}'\times\vec{d}-\vec{c}\times\vec{\epsilon}',$$

$$\vec{j}'=(\cosh\chi)\vec{j}+(\sinh\chi)(\vec{n}\times\vec{k}^{\phi})+\vec{a}\times\vec{p}'+\tfrac{1}{2}\vec{a}^2\vec{\beta}'+\vec{d}\times\vec{\epsilon}', \tag{4.2}$$

where the notation used is the same as in (2.3) with the additional vectors

$$\vec{\beta}=(0,0,\beta),\quad \vec{\epsilon}=(\epsilon_1,\epsilon_2,0),\quad \vec{c}=(0,0,c),\quad \vec{d}=(d_1,d_2,0).$$

The parameters c, d_1, and d_2 describe the group elements generated by B, E_1, and E_2, respectively. Notice that (h,p_1,p_2) represents the 3D energy-momentum vector covariant under (2+1) Lorentz transformations.

The invariants under the coadjoint action (4.2) are

$$C_0=\vec{\epsilon}^2-\vec{\beta}^2,$$

$$C_1=h^2-\vec{p}^2-2(\vec{k}\cdot\vec{\epsilon}-\vec{j}\cdot\vec{\beta}),$$

$$C_2=h\vec{\beta}+\vec{p}\times\vec{\epsilon}. \tag{4.3}$$

The first one is, of course, the invariant of the electromagnetic field under Lorentz transformations, $C_0=-F_{\mu\nu}F^{\mu\nu}$, where $F_{0i}=\epsilon_i$ and $F_{12}=\beta$. If $C_0>0$, $C_0<0$ or $C_0=0$ we say that the electromagnetic field (or the orbit) is of electric, magnetic, or perpendicular type, respectively.

The second invariant C_1 describes the interaction: it includes the electric coupling term $\vec{k}\cdot\vec{\epsilon}$, and the coupling of angular momentum and magnetic field, $\vec{j}\cdot\vec{\beta}$. The last invariant C_2 from (4.3) admits a covariant expression $C_2=-\varepsilon^{\mu\nu\sigma}p_\mu F_{\nu\sigma}$. It has no immediate interpretation, but its appearance is a consequence of the symmetries of the system.

Since we have three independent invariants the maximal dimension of the coadjoint orbits is six. In this work we will be concerned only with this kind of orbits, henceforth denoted $\mathcal{O}^{C_0}_{C_1C_2}$.

B. Symplectic structure

A suitable chart of coordinates for the points of the 9D differentiable manifold $\mathcal{PM}^*(2+1)$ is given by $(C_0,C_1,C_2,\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2)$. Each 6D orbit $\mathcal{O}^{C_0}_{C_1C_2}$ can be covered with just one chart $(\mathcal{O}^{C_0}_{C_1C_2},\varphi)$ with coordinates $(\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2)$. Indeed, from (4.3) we find that the Jacobian of the transformation

$$(\beta,h,j,\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2)\to(C_0,C_1,C_2,\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2)$$

equals $4\beta^3$. A singularity appears if $\beta=0$, but we shall deal here only with orbits of magnetic type $(\beta\neq 0)$.

In the chart $(\mathcal{O}^{C_0}_{C_1C_2},\varphi)$ the Poisson tensor Λ takes the form

$$\Lambda=-\beta\frac{\partial}{\partial\epsilon_1}\wedge\frac{\partial}{\partial k_2}+\beta\frac{\partial}{\partial\epsilon_2}\wedge\frac{\partial}{\partial k_1}-\beta\frac{\partial}{\partial p_1}\wedge\frac{\partial}{\partial p_2}-h\frac{\partial}{\partial p_1}\wedge\frac{\partial}{\partial k_1}-h\frac{\partial}{\partial p_2}\wedge\frac{\partial}{\partial k_2}-j\frac{\partial}{\partial k_1}\wedge\frac{\partial}{\partial k_2},\tag{4.4}$$

where β,h,j are functions of the coordinates obtained from relations (4.3). To make easy further comparisons with the nonrelativistic case we will represent it as a matrix (using the previous order of the coordinates)

$$\Lambda^{ij}=\begin{pmatrix}0&0&0&0&0&-\beta\\0&0&0&0&\beta&0\\0&0&0&-\beta&-h&0\\0&0&\beta&0&0&-h\\0&-\beta&h&0&0&-j\\\beta&0&0&h&j&0\end{pmatrix}\tag{4.5}$$

whose determinant is β^6. The symplectic two-form is

$$\omega=\frac{h^2-j\beta}{\beta^3}\mathrm{d}\epsilon_1\wedge\mathrm{d}\epsilon_2+\frac{h}{\beta^2}\mathrm{d}\epsilon_1\wedge\mathrm{d}p_1+\frac{1}{\beta}\mathrm{d}\epsilon_1\wedge\mathrm{d}k_2\frac{h}{\beta^2}\mathrm{d}\epsilon_2\wedge\mathrm{d}p_2-\frac{1}{\beta}\mathrm{d}\epsilon_2\wedge\mathrm{d}k_1+\frac{1}{\beta}\mathrm{d}p_1\wedge\mathrm{d}p_2.\tag{4.6}$$

Such a symplectic form is not canonical: the nonvanishing Poisson brackets are

$$\{\epsilon_i,k_l\}=-\varepsilon_{il}\beta,\quad\{p_i,p_l\}=\varepsilon_{il}\beta,\quad\{p_i,k_l\}=-\delta_{il}h,\quad\{k_i,k_l\}=-\varepsilon_{il}j,\quad i,l=1,2.\tag{4.7}$$

In order to find the equations of motion we need to know the Hamiltonian of the system. From the invariant C_2 [see (4.3)] we get

$$h=\frac{C_2}{\beta}+\frac{\vec{\epsilon}\times\vec{p}}{\beta},\tag{4.8}$$

where from (4.3) we can write $\beta=\sqrt{\vec{\epsilon}^2-C_0}$. Thus, we obtain

$$\dot{\epsilon}_i=0,\quad\dot{p}_i=-\epsilon_i,\quad\dot{k}_i=p_i,\quad i=1,2.\tag{4.9}$$

Equations (4.9) are extremely simple. The first one says that the fields are constant. The others look like the equations of motion for a nonrelativistic particle with a unit negative charge inside an electric field. Comparing the time evolution from these formulas with the transformation rules

(4.2) we can identify the time t with the parameter b. This is natural because b is associated to the Hamiltonian generator H.

Let us remark that the above relations are quite different from the usual ones derived from the standard Hamiltonian formalism. In that approach the Hamilton function is

$$H=\sqrt{m^2+\left(\vec{\pi}+\tfrac{1}{2}\vec{\beta}\times\vec{r}\right)^2}-\vec{\epsilon}\cdot\vec{r}, \tag{4.10}$$

where m denotes the mass of the particle and $\vec{r}$ its vector of position, being $(\vec{\pi},\vec{r})$ canonically conjugated variables. Then, the equations of motion are

$$\dot{\vec{\pi}}=\vec{\epsilon}-\frac{1}{2}\dot{\vec{r}}\times\vec{\beta},\quad \dot{\vec{r}}=\frac{1}{\mathcal{E}}\left(\vec{\pi}+\frac{1}{2}\vec{\beta}\times\vec{r}\right), \tag{4.11}$$

with $\mathcal{E}=H+\vec{\epsilon}\cdot\vec{r}$ the energy of the system. But, the "group" coordinates $\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2$ have not a simple interpretation in terms of $\vec{\pi}$ and $\vec{r}$ (4.11). In fact, there is not a punctual transformation relating both pictures. We shall comment on this problem more carefully in the last section.

V. NONRELATIVISTIC ANYONS IN AN EXTERNAL ELECTROMAGNETIC FIELD

The magnetic limit[25] of the Poincaré-Maxwell group, that we call Galilei-Maxwell group,[15] is the most suitable to describe nonrelativistic anyons in the presence of external covariant fields.

The Galilei-Maxwell group is a 10-dimensional (10D) Lie group, whose infinitesimal generators are those of $G(2+1)$, $\{H,P_1,P_2,K_1,K_2,J\}$, together with $\{E_1,E_2,B,M\}$. However, here, we will take into account also the central extension characterized by the nonvanishing commutator $[K_1,K_2]=\mathcal{K}$, leading to a group denoted simply GM(2+1). The nonvanishing commutators of its Lie algebra, $\mathcal{GM}(2+1)$, are

$$[E_i,K_j]=-\varepsilon_{ij}B,\quad [E_i,J]=-\varepsilon_{ij}E_j,$$

$$[H,P_i]=E_i,\quad [H,K_i]=-P_i,\quad [P_i,P_j]=-\varepsilon_{ij}B,$$

$$[P_i,K_j]=-\delta_{ij}M,\quad [P_i,J]=-\varepsilon_{ij}P_j,\quad [K_i,K_j]=\varepsilon_{ij}\mathcal{K},$$

$$[K_i,J]=-\varepsilon_{ij}K_j,K_j,\quad i,j=1,2. \tag{5.1}$$

It is interesting to point out that in a frame where the electric field $\vec{E}$ vanishes we recover the commutators corresponding to a pure magnetic Landau system.[15,26]

On the other hand, it is worthy to note that in order to relate the extended and nonextended GM algebras, we can redefine the basis generators inside the enveloping algebra taking into account the central character of M, $\mathcal{K}$, and B. So, we can write

$$K_i'=K_i+\lambda\varepsilon_{ij}P_j,\quad P_i'=P_i+\frac{M}{B}\varepsilon_{ij}E_j, \tag{5.2}$$

where $\lambda=(-M+\sqrt{M^2+\kappa B})/B$, and $M_e=\sqrt{M^2+\kappa B}$ is a kind of effective mass.[7] Then, the new commutators entering K_i',P_i' are the same as above except that

$$[K_i',K_j']=0. \tag{5.3}$$

A. Coadjoint orbits

Let us denote by $(m,\kappa,\beta,\epsilon_1,\epsilon_2,h,p_1,p_2,k_1,k_2,j)$ the coordinates of an arbitrary point of $\mathcal{G}^*(2+1)$ in a basis dual to $(M,\mathcal{K},B,E_1,E_2,H,P_1,P_2,K_1,K_2,J)$. The coadjoint action of an element $g=(\theta,\eta,c,\vec{d},b,\vec{a},v,\phi)\in\mathrm{GM}(2+1)$ on the dual space $\mathcal{GM}^*(2+1)$ is given by

$$m' = m,$$

$$\vec{\kappa}' = \vec{\kappa},$$

$$\vec{\beta}' = \vec{\beta},$$

$$\vec{\epsilon}' = \vec{\epsilon}^{\phi} - \vec{v} \times \vec{\beta},$$

$$h' = h - \vec{v} \cdot \vec{p}^{\phi} + \tfrac{1}{2} m \vec{v}^2 - \vec{a} \cdot (\vec{\epsilon}^{\phi} - \vec{v} \times \vec{\beta}),$$

$$\vec{p}' = \vec{p}^{\phi} - m\vec{v} - b(\vec{\epsilon}^{\phi} - \vec{v} \times \vec{\beta}) - \vec{\beta} \times \vec{a},$$

$$\vec{k}' = \vec{k}^{\phi} + m\vec{a} + b\vec{p}^{\phi} - \tfrac{1}{2} b^2 \vec{\epsilon}' + \vec{v} \times \vec{\kappa} - \vec{\beta} \times \vec{d} + \tfrac{1}{2} \vec{a} \times \vec{\beta},$$

$$\vec{j}' = \vec{j} - \vec{a} \times \vec{p}^{\phi} - \vec{v} \times \vec{k}^{\phi} + \tfrac{1}{2} \vec{\kappa} \cdot \vec{v}^2 + m\vec{a} \times \vec{v} + \tfrac{1}{2} \vec{\beta} \cdot \vec{a}^2 - \vec{d} \times \vec{\epsilon}^{\phi} + \tfrac{1}{2} b \vec{\epsilon}' \times \vec{a} - \vec{\beta}(\vec{d} \cdot \vec{v}). \tag{5.4}$$

Besides m, κ, and $C_0 \equiv \beta$ we have the following invariants of the coadjoint action:

$$C_1 = \vec{\beta}\vec{p}^2 - 2mh\vec{\beta} + 2\vec{\beta}(\vec{\epsilon} \cdot \vec{k}) - 2\beta^2 \vec{j} + \vec{\kappa}\vec{\epsilon}^2, \quad C_2 = 2\vec{\beta}^2 h + 2\vec{\beta} \cdot (\vec{p} \times \vec{\epsilon}) + m\vec{\epsilon}^2. \tag{5.5}$$

These invariants are the nonrelativistic version of (4.3). The invariance of the magnetic field $\vec{\beta}$ may be seen as the consequence of the invariance of the Lorentz force $\vec{F} = \vec{\epsilon} + \vec{v} \times \vec{\beta}$ under (homogeneous) Galilei transformations. A charged particle moving slowly can see mainly the magnetic field in our magnetic limit,[25]

$$\frac{\sqrt{\vec{\epsilon}^2}}{\beta} \ll 1. \tag{5.6}$$

Let us consider the relativistic invariant $C_0 = \vec{\epsilon}^2 - \beta^2$ from (4.3). Using (5.6) in the 0-term approximation term we obtain the nonrelativistic invariant

$$C_0 = -\beta_0^2.$$

We can omit the vector symbol because the magnetic field has only one component, so that

$$\beta = \sqrt{\beta_0^2 + \vec{\epsilon}^2} \overset{(5.6)}{\approx} \beta_0 + \frac{1}{2} \frac{\vec{\epsilon}^2}{\beta_0}. \tag{5.7}$$

By substituting

$$h \to m\left(1 + \frac{h}{m}\right), \quad j \to -\kappa\left(1 - \frac{j}{\kappa}\right), \quad \beta \to \beta\left(1 + \frac{1}{2}\frac{\vec{\epsilon}^2}{\beta^2}\right)$$

in the other invariants C_1 and C_2 of (4.3), and omitting terms of higher order in h/m, j/κ, and $\vec{\epsilon}^2/\beta^2$, we obtain their nonrelativistic counterparts of (5.5), respectively.

The classification of the coadjoint orbits is displayed in Appendix B. There are orbits of dimension 6 and 4, but the most important for us are the 6D orbits denoted $\mathcal{O}^{C_1 C_2}_{m\kappa\beta}$ with $\beta \neq 0$.

B. Symplectic structure

Each 6D orbit $\mathcal{O}^{C_1C_2}_{m\kappa\beta}$ can be covered with one chart $(\mathcal{O}^{C_1C_2}_{m\kappa\beta},\varphi)$. As coordinates we can choose $(\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2)$ since the Jacobian of the transformation

$$(m,\kappa,\beta,\epsilon_1,\epsilon_2,h,p_1,p_2,k_1,k_2,j)\to(m,\kappa,\beta,C_1,C_2,\epsilon_1,\epsilon_2,p_1,p_2,k_1,k_2)$$

equals $4\beta^4$ $(\neq 0)$. The Poisson tensor Λ on the orbit $\mathcal{O}^{C_1C_2}_{m\kappa\beta}$ is

$$\Lambda = m\frac{\partial}{\partial k_i}\wedge\frac{\partial}{\partial p_i}+\kappa\frac{\partial}{\partial k_1}\wedge\frac{\partial}{\partial k_2}-\beta\frac{\partial}{\partial p_1}\wedge\frac{\partial}{\partial p_2}-\beta\varepsilon^{ij}\frac{\partial}{\partial k_i}\wedge\frac{\partial}{\partial\epsilon_j}. \tag{5.8}$$

The components of Λ, written in matrix form, are

$$\Lambda^{ij}=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & -\beta \\ 0 & 0 & 0 & 0 & \beta & 0 \\ 0 & 0 & 0 & -\beta & -m & 0 \\ 0 & 0 & \beta & 0 & 0 & -m \\ 0 & -\beta & m & 0 & 0 & \kappa \\ \beta & 0 & 0 & m & -\kappa & 0 \end{pmatrix}, \tag{5.9}$$

The determinant of Λ is β^6 $(\neq 0$, for our orbits). The natural symplectic form on $\mathcal{O}^{C_1C_2}_{m\kappa\beta}$ is

$$\omega=\frac{\beta\kappa+m^2}{\beta^3}\mathrm{d}\epsilon_1\wedge\mathrm{d}\epsilon_2+\frac{m}{\beta^2}\mathrm{d}\epsilon_i\wedge\mathrm{d}p_i+\frac{1}{\beta}\varepsilon_{ij}\mathrm{d}k_i\wedge\mathrm{d}\epsilon_j+\frac{1}{\beta}\mathrm{d}p_1\wedge\mathrm{d}p_2. \tag{5.10}$$

Therefore the coordinates $(\epsilon_i,p_i,k_i;\ i=1,2)$ are not canonical since the nonvanishing Poisson brackets are

$$\{\epsilon_i,k_j\}=-\varepsilon_{ij}\beta,\quad \{p_1,p_2\}=-\beta,\quad \{p_i,k_j\}=-\delta_{ij}m,\quad \{k_1,k_2\}=\kappa. \tag{5.11}$$

Notice in particular that even the coordinates k_1,k_2 do not commute.

On the other hand, observe that the above tensor (5.9) coincides with (4.5) if we simply substitute h by m and j by $-\kappa$. The root of the proposed substitution is the fact that the Galilei-Maxwell group GM(2+1) is the nonrelativistic limit of the Poincaré-Maxwell group PM(2+1). We can look at κ as a nonrelativistic track of the angular momentum j (see also in this respect the arguments supplied in Ref. 4).

Using the invariant C_2 from (5.5) we get a Hamiltonian linear in momenta $\vec{p}$ [which is the nonrelativistic version of (4.8)],

$$h=-\frac{\vec{p}\times\vec{\epsilon}}{\beta}-\frac{m}{2\beta^2}\vec{\epsilon}^{\,2}+\frac{C_2}{2\beta^2}. \tag{5.12}$$

Observe that by a naive limit $\beta\to 0$ we do not recuperate the free Hamiltonian (3.12); in fact $\lim_{\beta\to 0}h$ is not defined, and the same happens with the Poisson tensor.

After simple calculations we obtain the equations of motion

$$\dot{\vec{\epsilon}}_i=0,\quad \dot{p}_i=-\epsilon_i,\quad \dot{k}_i=p_i,\quad i=1,2. \tag{5.13}$$

Of course, our system includes constant homogeneous fields $\vec{\epsilon},\vec{\beta}$ perpendicular to each other as we already knew from the coadjoint action. We can also see that β does not take part in any of the formulas (5.13), so, surprisingly, the equations of motion are not affected by the magnetic field. Comparing formulas (5.13) with transformation rules (5.4) we conclude that these two sets of equations are compatible if we identify the parameter b with time. Moreover, the equations of motion are also independent of the parameter κ.

It would be interesting to compare our results with those obtained in a more standard way following the minimal coupling recipe. For simplicity we will assume here that the exotic extension κ vanishes. Let us consider a nonrelativistic particle with a unit negative electric charge moving on a plane in a constant homogeneous electric $\vec{\epsilon}=(\epsilon_1,\epsilon_2,0)$ and magnetic $\vec{\beta}=(0,0,\beta)$ fields. A phase space for this system is a 4D symplectic manifold $(M,\tilde{\omega})$, where the differentiable manifold M is diffeomorphic to $\mathbb{R}^4$ with canonical coordinates denoted by π_1,π_2,r_1,r_2. The first pair $\vec{\pi}=(\pi_1,\pi_2,0)$ is interpreted as the generalized momentum and the second $\vec{r}=(r_1,r_2,0)$ is for the vector of position. The symplectic form is

$$\tilde{\omega}=\mathrm{d}\pi_1\wedge\mathrm{d}r_1+\mathrm{d}\pi_2\wedge\mathrm{d}r_2. \tag{5.14}$$

The Poisson tensor $\tilde{\Lambda}$ in coordinates (π_1,π_2,r_1,r_2) takes the natural form

$$\tilde{\Lambda}^{ij}=\begin{pmatrix}0&0&-1&0\\0&0&0&-1\\1&0&0&0\\0&1&0&0\end{pmatrix}. \tag{5.15}$$

Finally, the Hamiltonian is represented by the minimal coupling expression

$$H=\frac{1}{2m}\left(\vec{\pi}+\frac{1}{2}\vec{\beta}\times\vec{r}\right)^2+\vec{\epsilon}\cdot\vec{r}, \tag{5.16}$$

leading to the motion equations

$$\dot{\vec{\pi}}=-\vec{\epsilon}+\frac{1}{2}\vec{\beta}\times\dot{\vec{r}},\quad \dot{\vec{r}}=\frac{1}{m}\left(\vec{\pi}+\frac{1}{2}\vec{\beta}\times\vec{r}\right). \tag{5.17}$$

Integrals of the motion equations (5.17) are the Hamiltonian (5.16) and

$$C_1=\vec{\epsilon}\times\left(\vec{\pi}-\tfrac{1}{2}\vec{\beta}\times\vec{r}\right), \tag{5.18}$$

$$C_2=\left[\vec{\epsilon}\cdot\left(\vec{\pi}+\tfrac{1}{2}\vec{\beta}\times\vec{r}\right)\right]^2-2(\vec{\epsilon}\cdot\vec{r})[\vec{\beta}\cdot(\vec{\pi}\times\vec{\epsilon})-m\vec{\epsilon}^2]. \tag{5.19}$$

We can get canonical coordinates from the group coordinates $(\vec{p},\vec{k})$, but unfortunately, there is no point transformation connecting these two nonrelativistic interacting pictures.

VI. CONCLUDING REMARKS

The symmetry group of a system plus the formalism (Hamiltonian mechanics on a symplectic manifold) restrict the equations of motion, allow to define elementary systems, and may lead to interacting systems compatible with the symmetries. The natural framework to display such symmetries is the method of coadjoint orbits. In this way we get a manifold, the invariant symplectic form, and the Hamiltonian.

This situation is quite different for the Hamilton formulation of mechanics in the phase space. In this frame the same symplectic manifold (M,ω) may be used to describe physical systems with different Hamiltonians. In order to build a Hamiltonian for interactions, one is guided by other principles such as the minimal coupling rule. However, there is not a canonical way to display the symmetries in this context.

These two approaches have significative differences that could be appreciated along the examples worked in this paper. For instance, in our coadjoint orbit scheme, the Hamiltonians obtained for the interacting cases are linear in $\vec{p}$, the equations of motion depend on the electric field $\vec{\epsilon}$, while the magnetic field $\vec{\beta}$ takes part only in the symplectic two-form. These features are in sharp contrast to the usual interacting Hamiltonian in phase space.

Another difference is with respect to the role played by the fields. They are an integral part of the system in the group approach, while in the phase space they are treated as external parameters. The reason is that in our procedure we have considered the fields on the same foot as coordinates and momenta. In other words, the fields have been treated as dynamical fields instead of external fields, as usual. If we want to set a complete theory for the whole interacting system (particle +fields) it is expected that both components should take part of the system at the same level.

The group approach also enlightens us on how to go from a relativistic to a nonrelativistic description of the system in a very simple and natural way. So, manifolds, symplectic forms, Hamiltonians, invariants, and equations of motion are related through a contraction procedure.

The price for the simplicity of the group approach is the fact that we must use noncanonical and noncommuting coordinates which obscure the physical interpretation. (However this is usual in the new formulations of planar physics, see for instance, Refs. 16 and 27–30).

To show the explicit relation between the group approach and the formulation in phase space is an open problem. This situation of having different descriptions for the same system (one more appropriate to handle symmetries, the other adapted for an easier interpretation) happens also in quantum mechanics. In this framework symmetries can be described by unitary irreducible representations of symmetry groups in a representation space related to the coadjoint orbits as has been shown in Secs. III C and IV C. On the other side, quantum mechanical systems are usually described by means of wave functions of the configuration space. The connection between these two pictures sometimes is easy (the free case), but when interactions are included it is more involved.

Plyushchay for interesting discussions.

APPENDIX A: *G*-INVARIANT SYMPLECTIC STRUCTURES

This Appendix contains some basic information about Poisson structures on a space $\mathcal{G}^*$ dual to a Lie algebra $\mathcal{G}$. We start from the definition of the Poisson bracket on some real n-dimensional manifold M, then we concentrate on the case when the manifold M is an orbit $\mathcal{O}^*$ of the coadjoint action. We prove that $\mathcal{O}^*$ is endowed in a canonical way with a symplectic structure.

Let M be a real n-dimensional differentiable manifold. The set of smooth real-valued functions $C^\infty(M)$ with a commutative multiplication constitutes a ring.

The Poisson bracket, $\{\cdot,\cdot\}: C^\infty(M)\times C^\infty(M)\to C^\infty(M)$, on the manifold M is a bilinear relation satisfying the following conditions:

(1) antisymmetry $\{f_1,f_2\}=-\{f_2,f_1\}$,
(2) Jacobi's identity $\{f_1,\{f_2,f_3\}\}+\{f_2,\{f_3,f_1\}\}+\{f_3,\{f_1,f_2\}\}=0$,
(3) derivation rule $\{f_1,f_2f_3\}=f_2\{f_1,f_3\}+f_3\{f_1,f_2\}$,

for every $f_1,f_2,f_3\in C^\infty(M)$.

The first two properties equip $C^\infty(M)$ with the structure of a real Lie algebra. The derivation rule (known also as the Leibniz identity) and the bilinearity of the Poisson bracket say that for every $f\in C^\infty(M)$ there exists a vector field X_f such that

$$X_f g=\{f,g\},\quad \forall\, g\in C^\infty(M).$$

Let us cover some open subset $U\subset M$ by a chart (U,φ), such that $(x_1,\ldots,x_n)$ denotes the coordinates of $x\in U$ in this chart. In a natural basis $\partial/\partial x_i\equiv\partial_{x_i}$ $(i=1,\ldots,n)$ induced by the chart we have $X_f=(X_f)^i\partial_{x_i}$, where Einstein's sum convention is used. It is easy to check that

$$(X_f)^i = X_f(x_i) = \{f, x_i\}. \tag{A1}$$

Using (A1) we find that the Poisson bracket

$$\{f, g\} = X_f g = (X_f)^i \partial_{x_i} g = \{f, x_i\} \frac{\partial g}{\partial x_i}. \tag{A2}$$

On the other hand,

$$\{f, x_i\} = -\{x_i, f\} = -X_{x_i}(f) = -\{x_i, x_j\} \frac{\partial f}{\partial x_j} = \{x_j, x_i\} \frac{\partial f}{\partial x_j}. \tag{A3}$$

Setting (A3) into (A2) we finally have

$$\{f, g\} = \frac{\partial f}{\partial x_j} \frac{\partial g}{\partial x_i} \{x_j, x_i\}. \tag{A4}$$

Hence, it is enough to know the Poisson brackets of the coordinate functions $\{x_j, x_i\}$, $i, j = 1, \ldots, n$, to compute the Poisson bracket of any pair of functions. The expression (A4) defines a two-contravariant skew-symmetric tensor Λ by

$$\Lambda(\mathrm{d}f, \mathrm{d}g) = \{f, g\}. \tag{A5}$$

So, we conclude that the correspondence $f \to X_f$ defines a map $\pi(x): T_x^* M \to T_x M$ in every point $x \in M$. The rank of $\pi(x)$ is called the rank of the Poisson structure in x.

The differential equations that determine the integral curves of X_f in M are

$$\frac{\mathrm{d}x_i}{\mathrm{d}t} = \{f, x_i\}, \quad i = 1, \ldots, n. \tag{A6}$$

They look like Hamilton equations being $-f$ the Hamiltonian function. For this reason the vector fields X_f are called Hamiltonian vector fields and f is called the Hamiltonian of X_f.

Let us consider now the problem of defining a Poisson structure on the space $\mathcal{G}^*$, dual to a Lie algebra $\mathcal{G}$. For every smooth function $f \in \mathcal{C}^\infty(\mathcal{G}^*)$ its (total) differential $(\mathrm{d}f)_x$ at $x \in \mathcal{G}^*$ is a linear mapping $(\mathrm{d}f)_x: T_x\mathcal{G}^* \to \mathbb{R}$, where $T_x\mathcal{G}^*$ denotes the tangent space of $\mathcal{G}^*$ at the point x. The dual space $\mathcal{G}^*$ is a vector space and it can be identified with $T_x\mathcal{G}^*$. The differential $(Df)_x$ is the functional over the tangent space $T_x\mathcal{G}^*$ and, hence, also over $\mathcal{G}^*$. It means that $(Df)_x \in (\mathcal{G}^*)^*$ which is isomorphic to $\mathcal{G}$. Thus, to any function $f \in \mathcal{C}^\infty(\mathcal{G}^*)$ we assign $\delta_x f \in \mathcal{G}$, in such a way that for every $y \in \mathcal{G}^*$,

$$\langle y, \delta_x f \rangle = (\mathrm{d}f)_x(y) = \frac{d}{\mathrm{d}t} f(x + ty)|_{t=0}. \tag{A7}$$

The formula (A7) allows us to define the Poisson structure on $\mathcal{G}^*$ by

$$\{g, f\}(x) = \langle x, [\delta_x g, \delta_x f] \rangle. \tag{A8}$$

Defining the functions $\xi_a \in \mathcal{C}^\infty(\mathcal{G}^*)$, with $a \in \mathcal{G}$, by $\xi_a(x) = \langle x, a \rangle$ we obtain from (A7) that $\delta_x \xi_a = a$. Hence

$$\{\xi_a, \xi_b\}(x) = \langle x, [a, b] \rangle = \xi_{[a,b]}(x). \tag{A9}$$

If $\{a_1, \ldots, a_n\}$ is a basis of $\mathcal{G}$ then $\xi_i \equiv \xi_{a_i}$, $i = 1, \ldots, n$, can be chosen as a set of coordinate functions on $\mathcal{G}^*$. From (A4) and (A7) we obtain that the Poisson structure on $\mathcal{G}^*$ takes the form

$$\{f,g\}(x) = \frac{\partial f}{\partial \xi_i}\frac{\partial g}{\partial \xi_j}\{\xi_i,\xi_j\} = \frac{\partial f}{\partial \xi_i}\frac{\partial g}{\partial \xi_j}c_{ij}^k\xi_k, \tag{A10}$$

with c_{ij}^k being the structure constants of $\mathcal{G}$ relative to its basis $\{a_1,\ldots,a_n\}$. Thus, for a set of coordinate functions ξ_i, $i=1,\ldots,n$, on $\mathcal{G}^*$ we have

$$\{\xi_i,\xi_j\} = c_{ij}^k\xi_k, \tag{A11}$$

so that the Poisson bracket of $\{\xi_i,\xi_j\}$ is a linear function of ξ_k.

A special case of manifold with a Poisson structure is the symplectic manifold. A pair (M,ω) is called a symplectic manifold if M is a finite-dimensional differentiable manifold and ω a nondegenerate two-form satisfying the condition $\mathrm{d}\omega=0$. The nondegeneracy condition of ω is equivalent to the requirement that the rank of $\hat{\omega}: T_x(M)\to T_x^*(M)$, defined by

$$\langle\hat{\omega}(v),v'\rangle = \omega(v,v'),$$

is maximal at each point $x\in M$. The map $\hat{\omega}$ allows us to define a skew-symmetric contravariant tensor field Λ on M by

$$\Lambda(\alpha,\beta) = \omega(\hat{\omega}^{-1}(\alpha),\hat{\omega}^{-1}(\beta)), \quad \alpha,\beta\in T^*M. \tag{A12}$$

The tensor Λ constitutes the Poisson structure on M. Thus, when $\alpha=\mathrm{d}g$ and $\beta=\mathrm{d}f$ we obtain that

$$\{g,f\} = \Lambda(\mathrm{d}g,\mathrm{d}f) = \omega(\hat{\omega}^{-1}(\mathrm{d}g),\hat{\omega}^{-1}(\mathrm{d}f)). \tag{A13}$$

Let G be a Lie group and $\mathcal{G}$ its Lie algebra. For every element $g\in G$ the inner automorphism $i_g: G\to G$ defined as

$$i_g(g') = gg'g^{-1}$$

induces a Lie algebra automorphism $i_{g^*}:\mathcal{G}\to\mathcal{G}$ which gives rise to the adjoint representation of G on $\mathcal{G}$ by $\mathrm{Ad}_g=\exp i_{g^*}$. The coadjoint representation of G on $\mathcal{G}^*$ is now given by

$$\langle\mathrm{CoAd}_g(u),a\rangle = \langle u,\mathrm{Ad}_{g^{-1}}(a)\rangle, \quad u\in\mathcal{G}^*, \quad a\in\mathcal{G}. \tag{A14}$$

Each orbit $\mathcal{O}^*$ of the coadjoint action is a symplectic submanifold of the Poisson manifold $\mathcal{G}^*$, and it is endowed in a canonical way with a symplectic structure characterized by the two-form (Kirillov-Kostant-Souriau theorem)

$$\omega(X_a,X_b) = \langle u,[a,b]\rangle, \quad u\in\mathcal{O}^*, \quad a,b\in\mathcal{G}, \tag{A15}$$

where X_a is the fundamental vector field associated with the coadjoint action

$$(X_af)(u) = \frac{d}{\mathrm{d}t}f(\mathrm{CoAd}_{e^{-ta}u})\big|_{t=0}. \tag{A16}$$

The Poisson structure on $\mathcal{O}^*$, as a submanifold of $\mathcal{G}^*$, defined through the symplectic two-form ω (A15) coincides with that induced by the Poisson structure (A10) on $\mathcal{G}^*$.

APPENDIX B

We have the following Table I.

TABLE I. Coadjoint orbits classification for $\mathcal{GM}^*(2+1)$.

Constraints	Dimension	Invariants
$\beta\neq 0,\ m\neq 0,\ \kappa\neq 0$	6	$C_1=\frac{1}{2}\vec{\varepsilon}^2\cdot\vec{\kappa}+(\vec{\varepsilon}\cdot\vec{k})\cdot\vec{\beta}+\frac{1}{2}\vec{p}^2\cdot\vec{\beta}-mh\vec{\beta}-(\vec{j}\cdot\vec{\beta})\cdot\vec{\beta}$ $C_2=\vec{\beta}^2h+(\vec{p}\times\vec{\varepsilon})\cdot\vec{\beta}+\frac{m}{2}\vec{\varepsilon}^2$
$\beta=0,\ m\neq 0,\ \kappa\neq 0$	6	$C_1=-m/2\vec{p}^2+m^2h-m\vec{\varepsilon}\cdot\vec{k}+(\vec{p}\times\vec{\varepsilon})\cdot\vec{k}$ $C_2=\vec{\varepsilon}^2$
$m=0,\ \beta\neq 0,\ \kappa\neq 0$	6	$C_1=\frac{1}{2}\vec{\varepsilon}^2\cdot\vec{\kappa}+(\vec{\varepsilon}\cdot\vec{k})\cdot\vec{\beta}+\frac{1}{2}\vec{p}^2\cdot\vec{\beta}-(\vec{j}\cdot\vec{\beta})\cdot\vec{\beta}$ $C_2=h\cdot\vec{\beta}+(\vec{p}\times\vec{\varepsilon})$
$\kappa=0,\ \beta\neq 0,\ m\neq 0$	6	$C_1=(\vec{\varepsilon}\cdot\vec{k})\cdot\vec{\beta}+\frac{1}{2}\vec{p}^2\cdot\vec{\beta}-mh\cdot\vec{\beta}-(\vec{j}\cdot\vec{\beta})\cdot\vec{\beta}$ $C_2=\vec{\beta}^2h+(\vec{p}\times\vec{\varepsilon})\cdot\vec{\beta}+\frac{m}{2}\vec{\varepsilon}^2$

Certain hidden symmetries of crystals

Mario Nardone[a)]
Mathematical Institute, Oxford University, Oxford, OX1 3LB, United Kingdom

(Received 23 May 2005; accepted 19 September 2005; published online 24 March 2006)

Recently, among schemes for crystals classification, the arithmetic criterion has been introduced in solid-mechanics literature devoted to solid-to-solid phase transitions. Its main feature is to detect subtle symmetries ignored by standard classification schemes, e.g., space-group type classification. Using the arithmetic criterion, certain phase transitions can be identified by symmetry change, even when occurring between isosymmetric allotropes. Unfortunately, its original formulation is somewhat involved and not completely general. We give a general coordinate-free definition for it and prove that such a classification scheme has intrinsic character. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2121147]

I. INTRODUCTION

This is the first of a series of papers devoted to the systematic investigation of the arithmetic scheme for crystal structures classification. By crystal structures we mean point sets in the Euclidean space, possibly admitting a group of translational symmetries, each point of which carries a color. These are geometric models for aggregates of points, each point giving for example the (average) position of an atom or cluster of atoms, such as in crystalline solids, each color identifying, for instance, different types of atoms. These objects have varying nomenclature in the literature, such as *lattices with a basis*,[2,20] *ideal crystals*,[6] *multiregular point systems*,[5] *multilattices*.[24,25]

A basic way of describing their symmetries of crystal structures use their space groups. This leads to the well-known 219 types in three dimensions (230 types when orientation is taken into account).[15] One difficulty with this approach is that it only captures the intrinsic space geometries of the crystals, i.e., the orbifolds they generate,[26,21] ignoring the arrangement of the atoms with respect to these landscapes. As a consequence, crystals with reasonably different symmetry properties cannot be distinguished. Concretely this happens with isosymmetric solid-to-solid phase transformations, i.e., crystalline substances which exhibit distinct allotropes with the same space-group type[16,24,4] (see Fig. 4 for a simple theoretical example).

In this case, the existence of different symmetries for the two phases involved is confirmed by the presence of a phase transition. This raises the problem of how to define a good way of classifying structures so as to be able to distinguish between them even in the above-mentioned critical situation. While there exist well-known empirical lists of classes of structures such as Strukturberichte,[1] the literature does not currently show general, sufficiently subtle, accepted criteria for the classification of all the (possibly colored) crystal structures. This is evident in the comprehensive crystal structure database at http://cst-www.nrl.navy.mil/lattice/.

The arithmetic criterion has been recently developed in the context of solid mechanics and martensitic transformations, see Refs. 24, 25, and 3, following earlier works,[7,22,23] as a classification scheme for (colored) crystals based on symmetry. It extends to general structures the classical arithmetic method used in crystallography to classify simple lattices (i.e., crystals with one atom per primitive translational cell) into Bravais types,[6] obtaining, for instance, the well-known 14 Bravais types in three dimensions.

{2}	5	{2}	29
{1,1}	10	{1,1}	51

The classification into Bravais types considers the equivalence classes of natural representations of the point group on the translation group. The arithmetic method instead, involves the equivalence classes of natural representations of the point group on a particular group obtained combining the translation group with the group of permutations of the (colored) set of the translation-group orbits. It has been shown[24] that this actually produces a finer classification of crystals than that based on the space-group type (and even that by Pearson Symbol); see also Sec. V C.

Furthermore it produces symmetry hierarchies among crystals that are more general than the standard ones.[17] In Refs. 8, 11, 10, and 9 (see Table I for a summary of the corresponding results) the systematic enumeration of the classes of structures generated by the arithmetic criterion were worked out in the simplest cases, while in Ref. 10 the symmetry hierarchies among crystals were shown, again in the simplest cases.

Unfortunately the original definition of the arithmetic criterion is involved, and not directly expressed in a coordinate-free way, nor completely general for certain aspects. We think this is what has prevented its diffusion from solid mechanics and crystallography. In fact, it has natural applications in other fields, such as solid state physics and chemistry, in the investigation of diffusionless solid-to-solid phase transitions and *ab initio* computations of materials. Theoretical crystallographers and solid-mechanics researchers may also find the perspective presented here interesting. The only requirements for reading this paper are an understanding of basic crystallography and some familiarity with group theory.

Our main objective is to give a simpler and coordinate-free formulation of the arithmetic criterion, making it available to a wider spectrum of scientists. In doing this, we have developed a unified treatment for structures of any dimension, such as bulk crystalline materials, slabs, linear polymers and molecules, embedded in a Euclidean space of arbitrary dimension, possibly different from that of the structure considered. This lays the foundation for further generalization to modulated crystals and quasicrystals.

The classification according to the arithmetic criterion belongs, together with Bravais and space-group type schemes, to the family of classification criteria based on global symmetry, i.e., the space group of structures. There are other schemes based on different ideas, such as the topological and combinatorial properties of structures.[13] Notice that the structures we consider are modeled by points, maybe of different colors; no other information is encoded. In particular, we do not consider relations among points like chemical bonds, such as in Ref. 14, though a generalization aimed to include these features is straightforward.

The basic expected requirements for symmetry-based criteria are: to coincide with the Bravais classification scheme whenever applied to simple lattices; to have intrinsic character (in the sense that it is possible to formulate them directly in a coordinate-free way); and, possibly, to produce a finite number of equivalence classes once the number of (colored) atoms per (primitive translational) cell has been fixed. The criteria producing the classification into Bravais types, lattice complexes, or space-group types, all satisfy these properties. We show this is true for the arithmetic criterion too, though the finiteness property will be proved in a separate paper.

This paper is structured as follows. In Sec. II we give the basic definitions of (crystal) structures in a Euclidean space, while in Sec. III we state the minimal properties expected from any (symmetry-based) criterion classifying structures. In Sec. IV we review the standard space-

group type scheme, reformulated in such a way that the arithmetic principle can be introduced as an extension of it. In Sec. V we state, in a coordinate-free form, the generalized form of the arithmetic classification principle, and in Sec. VI we give some results pertaining to the arithmetic scheme and we conclude with some examples showing how sensitive this criterion is. In the Appendix we provide some background material used throughout the paper.

Notations and conventions. Our notation is close to Ref. 19, which can be consulted for a more detailed exposition of the mathematics summarized in the Appendix.

(1) We write maps à la Hormander: $f: X \ni x \mapsto y \in Y$.
(2) For A, B, C objects in a category, the symbol $\mathrm{Iso}(A,B)$ denotes the set of isomorphisms in that category from A to B; $\mathrm{Iso}(C)$ means $\mathrm{Iso}(C,C)$ and id_C refers to the identity morphism of C.
(3) When an equivalence relation is clear from the context, we denote by $[x]$ the equivalence class of the element x; sometimes, however, we omit the square brackets.
(4) A morphism is often depicted as an arrow between two objects. All diagram of objects and morphisms are understood to be commutative, i.e. one gets the same results whatever way one performs composition of morphisms between the same two objects.
(5) We omit zero submatrices and write $\left(\begin{array}{c|c} a & b \\ \hline & c \end{array}\right)$ for $\left(\begin{array}{c|c} a & b \\ \hline 0 & c \end{array}\right)$.
(6) The symbol $\square$ denotes the end of a proof.

II. PRELIMINARIES AND DEFINITION OF STRUCTURES

We first restate some basic notions regarding the symmetry of Euclidean spaces and structures, presented in a way suitable for later developments. (One can choose to operate within either the *oriented* or *nonoriented* context. In the former case one works with oriented Euclidean spaces and uses orientation-preserving affinities, isometries and their linear parts.)

A. Euclidean spaces and their space groups

Definition 2.1: Let $\mathbb{E}$ be a Euclidean space; the *space group* $G(\mathbb{E})$ of $\mathbb{E}$ is the group of all the isometries of $\mathbb{E}$. Other key concepts are:

(1) $L(\mathbb{E})$, the *translation group* of $\mathbb{E}$, is the (additive) group underlying $\mathbb{E}$;
(2) $P(\mathbb{E})$, the *point group* of $\mathbb{E}$, is the group of orthogonal linear maps of the vector space $L(\mathbb{E})$;
(3) $\eta: P(\mathbb{E}) \to \mathrm{Iso}(L(\mathbb{E}))$, the *action* of $P(\mathbb{E})$ on $L(\mathbb{E})$, is the natural action $q.t := qt$.

We write $\mathcal{I}: L(\mathbb{E}) \to G(\mathbb{E})$ for the map taking a vector to the translation by that vector; for clarity vectors will sometimes be written in bold. Choosing an origin O for $\mathbb{E}$ defines in a natural way a (*Group*-)morphism $\sigma: P(\mathbb{E}) \to G(\mathbb{E})$ called a *splitting* (*morphism*) of $\mathbb{E}$. The origin is the only point fixed by all the elements of the image of $\sigma: \sigma(q).O = O \; \forall\, q \in P(\mathbb{E})$.

B. Structures and their space groups

Next, we give the definition of structures. We make no *a priori* hypotheses on the (dimensions of the) Euclidean spaces involved. Hence the host Euclidean space, though sometimes omitted for brevity, is part of the data needed to specify a structure. In view of this generality, structures need not "fill" the underlying space. We say that a structure is *full* when it "fills" such a space, i.e., with notation introduced just below in the text, when $\dim_{\mathbb{R}} L(\mathbb{S}) = \dim_{\mathbb{R}} L(\mathbb{E})$. Full structures are those of Examples 2.4, 2.5, 5.8, 5.9, but not that of Example 5.10, for which $\dim_{\mathbb{R}} L(\mathbb{S}) = 0 < 3 = \dim_{\mathbb{R}} L(\mathbb{E})$. For a $\mathbb{Z}$-submodule N of an $\mathbb{R}$-module M, we write $\dim_{\mathbb{R}} N$ for $\dim_{\mathbb{R}} \mathbb{R}N$, where $\mathbb{R}N$ is the $\mathbb{R}$-span of N in M.

Definition 2.2: For a set of colors $\mathfrak{C}$, a $\mathfrak{C}$-*structure* embedded into the Euclidean space $\mathbb{E}$, which we write as $\mathbb{S} \hookrightarrow \mathbb{E}$, is a $\mathfrak{C}$-set $c(\mathbb{S}): S(\mathbb{S}) \to \mathfrak{C}$ with $S(\mathbb{S})$ a subset of $\mathbb{E}$. The concept of $\mathfrak{C}$-set is recalled in the Appendix. When $\mathfrak{C}$ is a made up of one only element we refer to the *noncolored*

case, colors playing no role at all. We will often speak of structures rather than $\mathfrak{C}$-structures when $\mathfrak{C}$ is clear from the context.

Definition 2.3: $G(\mathrm{S}) := \{g \in G(\mathbb{E}) \text{ such that } g.\mathrm{S}=\mathrm{S}\}$ is the *space group* of S. (In other words, the space group is made up of all the isometries mapping the set $S(\mathrm{S})$ in itself and respecting the colors of its points.) In this context (compare with Definition 2.1):

(1) $L(\mathrm{S}) := \mathcal{I}^{-1}(G(\mathrm{S}) \cap \mathcal{I}(L(\mathbb{E})))$ is the *translation group* (also known as *skeletal lattice*[24,25]) of S;
(2) $P(\mathrm{S}) := G(\mathrm{S})/\mathcal{I}(L(\mathrm{S}))$ is the *point group* of S;
(3) $\eta: P(\mathrm{S}) \to \mathrm{Iso}(L(\mathbb{E})_{L(\mathrm{S})})$ induced by $\eta: P(\mathbb{E}) \to \mathrm{Iso}(L(\mathbb{E}))$ is the *arithmetic point group* of S.

Notice that we do not restrict our attention only to structures S with a discrete translation group, i.e., with $\dim_{\mathbb{R}} L(\mathrm{S}) = \dim_{\mathbb{Z}} L(\mathrm{S})$.

C. Examples of structures

For a Euclidean space $\mathbb{E}$ choose an origin O and an orthonormal basis $(\mathbf{e}_i)_{i\in 1}$ for $L(\mathbb{E})$.

Example 2.4: The crystal of cesium chloride (CsCl).
$S(\mathrm{S}) := S_1 \amalg S_2$, where, for $L := \mathbb{Z}\mathbf{e}_1 + \mathbb{Z}\mathbf{e}_2 + \mathbb{Z}\mathbf{e}_3$,

$$S_1 := O + \mathbf{0} + L,$$

$$S_2 := O + \tfrac{1}{2}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) + L;$$

$c(\mathrm{S}) := (S_1 \to \{\mathrm{Cs}\}) \amalg (S_2 \to \{\mathrm{Cl}\})$.

Example 2.5: The crystal of C-diamond (C).
$S(\mathrm{S}) := S_1 \amalg S_2$, where, for $L := \mathbb{Z}\frac{1}{2}(\mathbf{e}_1+\mathbf{e}_2) + \mathbb{Z}\frac{1}{2}(\mathbf{e}_2+\mathbf{e}_3) + \mathbb{Z}\frac{1}{2}(\mathbf{e}_3+\mathbf{e}_1)$,

$$S_1 := O + \mathbf{0} + L,$$

$$S_2 := O + \tfrac{1}{4}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) + L;$$

$c(\mathrm{S}) := (S_1 \amalg S_2 \to \{\mathrm{C}\})$.

Example 2.6: The crystal of sodium (Na).
$S(\mathrm{S}) := \hat{S}_1 \amalg \hat{S}_2$, where, for $\hat{L} := \mathbb{Z}\mathbf{e}_1 + \mathbb{Z}\mathbf{e}_2 + \mathbb{Z}\mathbf{e}_3$,

$$\hat{S}_1 := O + \mathbf{0} + \hat{L},$$

$$\hat{S}_2 := O + \tfrac{1}{2}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) + \hat{L};$$

$c(\mathrm{S}) := (\hat{S}_1 \amalg \hat{S}_2 \to \{\mathrm{Na}\})$.

Equivalently, putting in evidence the entire translation group, we have: $S(\mathrm{S}) := S_1$, where, for $L := \mathbb{Z}\frac{1}{2}(-\mathbf{e}_1+\mathbf{e}_2+\mathbf{e}_3) + \mathbb{Z}\frac{1}{2}(+\mathbf{e}_1-\mathbf{e}_2+\mathbf{e}_3) + \mathbb{Z}\frac{1}{2}(+\mathbf{e}_1+\mathbf{e}_2-\mathbf{e}_3)$,

$$S_1 := O + \mathbf{0} + L;$$

$c(\mathrm{S}) := (S_1 \to \{\mathrm{Na}\})$.

III. GENERALITIES ON SCHEMES FOR CRYSTALS CLASSIFICATION

For a classification scheme written in terms of crystal bases (a crystal basis for E_L is an $\mathbb{R}$-basis of E which by restriction induces a $\mathbb{Z}$-basis of L) the restriction of having intrinsic character is usually stated by requiring its independence from the crystal bases chosen. We avoid the use of such bases, in which case such a property is expressed as follows (Fig. 1):

Definition 3.1: Let $\sim$ be an equivalence relation among structures. The equivalence $\sim$ has *intrinsic character* if for every couple $\mathrm{S}' \hookrightarrow \mathbb{E}'$, $\mathrm{S}'' \hookrightarrow \mathbb{E}''$ and every $\phi \in \mathrm{Aff}(\mathbb{E}', \mathbb{E}'')$ such that

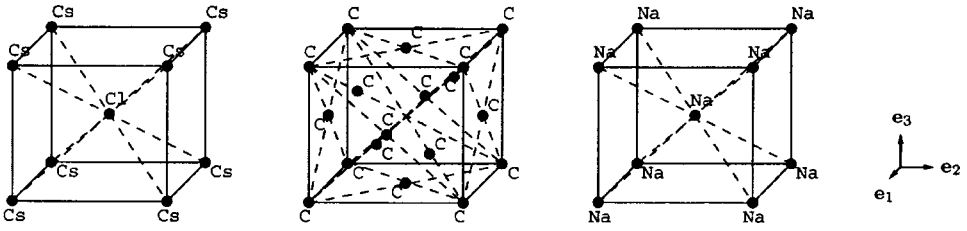

FIG. 1. From left of right: CsCl, C-Diamond, and Na crystals. Primitive (left) and conventional (middle and right) translational cells are shown.

$\mathbb{S}' \overset{\phi}{\to} \mathbb{S}''$ is a ($\mathfrak{C}$-*Set*-)isomorphism and $G(\mathbb{S}') \overset{\mathcal{C}_\phi}{\to} G(\mathbb{S}'')$ is a (*Group*-) isomorphism, we have $\mathbb{S}' \sim \mathbb{S}''$.

IV. CLASSIFYING STRUCTURES: SPACE-GROUP TYPE APPROACH REVISED

The arithmetic equivalence is formulated in terms of lattice groups of structures with respect to given essential arithmetic descriptors, while the space-group type equivalence is formulated in terms of space groups of structures. In some sense lattice groups generalize space groups and the arithmetic equivalence generalizes the space-group type equivalence. We reformulate the concepts of the space group of a structure and the space-group type equivalence in order to make this fact more evident, shortening the abstraction necessary to grasp the arithmetic criterion. To this purpose we rewrite space groups as objects encoding the absolute translational motion of primitive translational cells for each element of the point group. (A primitive translational cell is a fundamental domain for the action $\mathcal{I}L(\mathbb{S}) \to Iso(\mathbb{E})$.) Formally, we interpret them as representations of the point group on the translation group of the entire Euclidean space $L(\mathbb{E})$.

Fix a splitting $\sigma: P(\mathbb{E}) \to G(\mathbb{E})$. (Actually, in this context, a splitting should be thought as modulo $L(\mathbb{S})$, where the action of $L(\mathbb{S})$ on the set of splittings of $\mathbb{E}$ is $l.\sigma := \mathcal{C}_{\mathcal{I}(l)} \circ \sigma$.) Since $G(\mathbb{E}) = \mathcal{I}L(\mathbb{E}) \rtimes_\zeta \sigma P(\mathbb{E})$, where $\zeta: \sigma P(\mathbb{E}) \to \mathrm{Iso}(\mathcal{I}L(\mathbb{E}))$ is given by conjugation in $G(\mathbb{E})$, i.e., $\sigma(q).\mathcal{I}l := \mathcal{C}_{\sigma(q)}\mathcal{I}l$,[6] the following construction makes sense. For $t \in L(\mathbb{E})$ and $q \in P(\mathbb{E})$ write $t *_\sigma q$ for $\mathcal{I}(t) \circ \sigma(q)$. (The element $t *_\sigma \mathrm{id}$ is the same for every splitting σ and it will be denoted simply by $t * \mathrm{id}$.) Consider the (*Group*-)monomorphism (notice that $\eta: P(\mathbb{S}) \to \mathrm{Iso}(L(\mathbb{E})_{L(\mathbb{S})})$ is faithful, since $\eta: P(\mathbb{E}) \to \mathrm{Iso}(L(\mathbb{E}))$ is so):

$$G(\mathbb{S}) \hookrightarrow L(\mathbb{E}) \rtimes_\eta P(\mathbb{S}),$$

$$t *_\sigma q \mapsto \left(\begin{array}{c|c} \eta(q) & t \\ \hline & 1 \end{array} \right),$$

by restriction we get:

$$j: \mathcal{I}L(\mathbb{S}) \hookrightarrow j(\mathcal{I}L(\mathbb{S})),$$

$$\mathcal{I}(l) \mapsto \left(\begin{array}{c|c} \eta(\mathrm{id}) & l \\ \hline & 1 \end{array} \right).$$

The following (*Group*-)monomorphism is then naturally induced:

$$G(\mathbb{S})/\mathcal{I}L(\mathbb{S}) \hookrightarrow (L(\mathbb{E})/L(\mathbb{S})) \rtimes_\eta P(\mathbb{S}),$$

$$[t *_\sigma q] \mapsto \left(\begin{array}{c|c} \eta(q) & [t] \\ \hline & 1 \end{array} \right),$$

i.e.,

TABLE II. Some results on space-group type equivalence.

dim. transl. group	dim. Euclid. space	No. space-group types	Nomenclature
2	2	17	plane groups
2	3	80	layer groups
3	3	230	(3–) space groups

$$\mathfrak{G}_\sigma(\mathbb{S}):P(\mathbb{S}) \hookrightarrow (L(\mathbb{E})/L(\mathbb{S}))\rtimes_\eta P(\mathbb{S})$$

$$q \mapsto \left(\begin{array}{c|c} \eta(q) & [t] \\ \hline & 1 \end{array}\right). \tag{4.1}$$

Writing space groups explicitly, we omit the square brackets in the last expression and identify elements of $L(\mathbb{E})$ when they differ by an element of $L(\mathbb{S})$.

Remark 4.1: For a structure $\mathbb{S}$, we indicate by $\mathfrak{G}_\sigma(\mathbb{S})$ the image of the (*Group*-)morphism in (4.1) and we call it the *compact representation* of the space group of $\mathbb{S}$ relative to the splitting σ. This representation of the space group gets rid of the trivial part $L(\mathbb{S})$ pertaining to the translation group $L(\mathbb{E})$. Unlike $G(\mathbb{S})$, $\mathfrak{G}_\sigma(\mathbb{S})$ is always a finite group, and still keeps all the information of $G(\mathbb{S})$. In fact, there is a bijective correspondence between space groups and their compact representations:

$$\mathfrak{G}_\sigma(\mathbb{S}) = \left\{ \left(\begin{array}{c|c} \eta(q) & [t] \\ \hline & 1 \end{array}\right) \text{ such that } \left(\begin{array}{c|c} \eta(q) & t \\ \hline & 1 \end{array}\right) \in G(\mathbb{S}) \right\}$$

and

$$G(\mathbb{S}) = \left\{ \left(\begin{array}{c|c} \eta(q) & t \\ \hline & 1 \end{array}\right) \text{ such that } \left(\begin{array}{c|c} \eta(q) & [\tau] \\ \hline & 1 \end{array}\right) \in \mathfrak{G}(\mathbb{S})_\sigma, \text{ with } \mathcal{I}L(\mathbb{S}) \,.\, t = [\tau] \right\}.$$

Definition 4.2: Two structures $\mathbb{S}' \hookrightarrow \mathbb{E}', \mathbb{S}'' \hookrightarrow \mathbb{E}''$ are space-group type equivalent if there exists $\phi \in \mathrm{Aff}(\mathbb{E}', \mathbb{E}'')$ such that $\mathcal{C}_\phi: G(\mathbb{S}') \to G(\mathbb{S}'')$ is a (*Group*-)isomorphism.

In terms of compact representations of space groups, denoting by $\xi: Iso(E_L) \to Iso(E/L)$ the action induced by $E_L \ni t \mapsto [t] \in E/L$, we have:

Remark 4.3: Two structures $\mathbb{S}' \hookrightarrow \mathbb{E}', \mathbb{S}'' \hookrightarrow \mathbb{E}''$ are space-group type equivalent if and only if

1. $L(\mathbb{E}')_{L(\mathbb{S}')} = L(\mathbb{E}'')_{L(\mathbb{S}'')}$ (call them E_L),
2. there exists $([T], A) \in (E/L) \rtimes_\xi \mathrm{Iso}(E_L)$ such that $\mathcal{C}_{\left(\begin{array}{c|c} A & [T] \\ \hline & 1 \end{array}\right)}: \mathfrak{G}_{\sigma'}(\mathbb{S}') \to \mathfrak{G}_{\sigma''}(\mathbb{S}'')$ is a (*Group*-)isomorphism.

Again, performing explicit computation, we omit the square brackets in the last expression and identify elements of $L(\mathbb{E})$ differing by an element of $L(\mathbb{S})$.

Notice that in Remark 4.3, the structures enter only through their compact representations; the chosen splittings are not directly involved. In fact, we know that the concept of space-group type equivalence does not depend on the splittings chosen.

Some know results on space-group type quivalence

Table II shows some known results[15] which refer to the space-group type classification for structures with a discrete translation group. (In the nonoriented case, the "230" in such a table should be replaced by "219.")

V. CLASSIFYING STRUCTURES: THE ARITHMETIC APPROACH

A. Arithmetic description of structures

One way to look at crystal structures is as multilattices, i.e., unions of simple lattices[24,25] all with the same skeletal lattice. The most natural choice for it is the whole translation group of the structure they belong to. In this context, the orbit space $\mathbb{S}\backslash\mathcal{I}L(\mathbb{S})$ consists of one (colored) point for each of these simple lattices. The multiset (see the Appendix) associated to such an orbit space gives the number of such simple lattices, together with their color distribution, i.e., the number of "atoms," for each different species, in a primitive translational cell. We name these two concepts as follows:

Definition 5.1: For a structure $\mathbb{S}$, we call the $\mathfrak{C}$-set $\mathbb{S}\backslash\mathcal{I}L(\mathbb{S})$ the *arithmetic architecture* of $\mathbb{S}$, and the multiset associated to it, $|\mathbb{S}\backslash\mathcal{I}L(\mathbb{S})|$, the *arithmetic architecture type* of $\mathbb{S}$. For instance, simple lattices are those structures whose arithmetic architecture type is $\{1\}$, while structures with arithmetic architecture type $\{1, 2\}$ are those made up of $1+2=3$ translation-group orbits, two of them with the same color and the third one with a different color.

Example 5.2: Cesium chloride crystal CsCl (Example 2.4). The arithmetic description is

$$\mathbb{S}\backslash\mathcal{I}L(\mathbb{S}) = \{\underbrace{(S_1 \mapsto \{\mathrm{Cs}\})}_{1}, \underbrace{(S_2 \mapsto \{\mathrm{Cl}\})}_{1}\},$$

hence its arithmetic architecture type is $\{1, 1\}$.

Example 5.3: Diamond C (Example 1.5). The arithmetic description is

$$\mathbb{S}\backslash\mathcal{I}L(\mathbb{S}) = \{(\underbrace{S_1 \amalg S_2 \mapsto \{\mathrm{C}\}}_{2})\},$$

hence its arithmetic architecture type is $\{2\}$.

Example 5.4: Sodium crystal Na (Example 2.6). The arithmetic description is

$$\mathbb{S}\backslash\mathcal{I}L(\mathbb{S}) = \{\underbrace{(S_1 \mapsto \{\mathrm{Na}\})}_{1}\},$$

hence its arithmetic architecture type is $\{1\}$. Notice that we have to use the description in terms of the *whole* translation group; equivalently we have to refer to a *primitive* translational cell. For instance the arithmetic description:

$$\mathbb{S}\backslash\mathcal{I}L(\mathbb{S}) \overset{\text{(false)}}{=} \{\underbrace{(\hat{S}_1 \amalg \hat{S}_2 \mapsto \{\mathrm{Na}\})}_{2}\},$$

would wrongly lead us to conclude that the arithmetic architecture type is $\{2\}$.

B. Essential arithmetic descriptors of structures

We now introduce the concept of essential arithmetic descriptors for structures. This concept is close to the notion of bases relative to a primitive translational cell,[2,18] though its elements need not be confined to the closure of such a cell. A structure can be reconstructed from one of its essential arithmetic descriptors; in fact, an essential arithmetic descriptor is a minimal colored set generating the structure once the elements of its translation group are applied to such a set. Formally:

Definition 5.5: For a structure $\mathbb{S}$ and $\mathcal{A}$ a $\mathfrak{C}$-set isomorphic to the arithmetic architecture of $\mathbb{S}$, an *essential arithmetic descriptor* for $\mathbb{S}$ is a sub-$\mathfrak{C}$-set of the $\mathfrak{C}$-set $\mathbb{S}$, $(P_\alpha)_{\alpha\in\mathcal{A}}$, such that

$$\mathbb{S} = \amalg_{\alpha\in\mathcal{A}} P_\alpha + L(\mathbb{S}).$$

Actually an essential arithmetic descriptor should be thought of modulo $L(\mathbb{S})$ (the same transition for all of its points), i.e., as an element of $\mathbb{E}^{\mathcal{A}}\backslash L(\mathbb{S})$ rather than $\mathbb{E}^{\mathcal{A}}$, the action $L(\mathbb{S})\to \mathrm{Iso}(\mathbb{E}^{\mathcal{A}})$ being $l.(Q_\alpha)_{\alpha\in\mathcal{A}} := (Q_\alpha + l)_{\alpha\in\mathcal{A}}$.

Example 5.6: For the structure of C-Diamond in Example 2.5; the following is a 1-1 parametrization of the set of all its essential arithmetic descriptors:

$$c:\left(\left\{O + \mathbf{0} + \mathbf{1}_{(a,b,c)}, O + \tfrac{1}{4}(\mathbf{e}_1 + \mathbf{e}_2 + \mathbf{e}_3) + \mathbf{1}_{(d,e,f)}\right\} \mapsto \{\mathrm{C}\}\right),$$

with $\mathbf{1}_{(x,y,z)} := x\frac{1}{2}(\mathbf{e}_1+\mathbf{e}_2) + y\frac{1}{2}(\mathbf{e}_2+\mathbf{e}_3) + z\frac{1}{2}(\mathbf{e}_3+\mathbf{e}_1)$ and each of a,b,c,d,e,f ranging in the integers. In other words, every essential arithmetic descriptor appears for a unique value of $((a,b,c),(d,e,f))$. Notice that each essential arithmetic descriptor is a $\mathfrak{C}$-set.

For an essential arithmetic descriptor $(P_\alpha)_{\alpha\in\mathcal{A}}$ of $\mathbb{S}$ one has the ($\mathfrak{C}$-*Set*-)isomorphism $\Upsilon_{(P_\alpha)_{\alpha\in\mathcal{A}}}: \mathcal{A} \ni \alpha \mapsto \mathcal{I}L(\mathbb{S}).P_\alpha \in \mathbb{S}\backslash\mathcal{I}L(\mathbb{S})$. This simply describes the labeling in terms of the elements of $\mathcal{A}$, induced by the chosen essential arithmetic descriptor, for the simple lattices forming $\mathbb{S}$.

C. The lattice group of a structure

Lattice groups encode the relative (translational) motion of the "atoms" inside primitive translational cells for each element of the point group. These are representations of the point group on the group $W_{\mathcal{A}}(\mathbb{S}) := L(\mathbb{S})\chi\mathrm{Iso}(\mathcal{A})$ obtained by intertwining the translation group and the group of permutations of its arithmetic architecture.

Definition 5.7: Let $\mathbb{S}$ be a structure and $(P_\alpha)_{\alpha\in\mathcal{A}}$ an arithmetic descriptor for it. We will make use of the following group: $W_{\mathcal{A}}(\mathbb{S}) \rtimes_{\eta_{\mathcal{A}}} P(\mathbb{S})$, where $\eta_{\mathcal{A}}: P(\mathbb{S}) \to \mathrm{Iso}(W_{\mathcal{A}}(\mathbb{S}))$ is $q.((\omega_\alpha)_{\alpha\in\mathcal{A}}, \delta) := ((q.\omega_\alpha)_{\alpha\in\mathcal{A}}, \delta))$. Consider the (*Group*-)monomorphism:

$$G(\mathbb{S}) \to W_{\mathcal{A}}(\mathbb{S}) \rtimes_{\eta_{\mathcal{A}}} P(\mathbb{S}),$$

$$t*_\sigma q \mapsto \left(\begin{array}{c|c} \eta(q) & \omega(q) \\ \hline & \tilde{\delta}(q) \end{array}\right),$$

where, for $t*_\sigma q \in G(\mathbb{S})$, $(\omega(q), \delta(q)) \in W_{\mathcal{A}}(\mathbb{S})$ is uniquely determined by

$$(t*_\sigma q) \,.\, P_\alpha = (\omega(q)_\alpha * \mathrm{id}) \,.\, P_{\delta(q)(\alpha)} \;\forall\; \alpha \in \mathcal{A};$$

by restriction we get

$$j:\mathcal{I}L(\mathbb{S}) \hookrightarrow j\mathcal{I}L(\mathbb{S}),$$

$$\mathcal{I}(l) \mapsto \left(\begin{array}{c|c} \eta(\mathrm{id}) & (l)_{\alpha\in\mathcal{A}} \\ \hline & \mathrm{id} \end{array}\right).$$

Hence the following (*Group*-)monomorphism is induced:

$$G(\mathbb{S})/\mathcal{I}L(\mathbb{S}) \hookrightarrow (W_{\mathcal{A}}(\mathbb{S})/L(\mathbb{S})) \rtimes_{\eta_{\mathcal{A}}} P(\mathbb{S}),$$

$$[t*_\sigma q] \mapsto \left(\begin{array}{c|c} \eta(q) & [\omega(q)] \\ \hline & \tilde{\delta}(q) \end{array}\right).$$

i.e.,

$$\Lambda(\mathbb{S})_{(P_\alpha)_{\alpha\in\mathcal{A}}}: P(\mathbb{S}) \hookrightarrow (W_{\mathcal{A}}(\mathbb{S})/L(\mathbb{S})) \rtimes_{\eta_{\mathcal{A}}} P(\mathbb{S})$$

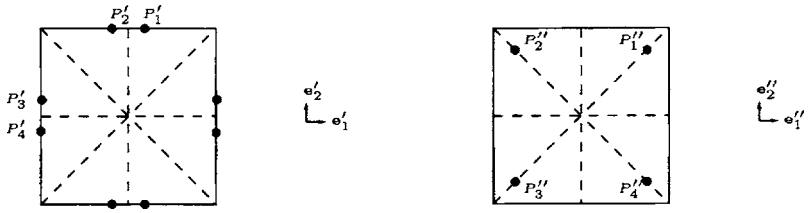

FIG. 2. The plane regular point systems *p*4*mm e* (left), and *p*4*mm f* (right) (basis vectors not in scale; primitive translational cells shown).

$$q \mapsto \left(\begin{array}{c|c} \eta(q) & [\omega(q)] \\ \hline & \widetilde{\delta}(q) \end{array} \right) \tag{5.1}$$

Although to obtain (5.1) we used a splitting for $\mathbb{E}$, this formula does not depend upon such a choice. We omitted the diagonal inclusion $j: L(\mathbb{S}) \ni l \mapsto ((l)_{\alpha\in\mathcal{A}}, \mathrm{id}) \in W_{\mathcal{A}}(\mathbb{S})$ (all columns, indexed by α, equal l). Similarly to what we did with the elements of compact representations of space groups, for the elements of lattice groups we omit square brackets and identify the top right submatrices differing by a matrix with all equal columns.

The group image $\Lambda(\mathbb{S})_{(P_\alpha)_{\alpha\in\mathcal{A}}}$ of $P(\mathbb{S})$ via (5.1) is called the *lattice group* of the structure $\mathbb{S}$ with respect to the essential arithmetic descriptor $(P_\alpha)_{\alpha\in\mathcal{A}}$.

Notice that, choosing a crystal basis for the structure $\mathbb{S} \hookrightarrow \mathbb{E}$, any element $\left(\begin{array}{c|c} \eta(q) & [\omega] \\ \hline & \widetilde{\delta} \end{array} \right)$ of its lattice group can be written referring to such a basis; in this case both $\eta(q)$ and ω are represented by matrices with integer coefficients.[24,25]

D. Examples of explicit computations of space groups and lattice groups of structures

Example 5.8: Consider the (full noncolored) structure $\mathbb{S}'$ sketched in Fig. 2—the plane regular point system *p*4*mm*#*d*.[15] Its arithmetic point group is $\eta'(P(\mathbb{S}')) = \langle 4^+(0,0), m(0,y)\rangle$. [Notations here are as in Ref. 15: $4^+(0,0)$ is the counterclock wise rotation by $+2\pi/4$ around the axis perpendicular to the page passing through the origin and pointing toward the reader, while $m(0,y)$ is the mirror reflection across the plane with axis $\mathbf{e}_2$ and passing through the origin.]

Referring to the figure, we choose the center of the square sketched as origin O' of the Euclidean space $\mathbb{E}'$, the points P'_1, P'_2, P'_3, P'_4 as essential arithmetic descriptor and the vectors $\mathbf{e}'_1, \mathbf{e}'_2$ shown as crystal basis.

The action of the point group on the origin O' is

$$\eta'^{-1} \,.\, 4^+(0,0) \mapsto (O' \mapsto O' + \mathbf{0}),$$

$$\eta'^{-1} \,.\, m(0,y) \mapsto (O' \mapsto O' + \mathbf{0}).$$

The action of the point group on the essential arithmetic descriptor P'_1, P'_2, P'_3, P'_4 is

$$\eta'^{-1} \,.\, 4^+(0,0) \mapsto \begin{pmatrix} P'_1 & \mapsto & P'_3 + \mathbf{0} \\ P'_2 & \mapsto & P'_4 + \mathbf{0} \\ P'_3 & \mapsto & P'_2 - \mathbf{e}'_2 \\ P'_4 & \mapsto & P'_1 - \mathbf{e}'_2 \end{pmatrix},$$

$$\eta'^{-1}\,.\,m(0,y)\mapsto\begin{pmatrix} P'_1 & \mapsto & P'_2+\mathbf{0}\\ P'_2 & \mapsto & P'_1+\mathbf{0}\\ P'_3 & \mapsto & P'_3+\mathbf{e}'_1\\ P'_4 & \mapsto & P'_4+\mathbf{e}'_1 \end{pmatrix}.$$

So the compact representation of the space group of $\mathbb{S}'$ written with respect to the origin O' and with coordinates relative to the basis $\mathbf{e}'_1,\mathbf{e}'_2$ is

$$\left\langle\left(\left(\begin{array}{cc|c} 0 & -1 & 0\\ 1 & 0 & 0\\ \hline & & 1 \end{array}\right),\left(\begin{array}{cc|c} -1 & 0 & 0\\ 0 & 1 & 0\\ \hline & & 1 \end{array}\right)\right)\right\rangle, \tag{g'}$$

while the lattice group of $\mathbb{S}'$ written with respect to the essential arithmetic descriptor P'_1,P'_2,P'_3,P'_4 and with coordinates relative to the basis $\mathbf{e}'_1,\mathbf{e}'_2$ is

$$\left\langle\left(\left(\begin{array}{cc|cccc} 0 & -1 & 0 & 0 & 0 & 0\\ 1 & 0 & 0 & 0 & -1 & -1\\ \hline & & 0 & 0 & 0 & 1\\ & & 0 & 0 & 1 & 0\\ & & 1 & 0 & 0 & 0\\ & & 0 & 1 & 0 & 0 \end{array}\right),\left(\begin{array}{cc|cccc} -1 & 0 & 0 & 0 & 1 & 1\\ 0 & 1 & 0 & 0 & 0 & 0\\ \hline & & 0 & 1 & 0 & 0\\ & & 1 & 0 & 0 & 0\\ & & 0 & 0 & 1 & 0\\ & & 0 & 0 & 0 & 1 \end{array}\right)\right)\right\rangle. \tag{λ'}$$

Incidentally, the action $\delta':P(\mathbb{S}')\to\mathrm{Iso}(\mathcal{A})$ in this case is

$$\eta''^{-1}\,.\,4^+(0,0)\mapsto(1,3,2,4),$$

$$\eta''^{-1}\,.\,m(0,y)\mapsto(1,2)(3)(4).$$

Example 5.9: Consider the (full noncolored) structure $\mathbb{S}''$ sketched in Fig. 2—the plane regular point system *p4mm#f*.[15] Its arithmetic point group is $\eta''(P(\mathbb{S}''))=\langle 4^+(0,0),m(0,y)\rangle$. (This is the same arithmetic point group as in the previous example, once we have identified the Euclidean spaces $\mathbb{E}',\mathbb{E}''$ via the affinity defined by $O'\mapsto O''$ and $\mathbf{e}'_i\mapsto\mathbf{e}''_i$. In addition, with this identification, the space groups of these two structures coincide.)

Referring to the figure, we choose the center of the square sketched as origin O'' of the Euclidean space $\mathbb{E}''$, the points P''_1,P''_2,P''_3,P''_4 as essential arithmetic descriptor and the vectors $\mathbf{e}''_1,\mathbf{e}''_2$ shown as crystal basis, the same as the one in the previous example identifying in an obvious way the two underlying Euclidean spaces. The action of the point group on the chosen origin for $\mathbb{E}''$ is

$$\eta''^{-1}\,.\,4^+(0,0)\mapsto(O''\mapsto O''+\mathbf{0}),$$

$$\eta''^{-1}\,.\,m(0,y)\mapsto(O''\mapsto O''+\mathbf{0}),$$

while the action of the point group on the chosen essential arithmetic descriptor is

$$\eta''^{-1}\,.\,4^+(0,0)\mapsto\begin{pmatrix} P''_1 & \mapsto & P''_2+\mathbf{0}\\ P''_2 & \mapsto & P''_3+\mathbf{0}\\ P''_3 & \mapsto & P''_4+\mathbf{0}\\ P''_4 & \mapsto & P''_1+\mathbf{0} \end{pmatrix},$$

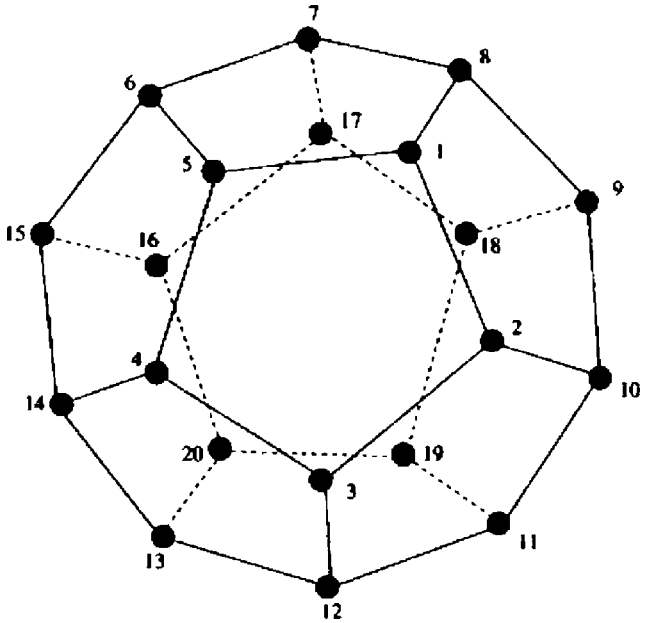

FIG. 3. The fullerene C_{20} molecule. Numbering according to IUPAC Recommendations 2004; see Ref. 12, Ref. No. 20:1, CAS Reg. No. 104375-45-3.

$$\eta''^{-1}\,.\,m(0,y)\mapsto\begin{pmatrix} P_1'' & \mapsto & P_2''+\mathbf{0} \\ P_2'' & \mapsto & P_1''+\mathbf{0} \\ P_3'' & \mapsto & P_4''+\mathbf{0} \\ P_4'' & \mapsto & P_3''+\mathbf{0} \end{pmatrix}.$$

Hence the compact representation of the space group of $\mathbb{S}''$ written with respect to the origin O'' of $\mathbb{E}''$ and with coordinates relative to the basis $\mathbf{e}_1'', \mathbf{e}_2''$ is

$$\left\langle\left(\begin{array}{cc|c} 0 & -1 & 0 \\ 1 & 0 & 0 \\ \hline & & 1 \end{array}\right),\left(\begin{array}{cc|c} -1 & 0 & 0 \\ 0 & 1 & 0 \\ \hline & & 1 \end{array}\right)\right\rangle, \qquad (g'')$$

while the lattice group of $\mathbb{S}''$ written with respect to the above essential arithmetic descriptor and with coordinates relative to the chosen crystal basis is

$$\left\langle\left(\begin{array}{cc|cccc} 0 & -1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & -1 & -1 \\ \hline & & 0 & 0 & 0 & 1 \\ & & 0 & 0 & 1 & 0 \\ & & 1 & 0 & 0 & 0 \\ & & 0 & 1 & 0 & 0 \end{array}\right),\left(\begin{array}{cc|cccc} -1 & 0 & 0 & 0 & 1 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ \hline & & 0 & 1 & 0 & 0 \\ & & 1 & 0 & 0 & 0 \\ & & 0 & 0 & 1 & 0 \\ & & 0 & 0 & 0 & 1 \end{array}\right)\right\rangle. \qquad (\lambda'')$$

The action $\delta'': P(\mathbb{S}'') \to \mathrm{Iso}(\mathcal{A})$ is

$$\eta''^{-1}\,.\,4^{+}(0,0)\mapsto(1,2,3,4),$$

$$\eta''^{-1}\,.\,m(0,y)\mapsto(1,2)(3,4).$$

Example 5.10: Consider the {C}-structure $\mathbb{S}$ sketched in Fig. 3, modeling C_{20} fullerene mol-

ecule. Its arithmetic point group is $\eta(P(\mathbb{S}))=\langle 5_a^+, 5_b^+, m\rangle$. [We use the following (nonstandard) notation: 5_a^+ (respectively, 5_b^+) denotes the counterclock wise rotation by $+2\pi/5$ around the axis perpendicular to the two faces with vertices 5, 4, 3, 2, 1 (respectively, 1, 8, 7, 6, 5) and 20, 19, 18, 17, 16 (respectively, 20, 13, 12, 11, 19), pointing from the latter to the former and passing through the origin; m denotes the mirror reflection across the plane passing through vertices 3, 7, 12, 17.]

Referring to the figure, we choose the center of the square sketched as origin O of the Euclidean space $\mathbb{E}$, the points $P_1,\ldots,P_{20}$ as essential arithmetic descriptor (denoted simply by 1,…,20 in the figure).

The action of the point group on the chosen origin for $\mathbb{E}$ is

$$\eta^{-1}\,.\,5_a^+ \mapsto (O \mapsto O+\mathbf{0}),$$

$$\eta^{-1}\,.\,5_b^+ \mapsto (O \mapsto O+\mathbf{0}),$$

$$\eta^{-1}\,.\,m \mapsto (O \mapsto O+\mathbf{0}),$$

while the action of the point group on the chosen essential arithmetic descriptor is

$$\eta^{-1}\,.\,5_a^+ \mapsto \begin{pmatrix} P_1 & \mapsto & P_{\delta(\eta^{-1}.5_a^+)(1)}+\mathbf{0} \\ & \cdots & \\ P_{20} & \mapsto & P_{\delta(\eta^{-1}.5_a^+)(20)}+\mathbf{0} \end{pmatrix},$$

$$\eta^{-1}\,.\,5_b^+ \mapsto \begin{pmatrix} P_1 & \mapsto & P_{\delta(\eta^{-1}.5_b^+)(1)}+\mathbf{0} \\ & \cdots & \\ P_{20} & \mapsto & P_{\delta(\eta^{-1}.5_b^+)(20)}+\mathbf{0} \end{pmatrix},$$

$$\eta^{-1}\,.\,m \mapsto \begin{pmatrix} P_1 & \mapsto & P_{\delta(\eta^{-1}.m)(1)}+\mathbf{0} \\ & \cdots & \\ P_{20} & \mapsto & P_{\delta(\eta^{-1}.m)(20)}+\mathbf{0} \end{pmatrix},$$

where the action $\delta: P(\mathbb{S}) \to \mathrm{Iso}(\mathcal{A})$ is

$$\eta^{-1}\,.\,5_a^+ \mapsto (5,4,3,2,1)(14,12,10,8,6)(15,13,11,9,7)(20,19,18,17,16),$$

$$\eta^{-1}\,.\,5_b^+ \mapsto (1,8,7,6,5)(2,9,17,15,4)(3,10,18,16,14)(11,19,20,13,12),$$

$$\eta^{-1}\,.\,m \mapsto (1,5)(2,4)(3)(6,8)(7)(9,15)(10,14)(11,13)(12)(16,18)(17)(19,20).$$

From this, the lattice group of $\mathbb{S}$ written with respect to the above essential arithmetic descriptor can be immediately written, though the matrix notation is awkward. Notice that in the definition of wreath product we used matrix notation just to avoid being too abstract. The drawback of this choice is a cumbersome notation in a case like the above where the arithmetic architecture is large. In such a case one should switch to cycles' notation; the modifications are straightforward.

E. Relationship between space groups and lattice groups

As we said, while space groups keep track of the absolute translational motion of primitive translational cells, lattice groups record the relative (translational) motion of the "atoms" inside such cells. Hence there seems to be no correlation between space groups and lattice groups, but

actually the latter can be recovered from the former (but not vice-versa;[24,25] see also Examples 6.4, 6.5). The reason is that the baricenter of the "atoms" inside a primitive translational cell, being rigidly attached to it, determines its position. Formally:

Remark 5.11: The following is a (*Group*-)isomorphism:

$$\Lambda(\mathbb{S})_{(P_\alpha)_{\alpha\in\mathcal{A}}} \ni \left(\begin{array}{c|c} \eta(q) & [\omega(q)] \\ \hline & \widetilde{\delta}(q) \end{array}\right) \mapsto \left(\begin{array}{c|c} \eta(q) & [\overline{\omega(q)} + (\mathrm{id} - q)\,.\,(\bar{P} - O)] \\ \hline & 1 \end{array}\right) \in \mathfrak{G}_\sigma(\mathbb{S}),$$

fitting the diagram:

$$\begin{array}{ccc} \Lambda(\mathbb{S})_{(P_\alpha)_{\alpha\in\mathcal{A}}} & \longrightarrow & P(\mathbb{S}) \\ \downarrow & & \downarrow \mathrm{id} \\ \mathfrak{G}_\sigma(\mathbb{S}) & \longrightarrow & P(\mathbb{S}) \end{array},$$

where, for $[(\omega_\alpha)_{\alpha\in\mathcal{A}}] \in L(\mathbb{S})^{\mathcal{A}}/L(\mathbb{S})$, $[\bar{\omega}] \in L(\mathbb{E})/L(\mathbb{S})$ is well defined as [average of $(\omega_\alpha)_{\alpha\in\mathcal{A}}$]. Hence the lattice group retains (strictly) more information than the space group.

Example 5.12: We apply this remark to obtain the space group from the lattice group in some explicit cases.

1. Example 4.8. $\overline{P'} = O' - \frac{1}{4}\mathbf{e}_1' + \frac{1}{4}\mathbf{e}_2'$; from (λ') we get $\overline{\omega'(\eta''^{-1}.4^+(0,0))} = -\frac{1}{2}\mathbf{e}_2'$, $\omega'(\eta''^{-1}.m(0,y)) = \frac{1}{2}\mathbf{e}_1'$ and, by Remark 5.11, we get (g').

2. Example 4.9. $P'' = O'' + \mathbf{0}$; (λ'') gives $\overline{\omega''(\eta''^{-1}.4^+(0,0))} = \mathbf{0}$, $\overline{\omega''(\eta''^{-1}.m(0,y))} = \mathbf{0}$; by Remark 5.11 we get (g'').

F. The arithmetic classification principle

We are now ready to give an intrinsic definition of the arithmetic equivalence for structures. Write $\eta_{\mathcal{A}}: E_L \to Iso\,(W_{\mathcal{A}})$ for $A.((\omega_\alpha)_{\alpha\in\mathcal{A}}, \delta) := ((A.\omega_\alpha)_{\alpha\in\mathcal{A}}, \delta)$.

Definition 5.13: Two structures with the same arithmetic architecture $\mathcal{A}$, $\mathbb{S}' \hookrightarrow \mathbb{E}'$ and $\mathbb{S}'' \hookrightarrow \mathbb{E}''$, are *arithmetically equivalent* if

1. $L(\mathbb{E}')_{L(\mathbb{S}')} = L(\mathbb{E}'')_{L(\mathbb{S}'')}$ (call them E_L), and hence $W_{\mathcal{A}}(\mathbb{S}') = W_{\mathcal{A}}(\mathbb{S}'')$ (call them $W_{\mathcal{A}}$),

2. for $(P'_\alpha)_{\alpha\in\mathcal{A}}$, $(P''_\alpha)_{\alpha\in\mathcal{A}}$ essential arithmetic descriptors for $\mathbb{S}'$, $\mathbb{S}''$, respectively, there exist $(([\Omega], \Delta), A) \in (W_{\mathcal{A}}/L) \rtimes_{\eta_{\mathcal{A}}} Iso(E_L)$ such that

$$\mathcal{C}\left(\begin{array}{c|c} A & [\Omega] \\ \hline & \widetilde{\Delta} \end{array}\right) : \Lambda(\mathbb{S}')_{(P'_\alpha)_{\alpha\in\mathcal{A}}} \to \Lambda(\mathbb{S}'')_{(P''_\alpha)_{\alpha\in\mathcal{A}}} \text{ is a (Group-)isomorphism.} \tag{5.2}$$

Explicitly, the conjugation in (5.2) is:

$$\mathcal{C}\left(\begin{array}{c|c} A & [\Omega] \\ \hline & \widetilde{\Delta} \end{array}\right)\left(\begin{array}{c|c} \eta'(q') & [\omega'] \\ \hline & \widetilde{\delta'} \end{array}\right) = \left(\begin{array}{c|c} \eta''(\eta''^{-1}\mathcal{C}_A\eta'(q')) & [A\,.\,\omega'\widetilde{\Delta}^{-1} + (\Omega\widetilde{\Delta}^{-1}.\widetilde{C_\Delta(\delta')} - \eta''^{-1}\mathcal{C}_A\eta'(q')\,.\,\Omega\widetilde{\Delta}^{-1})] \\ \hline & \widetilde{C_\Delta(\delta')} \end{array}\right),$$

where the symbol "$\widetilde{\ }$" refers to the standard permutation representation (see the Appendix). This definition should be compared with that of Ref. 24. Although slightly different, they are equivalent; the main differences are: (a) the use of a different representation, where we use the standard one, for the colored permutations; (b) the use, in $W_{\mathcal{A}}$, of the quotient with respect to the first component $((1,0,\ldots,0)L(\mathbb{S}), \mathrm{id})$, where we use that with respect to the diagonal $((1,\ldots,1)L(\mathbb{S}), \mathrm{id})$.

Remark 5.15: By proceeding in a more involved way, one can avoid, in Definition 5.13, to assume *a priori* that the two structures share the same arithmetic architecture, and show this is a necessary consequence of their arthmetic equivalence.

In Definition 5.13, the structures are involved only through their lattice groups; the chosen essential arithmetic descriptors are not directly involved. Actually:

Remark 5.15: Definition 5.13 does not depend on the essential arithmetic descriptors chosen.

Proof: Let $(P'_\alpha)_{\alpha\in\mathcal{A}}$, $(P''_\alpha)_{\alpha\in\mathcal{A}}$, be two essential arithmetic descriptors for a structure $\mathbb{S}$. By definition there exists $t\in L(\mathbb{E})/L(\mathbb{S})$ and $(\Omega,\Delta)\in W_{\mathcal{A}}(\mathbb{S})/L(\mathbb{S})$ such that

$$(t*_\sigma \mathrm{id})\,.\,P'_\alpha=(\Omega_\alpha*\mathrm{id})\,.\,P''_{\Delta(\alpha)}\ \forall\ \alpha\in\mathcal{A}.$$

It is straightforward to see that $\mathcal{C}_{\left(\begin{array}{c|c}\eta(\mathrm{id}) & [\Omega]\\ \hline & \tilde{\Delta}\end{array}\right)}:\Lambda(\mathbb{S})_{(P'_\alpha)_{\alpha\in\mathcal{A}}}\to\Lambda(\mathbb{S})_{(P''_\alpha)_{\alpha\in\mathcal{A}}}$ is a (*Group*-) isomorphism satisfying condition (5.2). □

VI. SOME RESULTS ON THE ARITHMETIC CLASSIFICATION SCHEME

A. Basic features of the arithmetic criterion

We now show that the arithmetic criterion satisfies the basic requirements for any symmetry-based classification schemes mentioned in Sec. I.

Remark 6.1: The arithmetic criterion coincides with the Bravais classification scheme when restricted to simple lattices.

Proof: When $|\mathcal{A}|$ is made up of one only element, $W_{\mathcal{A}}$ is the trivial group; the conclusion is now straightforward from the definitions. □

Remark 6.2: The arithmetic criterion has intrinsic character.

Proof: Let $\mathbb{S}'\hookrightarrow\mathbb{E}'$, $\mathbb{S}''\hookrightarrow\mathbb{E}''$ be two structures, $\phi\in\mathrm{Aff}(\mathbb{E}',\mathbb{E}'')$ with $\mathbb{S}'\overset{\phi}{\to}\mathbb{S}''$ ($\mathfrak{C}$-*Set*-)isomorphism and $G(\mathbb{S}')\overset{C_\phi}{\to}G(\mathbb{S}'')$ (*Group*-)isomorphism. We must prove that $\mathbb{S}'$ and $\mathbb{S}''$ are arithmetically equivalent. To do so, let $(P'_\alpha)_{\alpha\in\mathcal{A}}$ be an essential arithmetic descriptor for $\mathbb{S}'$ and $(P''_\alpha)_{\alpha\in\mathcal{A}}:=\phi(P'_\alpha)_{\alpha\in\mathcal{A}}$, with $c(P''_\alpha)_{\alpha\in\mathcal{A}}:=c(P'_\alpha)_{\alpha\in\mathcal{A}}$. It is easily seen that $(P''_\alpha)_{\alpha\in\mathcal{A}}$ is an essential arithmetic descriptor for $\mathbb{S}''$. We prove that:

$$\mathcal{C}_{\left(\begin{array}{c|c}A & [0]\\ \hline & \tilde{\mathrm{id}}\end{array}\right)}:\Lambda(\mathbb{S}')_{(P'_\alpha)_{\alpha\in\mathcal{A}}}\to\Lambda(\mathbb{S}'')_{(P''_\alpha)_{\alpha\in\mathcal{A}}}\ \text{is a (}\textit{Group}\text{-)isomorphism,}$$

where $A:=\mathcal{I}''^{-1}\circ\phi\circ\mathcal{I}'$. We establish $\mathcal{C}_{\left(\begin{array}{c|c}A & [0]\\ \hline & \tilde{\mathrm{id}}\end{array}\right)}:\Lambda(\mathbb{S}')_{(P'_\alpha)_{\alpha\in\mathcal{A}}}\hookrightarrow\Lambda(\mathbb{S}'')_{(P''_\alpha)_{\alpha\in\mathcal{A}}}$, the other inclusion being shown in an analogous way. Take $\left(\begin{array}{c|c}\eta'(q') & [\omega']\\ \hline & \tilde{\delta}'\end{array}\right)\in\Lambda(\mathbb{S}')_{(P'_\alpha)_{\alpha\in\mathcal{A}}}$; hence:

$(([\omega'],\delta'),q')\in(W_{\mathcal{A}}/L)\rtimes_{\eta_{\mathcal{A}}}P$ and there exists a unique $[t']\in E/L$ such that

$$(t'*_{\sigma'}q')\,.\,P'_\alpha=(\omega'_\alpha*\mathrm{id})\,.\,P'_{\delta'(\alpha)}\ \forall\ \alpha\in\mathcal{A}.$$

By inserting the identity $\phi^{-1}\circ\phi=\mathrm{id}$ into the left-hand side, pre-composing both sides by ϕ and defining $A:=\mathcal{I}''^{-1}\circ\phi\circ\mathcal{I}'$, we have:

$$\mathcal{C}_\phi(t'*_{\sigma'}q')\phi\,.\,P'_\alpha=(A\,.\,\omega'_\alpha*\mathrm{id})\,.\,\phi P'_{\delta'(\alpha)}\ \forall\ \alpha\in\mathcal{A}.$$

By construction $(P''_\alpha)_{\alpha\in\mathcal{A}}=\phi(P'_\alpha)_{\alpha\in\mathcal{A}}$; hence we have:

$$\mathcal{C}_\phi(t'*_{\sigma'}q')\,.\,P''_\alpha=(A\,.\,\omega'_\alpha*\mathrm{id})\,.\,P''_{\delta'(\alpha)}\ \forall\ \alpha\in\mathcal{A}.$$

Defining $[T]\in E/L$ by $\phi=:T*_{\sigma''}A$ (it depends on the splittings σ',σ''):

$$((At' *_{\sigma''}(\mathrm{id} - \eta''^{-1}(\mathcal{C}_A(\eta'(q')))) \,.\, T) *_{\sigma''} \mathcal{C}_A(\eta'(q'))) \,.\, P''_\alpha = (A \,.\, \omega'_\alpha * \mathrm{id}) \,.\, P''_{\delta'(\alpha)} \;\forall\; \alpha \in \mathcal{A}.$$

For $[t''] := A[t'] *_{\sigma''} (\mathrm{id} - \eta''^{-1}\mathcal{C}_A\eta'(q')) \,.\, [T]$, we have:

$$(([A \,.\, \omega'], \delta'), \eta''^{-1}\mathcal{C}_A\eta'(q')) \in (W_{\mathcal{A}}/L) \times_{\eta_{\mathcal{A}}} P$$

and

$$(t'' *_{\sigma''} \eta''^{-1}\mathcal{C}_A\eta'(q')) \,.\, P''_\alpha = (A \,.\, \omega'_\alpha * \mathrm{id}) \,.\, P''_{\delta'(\alpha)} \;\forall\; \alpha \in \mathcal{A}.$$

Therefore, by the explicit formula for conjugation in (5.2), we get:

$$\left(\begin{array}{c|c} \eta''(\eta''^{-1}\mathcal{C}_A\eta'(q')) & [A \,.\, \omega'] \\ \hline & \widetilde{\delta}' \end{array}\right) \in \Lambda(\mathbb{S}'')_{(P''_\alpha)_{\alpha\in\mathcal{A}}},$$

i.e.,

$$\mathcal{C}_{\left(\begin{array}{c|c} A & [0] \\ \hline & \widetilde{\mathrm{id}} \end{array}\right)} \left(\begin{array}{c|c} \eta'(q') & [\omega'] \\ \hline & \widetilde{\delta}' \end{array}\right) \in \Lambda(\mathbb{S}'')_{(P''_\alpha)_{\alpha\in\mathcal{A}}},$$

and we are finished. □

In view of the intrinsic character of the arithmetic principle, its finiteness property can be formulated as follows:

Remark 6.3: There exists only a finite number of arithmetic nonequivalent classes of structures with given finite arithmetic architecture type and given space-group type.

B. Some known results on arithmetic classification

We summarize in Table I some known results[6,8,9,15,25,11] which refer to the arithmetic classification of full structures in dimensions 2 and 3.

C. Examples of arithmetically nonequivalent isosymmetric structures

We conclude with two examples of structures which are space-group type, but not arithmetically, equivalent. These show once more that the arithmetic scheme is finer than classification by space-group type.

Example 6.4: The two structures described in Examples 5.8, 5.9 have the same space-group type *p*4*mm* (actually the same space group once their Euclidean spaces are identified as we did earlier), same arithmetic architecture type {4}, and same geometric architecture type {1}. (The geometric architecture type describes the number of space-group orbits forming a structure and their colors, much the same way the arithmetic architecture type describes the number of translation-group orbits forming a structure and their colors. In other words, the crystallographic architecture type gives the number of "atoms," of each different species, that are present in a asymmetric cell.[15]) Notice anyway that the two structures are space-group orbits of different lattice complexes, *p*4*mm#d* and *p*4*mm#f*, respectively.[15,6].

Example 6.5: The following, taken from Ref. 24, is a subtler example. Figure 4 shows two structures with the same space-group type *Pmmm* (even the same space group if their Euclidean spaces are identified in the obvious way), same arithmetic architecture type {3} (the space-group type together with the arithmetic architecture type amounts to giving the colored version of the Pearson symbol[15]), same geometric architecture type {3}, whose space-group orbits all belong to the same lattice complex *Pmmm#a*. These two structures have *symmetry* properties whose differences are detected by the arithmetic scheme (Ref. 24) but not by any of the established criteria currently used in crystallography or physics.

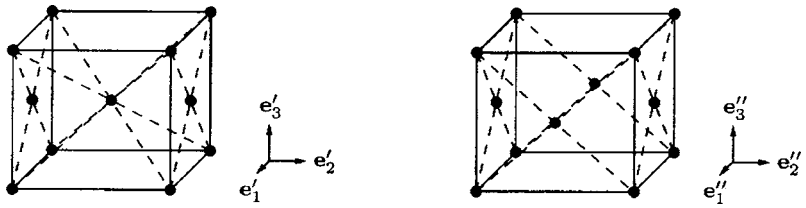

FIG. 4. Example of isosymmetric structures (Ref. 24). All the faces are rectangles (primitive translational cells shown).

APPENDIX

We briefly recall the essential mathematics we need; see Ref. 19 for more details.

1. Set theory

a. For a family of sets $(X_\alpha)_{\alpha\in\mathcal{A}}$ (respectively, maps $(X_\alpha \overset{f_\alpha}{\to} Y_\alpha)_{\alpha\in\mathcal{A}}$), $\amalg_{\alpha\in\mathcal{A}}(X_\alpha)$ (respectively, $\amalg_{\alpha\in\mathcal{A}}(X_\alpha \overset{f_\alpha}{\to} Y_\alpha)$) denotes their *disjoint union*. For an indexing set $\mathcal{A}$ and a set X (respectively, a map $X \overset{f}{\to} Y$), $X^{\mathcal{A}}$ (respectively, $f^{\mathcal{A}}$) denotes the *direct product* of copies of the set X (respectively, the map $X \overset{f}{\to} Y$), one copy for each element of $\mathcal{A}$.

b. For any given set $\mathfrak{C}$, to be interpreted as a set of colors, we define the $\mathfrak{C}$-*Set* category as follows: an object is a (*Set*-)morphism $c: S \to \mathfrak{C}$ (S is a set S and c specifies how S is colored); a morphism between the objects $c': S' \to \mathfrak{C}$ and $c'': S'' \to \mathfrak{C}$ is a (*Set*-)morphism $f: S' \to S''$ preserving colors, i.e., such that

$$\begin{array}{ccc} S' & \xrightarrow{c'} & \mathfrak{C} \\ f\downarrow & & \downarrow \mathrm{id}\,. \\ S'' & \xrightarrow{c''} & \mathfrak{C} \end{array}$$

Clearly in the noncolored case, i.e., when $\mathfrak{C}$ is made up of one only element, the $\mathfrak{C}$-*Set* category and the *Set* category are equivalent; in this case $c: S \to \mathfrak{C}$ is trivially determined by S only.

c. For a $\mathfrak{C}$-set $\mathbb{X}$, we write $|\mathbb{X}|$ for its associated *multiset*. This is the nonordered family of natural numbers (repetitions are allowed) counting the elements of $\mathbb{X}$ for each of its colors. For example, for $\mathbb{X} = (\{a,b\} \mapsto \alpha) \amalg (\{c\} \mapsto \beta) \amalg (\{d,e\} \mapsto \gamma)$, we have $|\mathbb{X}| = \{1,2,2\}$.

2. Group theory

a. For a group G and $g \in G$, $\mathcal{C}_g$: $G \ni h \mapsto ghg^{-1} \in G$ denotes the *conjugation* by g. $\langle (g_k)_{k\in K} \rangle$ denotes the subgroup of G generated by $(g_k)_{k\in K}$.

The next two definitions give the construction of certain groups. Instead of using the more compact description, we represent them more concretely via suitable matrix groups; although this is somewhat awkward, it avoids excessive formal style.

b. Given two groups X, Z and an action $\eta: Z \to \mathrm{Iso}(X)$, the *semi-direct product* $X \rtimes_\eta Z$ can be described, when η is faithful, by the group of matrices of the form:

$$\left(\begin{array}{c|c} \eta(z) & x \\ \hline & \mathrm{id} \end{array}\right),$$

with $z \in Z$ and $x \in X$. Performing the matrix product, one formally proceeds by paying attention to the order of the operations involved; the product operation must be replaced by the action of $\mathrm{Iso}(X)$ on X, while the sum operation by $\cdot_{X^{\mathrm{op}}}$; X^{op} is the opposite group of X. In this paper X can be non-Abelian, so strictly speaking, the common matrix notation is slightly out of place. The matrix shown above is denoted by (x,z). Explicitly:

$$\left(\begin{array}{c|c} \eta(z') & x' \\ \hline & \mathrm{id} \end{array}\right) \cdot_{X \rtimes_\eta Z} \left(\begin{array}{c|c} \eta(z'') & x'' \\ \hline & \mathrm{id} \end{array}\right) = \left(\begin{array}{c|c} \eta(z' \cdot_Z z'') & x' \cdot_X (\eta(z') \,.\, x'') \\ \hline & \mathrm{id} \end{array}\right).$$

c. For H a group, I a $\mathfrak{C}$-set and S a subgroup of $\mathrm{Iso}(I)$, the *wreath product* $H \chi S$ can be described by the group of matrices of the form:

$$\left(\begin{array}{c|c} \mathrm{id} & \omega \\ \hline & \widetilde{\delta} \end{array}\right).$$

The right part of the matrix has columns indexed by the elements of I, $\omega = (\omega_i)_{i \in I} \in H^I$ and $\widetilde{\delta}$ is the standard representation of $\delta \in Iso(I)$ on the set I. The matrix shown above is denoted by (ω, δ). Explicitly:

$$\left(\begin{array}{c|c} \mathrm{id} & \omega' \\ \hline & \widetilde{\delta'} \end{array}\right) \cdot_{H \chi S} \left(\begin{array}{c|c} \mathrm{id} & \omega'' \\ \hline & \widetilde{\delta''} \end{array}\right) = \left(\begin{array}{c|c} \mathrm{id} & \omega'' \cdot_H (\omega' \,.\, \widetilde{\delta''}) \\ \hline & \widetilde{\delta' \cdot_S \delta''} \end{array}\right).$$

d. For G a group and H a subgroup of it, G_H denotes them when considered simultaneously. In particular, $\mathrm{Iso}(G_H)$ is the subset of $\mathrm{Iso}(G)$ whose elements induce morphisms in $\mathrm{Iso}(H)$.

3. Group actions

a. Given an action $\delta: G \to \mathrm{Iso}(X)$, $X \backslash G$ denotes the *G-orbit space* of X relative to δ; the points of $X \backslash G$ are called the orbits of G acting on X via δ. The natural projection is $X \ni x \mapsto [x] \in X \backslash G$. An action $\eta: G \to \mathrm{Iso}(X)$ is *faithful* if $\eta: G \to \mathrm{Iso}(X)$ is injective.

b. A (*Group*-)morphism $\delta: G \to \mathrm{Iso}(X)$ with G group and X $\mathfrak{C}$-set is called a *permutation representation* of the group G on the $\mathfrak{C}$-set X. We write the elements of $\mathrm{Iso}(X)$ via cycles' notation[19] or via the standard linear permutation representation. The latter is constructed as follows: for a set $\mathcal{A}$, consider the abstract vector space with $(\alpha)_{\alpha \in \mathcal{A}}$ as basis, then the standard linear permutation representation of $\delta \in \mathrm{Iso}(\mathcal{A})$ is the (*Vectorspace*-)morphism sending the vector α to the vector $\delta(\alpha)$. For example, let $\mathcal{A} = \{a,b,c\}$; representing the permutation via cycles' notation we have (we write the elements of the basis $\mathcal{A}$ from left to right in the order a,b,c):

$$(a)(b)(c) \rightsquigarrow \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (a,b)(c) \rightsquigarrow \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad (a,b,c) \rightsquigarrow \begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}.$$

Markov property and strong additivity of von Neumann entropy for graded quantum systems

Hajime Moriya
Department of Mathematics, Graduate School of Science, Hokkaido University Kita 10, Nishi 8, Kita-Ku, Sapporo, Hokkaido, 060-0810, Japan

(Received 28 October 2005; accepted 24 January 2006; published online 27 March 2006)

The quantum Markov property is equivalent to the strong additivity of von Neumann entropy for graded quantum systems. The additivity of von Neumann entropy for bipartite graded systems implies the statistical independence of states. However, the structure of Markov states for graded systems is different from that for tensor-product systems which have trivial grading. For three-composed graded systems we have U(1)-gauge invariant Markov states whose restriction to the marginal pair of subsystems is nonseparable. © *2006 American Institute of Physics.*

I. INTRODUCTION

We are interested in characterization of state correlations for general composite systems which do not necessarily satisfy the local commutativity. Here we specifically consider finite-dimensional quantum systems with graded commutation relations. For such systems as well, we can divide the total system into the subsystem on a specified region and that on its complement region and discuss the nature of state correlations between them as in the tensor-product systems.

We have pointed out that known criterions of separability for tensor-product systems should be altered for lattice fermion systems[11] when fermion hopping terms are present. (Note that purely fermionic correlation due to fermion hopping terms cannot be distilled to use.)

We are going to discuss quantum Markov property,[1] a quantum version of Markov property invented by Accardi. This is given by means of quasiconditional expectations and has played various roles, see, e.g., Ref. 2. We can view the Markov property as a kind of characterization of state correlation for composite systems. A pivotal example of quantum composite systems is tensor product of Hilbert spaces for which lots of works, prominently those on Markov chains for one-dimensional quantum spin lattice systems have been done.

We note that the definition of Markov property has been given under a very general setting that is not limited to the most familiar case of tensor-product systems. That is, it does not require in principle any specific *algebraic location* among subsystems imbedded in the total system.[3] Its detailed analysis for the setting of nonindependent systems, however, has started only recently. Reference 4 investigates Markov chains for one-dimensional (spinless) fermion lattice systems. It has been clarified there that the notion of Markov property and of the Markov chain is well applicable to fermion lattice systems. [More precisely, the above Markov chain refers to (d)-Markovian chain,[1] see also Ref. 13 on the generalized Markov chain.] Furthermore, a class of U(1)-gauge invariant Markov chains with fermionic hopping correlations is given.[4]

It has been shown that the Markov property is tightly related to the sufficiency of conditional expectations through the strong subadditivity of von Neumann entropy: A state of a three-composed tensor-product system is Markovian if and only if it takes the equality for the strong subadditivity inequality of entropy, which will be referred to as "the strong additivity of entropy."[16,6,12,7]

We show that a similar equivalence relation of the Markov property and the strong additivity of entropy is valid for graded quantum systems. Its proof proceeds in much the same way as that

for the tensor-product case following Ref. 15 (whose methods and results can be used in the present nonindependent situation) with some simple modifications due to the grading.

We now introduce the graded systems under our consideration. Let $\mathfrak{F}$ be a lattice and $\{\mathcal{A}_{\mathbf{I}};\mathbf{I}\in\mathfrak{F}\}$ be a family of $*$-algebras that have a common unital element denoted $\mathbf{1}$. If $\mathbf{I}\subset\mathbf{J}$, then $\mathcal{A}_{\mathbf{I}}\subset\mathcal{A}_{\mathbf{J}}$, and if $\mathbf{I}\cap\mathbf{J}=\emptyset$, then $\mathcal{A}_{\mathbf{I}}\cap\mathcal{A}_{\mathbf{J}}=\mathbb{C}\mathbf{1}$. Let Θ be an involutive $*$-automorphism of $\mathcal{A}$ that determines the grading as

$$\mathcal{A}^e := \{A\in\mathcal{A}\,|\,\Theta(A)=A\},\quad \mathcal{A}^o := \{A\in\mathcal{A}\,|\,\Theta(A)=-A\}. \tag{1}$$

We assume that our grading transformation Θ is nontrivial. The above $\mathcal{A}^e$ and $\mathcal{A}^o$ (which is not empty) are called the even and odd parts of $\mathcal{A}$. For $\mathbf{I}\in\mathfrak{F}$

$$\mathcal{A}^e_{\mathbf{I}} := \mathcal{A}^e\cap\mathcal{A}_{\mathbf{I}},\quad \mathcal{A}^o_{\mathbf{I}} := \mathcal{A}^o\cap\mathcal{A}_{\mathbf{I}}. \tag{2}$$

For $A\in\mathcal{A}(\mathcal{A}_{\mathbf{I}})$ we have the even-odd decomposition:

$$A=A_+ + A_-,\quad A_+ := \tfrac{1}{2}(A+\Theta(A))\in\mathcal{A}^e(\mathcal{A}^e_{\mathbf{I}}),\quad A_- := \tfrac{1}{2}(A-\Theta(A))\in\mathcal{A}^o(\mathcal{A}^o_{\mathbf{I}}). \tag{3}$$

We introduce U(1) gauge transformation:

$$\gamma_\theta(a_i^*)=e^{i\theta}a_i^*,\quad \gamma_\theta(a_i)=e^{-i\theta}a_i \tag{4}$$

for $\theta\in\mathbb{C}^1$. A state invariant under Θ is called even, and that invariant under γ_θ for any $\theta\in\mathbb{C}^1$ is called U(1)-gauge invariant.

If a pair of subsets $\mathbf{I}$ and $\mathbf{J}$ of $\mathfrak{F}$ are disjoint, then the following graded commutation relations hold:

$$[\mathcal{A}^e_{\mathbf{I}},\mathcal{A}^e_{\mathbf{J}}]=0,\quad [\mathcal{A}^e_{\mathbf{I}},\mathcal{A}^o_{\mathbf{J}}]=0,\quad [\mathcal{A}^o_{\mathbf{I}},\mathcal{A}^e_{\mathbf{J}}]=0,\quad \{\mathcal{A}^o_{\mathbf{I}},\mathcal{A}^o_{\mathbf{J}}\}=0, \tag{5}$$

where $[A,B]=AB-BA$ denotes the commutator and $\{A,B\}=AB+BA$ the anticommutator.

We assume that $\mathcal{A}_{\mathbf{I}}$ is isomorphic to a finite-dimensional type-I factor (a full matrix algebra) for any $\mathbf{I}\in\mathfrak{F}$. Under this assumption, there is a unitary $v_{\mathbf{I}}$ in $\mathcal{A}_{\mathbf{I}}$ that implements Θ on $\mathcal{A}_{\mathbf{I}}$ as

$$v_{\mathbf{I}}^*(A)v_{\mathbf{I}}=\Theta(A),\quad A\in\mathcal{A}_{\mathbf{I}}. \tag{6}$$

This $v_{\mathbf{I}}$ is even, since $\Theta(v_{\mathbf{I}})=v_{\mathbf{I}}^*(v_{\mathbf{I}})v_{\mathbf{I}}=(v_{\mathbf{I}}^*v_{\mathbf{I}})v_{\mathbf{I}}=v_{\mathbf{I}}$. For disjoint $\mathbf{I}$ and $\mathbf{J}$, the unitary $v_{\mathbf{I}\cup\mathbf{J}}$ of (6) for $\mathcal{A}_{\mathbf{I}\cup\mathbf{J}}$ is given by $v_{\mathbf{I}}v_{\mathbf{J}}$.

The lattice fermion system is a typical example of the graded quantum systems. Let a_i^* and a_i be creation and annihilation operators on the specified site i in a lattice. For each finite subset $\mathbf{I}$, the subsystem $\mathcal{A}_{\mathbf{I}}$ are generated by a_i^* and a_i in $\mathbf{I}$. The even-odd grading transformation is given by

$$\Theta(a_i^*)=-a_i^*,\quad \Theta(a_i)=-a_i.$$

The unitary $v_{\mathbf{I}}$ is given by $v_{\mathbf{I}}:=\Pi_{i\in\mathbf{I}}v_i$, $v_i:=a_i^*a_i-a_ia_i^*$.

We shall provide the plan of this paper. In Sec. II we introduce a formula of strong subadditivity of entropy (SSA)[8] in terms of the densities with respect to the tracial state for general composite systems made of finite-dimensional type-I factors. For the graded systems, it becomes the familiar formula of SSA in terms of the density matrices with respect to the matrix trace.

In Sec. III, the equivalence of the Markov property and the strong additivity of entropy for even states of the graded systems is shown. For noneven states, we have a weak result.

In Sec. IV, we consider restrictions of Markov states onto the marginal subsystems that are separated from each other. It was shown in Refs. 6 and 12 that a Markov state of a three-composed tensor-product system is separable (classically correlated) with respect to the marginal pair of subsystems. We show that this statement is invalid for the graded systems; there are U(1)-gauge invariant (hence obviously even) Markov states that are nonseparable for the marginal pair. Intuitively speaking, such Markov states have fermion hopping correlations between the marginal subsystems.

In Sec. V, we show that a state of a graded bipartite system satisfies the additivity of von Neumann entropy if and only if it is a product state. This is almost obvious if the state under consideration is assumed to be even. The point is that the evenness (at least on one of the pair of subsystems) follows from the additivity of entropy.

II. STRONG SUBADDITIVITY OF ENTROPY

We provide the strong subadditivity of entropy for a general setting that encompasses non-independent systems. Let $\mathcal{A}$ be a finite-dimensional type-I factor. Let τ denote the tracial state on $\mathcal{A}$. If an element $d \in \mathcal{A}$ is positive and normalized as $\tau(d)=1$, then it is called a density. For any state φ of $\mathcal{A}$, there exists a unique density $\rho_\varphi \in \mathcal{A}$ called the density of φ satisfying that

$$\varphi(a) = \tau(\rho_\varphi a), \quad a \in \mathcal{A}.$$

For the tracial state τ, its density is obviously $\mathbf{1}$, the unity of $\mathcal{A}$.

Let ρ_1 and ρ_2 be a pair of densities of $\mathcal{A}$. The relative entropy for them is defined by

$$H(\rho_1,\rho_2) := \tau(\rho_1(\ln \rho_1 - \ln \rho_2)) \tag{7}$$

if the support of ρ_1 is contained in ρ_2. Otherwise, we set it $+\infty$. For a pair of two states φ and ψ on $\mathcal{A}$, their relative entropy is

$$H(\varphi,\psi) := H(\rho_\varphi,\rho_\psi). \tag{8}$$

We define the entropy for a given state φ as

$$\hat{S}(\varphi) := -\varphi(\ln \rho_\varphi). \tag{9}$$

We see

$$\hat{S}(\varphi) = -H(\varphi,\tau).$$

Probably the following is a more frequently used definition of entropy:

$$S(\varphi) := -\mathbf{Tr}(D_\varphi \ln D_\varphi) = -\varphi(\ln D_\varphi),$$

where $\mathbf{Tr}$ is the matrix trace that takes 1 for each one-dimensional projection, and D_φ denotes the density matrix of φ with respect to $\mathbf{Tr}$. We see

$$\hat{S}(\varphi) = S(\varphi) - S(\tau) = S(\varphi) - \ln \mathbf{Tr}(\mathbf{1}) \tag{10}$$

for any state φ. Hence if $\mathcal{A}$ is a n by n full matrix algebra, $n \in \mathbb{N}$, then the difference $S(\varphi) - \hat{S}(\varphi)$ is constantly $\ln n$.

Let $\mathcal{B}$ be a subalgebra of $\mathcal{A}$. We denote the (uniquely determined) conditional expectation from $\mathcal{A}$ onto $\mathcal{B}$ with respect to the tracial state by $E_{\mathcal{B}}^{\mathcal{A}}$. Here, the upper-right subscript of E indicates the domain and the lower-right the range. Let $\varphi_{\mathcal{B}}$ denote the restriction of φ to $\mathcal{B}$. Then the density of $\varphi_{\mathcal{B}}$ is given by that of φ as

$$\rho_{\varphi_{\mathcal{B}}} = E_{\mathcal{B}}^{\mathcal{A}}(\rho_\varphi). \tag{11}$$

We have

$$\hat{S}(\varphi_{\mathcal{B}}) - \hat{S}(\varphi) = H(\rho_\varphi,\rho_{\varphi_{\mathcal{B}}}) = H\left(\varphi,\varphi_{\mathcal{B}} \otimes \mathrm{tr}\big|_{\mathcal{A}\cap\mathcal{B}'}\right) = H(\varphi,\varphi\circ E_{\mathcal{B}}^{\mathcal{A}}). \tag{12}$$

As a special case of (12),

$$\hat{S}(\varphi_{\mathcal{B}}) = \hat{S}(\varphi\circ E_{\mathcal{B}}^{\mathcal{A}}). \tag{13}$$

In fact, we have so far assumed that φ is a faithful state, but (12) is valid when φ is nonfaithful. To see this, we take $\varepsilon\cdot\tau+(1-\varepsilon)\varphi$ where ε is a positive small number and then take the limit $\varepsilon\to 0$.

Let us take three disjoint subsets A, B, and C. Let $\mathcal{A}_{ABC}$, $\mathcal{A}_{AB}$, $\mathcal{A}_{BC}$, and $\mathcal{A}_B$ denote finite-dimensional quantum systems corresponding to the indexes. Let $E_{A,B}^{A,B,C}$ and $E_A^{A,B}$ denote the trace preserving conditional expectation from $\mathcal{A}_{ABC}$ onto $\mathcal{A}_{AB}$ and that from $\mathcal{A}_{AB}$ onto $\mathcal{A}_A$, respectively. We use similar notations for other indexes. If the domain is the total system $\mathcal{A}_{ABC}$, then we simply write, e.g., $E_{A,B}$ instead of $E_{A,B}^{A,B,C}$ when there is no fear of confusion.

The following five conditions, called the commuting square condition, are all equivalent to each other:

(1) $E_{A,B}|\mathcal{A}_{BC}=E_B^{B,C}$,
(2) $E_{B,C}|\mathcal{A}_{AB}=E_B^{A,B}$,
(3) $\mathcal{A}_B=\mathcal{A}_{AB}\cap\mathcal{A}_{BC}$ and $E_{A,B}E_{B,C}=E_{B,C}E_{A,B}$,
(4) $E_{A,B}E_{B,C}=E_B$,
(5) $E_{B,C}E_{A,B}=E_B$.

If our three-composed system $\mathcal{A}_{ABC}$ satisfies this commuting square condition, then the strong subadditivity of entropy $\hat{S}(\psi)$ for any state ψ follows. The proof is standard and easy, but we recapture it for completeness.

Proposition 1: Let $\mathcal{A}_{ABC}$, $\mathcal{A}_{AB}$, $\mathcal{A}_{BC}$, and $\mathcal{A}_B$ be finite-dimensional factors satisfying the commuting square condition, and let ψ_{ABC} be an arbitrary state on $\mathcal{A}_{ABC}$. Then

$$\hat{S}(\psi_{ABC})-\hat{S}(\psi_{AB})-\hat{S}(\psi_{BC})+\hat{S}(\psi_B)\leqslant 0. \tag{14}$$

Furthermore, if the system satisfies the graded commutation relations (5), then

$$S(\psi_{ABC})-S(\psi_{AB})-S(\psi_{BC})+S(\psi_B)\leqslant 0. \tag{15}$$

Proof: By (12) and (13), and the relation $E_{B,C}E_{A,B}=E_{A,B}E_{B,C}=E_B$, we obtain

$$\begin{aligned}\hat{S}(\psi_{BC})-\hat{S}(\psi_{ABC}) &= H(\psi_{ABC},\psi_{ABC}\circ E_{B,C})\geqslant H(\psi_{ABC}\circ E_{A,B},\psi_{ABC}\circ E_{B,C}\circ E_{A,B})\\ &= H(\psi_{ABC}\circ E_{A,B},\psi_{ABC}\circ E_{A,B}\circ E_{B,C})=H(\psi_{ABC}\circ E_{A,B},\psi_{ABC}\circ E_B)\\ &= \hat{S}(\psi_{ABC}\circ E_B)-\hat{S}(\psi_{ABC}\circ E_{A,B})=\hat{S}(\psi_B)-\hat{S}(\psi_{AB}),\end{aligned} \tag{16}$$

where the inequality is due to the monotonicity of relative entropy under the action of completely positive maps.

Let us turn to the graded systems of finite-dimensional factors, which satisfy the commuting square condition.[5] Suppose that $\mathbf{I}$ and $\mathbf{J}$ are disjoint subsets. Then the matrix trace on $\mathcal{A}_{\mathbf{I}\cup\mathbf{J}}$ denoted $\mathbf{Tr}_{\mathbf{I}\cup\mathbf{J}}$ is given by the product extension of those in $\mathcal{A}_{\mathbf{I}}$ and in $\mathcal{A}_{\mathbf{J}}$ denoted $\mathbf{Tr}_{\mathbf{I}}$ and $\mathbf{Tr}_{\mathbf{J}}$, respectively. Thus we have $\mathbf{Tr}_{\mathbf{I}\cup\mathbf{J}}(\mathbf{1})=\mathbf{Tr}_{\mathbf{I}}(\mathbf{1})\times\mathbf{Tr}(\mathbf{1})$. Now (14) and (10) imply (15). ■

As this proposition indicates, the strong additivity of entropy is satisfied irrespective of whether states are even or not. In Refs. 9 and 10 we have shown that noneven states may induce pathological state correlations and some entropy inequalities known for tensor-product systems do not hold in general for the graded systems.

III. MARKOV PROPERTY AND STRONG ADDITIVITY

It is obvious that the equality of (14) and of (15) is equivalent to that of (16), i.e.,

$$H(\psi_{ABC},\psi_{ABC}\circ E_{B,C})=H(\psi_{ABC}\circ E_{A,B},\psi_{ABC}\circ E_B), \tag{17}$$

equivalently,

$$H(\rho_{\psi_{ABC}},\rho_{\psi_{BC}})=H(\rho_{\psi_{AB}},\rho_{\psi_B}). \tag{18}$$

By a general result of the sufficiency given in Ref. 15, (17) implies that the conditional expectation $E_{A,B}$ is sufficient for $\psi_{ABC}\circ E_{B,C}$ and ψ_{ABC}, that is, there exists a completely positive map that recovers $\psi_{ABC}\circ E_{B,C}$ and ψ_{ABC} from $\psi_{ABC}\circ E_{B,C}\circ E_{A,B}$ and $\psi_{ABC}\circ E_{A,B}$, respectively. The canonical form of such maps is given as follows.[12]

Let α denote the completely positive map on $\mathcal{A}$ defined by

$$\alpha(X) := \rho_{\psi_B}{}^{-1/2} E_{A,B}(\rho_{\psi_{BC}}{}^{1/2} X \rho_{\psi_{BC}}{}^{1/2}) \rho_{\psi_B}{}^{-1/2}, \quad X \in \mathcal{A}_{ABC}. \tag{19}$$

Let $T^\sharp$ denote the dual of α with respect to the tracial stare, which is written as

$$T^\sharp(X) := \rho_{\psi_{BC}}{}^{1/2} \rho_{\psi_B}{}^{-1/2} X \rho_{\psi_B}{}^{-1/2} \rho_{\psi_{BC}}{}^{1/2}, \quad X \in \alpha(\mathcal{A}_{ABC}). \tag{20}$$

It is easy to see $T^\sharp(\rho_{\psi_B}) = \rho_{\psi_{BC}}$. Also $T^\sharp(\rho_{\psi_{AB}}) = \rho_{\psi_{ABC}}$ is satisfied if and only if $E_{A,B}$ is sufficient for the given pair of states ψ_{ABC} and $\psi_{ABC}\circ E_{B,C}$, equivalently, (17) holds.

The following is a more or less summary of the contents stated above. It corresponds to Theorem 5.2 of Ref. 16 and also Sec. V of Ref. 12 where the statement is for the tensor-product systems.

Proposition 2: Let $\mathcal{A}_{ABC}$, $\mathcal{A}_{AB}$, $\mathcal{A}_{BC}$, and $\mathcal{A}_B$ be finite-dimensional factors satisfying the commuting square condition. Let ψ_{ABC} be an arbitrary faithful state on $\mathcal{A}_{ABC}$. The strong additivity of von Neumann entropy, i.e.,

$$S(\psi_{ABC}) - S(\psi_{AB}) - S(\psi_{BC}) + S(\psi_B) = 0 \tag{21}$$

is satisfied if and only if $E_{A,B}$ is sufficient for the pair of states ψ_{ABC} and $\psi_{ABC}\circ E_{B,C}$. Let α denote the ψ_{ABC}-preserving (and $\psi_{ABC}\circ E_{B,C}$-preserving) conditional expectation from $\mathcal{A}_{ABC}$ to $\mathcal{A}_{AB}$ given as (19). Let $T^\sharp$ denote the dual of this α with respect to the tracial state whose concrete formula is given as (20). This $T^\sharp$ gives the canonical left inverse of $E_{A,B}$ for the densities of ψ_{ABC} and $\psi_{ABC}\circ E_{B,C}$, that is,

$$T^\sharp(\rho_{\psi_B}) = \rho_{\psi_{BC}} \tag{22}$$

and

$$T^\sharp(\rho_{\psi_{AB}}) = \rho_{\psi_{ABC}}. \tag{23}$$

The set of fixed points of α contains $\mathcal{A}_A^e$. If the state ψ_{ABC} is even, then the set of fixed points of α contains $\mathcal{A}_A$ and accordingly the Markov property of ψ_{ABC} with respect to a triplet $(\mathcal{A}_A, \mathcal{A}_B, \mathcal{A}_C)$ is satisfied.

Proof: We shall confirm the part about the fixed point elements of α. Take $X \in \mathcal{A}_A^e$, which is in the commutant of $\mathcal{A}_{BC}$. We have

$$\begin{aligned}\alpha(X) &= \rho_{\psi_B}^{-1/2} E_{A,B}(\rho_{\psi_{BC}}^{1/2} X \rho_{\psi_{BC}}^{1/2}) \rho_{\psi_B}^{-1/2} = \rho_{\psi_B}^{-1/2} E_{A,B}(X \rho_{\psi_{BC}}) \rho_{\psi_B}^{-1/2} = \rho_{\psi_B}^{-1/2} X E_{A,B}(\rho_{\psi_{BC}}) \rho_{\psi_B}^{-1/2} \\ &= \rho_{\psi_B}^{-1/2} X E_{A,B}(E_{B,C}(\rho_{\psi_{BC}})) \rho_{\psi_B}^{-1/2} = \rho_{\psi_B}^{-1/2} X E_B(\rho_{\psi_{BC}}) \rho_{\psi_B}^{-1/2} = \rho_{\psi_B}^{-1/2} X \rho_{\psi_B} \rho_{\psi_B}^{-1/2} = X \rho_{\psi_B}^{-1/2} \rho_{\psi_B} \rho_{\psi_B}^{-1/2} = X.\end{aligned} \tag{24}$$

Suppose now that ψ_{ABC} is even. Then $\rho_{\psi_{BC}} \in \mathcal{A}_{BC}^e$ and also $\rho_{\psi_B} \in \mathcal{A}_B^e$ commute with any $X \in \mathcal{A}_A$. Hence we see that the above set of equalities (24) holds for this case. ■

From this result, if an even state satisfies the strong additivity of entropy, then the Markov property with respect to a triplet $(\mathcal{A}_A, \mathcal{A}_B, \mathcal{A}_C)$ in the sense of Ref. 1 (cf. Lemma 11.3 of Ref. 14) is satisfied. This in fact precisely specifies what we mean by the Markov property.

IV. MARKOV STATES ON THE MARGINAL SUBSYSTEMS

The definition of separable states (i.e., classically correlated states) for nonindependent systems is much the same as that for the tensor-product systems.[11] That is, if a state is written as a convex sum of some product states, then it is called a separable state. Let A and C be a pair of disjoint subsets, and ω be a state on $\mathcal{A}_{AC}$. If

$$\omega(XY) = \omega(X)\omega(Y) \tag{25}$$

for all $X \in \mathcal{A}_A$ and $Y \in \mathcal{A}_C$, then ω is called a product state with respect to the pair $(\mathcal{A}_A, \mathcal{A}_C)$. It is easy to see that the product property in the converse order,

$$\omega(YX) = \omega(Y)\omega(X) = \omega(XY) \tag{26}$$

follows from (25) and the graded commutation relations.

We discuss the property of Markov states with respect to $(\mathcal{A}_A, \mathcal{A}_B, \mathcal{A}_C)$ for the marginal subsystem $\mathcal{A}_{AC}$. As we announced in the introduction, Corollary 7 of Ref. 6 is invalid for the graded systems.

Proposition 3: For a three-composed graded system $(\mathcal{A}_A, \mathcal{A}_B, \mathcal{A}_C)$, *there exist U(1)-gauge invariant states that satisfy the Markov property for* $(\mathcal{A}_A, \mathcal{A}_B, \mathcal{A}_C)$ but are nonseparable for $(\mathcal{A}_A, \mathcal{A}_C)$.

We shall construct such Markov states. Using the Jordan-Wigner transformation, we set a three-composed tensor-product system in the following way. Let υ_A, υ_B, and $\upsilon_{A,B}$ denote the unitaries implementing Θ on the specified subsystems. Let $\mathcal{A}^s_A := \mathcal{A}_A$, $\mathcal{A}^s_{AB} := \mathcal{A}_{AB}$, $\mathcal{A}^s_{ABC} := \mathcal{A}_{ABC}$, $\mathcal{A}^s_B := \{\mathcal{A}^e_B, \upsilon_A \mathcal{A}^o_B\}$, $\mathcal{A}^s_C := \{\mathcal{A}^e_C, \upsilon_{A,B}\mathcal{A}^o_C\}$, and $\mathcal{A}^s_{BC} := \{\mathcal{A}^e_{BC}, \upsilon_A \mathcal{A}^o_{BC}\}$ where the notation $\{,\}$ denotes the algebra generated by the arguments. They induce a tensor-product system $\mathcal{A}^s_{ABC} = \mathcal{A}^s_A \otimes \mathcal{A}^s_B \otimes \mathcal{A}^s_C$. We assign finite-dimensional Hilbert spaces $\mathcal{H}_{\bar{A}}$, $\mathcal{H}_{\bar{B}}$ and $\mathcal{H}_{\bar{C}}$ to $\mathcal{A}^s_A$, $\mathcal{A}^s_B$ and $\mathcal{A}^s_C$, respectively. We will use the next lemma later. Its proof is obvious.

Lemma 4: Let ψ_{ABC} *be an arbitrary even state on* $\mathcal{A}_{ABC}$. *It satisfies*

$$S(\psi_{ABC}) - S(\psi_{AB}) - S(\psi_{BC}) + S(\psi_B) = 0, \tag{27}$$

if and only if

$$S(\psi_{ABC}) - S(\psi|_{\mathcal{A}^s_{AB}}) - S(\psi|_{\mathcal{A}^s_{BC}}) + S(\psi|_{\mathcal{A}^s_B}) = 0. \tag{28}$$

For a while we will focus on the two composed system, $\mathcal{A}_{AC}$. In Ref. 11 we have discussed how the state correlation (separability, nonseparability) will remain or change under the Jordan-Wigner transformation which maps the CAR pair $(\mathcal{A}_A, \mathcal{A}_C)$ to $(\mathcal{A}_A, \mathcal{A}^{\tilde{s}}_C)$, where $\mathcal{A}^{\tilde{s}}_C$ denotes the commutant of $\mathcal{A}_A$ in $\mathcal{A}_{AC}$ and is explicitly given as $\{\mathcal{A}^e_C, \upsilon_A \mathcal{A}^o_C\}$. (Note that $\mathcal{A}^{\tilde{s}}_C$ is different from previously introduced $\mathcal{A}^s_C$.) It has been shown that the set of all separable states for the CAR pair is strictly smaller than that for the tensor-product pair. That is, if ω_{AC} is a separable state for the pair $(\mathcal{A}_A, \mathcal{A}_C)$, then so it is for $(\mathcal{A}_A, \mathcal{A}^{\tilde{s}}_C)$. However, there exist U(1)-invariant states that are separable for the latter but nonseparable for the former. We introduce an example of such states from Ref. 11.

Let k_A and k_C be some nonzero odd elements in $\mathcal{A}_A$ and in $\mathcal{A}_C$, e.g., field operators on specified regions. Let $K := 1/2(k^*_A k_C - k_A k^*_C)$ which is self-adjoint and denotes fermion-hopping interaction between $\mathcal{A}_A$ and $\mathcal{A}_C$. Suppose that $\|k_A\| \leqslant 1 \|k_C\| \leqslant 1$, then $\|K\| \leqslant 1$. For $\lambda \in \mathbb{R}$, $|\lambda| \leqslant 1$, $\rho_{AC,\lambda} := 1 + \lambda K$ gives a density operator. For $0 < |\lambda| \leqslant 1$, the state on $\mathcal{A}_{AC}$ with its density $\rho_{AC,\lambda}$ gives a state satisfying all the desired conditions.

Now take such a U(1)-gauge invariant state ω_{AC} on $\mathcal{A}_{AC}$. It has a state decomposition $\omega_{AC} = \sum^n_{i=1} \lambda_i \omega_{AC,i}$, $0 < \lambda_i < 1$, $\Sigma \lambda_i = 1$, such that each $\omega_{AC,i}$ is a product state for $(\mathcal{A}_A, \mathcal{A}^{\tilde{s}}_C)$, but has no product-state decomposition for $(\mathcal{A}_A, \mathcal{A}_C)$. From this, we are going to construct a state on $\mathcal{A}_{ABC}$ that proves Proposition 3.

Let us assume that the dimension of $\mathcal{H}_{\bar{B}}$ is equal or more than n. Then we have a set of n non-zero even orthogonal projections $p_i \in \mathcal{A}^e_B$, $1 \leqslant i \leqslant n$. Let $\omega_{B,i}(X) := \tau(p_i X)/\tau(p_i)$, for $X \in \mathcal{A}_B$.

Those are all even states of $\mathcal{A}_B$. Let $\omega_{ABC} := \Sigma_{i=1}^{n} \lambda_i \omega_{AC,i} \circ \omega_{B,i}$, where $\omega_{AC,i} \circ \omega_{B,i}$ denotes the (uniquely determined) product state extension of $\omega_{AC,i}$ on $\mathcal{A}_{AC}$ and $\omega_{B,i}$ on $\mathcal{A}_B$, see Ref. 5.

We will see that $\omega_{AC,i} \circ \omega_{B,i}$ gives a product state for $(\mathcal{A}_A, \mathcal{A}_C^s)$ when restricted to $\mathcal{A}_A \otimes \mathcal{A}_C^s$. We must check this for the product element ac_+ such that $a \in \mathcal{A}_A$ and $c_+ \in \mathcal{A}_C^e$, and for $a(v_A v_B c_-)$ such that $a \in \mathcal{A}_A$ and $c_- \in \mathcal{A}_C^o$. We have

$$\omega_{AC,i} \circ \omega_{B,i}(ac_+) = \omega_{AC,i}(ac_+) = \omega_{AC,i}(a)\omega_{AC,i}(c_+) = \omega_{AC,i} \circ \omega_{B,i}(a)\omega_{AC,i} \circ \omega_{B,i}(c_+), \tag{29}$$

and using the product property of $\omega_{AC,i}$ for $(\mathcal{A}_A, \mathcal{A}_C^{\tilde{s}})$,

$$\begin{aligned}\omega_{AC,i} \circ \omega_{B,i}(av_A v_B c_-) &= \omega_{AC,i} \circ \omega_{B,i}(av_A c_- v_B) = \omega_{AC,i}(av_A c_-)\omega_{B,i}(v_B) = \omega_{AC,i}(a)\omega_{AC,i}(v_A c_-)\omega_{B,i}(v_B) \\ &= \omega_{AC,i}(a)\omega_{AC,i} \circ \omega_{B,i}(v_A c_- v_B) = \omega_{AC,i} \circ \omega_{B,i}(a)\omega_{AC,i} \circ \omega_{B,i}(v_A v_B c_-). \end{aligned} \tag{30}$$

Hence, $\omega_{AC,i} \circ \omega_{B,i}$ has a product state restriction, and accordingly ω_{ABC} has a separable state restriction for $(\mathcal{A}_A, \mathcal{A}_C^s)$. We conclude that our ω_{ABC} has the structure as in Theorem 6 of Ref. 6 or as the formula (14) of Ref. 12 with respect to $(\mathcal{H}_A^-, \mathcal{H}_B^-, \mathcal{H}_C^-)$. Hence, it satisfies the Markov property with respect to $(\mathcal{A}_A^s, \mathcal{A}_B^s, \mathcal{A}_C^s)$.

From the equivalence of the Markov property and the strong additivity of entropy for three-composed tensor-product systems, which has been shown in the above references, (28) is satisfied for ω_{ABC}. Since it is even, it satisfies (27) as well and, hence, is Markovian with respect to $(\mathcal{A}_A^s, \mathcal{A}_B^s, \mathcal{A}_C^s)$ by Proposition 2. As $\omega_{AC}|_{\mathcal{A}_{AC}} = \omega_{AC}$ is obviously nonseparable for $(\mathcal{A}_A, \mathcal{A}_C)$ by definition, ω_{ABC} gives a state showing Proposition 3.

V. ADDITIVITY OF VON NEUMANN ENTROPY AND THE PRODUCT PROPERTY

In this section, we consider a two-composed graded system $\mathcal{A}_{AC}$ generated by $\mathcal{A}_A$ and $\mathcal{A}_C$. Namely, we treat the case where the intersection region B is trivial. Then the strong subadditivity of entropy (15) becomes

$$S(\psi_{AC}) - S(\psi_A) - S(\psi_C) \leqslant 0, \tag{31}$$

which is called the subadditivity of entropy. We discuss characterization of additivity of entropy, i.e., the condition of equality of this inequality.

The answer is very simple for tensor-product systems: a state satisfies the additivity of entropy if and only if it is a product state. For the graded system, we can show a similar result easily under the assumption that the marginal states ψ_A and ψ_C are not both noneven. Let $\psi_A \circ \psi_C$ denote the product state of $\mathcal{A}_{AC}$ whose restrictions to $\mathcal{A}_A$ and $\mathcal{A}_C$ are ψ_A and ψ_C. Its existence is guaranteed if ψ_A and/or ψ_C is even. Then we have

$$S(\psi_{AC}) - S(\psi_A) - S(\psi_C) = -H(\psi_{AC}, \psi_A \circ \psi_C) \leqslant 0. \tag{32}$$

By the strict positivity of relative entropy, it is 0 if and only if $\psi_{AC} = \psi_A \circ \psi_C$.

Now we drop the evenness assumption on the states. If ψ_A and ψ_C are both noneven, then there is no product state extension for them.[5] Hence, the above argument using the strict positivity of relative entropy does not work for the general case.

Using Ref 12 we obtain the following result.

Proposition 5: Let ψ_{AC} be a state of the two-composed graded system $\mathcal{A}_{AC}$. It satisfies the additivity of entropy

$$S(\psi_{AC}) - S(\psi_A) - S(\psi_C) = 0, \tag{33}$$

if and only if it is a product state for $(\mathcal{A}_A, \mathcal{A}_C)$. If it is the case, at least one of ψ_A and ψ_C is even.

Proof: The equivalence of (33) and (18) when the middle part B is empty implies that (33) is equivalent to

$$H(\rho_{\psi_{AC}},\rho_{\psi_C}) = H(\rho_{\psi_A},\mathbf{1}). \tag{34}$$

This is equivalent to say that E_A is sufficient for $\rho_{\psi_{AC}}$ and ρ_{ψ_C}. Now from (20) the canonical left inverse of E_A for those densities is given by

$$T^\sharp(X) := \rho_{\psi_C}^{1/2} X \rho_{\psi_C}^{1/2}, \quad X \in \mathcal{A}_A. \tag{35}$$

Hence we have

$$\rho_{\psi_{AC}} = T^\sharp(\rho_{\psi_A}) = \rho_{\psi_C}^{1/2} \rho_{\psi_A} \rho_{\psi_C}^{1/2}. \tag{36}$$

Exchanging A and C and repeating the same argument as above, we have also

$$\rho_{\psi_{AC}} = \rho_{\psi_A}^{1/2} \rho_{\psi_C} \rho_{\psi_A}^{1/2}. \tag{37}$$

Let us take the decomposition of ρ_{ψ_A} into its even-odd parts and that of ρ_{ψ_C} as in (3),

$$\rho_{\psi_A} = \rho_{\psi_{A^+}} + \rho_{\psi_{A^-}}, \quad \rho_{\psi_{A^+}} \in \mathcal{A}_A^e, \quad \rho_{\psi_{A^-}} \in \mathcal{A}_A^o,$$

$$\rho_{\psi_C} = \rho_{\psi_{C^+}} + \rho_{\psi_{C^-}}, \quad \rho_{\psi_{C^+}} \in \mathcal{A}_C^e, \quad \rho_{\psi_{C^-}} \in \mathcal{A}_C^o. \tag{38}$$

Similarly take the even-odd decomposition of $\rho_{\psi_A}^{1/2}$ and that of $\rho_{\psi_C}^{1/2}$ in the following:

$$\rho_{\psi_A}^{1/2} = a_+ + a_-, \quad a_+ \in \mathcal{A}_A^e, \quad a_- \in \mathcal{A}_A^o,$$

$$\rho_{\psi_C}^{1/2} = c_+ + c_-, \quad c_+ \in \mathcal{A}_C^e, \quad c_- \in \mathcal{A}_C^o. \tag{39}$$

Since the densities are positive hence self-adjoint, each of a_+, a_-, c_+, and c_- is self-adjoint. We have

$$\rho_{\psi_A} = (\rho_{\psi_A}^{1/2})^2 = a_+^2 + a_-^2 + a_+a_- + a_-a_+,$$

$$\rho_{\psi_{A^+}} = a_+^2 + a_-^2,$$

$$\rho_{\psi_{A^-}} = a_+a_- + a_-a_+, \tag{40}$$

and

$$\rho_{\psi_C} = c_+^2 + c_-^2 + c_+c_- + c_-c_+,$$

$$\rho_{\psi_{A^+}} = c_+^2 + c_-^2,$$

$$\rho_{\psi_{A^-}} = c_+c_- + c_-c_+. \tag{41}$$

Now we shall express the equality $\rho_{\psi_C}^{1/2}\rho_{\psi_A}\rho_{\psi_C}^{1/2} = \rho_{\psi_A}^{1/2}\rho_{\psi_C}\rho_{\psi_A}^{1/2} = \rho_{\psi_{AC}}$ in terms of a_+, a_-, c_+, and c_-. We compute

$$\begin{aligned}
\rho_{\psi_C}^{1/2}\rho_{\psi_A}\rho_{\psi_C}^{1/2} &= \rho_{\psi_C}^{1/2}(\rho_{\psi_{A^+}} + \rho_{\psi_{A^-}})\rho_{\psi_C}^{1/2} = (\rho_{\psi_{A^+}}\rho_{\psi_C}^{1/2} + \rho_{\psi_{A^-}}\Theta(\rho_{\psi_C}^{1/2}))\rho_{\psi_C}^{1/2} = \rho_{\psi_{A^+}}\rho_{\psi_C} + \rho_{\psi_{A^-}}\Theta(\rho_{\psi_C}^{1/2})\rho_{\psi_C}^{1/2} \\
&= (a_+^2 + a_-^2)(c_+^2 + c_-^2 + c_+c_- + c_-c_+) + (a_+a_- + a_-a_+)(c_+ - c_-)(c_+ + c_-) \\
&= a_+^2(c_+^2 + c_-^2 + c_+c_- + c_-c_+) + a_-^2(c_+^2 + c_-^2 + c_+c_- + c_-c_+) + a_+a_-(c_+^2 - c_-^2 - c_-c_+ + c_+c_-)
\end{aligned}$$

$$+ a_-a_+(c_+^2 - c_-^2 - c_-c_+ + c_+c_-). \tag{42}$$

Also,

$$\begin{aligned}\rho_{\psi_A}^{1/2}\rho_{\psi_C}\rho_{\psi_A}^{1/2} &= \rho_{\psi_A}^{1/2}(\rho_{\psi_{C^+}} + \rho_{\psi_{C^-}})\rho_{\psi_A}^{1/2} = \rho_{\psi_A}\rho_{\psi_{C^+}} + \rho_{\psi_A}^{1/2}\Theta(\rho_{\psi_A}^{1/2})\rho_{\psi_{C^-}} \\ &= (a_+^2 + a_-^2 + a_+a_- + a_-a_+)(c_+^2 + c_-^2) + (a_+^2 - a_-^2 - a_+a_- + a_-a_+)(c_+c_- + c_-c_+) \\ &= a_+^2(c_+^2 + c_-^2 + c_+c_- + c_-c_+) + a_-^2(c_+^2 + c_-^2 - c_+c_- - c_-c_+) + a_+a_-(c_+^2 + c_-^2 - c_+c_- - c_-c_+) \\ &\quad + a_-a_+(c_+^2 + c_-^2 + c_+c_- + c_-c_+). \end{aligned} \tag{43}$$

Equating (42) and (43), we have

$$a_-^2(c_+c_- + c_-c_+) + a_+a_-(-c_-^2 + c_+c_-) + a_-a_+(-c_-^2 - c_-c_+) = 0. \tag{44}$$

Taking the even and odd parts of this, we have

$$a_+a_-c_+c_- - a_-a_+c_-c_+ = 0, \tag{45}$$

$$a_-^2(c_+c_- + c_-c_+) - (a_+a_- + a_-a_+)c_-^2 = 0. \tag{46}$$

By acting the unitary transformation $\mathrm{Ad}(v_A)$ on both sides of (46) where v_A in $\mathcal{A}_A^e$ gives the implementation of Θ on $\mathcal{A}_A$ as (6), we have

$$a_-^2(c_+c_- + c_-c_+) + (a_+a_- + a_-a_+)c_-^2 = 0.$$

By averaging this and (46), we have

$$a_-^2(c_+c_- + c_-c_+) = 0. \tag{47}$$

Similarly, we have

$$(a_+a_- + a_-a_+)c_-^2 = 0. \tag{48}$$

We will see that from (45), (47), and (48), our assertion, i.e., the evenness of ρ_{ψ_A} or (and) ρ_{ψ_C} follows. For (47) to be satisfied,

$$a_-^2 = 0 \quad \text{or/and } (c_+c_- + c_-c_+) = 0, \tag{49}$$

as $a_-^2 \in \mathcal{A}_A^e$ and hence $a_-^2(c_+c_- + c_-c_+) = a_-^2 \otimes (c_+c_- + c_-c_+) = 0$. In the same way,

$$c_-^2 = 0 \quad \text{or/and } (a_+a_- + a_-a_+) = 0. \tag{50}$$

If $a_-^2 = 0$, then $a_- = 0$ since a_- is self-adjoint. Therefore, $\rho_{\psi_A}^{1/2}$ is even and so ρ_{ψ_A} is. If $c_-^2 = 0$, then ρ_{ψ_C} is even. We now consider the remaining possibility, i.e., the case where $a_+a_- + a_-a_+ = c_+c_- + c_-c_+ = 0$. This implies that $\rho_{\psi_{A^-}} = \rho_{\psi_{C^-}} = 0$, namely both of ρ_{ψ_A} and ρ_{ψ_C} are even. In conclusion, at least one of the marginal states ρ_{ψ_A} and ρ_{ψ_C} should be even.

Now we know that the product state $\psi_A \circ \psi_C$ exists and can use the argument in (32) that leads to our desired assertion. ■

We shall go back to three-composed systems and comment on the condition of the strong additivity of entropy. For now, we are only able to produce the desiarble form of Markov property for even states. We guess that the assumed strong additivity of entropy may control in a certain sense *nonevenness* of the states satisfying this as for the case of two-composed systems above. Without the evenness assumption, we need more involved analysis to understand the structure of those states satisfying the strong additivity of entropy.

(Received 29 December 2005; accepted 31 January 2006; published online 29 March 2006)

Using automorphisms σ of finite-dimensional Lie algebras and classical skew-symmetric *r*-matrices we construct "twisted" nonskew symmetric *r*-matrices with the spectral parameters. Using them and results of our previous papers we construct new quantum spin chains that generalize famous Gaudin spin chains. We consider several examples of the twisted nonskew symmetric *r*-matrices and the corresponding Gaudin-type systems. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2179052]

I. INTRODUCTION

Gaudin models[1] are one of the most celebrated integrable models of mathematical physics. They were shown to be connected with the conformal field theory via solutions of the Knizhnik-Zamolodchikov equations,[2,3] and with the BCS model in one dimension.[4,5] These facts give a special importance to their investigation. Standard Gaudin spin chains,[1,6,7] are connected with the skew-symmetric classical *r*-matrices introduced in Ref. 8, i.e., with the skew symmetric solutions of the classical Yang-Baxter equations, which were investigated and classified in Ref. 9.

In the papers[10] we have constructed new integrable classical spin chains starting from the general non-skew symmetric solutions of the "generalized" classical Yang-Baxter equations (a dualized form of the modified Yang-Baxter equations[11–13]) with values in a semisimple (reductive) Lie algebras $\mathfrak{g}$. In particular we have constructed the second order in spin variables Hamiltonians of these systems and showed that they are direct analogs of the famous Gaudin Hamiltonians. We have called our systems "generalized Gaudin systems." In our previous paper[14] we have considered a problem of the quantization of the generalized Gaudin systems. The quantization of the basic (spin) variables is achieved by the standard procedure of substitution of the Lie-Poisson bracket on $\mathfrak{g}^{\oplus N}$ by commutator, or by other words in passing from $(S(\mathfrak{g}^{\oplus N}),\{\ ,\ \})$ to $(\mathfrak{A}(\mathfrak{g}^{\oplus N}),[\ ,\ ])$ or some of its representations in the Hilbert space $\mathcal{H}$. Nevertheless, due to the problem of ordering, such a simple recipe does not solve the problem of commutativity of the classically Poisson-commutative integrals which are nonlinear in basic variables. At the present moment no general approach to a proof of the quantum integrability of such the classical integrable systems is known. That is why we have dealt with this problem in the case of the our systems directly. In Ref. 14 we have given a direct proof that after symmetrization in spin variables generalized Gaudin Hamiltonians stay commutative also in the quantum case. We have also considered a class of examples of nonskew *r*-matrices with spectral parameters connected with some special infinite-dimensional Lie algebras of Ref. 15 and associated quantum Gaudin Hamiltonians.

In the present paper we consider other important class of examples of nonskew *r*-matrices and associated Gaudin-type systems. We show that for each classical skew-symmetric *r*-matrix $r(u-v)$, which is *anti-invariant* with respect to some automorphism σ of the second order of the Lie algebra $\mathfrak{g}$, prolonged to the algebra of functions, it is possible to define "twisted" nonskew *r*-matrix $r^{\sigma}_{12}(u,v)$ given by the following formula:

[a)]Electronic mail: tskrypnyk@imath.kiev.ua

$$r_{12}^{\sigma}(u,v) = r_{12}(u-v) - r_{12}^{\sigma_2}(u+v), \quad \text{where } r_{12}^{\sigma_2}(u+v) = (1 \otimes \sigma) r_{12}(u+v). \tag{1}$$

We consider examples of the r-matrices (1) associated with the rational r-matrix of Yang and elliptic r-matrix of Belavin[16] in details.

With the help of the r-matrices (1) we construct new quantum-commuting Gaudin-type Hamiltonians. They have the following form:

$$\hat{H}^l = \sum_{k=1,k\neq l}^{N} \sum_{\alpha,\beta=1}^{\dim \mathfrak{g}} (r^{\alpha\beta}(u_k - u_l) - (r^{\sigma_2})^{\alpha\beta}(u_k + u_l)) \hat{S}_{\alpha}^{k} \hat{S}_{\beta}^{l} - \sum_{\alpha,\beta=1}^{\dim \mathfrak{g}} (r^{\sigma_2})^{\alpha\beta}(2u_l) \hat{S}_{\alpha}^{l} \hat{S}_{\beta}^{l}, \tag{2}$$

where N is a number of sites, $\hat{S}_{\alpha}^{l}$, $\hat{S}_{\beta}^{k}$ are components of the generalized spin operators in the site l and k, correspondingly, that obey the commutation relations of $\mathfrak{g}^{\oplus N}$, $r^{\alpha\beta}(u_k - u_l)$ are the matrix elements of the $\mathfrak{g} \otimes \mathfrak{g}$-valued skew symmetric classical r matrix and u_k, $k \in 1, N$ are nonzero complex numbers such that $u_k \neq \pm u_l$.

We consider examples of such Hamiltonians, in particular, those connected with the "twisted" Belavin sl(n) elliptic r-matrix. In the most physically important case of $\mathrm{sl}(2) \simeq \mathrm{so}(3)$ we obtain the following quantum spin chain Hamiltonians:

$$\hat{H}^l = \sum_{k=1,k\neq l}^{N} \sum_{i=1}^{3} (w_i(u_k - u_l) - w_i(u_k + u_l)) \hat{S}_{i}^{k} \hat{S}_{i}^{l} - \sum_{i=1}^{3} w_i(2u_l) \hat{S}_{i}^{l} \hat{S}_{i}^{l}, \tag{3}$$

where $\hat{S}_{i}^{k}$ are the components of the usual spin operators and $w_i(u_k)$ are expressed via the elliptic Jacobi functions.[8]

The structure of the present paper is the following: in the second section we introduce the main definitions and notations and formulate the theorem concerning the commutativity of the generalized Gaudin Hamiltonians associated with the nonskew symmetric r-matrices. In the third section we consider the construction of the nonskew symmetric classical r-matrices with the spectral parameter using automorphism of $\mathfrak{g}$ of the second order and skew symmetric classical r-matrices. In the fourth section we consider the generalized Gaudin Hamiltonians (10) associated with the constructed in the preceding section "twisted" classical r-matrices. In the appendix we give the direct proof of the commutativity of such Hamiltonians.

II. INTEGRABLE SPIN CHAINS AND CLASSICAL *r*-MATRICES

Let $\mathfrak{g}$ be a simple (reductive) Lie algebra. Let $X_{\alpha}, \alpha = 1, \dim \mathfrak{g}$ be some basis in $\mathfrak{g}$ with the commutation relations

$$[X_{\alpha}, X_{\beta}] = \sum_{\gamma=1}^{\dim \mathfrak{g}} C_{\alpha\beta}^{\gamma} X_{\gamma}. \tag{4}$$

Let $\hat{S}_{\alpha}^{i}, \alpha = 1, \dim \mathfrak{g}$, $i = 1, N$ be linear operators in some Hilbert space that constitute Lie algebra isomorphic to $\mathfrak{g}^{\oplus N}$ with the commutation relations

$$[\hat{S}_{\alpha}^{i}, \hat{S}_{\beta}^{j}] = \delta^{ij} \sum_{\gamma=1}^{\dim \mathfrak{g}} C_{\alpha\beta}^{\gamma} \hat{S}_{\gamma}^{j}. \tag{5}$$

We will consider operators $\hat{S}_{\alpha}$ to be α component of the "generalized spin operator." Then operators $\hat{S}_{\alpha}^{i}$ could be interpreted as the α component of the generalized spin operator living at the i-cite of the generalized spin chain.

Remark 1: In the case $\mathfrak{g} = \mathrm{so}(3)$ operators $\hat{S}_{a}, \alpha = 1, 3$ are components of the usual spin and operator and $\hat{S}_{\alpha}^{i}$ have the usual $\mathrm{so}(3)^{\oplus N}$ commutation relations,

$$[\hat{S}^i_\alpha, \hat{S}^j_\beta] = \delta^{ij} \sum_{\gamma=1}^{3} \epsilon_{\alpha\beta\gamma} \hat{S}^j_\gamma. \tag{6}$$

We will be interested in a construction of a family of the second order in "spin" variable $\hat{S}^i_\alpha$ mutually commuting operators $\hat{H}^j, j=1,N$ that generalize standard Gaudin Hamiltonians.

We will need the following definition.

Definition 1: A function of two complex variables $r(u_1,u_2)$ with values in the tensor square of the algebra $\mathfrak{g}$ is called a classical r-matrix if it satisfies the following "general" or "generalized" classsical Yang-Baxter equation:

$$[r_{12}(u_1,u_2), r_{13}(u_1,u_3)] = [r_{23}(u_2,u_3), r_{12}(u_1,u_2)] - [r_{32}(u_3,u_2), r_{13}(u_1,u_3)], \tag{7}$$

where $r_{12}(u_1,u_2) \equiv \Sigma_{\alpha,\beta=1}^{\dim \mathfrak{g}} r^{\alpha\beta}(u_1,u_2) X_\alpha \otimes X_\beta \otimes 1$, etc. (This equation first appeared in somewhat different form in Refs. 11 and 13. In the present form it appeared later in Ref. 17.)

Remark 2: If the matrix $r(u_1,u_2)$ is "skew," i.e., $r_{12}(u_1,u_2) = -r_{21}(u_2,u_1)$ Eq. (7) passes into the usual classical Yang-Baxter equation

$$[r_{12}(u_1,u_2), r_{13}(u_1,u_3)] = [r_{23}(u_2,u_3), r_{12}(u_1,u_2) + r_{13}(u_1,u_3)]. \tag{8}$$

Due to the fact that all solutions of the equations (8) are skew[18] each solution of (8) is also a solution of (7).

Remark 3: Note, that by reparametrizations and gauge transformations each solution of the equation (8) could be transformed to the form $r_{12}(u_1,u_2) \equiv r_{12}(u_1-u_2)$.[18] This statement is not true for general nonskew solutions of the equation (7).

Let us fix N distinct points $\{u_k\}$ on the complex plane such that in the neighborhood of these points $r(u,v)$ possesses the following decomposition:

$$r(u,v) = \frac{\hat{c}}{(u-v)} + r_0(u,v), \tag{9}$$

where $r_0(u,v)$ is a regular in the neighborhood of $u=u_k$, $v=u_m$, $k,m \in 1,N$ $\mathfrak{g} \otimes \mathfrak{g}$-valued function, $\hat{c} \in \mathfrak{g} \otimes \mathfrak{g}$ is the tensor Casimir, $\hat{c} = \Sigma_{\alpha,\beta} g^{\alpha\beta} X_\alpha \otimes X_\beta$, $g^{\alpha\beta}$ is the nondegenerate invariant metric on $\mathfrak{g}$.

The following theorem holds true.[14]

Theorem 2.1: *Let $r(u_i,u_j) \equiv \Sigma_{\alpha,\beta=1}^{\dim \mathfrak{g}} r^{\alpha\beta}(u_i,u_j) X_\alpha \otimes X_\beta$ be the classical r-matrix and $r_0(u_i,u_j)$ its regular part. Then the second order in spin variables operators $\hat{H}^l, l=1,N$ of the type*

$$\hat{H}^l = \sum_{k=1,k\neq l}^{N} \sum_{\alpha,\beta=1}^{\dim \mathfrak{g}} r^{\alpha\beta}(u_k,u_l) \hat{S}^k_\alpha \hat{S}^l_\beta + \frac{1}{2} \sum_{\alpha,\beta=1}^{\dim \mathfrak{g}} r_0^{\alpha\beta}(u_l,u_l) (\hat{S}^l_\alpha \hat{S}^l_\beta + \hat{S}^l_\beta \hat{S}^l_\alpha) \tag{10}$$

form commutative family in the universal enveloping algebra $\mathfrak{A}(\mathfrak{g}^{\oplus N})$ and its representations.

Remark 4: In the case of the skew symmetric r-matrices we have that $r_0^{\alpha,\beta}(u_l,u_l) = -r_0^{\beta,\alpha}(u_l,u_l)$ and, hence, additional term in the corresponding Hamiltonian $\hat{H}^l$ turns zero and $\hat{H}^l$ coincides with the standard Gaudin Hamiltonian.

Remark 5: Theorem 2.1 implies also commutativity of the corresponding classical Hamiltonians with respect to the natural Lie-Poisson bracket. Their classical commutativity was shown by an other method in Ref. 10. For the case of a $\mathfrak{g}$ of a higher rank these Hamiltonians do not form complete family of the commuting integrals and should be completed by the "higher" integrals.[10] Proof of their quantum commutativity is a separate complicated problem even in the case of the standard skew symmetric r-matrices. This problem for the case of the general skew symmetric r-matrices was approached in Ref. 19 and solved for the case of the simplest rational r-matrix in Ref. 20.

III. AUTOMORPHISMS OF THE SECOND ORDER AND "TWISTED" NONSKEW *r*-MATRICES

In this section we construct nonskew symmetric classical r-matrices with spectral parameters starting from the standard skew symmetric classical r-matrices with spectral parameters.

Let σ be involutive automorphism of $\mathfrak{g}$, i.e., $\sigma^2=1$ and $\sigma([X,Y])=[\sigma(X),\sigma(Y)]$, $\forall X,Y\in\mathfrak{g}$. We will use the following notations: $\sigma_1=\sigma\otimes 1$, $\sigma_2=1\otimes\sigma$, etc. Let $\widetilde{\sigma}$ be a lift of σ onto the algebra of $\mathfrak{g}$-valued functions given by the formula $\widetilde{\sigma}X(u)=\sigma X(-u)$, and on the level of their tensor product by the formula $(\widetilde{\sigma}_1\widetilde{\sigma}_2)r_{12}(u,v)=(\sigma_1\sigma_2)r_{12}(-u,-v)$, etc.

The following theorem holds true.

Theorem 3.1: *Let $r_{12}(u-v)$ be skew symmetric r-matrix, i.e., a solution of the equation (8) which is anti-invariant with respect to the action of the automorphism $\widetilde{\sigma}$,*

$$\widetilde{(\sigma_1\sigma_2)}r_{12}(u-v)=-r_{12}(u-v). \tag{11}$$

Then (i) the function $r_{12}^{\sigma_2}(u+v)\equiv\sigma_2 r_{12}(u+v)$ is symmetric,

$$r_{12}^{\sigma_2}(u+v)=r_{21}^{\sigma_1}(u+v)=-r_{12}^{\sigma_1}(-u-v), \tag{12}$$

(ii) the function

$$r_{12}^{\sigma}(u,v)=r_{12}(u-v)-r_{12}^{\sigma_2}(u+v)=r_{12}(u-v)+r_{12}^{\sigma_1}(-u-v), \tag{13}$$

is a nonskew symmetric solution of the equation (7).

Remark 6: Note, that formula (13) differs from the one that can be extracted from Ref. 13. Indeed, in Ref. 13 it is imposed the condition of invariance of the r-matrix $r(u-v)$ under the action of $\widetilde{\sigma}$, $\widetilde{(\sigma_1\sigma_2)}r_{12}(u-v)=r_{12}(u-v)$ instead of the anti-invariance condition (11). Using formula of Ref. 13 for the case $\sigma^2=1$ one obtains the different formula, $r_{12}^{\sigma}(u,v)=r_{12}(u-v)+r_{12}^{\sigma_2}(u+v)$, which is not true for anti-invariant r-matrices $r_{12}(u-v)$.

Remark 7: The construction of the theorem holds also in the case of the trivial involutive automorphism $\sigma\equiv 1$. In this case $\widetilde{\sigma}(X(u))=X(-u)$ and anti-invariance condition for $r_{12}(u-v)$ is equivalent to the condition $r_{12}(u-v)=-r_{12}(v-u)$, or taking into account skew symmetry of $r(u-v)$ to the following symmetry condition: $r_{12}(u-v)=r_{21}(u-v)$.

Proof: Let us at first prove item (i). At first let us note that using skew symmetry, $r_{12}(u+v)=-r_{21}(-v-u)$ condition (11) is easily shown to be equivalent to the condition $(\sigma_1\sigma_2)r_{12}(u+v)=r_{21}(u+v)$. Now it is easy to see that due to the equality $\sigma_1^2=1$ this implies identity $r_{12}^{\sigma_2}(u+v)=r_{21}^{\sigma_1}(u+v)$. Using the skew symmetry condition for $r(u+v)$ again we obtain $r_{21}^{\sigma_1}(u+v)=-r_{12}^{\sigma_1}(-u-v)$. This proves item (i).

Let us now prove item (ii). For this purpose we must show that generalized classical Yang-Baxter equation (7) for the r-matrix $r^{\sigma}(u,v)$ given by the formula (13) follows from the usual classical Yang-Baxter equation (8) for the r-matrix $r_{12}(u-v)$. We must prove that

$$\begin{aligned}[r_{12}(u_1-u_2)+r_{12}^{\sigma_1}(-u_1-u_2),r_{13}(u_1-u_3)+r_{13}^{\sigma_1}(-u_1-u_3)]=[r_{23}(u_2-u_3)+r_{23}^{\sigma_2}(-u_2-u_3),r_{12}(u_1-u_2)+r_{12}^{\sigma_1}(-u_1-u_2)]\\-[r_{32}(u_3-u_2)+r_{32}^{\sigma_3}(-u_3-u_2),r_{13}(u_1-u_3)+r_{13}^{\sigma_1}(-u_1-u_3)].\end{aligned}$$

This equation is equivalent to the following four equations:

$$[r_{12}(u_1-u_2),r_{13}(u_1-u_3)]=[r_{23}(u_2-u_3),r_{12}(u_1-u_2)+r_{13}(u_1-u_3)], \tag{14a}$$

$$[r_{12}^{\sigma_1}(-u_1-u_2),r_{13}^{\sigma_1}(-u_1-u_3)]=[r_{23}(u_2-u_3),r_{12}^{\sigma_1}(-u_1-u_2)+r_{13}^{\sigma_1}(-u_1-u_3)], \tag{14b}$$

$$[r_{12}(u_1-u_2),r_{13}^{\sigma_1}(-u_1-u_3)]=[r_{23}^{\sigma_2}(-u_2-u_3),r_{12}(u_1-u_2)]-[r_{32}^{\sigma_3}(-u_2-u_3),r_{13}^{\sigma_1}(-u_1-u_3)], \tag{14c}$$

$$[r_{12}^{\sigma_1}(-u_1-u_2),r_{13}(u_1-u_3)]=[r_{23}^{\sigma_2}(-u_2-u_3),r_{12}^{\sigma_1}(-u_1-u_2)]-[r_{32}^{\sigma_3}(-u_2-u_3),r_{13}(u_1-u_3)]. \tag{14d}$$

Equation (14a) is the standard Yang-Baxter equation which is satisfied by $r(u_1-u_2)$ by the conditions of the theorem. Equation (14b) passes to the equation (14a) after the change of variable $u_1\to -u_1$ and action on both sides of the automorphism σ_1.

Changing the sign of the variable u_3 in the equation (14c) and taking into account that $r_{13}^{\sigma_1}(-u_1+u_3)=-r_{31}^{\sigma_1}(u_1-u_3)=-r_{13}^{\sigma_3}(u_1-u_3)$ and $r_{23}^{\sigma_2}(-u_2+u_3)=-r_{23}^{\sigma_3}(u_2-u_3)$, we see that Eq. (14c) is equivalent to the following equation:

$$[r_{12}(u_1-u_2),r_{13}^{\sigma_3}(u_1-u_3)]=[r_{23}^{\sigma_3}(u_2-u_3),r_{12}(u_1-u_2)]-[r_{32}^{\sigma_3}(u_3-u_2),r_{13}^{\sigma_3}(u_1-u_3)].$$

Acting on both sides of this equation by the automorphism σ_3 we obtain that Eq. (14c) is also equivalent to Eq. (14a). At last Eq. (14d) is equivalent to (14c). To see this it is enough to change indices $2\leftrightarrow 3$ in Eq. (14d).

Theorem is proved.

Let us consider several examples of this construction.

Example 1: Let $\mathfrak{g}=\mathrm{gl}(n)$ and $r(u-v)=(u-v)^{-1}\Sigma_{i,j=1}^{n}X_{ij}\otimes X_{ji}$, is r-matrix of Yang. Here $(X_{ij})_{\alpha\beta}=\delta_{i\alpha}\delta_{j\beta}$ is the standard matrix basis of $\mathrm{gl}(n)$. Let us consider automorphism $\widetilde{\sigma}$ of $\mathrm{gl}(n)$ given on the basis elements by the formula $\sigma(X_{ij})=-X_{ji}$. It is easy to show, that $\widetilde{\sigma_1\sigma_2}(r(u-v))=-r(u-v)$. Hence by the virtue of Theorem 3.1 we obtain that the following $\mathrm{gl}(n)\otimes\mathrm{gl}(n)$-valued function

$$r^{\sigma}(u,v)=(u-v)^{-1}\sum_{i,j=1}^{n}X_{ij}\otimes X_{ji}+(u+v)^{-1}\sum_{i,j=1}^{n}X_{ij}\otimes X_{ij} \tag{15}$$

satisfies the generalized classical Yang-Baxter equation (7). This r-matrix coincides with the classical r-matrix found previously in Ref. 21.

Example 2: Let us consider the case $\mathfrak{g}=\mathrm{sl}(n)$ and the classical elliptic r-matrix of Ref. 16,

$$r(u-v)=\sum_{a\in Z_n^2\setminus\{0\}}\epsilon(a)w_a(u-v)X_{\alpha}\otimes X_{-\alpha}, \tag{16}$$

where $a=(a_1,a_2)$, $\epsilon(a)=e^{(2\pi i a_1 a_2)/n}$, $Z_n^2=Z_n\times Z_n$ and $Z_n=\mathbb{Z}/n\mathbb{Z}$, $w_a(u)$ is expressed via the θ-functions with characteristic:

$$w_a(u)=\frac{\theta_{(a_2/n+1/2,a_1/n+1/2)}(u)\,\theta'_{1/2,1/2}(0)}{\theta_{1/2,1/2}(u)\,\theta_{a_2/n+1/2,a_1/n+1/2}(0)}, \tag{17}$$

and basic elements X_{α} satisfy the following commutation relations:[22]

$$[X_a,X_b]=\alpha_{a,b}X_{a+b}, \tag{18}$$

where $\alpha_{a,b}=e^{(2\pi i a_2 b_1)/n}-e^{(2\pi i a_1 b_2)/n}$. Using the fact that $\alpha_{-a,-b}=\alpha_{a,b}$ it is easy to see, that the map $\sigma(X_a)=X_{-a}$ is the automorphism of $\mathrm{sl}(n)$. Moreover, from the skew symmetry of $r(u-v)$ it follows that $w_a(u-v)=-w_{-a}(v-u)$ and $\epsilon(a)=\epsilon(-a)$, and it is straightforward to show that $(\widetilde{\sigma_1\sigma_2})r_{12}(u-v)=-r_{12}(u-v)$. Hence we can use the formula (13) and obtain the following "twisted" elliptic r-matrix:

$$r^{\sigma}(u,v)=\sum_{a\in Z_n^2\setminus\{0\}}\epsilon(a)(w_a(u-v)X_{\alpha}\otimes X_{-\alpha}-w_a(u+v)X_{\alpha}\otimes X_{\alpha}). \tag{19}$$

Example 3: Let us consider in details the previous example but in the special case $\mathfrak{g}=\mathrm{sl}(2)$. Introducing new generators $X_1=i/2X_{(1,1)}$, $X_2=i/2X_{(0,1)}$, $X_3=1/2X_{(1,0)}$ we obtain the following commutation relations: $[X_i,X_j]=\epsilon_{ijk}X_k$, which reflect isomorphism $\mathrm{sl}(2,\mathbb{C})\simeq\mathrm{so}(3,\mathbb{C})$. Taking into account that in the group Z_2^2 we have that $a=-a$ and, hence, we obtain that formula (16) (up to a coefficient) acquires the form of Sklyanin,[8]

$$r(u-v)=\sum_{k=1}^{3} w_k(u-v)X_k\otimes X_k, \tag{20}$$

where $w_k(u)$ are expressed via Jacobi functions, $w_1(u)=1/\mathrm{sn}(u)$, $w_2(u)=\mathrm{dn}(u)/\mathrm{sn}(u)$, $w_3(u)=\mathrm{cn}(u)/\mathrm{sn}(u)$.

It is easy to see that in this case $\sigma=1$ and $r_{12}(u-v)=-r_{12}(v-u)$ due to the fact that functions $w_k(u)$ are odd. Hence the condition of Theorem 3.1 is true and we obtain the following nonskew symmetric so (3) elliptic r-matrix:[10]

$$r^{\sigma}(u,v)=\sum_{k=1}^{3}(w_k(u-v)-w_k(u+v))X_\kappa\otimes X_\kappa. \tag{21}$$

This r-matrix could also be obtained using the results of Refs. 23 or 24.

IV. INTEGRABLE SPIN CHAINS ASSOCIATED WITH $r^{\sigma}(u,v)$

In this section using classical r-matrices constructed in the preceding section will explicitly obtain Hamiltonians of the new integrable quantum spin chains (10).

The following theorem holds true.

Theorem 4.1: *Let $r(u-v)$ be the classical skew symmetric r-matrix satisfying equation (8). Let $u_k, k\in 1,N$ be some fixed nonzero complex numbers such that $u_k\neq\pm u_l$. Then the second order in spin variables $\hat{S}^k_\alpha$ operators $\hat{H}^l, l=1,N$ of the type*

$$\hat{H}^l=\sum_{k=1,k\neq l}^{N}\sum_{\alpha,\beta=1}^{\dim\mathfrak{g}}(r^{\alpha\beta}(u_k-u_l)-(r^{\sigma_2})^{\alpha\beta}(u_k+u_l))\hat{S}^k_\alpha\hat{S}^l_\beta-\sum_{\alpha,\beta=1}^{\dim\mathfrak{g}}(r^{\sigma_2})^{\alpha\beta}(2u_l)\hat{S}^l_\alpha\hat{S}^l_\beta \tag{22}$$

form commutative family in the universal enveloping algebra $\mathfrak{A}(\mathfrak{g}^{\oplus N})$ and its representations.

Proof: Proof of this theorem follows from the Theorems 2.1 and 3.1. It is necessary only to find out the explicit form of the tensor $r^{\sigma}_0(u,u)$. By the direct calculation we obtain that

$$r^{\sigma}_0(u,u)=\lim_{v\to u}(r(u-v)-r^{\sigma_2}(u+v)-(u-v)^{-1}\hat{c})=r^0-r^{\sigma_2}(2u), \tag{23}$$

where we have used that $r(u-v)=(u-v)^{-1}\hat{c}+r^0+\Sigma_{k=1}^{\infty}r^k(u-v)^k$.

Now, substituting the explicit expression for the "twisted" classical r-matrix (13) and its regular part (23) into the formula (10) and taking into account skew symmetry of the tensor r^0 and symmetry of the tensor $r^{\sigma_2}_{12}(2u)$ we obtain the formula (22).

Theorem is proved.

Remark 8: Note that due to the symmetry of the tensor $r^{\sigma_2}_{12}(2u)$ no additional symmetrization of the operators $\hat{S}^l_\alpha,\hat{S}^l_\beta$ as in formula (10) is needed in the formula (22).

Remark 9: Theorem 4.1 could be also proved directly without appealing to the more general Theorem 2.1. Moreover, proof of this theorem in such a case is much simpler and we expose it for the sake of completeness in the Appendix.

Let us consider concrete examples of the formula (22) for the concrete r-matrices.

Example 4: Let us consider the case $\mathfrak{g}=\mathrm{gl}(n)$ and r-matrix $r^{\sigma}(u,v)$ from the Example 1. In this case the spin operators are labeled by two matrix indices, i.e., $\hat{S}^k_\alpha\equiv\hat{S}^k_{ij}$ and we obtain the following explicit formula for the commuting Gaudin-type Hamiltonians $\hat{H}^l, l\in 1,N$:

$$\hat{H}^l = \sum_{k=1,k\neq l}^{N} (u_k - u_l)^{-1} \sum_{i,j=1}^{n} \hat{S}_{ij}^k \hat{S}_{ji}^l + \sum_{k=1,k\neq l}^{N} (u_k + u_l)^{-1} \sum_{i,j=1}^{n} \hat{S}_{ij}^k \hat{S}_{ij}^l + (2u_l)^{-1} \sum_{i,j=1}^{n} \hat{S}_{ij}^l \hat{S}_{ij}^l, \tag{24}$$

where commutation relations among the generalized spin operators are

$$[\hat{S}_{ij}^m, \hat{S}_{kl}^n] = \delta^{mn}(\delta_{kj}\hat{S}_{il}^n - \delta_{il}\hat{S}_{kj}^n).$$

Example 5: Let us consider the case $\mathfrak{g}=\mathrm{sl}(n)$ and nonskew symmetric elliptic r matrix $r^{\sigma}(u,v)$ from the Example 2. This example yields the following commuting generalized Gaudin-type Hamiltonians $\hat{H}^l, l \in 1,N$:

$$\hat{H}^l = \sum_{k=1,k\neq l}^{N} \left(\sum_{a\in Z_n^2\setminus 0} \epsilon(a) w_a(u_k - u_l) \hat{S}_a^k \hat{S}_{-a}^l - \sum_{a\in Z_n^2\setminus 0} \epsilon(a) w_a(u_k + u_l) \hat{S}_a^k \hat{S}_a^l \right) - \sum_{a,b\in Z_n^2\setminus 0} \epsilon(a) w_a(2u_l) \hat{S}_a^l \hat{S}_a^l. \tag{25}$$

Commutation relations among the generalized spin operators are

$$[\hat{S}_a^n, \hat{S}_b^m] = \delta^{nm} \alpha_{a,b} \hat{S}_{a+b}^m. \tag{26}$$

Example 6: Let us consider the case $\mathfrak{g}=\mathrm{sl}(2)\simeq \mathrm{so}(3)$ and nonskew symmetric elliptic r matrix $r^{\sigma}(u,v)$ from the Example 3. This example yields the following commuting Gaudin-type Hamiltonians $\hat{H}^l, l \in 1,N$,

$$\hat{H}^l = \sum_{k=1,k\neq l}^{N} \sum_{i=1}^{3} (w_i(u_k - u_l) - w_i(u_k + u_l)) \hat{S}_i^k \hat{S}_i^l - \sum_{i=1}^{3} w_i(2u_l) \hat{S}_i^l \hat{S}_i^l. \tag{27}$$

Commutation relations among the usual spin operators are standard,

$$[\hat{S}_i^n, \hat{S}_j^m] = \delta^{nm} \epsilon_{ijk} \hat{S}_k^m. \tag{28}$$

Hamiltonian (27) is a quantum version of classical Hamiltonian obtained by us in Ref. 10.

Example 7: Finally, let us consider the previous example in the special cases $N=1$ and $N=2$ in order to show that our quantum spin systems is a generalization of the well known ones. Indeed, in the case $N=1$ our construction yields the following Hamiltonian:

$$\hat{H}^1 = -\sum_{i=1}^{3} w_i(2u_1) \hat{S}_i^1 \hat{S}_i^1.$$

Setting $w_k(2u_1) = -J_k$ we obtain quantum Hamiltonian of the anisotropic Euler top,

$$\hat{H}^1 = \sum_{k=1}^{3} J_k \hat{S}_k^1 \hat{S}_k^1.$$

In the case $N=2$ we have two spin operators and two commuting Gaudin-type Hamiltonians,

$$\hat{H}^1 = \sum_{i=1}^{3} (w_i(u_2 - u_1) - w_i(u_1 + u_2)) \hat{S}_i^2 \hat{S}_i^1 - \sum_{i=1}^{3} w_i(2u_1) \hat{S}_i^1 \hat{S}_i^1,$$

$$\hat{H}^2 = \sum_{i=1}^{3} (w_i(u_1 - u_2) - w_i(u_1 + u_2)) \hat{S}_i^1 \hat{S}_i^2 - \sum_{i=1}^{3} w_i(2u_2) \hat{S}_i^2 \hat{S}_i^2.$$

These Hamiltonians are exactly quantized Hamiltonians of the classical Steklov system on $\mathrm{so}(3)+\mathrm{so}(3)$ in the form proposed in Ref. 22.

V. CONCLUSION AND DISCUSSION

In the present paper using automorphisms of the second order of semisimple Lie algebras $\mathfrak{g}$ and standard skew symmetric $\mathfrak{g}\otimes\mathfrak{g}$-valued r-matrices we have constructed new nonskew symmetric classical r-matrices with the spectral parameters. Using them we have explicitly constructed new integrable quantum Gaudin-type spin chains. We have considered several examples of our nonskew symmetric r-matrices and the corresponding commuting quantum Hamiltonians.

An interesting and important mathematical problem is a diagonalization of these Hamiltonians, i.e., an explicit construction of their eigenvectors and eigenvalues. It would be also interesting to find direct physical applications for the constructed integrable spin systems. One of the possible applications of our models are integrable fermionic systems with BCS-type Hamiltonians.[4,5] We hope, that using our results it will be possible to obtain an exactly solvable generalization of the one-dimensional BCS Hamiltonian. The work over these problems is now in progress and we will return to them in our future presentations.

APPENDIX: DIRECT PROOF OF THE THEOREM 4.1

We will prove the theorem directly showing that $[\hat{H}^k,\hat{H}^l]=0\,\forall\, k,l,k\neq l$. The first stage of the proof is independent of the choice of the concrete r-matrix $r^{\alpha\beta}(u_k,u_l)$ and repeats the part of the proof of the Theorem 2.1 in details exposed in Ref. 14.

Let us represent our Hamiltonians as follows: $\hat{H}^k=\hat{H}^k_0+\hat{H}^k_1$, $\hat{H}^l=\hat{H}^l_0+\hat{H}^l_1$, where

$$\hat{H}^l_0=\sum_{\alpha,\beta=1}^{\dim\mathfrak{g}}\sum_{k\neq l}^{N} r^{\alpha\beta}(u_k,u_l)\hat{S}^k_\alpha\hat{S}^l_\beta,\hat{H}^l_1=1/2\sum_{\alpha,\beta=1}^{\dim\mathfrak{g}} r_0^{\alpha\beta}(u_l,u_l)(\hat{S}^l_\alpha\hat{S}^l_\beta+\hat{S}^l_\beta\hat{S}^l_\alpha).$$

Here we use the notation of the Sec. I. It is easy to see that $[\hat{H}^k_1,\hat{H}^l_1]=0$, and hence,

$$[\hat{H}^k,\hat{H}^l]=[\hat{H}^k_0,\hat{H}^l_0]+[\hat{H}^k_0,\hat{H}^l_1]+[\hat{H}^k_1,\hat{H}^l_0]. \tag{A1}$$

Let us calculate each of this summands separately,

$$\begin{aligned}
[\hat{H}^k_0,\hat{H}^l_0]&=\sum_{m\neq k}\sum_{n\neq l}\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_m,u_k)r^{\gamma,\delta}(u_n,u_l)[\hat{S}^m_\alpha\hat{S}^k_\beta,\hat{S}^n_\gamma\hat{S}^l_\delta]\\
&=\sum_{m,n\neq k,l}\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_m,u_k)r^{\gamma,\delta}(u_n,u_l)[\hat{S}^m_\alpha\hat{S}^k_\beta,\hat{S}^n_\gamma\hat{S}^l_\delta]\\
&\quad+\sum_{n\neq l,k}\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_l,u_k)r^{\gamma,\delta}(u_n,u_l)[\hat{S}^l_\alpha\hat{S}^k_\beta,\hat{S}^n_\gamma\hat{S}^l_\delta]+\sum_{m\neq k,l}\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_m,u_k)r^{\gamma,\delta}(u_k,u_l)\\
&\quad\times[\hat{S}^m_\alpha\hat{S}^k_\beta,\hat{S}^k_\gamma\hat{S}^l_\delta]+\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_l,u_k)r^{\gamma,\delta}(u_k,u_l)[\hat{S}^l_\alpha\hat{S}^k_\beta,\hat{S}^k_\gamma\hat{S}^l_\delta]\\
&=\sum_{m\neq k,l} r^{\alpha,\beta}(u_m,u_k)r^{\gamma,\delta}(u_m,u_l)C^\kappa_{\alpha\gamma}\hat{S}^m_\kappa\hat{S}^k_\beta\hat{S}^l_\delta+\sum_{m\neq l,k}\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_l,u_k)r^{\gamma,\delta}(u_m,u_l)C^\kappa_{\alpha\delta}\hat{S}^l_\kappa\hat{S}^k_\beta\hat{S}^m_\gamma\\
&\quad+\sum_{m\neq k,l}\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_m,u_k)r^{\gamma,\delta}(u_k,u_l)C^\kappa_{\beta\gamma}\hat{S}^m_\alpha\hat{S}^k_\kappa\hat{S}^l_\delta+\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_l,u_k)r^{\gamma,\delta}(u_k,u_l)[\hat{S}^l_\alpha\hat{S}^k_\beta,\hat{S}^k_\gamma\hat{S}^l_\delta].
\end{aligned}$$

Note that in the first three summands of the final expression on the right-hand side of this equality indices m,k,l are all different and the order of the operators, $\hat{S}^m_\kappa$, $\hat{S}^k_\beta$, $\hat{S}^l_\delta$, is not important. Let us consider these summands in more details. Taking into account that $r_{12}(u_m,u_k)=\sum_{\alpha,\beta=1}^{\dim \mathfrak{g}} r^{\alpha\beta}(u_m,u_k)X_\alpha\otimes X_\beta\otimes 1$, $r_{13}(u_m,u_l)=\sum_{\gamma,\delta=1}^{\dim \mathfrak{g}} r^{\gamma\delta}(u_m,u_l)X_\gamma\otimes 1\otimes X_\delta$, $r_{23}(u_k,u_l)=\sum_{\gamma,\delta=1}^{\dim \mathfrak{g}} r^{\gamma\delta}(u_k,u_l)1\otimes X_\gamma\otimes X_\delta$, $r_{32}(u_l,u_k)=\sum_{\alpha,\beta=1}^{\dim \mathfrak{g}} r^{\alpha\beta}(u_k,u_l)1\otimes X_\beta\otimes X_\alpha$ we obtain that they can be rewritten in the following way:

$$\langle [r_{12}(u_m,u_k),r_{13}(u_m,u_l)]+[r_{12}(u_m,u_k),r_{23}(u_k,u_l)]+[r_{32}(u_l,u_k),r_{13}(u_m,u_l)],\hat{S}^m_1\hat{S}^k_2\hat{S}^l_3\rangle,$$

where we have used the following notations:

$$\hat{S}^m_1=\sum_{\alpha=1}^{\dim \mathfrak{g}}\hat{S}^m_\alpha X^\alpha\otimes 1\otimes 1,\quad \hat{S}^k_2=\sum_{\beta=1}^{\dim \mathfrak{g}} 1\otimes \hat{S}^m_\beta X^\beta\otimes 1,\quad \hat{S}^l_3=\sum_{\delta=1}^{\dim \mathfrak{g}} 1\otimes 1\otimes \hat{S}^m_\delta X^\delta,$$

and $\langle,\rangle$ is a scalar product on $\mathfrak{g}\otimes\mathfrak{g}\otimes\mathfrak{g}$ extended in a natural way from the scalar product on $\mathfrak{g}$ and $\langle X_\alpha,X^\beta\rangle=\delta^\beta_\alpha$. By the virtue of the generalized Yang-Baxter equation these summands cancel. Hence, we obtain

$$[\hat{H}^k_0,\hat{H}^l_0]=\sum_{\alpha,\beta,\gamma,\delta} r^{\alpha,\beta}(u_l,u_k)r^{\gamma,\delta}(u_k,u_l)[\hat{S}^l_\alpha\hat{S}^k_\beta,\hat{S}^k_\gamma\hat{S}^l_\delta]. \tag{A2}$$

This expression could be rewritten as $[\hat{H}^k_0,\hat{H}^l_0]=[\hat{H}^{k,l},\hat{H}^{l,k}]$, where

$$\hat{H}^{k,l}=\sum_{\alpha,\beta} r^{\alpha,\beta}(u_l,u_k)\hat{S}^l_\alpha\hat{S}^k_\beta,\quad \hat{H}^{l,k}=\sum_{\beta,\alpha} r^{\beta,\alpha}(u_k,u_l)\hat{S}^k_\beta\hat{S}^l_\alpha.$$

Let us now use the explicit form of our twisted r-matrices,

$$r^{\alpha,\beta}(u_l,u_k)=r^{\alpha,\beta}(u_l-u_k)-(r^{\sigma_2})^{\alpha,\beta}(u_l+u_k),$$

$$r^{\beta,\alpha}(u_k,u_l)=r^{\beta,\alpha}(u_k-u_l)-(r^{\sigma_2})^{\beta,\alpha}(u_l+u_k).$$

Using the skew symmetry of $r(u_l-u_k)$: $r^{\alpha,\beta}(u_l-u_k)=-r^{\beta,\alpha}(u_k-u_l)$ and symmetry of $r^{\sigma_2}(u_l+u_k)$: $(r^{\sigma_2})^{\alpha,\beta}(u_l+u_k)=(r^{\sigma_2})^{\beta,\alpha}(u_l+u_k)$ we obtain that in our case $\hat{H}^{k,l}$ and $\hat{H}^{k,l}$ can be rewritten as follows:

$$\hat{H}^{k,l}=-\hat{h}^{kl}_--\hat{h}^{kl}_+,\hat{H}^{l,k}=\hat{h}^{kl}_--\hat{h}^{kl}_+, \tag{A3}$$

where $\hat{h}^{k,l}_-=\sum_{\alpha,\beta}r^{\beta,\alpha}(u_k-u_l)\hat{S}^l_\alpha\hat{S}^k_\beta$, $\hat{h}^{k,l}_+=\sum_{\alpha,\beta}(r^{\sigma_2})^{\alpha,\beta}(u_k+u_l)\hat{S}^l_\alpha\hat{S}^k_\beta$. Hence we obtain

$$[\hat{H}^k_0,\hat{H}^l_0]=2[\hat{h}^{kl}_-,\hat{h}^{kl}_+]=2\sum_{\alpha,\beta,\gamma,\delta} r^{\beta,\alpha}(u_k-u_l)(r^{\sigma_2})^{\gamma,\delta}(u_k+u_l)[\hat{S}^k_\beta\hat{S}^l_\alpha,\hat{S}^k_\gamma\hat{S}^l_\delta]. \tag{A4}$$

Let us consider in details the expression $[\hat{S}^l_\alpha\hat{S}^k_\beta,\hat{S}^k_\gamma\hat{S}^l_\delta]=\hat{S}^l_\alpha\hat{S}^l_\delta[\hat{S}^k_\beta,\hat{S}^k_\gamma]+[\hat{S}^l_\alpha,\hat{S}^l_\delta]\hat{S}^k_\gamma\hat{S}^k_\beta$. Let us show that this expression is symmetric with respect to the permutation of the operators with the same upper indices. We have

$$\begin{aligned}[\hat{S}^l_\alpha\hat{S}^k_\beta,\hat{S}^k_\gamma\hat{S}^l_\delta]&=\tfrac{1}{2}(\hat{S}^l_\alpha\hat{S}^l_\delta+\hat{S}^l_\delta\hat{S}^l_\alpha)[\hat{S}^k_\beta,\hat{S}^k_\gamma]+\tfrac{1}{2}[\hat{S}^l_\alpha,\hat{S}^l_\delta](\hat{S}^k_\gamma\hat{S}^k_\beta+\hat{S}^k_\beta\hat{S}^k_\gamma)+\tfrac{1}{2}([\hat{S}^l_\alpha,\hat{S}^l_\delta][\hat{S}^k_\beta,\hat{S}^k_\gamma]+[\hat{S}^l_\alpha,\hat{S}^l_\delta][\hat{S}^k_\gamma,\hat{S}^k_\beta])\\&=\tfrac{1}{2}C^\kappa_{\beta\gamma}(\hat{S}^l_\alpha\hat{S}^l_\delta+\hat{S}^l_\delta\hat{S}^l_\alpha)\hat{S}^k_\kappa+\tfrac{1}{2}C^\kappa_{\alpha\delta}\hat{S}^l_\kappa(\hat{S}^k_\gamma\hat{S}^k_\beta+\hat{S}^k_\beta\hat{S}^k_\gamma),\end{aligned}$$

We obtain that formula (A2) can be rewritten in the symmetrized tensor form,

$$[\hat{H}_0^k,\hat{H}_0^l]=\langle[r_{12}(u_k-u_l),r_{13}^{\sigma_3}(u_k+u_l)],\hat{S}_1^k((\hat{S}_2^l\hat{S}_3^l))\rangle-\langle[r_{23}^{\sigma_3}(u_l+u_k),r_{13}(u_k-u_l)],((\hat{S}_1^k\hat{S}_2^k))\hat{S}_3^l\rangle, \tag{A5}$$

where $((\hat{S}_2^l\hat{S}_3^l))\equiv\Sigma_{\alpha\beta}(\hat{S}_\alpha^l\hat{S}_\beta^l+\hat{S}_\beta^l\hat{S}_\alpha^l)1\otimes X_\alpha\otimes X_\beta$, $((\hat{S}_1^k\hat{S}_2^k))\equiv\Sigma_{\alpha\beta}(\hat{S}_\alpha^k\hat{S}_\beta^k+\hat{S}_\beta^k\hat{S}_\alpha^k)X_\alpha\otimes X_\beta\otimes 1$ and we have used the symmetry of the tensors $r_{23}^{\sigma_3}(u_l+u_k)$ and $r_{13}^{\sigma_3}(u_k+u_l)$.

Let us now explicitly calculate expression $[\hat{H}_1^k,\hat{H}_0^l]$,

$$\begin{aligned}
[\hat{H}_1^k,\hat{H}_0^l]&=\frac{1}{2}\sum_{m\neq k}\sum_{\alpha,\beta,\gamma,\delta}r^{\alpha,\beta}(u_m,u_k)r_0^{\gamma,\delta}(u_l,u_l)[\hat{S}_\alpha^m\hat{S}_\beta^k,(\hat{S}_\gamma^l\hat{S}_\delta^l+\hat{S}_\delta^l\hat{S}_\gamma^l)]\\
&=\frac{1}{2}\sum_{m\neq k}\sum_{\alpha,\beta,\gamma,\delta}(r^{\beta,\alpha}(u_k-u_m)+(r^{\sigma_2})^{\alpha,\beta}(u_m+u_k))(r^{\sigma_2})^{\gamma,\delta}(2u_l)[\hat{S}_\alpha^m\hat{S}_\beta^k,(\hat{S}_\gamma^l\hat{S}_\delta^l+\hat{S}_\delta^l\hat{S}_\gamma^l)]\\
&=\frac{1}{2}\sum_{\alpha,\beta,\gamma,\delta}(r^{\beta,\alpha}(u_k-u_l)+(r^{\sigma_2})^{\alpha,\beta}(u_l+u_k))(r^{\sigma_2})^{\gamma,\delta}(2u_l)[\hat{S}_\alpha^l\hat{S}_\beta^k,(\hat{S}_\gamma^l\hat{S}_\delta^l+\hat{S}_\delta^l\hat{S}_\gamma^l)]\\
&=\frac{1}{2}\sum_{\alpha,\beta,\gamma,\delta,\kappa}(r^{\beta,\alpha}(u_k-u_l)+(r^{\sigma_2})^{\alpha,\beta}(u_l+u_k))(r^{\sigma_2})^{\gamma,\delta}(2u_l)\hat{S}_\beta^k(C_{\alpha\delta}^\kappa(\hat{S}_\kappa^l\hat{S}_\gamma^l+\hat{S}_\kappa^l\hat{S}_\gamma^l)\\
&\quad+C_{\alpha\gamma}^\kappa(\hat{S}_\kappa^l\hat{S}_\delta^l+\hat{S}_\kappa^l\hat{S}_\delta^l))=\langle[r_{12}(u_k-u_l)+r_{13}^{\sigma_3}(u_l+u_k),r_{23}^{\sigma_3}(2u_l)],\hat{S}_1^k((\hat{S}_2^l\hat{S}_3^l))\rangle,
\end{aligned} \tag{A6}$$

where we have used symmetry of the tensors $(r^{\sigma_3})_{13}(u_l+u_k)$ and $(r^{\sigma_3})_{23}(2u_l)$.

In analogous way we obtain

$$[\hat{H}_0^k,\hat{H}_1^l]=-\langle[r_{12}^{\sigma_2}(2u_k),r_{13}(u_k-u_l)-r_{23}^{\sigma_3}(u_k+u_l)],((\hat{S}_1^k\hat{S}_2^k))\hat{S}_3^l\rangle. \tag{A7}$$

On the other hand, using identities (14b) and (14d) and condition (12) it is easy to show that

$$[r_{12}(u_k-u_l),r_{13}^{\sigma_3}(u_k+u_l)]=-([r_{12}(u_k-u_l)+r_{13}^{\sigma_3}(u_k+u_l),r_{23}^{\sigma_3}(2u_l)]), \tag{A8}$$

$$[r_{13}(u_k-u_l),r_{23}^{\sigma_3}(u_k+u_l)]=[r_{12}^{\sigma_2}(2u_k),r_{13}(u_k-u_l)-r_{23}^{\sigma_3}(u_k+u_l)]. \tag{A9}$$

Substituting equalities (A8) and (A9) into expression (A5) and then substituting (A5) together with the expressions (A6) and (A7) into the equation (A1) we obtain that $[\hat{H}^k,\hat{H}^l]=0$.

Theorem is proved.

(Received 13 July 2005; accepted 1 February 2006; published online 29 March 2006)

We consider symmetries on the C^*-algebra of the discrete Heisenberg group and their generalization to the generalized discrete Heisenberg groups, and study the structure of the crossed products by the symmetries and their fixed point algebras, and also compute the stable rank of the crossed products and their fixed point algebras. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2180625]

INTRODUCTION

The group C^*-algebras of either Lie, discrete, or locally compact groups have been very interesting objects in the theory of C^*-algebras (cf. Dixmier[8] and Pedersen[17]). Among many things, their (algebraic) structure is well studied to some great extent. For this subject, see Green[12] or Poguntke.[19] In particular, it is shown by Ref. 19, Theorem 2, that the group C^*-algebra of a connected Lie group has only either the C^*-algebra of compact operators on a (finite or infinite dimensional) Hilbert space, noncommutative tori or their tensor products as simple quotients. On the other hand, symmetries on C^*-algebras regarded as as noncommutative spaces have been of much interest and studied well. See Ref. 2 for symmetries of the CAR algebras, and see Bratteli, Elliott, Evans, and Kishimoto (Refs. 4–6) for symmetries on the irrational or rational rotation C^*-algebras, and see also Ref. 3 for symmetries on certain noncommutative tori. Recently, the ultimate result for symmetries on noncommutative tori has been obtained by Phillips.[18]

Our first interest is to study the structure of the group C^*-algebras of discrete solvable groups and to compute their stable rank since little is known about this case in the literature. As the first step toward this program, we consider symmetries on the group C^*-algebra of the discrete Heisenberg group and their generalization to the generalized discrete Heisenberg groups. After we obtained the structure of the crossed products of those group C^*-algebras by the symmetries, we find as a corollary that group C^*-algebras of solvable discrete groups may have certain simple AF algebras as quotients. Compared with the result of Ref. 19 mentioned above, this consequence as a point of view seems to be interesting. We also obtain that group C^*-algebras of disconnected Lie groups may have certain AH algebras (in fact AT algebras) as simple quotients. The estimates of the stable rank of the crossed products by the symmetries and their fixed point algebras should be also interesting. Indeed, we show that the estimates of the stable rank for the group C^*-algebras of solvable discrete groups are different from those for nilpotent discrete groups obtained in Ref. 14 in the sense that the stable rank of the group C^*-algebras is determined by the spaces of all two-dimensional irreducible representations of the groups, and however, the stable rank of their fixed point algebras is estimated by the spaces of all one-dimensional representations of them. See Ref. 20 for the stable rank of C^*-algebras, and see also Refs. 15, 21, and 24 for some results on the stable rank.

The contents of this paper are as follows: Section I, the symmetries; Sec. II, the structure; Sec. III, the stable rank, and Sec. IV, applications to Lie group C^*-algebras. In Sec. I we construct the symmetries mentioned above by a simple procedure. This construction method to obtain symmetries and to derive solvable discrete groups from nilpotent ones could prove useful in other

a)Electronic mail: sudo@math.u-ryukyu.ac.jp

situations. In Sec. II we consider the structure of the crossed products of the group C^*-algebras of the generalized discrete Heisenberg groups by the symmetries and their fixed point algebras. For the proofs, we use some results of Bratteli, Elliott, Evans, and Kishimoto (Refs. 4–6) about noncommutative spheres, which are crossed products of rotation algebras by the flips and their fixed point algebras. In fact, the crossed products by some (canonical ones) of our symmetries and their fixed point algebras are continuous field C^*-algebras with fibers given by noncommutative spheres in the sense above, but not always as shown below. In Sec. III we estimate the stable rank of the crossed products by our symmetries and their fixed point algebras using the structure of Sec. II, some basic results on the stable rank and an estimate for the stable rank of continuous field C^*-algebras (Ref. 13). In Sec. IV we apply the methods above to the group C^*-algebras of the Mautner groups and Dixmier groups and their generalizations. See also Refs. 27, 32, and 30 and Refs. 33 and 34 for the structure and stable rank of the group C^*-algebras of certain connected solvable Lie groups and see Refs. 28, 29, and 31 for the cases of certain disconnected solvable Lie groups.

I. THE SYMMETRIES

Notation: Let $C^*(G)$ be the (full) group C^*-algebra of a locally compact group G (cf. Refs. 8 and 17). Let $\mathfrak{A}\rtimes_\alpha G$ be the (full) crossed product of a C^*-algebra $\mathfrak{A}$ by a locally compact group G with α an action by automorphisms of $\mathfrak{A}$.[17]

Recall that the discrete Heisenberg group of rank 3 is

$$H_3^{\mathbb{Z}}=\left\{g=(c,b,a)=\begin{pmatrix}1 & a & c\\ 0 & 1 & b\\ 0 & 0 & 1\end{pmatrix}\middle| a,b,c\in\mathbb{Z}\right\}.$$

Define the semidirect product $H_3^{\mathbb{Z}}\rtimes_{\beta^{(1)}}\mathbb{Z}_2$ to be the group generated by $H_3^{\mathbb{Z}}$ and the diagonal matrix $d_1=-1\oplus 1\oplus 1$ (the diagonal sum), where the action $\beta^{(1)}$ of $\mathbb{Z}_2$ is defined by $\beta^{(1)}_{-1}(c,b,a)=d_1gd_1^{-1}=(-c,b,-a)\in H_3^{\mathbb{Z}}$.

Similarly, we define the semidirect product $H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2$ generated by $H_3^{\mathbb{Z}}$ and the diagonal matrix $d_2=1\oplus -1\oplus 1$, where the action $\beta^{(2)}$ of $\mathbb{Z}_2$ is defined by $\beta^{(2)}_{-1}(c,b,a)=d_2gd_2^{-1}=(c,-b,-a)\in H_3^{\mathbb{Z}}$. Moreover, define the semidirect product $H_3^{\mathbb{Z}}\rtimes_{\beta^{(3)}}\mathbb{Z}_2$ generated by $H_3^{\mathbb{Z}}$ and the diagonal matrix $d_3=1\oplus 1\oplus -1$, where the action $\beta^{(3)}$ of $\mathbb{Z}_2$ is defined by $\beta^{(3)}_{-1}(c,b,a)=d_3gd_3^{-1}=(-c,-b,a)\in H_3^{\mathbb{Z}}$.

Furthermore, we may take the following diagonal matrices: $d_{1,2}=-1\oplus -1\oplus 1$, $d_{1,3}=-1\oplus 1\oplus -1$, and $d_{2,3}=1\oplus -1\oplus -1$ to define the semidirect products with the, respectively, corresponding actions $\beta^{(1,2)}$, $\beta^{(1,3)}$, and $\beta^{(2,3)}$. But it follows from direct computation that $\beta^{(1,2)}=\beta^{(3)}$, $\beta^{(1,3)}=\beta^{(2)}$, and $\beta^{(2,3)}=\beta^{(1)}$.

Let $C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(j)}}\mathbb{Z}_2)$ be the group C^*-algebra of $H_3^{\mathbb{Z}}\rtimes_{\beta^{(j)}}\mathbb{Z}_2$ for $1\leqslant j\leqslant 3$. Then $C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(j)}}\mathbb{Z}_2)$ is isomorphic to the crossed product $C^*(H_3^{\mathbb{Z}})\rtimes_{\beta^{(j)}}\mathbb{Z}_2$ of the group C^*-algebra $C^*(H_3^{\mathbb{Z}})$ by the action $\beta^{(j)}$ of $\mathbb{Z}_2$. Let U,V,W be the unitaries generating $C^*(H_3^{\mathbb{Z}})$, respectively, corresponding to the following matrices: (0,0,1), (0,1,0), and $(1,0,0)\in H_3^{\mathbb{Z}}$. By definition of the actions $\beta^{(j)}$ of $\mathbb{Z}_2$ (called symmetries), we obtain

Proposition 1.1: There exist symmetries $\beta^{(j)}(1\leqslant j\leqslant 3)$ on the group C^*-algebra $C^*(H_3^{\mathbb{Z}})$ with U, V, W the canonical generators such that

$$\beta^{(1)}(U)=U^*,\quad \beta^{(1)}(V)=V,\quad \beta^{(1)}(W)=W^*,$$

$$\beta^{(2)}(U)=U^*,\quad \beta^{(2)}(V)=V^*,\quad \beta^{(2)}(W)=W,$$

$$\beta^{(3)}(U)=U,\quad \beta^{(3)}(V)=V^*,\quad \beta^{(3)}(W)=W^*.$$

Recall that the discrete Heisenberg group of rank $2n+1$ is

$$H_{2n+1}^{\mathbb{Z}} = \left\{ g = (c,b,a) = \begin{pmatrix} 1 & a & c \\ 0_n^t & 1_n & b^t \\ 0 & 0_n & 1 \end{pmatrix} | a,b \in \mathbb{Z}^n, c \in \mathbb{Z} \right\},$$

where 1_n is the $n \times n$ identity matrix, $0_n = (0) \in \mathbb{Z}^n$, and b^t, 0_n^t are the transposes of b, 0_n, respectively. Define the semidirect product $H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta^{(1)}} \mathbb{Z}_2$ to be the group generated by $H_{2n+1}^{\mathbb{Z}}$ and the diagonal matrix $d_1 = -1 \oplus 1_n \oplus 1$, where the action $\beta^{(1)}$ of $\mathbb{Z}_2$ is defined by $\beta_{-1}^{(1)}(c,b,a) = d_1 g d_1^{-1} = (-c,b,-a) \in H_{2n+1}^{\mathbb{Z}}$, where $-a = (-a_j) \in \mathbb{Z}^n$.

Similarly, define the semidirect product $H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta^{(n+2)}} \mathbb{Z}_2$ to be the group generated by $H_{2n+1}^{\mathbb{Z}}$ and the diagonal matrix $d_{n+2} = 1 \oplus 1_n \oplus -1$, where the action $\beta^{(n+2)}$ of $\mathbb{Z}_2$ is defined by $\beta_{-1}^{(n+2)}(c,b,a) = d_{n+2} g d_{n+2}^{-1} = (-c,-b,a) \in H_{2n+1}^{\mathbb{Z}}$, where $-b = (-b_j) \in \mathbb{Z}^n$.

Furthermore, for $2 \leqslant j \leqslant n+1$ we define the semidirect product $H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta^{(j)}} \mathbb{Z}_2$ generated by $H_3^{\mathbb{Z}}$ and the diagonal matrix $d_j = 1_{j-1} \oplus -1 \oplus 1_{n+2-j}$, where the action $\beta^{(j)}$ of $\mathbb{Z}_2$ is defined by

$$\beta_{-1}^{(j)}(c,b,a) = d_j g d_j^{-1} = (c, b - 2\tilde{b_j}, a - 2\tilde{a_j}),$$

where $\tilde{b_j} = (0,\ldots,0,b_j,0,\ldots,0)$ and $\tilde{a_j} = (0,\ldots,0,a_j,0,\ldots,0)$ (b_j, a_j are jth components).

Let $C^*(H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta^{(j)}} \mathbb{Z}_2)$ be the group C^*-algebra of $H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta^{(j)}} \mathbb{Z}_2$ for $1 \leqslant j \leqslant n+2$. Then $C^*(H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta^{(j)}} \mathbb{Z}_2)$ is isomorphic to the crossed product $C^*(H_{2n+1}^{\mathbb{Z}}) \rtimes_{\beta^{(j)}} \mathbb{Z}_2$ of the group C^*-algebra $C^*(H_{2n+1}^{\mathbb{Z}})$ by the symmetry $\beta^{(j)}$. Let U_j, V_j, W ($1 \leqslant j \leqslant n$) be the unitaries generating $C^*(H_{2n+1}^{\mathbb{Z}})$, respectively, corresponding to the following diagonal matrices: $(0,0_n,\tilde{1_j})$, $(0,\tilde{1_j},0_n)$, and $(1,0_n,0_n)$, where $\tilde{1_j} = \tilde{a_j}$ with $a_j = 1$. By definition of the actions $\beta^{(j)}$ of $\mathbb{Z}_2$ (called symmetries), we obtain the following.

Proposition 1.2: There exist symmetries $\beta^{(j)}$ ($1 \leqslant j \leqslant n+2$) on the group C^*-algebra $C^*(H_{2n+1}^{\mathbb{Z}})$ with U_j, V_j, W ($1 \leqslant j \leqslant n$) the generators such that

$$\beta^{(1)}(U_j) = U_j^*, \quad \beta^{(1)}(V_j) = V_j \quad (1 \leqslant j \leqslant n), \quad \beta^{(1)}(W) = W^*,$$

$$\beta^{(n+2)}(U_j) = U_j, \quad \beta^{(n+2)}(V_j) = V_j^* \quad (1 \leqslant j \leqslant n), \quad \beta^{(n+2)}(W) = W^*,$$

and for $2 \leqslant j \leqslant n+1$,

$$\beta^{(j)}(U_j) = U_j^*, \quad \beta^{(j)}(V_j) = V_j^*, \quad \beta^{(j)}(W) = W,$$

$$\beta^{(j)}(U_k) = U_k \quad (k \neq j), \quad \beta^{(j)}(V_k) = V_k \quad (k \neq j).$$

Moreover, define the semidirect product $H_{2n+1}^{\mathbb{Z}} \rtimes_{\gamma} \mathbb{Z}_2$ to be the group generated by $H_{2n+1}^{\mathbb{Z}}$ and the diagonal matrix $d_{1_n} = 1 \oplus -1_n \oplus 1$, where the action γ of $\mathbb{Z}_2$ is defined by $\gamma_{-1}(c,b,a) = d_{1_n} g d_{1_n}^{-1} = (c,-b,-a) \in H_{2n+1}^{\mathbb{Z}}$.

Definition: We say that an action β of $\mathbb{Z}_2$ on the group C^*-algebra $C^*(H_{2n+1}^{\mathbb{Z}})$ is a canonical symmetry if it is induced from a semidirect product $H_{2n+1}^{\mathbb{Z}} \rtimes_{\beta} \mathbb{Z}_2$ generated by $H_{2n+1}^{\mathbb{Z}}$ and an $(n+2) \times (n+2)$ diagonal matrix with 1 or -1 on the diagonal, where β is the adjoint action by the diagonal matrix.

Proposition 1.3: There exist $2^{n+1} - 1$ nontrivial canonical symmetries on the group C^*-algebra $C^*(H_{2n+1}^{\mathbb{Z}})$. In particular, if one of the symmetries is γ defined above, then

$$\gamma(U_j) = U_j^*, \quad \gamma(V_j) = V_j^* \quad (1 \leqslant j \leqslant n), \quad \gamma(W) = W,$$

where U_j, V_j, W are generating unitaries of $C^*(H_{2n+1}^{\mathbb{Z}})$.

Proof: Let d be the diagonal matrix associated with a canonical symmetry. Note that $dgd^{-1} = dgd = (-d)g(-d)^{-1}$ for $g \in H_{2n+1}^{\mathbb{Z}}$. Thus, the number of choosing diagonal matrices with 1 or -1 on the diagonal is reduced to $2^{n+2}/2 = 2^{n+1}$. Since $1_{n+2} g 1_{n+2} = (-1_{n+2}) g (-1_{n+2}) = g$ for $g \in H_{2n+1}^{\mathbb{Z}}$, there are $2^{n+1} - 1$ nontrivial canonical symmetries. □

II. THE STRUCTURE

Notation: We identify elements z of $\mathbb{T}$ with $\theta \in \mathbb{R}(\mathrm{mod}\ 1)$ via $z=e^{2\pi i\theta}$, and write $\theta \in \mathbb{T}$. Let $C(X)$ be the C^*-algebra of continuous complex-valued functions on a compact Hausdorff space X. For a C^*-algebra $\mathfrak{A}$, let $C(X,\mathfrak{A})$ be the C^*-algebra of continuous $\mathfrak{A}$-valued functions on X. Let $\Gamma(X,\{\mathfrak{A}_t\}_{t\in X})$ be the continuous field C^*-algebra of continuous operator fields on X with fibers $\mathfrak{A}_t$ for $t \in X$ C^*-algebras (Ref. 8). An AF algebra is an inductive limit of finite-dimensional C^*-algebras, and an AT algebra is an inductive limit of matrix algebras over $C(\mathbb{T})$, and an AH algebra is an inductive limit of homogeneous C^*-algebras (cf. Ref. 23).

Theorem 2.1: *The crossed product $C^*(H_3^{\mathbb{Z}})\rtimes_{\beta^{(2)}}\mathbb{Z}_2$ is isomorphic to the continuous field C^*-algebra $\Gamma(\mathbb{T},\{\mathfrak{A}_\theta\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})$, where $\mathfrak{A}_\theta$ are rotation algebras for $\theta\in\mathbb{R}(mod\ 1)$.*

Proof: Since $H_3^{\mathbb{Z}}$ is isomorphic to the semidirect product $\mathbb{Z}^2\rtimes\mathbb{Z}$ through the identification between $g\in H_3^{\mathbb{Z}}$ and (c,b,a) for $c,b,a\in\mathbb{Z}$, $C^*(H_3^{\mathbb{Z}})$ is isomorphic to $C^*(\mathbb{Z}^2)\rtimes\mathbb{Z}$. By the Fourier transform, $C^*(\mathbb{Z}^2)\rtimes\mathbb{Z}\cong C(\mathbb{T}^2)\rtimes\mathbb{Z}$. Furthermore, we have

$$C(\mathbb{T}^2)\rtimes\mathbb{Z}\cong\Gamma(\mathbb{T},\{C(\mathbb{T})\rtimes_\theta\mathbb{Z}\}_{\theta\in\mathbb{T}})$$

and $C(\mathbb{T})\rtimes_\theta\mathbb{Z}=\mathfrak{A}_\theta$ (cf. Ref. 1). Therefore, we obtain

$$C^*(H_3^{\mathbb{Z}})\rtimes_{\beta^{(2)}}\mathbb{Z}_2\cong\Gamma(\mathbb{T},\{\mathfrak{A}_\theta\}_{\theta\in\mathbb{T}})\rtimes\mathbb{Z}_2\cong\Gamma(\mathbb{T},\{\mathfrak{A}_\theta\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})$$

since $\mathfrak{A}_\theta$ generated by U,V are invariant under $\mathbb{Z}_2$, and note also that $C(\mathbb{T})$ generated by W is the center of $C^*(H_3^{\mathbb{Z}})\rtimes_{\beta^{(2)}}\mathbb{Z}_2$ since W is fixed by $\beta^{(2)}$ (see Proposition 1.1) (cf. Ref. 16 Theorem 1.2 and see also Ref. 22). □

Remark: Since the action of $\mathbb{Z}_2$ on $\mathfrak{A}_\theta$ is the flip, the crossed product $\mathfrak{A}_\theta\rtimes\mathbb{Z}_2$ for θ irrational is a simple C^*-algebra with a unique tracial state by Ref. 4 and is AF by Ref. 6, Theorem 1.1. In fact, the crossed products $\mathfrak{A}_\theta\rtimes\mathbb{Z}_2$ are inductive limits of finite direct sums of the building blocks $C_{n,k}$ defined by $C_{n,k}=M_n(\mathbb{C})\otimes C_k$ for $n\geqslant 1$ and $k=-1,0,1,2$, where $C_{-1}=\mathbb{C}$, $C_0=C([-1,1])$, $C_1=\{f\in C([0,1],M_2(\mathbb{C}))\,|\,f(0)\in\mathbb{C}\oplus\mathbb{C}\}$, and

$$C_2=\{f\in C([-1,1],M_2(\mathbb{C}))\,|\,f(-1)\in\mathbb{C}^2,f(1)\in\mathbb{C}^2\}$$

(see Ref. 6, Corollary 7.4). Then it follows that the crossed products are AF since they are simple with unique tracial states (Ref. 6, Theorem 8.1 and see Ref. 25). If $\theta=p/q$ with p, q mutually prime positive integers, the crossed products $\mathfrak{A}_\theta\rtimes\mathbb{Z}_2$ are regarded as certain subalgebras of $C(S^2,M_{2q}(\mathbb{C}))$ (Ref. 5, Theorem 1.3).

Moreover, we have the following.

Theorem 2.2: *The crossed product $C^*(H_{2n+1}^{\mathbb{Z}})\rtimes_\gamma\mathbb{Z}_2$ is isomorphic to the continuous field C^*-algebra $\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})$, where $\mathfrak{A}_\theta$ are rotation algebras for $\theta\in\mathbb{R}(mod\ 1)$.*

Proof: Since $H_{2n+1}^{\mathbb{Z}}$ is isomorphic to the semidirect product $\mathbb{Z}^{n+1}\rtimes\mathbb{Z}^n$ through the identification between $g\in H_{2n+1}^{\mathbb{Z}}$ and (c,b,a) for $c\in\mathbb{Z}$, b, $a\in\mathbb{Z}^n$, $C^*(H_{2n+1}^{\mathbb{Z}})$ is isomorphic to $C^*(\mathbb{Z}^{n+1})\rtimes\mathbb{Z}^n$. By the Fourier transform, $C^*(\mathbb{Z}^{n+1})\rtimes\mathbb{Z}^n\cong C(\mathbb{T}^{n+1})\rtimes\mathbb{Z}^n$. Furthermore, we have

$$C(\mathbb{T}^{n+1})\rtimes\mathbb{Z}^n\cong\Gamma(\mathbb{T},\{C(\mathbb{T}^n)\rtimes_\theta\mathbb{Z}^n\}_{\theta\in\mathbb{T}})$$

and $C(\mathbb{T}^n)\rtimes_\theta\mathbb{Z}^n=\otimes^n\mathfrak{A}_\theta$. Therefore, we obtain

$$C^*(H_{2n+1}^{\mathbb{Z}})\rtimes_\gamma\mathbb{Z}_2\cong\Gamma(\mathbb{T},\{\otimes^n\mathfrak{A}_\theta\}_{\theta\in T})\rtimes\mathbb{Z}_2\cong\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})$$

since $\otimes^n\mathfrak{A}_\theta$ generated by U_j, $V_j(1\leqslant j\leqslant n)$ are invariant under $\mathbb{Z}_2$, and note also that $C(\mathbb{T})$ generated by W is the center of $C^*(H_{2n+1}^{\mathbb{Z}})\rtimes_\gamma\mathbb{Z}_2$ since W is fixed by γ (see Proposition 1.3) (cf. Ref. 16, Theorem 1.2 and see also Ref. 22). □

Remark: Since the action of $\mathbb{Z}_2$ on $\otimes^n\mathfrak{A}_\theta$ is the flip, the crossed product $(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2$ for θ irrational is a simple AF algebra by Refs. 4 and 6 (or Ref. 18, Theorem 10.11).

Corollary 2.3: The group C^*-algebras of solvable discrete groups may have certain AF algebras as simple quotients.

Proof: For instance, we take $H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2$ as a solvable discrete group. □

Corollary 2.4: The group C^*-algebras of solvable discrete groups may have certain AT algebras as simple quotients.

Proof: For instance, we take $H^{\mathbb{Z}}_{2n+1} \rtimes_{\beta^{(2)}} \mathbb{Z}_2$ as a solvable discrete group. In this case, we have

$$C^*(H^{\mathbb{Z}}_{2n+1}) \rtimes_{\beta^{(2)}} \mathbb{Z}_2 \cong \Gamma(\mathbb{T}, \{(\otimes^n \mathfrak{A}_\theta) \rtimes \mathbb{Z}_2\}_{\theta \in \mathbb{T}})$$

and $(\otimes^n \mathfrak{A}_\theta) \rtimes \mathbb{Z}_2 \cong (\mathfrak{A}_\theta \rtimes \mathbb{Z}_2) \otimes (\otimes^{n-1} \mathfrak{A}_\theta)$ since U_1, V_1 are invariant under $\mathbb{Z}_2$ and the action of $\mathbb{Z}_2$ is trivial elsewhere. If θ is irrational, $\mathfrak{A}_\theta \rtimes \mathbb{Z}_2$ is a simple AF algebra by Refs. 4 and 6, and $\mathfrak{A}_\theta$ is a simple AT algebra by Ref. 10, where an AT algebra is an inductive limit of direct sums of matrix algebras over $C(\mathbb{T})$. Therefore, $(\otimes^n \mathfrak{A}_\theta) \rtimes \mathbb{Z}_2$ with the tensor product decomposition is a simple AH algebra. Furthermore, since $\mathfrak{A}_\theta$ has real rank zero by Choi-Elliott[7] we have that the tensor product $\otimes^{n-1} \mathfrak{A}_\theta$ is in fact an AT algebra by Elliott-Gong (Ref. 11, Theorems 3.11 and 3.19). Hence $(\otimes^n \mathfrak{A}_\theta) \rtimes \mathbb{Z}_2$ is an AT algebra. □

Theorem 2.5: *The fixed point algebra $C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}}$ associated with the crossed product $C^*(H^{\mathbb{Z}}_3) \rtimes_{\beta^{(2)}} \mathbb{Z}_2$ is isomorphic to $\Gamma(\mathbb{T}, \{\mathfrak{A}_\theta^{\beta^{(2)}}\}_{\theta \in \mathbb{T}})$ the associated continuous field C^*-algebra, where $\mathfrak{A}_\theta^{\beta^{(2)}}$ are the fixed point algebras of the rotation algebras $\mathfrak{A}_\theta$ for $\theta \in \mathbb{R}(mod\ 1)$.*

Proof: Note that $C(\mathbb{T})$ generated by W is contained in $C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}}$ and is the center. Thus, $C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}}$ is written as the C^*-algebra of a continuous field on $\mathbb{T}$ with fibers contained in $\mathfrak{A}_\theta \rtimes \mathbb{Z}_2$. In fact, the fibers are given by $\mathfrak{A}_\theta^{\beta^{(2)}}$. □

Remark: The fixed point algebra $\mathfrak{A}_\theta^{\beta^{(2)}}$ for θ irrational is a simple AF algebra. Indeed, the fixed point algebras $\mathfrak{A}_\theta^{\beta^{(2)}}$ for θ irrational are corners of $\mathfrak{A}_\theta \rtimes_{\beta^{(2)}} \mathbb{Z}_2$. Hence they are AF. If $\theta = p/q$ with p, q mutually prime positive integers, the fixed point algebras $\mathfrak{A}_\theta^{\beta^{(2)}}$ are regarded as certain subalgebras of $C(S^2, M_q(\mathbb{C}))$ (Ref. 5, Theorem 1.2). If $q \geqslant 3$, then $\mathfrak{A}_\theta^{\beta^{(2)}}$ and $\mathfrak{A}_\theta \rtimes_{\beta^{(2)}} \mathbb{Z}_2$ are Morita equivalent, but not for $q=1$ or $q=2$.

Furthermore, we have the following.

Theorem 2.6: *The fixed point algebra $C^*(H^{\mathbb{Z}}_{2n+1})^\gamma$ associated with the crossed product $C^*(H^{\mathbb{Z}}_{2n+1}) \rtimes_\gamma \mathbb{Z}_2$ is isomorphic to $\Gamma(\mathbb{T}, \{(\otimes^n \mathfrak{A}_\theta)^\gamma\}_{\theta \in \mathbb{T}})$ the associated continuous field C^*-algebra, where $(\otimes^n \mathfrak{A}_\theta)^\gamma$ are the fixed point algebras of the noncommutative tori $\otimes^n \mathfrak{A}_\theta$ for $\theta \in \mathbb{R}(mod\ 1)$.*

Proof: Note that $C(\mathbb{T})$ generated by W is contained in $C^*(H^{\mathbb{Z}}_{2n+1})^\gamma$ and is the center. Thus, $C^*(H^{\mathbb{Z}}_{2n+1})^\gamma$ is written as the C^*-algebra of a continuous field on $\mathbb{T}$ with fibers contained in $(\otimes^n \mathfrak{A}_\theta) \rtimes \mathbb{Z}_2$. In fact, the fibers are given by $(\otimes^n \mathfrak{A}_\theta)^\gamma$. □

Remark: The fixed point algebra $(\otimes^n \mathfrak{A}_\theta)^\gamma$ for θ irrational is a simple AF algebra. Indeed, the fixed point algebras $(\otimes^n \mathfrak{A}_\theta)^\gamma$ for θ irrational are corners of $(\otimes^n \mathfrak{A}_\theta) \rtimes_\gamma \mathbb{Z}_2$. Hence they are AF. See also Ref. 3 Theorem 3.1.

We next consider the case of symmetries $\beta^{(1)}, \beta^{(3)}$ in Proposition 1.1.

Theorem 2.7: *The crossed products $C^*(H^{\mathbb{Z}}_3) \rtimes_{\beta^{(j)}} \mathbb{Z}_2$ $(j=1,3)$ are isomorphic to $C(\mathbb{T}^2) \rtimes (\mathbb{Z}_2 \times \mathbb{Z})$ which has the decomposition into the following exact sequence:*

$$0 \to \Gamma_0((0,\pi), \{C((\{z\} \times \mathbb{T}) \sqcup (\{\bar{z}\} \times \mathbb{T})) \rtimes (\mathbb{Z}_2 \times \mathbb{Z})\}_{z \in (0,\pi)})$$
$$\to C(\mathbb{T}^2) \rtimes (\mathbb{Z}_2 \times \mathbb{Z}) \to C^*(\mathbb{Z}_2) \otimes (C(\mathbb{T}) \rtimes \mathbb{Z} \oplus C(\mathbb{T}) \rtimes_{-1} \mathbb{Z}) \to 0,$$

where the closed ideal is the C^*-algebra of continuous operator fields on $(0,\pi)$ vanishing at infinity with fibers double rotation C^*-algebras on the disjoint union $\mathbb{T} \sqcup \mathbb{T}$ that we call, and the actions of two crossed products in the quotient are the flip and the minus flip on $\mathbb{T}$, respectively. Moreover, the double rotation C^*-algebras for irrational $z \in (0,\pi)$ are isomorphic to $(\mathfrak{A}_z \oplus \mathfrak{A}_{\bar{z}}) \rtimes \mathbb{Z}_2$ and are simple AF algebras.

Proof: As in the proof of Theorem 2.1, we have $C^*(H^{\mathbb{Z}}_3) \cong C(\mathbb{T}^2) \rtimes \mathbb{Z}$. Furthermore, note that

$$(C(\mathbb{T}^2) \rtimes \mathbb{Z}) \rtimes_{\beta^{(3)}} \mathbb{Z}_2 \cong C(\mathbb{T}^2) \rtimes (\mathbb{Z}_2 \times \mathbb{Z})$$

since $\beta^{(3)}(U) = U$ so that the actions of $\mathbb{Z}$ and $\mathbb{Z}_2$ commute. For $j=1$, we replace the role of U with that of V via $(W,V,U) \leftrightarrow (W,U,V)$ exchanging the order in $C(\mathbb{T}^2) \rtimes \mathbb{Z}$. Since $\beta^{(1)}(V) = V$, we can

replace $\beta^{(3)}$ with $\beta^{(1)}$ in the isomorphism above. Set $\beta=\beta^{(j)}$ for $j=1,3$. The action β on $\mathbb{T}$ is given by

$$\beta_{(-1,1)}(z,w)=\beta_{(1,1)}\beta_{(-1,0)}(z,w)=\beta_{(1,1)}(\bar{z},\bar{w})=(\bar{z},\bar{z}\bar{w})\in\mathbb{T}^2$$

for $(-1,1)\in\mathbb{Z}_2\times\mathbb{Z}$. It follows that the closed subspaces $\{\pm1\}\times\mathbb{T}$ of $\mathbb{T}^2$ are invariant under β, and $\mathbb{Z}_2$ acts trivially on the subspace. Since $\beta_{(-1,1)}(1,w)=(1,\bar{w})$ and $\beta_{(-1,1)}(-1,w)=(-1,-\bar{w})$, the actions on $\{1\}\times\mathbb{T}$ and $\{-1\}\times\mathbb{T}$ are the flip and the minus flip, respectively. Therefore, we obtain

$$C(\mathbb{T}^2)\rtimes(\mathbb{Z}_2\times\mathbb{Z})\to C(\{\pm1\}\times\mathbb{T})\rtimes(\mathbb{Z}_2\times\mathbb{Z})\cong C^*(\mathbb{Z}_2)\otimes(C(\mathbb{T})\rtimes\mathbb{Z}\oplus C(\mathbb{T})\rtimes_{-1}\mathbb{Z})\to 0.$$

Furthermore, note that the disjoint unions $(\{z\}\times\mathbb{Z})\sqcup(\bar{z}\times\mathbb{T})$ in $\mathbb{T}^2$ for $z\neq\pm1$ are invariant under β. Thus the kernel of the onto homomorphism above is given by

$$\Gamma_0((0,\pi),\{C((\{z\}\times\mathbb{T})\sqcup(\{\bar{z}\}\times\mathbb{T}))\rtimes(\mathbb{Z}_2\times\mathbb{Z})\}_{z\in(0,\pi)}),$$

where we identify the quotient space $(\mathbb{T}\backslash\{\pm1\})/\mathbb{Z}_2$ with $(0,\pi)$. Simplicity of the fibers for irrational $z\in(0,\pi)$ follows from minimality of the action β on $(\{z\}\times\mathbb{T})\sqcup(\{\bar{z}\}\times\mathbb{T})$, that is, any orbit under β in this disjoint union is dense in it. Note that $\beta_{(1,n)}(z,w)=(z,z^nw)\in\{z\}\times\mathbb{T}$ and $\beta_{(1,n)}\times(\bar{z},w)=(\bar{z},(\bar{z})^nw)\in\{\bar{z}\}\times\mathbb{T}$. Moreover, we note that

$$C((\{z\}\times\mathbb{T})\sqcup(\{\bar{z}\}\times\mathbb{T}))\rtimes(\mathbb{Z}_2\times\mathbb{Z})\cong C((\{z\}\times\mathbb{T})\sqcup(\{\bar{z}\}\times\mathbb{T}))\rtimes\mathbb{Z}\rtimes\mathbb{Z}_2\cong(\mathfrak{A}_z\oplus\mathfrak{A}_{\bar{z}})\rtimes\mathbb{Z}_2.$$

Also observe that the crossed products $\mathfrak{A}_z\rtimes\mathbb{Z}_2$ and $\mathfrak{A}_{\bar{z}}\rtimes\mathbb{Z}_2$ are C^*-subalgebras of $(\mathfrak{A}_z\oplus\mathfrak{A}_{\bar{z}})\rtimes\mathbb{Z}_2$, and their union is equal to it. Since the crossed products $\mathfrak{A}_z\rtimes\mathbb{Z}_2$ and $\mathfrak{A}_{\bar{z}}\rtimes\mathbb{Z}_2$ for irrational z are AF algebras with building blocks invariant under the flip, it follows that $(\mathfrak{A}_z\oplus\mathfrak{A}_{\bar{z}})\rtimes\mathbb{Z}_2$ is also AF. □

Theorem 2.8: *The fixed point algebras $C^*(H_3^{\mathbb{Z}})^{\beta^{(j)}}$ associated with the crossed products $C^*(H_3^{\mathbb{Z}})\rtimes_{\beta^{(j)}}\mathbb{Z}_2$ $(j=1,3)$ are isomorphic to $C(\mathbb{T}^2)^{\beta^{(j)}}\rtimes\mathbb{Z}$ which are isomorphic to*

$$C(S^2/\mathbb{T}\times\mathbb{T})\rtimes\mathbb{Z}\cong\Gamma([0,\pi],\{C(\mathbb{T}\cup_1\mathbb{T})\rtimes_\theta\mathbb{Z}\}_{\theta\in(0,\pi)}\cup\{C([\pi,2\pi])\rtimes_\theta\mathbb{Z}\}_{\theta=0}\cup\{C(\mathbb{T})\rtimes_\theta\mathbb{Z}\}_{\theta=\pi}),$$

the continuous field C^*-algebra on $[0,\pi]$ with fibers the double rotation algebras $C(\mathbb{T}\cup_1\mathbb{T})\rtimes_\theta\mathbb{Z}$ on the space $\mathbb{T}\cup_1\mathbb{T}$ attached at $1\in\mathbb{T}$ for $\theta\in(0,\pi]$ and $C([\pi,2\pi])\rtimes_0\mathbb{Z}=C([\pi,2\pi]\times\mathbb{T})$, and $S^2/\mathbb{T}\times\mathbb{T}$ is obtained from S^2 identifying four edges in S^2 to make two circles $\mathbb{T}$.

Proof: As in the proof of Theorem 2.7, we have that for $\beta=\beta^{(j)}$ $(j=1,3)$,

$$C^*(H_3^{\mathbb{Z}})\rtimes_{\beta^{(j)}}\mathbb{Z}_2\cong C(\mathbb{T}^2)\rtimes_\beta\mathbb{Z}_2\rtimes\mathbb{Z}.$$

Since $C(\mathbb{T}^2)^\beta=C(S^2)$ (Ref. 5), we have $C^*(H_3^{\mathbb{Z}})^\beta=C(S^2)\rtimes\mathbb{Z}$. We may view S^2 as follows. Consider the space obtained from $\{(s,t)\in[0,2\pi]\times[0,2\pi]\,|\,s\leqslant t\}$ by identifying the points $(s,0)$ with $(2\pi-s,0)$ for $0\leqslant s\leqslant\pi$, $(2\pi,t)$ with $(2\pi,2\pi-t)$ for $0\leqslant t\leqslant\pi$, and (0,0) with both $(0,2\pi)$ and $(2\pi,2\pi)$, and consider the space obtained from $\{(s,t)\in[0,2\pi]\times[0,2\pi]\,|\,s\geqslant t\}$ by identifying the points $(0,t)$ with $(0,2\pi-t)$ for $0\leqslant t\leqslant\pi$, $(s,2\pi)$ with $(2\pi-s,2\pi)$ for $0\leqslant s\leqslant\pi$, and (0,0) with both $(2\pi,0)$ and $(2\pi,2\pi)$. Then we attach the spaces along with the line $\{(s,s)\,|\,0\leqslant s\leqslant2\pi\}$ and obtain the attached space that is homeomorphic to S^2. Moreover, we need to identify the edges (circles) $\{(s,t)\,|\,0\leqslant s\leqslant\pi\}$ for $t=0,1$ and $\{(s,t)\,|\,0\leqslant t\leqslant\pi\}$ for $s=0,1$ in S^2 to make two circles $\mathbb{T}$. Thus, we need to replace S^2 with $S^2/\mathbb{T}\times\mathbb{T}$.

Since the subspaces $\{(s,0)\,|\,0\leqslant s\leqslant\pi\}$, $\{(s,t)\,|\,0\leqslant s\leqslant2\pi,t=s,t=2\pi-s\}$ for $s\in(0,\pi)$, and $\{(s,t)\,|\,0\leqslant s\leqslant2\pi,t=\pi\}$ are invariant under the action of $\mathbb{Z}$, we obtain the decomposition as in the claim. □

III. THE STABLE RANK

Notation and facts: For a unital C^*-algebra $\mathfrak{A}$, its stable rank $\mathrm{sr}(\mathfrak{A})$ is defined to be the smallest integer $n\geqslant1$ such that any element (a_j) of $\mathfrak{A}^n$ is approximated by elements (b_j) of $\mathfrak{A}^n$

such that $\Sigma_{j=1}^{n} b_j^* b_j$ are invertible in $\mathfrak{A}$. For a nonunital C^*-algebra $\mathfrak{A}$, its stable rank is defined to be that of the unitization $\mathfrak{A}^+$ by $\mathbb{C}$ (see Ref. 20). For x a real number, by $[x]$ we mean the maximum integer $\leqslant x$, and by $\{x\}$ we mean the least integer $\geqslant x$ in what follows. In particular, recall that

$$\mathrm{sr}(C_0(X)) = [\dim X^+/2] + 1, \quad \mathrm{sr}(M_n(\mathfrak{A})) = \{(\mathrm{sr}(\mathfrak{A}) - 1)/2\} + 1$$

for X a locally compact Hausdorff space, X^+ its one point compactification, and $C_0(X)$ the C^*-algebra of continuous functions on X vanishing at infinity, and $M_n(\mathfrak{A})$ the $n \times n$ matrix algebra over $\mathfrak{A}$ a C^*-algebra (see Ref. 20, Proposition 1.7 and Theorem 6.1). Note that $C_0(X)^+ \cong C(X^+)$. For a (unital) C^*-algebra $\mathfrak{A}$, its connected stable rank $\mathrm{csr}(\mathfrak{A})$ is defined to be the smallest integer $n \geqslant 1$ such that the set of all (b_j) of $\mathfrak{A}^n$ with $\Sigma_{j=1}^{n} b_j^* b_j$ invertible in $\mathfrak{A}$ is connected (see Ref. 20). Recall that

$$\max\{\mathrm{sr}(\mathfrak{I}), \mathrm{sr}(\mathfrak{A}/\mathfrak{I})\} \leqslant \mathrm{sr}(\mathfrak{A}) \leqslant \max\{\mathrm{sr}(\mathfrak{I}), \mathrm{sr}(\mathfrak{A}/\mathfrak{I}), \mathrm{csr}(\mathfrak{A}/\mathfrak{I})\}$$

for a short exact sequence: $0 \to \mathfrak{I} \to \mathfrak{A} \to \mathfrak{A}/\mathfrak{I} \to 0$ of C^*-algebras (Ref. 20, Theorems 4.3, 4.4, and 4.11). Also recall that

$$\mathrm{csr}(M_n(\mathfrak{A})) \leqslant \{(\mathrm{csr}(\mathfrak{A}) - 1)/n\} + 1, \quad \mathrm{csr}(C_0(X)) \leqslant [(\dim X^+ + 1)/2] + 1$$

for $\mathfrak{A}$ a C^*-algebra and X a locally compact Hausdorff space (Ref. 21, Theorem 4.7 and Ref. 15, Corollary 2.5). Moreover,

$$\mathrm{sr}(\Gamma(X, \{\mathfrak{A}_t\}_{t \in X})) \leqslant \sup_{t \in X} \mathrm{sr}(C([0,1]^k) \otimes \mathfrak{A}_t)$$

for $\Gamma(X, \{\mathfrak{A}_t\}_{t \in X})$ a continuous field C^*-algebra on a σ-compact, locally compact k-dimensional metric space X with fibers $\mathfrak{A}_t$ unital C^*-algebras by Ref. 14 (see also Ref. 13 for the case where $X = [0,1]$ the interval or $\mathbb{T}$ the torus) and see Ref. 8, Chap. 10 for continuous field C^*-algebras.

Lemma 3.1: The crossed product $C(\mathbb{T}^2) \rtimes \mathbb{Z}_2$ by the flip has a composition series such that

$$0 \to \mathfrak{I} \to C(\mathbb{T}^2) \rtimes \mathbb{Z}_2 \to \oplus^4 \mathbb{C}^2 \to 0,$$

$$0 \to C_0(\mathbb{R}^2) \otimes M_2(\mathbb{C}) \to \mathfrak{I} \to \oplus^4 C_0(\mathbb{R}) \otimes M_2(\mathbb{C}) \to 0.$$

Proof: Note that the flip on $\mathbb{T}^2$ is given by $(z, w) \mapsto (\bar{z}, \bar{w}) \in \mathbb{T}^2$. Since the four points $(\pm 1, \pm 1) \in \mathbb{T}^2$ are fixed under the flip, we have the following exact sequence:

$$0 \to C_0(\mathbb{T}^2 \setminus \{(\pm 1, \pm 1)\}) \rtimes \mathbb{Z}_2 \to C(\mathbb{T}^2) \rtimes \mathbb{Z}_2 \to \mathbb{C}^4 \rtimes \mathbb{Z}_2 \to 0$$

and $\mathbb{C}^4 \rtimes \mathbb{Z}_2 \cong \oplus^4 C^*(\mathbb{Z}_2) \cong \oplus^4 \mathbb{C}^2$, where $C_0(\mathbb{T}^2 \setminus \{(\pm 1, \pm 1)\})$ is the C^*-algebra of continuous functions on $\mathbb{T}^2 \setminus \{(\pm 1, \pm 1)\}$ vanishing at infinity. Since the subspaces $\{\pm 1\} \times (\mathbb{T} \setminus \{\pm 1\})$ and $(\mathbb{T} \setminus \{\pm 1\}) \times \{\pm 1\}$ are disjoint and closed in $\mathbb{T}^2 \setminus \{(\pm 1, \pm 1)\}$, we have

$$\begin{aligned} 0 \to C_0((\mathbb{T} \setminus \{\pm 1\}) \times (\mathbb{T} \setminus \{\pm 1\})) \rtimes \mathbb{Z}_2 \to C_0(\mathbb{T}^2 \setminus \{(\pm 1, \pm 1)\}) \rtimes \mathbb{Z}_2 \\ \to C_0(\{\pm 1\} \times (\mathbb{T} \setminus \{\pm 1\})) \rtimes \mathbb{Z}_2 \otimes C_0\left((\mathbb{T} \setminus \{\pm 1\}) \times \{\pm 1\})\right) \rtimes \mathbb{Z}_2 \to 0. \end{aligned}$$

In addition, we have

$$C_0(\{(\pm 1\} \times (\mathbb{T} \setminus \{\pm 1\})) \rtimes \mathbb{Z}_2 \cong \oplus^2 C_0(\mathbb{T} \setminus \{\pm 1\}) \rtimes \mathbb{Z}_2,$$

$$C_0((\mathbb{T} \setminus \{\pm 1\}) \times \{\pm 1\}) \rtimes \mathbb{Z}_2 \cong \oplus^2 (\mathbb{T} \setminus \{\pm 1\}) \rtimes \mathbb{Z}_2.$$

Moreover, we obtain

$$C_0(\mathbb{T} \setminus \{\pm 1\}) \rtimes \mathbb{Z}_2 \cong C_0((0, \pi)) \otimes \mathbb{C}^2 \rtimes \mathbb{Z}_2 \cong C_0(\mathbb{R}) \otimes M_2(\mathbb{C}),$$

$$C_0((\mathbb{T}\setminus\{\pm 1\})^2)\rtimes \mathbb{Z}_2 \cong C_0((0,\pi)^2)\otimes \mathbb{C}^2 \rtimes \mathbb{Z}_2 \cong C_0(\mathbb{R}^2)\otimes M_2(\mathbb{C})$$

since the flip on $\mathbb{T}\setminus\{\pm 1\}$ is the reflection on it. □

Remark: Compare this result with Eilers-Loring-Pedersen (Ref. 9, 4.3) using the different methodology.

Theorem 3.2: *The C^*-algebra $C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)$ of the discrete solvable group $H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2$ has stable rank* 2. *In the process we obtain*

$$\mathrm{sr}(C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)) = 2 = \mathrm{sr}(C(\mathbb{T}^2)\rtimes \mathbb{Z}_2)$$

and

$$\mathrm{sr}(C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)) = [\dim(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)_2^{\wedge}/2]+1 = \mathrm{sr}(C_0(\mathbb{R}^2)\otimes M_2(\mathbb{C})) = \{[2/2]/2\}+1 = \{1/2\}+1 = 2,$$

and

$$\mathrm{sr}(C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)) \neq [\dim(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)_1^{\wedge}/2]+1 = [0/2]+1 = 1,$$

where $(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)_1^{\wedge}$, $(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)_2^{\wedge}$ are the spaces of all 1,2*-dimensional irreducible representations of $H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2$, respectively.*

Proof: Using Theorem 2.1 and Ref. 13 we obtain

$$\mathrm{sr}(C^*(H_3^{\mathbb{Z}}\rtimes_{\beta^{(2)}}\mathbb{Z}_2)) = \mathrm{sr}(\Gamma(\mathbb{T},\{\mathfrak{A}_\theta\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})) \leqslant \sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta\rtimes\mathbb{Z}_2)).$$

Since $\mathfrak{A}_\theta\rtimes\mathbb{Z}_2$ for θ irrational are AF, the fibers $C(\mathbb{T},\mathfrak{A}_\theta\rtimes\mathbb{Z}_2)$ for θ irrational are AT algebras. Hence we have $\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta\rtimes\mathbb{Z}_2))=1$.

When $\theta=0$, using Lemma 3.1 we have

$$0\to C(\mathbb{T},\mathfrak{I})\to C(\mathbb{T},C(\mathbb{T}^2)\rtimes\mathbb{Z}_2)\to C(\mathbb{T},\oplus^4\mathbb{C}^2)\to 0,$$

$$0\to C_0(\mathbb{T}\times\mathbb{R}^2)\otimes M_2(\mathbb{C})\to C(\mathbb{T},\mathfrak{I})\to \oplus^4 C_0(\mathbb{T}\times\mathbb{R})\otimes M_2(\mathbb{C})\to 0,$$

and $C(\mathbb{T},\oplus^4\mathbb{C}^2)\cong\oplus^8 C(\mathbb{T})$. By Ref. 20, Proposition 1.7 and Theorem 6.1,

$$\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R}^2)\otimes M_2(\mathbb{C})) = \{(\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R}^2))-1)/2\}+1 = \{[3/2]/2\}+1 = 2,$$

$$\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R})\otimes M_2(\mathbb{C})) = \{(\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R}))-1)/2\}+1 = \{[2/2]/2\}+1 = 2.$$

By Ref. 21, Theorem 4.7 and Ref. 15, Corollary 2.5 we have

$$\mathrm{csr}(C_0(\mathbb{T}\times\mathbb{R})\otimes M_2(\mathbb{C})) \leqslant \{(\mathrm{csr}(C_0(\mathbb{T}\times\mathbb{R}))-1)/2\}+1 \leqslant \{[3/2]/2\}+1 = 2.$$

Therefore, using Ref. 20, Theorems 4.3, 4.4, and 4.11 we obtain $\mathrm{sr}(C(\mathbb{T},\mathfrak{I}))=2$. Since $\mathrm{sr}(C(\mathbb{T}))=1$ and $\mathrm{csr}(C(\mathbb{T}))=2$ (Ref. 24, p. 381), we obtain $\mathrm{sr}(C(\mathbb{T},C(\mathbb{T}^2)\rtimes\mathbb{Z}_2))=2$ by Ref. 20, Theorems 4.3, 4.4, and 4.11. Similarly, using Lemma 3.1 and the argument above for computing stable rank we also have $\mathrm{sr}(C(\mathbb{T}^2)\rtimes\mathbb{Z}_2)=2$.

For $\theta=p/q$ nonzero rationals for mutually prime positive integers p,q, it is shown by Ref. 5, Theorem 1.3 that

$$\mathfrak{A}_\theta\rtimes\mathbb{Z}_2 \cong \Gamma(S^2,\{M_{2q}(\mathbb{C})\}_{t\in S^2\setminus\cup_{j=0}^3\{p_j\}}\cup\{\mathfrak{M}_{p_j}\}_{0\leqslant j\leqslant 3}),$$

the continuous field C^*-algebra on the two-dimensional sphere S^2 with fibers $M_{2q}(\mathbb{C})$ for $t\in S^2\setminus\cup_{j=0}^3\{p_j\}$ and $\mathfrak{M}_{p_j}$ at certain points p_j of S^2 for $0\leqslant j\leqslant 3$, where $\mathfrak{M}_{p_j}$ are subalgebras of $M_{2q}(\mathbb{C})$ that are the sums of certain two matrix algebras over $\mathbb{C}$. Hence, by Ref. 13 we obtain

$$\begin{aligned}\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta \rtimes \mathbb{Z}_2)) &= \mathrm{sr}(\Gamma(\mathbb{T}\times S^2,\{M_{2q}(\mathbb{C})\}_{t\in S^2\setminus\cup_{j=0}^3\{p_j\}}\cup\{\mathfrak{M}_{p_j}\}_{0\leqslant j\leqslant 3}))\\ &\leqslant \max\{\mathrm{sr}(C(\mathbb{T}\times S^2,M_{2q}(\mathbb{C}))),\max_{0\leqslant j\leqslant 3}\{\mathrm{sr}(C(\mathbb{T}\times S^2,\mathfrak{M}_{p_j}))\}\}\\ &\leqslant \max\{\{[3/2]/2q\}+1,\max_{0\leqslant j\leqslant 3}\{\{3/2]/q_j\}+1\}\}\leqslant 2,\end{aligned}$$

where $\mathfrak{M}_{p_j}=M_{q_j}(\mathbb{C})\oplus M_{q_j'}(\mathbb{C})$ for $1\leqslant q_j\leqslant q_j'$.

Therefore, we obtain

$$2=\mathrm{sr}(C(\mathbb{T}^2)\rtimes\mathbb{Z}_2)\leqslant \mathrm{sr}(\Gamma(\mathbb{T},\{\mathfrak{A}_\theta\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}}))\leqslant \sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta\rtimes\mathbb{Z}_2))=2.$$

Furthermore, using Lemma 3.1 and from the discussions above we conclude that the dimension of the space $(H_3^{\mathbb{Z}}\rtimes_\gamma\mathbb{Z}_2)_2^\wedge$ is equal to the dimension of $\mathbb{R}^2$, and the dimension of the space $(H_3^{\mathbb{Z}}\rtimes_\gamma\mathbb{Z}_2)_1^\wedge$ is equal to zero since it corresponds to $\oplus^4\mathbb{C}^2$. □

Lemma 3.3: The crossed product $C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2$ by the flip has a composition series $\{\mathfrak{J}_j\}_{j=0}^{2n+1}$ such that $\mathfrak{J}_0=\{0\}$, $\mathfrak{J}_{2n+1}=C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2$ and

$$0\to\mathfrak{J}_{2n}\to C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2\to\oplus^{2^{2n}}\mathbb{C}^2\to 0,$$

$$\mathfrak{J}_{2n-k+1}/\mathfrak{J}_{2n-k}\cong\oplus^{\binom{2n}{k}}\oplus^2 C_0(\mathbb{R}^k)\otimes M_2(\mathbb{C})\quad(1\leqslant k\leqslant 2n).$$

Proof: Note that the flip on $\mathbb{T}^{2n}$ is given by $(z_j,w_j)_{j=1}^n\mapsto(\bar z_j,\bar w_j)_{j=1}^n\in\mathbb{T}^{2n}=\Pi^n\mathbb{T}^2$. Since the 2^{2n} points $(\pm1,\pm1)_{j=1}^n\in\mathbb{T}^{2n}$ are fixed under the flip, we have the following exact sequence:

$$0\to C_0(\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\})\rtimes\mathbb{Z}_2\to C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2\to\mathbb{C}^{2^{2n}}\rtimes\mathbb{Z}_2\to 0$$

and $\mathbb{C}^{2^{2n}}\rtimes\mathbb{Z}_2\cong\oplus^{2^{2n}}C^*(\mathbb{Z}_2)\cong\oplus^{2^{2n}}\mathbb{C}^2$, where $C_0(\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\})$ is the C^*-algebra of continuous functions on $\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\}$ vanishing at infinity. Since the $2n$ subspaces

$$((\mathbb{T}\setminus\{\pm1\})\times\{\pm1\})\times(\pm1,\pm1)\times\cdots\times(\pm1,\pm1),$$

$$(\{\pm1\}\times(\mathbb{T}\setminus\{\pm1\}))\times(\pm1,\pm1)\times\cdots\times(\pm1,\pm1),$$

$$(\pm1,\pm1)\times((\mathbb{T}\setminus\{\pm1\})\times\{\pm1\})\times(\pm1,\pm1)\times\cdots\times(\pm1,\pm1),\cdots,$$

$$(\pm1,\pm1)\times\cdots\times(\pm1,\pm1)\times(\{\pm1\}\times(\mathbb{T}\setminus\{\pm1\}))\subset\Pi^n\mathbb{T}^2$$

are disjoint and closed in $\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\}$, we have

$$0\to C_0(X_{2n-1})\rtimes\mathbb{Z}_2\to C_0(\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\})\rtimes\mathbb{Z}_2\to\oplus^{2n}\oplus^2 C_0(\mathbb{T}\setminus\{\pm1\})\rtimes\mathbb{Z}_2\to 0,$$

where X_{2n-1} is the complement of the union of the $4n$ closed subspaces homeomorphic to $\mathbb{T}\setminus\{\pm1\}$ in $\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\}$. Inductively, we have the following exact sequences for $1\leqslant k\leqslant 2n-1$:

$$0\to C_0(X_{2n-k})\rtimes\mathbb{Z}_2\to C_0(X_{2n-k+1})\rtimes\mathbb{Z}_2\to\oplus^{\binom{2n}{k}}\oplus^2 C_0((\mathbb{T}\setminus\{\pm1\})^k)\rtimes\mathbb{Z}_0\to 0,$$

where the combination $\binom{2n}{k}$ corresponds to choosing k copies of the subspace $\mathbb{T}\setminus\{\pm1\}$ of $\mathbb{T}$ in $\mathbb{T}^{2n}$, and $X_{2n}=\mathbb{T}^{2n}\setminus\{(\pm1,\pm1)_{j=1}^n\}$ and $X_1=(\mathbb{T}\setminus\{\pm1\})^{2n}$. Moreover, we obtain

$$C_0((\mathbb{T}\setminus\{\pm1\})^k)\rtimes\mathbb{Z}_2\cong C_0((0,\pi)^k)\otimes\mathbb{C}^2\rtimes\mathbb{Z}_2\cong C_0(\mathbb{R}^k)\otimes M_2(\mathbb{C})$$

since the flip on $(\mathbb{T}\setminus\{\pm1\})^k$ is the reflection on it. □

Theorem 3.4: *The C^*-algebra $C^*(H_{2n+1}^{\mathbb{Z}}\rtimes_\gamma\mathbb{Z}_2)$ of the discrete solvable group $H_{2n+1}^{\mathbb{Z}}\rtimes_\gamma\mathbb{Z}_2$ has stable rank $\{n/2\}+1$. In the process we obtain*

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2))=\{n/2\}+1=\mathrm{sr}(C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)$$

and

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2))=[\dim(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2)^\wedge_2/2]+1=\mathrm{sr}(C_0(\mathbb{R}^{2n})\otimes M_2(\mathbb{C}))=\{[2n/2]/2\}+1=\{n/2\}+1,$$

and

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2))\neq[\dim(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_1)^\wedge_1/2]+1=[0/2]+1=0,$$

where $(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2)^\wedge_1$, $(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2)^\wedge_2$ *are the spaces of all* 1,2*-dimensional irreducible representations of* $H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2$, *respectively*.

Proof: Using Theorem 2.2 and Ref. 13 we obtain

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2))=\mathrm{sr}(\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})\leqslant\sup_{\theta\in T}\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2)).$$

Since $(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2$ for θ irrational are AF, the fibers $C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2)$ for θ irrational are AT algebras. Hence we have $\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2))=1$.

When $\theta=0$, by using Lemma 3.3, $C(\mathbb{T},C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)$ has a composition series $\{\mathfrak{K}_j\}_{j=0}^{2n+1}$ such that $\mathfrak{K}_0=\{0\}$, $\mathfrak{K}_{2n+1}=C(\mathbb{T},C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)$ and

$$0\to\mathfrak{K}_{2n}\to C(\mathbb{T},C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)\to\oplus^{2^{2n}}\oplus^2C(\mathbb{T})\to 0,$$

$$\mathfrak{K}_{2n-k+1}/\mathfrak{K}_{2n-k}\cong\oplus^{\binom{2n}{k}}\oplus^2C_0(\mathbb{T}\times\mathbb{R}^k)\otimes M_2(\mathbb{C})$$

for $1\leqslant k\leqslant 2n$. By Ref. 20, Proposition 1.7 and Theorem 6.1,

$$\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R}^k)\otimes M_2(\mathbb{C}))=\{(\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R}^k))-1)/2\}+1=\{[(k+1)/2]/2\}+1.$$

In particular, if $k=2n$, then $\mathrm{sr}(C_0(\mathbb{T}\times\mathbb{R}^{2n})\otimes M_2(\mathbb{C}))=\{n/2\}+1$. By Ref. 21, Theorem 4.7 and Ref. 15, Corollary 2.5 we have

$$\mathrm{csr}(C_0(\mathbb{T}\times\mathbb{R}^k)\otimes M_2(\mathbb{C}))\leqslant\{(\mathrm{csr}(C_0(\mathbb{T}\times\mathbb{R}^k))-1)/2\}+1\leqslant\{[(2+k)/2]/2\}+1.$$

In particular, if $k=2n-1$, then $\mathrm{csr}(C_0(\mathbb{T}\times\mathbb{R}^{2n-1})\otimes M_2(\mathbb{C}))\leqslant\{n/2\}+1$. Therefore, inductively using Ref. 20, Theorems 4.3, 4.4, and 4.11 to the finite composition series of $C(\mathbb{T},C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)$ we obtain

$$\mathrm{sr}(C(\mathbb{T},C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2))=\{n/2\}+1.$$

Similarly, using Lemma 3.3 and the argument above for computing the stable rank we also have $\mathrm{sr}(C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)=\{n/2\}+1$.

For $\theta=p/q$ nonzero rationals for mutually prime positive integers p,q, it follows from Ref. 5, Theorem 1.3 that

$$\otimes^n(\mathfrak{A}_\theta\rtimes\mathbb{Z}_2)\cong\otimes^n\Gamma(S^2,\{M_{2q}(\mathbb{C})\}_{t\in S^2\setminus\cup_{j=0}^3\{p_j\}}\cup\{\mathfrak{M}_{p_j}\}_{0\leqslant j\leqslant 3}),$$

which is viewed as the continuous field C^*-algebra on the product space Π^nS^2 with fibers $\otimes^2M_{2q}(\mathbb{C})\cong M_{2^nq^n}(\mathbb{C})$ for $t\in\Pi^n(S^2\setminus\cup_{j=0}^3\{p_j\})$ and n-fold tensor products of some copies of $M_{2q}(\mathbb{C})$ and $\mathfrak{M}_{p_j}$ for other points of Π^nS^2. Since $(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2$ is a canonical subalgebra of $\otimes^n(\mathfrak{A}_\theta\rtimes\mathbb{Z}_2)$, it can also be viewed as the continuous field on Π^nS^2 with fibers $M_{2q^n}(\mathbb{C})$ for $t\in\Pi^n(S^2\setminus\cup_{j=0}^3\{p_j\})$ and n-fold tensor products of some copies of $M_q(\mathbb{C})$ and $\mathfrak{M}_{p_j}$ and one copy of $M_{2q}(\mathbb{C})$ for other points of Π^nS^2. Let $\mathfrak{B}_t$ for $t\in\Pi^nS^2$ be those fibers and let $M_{l_t}=\mathfrak{B}_t$ or M_{l_t} be the direct factor of $\mathfrak{B}_t$ with the size l_t smallest among direct factors of $\mathfrak{B}_t$. By Ref. 13 we obtain

$$\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2))=\mathrm{sr}(\Gamma(\Pi^nS^2,\{C(\mathbb{T},\mathfrak{B}_t)\}_{t\in\Pi^nS^2})$$
$$\leqslant\sup_{t\in\Pi^nS^2}\mathrm{sr}(C(\mathbb{T}\times\Pi^nS^2,M_{l_t}(\mathbb{C})))=\sup_{t\in\Pi^nS^2}\{[(1+2n)/2]/l_t\}+1\leqslant\{n/2\}+1.$$

Therefore, we obtain

$$\{n/2\}+1=\mathrm{sr}(C(\mathbb{T}^{2n})\rtimes\mathbb{Z}_2)\leqslant\mathrm{sr}(\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2\}_{\theta\in\mathbb{T}})$$
$$\leqslant\sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)\rtimes\mathbb{Z}_2))=\{n/2\}+1.$$

Furthermore, using Lemma 3.3 and from the discussions above we conclude that the dimension of the space $(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2)^\wedge_2$ is equal to the dimension of $\mathbb{R}^{2n}$, and the dimension of the space $(H^{\mathbb{Z}}_{2n+1}\rtimes_\gamma\mathbb{Z}_2)^\wedge_1$ is equal to zero since it corresponds to $\oplus^{2^{2n}}\mathbb{C}^2$. □

Remark: Reference 14 shows that for Γ a finitely generated, torsion free, two-step nilpotent (discrete) group and $C^*(\Gamma)$ its group C^*-algebra,

$$\mathrm{sr}(C^*(\Gamma))=\mathrm{sr}(C(\Gamma^\wedge_1))=[\dim\Gamma^\wedge_1/2]+1,$$

where $\Gamma^\wedge_1$ is the space of one-dimensional representations of Γ. See also the same equality for Γ a nilpotent Lie group[33] (for the simply connected case) and Ref. 26 (for the connected case). Furthermore, by Ref. 34, for G a simply connected solvable Lie group,

$$\mathrm{sr}(C^*(G))=\min\{\dim G,\max\{2,\mathrm{sr}(C_0(G^\wedge_1))\}\}.$$

Our theorem above says that this formula for a discrete solvable group Γ is not valid even if replacing $\dim G$ with the rank of Γ.

Theorem 3.5: *The fixed point algebra $C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}}$ associated with the crossed product $C^*(H^{\mathbb{Z}}_3)\rtimes_{\beta^{(2)}}\mathbb{Z}_2$ has stable rank* 2. *In the process we obtain*

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}})=2=\mathrm{sr}(C(\mathbb{T}^2)^{\beta^{(2)}})$$

and

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}})=\mathrm{sr}(C((C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}})^\wedge_1))=\mathrm{sr}(C(S^2))=[\dim S^2/2]+1=2,$$

where $(C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}})^\wedge_1$ means the space of all one-dimensional representations of $C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}}$.

Proof: By Theorem 2.5 we have $C^*(H^{\mathbb{Z}}_3)^{\beta^{(2)}}\cong\Gamma(\mathbb{T},\{\mathfrak{A}_\theta^{\beta^{(2)}}\}_{\theta\in\mathbb{T}})$, where $\mathfrak{A}_\theta^{\beta^{(2)}}$ are the fixed point algebras of the rotation algebras $\mathfrak{A}_\theta$ for $\theta\in\mathbb{R}(\mathrm{mod}\,1)$. By Ref. 13 we obtain

$$\mathrm{sr}(\Gamma(\mathbb{T},\{\mathfrak{A}_\theta^{\beta^{(2)}}\}_{\theta\in\mathbb{T}}))\leqslant\sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta^{\beta^{(2)}})).$$

If θ is irrational, then $\mathfrak{A}_\theta^{\beta^{(2)}}$ is an AF algebra. Hence $C(\mathbb{T},\mathfrak{A}_\theta^{\beta^{(2)}})$ is an AT algebra. Therefore, we have $\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta^{\beta^{(2)}}))=1$.

If $\theta=0$, then $\mathfrak{A}_0^{\beta^{(2)}}=C(S^2)$ (Ref. 5, a remark after Theorem 1.2). Since $C(\mathbb{T},C(S^2))\cong C(\mathbb{T}\times S^2)$, we have $\mathrm{sr}(C(\mathbb{T},C(S^2)))=[3/2]+1=2$.

For $\theta=p/q$ nonzero rationals for mutually prime positive integers p,q, it is shown by Ref. 5, Theorem 1.2 that

$$\mathfrak{A}_\theta^{\beta^{(2)}}\cong\Gamma(S^2,\{M_q(\mathbb{C})\}_{t\in S^2\setminus\cup_{j=0}^3\{p_j\}}\cup\{\mathfrak{M}_{p_j}\}_{0\leqslant j\leqslant 3}),$$

the continuous field C^*-algebra on S^2 with fibers $M_q(\mathbb{C})$ for $t\in S^2\setminus\cup_{j=0}^3\{p_j\}$ and $\mathfrak{M}_{p_j}$ at certain points p_j of S^2 for $0\leqslant j\leqslant 3$, where $\mathfrak{M}_{p_j}$ are subalgebras of $M_q(\mathbb{C})$ that are the sums of certain two matrix algebras over $\mathbb{C}$. Hence, by Ref. 13 we obtain

$$\begin{aligned}\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta^{\beta^{(2)}})) &= \mathrm{sr}(\Gamma(\mathbb{T}\times S^2,\{M_q(\mathbb{C})\}_{t\in S^2\setminus\cup_{j=0}^3\{p_j\}}\cup\{\mathfrak{M}_{p_j}\}_{0\leqslant j\leqslant 3}))\\ &\leqslant \max\{\mathrm{sr}(C(\mathbb{T}\times S^2,M_q(\mathbb{C}))),\max_{0\leqslant j\leqslant 3}\{\mathrm{sr}(C(\mathbb{T}\times S^2,\mathfrak{M}_{p_j}))\}\}\\ &\leqslant \max\{\{[3/2]/q\}+1,\max_{0\leqslant j\leqslant 3}\{\{[3/2]/q_j\}+1\}\}\leqslant 2,\end{aligned}$$

where $\mathfrak{M}_{p_j}=M_{q_j}(\mathbb{C})\oplus M_{q_j'}(\mathbb{C})$ with $1\leqslant q_j\leqslant q_j'$.

Therefore, we obtain

$$2=\mathrm{sr}(C(\mathbb{T}^2)^{\beta^{(2)}})\leqslant \mathrm{sr}(\Gamma(\mathbb{T},\{\mathfrak{A}_\theta^{\beta^{(2)}}\}_{\theta\in\mathbb{T}}))\leqslant \sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},\mathfrak{A}_\theta^{\beta^{(2)}}))=2.$$

□

Theorem 3.6: *The fixed point algebra $C^*(H_{2n+1}^{\mathbb{Z}})^\gamma$ associated with the crossed product $C^*(H_{2n+1}^{\mathbb{Z}})\rtimes_\gamma\mathbb{Z}_2$ has stable rank $n+1$. In the process we obtain*

$$\mathrm{sr}(C^*(H_{2n+1}^{\mathbb{Z}})^\gamma)=n+1=\mathrm{sr}(C(\Pi^n\mathbb{T}^2)^\gamma)$$

and

$$\mathrm{sr}(C^*(H_{2n+1}^{\mathbb{Z}})^\gamma)=\mathrm{sr}(C((C^*(H_{2n+1}^{\mathbb{Z}})^\gamma)_1^\wedge))=\mathrm{sr}(C(\Pi^nS^2))=[2n/2]+1=n+1,$$

where $(C^*(H_{2n+1}^{\mathbb{Z}})^\gamma)_1^\wedge$ means the space of all one-dimensional representations of $C^*(H_{2n+1}^{\mathbb{Z}})^\gamma$.

Proof: By Theorem 2.6 we have

$$C^*(H_{2n+1}^{\mathbb{Z}})^\gamma\cong\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)^\gamma\}_{\theta\in\mathbb{T}}),$$

where $(\otimes^n\mathfrak{A}_\theta)^\gamma$ are the fixed point algebras of the noncommutative tori $(\otimes^n\mathfrak{A}_\theta)$ for $\theta\in\mathbb{R}(\mathrm{mod}\,1)$. By Ref. 13 we obtain

$$\mathrm{sr}(\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)^\gamma\}_{\theta\in\mathbb{T}}))\leqslant\sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)^\gamma)).$$

If θ is irrational, then $(\otimes^n\mathfrak{A}_\theta)^\gamma$ is an AF algebra. Hence $C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)^\gamma)$ is an AT algebra. Therefore, we have $\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)^\gamma))=1$.

If $\theta=0$, then $(\otimes^n\mathfrak{A}_0)^\gamma=C(\Pi^nS^2)$. Since $C(\mathbb{T},C(\Pi^nS^2))\cong C(\mathbb{T}\times\Pi^nS^2)$, we have $\mathrm{sr}(C(\mathbb{T},C(\Pi^nS^2)))=[(2n+1)/2]+1=n+1$.

For $\theta=p/q$ nonzero rationals for mutually prime positive integers p,q, it follows from Ref. 5, Theorem 1.2 that

$$(\otimes^n\mathfrak{A}_\theta)^\gamma\cong\otimes^n\Gamma(S^2,\{M_q(\mathbb{C})\}_{t\in S^2\setminus\cup_{j=0}^3\{p_j\}}\cup\{\mathfrak{M}_{p_j}\}_{0\leqslant j\leqslant 3}),$$

which is viewed as the continuous field C^*-algebra on Π^nS^2 with fibers $\otimes^nM_q(\mathbb{C})\cong M_{q^n}(\mathbb{C})$ for $t\in\Pi^n(S^2\setminus\cup_{j=0}^3\{p_j\})$ and n-fold tensor products of some copies of $M_q(\mathbb{C})$ and $\mathfrak{M}_{p_j}(0\leqslant j\leqslant 3)$ at other points of Π^nS^2, where $\mathfrak{M}_{p_j}$ are subalgebras of $M_q(\mathbb{C})$ that are the sums of certain two matrix algebras over $\mathbb{C}$. Let $\mathfrak{B}_t$ for $t\in\Pi^nS^2$ be those fibers and let $M_{l_t}(\mathbb{C})=M_{q^n}(\mathbb{C})$ or $M_{l_t}(\mathbb{C})$ be the direct factor with the size l_t smallest among direct factors of $\mathfrak{B}_t$. Hence, by Ref. 13 we obtain

$$\begin{aligned}\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)^\gamma)) &= \mathrm{sr}(\Gamma(\mathbb{T}\times\Pi^nS^2,\{\mathfrak{B}_t\}_{t\in\Pi^nS^2}))\\ &\leqslant \sup_{t\in\Pi^nS^2}\mathrm{sr}(C(\mathbb{T}\times\Pi^nS^2,M_{l_t}(\mathbb{C})))\leqslant\{[(2n+1)/2]/l_t\}+1\leqslant\{n/2\}+1.\end{aligned}$$

Therefore, we obtain

$$n+1=\mathrm{sr}(C(\Pi^n\mathbb{T}^2)^\gamma)\leqslant\mathrm{sr}(\Gamma(\mathbb{T},\{(\otimes^n\mathfrak{A}_\theta)^\gamma\}_{\theta\in\mathbb{T}}))\leqslant\sup_{\theta\in\mathbb{T}}\mathrm{sr}(C(\mathbb{T},(\otimes^n\mathfrak{A}_\theta)^\gamma))=n+1.$$

□

Corollary 3.7: We obtain

$$\mathrm{sr}(C^*(H^{\mathbb{Z}}_{2n+1})\rtimes_\gamma \mathbb{Z}_2) = \{n/2\} + 1 \leqslant n + 1 = \mathrm{sr}(C^*(H^{\mathbb{Z}}_{2n+1})^\gamma)$$

for $n \geqslant 1$, *where* $\gamma = \beta^{(2)}$ *when* $n = 1$.

Theorem 3.8: *The crossed products* $C^*(H^{\mathbb{Z}}_3)\rtimes_{\beta(j)}\mathbb{Z}_2$ $(j=1,3)$ *have stable rank* 2. *Furthermore, we obtain* $\mathrm{sr}(C^*(H^{\mathbb{Z}}_3)^{\beta^{(j)}}) = 2$.

Proof: By Theorem 2.7, we may view $C^*(H^{\mathbb{Z}}_3)\rtimes_{\beta(j)}\mathbb{Z}_2$ as the continuous field C^*-algebra on $[0,\pi]$ with fibers simple AF algebras $(\mathfrak{A}_z \oplus \mathfrak{A}_{\bar{z}})\rtimes\mathbb{Z}_2$ for $z \in (0,\pi)$, $C^*(\mathbb{Z}_2)\otimes(C(\mathbb{T})\rtimes\mathbb{Z})$ at 0, and $C^*(\mathbb{Z}_2)\otimes(C(\mathbb{T})\rtimes_{-1}\mathbb{Z})$ at π. Using Lemma 3.1 and the methods of Theorem 3.2 similarly, one can obtain the conclusion. Using Theorem 2.8 we obtain the claim for the fixed point algebras $C^*(H^{\mathbb{Z}}_3)^{\beta^{(j)}}$ $(j=1,3)$. □

IV. APPLICATIONS TO LIE GROUP C^*-ALGEBRAS

Using the methods of Sec. I one can construct symmetries on the C^*-algebras of Lie groups such as the Mautner group M_5 (a real five-dimensional solvable Lie group $\mathbb{C}^2\rtimes_\alpha\mathbb{R}$ with α the action defined by $\alpha_t(z,u) = (e^{2\pi i t}z, e^{2\pi i\theta t}w)$ for $z, w \in \mathbb{C}$ and θ an irrational) and the Dixmier group D_7 (a real seven-dimensional solvable Lie group $\mathbb{C}^2\rtimes_\alpha H^{\mathbb{R}}_3$ a semidirect product by the real three-dimensional Heisenberg Lie group with α the action defined by $\alpha_g(z,w) = (e^{ia}z, e^{ib}w)$ for z, $w \in \mathbb{C}$ and $g = (c,b,a) \in H^{\mathbb{R}}_3$) (cf. Refs. 27 and 32). Indeed, the symmetries on $C^*(M_5)$ and $C^*(D_7)$ are induced from the flip on $\mathbb{C}^2$ in $\mathbb{C}^2\rtimes_\alpha\mathbb{R}$ and $\mathbb{C}^2\rtimes H^{\mathbb{R}}_3$, respectively. Moreover, the structure of $C^*(M_5)$ as a continuous field C^*-algebra is given by

$$C^*(M_5) \cong \Gamma_0([0,\infty)^2, \{C(\mathbb{T}^2)\rtimes_\theta\mathbb{R}\}_{t\in(0,\infty)^2} \cup \{C(\mathbb{T})\rtimes\mathbb{R}\}_{t\in(\{0\}\times(0,\infty))\cup((0,\infty)\times\{0\})} \cup \{C^*(\mathbb{R})\}_{t=(0,0)}),$$

where $C(\mathbb{T}^2)\rtimes_\theta\mathbb{R} \cong \mathbb{K}\otimes\mathfrak{A}_\theta$ with $\mathfrak{A}_\theta$ the irrational rotation algebra with θ and $\mathbb{K}$ the C^*-algebra of compact operators, and $C(\mathbb{T})\rtimes\mathbb{R} \cong \mathbb{K}\otimes C(\mathbb{T})$ (cf. Ref. 27). On the other hand, the structure of $C^*(D_7)$ as a continuous field C^*-algebra is given by

$$C^*(D_7) \cong \Gamma_0([0,\infty)^2, \{C(\mathbb{T}^2)\rtimes H^{\mathbb{R}}_3\}_{t\in(0,\infty)^2} \cup \{C(\mathbb{T})\rtimes H^{\mathbb{R}}_3\}_{t\in(\{0\}\times(0,\infty))\cup((0,\infty)\times\{0\})} \cup \{C^*(H^{\mathbb{R}}_3)\}_{t=(0,0)}),$$

where the fibers are decomposed into the following (cf. Ref. 32):

$$C(\mathbb{T}^2)\rtimes H^{\mathbb{R}}_3 \cong \Gamma_0(\mathbb{R}, \{\mathfrak{A}_\theta\otimes\mathbb{K}\}_{\theta\in\mathbb{R}}),$$

$$C(\mathbb{T})\rtimes H^{\mathbb{R}}_3 \cong \Gamma_0(\mathbb{R}, \{C(\mathbb{T})\otimes\mathbb{K}\}_{\theta\in\mathbb{R}\setminus\{0\}} \cup \{C_0(\mathbb{R}\times\mathbb{T})\otimes\mathbb{K}\}_{\theta=0}),$$

$$C^*(H^{\mathbb{R}}_3) \cong \Gamma_0(\mathbb{R}, \{\mathbb{K}\}_{\theta\in\mathbb{R}\setminus\{0\}} \cup \{C_0(\mathbb{R}^2)\}_{\theta=0}).$$

Note that the centers of the left-hand sides are given by the center of $C^*(H^{\mathbb{R}}_3)$ that is isomorphic to $C^*(\mathbb{R}) \cong C_0(\mathbb{R})$.

From the above and further analysis we have the following.

Theorem 4.1: *There exist symmetries on the group* C^**-algebras* $C^*(M_5)$ *and* $C^*(D_7)$ *of* $M_5 = \mathbb{C}^2\rtimes\mathbb{R}$ *and* $D_7 = \mathbb{C}^2\rtimes H^{\mathbb{R}}_3$ *induced from the flip on* $\mathbb{C}^2$. *Moreover, the structures of* $C^*(M_5)\rtimes\mathbb{Z}_2$ *and* $C^*(D_7)\rtimes\mathbb{Z}_2$ *by the symmetries are given by*

$$C^*(M_5)\rtimes\mathbb{Z}_2 \cong \Gamma_0([0,\infty)^2, \{\mathbb{K}\otimes\mathfrak{A}_\theta\rtimes\mathbb{Z}_2\}_{t\in(0,\infty)^2} \cup \{\mathbb{K}\otimes C(\mathbb{T})\rtimes\mathbb{Z}_2\}_{t\in(\{0\}\times(0,\infty))\cup((0,\infty)\times\{0\})} \cup \{C^*(\mathbb{R}\times\mathbb{Z}_2)\}_{t=(0,0)})$$

and

$$C^*(D_7)\rtimes\mathbb{Z}_2 \cong \Gamma_0([0,\infty)^2, \{C(\mathbb{T}^2)\rtimes H^{\mathbb{R}}_3\rtimes\mathbb{Z}_2\}_{t\in(0,\infty)^2} \cup \{C(\mathbb{T})\rtimes H^{\mathbb{R}}_3\rtimes\mathbb{Z}_2\}_{t\in(\{0\}\times(0,\infty))\cup((0,\infty)\times\{0\})} \cup \{C^*(H^{\mathbb{R}}_3\times\mathbb{Z}_2)\}_{t=(0,0)}),$$

where the fibers are decomposed into the following:

$$C(\mathbb{T}^2) \rtimes H_3^{\mathbb{R}} \rtimes \mathbb{Z}_2 \cong \Gamma_0(\mathbb{R}, \{\mathfrak{A}_\theta \otimes \mathbb{K} \rtimes \mathbb{Z}_2\}_{\theta \in \mathbb{R}\setminus\{0\}} \cup \{\mathbb{K} \otimes C(\mathbb{T}^2) \rtimes \mathbb{Z}_2\}_{\theta=0}),$$

$$C(\mathbb{T}) \rtimes H_3^{\mathbb{R}} \rtimes \mathbb{Z}_2 \cong \Gamma_0(\mathbb{R}, \{C(\mathbb{T}) \otimes \mathbb{K} \rtimes \mathbb{Z}_2\}_{\theta \in \mathbb{R}\setminus\{0\}} \cup \{C_0(\mathbb{R} \times \mathbb{T}) \otimes \mathbb{K} \rtimes \mathbb{Z}_2\}_{\theta=0}).$$

Remark: Note that the fibers $\mathbb{K} \otimes \mathfrak{A}_\theta \rtimes \mathbb{Z}_2$ for θ irrational involved in the decompositions above are simple AF algebras.

Corollary 4.2: The group C^*-algebras of disconnected solvable Lie groups may have certain AF algebras as simple quotients.

Proof: For instance, we take $M_5 \rtimes \mathbb{Z}_2$ or $D_7 \rtimes \mathbb{Z}_2$ considered above as a disconnected solvable Lie group. □

Corollary 4.3: The group C^*-algebras of disconnected solvable Lie groups may have certain AT algebras as simple quotients.

Proof: For instance, for the generalized Dixmier group D_{6n+1} considered in Ref. 32 we define a disconnected solvable Lie group $D_{6n+1} \rtimes \mathbb{Z}_2$ similarly and extensively. See Ref. 32 for the structure of $C^*(D_{6n+1})$. Using this we obtain the similar result as Theorem 4.1. In particular, $C^*(D_{6n+1} \rtimes \mathbb{Z}_2)$ has a simple AH algebra $(\otimes \mathfrak{A}_\theta) \otimes \mathbb{K} \rtimes \mathbb{Z}_2$ as a quotient, and this AH algebra is in fact an AT algebra by the same reason as given in the proof of Corollary 2.4. □

Theorem 4.4: *The crossed product $C^*(M_5) \rtimes \mathbb{Z}_2$ has stable rank* 2, *and for the crossed product $C^*(D_7) \rtimes \mathbb{Z}_2$, we have $2 \leqslant \mathrm{sr}(C^*(D_7) \rtimes \mathbb{Z}_2) \leqslant 3$. Furthermore, we obtain*

$$\mathrm{sr}(C^*(M_5) \rtimes \mathbb{Z}_2) = 2 = \mathrm{sr}(\mathbb{K} \otimes C([1,2]^2) \otimes M_2(\mathbb{C})),$$

where $\mathbb{K} \otimes C([1,2]^2) \otimes M_2(\mathbb{C})$ is a certain quotient of $C^*(M_5) \rtimes \mathbb{Z}_2$, and

$$\mathrm{sr}(C^*(M_5) \rtimes \mathbb{Z}_2) \neq [\dim(C^*(M_5) \rtimes \mathbb{Z}_2)_1^\wedge/2] + 1 = [1/2] + 1 = 1,$$

while $(C^*(D_7) \rtimes \mathbb{Z}_2)_1^\wedge$ is $\mathbb{R}^2$, where $(C^*(M_5) \rtimes \mathbb{Z}_2)_1^\wedge$, $(C^*(D_7) \rtimes \mathbb{Z}_2)_1^\wedge$ are the spaces of all one-dimensional representations of $C^*(M_5) \rtimes \mathbb{Z}_2$, $C^*(D_7) \rtimes \mathbb{Z}_2$, respectively.

Proof: We use the structures of $C^*(M_5) \rtimes \mathbb{Z}_2$ and $C^*(D_7) \rtimes \mathbb{Z}_2$ in Theorem 4.1. By Ref. 13 and Ref. 20, Proposition 1.7 and Theorems 3.6 and 6.4, we obtain

$$\begin{aligned}\mathrm{sr}(C^*(M_5) \rtimes \mathbb{Z}_2) \leqslant \max\{&\mathrm{sr}(C_0([0,\infty)^2) \otimes \mathbb{K} \otimes \mathfrak{A}_\theta \rtimes \mathbb{Z}_2),\\ &\mathrm{sr}(C_0([0,\infty)^2) \otimes \mathbb{K} \otimes C(\mathbb{T}) \rtimes \mathbb{Z}_2),\\ &\mathrm{sr}(C_0([0,\infty)^2) \otimes C_0(\mathbb{K} \times \mathbb{Z}_2))\} = \max\{2,2,2\} = 2\end{aligned}$$

and

$$\begin{aligned}\mathrm{sr}(C^*(D_7) \rtimes \mathbb{Z}_2) \leqslant \max\{&\mathrm{sr}(C_0([0,\infty)^2) \otimes C(\mathbb{T}^2) \rtimes H_3^{\mathbb{R}} \rtimes \mathbb{Z}_2),\\ &\mathrm{sr}(C_0([0,\infty)^2) \otimes C(\mathbb{T}) \rtimes H_3^{\mathbb{R}} \rtimes \mathbb{Z}_2),\\ &\mathrm{sr}(C_0([0,\infty)^2) \otimes C^*(H_3^{\mathbb{R}} \times \mathbb{Z}_2))\}.\end{aligned}$$

Furthermore, we obtain

$$\mathrm{sr}(C_0([0,\infty)^2) \otimes C(\mathbb{T}^2) \rtimes H_3^{\mathbb{R}} \rtimes \mathbb{Z}_2) \leqslant \sup_{\theta \in \mathbb{R}} \mathrm{sr}(C_0(\mathbb{R} \times [0,\infty)^2) \otimes \mathbb{K} \otimes \mathfrak{A}_\theta \rtimes \mathbb{Z}_2) = 2,$$

$$\mathrm{sr}(C_0([0,\infty)^2) \otimes C(\mathbb{T}) \rtimes H_3^{\mathbb{R}} \rtimes \mathbb{Z}_2) \leqslant \sup_{\theta \in \mathbb{R}} \mathrm{sr}(C_0(\mathbb{R} \times [0,\infty)^2) \otimes \mathbb{K} \otimes C(\mathbb{T}) \rtimes \mathbb{Z}_2) = 2,$$

$$\mathrm{sr}(C_0([0,\infty)^2)\otimes C^*(H_3^{\mathbb{R}}\times\mathbb{Z}_2)) \leqslant \max\{\mathrm{sr}(C_0(\mathbb{R}\times[0,\infty)^2)\otimes\mathbb{K}\otimes C(\mathbb{Z}_2)),\ \mathrm{sr}(C_0(\mathbb{R}\times[0,\infty)^2)\otimes C_0(\mathbb{R}^2\times\mathbb{Z}_2))\} = \max\{2,3\} = 3.$$

On the other hand, we have

$$\mathrm{sr}(C^*(M_5)\rtimes\mathbb{Z}_2) \geqslant \mathrm{sr}(\mathbb{K}\otimes C([1,2]^2)\otimes M_2(\mathbb{C})) = 2$$

since $C_0(\mathbb{T}\backslash\{\pm1\})\rtimes\mathbb{Z}_2\cong C_0(\mathbb{R})\otimes M_2(\mathbb{C})$ and $\mathbb{K}\otimes C([1,2])\otimes M_2(\mathbb{C})\otimes C([1,2])$ is a quotient of $C^*(M_5)\rtimes\mathbb{Z}_2$, where the first interval $[1,2]$ corresponds to the closed subset of $\mathbb{R}$ of $C_0(\mathbb{R})$, and the second interval $[0,1]$ corresponds to the closed subset of the subspace $\{0\}\times(0,\infty)$ in the base space $[0,\infty)^2$.

Furthermore, it follows from Theorem 4.1 that the space $(C^*(M_5)\rtimes\mathbb{Z}_2)_1^\wedge$ is given by $\mathbb{R}\times\mathbb{Z}_2$. Hence its dimension is one. Also, we have $(C^*(D_7)\rtimes\mathbb{Z}_2)_1^\wedge$ is $\mathbb{R}^2\times\mathbb{Z}_2$ from Theorem 4.1 and the decompositions of $C^*(D_7)$ and $C^*(H_3^{\mathbb{R}})$ given before Theorem 4.1. □

Theorem 4.5: *The structures of the fixed point algebras $C^*(M_5)^\gamma$, $C^*(D_7)^\gamma$ associated with the crossed products $C^*(M_5)\rtimes_\gamma\mathbb{Z}_2$, $C^*(D_7)\rtimes_\gamma\mathbb{Z}_2$ are given by*

$$C^*(M_5)^\gamma \cong \Gamma_0([0,\infty)^2,\{\mathbb{K}\otimes\mathfrak{A}_\theta^\gamma\}_{t\in(0,\infty)^2}\cup\{\mathbb{K}\otimes C(\mathbb{T})^\gamma\}_{t\in(\{0\}\times(0,\infty))\cup((0,\infty)\times\{0\})}\cup\{C^*(\mathbb{R}\times\mathbb{Z}_2)\}_{t=(0,0)}),$$

and

$$C^*(D_7)^\gamma \cong \Gamma_0([0,\infty)^2,\{(C(\mathbb{T}^2)\rtimes H_3^{\mathbb{R}})^\gamma\}_{t\in(0,\infty)^2} \cup\{(C(\mathbb{T})\rtimes H_3^{\mathbb{R}})^\gamma\}_{t\in(\{0\}\times(0,\infty))\cup((0,\infty)\times\{0\})}\cup\{C^*(H_3^{\mathbb{R}}\times\mathbb{Z}_2)\}_{t=(0,0)}),$$

where the fibers are decomposed into the following:

$$(C(\mathbb{T}^2)\rtimes H_3^{\mathbb{R}})^\gamma \cong \Gamma_0(\mathbb{R},\{\mathbb{K}\otimes\mathfrak{A}_\theta^\gamma\}_{\theta\in\mathbb{R}}),$$

$$(C(\mathbb{T})\rtimes H_3^{\mathbb{R}})^\gamma \cong \Gamma_0(\mathbb{R},\{\mathbb{K}\otimes C(\mathbb{T})^\gamma\}_{\theta\in\mathbb{R}\backslash\{0\}}\cup\{\mathbb{K}\otimes C_0(\mathbb{R}\times\mathbb{T})^\gamma\}_{\theta=0}).$$

Remark: Note that the fibers $\mathbb{K}\otimes\mathfrak{A}_\theta^\gamma$ for θ irrational involved in the decompositions above are simple AF algebras.

Theorem 4.6: *For the fixed point algebras $C^*(M_5)^\gamma$ and $C^*(D_7)^\gamma$, we have*

$$1 \leqslant \mathrm{sr}(C^*(M_5)^\gamma) \leqslant 2, \quad 2 \leqslant \mathrm{sr}(C^*(D_7)^\gamma) \leqslant 3.$$

Furthermore, we have

$$[\dim(C^*(M_5)^\gamma)_1^\wedge/2]+1 = [1/2]+1 = 1, \quad [\dim(C^*(D_7)^\gamma)_1^\wedge/2]+1 = [2/2]+1 = 2,$$

where $(C^*(M_5)^\gamma)_1^\wedge$, $(C^*(D_7)^\gamma)_1^\wedge$ are the spaces of all one-dimensional representations of $C^*(M_5)^\gamma$, $C^*(D_7)^\gamma$, respectively.

Proof: We use the structures of $C^*(M_5)^\gamma$ and $C^*(D_7)^\gamma$ given in Theorem 4.5. By Ref. 13 and Ref. 20, Proposition 1.7 and Theorems 3.6 and 6.4,

$$\mathrm{sr}(C^*(M_5)^\gamma) \leqslant \max\{\mathrm{sr}(C_0([0,\infty)^2)\otimes\mathbb{K}\otimes\mathfrak{A}_\theta^\gamma), \mathrm{sr}(C_0([0,\infty)^2)\otimes\mathbb{K}\otimes C(\mathbb{T})^\gamma), \mathrm{sr}(C_0([0,\infty)^2)\otimes\mathbb{K}\otimes C_0(\mathbb{R}\times\mathbb{Z}_2))\} = \max\{2,2,2\} = 2$$

and

$$\begin{aligned}\mathrm{sr}(C^*(D_7)^\gamma) \leqslant \max\{&\mathrm{sr}(C_0([0,\infty)^2) \otimes (C(\mathbb{T}^2) \rtimes H_3^{\mathbb{R}})^\gamma),\\ &\mathrm{sr}(C_0([0,\infty)^2) \otimes (C(\mathbb{T}) \rtimes H_3^{\mathbb{R}})^\gamma),\\ &\mathrm{sr}(C_0([0,\infty)^2) \otimes C^*(H_3^{\mathbb{R}} \times \mathbb{Z}_2))\}.\end{aligned}$$

Furthermore, we obtain

$$\mathrm{sr}(C_0([0,\infty)^2) \otimes (C(\mathbb{T}^2) \rtimes H_3^{\mathbb{R}})^\gamma) \leqslant \sup_{\theta\in\mathbb{R}} \mathrm{sr}(C_0(\mathbb{R} \times [0,\infty)^2) \otimes \mathbb{K} \otimes \mathfrak{A}_\theta^\gamma) = 2,$$

$$\mathrm{sr}(C_0([0,\infty)^2) \otimes (C(\mathbb{T}) \rtimes H_3^{\mathbb{R}})^\gamma) \leqslant \sup_{\theta\in\mathbb{R}} \mathrm{sr}(C_0(\mathbb{R} \times [0,\infty)^2) \otimes \mathbb{K} \otimes C(\mathbb{T})^\gamma) = 2,$$

$$\begin{aligned}\mathrm{sr}(C_0([0,\infty)^2) \otimes C^*(H_3^{\mathbb{R}} \times \mathbb{Z}_2)) \leqslant \max\{&\mathrm{sr}(C_0(\mathbb{R} \times [0,\infty)^2) \otimes \mathbb{K} \otimes \mathbb{C}^2), \mathrm{sr}(C_0(\mathbb{R} \times [0,\infty)^2) \otimes C_0(\mathbb{R}^2)\\ &\otimes \mathbb{C}^2)\} = \max\{2,3\} = 3.\end{aligned}$$

Furthermore, it follows from Theorem 4.5 that the space $(C^*(M_5)^\gamma)_1^\wedge$ is given by $\mathbb{R}\times\mathbb{Z}_2$, and the space $(C^*(D_7)^\gamma)_1^\wedge$ is given by $\mathbb{R}^2\times\mathbb{Z}_2$.

Furthermore, we can define symmetries on the generalized Mautner groups M_{2n+m} (the semidirect products $\mathbb{C}^n\rtimes_\alpha\mathbb{R}^m$ with α multirotations on $\mathbb{C}^n$)[30] and the generalized Dixmier groups D_{6n+1} (the semidirect product $\mathbb{C}^{2n}\rtimes_\alpha H_{2n+1}^{\mathbb{R}}$ by the generalized Heisenberg groups $H_{2n+1}^{\mathbb{R}}$ with α multirotations on $\mathbb{C}^{2n}$)[32] induced from the flips on $\mathbb{C}^n$ and $\mathbb{C}^{2n}$, respectively.

Theorem 4.7: *There exist symmetries on the group C^*-algebras $C^*(M_{2n+m})$ and $C^*(D_{6n+1})$ of the generalized Mautner groups $M_{2n+m}=\mathbb{C}^n\rtimes\mathbb{R}^m$ and the generalized Dixmier groups $D_{6n+1}=\mathbb{C}^{2n}\rtimes H_{2n+1}^{\mathbb{R}}$ induced from the flip on $\mathbb{C}^n$ and $\mathbb{C}^{2n}$, respectively. Moreover, the structures of $C^*(M_{2n+m})\rtimes\mathbb{Z}_2$ and $C^*(D_{6n+1})\rtimes\mathbb{Z}_2$ by the symmetries are given by*

$$\begin{aligned}C^*(M_{2n+m}) \rtimes \mathbb{Z}_2 \cong \Gamma_0([0,\infty)^n, &\{C(\mathbb{T}^n) \rtimes \mathbb{R}^m \rtimes \mathbb{Z}_2\}_{t\in(0,\infty)^n}\\ &\cup \cup_{k=1}^{n-1}\{C(\mathbb{T}^k) \rtimes \mathbb{R}^m \rtimes \mathbb{Z}_2\}_{t\in\sqcup\binom{n}{k}(0,\infty)^k} \cup \{C^*(\mathbb{R}^m \times \mathbb{Z}_2)\}_{t=(0,\ldots,0)\in\mathbb{C}^n}),\end{aligned}$$

where the fibers $C(\mathbb{T}^k)\rtimes\mathbb{R}^m\rtimes\mathbb{Z}_2$ $(1\leqslant k\leqslant n)$ are given by

$$\mathbb{K} \otimes C_0(\mathbb{T}^{k-l} \times \mathbb{R}^s) \rtimes \mathbb{Z}_2,$$

$$\mathbb{K} \otimes C_0(\mathbb{T}^{k-l} \times \mathbb{R}^s) \otimes \mathfrak{A}_\Theta \rtimes \mathbb{Z}_2$$

for certain $0\leqslant l\leqslant k$ and $0\leqslant s\leqslant m-1$ and $\mathfrak{A}_\Theta$ a certain noncommutative torus, and

$$\begin{aligned}C^*(D_{6n+1}) \rtimes \mathbb{Z}_2 \cong \Gamma_0([0,\infty)^{2n}, &\{C(\mathbb{T}^{2n}) \rtimes H_{2n+1}^{\mathbb{R}} \rtimes \mathbb{Z}_2\}_{t\in(0,\infty)^{2n}}\\ &\cup \cup_{k=1}^{n-1}\{C(\mathbb{T}^k) \rtimes H_{2n+1}^{\mathbb{R}} \rtimes \mathbb{Z}_2\}_{t\in\sqcup\binom{2n}{k}(0,\infty)^k} \cup \{C^*(H_{2n+1}^{\mathbb{R}} \times \mathbb{Z}_2)\}_{t=(0,\ldots,0)\in\mathbb{C}^{2n}}),\end{aligned}$$

where the fibers $C(\mathbb{T}^k)\rtimes H_{2n+1}^{\mathbb{R}}\rtimes\mathbb{Z}_2$ $(1\leqslant k\leqslant 2n)$ are given by

$$C(\mathbb{T}^k) \rtimes H_{2n+1}^{\mathbb{R}} \rtimes \mathbb{Z}_2 \cong \Gamma_0(\mathbb{R}, \{\mathbb{K} \otimes (\otimes^s\mathfrak{A}_\theta) \otimes C(\mathbb{T}^l) \rtimes \mathbb{Z}_2\}_{\theta\in\mathbb{R}\setminus\{0\}} \cup \{\mathbb{K} \otimes C_0(\mathbb{R}^{2n-k} \times \mathbb{T}^k) \rtimes \mathbb{Z}_2\}_{\theta=0})$$

for certain $2s+l=k$ with s, $l\geqslant 0$.

Moreover, the structures of the fixed point algebras $C^*(M_{2n+m})^\gamma$, $C^*(D_{6n+1})^\gamma$ by the symmetries are given by replacing the above fibers $C(\mathbb{T}^k)\rtimes\mathbb{R}^m\rtimes\mathbb{Z}_2$ with $(C(\mathbb{T}^k)\rtimes\mathbb{R}^m)^\gamma$ and the above fibers $C(\mathbb{T}^k)\rtimes H_{2n+1}^{\mathbb{R}}\rtimes\mathbb{Z}_2$ with $(C(\mathbb{T}^k)\rtimes H_{2n+1}^{\mathbb{R}})^\gamma$, respectively, and the replaced fibers are, respectively, isomorphic to

$$\mathbb{K} \otimes C_0(\mathbb{T}^{k-l} \times \mathbb{R}^s)^\gamma \quad or \quad \mathbb{K} \otimes (C_0(\mathbb{T}^{k-l} \times \mathbb{R}^s) \otimes \mathfrak{A}_\Theta)^\gamma,$$

$$\Gamma_0(\mathbb{R},\{\mathbb{K}\otimes((\otimes^s\mathfrak{A}_\theta)\otimes C(\mathbb{T}^l))^\gamma\}_{\theta\in\mathbb{R}\setminus\{0\}}\cup\{\mathbb{K}\otimes C_0(\mathbb{R}^{2n-k}\times\mathbb{T}^k)^\gamma\}_{\theta=0}).$$

Theorem 4.8: *For the crossed products* $C^*(M_{2n+m})\rtimes\mathbb{Z}_2$ *and* $C^*(D_{6n+1})\rtimes\mathbb{Z}_2$, *we have*

$$[m/2]+1\leqslant \mathrm{sr}(C^*(M_{2n+m})\rtimes\mathbb{Z}_2)\leqslant[(n+m)/2]+1,$$

$$n+1\leqslant \mathrm{sr}(C^*(D_{6n+1})\rtimes\mathbb{Z}_2)\leqslant 2n+1.$$

For the their fixed point algebras $C^*(M_{2n+m})^\gamma$, $C^*(D_{6n+1})^\gamma$,

$$[m/2]+1\leqslant \mathrm{sr}(C^*(M_{2n+m})^\gamma)\leqslant[(n+m)/2]+1,$$

$$n+1\leqslant \mathrm{sr}(C^*(D_{6n+1})^\gamma)\leqslant 2n+1.$$

Furthermore, we have

$$[\dim(C^*(M_{2n+m})\rtimes\mathbb{Z}_2)^\wedge_1/2]+1=[m/2]+1=[\dim(C^*(M_{2n+m})^\gamma)^\wedge_1/2]+1,$$

$$[\dim(C^*(D_{6n+1})\rtimes\mathbb{Z}_2)^\wedge_1/2]+1=n+1=[\dim(C^*(D_{6n+1})^\gamma)^\wedge_1/2]+1,$$

where for $G=C^*(M_{2n+m})\rtimes\mathbb{Z}_2$, $C^*(M_{2n+m})^\gamma$, $C^*(D_{6n+1})\rtimes\mathbb{Z}_2$, *or* $C^*(D_{6n+1})^\gamma$, $G^\wedge_1$ *is the space of all one-dimensional representations of* G.

Proof: We use the structures of the crossed products and the fixed point algebras in the statement given in Theorem 4.7, and estimate their stable rank as given in the proofs of Theorems 4.4 and 4.6. In particular, note that

$$\mathrm{sr}(C_0([0,\infty)^n\times\mathbb{R}^m))=[(n+m)/2]+1,\quad \mathrm{sr}(C^*(\mathbb{R}^m))=[m/2]+1$$

for the stable rank of $C^*(M_{2n+m})\rtimes\mathbb{Z}_2$ and $C^*(M_{2n+m})^\gamma$, and

$$\mathrm{sr}(C_0([0,\infty)^{2n}\times\mathbb{R}^{2n}))=2n+1,\quad \mathrm{sr}(C_0(\mathbb{R}^{2n}))=n+1$$

for the stable rank of $C^*(D_{6n+1}))\rtimes\mathbb{Z}_2$ and $C^*(D_{6n+1}))^\gamma$.

Furthermore, note that the spaces $(C^*(M_{2n+m})\rtimes\mathbb{Z}_2)^\wedge_1$, $(C^*(M_{2n+m})^\gamma)^\wedge_1$ are given by $\mathbb{R}^m\times\mathbb{Z}_2$, and the spaces $(C^*(D_{6n+1})\rtimes\mathbb{Z}_2)^\wedge_1$, $(C^*(D_{6n+1})^\gamma)^\wedge_1$ are given by $\mathbb{R}^{2n}\times\mathbb{Z}_2$. □

(Received 4 February 2005; accepted 1 February 2006; published online 31 March 2006)

We use AdS/CFT inspired methods to study the Racah coefficients for type I representations of the Lorentz group $SO_0(1,d+1)$ with $d>1$. For such representations (a multiple of) the Racah coefficient can be represented as an integral of a product of six bulk-to-bulk propagators over four copies of the hyperbolic space H_{d+1}. To compute the integrals we represent the bulk-to-bulk propagators in terms of bulk-to-boundary ones. The bulk integrals can be computed explicitly, and the boundary integrations are carried out by introducing Feynman parameters. The final result is an integral representation of the Racah coefficient given by four Barnes-Mellin type integrals. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2180626]

I. INTRODUCTION AND THE MAIN RESULT

Racah or Racah-Wigner (RW) coefficients or, as they are often called, $6j$-symbols are important objects in group representation theory. They depend on six irreducible representations of the group and are obtained by multiplying four Clebsch-Gordan coefficients and summing over the basis labels. Explicit formulas for RW coefficients are available for the case of group SU(2). They are given by a (finite) generalized hypergeometric series ${}_4F_3(1)$ of unit argument.[1] RW coefficients for other compact groups, especially the unitary group $U(n)$ and the rotation group $SO(n)$ have also been computed. For noncompact groups these coefficients have received much less attention. This has to do with the envisaged physical application of the RW coefficients: they figure prominently in the lattice approach to QCD. As QCD concerns itself with compact gauge groups such as $SU(n)$ there is no field theoretic motivation to compute the noncompact RW coefficients. This situation changed with the introduction of the spin foam models of quantum gravity.[2] Here of physical interest are exactly models with noncompact groups such as the Lorentz group. These models use RW and other similar coefficients in an essential way.[3] It thus became of importance to study and derive explicit expressions for the noncompact RW coefficients. Of particular interest are the Lorentz group RW coefficients. This is the problem that is considered in the present paper. Another obvious complication that arises in the noncompact case is that the unitary representations are infinite dimensional. Sums of the compact case get replaced by integrals; the problem requires a more careful analytical treatment, including a careful analysis of the convergence of all the expressions. This paper gives such a treatment for $SO_0(1,d+1)$ RW coefficients for type I representations, for $d>1$. Here $SO_0(1,d+1)$ denotes the connected component of $SO(1,d+1)$. We shall assume $d>1$ throughout the paper when not explicitly mentioned otherwise.

Motivations for considering the RW coefficients for type I representations are twofold: (i) these are the representations that are of importance for quantum gravity applications;[3,4] (ii) RW

coefficients for type I representations can be obtained from a certain integral over several copies of the hyperbolic space. As we show in this paper, these integrals and thus the RW coefficients can be given in terms of four Barnes-Mellin-type integrals. One may be able to use this integral representation for an analytic continuation, and in this way obtain RW coefficients for other representations.

We recall here some basic facts about $SO_0(1,d+1)$ representation theory.[5] Representations of type I form the most degenerate series of representations. At the same time they are the simplest and the most studied ones. These irreducible unitary representations appear in the decomposition of the space $L^2(H_{d+1})$ of square integrable functions on the hyperbolic space H_{d+1} into irreducible representations. Thus, type I representations can be realized in the space of $L^2(H_{d+1})$ functions. It is this realization that will be the starting point for our analysis.

These representations can also be realized in the space of homogeneous functions on the light cone in Minkowski space $M^{1,d+1}$. We shall refer to minus degree of homogeneity by the conformal dimension Δ of the representation. For representations of type I,

$$\Delta = d/2 + i\rho, \quad \rho \in \mathbb{R}. \tag{1.1}$$

There is another important series of unitary representations with real integral Δ. We shall not consider them here. We shall also require a notion of the dual representation. Its conformal dimension $\bar{\Delta}$ is such that

$$\Delta + \bar{\Delta} = d. \tag{1.2}$$

The dual representation is an equivalent representation.

A brief description of the logic of the paper is as follows. We represent the RW coefficient as an integral over four copies of the hyperbolic space of a product of six "propagators," the corresponding expression to be given in the main text. This way of representing the $6j$-symbols was proposed in Ref. 4 and later explored in papers by many authors, in particular Refs. 3 and 6. In Ref. 3 the bulk-to-bulk propagator was represented as a composition of two "bulk-to-boundary" ones. This representation will be of central importance for us in this paper. The terminology "bulk-to-boundary" and "bulk-to-bulk" is that used in the AdS/CFT context.[7]

Replacing each bulk-to-bulk propagator by a composition of two bulk-to-boundary ones and using the usual field theoretic trick of Feynman parameters, all the integrals over the hyperbolic space as well as over the boundary can be taken. Moreover, as we shall see, all the integrals over the Feynman parameters can be taken as well, at the expense of introducing four Barnes-Mellin-type integrals. The expression we end up with has these four integrals remaining. Our final result for the RW coefficient is

$$\begin{aligned}(6\Delta) = {} & K_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6} K_{\Delta_4,\bar{\Delta}_2,\bar{\Delta}_3,\bar{\Delta}_5,\Delta_6} \int \frac{d\lambda\, ds}{(2\pi i)^2} \int \frac{d\lambda'\, ds'}{(2\pi i)^2} \Gamma(-s)\Gamma(-\lambda)\Gamma(-s')\Gamma(-\lambda') \\ & \times \Gamma(\gamma - s)\Gamma(\delta - \lambda)\Gamma(\alpha + s + \lambda)\Gamma(\beta + s + \lambda)\Gamma(\gamma' - s')\Gamma(\delta' - \lambda')\Gamma(\alpha' + s' + \lambda') \\ & \times \Gamma(\beta' + s' + \lambda')\pi^{d/2} \frac{\Upsilon_d(\lambda - s' - \lambda' - A)\Upsilon_d(\lambda' - s - \lambda + A)}{\Upsilon_d(-s - s')},\end{aligned} \tag{1.3}$$

where

$$\Upsilon_d(x) = \frac{\Gamma(x)}{\Gamma(d/2 - x)}. \tag{1.4}$$

The integration contour in each of the four variables is parallel to the imaginary axis at $\mathrm{Re}(z) = r$, where the parameter r can be chosen freely in the interval $-d/8 < r < 0$. Various quantities that appear in (1.3) are defined as follows:

$$\alpha = \frac{\overline{\Delta_1} + \Delta_3 - \Delta_2}{2}, \quad \alpha' = \frac{\overline{\Delta_4} + \overline{\Delta_6} - \overline{\Delta_2}}{2},$$

$$\beta = \frac{\overline{\Delta_1} + \Delta_6 - \Delta_5}{2}, \quad \beta' = \frac{\overline{\Delta_4} + \overline{\Delta_3} - \overline{\Delta_5}}{2},$$

$$\gamma = \frac{\Delta_2 - \Delta_3 + \Delta_5 - \Delta_6}{2}, \quad \gamma' = \frac{\overline{\Delta_2} - \overline{\Delta_3} + \overline{\Delta_5} - \overline{\Delta_6}}{2}, \tag{1.5}$$

$$\delta = \frac{\Delta_1 - \overline{\Delta_1}}{2}, \quad \delta' = \frac{\Delta_4 - \overline{\Delta_4}}{2},$$

$$A = \frac{\Delta_1 - \Delta_4 + \Delta_2 + \Delta_5 - d}{2},$$

$$K_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6} = \frac{\pi^{3d/2}\Gamma\left(\frac{\Delta_1+\Delta_2+\Delta_3-d}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_5+\Delta_6-d}{2}\right)\Gamma\left(\frac{\Delta_2+\Delta_3-\Delta_1}{2}\right)\Gamma\left(\frac{\Delta_5+\Delta_6-\Delta_1}{2}\right)}{4\Gamma^2(\Delta_1)\Gamma(\Delta_2)\Gamma(\Delta_3)\Gamma(\Delta_5)\Gamma(\Delta_6)}.$$

As is shown in the main text, for type I representations the Barnes-Mellin integrals in (1.3) converge in absolute value, so that this formula gives a well-defined representation of the RW coefficient. The expression (1.3) can potentially be used for numerical study of the $6j$-symbol as well as for the study of the asymptotics. We do not consider these problems in the present paper.

Given the answer (1.3) for the RW coefficient one may ask if it is "as expected" from general considerations. For instance, it can be expected that the noncompact case answer can be obtained by some "analytic continuation" from the one of the compact case. By "analytic continuation" one could mean some procedure of rather free manipulation with the compact answer by replacing the finite sums with integrals and continuing the representation labels to complex values. For example, the answer for the SU(2) RW coefficient is given by a single finite sum. Should one expect the $SO_0(1,2)$, and more generally $SO_0(1,d+1)$, RW coefficient to be given by a single integral? Here we would like to argue against this expectation.

As is clear from the computation of the $6j$-symbol given in Ref. 1, the fact that representations of SU(2) are highest weight is used in an essential way. The idea of the computation is as follows. Consider a product of three Clebsch-Gordan coefficients contracted to form a "star-triangle." When the Clebsch-Gordan coefficients are appropriately normalized, this star-triangle is proportional to a single Clebsch-Gordan coefficient with the proportionality coefficient being the $6j$-symbol,

$$\sum_{m_{ij}} C^{l_1 l_{12} l_{13}}_{m_1 m_{12} m_{13}} C^{l_2 l_{23} l_{12}}_{m_2 m_{23} m_{12}} C^{l_3 l_{13} l_{23}}_{m_3 m_{13} m_{23}} = (6j) C^{l_1 l_2 l_3}_{m_1 m_2 m_3}. \tag{1.6}$$

Here the m-labels should satisfy a conservation law for each Clebsch-Gordan coefficient,

$$m_1 = m_{12} + m_{13}, \quad m_2 = m_{23} + m_{12}, \quad m_3 = m_{23} - m_{13}, \quad m_2 = m_1 + m_3. \tag{1.7}$$

Thus, there is only a single loop "momentum" to be summed over. Each Clebsch-Gordan coefficient is also given by a finite sum, see Ref. 1. Therefore, we have four sums on the left-hand side and one sum times the $6j$-symbol on the right-hand side. What simplifies the computation considerably is that one can set the basis labels m_1, m_2 to be highest weight. For such values of m the

sum that gives the Clebsch-Gordan coefficient reduces to a single term. Thus, if we set two of the external states to be highest weight, we get only two sums remaining on the left-hand side and no sum times the $6j$ on the right. One of the summations on the left-hand side can be carried out explicitly using Gauss's sum. One gets an expression for the $6j$ given by a single sum.

Let us now return to the noncompact case. Going to a "momentum" basis, analogous to the m-basis of SU(2), one can have momentum conserved at each vertex. One analogously will have to do only a single integral over the loop momentum. However, in the momentum basis the Clebsch-Gordan coefficients are no longer as simple as in (4.13). One should expect an integral representation with at least one integral. Now, the type I representations are not highest or lowest weight. Thus, there is no simplification of the momentum basis Clebsch-Gordan coefficients that can be used in the computation of the $6j$-symbol. The total number of integrals remains at least four on the left-hand side and at least one on the right-hand side. Thus, at the very best one expects the noncompact $6j$-symbol for type I representations to be given by three integrals. We have tried to further simplify our answer (1.3) in line with this this expectation. Unfortunately, no summation theorems for the generalized hypergeometric series seem to be applicable, and we were not able to simplify the result further. It thus remains an interesting open problem to find a simpler representation for the RW coefficient than the one given by (1.3).

This paper is organized as follows. We start in Sec. II by reviewing the bulk-to-bulk and bulk-to-boundary propagators. Section III gives a formula for the RW coefficients in terms of bulk-to-bulk propagators, as well as another convenient representation in terms of a boundary 4-point function. In Sec. IV we compute the 3-point function, and in Sec. V we discuss its normalization. An important regularization procedure is introduced here. In Sec. VI we compute the 4-point function. Finally, in Sec. VII we compute the remaining sphere integrals. Certain technical results are given in two appendixes.

II. BULK-TO-BULK AND BULK-TO-BOUNDARY PROPAGATORS

In this section we allow d to be any positive integer.

We consider the d-dimensional conformal group $\mathrm{SO}_0(1,d+1)$. One of the associated homogeneous spaces is the hyperbolic space $H_{d+1}=\mathrm{SO}_0(1,d+1)/\mathrm{SO}(d+1)$. The space $L^2(H_{d+1})$ of square integrable functions on H_{d+1} decomposes into irreducible representations of the so-called type I series. More generally, the most degenerate series of representations of the conformal group is that in the space of homogeneous functions on the light cone in Minkowski space $M^{1,d+1}$. Functions of degree of homogeneity $-\Delta$ form an irreducible representation of "conformal dimension" Δ. Not all of these representations are unitary. For unitary representations of type I the conformal dimension is given by (1.1).

Thoughout the paper, we label the representations by their conformal dimension Δ. While the final results will be justified only for the type I values (1.1), several intermediate results remain valid for more general values, and we present the intermediate results in this form in view of potential extensions beyond type I representations.

To proceed, we need the notions of bulk-to-bulk and bulk-to-boundary propagators.[7] We use the upper half-space model of H_{d+1}. Let the coordinates in the upper half-space be $(\xi_0>0,\xi_i)$, $i=1,\ldots,d$. The metric is then

$$\mathrm{d}s^2=\frac{1}{\xi_0^2}\left(\mathrm{d}\xi_0^2+\sum_i \mathrm{d}\xi_i^2\right). \tag{2.1}$$

The boundary of H_{d+1} is the set of points with $\xi_0=0$ and the point at infinity. When referring to points of the boundary we shall use a different letter $x:x_i=\xi_i$.

Following Ref. 7, we introduce the following function of a point on the boundary x and a bulk point ξ in H_{d+1}:

$$K_\Delta(\xi,x)=\frac{\xi_0^\Delta}{(\xi_0^2+|\xi-x|^2)^\Delta}. \tag{2.2}$$

We refer to this function as the bulk-to-boundary propagator. Another, more familiar from mathematics literature, expression for this object is given by

$$K_\Delta(\hat{\xi},\hat{x})=(\hat{\xi}\cdot\hat{x})^{-\Delta}, \tag{2.3}$$

where the vectors $\hat{\xi}$ and $\hat{x}$ in Minkowski space $M^{1,d+1}$ are the representatives of, respectively, ξ and x in the hyperboloid model of H_{d+1} and the dot product is the Minkowski pairing. $\hat{\xi}$ is unit timelike and $\hat{x}$ is null.

The bulk-to-bulk propagator is obtained by taking a product of two propagators (2.2), one for representation Δ, another for the dual representation $\bar{\Delta}$, and integrating over the point on the boundary:

$$K_\Delta(\xi_1,\xi_2)=\int_{S^d} d^dx K_\Delta(\xi_1,x)K_{\bar{\Delta}}(\xi_2,x). \tag{2.4}$$

We have denoted the integration domain, $x\in\mathbb{R}^d$, by S^d as a reminder of the boundary topology in the Poincare ball model of H_{d+1}. As the integrand is asymptotic to a constant times $|x|^{-2d}$ at $|x|\to\infty$, the integral converges for all $\Delta\in\mathbb{C}$.

The bulk-to-bulk propagator (2.4) can be computed explicitly. To begin, assume $\mathrm{Re}(\Delta)>0$ and $\mathrm{Re}(\bar{\Delta})>0$. Using the Feynman representation reviewed in Appendix A, we obtain

$$K_\Delta(\xi_1,\xi_2)=\frac{(\xi_1^0)^\Delta(\xi_2^0)^{\bar{\Delta}}}{\Gamma(\Delta)\Gamma(\bar{\Delta})}\int_{S^d} d^dx\int \mathrm{d}t\,\mathrm{d}u\, t^{\Delta-1}u^{\bar{\Delta}-1}\times e^{-t(\xi_1^0)^2-u(\xi_2^0)^2-t|\xi_1-x|^2-u|\xi_2-x|^2}. \tag{2.5}$$

Taking the integral over x yields

$$K_\Delta(\xi_1,\xi_2)=\frac{(\xi_1^0)^\Delta(\xi_2^0)^{\bar{\Delta}}}{\Gamma(\Delta)\Gamma(\bar{\Delta})}\int \mathrm{d}t\,\mathrm{d}u\, t^{\Delta-1}u^{\bar{\Delta}-1}e^{-t(\xi_1^0)^2-u(\xi_2^0)^2}\frac{\pi^{d/2}}{(t+u)^{d/2}}e^{-[tu/(t+u)]|\xi_1-\xi_2|^2}.$$

By construction, $K_\Delta(\xi_1,\xi_2)$ is invariant under the action of the Lorentz group and hence depends on ξ_1 and ξ_2 only through their hyperbolic distance l. Using this invariance, we can choose $\xi_1=(\xi_1^0,0)$ and $\xi_2=(\xi_2^0,0)$, in which case

$$l=\ln(\xi_1^0/\xi_2^0). \tag{2.6}$$

Writing $\mu=e^l$ and rescaling the integration variables, we obtain

$$K_\Delta(\xi_1,\xi_2)=\frac{\pi^{d/2}\mu^\Delta}{\Gamma(\Delta)\Gamma(\bar{\Delta})}\int\frac{\mathrm{d}t\,\mathrm{d}u}{(t+u)^{d/2}}t^{\Delta-1}u^{\bar{\Delta}-1}e^{-t\mu^2-u}. \tag{2.7}$$

The integrals over t and u can now be taken with the change of variables

$$\lambda=\frac{t}{t+u},\quad \mathrm{d}t\,\mathrm{d}u=\frac{u\,\mathrm{d}\lambda\,\mathrm{d}u}{(1-\lambda)^2}, \tag{2.8}$$

where $0<\lambda<1$. We get

$$K_\Delta(\xi_1,\xi_2)=\frac{\pi^{d/2}\mu^\Delta}{\Gamma(\Delta)\Gamma(\bar{\Delta})}\int_0^1\frac{\mathrm{d}\lambda}{(1-\lambda)^{2-d/2}}\int_0^\infty\frac{\mathrm{d}u}{u^{d/2-1}}\left(\frac{\lambda u}{1-\lambda}\right)^{\Delta-1}u^{\bar{\Delta}-1}e^{-u\{[\lambda\mu^2/(1-\lambda)]+1\}}. \tag{2.9}$$

The integral over u gives

$$K_\Delta(\xi_1,\xi_2)=\frac{\pi^{d/2}\mu^\Delta\Gamma(d/2)}{\Gamma(\Delta)\Gamma(\overline{\Delta})}\int_0^1 \mathrm{d}\lambda\,\lambda^{\Delta-1}(1-\lambda)^{d-\Delta-1}(1-\lambda(1-\mu^2))^{-d/2}. \tag{2.10}$$

Using the integral representation of the hypergeometric function,

$$F(a,b,c;z)=\frac{\Gamma(c)}{\Gamma(b)\Gamma(c-b)}\int_0^1 \mathrm{d}t\,t^{b-1}(1-t)^{c-b-1}(1-tz)^{-a}, \tag{2.11}$$

we finally obtain

$$K_\Delta(\xi_1,\xi_2)=\frac{\pi^{d/2}\mu^\Delta\Gamma(d/2)}{\Gamma(d)}F(d/2,\Delta,d,1-\mu^2). \tag{2.12}$$

By analytic continuation, the result (2.12) holds for all $\Delta\in\mathbb{C}$. Note that there is no singularity when Δ is a nonpositive integer; the hypergeometric series just terminates then. We also note that, in view of the identity

$$F(c-a,c-b,c;z)=(1-z)^{a+b-c}F(a,b,c;z) \tag{2.13}$$

we have $K_\Delta(\xi_1,\xi_2)=K_{\overline{\Delta}}(\xi_1,\xi_2)$. Thus, the bulk-to-bulk propagator is a nonoriented one. Indeed, the change of orientation is equivalent to the replacement $\Delta\to\overline{\Delta}$, but this does not change the propagator.

The result (2.12) can be expressed in terms of a Legendre function.[8] For $d=1$, the formula was given in Ref. 6. For $d=2$, the result can be given in terms of an elementary function as

$$K_\Delta(\xi_1,\xi_2)=\frac{\pi}{\Delta-1}\frac{\sinh(\Delta-1)l}{\sinh l}. \tag{2.14}$$

For type I representations this reduces to

$$K_\rho(\xi_1,\xi_2)=\frac{\pi}{\rho}\frac{\sin\rho l}{\sinh l}. \tag{2.15}$$

III. RACAH-WIGNER COEFFICIENTS

We shall compute the RW coefficients through an object called the (6Δ) symbol, given by an integral over four copies of H_{d+1} of a product of six bulk-to-bulk propagators:

$$(6\Delta)=\int_{H_{d+1}}\mathrm{d}\xi_1\cdots\mathrm{d}\xi_4\prod_{i<j}K_{\Delta_{ij}}(\xi_i,\xi_j). \tag{3.1}$$

Here $i,j=1,\ldots,4$ enumerate the points integrated over and Δ_{ij} are the six representations that the (6Δ) symbols depend upon. We begin formally with general $\Delta_{ij}\in\mathbb{C}$ but will eventually specialize to the type I values (1.1). Since the non-type-I representations are not realizable in $L^2(H_{d+1})$, we do not expect that the integral (3.1) can be made convergent for them even after eliminating the infinite volume factor by the procedure of Sec. V.

The relation between the (6Δ) symbol (3.1) and the RW coefficients has been discussed in Ref. 4. To make the present paper self-contained, we shall briefly recall the relation here.

By definition, the representations of type I (with respect to a subgroup H) are those which contain a vector invariant under H. When $G=\mathrm{SO}_0(1,d+1)$, the subgroup H is taken to be the maximal compact subgroup $H=\mathrm{SO}(d+1)$. Let π^ρ be a type I representation, labelled by the index ρ, and let ω be an H-invariant vector. We define on G the function ϕ^ρ as the $\omega\omega$ matrix element of π^ρ,

$$\phi^{\rho}(g) := t^{\rho}_{\omega\omega}(g) := \langle \omega | \pi^{\rho}(g) | \omega \rangle. \tag{3.2}$$

ϕ^{ρ} is called a *spherical* function. Given ϕ^{ρ}, we define the kernel

$$K_{\rho}(g_1, g_2) := \phi^{\rho}(g_1^{-1} g_2). \tag{3.3}$$

As ω is invariant under H, (3.2) shows that ϕ^{ρ} projects into a function on the double coset $H\backslash G/H$, and (3.3) then shows that the kernel projects into a function on two copies of the homogeneous space G/H. In the case of $G=\mathrm{SO}_0(1,d+1)$ and $H=\mathrm{SO}(d+1)$, this homogeneous space is the hyperbolic space H^{d+1}, and from the explicit evaluation of the spherical function in Sec. 9.3.1 of Ref. 5 it is seen that the kernel (3.3) concides (up to a multiple that depends on the normalization of ω) with the bulk-to-bulk propagator (2.12).

Next, we recall the definition of the Clebsch-Gordon coefficients. Given two (irreducible) representations V^{ρ_1}, V^{ρ_2} of G, one can decompose the tensor product representation $V^{\rho_1} \otimes V^{\rho_2}$ into irreducible representations V^{ρ} as

$$V^{\rho_1} \otimes V^{\rho_2} = \oplus_{\rho_3} n(\rho_3) V^{\rho_3}, \tag{3.4}$$

where $n(\rho)$ are multiplicities. The Clebsch-Gordan coefficients are the matrix elements of the intertwining map defined by this decomposition. Explicitly, if i_1 and i_2 are vectors in, respectively, V^{ρ_1} and V^{ρ_2}, we have

$$|i_1\rangle \otimes |i_2\rangle = \sum_{\alpha \rho_3 i_3} {}^{\alpha}C^{\rho_3 i_3}_{\rho_1 i_1 \rho_2 i_2} |i_3\rangle, \tag{3.5}$$

where $\{i_3\}$ is a (generalized) basis in V^{ρ_3}, the sum on the right-hand side includes a sum over the multiplicity label $\alpha=1,\ldots,n(\rho_3)$, and the sum over the other labels is understood in the sense of a sum or an integral depending on whether the labels are discrete or continuous. The C's on the right-hand side are then the Clebsch-Gordan coefficients in the respective bases.

We will further need the orthogonality relation for the matrix elements $t^{\rho}_{i_1 i_2}(g) := \langle i_1 | \pi^{\rho}(g) | i_2 \rangle$. This relation reads

$$\int \mathrm{d}g \, t^{\rho_1}_{i_1 j_1}(g) t^{\rho_2}_{i_2 j_2}(g) = \delta^{\rho_1 \rho_2} \delta_{i_1 i_2} \delta_{j_1 j_2}, \tag{3.6}$$

where we have used the reality of the matrix elements for $G=\mathrm{SO}_0(1,d+1)$, and the δ's on the right-hand side are understood as Kronecker or Dirac deltas as appropriate. For a compact group, whose representations are finite dimensional, the right-hand side of (3.6) would usually be normalized to include the factor $1/\dim(j_1)$, but in our case of a noncompact group the representations are infinite dimensional and such a normalization is not an option. Using (3.5) and (3.6), it is then possible to compute the integral of the product of three matrix elements, with the result

$$\int \mathrm{d}g \, t^{\rho_1}_{i_1 j_1}(g) t^{\rho_2}_{i_2 j_2}(g) t^{\rho_3}_{i_3 j_3}(g) = \sum_{\alpha} {}^{\alpha}C^{\rho_3 i_3}_{\rho_1 i_1 \rho_2 i_2} \, {}^{\alpha}C^{\rho_3 j_3}_{\rho_1 j_1 \rho_2 j_2}. \tag{3.7}$$

Now, when the multiplicity of type I representations in the tensor product (3.4) of two such representations is equal to 1, the multiplicity label on the type I Clebsch-Gordan coefficients becomes redundant, and it can be shown from (3.7) that the (6Δ) symbol (3.1) equals the usual type I RW coefficient, constructed from the Clebsch-Gordan coefficients, multiplied by four factors of the form $C^{\rho_3 \omega}_{\rho_1 \omega \rho_2 \omega}$, one such factor coming from each ξ in (3.1). In this case one can therefore regard the (6Δ) symbol (3.1) as the type I RW coefficient up to a certain normalization factor. When the multiplicity of type I representations in the tensor product of two such representations is not equal to 1, on the other hand, the multiplicity label on the type I Clebsch-Gordan coefficients cannot be dropped. The (6Δ) symbol (3.1) involves then factors of the form ${}^{\alpha}C^{\rho_3 \omega}_{\rho_1 \omega \rho_2 \omega}$

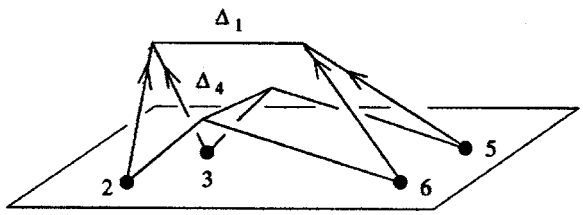

FIG. 1. Expression for the Racah-Wigner coefficient in terms of the 4-point functions.

for each ξ, and there is a sum over the four independent multiplicity labels. As the type I RW coefficients then have a multiplicity label corresponding to each ξ, the (6Δ) symbol (3.1) is no longer a simple multiple of the type I RW coefficients.

Thus, to establish the relation of the (6Δ) symbol (3.1) to the usual RW coefficients it remains to find the multiplicity of type I representations in the tensor product (3.4) of two such representations. For $SO_0(1,2)$ this multiplicity is known to be 2.[9] The $SO_0(1,2)$ (6Δ) symbol (3.1) is therefore not a simple multiple of (any of the) RW coefficients. The $SO_0(1,2)$ (6Δ) symbol (3.1) can still be computed and used as a basis of a state sum model,[6] but its group theoretic interpretation does not appear straightforward.

For $SO_0(1,d+1)$ with $d>1$, the multiplicity of type I representations in the tensor product (3.4) of two such representations is one. To see this, we recall that the principal series representations can be obtained as the induced representations of the parabolic subgroup MAN, where N is the d-dimensional Abelian group of null rotations, A is the one-dimensional group of dilatations and $M=SO(d)$, and in particular the type I representations are induced from the *trivial* representation of M.[10] The claim then follows from Theorem 16 of Ref. 11 and the discussion of $SO_0(1,d+1)$ on pages 182–183 therein. This establishes the relation of our (6Δ) symbol (3.1) to the usual RW coefficients for $SO_0(1,d+1)$ with $d>1$.

To proceed with the analysis of the (6Δ) symbol, we represent four of the six bulk-to-bulk propagators in (3.1) as in (2.4), while leaving the two bulk-to-bulk propagators corresponding to the opposite edges of the tetrahedron in their original form. By doing this one achieves the representation as is shown in Fig. 1.

Thus, let us introduce the following object:

$$D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)=\int_{H_{d+1}} \mathrm{d}\xi\,\mathrm{d}\eta\,K_{\Delta_2}(\xi,x_2)K_{\Delta_3}(\xi,x_3)K_{\Delta_1}(\xi,\eta)K_{\Delta_5}(\eta,x_5)K_{\Delta_6}(\eta,x_6). \tag{3.8}$$

This quantity is a particular 4-point function on the boundary. With the help of this 4-point function, the RW coefficient can be written as

$$(6\Delta)=\int_{S^d} d^dx_2 d^dx_3 d^dx_5 d^dx_6 D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)D_{\Delta_4,\bar{\Delta}_2,\bar{\Delta}_6,\bar{\Delta}_5,\bar{\Delta}_3}(x_2,x_6,x_5,x_3). \tag{3.9}$$

This representation is much more convenient than the one given by (3.1), since the 4-point function $D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)$ can be computed explicitly. Computing the RW coefficient then reduces to the computation of the S^d integrals in (3.9). As we shall see in Sec. V, after a certain gauge fixing that is necessary to render the results finite, what one has is actually not four integrals but a single integral over the sphere. This makes the representation (3.9) very convenient for practical applications. We note that this representation is only available in the context of noncompact conformal groups, when there is a boundary and the associated representation (2.4). For compact groups like $SO(n)$ one can also compute the RW coefficients for type I representations by integrating over the appropriate homogeneous manifold. However, there is no analog of the representation (3.9).

Thus, we would like to compute the 4-point function given by (3.8). In order to do this, we use the representation (2.4) for the remaining bulk propagator. Thus, we represent the 4-point function as

$$D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)=\int d^dx_1 C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)C^{-}_{\Delta_1,\Delta_5,\Delta_6}(x_1,x_5,x_6), \tag{3.10}$$

where we have defined the 3-point function

$$C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)=\int_{H_{d+1}} \mathrm{d}\xi\, K_{\Delta_1}(\xi,x_1)K_{\Delta_2}(\xi,x_2)K_{\Delta_3}(\xi,x_3). \tag{3.11}$$

We need to find this 3-point function.

IV. 3-POINT FUNCTION

We note in passing that the 3-point function (3.11) is the Clebsch-Gordan coefficient when the representations are realized in the space of functions on the boundary. Since $d>1$ by assumption, these Clebsch-Gordon coefficients have no multiplicity indices.

The conditions for the integral in (3.11) to converge are

$$\mathrm{Re}\left(\sum_i \Delta_i\right)>d \tag{4.1}$$

and

$$\mathrm{Re}(\Delta_1+\Delta_2-\Delta_3)>0,\quad \mathrm{Re}(\Delta_2+\Delta_3-\Delta_1)>0,\quad \mathrm{Re}(\Delta_1+\Delta_3-\Delta_2)>0. \tag{4.2}$$

These conditions can be conveniently obtained by transforming to the Poincare ball model of H_{d+1}: (4.2) comes from neighborhoods of the three boundary points x_i, and (4.1) comes from the remaining part of the boundary. Note that (4.2) implies $\mathrm{Re}(\Delta_i)>0$ for all i. Note also that the convergence holds for type I representations.

In order to compute the bulk integral we use the Feynman parametrization (A1) for each of the bulk-to-boundary propagators. We get

$$\begin{aligned}C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)=&\frac{1}{\Gamma(\Delta_1)}\frac{1}{\Gamma(\Delta_2)}\frac{1}{\Gamma(\Delta_3)}\int_0^\infty \mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3\, t_1^{\Delta_1-1}t_2^{\Delta_2-1}t_3^{\Delta_3-1}\\&\times\int_0^\infty\frac{\mathrm{d}\xi_0}{\xi_0^{d+1}}\xi_0^{\Sigma_i\Delta_i}\int_{S^d}d^d\xi e^{-t_1(\xi_0^2+|\xi-x_1|^2)-t_2(\xi_0^2+|\xi-x_2|^2)-t_3(\xi_0^2+|\xi-x_3|^2)}.\end{aligned} \tag{4.3}$$

We now use the formulas (A2) and (A3) of Appendix A to get

$$\begin{aligned}C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)=&\frac{\pi^{d/2}\Gamma\left(\frac{\Sigma_i\Delta_i-d}{2}\right)}{2\Gamma(\Delta_1)\Gamma(\Delta_2)\Gamma(\Delta_3)}\int_0^\infty \mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3\, t_1^{\Delta_1-1}t_2^{\Delta_2-1}t_3^{\Delta_3-1}\\&\times(S_t)^{-(\Sigma_i\Delta_i)/2}e^{-(1/S_t)(\Sigma_{i<j}t_it_j|x_i-x_j|^2)}.\end{aligned} \tag{4.4}$$

We now make a series of changes of variables of integration. The first change is

$$t_i=(S_t)^{1/2}t_i'=\left(\sum_j t_j'\right)t_i',\quad \det\left(\frac{\partial t_i}{\partial t_j'}\right)=2(S_t)^{3/2}. \tag{4.5}$$

Removing the primes, we get

$$C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)=\frac{\pi^{d/2}\Gamma\left(\frac{\Sigma_i\Delta_i-d}{2}\right)}{\Gamma(\Delta_1)\Gamma(\Delta_2)\Gamma(\Delta_3)}\int_0^\infty \mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3\,t_1^{\Delta_1-1}t_2^{\Delta_2-1}t_3^{\Delta_3-1}e^{-\Sigma_{i<j}t_it_jx_{ij}^2}. \tag{4.6}$$

Here we have introduced

$$x_{ij}=|x_i-x_j|. \tag{4.7}$$

The second change of variables is

$$t_1t_2\to\frac{t_1t_2}{x_{12}^2},\quad t_1t_3\to\frac{t_1t_3}{x_{13}^2},\quad t_2t_3\to\frac{t_2t_3}{x_{23}^2}. \tag{4.8}$$

The integral reduces to

$$\begin{aligned}C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)=&\frac{1}{(x_{12})^{\Delta_1+\Delta_2-\Delta_3}(x_{13})^{\Delta_1+\Delta_3-\Delta_2}(x_{23})^{\Delta_2+\Delta_3-\Delta_1}}\\&\times\frac{\pi^{d/2}\Gamma\left(\frac{\Sigma_i\Delta_i-d}{2}\right)}{\Gamma(\Delta_1)\Gamma(\Delta_2)\Gamma(\Delta_3)}\int_0^\infty \mathrm{d}t_1\,\mathrm{d}t_2\,\mathrm{d}t_3\,t_1^{\Delta_1-1}t_2^{\Delta_2-1}t_3^{\Delta_3-1}e^{-\Sigma_{i<j}t_it_j}.\end{aligned} \tag{4.9}$$

It is now possible to take the remaining integral in Feynman parameters by the following change of variables:

$$t_1t_2=u_3,\quad t_1t_3=u_2,\quad t_2t_3=u_1, \tag{4.10}$$

so that

$$t_1^2=\frac{u_2u_3}{u_1},\quad t_2^2=\frac{u_1u_3}{u_2},\quad t_3^2=\frac{u_1u_2}{u_3},\quad \det\left(\frac{\partial t_i}{\partial u_j}\right)=\frac{1}{2\sqrt{u_1u_2u_3}}. \tag{4.11}$$

The integral over t_i thus reduces to

$$\begin{aligned}&\frac{1}{2}\int_0^\infty \mathrm{d}u_1\,\mathrm{d}u_2\,\mathrm{d}u_3\,u_1^{(\Delta_2+\Delta_3-\Delta_1-2)/2}u_2^{(\Delta_1+\Delta_3-\Delta_2-2)/2}u_3^{(\Delta_1+\Delta_2-\Delta_3-2)/2}e^{-u_1-u_2-u_3}\\&\quad=\frac{1}{2}\Gamma\left(\frac{\Delta_2+\Delta_3-\Delta_1}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_3-\Delta_2}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_2-\Delta_3}{2}\right).\end{aligned} \tag{4.12}$$

Thus, we get for the Clebsch-Gordan coefficients,

$$C_{\Delta_1,\Delta_2,\Delta_3}(x_1,x_2,x_3)=\frac{C(\Delta_1,\Delta_2,\Delta_3)}{(x_{12})^{\Delta_1+\Delta_2-\Delta_3}(x_{13})^{\Delta_1+\Delta_3-\Delta_2}(x_{23})^{\Delta_2+\Delta_3-\Delta_1}}, \tag{4.13}$$

where

$$C(\Delta_1,\Delta_2,\Delta_3)=\frac{\pi^{d/2}\Gamma\left(\frac{\Delta_1+\Delta_2+\Delta_3-d}{2}\right)\Gamma\left(\frac{\Delta_2+\Delta_3-\Delta_1}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_3-\Delta_2}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_2-\Delta_3}{2}\right)}{2\Gamma(\Delta_1)\Gamma(\Delta_2)\Gamma(\Delta_3)}. \tag{4.14}$$

V. NORMALIZATION OF THE CLEBSCH-GORDAN COEFFICIENTS: GAUGE FIXING PROCEDURE

In this section we introduce a certain gauge fixing procedure that is necessary to render the integrals defining the RW coefficient finite. We do this considering as an example the question of normalization of the Clebsch-Gordan coefficient. To this end, let us compute the so-called theta symbol given by

$$\theta(\Delta_1,\Delta_2,\Delta_3)=\int_{H_{d+1}} \mathrm{d}\xi_1\,\mathrm{d}\xi_2\,K_{\Delta_1}(\xi_1,\xi_2)K_{\Delta_2}(\xi_1,\xi_2)K_{\Delta_3}(\xi_1,\xi_2). \tag{5.1}$$

Using the expression for the $3j$-symbol that we have just computed, this becomes

$$\theta(\Delta_1,\Delta_2,\Delta_3)=C(\Delta_1,\Delta_2,\Delta_3)C(\overline{\Delta}_1,\overline{\Delta}_2,\overline{\Delta}_3)\int_{S^d} d^dx_1d^dx_2d^dx_3\frac{1}{d_{12}^dx_{13}^dx_{23}^d}. \tag{5.2}$$

The integral over x_1,x_2,x_3 in (5.2) is divergent. This divergence is a manifestation of the obvious divergence in integrating over H_{d+1} a function that is invariant under the isometries: The integral is proportional to the infinite volume of H_{d+1}. As the volume of H_{d+1} is related to the volume of the Lorentz group, the divergence ultimately comes from the fact that the Lorentz group is noncompact.

In (5.1), the divergence can be removed by fixing one of the integration points and only integrating over the remaining one. To remove the divergence in (5.2), and in similar integrals with more integration points, we can use the action of the conformal group on the sphere to put three of the integration points to specific locations. For $d=2$ this procedure completely fixes the $\mathrm{SO}_0(1,d+1)$ invariance and hence eliminates the divergence.[12] For $d>2$ this procedure fixes the $\mathrm{SO}_0(1,d+1)$ invariance up to the $\mathrm{SO}(d-1)$ subgroup that leaves the three prescribed points invariant, but as this subgroup is compact, the divergence has again been eliminated.

To implement this procedure, one needs to find the Faddeev-Popov determinant that makes the result independent of the locations to which the three integration points are fixed. We shall do this in Appendix B by decomposing the Haar measure on $\mathrm{SO}_0(1,d+1)$ in terms of the locations of the three fixed points and the invariantly normalized volume of the compact subgroup $\mathrm{SO}(d-1)$ (which is trivial for $d=2$). The result is the replacement

$$\prod_i d^dx_i \to |x_A-x_B|^d|x_A-x_C|^d|x_B-x_C|^d\times\delta^d(x_A-x_A^0)\delta^d(x_B-x_B^0)\delta^d(x_C-x_C^0)\prod_i d^dx_i, \tag{5.3}$$

where x_A, x_B, and x_C are the three integration points that are fixed, respectively, to the locations x_A^0, x_B^0, and x_C^0. For $d=2$, formula (5.3) reduces to that found in Ref. 12.

In the divergent integral (5.2), the gauge fixing (5.3) simply removes the integral. This gives for the normalization of the Clebsch-Gordan coefficients the formula

$$\theta(\Delta_1,\Delta_2,\Delta_3)=C(\Delta_1,\Delta_2,\Delta_3)C(\overline{\Delta}_1,\overline{\Delta}_2,\overline{\Delta}_3). \tag{5.4}$$

VI. COMPUTATION OF THE 4-POINT FUNCTION

Using the expression (4.13) for the 3-point function, the 4-point function becomes

$$D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6) = C_{\Delta_1,\Delta_2,\Delta_3} C^{-}_{\Delta_1,\Delta_5,\Delta_6} \int_{S^d} d^d x_1 \frac{1}{(x_{12})^{\Delta_1+\Delta_2-\Delta_3}(x_{13})^{\Delta_1+\Delta_3-\Delta_2}(x_{23})^{\Delta_2+\Delta_3-\Delta_1}} \times \frac{1}{(x_{15})^{\bar{\Delta}_1+\Delta_5-\Delta_6}(x_{16})^{\bar{\Delta}_1+\Delta_6-\Delta_5}(x_{56})^{\Delta_5+\Delta_6-\bar{\Delta}_1}}. \tag{6.1}$$

In addition to the convergence conditions of Sec. IV for each of the 3-point functions, the conditions for the integral in (6.1) to converge are

$$\mathrm{Re}(\Delta_1+\Delta_2-\Delta_3) < d, \quad \mathrm{Re}(\Delta_1+\Delta_3-\Delta_2) < d,$$

$$\mathrm{Re}(\bar{\Delta}_1+\Delta_5-\Delta_6) < d, \quad \mathrm{Re}(\bar{\Delta}_1+\Delta_6-\Delta_5) < d. \tag{6.2}$$

Note that these conditions are satisfied for the type I representations.

We see that only four of the quantities in the denominator involve x_1. In order to take the integral, let us use the Feynman representation for them. In other words, let us consider

$$I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6) = \int_0^\infty \mathrm{d}t_{12}\,\mathrm{d}t_{13}\,\mathrm{d}t_{15}\,\mathrm{d}t_{16} \times t_{12}^{[(\Delta_1+\Delta_2-\Delta_3)/2]-1} t_{13}^{[(\Delta_1+\Delta_3-\Delta_2)/2]-1} t_{15}^{[(\bar{\Delta}_1+\Delta_5-\Delta_6)/2]-1} t_{16}^{[(\bar{\Delta}_1+\Delta_6-\Delta_5)/2]-1} \times \int_{S^d} d^d x_1 e^{-t_{12}x_{12}^2 - t_{13}x_{13}^2 - t_{15}x_{15}^2 - t_{16}x_{16}^2}. \tag{6.3}$$

In terms of this function

$$D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6) = \frac{I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)}{(x_{23})^{\Delta_2+\Delta_3-\Delta_1}(x_{56})^{\Delta_5+\Delta_6-\bar{\Delta}_1}} \times \frac{C_{\Delta_1,\Delta_2,\Delta_3} C^{-}_{\Delta_1,\Delta_5,\Delta_6}}{\Gamma\left(\frac{\Delta_1+\Delta_2-\Delta_3}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_3-\Delta_2}{2}\right)\Gamma\left(\frac{\bar{\Delta}_1+\Delta_5-\Delta_6}{2}\right)\Gamma\left(\frac{\bar{\Delta}_1+\Delta_6-\Delta_5}{2}\right)}. \tag{6.4}$$

Let us now evaluate the function (6.3). The integral over x_1 is taken using (A3)

$$\int_{S^d} d^d x_1 e^{-t_{12}x_{12}^2 - t_{13}x_{13}^2 - t_{15}x_{15}^2 - t_{16}x_{16}^2} = \frac{\pi^{d/2}}{(S_t^1)^{d/2}} e^{-(t_{12}t_{13}x_{23}^2 + t_{12}t_{15}x_{25}^2 + t_{12}t_{16}x_{26}^2 + t_{13}t_{15}x_{35}^2 + t_{13}t_{16}x_{36}^2 + t_{15}t_{16}x_{56}^2)/S_t^1}, \tag{6.5}$$

where

$$S_t^1 = t_{12} + t_{13} + t_{15} + t_{16}. \tag{6.6}$$

Let us now make a series of changes of variables. First, let us choose

$$t_{1i} = (S_t^1)^{1/2} t'_{1i}, \quad \det\left(\frac{\partial t_{1i}}{\partial t'_{1i}}\right) = 2(S_t^1)^2. \tag{6.7}$$

After this change of variables we get

$$I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6) = 2\pi^{d/2}\int_0^\infty \mathrm{d}t_{12}\,\mathrm{d}t_{13}\,\mathrm{d}t_{15}\,\mathrm{d}t_{16}$$
$$\times t_{12}^{[(\Delta_1+\Delta_2-\Delta_3)/2]-1} t_{13}^{[(\Delta_1+\Delta_3-\Delta_2)/2]-1} t_{15}^{[(\bar{\Delta}_1+\Delta_5-\Delta_6)/2]-1} t_{16}^{[(\bar{\Delta}_1+\Delta_6-\Delta_5)/2]-1}$$
$$\times e^{-t_{12}t_{13}x_{23}^2-t_{12}t_{15}x_{25}^2-t_{12}t_{16}x_{26}^2-t_{13}t_{15}x_{35}^2-t_{13}t_{16}x_{36}^2-t_{15}t_{16}x_{56}^2}. \tag{6.8}$$

The second change of variables is

$$t_{12}t_{13}\to\frac{t_{12}t_{13}}{x_{23}^2},\quad t_{12}t_{15}\to\frac{t_{12}t_{15}}{x_{25}^2},\quad t_{12}t_{16}\to\frac{t_{12}t_{16}}{x_{26}^2},\quad t_{13}t_{15}\to\frac{t_{13}t_{15}}{x_{35}^2}. \tag{6.9}$$

As a consequence we get

$$t_{13}t_{16}=\frac{t_{13}t_{15}t_{12}t_{16}}{t_{12}t_{15}}\to\frac{x_{25}^2}{x_{35}^2x_{26}^2}t_{13}t_{16},\quad t_{15}t_{16}=\frac{t_{13}t_{15}t_{12}t_{16}}{t_{12}t_{13}}\to\frac{x_{23}^2}{x_{35}^2x_{26}^2}t_{15}t_{16}. \tag{6.10}$$

Or, equivalently,

$$t_{12}\to t_{12}\frac{x_{35}}{x_{23}x_{25}},\quad t_{13}\to t_{13}\frac{x_{25}}{x_{23}x_{35}},\quad t_{15}\to t_{15}\frac{x_{23}}{x_{25}x_{35}},\quad t_{16}\to t_{16}\frac{x_{25}x_{23}}{x_{26}^2x_{35}}. \tag{6.11}$$

As the result of this transformation we get

$$I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)=\frac{2\pi^{d/2}}{(x_{23})^{\Delta_1-\bar{\Delta}_1}(x_{25})^{\Delta_2-\Delta_3+\Delta_5-\Delta_6}(x_{26})^{\bar{\Delta}_1+\Delta_6-\Delta_5}(x_{35})^{\bar{\Delta}_1+\Delta_3-\Delta_2}}$$
$$\times\int_0^\infty \mathrm{d}t_{12}\,\mathrm{d}t_{13}\,\mathrm{d}t_{15}\,\mathrm{d}t_{16}\,e^{-t_{12}t_{13}-t_{12}t_{15}-t_{12}t_{16}-t_{13}t_{15}-t_{13}t_{16}u-t_{15}t_{16}v}$$
$$\times t_{12}^{[(\Delta_1+\Delta_2-\Delta_3)/2]-1} t_{13}^{[(\Delta_1+\Delta_3-\Delta_2)/2]-1} t_{15}^{[(\bar{\Delta}_1+\Delta_5-\Delta_6)/2]-1} t_{16}^{[(\bar{\Delta}_1+\Delta_6-\Delta_5)/2]-1}. \tag{6.12}$$

Here we have introduced the cross ratios,

$$u=\frac{x_{25}^2x_{36}^2}{x_{26}^2x_{35}^2},\quad v=\frac{x_{23}^2x_{56}^2}{x_{26}^2x_{35}^2}. \tag{6.13}$$

The two cross ratios are related for $d=2$ but independent for $d>2$.

We now specialize to the type I representations.

To compute the integrals over the Feynman parameters we, following an analogous computation in Ref. 13, use the Mellin-Barnes integral representation:

$$e^{-z}=\frac{1}{2\pi i}\int_{r-i\infty}^{r+i\infty}\mathrm{d}s\,\Gamma(-s)z^s,\quad r<0,\quad |\arg z|<\frac{\pi}{2}. \tag{6.14}$$

Thus, the integral over Feynman parameters becomes

$$\frac{1}{2}I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(u,v) := \int\frac{\mathrm{d}\lambda\,\mathrm{d}s}{(2\pi i)^2}\Gamma(-\lambda)\Gamma(-s)u^sv^\lambda\int_0^\infty \mathrm{d}t_{12}\,\mathrm{d}t_{13}\,\mathrm{d}t_{15}\,\mathrm{d}t_{16}\,e^{-t_{12}t_{13}-t_{12}t_{15}-t_{12}t_{16}-t_{13}t_{15}}$$
$$\times t_{12}^{[(\Delta_1+\Delta_2-\Delta_3)/2]-1} t_{13}^{[(\Delta_1+\Delta_3-\Delta_2)/2]+s-1} t_{15}^{[(\bar{\Delta}_1+\Delta_5-\Delta_6)/2]+\lambda-1} t_{16}^{[(\bar{\Delta}_1+\Delta_6-\Delta_5)/2]+s+\lambda-1}. \tag{6.15}$$

To justify the interchange of integrals that has led to (6.15), we assume that the parameter r in the

two Mellin-Barnes contours is the same and satisfies $-d/8<r<0$. This guarantees that the exponent of each t_{ij} in (6.15) has real part greater than -1.

In the Feynman parameter integrals, we change variables by

$$t_{12}t_{13}=u_1, \quad t_{12}t_{15}=u_2, \quad t_{12}t_{16}=u_3, \quad t_{13}t_{15}=u_4, \tag{6.16}$$

or, equivalently,

$$t_{12}^2=\frac{u_1u_2}{u_4}, \quad t_{13}^2=\frac{u_1u_4}{u_2}, \quad t_{15}^2=\frac{u_2u_4}{u_1}, \quad t_{16}^2=u_3^2\frac{u_4}{u_1u_2}. \tag{6.17}$$

The Jacobian of this transformation is

$$\det\left(\frac{\partial t_{1i}}{\partial u_j}\right)=\frac{1}{2u_1u_2}. \tag{6.18}$$

Therefore, we get

$$I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(u,v)=\int\frac{\mathrm{d}\lambda\,\mathrm{d}s}{(2\pi i)^2}\Gamma(-\lambda)\Gamma(-s)u^sv^\lambda\Gamma(\alpha+s+\lambda)\Gamma(\beta+s+\lambda)\Gamma(\gamma-s)\Gamma(\delta-\lambda), \tag{6.19}$$

where we have introduced the following quantities:

$$\begin{aligned}\alpha&=\frac{\overline{\Delta_1}+\Delta_3-\Delta_2}{2},\\ \beta&=\frac{\overline{\Delta_1}+\Delta_6-\Delta_5}{2},\\ \gamma&=\frac{\Delta_2-\Delta_3+\Delta_5-\Delta_6}{2},\\ \delta&=\frac{\Delta_1-\overline{\Delta_1}}{2}.\end{aligned} \tag{6.20}$$

Combining this, and the expressions (6.12) and (6.4), we have for the 4-point function,

$$\begin{aligned}D_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(x_2,x_3,x_5,x_6)&=K_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}\frac{I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(u,v)}{(x_{25})^{\Delta_2-\Delta_3+\Delta_5-\Delta_6}}\\ &\times\frac{1}{(x_{23})^{\Delta_2+\Delta_3-\overline{\Delta_1}}(x_{26})^{\overline{\Delta_1}+\Delta_6-\Delta_5}(x_{35})^{\overline{\Delta_1}+\Delta_3-\Delta_2}(x_{56})^{\Delta_5+\Delta_6-\overline{\Delta_1}}},\end{aligned} \tag{6.21}$$

where we have introduced

$$K_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}=\frac{\pi^{d/2}C_{\Delta_1,\Delta_2,\Delta_3}C_{\bar{\Delta}_1,\Delta_5,\Delta_6}}{\Gamma\left(\frac{\Delta_1+\Delta_2-\Delta_3}{2}\right)\Gamma\left(\frac{\Delta_1+\Delta_3-\Delta_2}{2}\right)\Gamma\left(\frac{\bar{\Delta}_1+\Delta_5-\Delta_6}{2}\right)\Gamma\left(\frac{\bar{\Delta}_1+\Delta_6-\Delta_5}{2}\right)}. \tag{6.22}$$

Thus, essentially all nontriviality of the 4-point function is in the dependence of the function $I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(u,v)$ given by (6.19) on the two cross ratios u,v. The integral representation (6.19) that we have obtained may be used to derive power series expansions of $I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(u,v)$ in u and v.[13]

VII. COMPUTATION OF THE RACAH-WIGNER COEFFICIENTS

Having obtained the 4-point function we can use this result to compute the RW coefficients. Recalling (3.9), we get

$$\begin{aligned}(6\Delta)=&K_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}K_{\Delta_4,\bar{\Delta}_2,\bar{\Delta}_3,\bar{\Delta}_5,\bar{\Delta}_6}\int_{S^d}\frac{d^dx_2d^dx_3d^dx_5d^dx_6}{x_{23}^dx_{26}^dx_{35}^dx_{56}^d}\\&\times\left(\frac{1}{v}\right)^{(\Delta_1-\Delta_4+\Delta_2+\Delta_5-d)/2}I_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6}(u,v)I_{\Delta_4,\bar{\Delta}_2,\bar{\Delta}_6,\bar{\Delta}_5,\bar{\Delta}_3}(u/v,1/v).\end{aligned} \tag{7.1}$$

Here we have used the fact that under the exchange of x_3, x_6 we have $v\to 1/v$, $u\to u/v$. We have also used the relation (1.2) between the conformal dimension and its dual and combined all powers of x_{ij}. Note that the integration measure in (7.1) is exactly right to give an invariant expression, as this measure can be verified to be invariant under conformal transformations of the x_i.

What remains is to compute the sphere integrals in (7.1). This integral is

$$I_d(a,b)=\int_{S^d}\frac{\mathrm{d}x_2\,\mathrm{d}x_3\,\mathrm{d}x_5\,\mathrm{d}x_6}{x_{23}^dx_{56}^dx_{26}^dx_{35}^d}\left(\frac{x_{23}x_{56}}{x_{26}x_{35}}\right)^{2a}\left(\frac{x_{25}x_{36}}{x_{26}x_{35}}\right)^{2b}, \tag{7.2}$$

where

$$a=-A+\lambda-s'-\lambda',\quad b=s+s',\quad A=\frac{\Delta_1-\Delta_4+\Delta_2+\Delta_5-d}{2}. \tag{7.3}$$

As it stands, the integral (7.2) still diverges because of the volume of the gauge group. We eliminate this divergence by the replacement (5.3), leaving x_2 to be integrated over but fixing the locations of the other three points. The integral becomes

$$I_d(a,b)=|x_3^0-x_6^0|^d\left|\frac{x_5^0-x_6^0}{x_3^0-x_5^0}\right|^{2a}\left|\frac{x_3^0-x_6^0}{x_3^0-x_5^0}\right|^{2b}\widetilde{I}_d(a,b), \tag{7.4}$$

where

$$\widetilde{I}_d(a,b)=\int_{S^d}\mathrm{d}x_2\frac{|x_2-x_3^0|^{2a-d}|x_2-x_5^0|^{2b}}{|x_2-x_6^0|^{2a+2b+d}}. \tag{7.5}$$

The convergence conditions in (7.5) are

$$\mathrm{Re}(a)>0,\quad \mathrm{Re}(b+d/2)>0,\quad \mathrm{Re}(a+b)<0, \tag{7.6}$$

and they are satisfied for our Mellin-Barnes contour choice, $-d/8<r<0$.

To compute the integral over x_2 we use the Feynman parametrization. We have

$$\widetilde{I}_d(a,b) = \frac{1}{\Gamma(d/2-a)\Gamma(-b)\Gamma(a+b+d/2)} \int_{S^d} dx_2 t_3^{d/2-a-1} t_5^{-b-1} t_6^{a+b+d/2-1} \times e^{-t_3|x_2-x_3^0|^2 - t_5|x_2-x_5^0|^2 - t_6|x_2-x_6^0|^2}. \tag{7.7}$$

We have already dealt with essentially the same integral in Sec. IV, formula (4.3). Thus, we shall be sketchy here. One first takes the x_2 integral using (A3). One then makes a series of rescalings of Feynman parameters t_i. The powers of these parameters in (7.7) are such that the rescaling (4.5) completely removes the quantity S_t from the integral. Rescaling (4.8) takes the differences $|x_i^0 - x_j^0|$ out of the integral, and their resulting powers are exactly such that they cancel the similar quantities in (7.4). The last change of variables (4.10) reduces all the integrals to those giving Γ-functions. The final result is

$$I_d(a,b) = \frac{\pi^{d/2}\Gamma(a)\Gamma(d/2+b)\Gamma(-a-b)}{\Gamma(d/2-a)\Gamma(-b)\Gamma(a+b+d/2)} = \frac{\pi^{d/2}\Upsilon_d(a)\Upsilon_d(-a-b)}{\Upsilon_d(-b)}, \tag{7.8}$$

where we have introduced a dimension-dependent Υ-function given by

$$\Upsilon_d(x) = \frac{\Gamma(x)}{\Gamma(d/2-x)}. \tag{7.9}$$

Substituting the values (7.3) of the parameters a and b, our final result for the (6Δ) symbol is

$$\begin{aligned}(6\Delta) = K_{\Delta_1,\Delta_2,\Delta_3,\Delta_5,\Delta_6} K_{\Delta_4,\bar{\Delta}_2,\bar{\Delta}_3,\bar{\Delta}_5,\bar{\Delta}_6} \times \pi^{d/2} \int \frac{\mathrm{d}\lambda\, \mathrm{d}s}{(2\pi i)^2} \int \frac{\mathrm{d}\lambda'\, \mathrm{d}s'}{(2\pi i)^2} \Gamma(-s)\Gamma(-\lambda)\Gamma(-s')\Gamma(-\lambda') \\ \times \Gamma(\gamma-s)\Gamma(\delta-\lambda)\Gamma(\alpha+s+\lambda)\Gamma(\beta+s+\lambda)\Gamma(\gamma'-s')\Gamma(\delta'-\lambda')\Gamma(\alpha'+s'+\lambda') \\ \times \Gamma(\beta'+s'+\lambda') \frac{\Upsilon_d(\lambda-s'-\lambda'-A)\Upsilon_d(\lambda'-s-\lambda+A)}{\Upsilon_d(-s-s')}.\end{aligned} \tag{7.10}$$

Using Stirling's formula and the assumption $-d/8 < r < 0$ for the Mellin-Barnes contours, it can be verified that the quadruple integral in (7.10) is convergent in absolute value. Equation (7.10) therefore gives a manifestly well-defined expression for the (6Δ) symbol.

APPENDIX A: INTEGRALS

In this appendix we give the formulas that are central to the methods of integration that we use. The same method was exploited in the context of AdS/CFT correspondence, see e.g., Ref. 13. The standard Feynman parameter method is based on the following representation:

$$\frac{1}{z^\lambda} = \frac{1}{\Gamma(\lambda)} \int_0^\infty \mathrm{d}t\, t^{\lambda-1} e^{-tz}. \tag{A1}$$

We shall also need the following two integrals:

$$\int_0^\infty \frac{\mathrm{d}\xi_0}{\xi_0^{d+1}} \xi_0^{\Sigma_i \Delta_i} e^{-\Sigma_i t_i \xi_0^2} = \frac{1}{2} (S_t)^{(d-\Sigma_i\Delta_i)/2} \Gamma\left(\frac{\sum_i \Delta_i - d}{2}\right) \tag{A2}$$

and

$$\int_{S^d} d^d x e^{-\Sigma_i t_i |x - x_i|^2} = \frac{\pi^{d/2}}{S_t^{d/2}} e^{-(1/S_t)(\Sigma_{i<j} t_i t_j |x_i - x_j|^2)}. \tag{A3}$$

In both of these formulas,

$$S_t = \sum_i t_i. \tag{A4}$$

APPENDIX B: GAUGE-FIXED INTEGRATION MEASURE

In this appendix we verify that the gauge-fixing procedure (5.3) results from decomposing the Haar measure on $\mathrm{SO}_0(1,d+1)$ as stated in Sec. V. We assume $d>1$ as in the main text.

1. Notation

We first recall some basic properties of the conformal group.[10]

We view $\mathrm{SO}_0(1,d+1)$ as the matrix group in its defining representation, acting on $\mathbb{R}^{1,d+1}$ by matrix multiplication of a column vector. We write the points in $\mathbb{R}^{1,d+1}$ as $(t,y,z^1,\ldots,z^d) =: (t,y,z)$, where z is in $\mathbb{R}^d$.

The action of $\mathrm{SO}_0(1,d+1)$ as the conformal group on $\mathbb{R}^d \cup \{\infty\}$ is obtained from that on the future null cone in $\mathbb{R}^{1,d+1}$, $t=\sqrt{y^2+z^2}$, by parameterizing the cone as $(t,y,z)=s\left(\frac{1}{2}(1+x^2), \frac{1}{2}(1-x^2), x\right)$, where $s \geqslant 0$ and $x \in \mathbb{R}^d \cup \{\infty\}$. The point $x=\infty$ corresponds to the null ray $t+y=0=z$.

If $q \in \mathbb{R}^d$ and $\lambda > 0$, we define the $\mathrm{SO}_0(1,d+1)$ matrices

$$N_+(q) := \begin{pmatrix} 1+\frac{1}{2}q^2 & \frac{1}{2}q^2 & q^T \\ -\frac{1}{2}q^2 & 1-\frac{1}{2}q^2 & -q^T \\ q & q & \mathbb{I}_d \end{pmatrix}, \tag{B1}$$

$$N_-(q) := \begin{pmatrix} 1+\frac{1}{2}q^2 & -\frac{1}{2}q^2 & q^T \\ \frac{1}{2}q^2 & 1-\frac{1}{2}q^2 & q^T \\ q & -q & \mathbb{I}_d \end{pmatrix}, \tag{B2}$$

$$A(\lambda) := \begin{pmatrix} \frac{1}{2}(\lambda^{-1}+\lambda) & \frac{1}{2}(\lambda^{-1}-\lambda) & 0 \\ \frac{1}{2}(\lambda^{-1}-\lambda) & \frac{1}{2}(\lambda^{-1}+\lambda) & 0 \\ 0 & 0 & \mathbb{I}_d \end{pmatrix}, \tag{B3}$$

where q is viewed as a column vector and $\mathbb{I}_d$ is the $d \times d$ unit matrix. In terms of the action on $\mathbb{R}^{1,d+1}$, $N_\pm(q)$ are null rotations and $A(\lambda)$ is a boost. The conformal action of $N_+(q)$ on $\mathbb{R}^d$ is the translation $x \mapsto x+q$, the action of $N_-(q)$ is the proper conformal transformation $x/(x^2) \mapsto x/(x^2)+q$, and the action of $A(\lambda)$ is the dilatation $x \mapsto \lambda x$.

Finally, if u and v are two unit vectors in $\mathbb{R}^d$, $u \neq -v$, we define the $\mathrm{SO}(d)$ matrix

$$\widetilde{S}(v,u) := \mathbb{I}_d + 2v \otimes u^T - \frac{(u+v) \otimes (u+v)^T}{1+u \cdot v}. \tag{B4}$$

$\widetilde{S}(v,u)$ is a rotation in the plane of u and v and takes u to v, reducing to $\mathbb{I}_d$ when $u=v$. Given $\widetilde{S}(v,u)$, we define the corresponding block-diagonal $\mathrm{SO}_0(1,d+1)$ matrix by $S(v,u) := \mathrm{diag}(\mathbb{I}_2, \widetilde{S}(v,u))$.

2. Parametrization

Let x_A, x_B, and x_C be three distinct points in $\mathbb{R}^d$. We set

$$x_D := \frac{x_{AB}^2 x_{AC}^2}{x_{BC}^2}\left(\frac{x_B - x_A}{x_{AB}^2} - \frac{x_C - x_A}{x_{AC}^2}\right), \tag{B5}$$

where $x_{ij} := |x_i - x_j|$ as in the main text. As $|x_D| = x_{AB} x_{AC} x_{BC}^{-1}$, it follows that $x_D \neq 0$.

Let v be a unit vector in $\mathbb{R}^d$. When $x_D/|x_D| \neq -v$, we define

$$h(x_A,x_B,x_C) := S(v, x_D/|x_D|) A(1/|x_D|) N_-(b) N_+(a), \tag{B6}$$

where $a := -x_A$ and $b := x_{AC}^{-2}(x_A - x_C)$. A direct computation shows that the conformal action of h takes the triple (x_A,x_B,x_C) to the triple $(0,v,\infty)$. Each $\mathrm{SO}_0(1,d+1)$ matrix g whose conformal action takes (x_A,x_B,x_C) to $(0,v,\infty)$ can therefore be uniquely written as

$$g = Rh, \tag{B7}$$

where $R = \mathrm{diag}(\mathbb{I}_2, \widetilde{R})$ and $\widetilde{R}$ is an $\mathrm{SO}(d)$ matrix in the $\mathrm{SO}(d-1)$ subgroup that fixes v. Note that this subgroup is trivial for $d=2$ but nontrivial for $d>2$.

If v is considered fixed, the above discussion shows that formulas (B6) and (B7) give a unique parameterization of an open subset in $\mathrm{SO}_0(1,d+1)$ by the triple (x_A,x_B,x_C) and a group isomorphic to $\mathrm{SO}(d-1)$. This parametrization does not cover all of $\mathrm{SO}_0(1,d+1)$, but the missing subset is of measure zero and can be recovered by choosing a different v and by limits in which one of x_A, x_B, and x_C is taken to infinity.

Now, the right action of $\mathrm{SO}_0(1,d+1)$ on (B7) induces on the triple (x_A,x_B,x_C) the conformal $\mathrm{SO}_0(1,d+1)$ action of the main text. To eliminate the volume divergence of the main text, we therefore need to write the Haar measure on $\mathrm{SO}_0(1,d+1)$ in the decomposition (B7) and identify the part of the measure that is associated with the noncompact factor h. If this measure is $\mu(x_A,x_B,x_C)\, d^d x_A d^d x_B d^d x_C$, the divergence will be eliminated by the replacement

$$d^d x_A d^d x_B d^d x_C \to \frac{\delta^d(x_A - x_A^0)\,\delta^d(x_B - x_B^0)\,\delta^d(x_C - x_C^0)}{\mu(x_A,x_B,x_C)} d^d x_A d^d x_B d^d x_C, \tag{B8}$$

where the distinct points x_A^0, x_B^0, and x_C^0 can be chosen arbitrarily.

3. Measure computation

From (B6) and (B7) we find

$$(AR)^{-1}(\mathrm{d}g\, g^{-1})(AR) = R^{-1}\,\mathrm{d}R + \mathrm{d}S\, S^{-1} + SQS^{-1}, \tag{B9}$$

where

$$
\begin{aligned}
Q = (|x_D|^{-1} d(|x_D|) + 2b \cdot \mathrm{d}a) &\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \\
&+ \begin{pmatrix} 0 & 0 & (1+b^2)\mathrm{d}a^T - 2(b\cdot \mathrm{d}a)b^T + \mathrm{d}b^T \\ 0 & 0 & 0 \\ (1+b^2)\mathrm{d}a - 2(b\cdot \mathrm{d}a)b + \mathrm{d}b & 0 & 0 \end{pmatrix} \\
&+ \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & (1-b^2)\mathrm{d}a^T + 2(b\cdot \mathrm{d}a)b^T - \mathrm{d}b^T \\ 0 & (1-b^2)\mathrm{d}a + 2(b\cdot \mathrm{d}a)b - \mathrm{d}b & 0 \end{pmatrix} \\
&+ \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 2(b\otimes \mathrm{d}a^T - \mathrm{d}a \otimes b^T) \end{pmatrix}. \qquad \text{(B10)}
\end{aligned}
$$

The explicit form of the term $\mathrm{d}S\, S^{-1}$ can be found from (B4).

To find the part of the Haar measure that corresponds to the noncompact factor h, we project the right-hand side of (B9) to the subspace orthogonal (with respect to the Killing form) to the subspace generated by $R^{-1}\,\mathrm{d}R$. Choosing v for concreteness to be (1,0,0,…), this amounts to setting the lower-right $(d-1)\times(d-1)$ block to zero but leaving the other components unchanged. From the coefficients of the remaining $3d$ Lie algebra elements we can then identify the $3d \times 3d$ determinant that gives the desired measure. Evaluating the determinant by elementary matrix algebra techniques, we find that this measure is

$$
\frac{d^d x_A d^d x_B d^d x_C}{|x_A - x_B|^d |x_B - x_C|^d |x_C - x_A|^d}. \qquad \text{(B11)}
$$

Hence the gauge fixing procedure (5.3) follows.

As a check, it can be directly verified that the measure (B11) is invariant under the conformal action of $\mathrm{SO}_0(1,d+1)$.

(Received 7 November 2005; accepted 1 February 2006; published online 31 March 2006)

We study a general class of line-soliton solutions of the Kadomtsev-Petviashvili II (KPII) equation by investigating the Wronskian form of its tau-function. We show that, in addition to the previously known line soliton solutions of KPII, this class also contains a large variety of multisoliton solutions, many of which exhibit nontrivial spatial interaction patterns. We also show that, in general, such solutions consist of unequal numbers of incoming and outgoing line solitons. From the asymptotic analysis of the tau function, we explicitly characterize the incoming and outgoing line solitons of this class of solutions. We illustrate these results by discussing several examples. © *2006 American Institute of Physics.*

I. INTRODUCTION

The Kadomtsev-Petviashvili (KP) equation

$$\frac{\partial}{\partial x}\left(-4\frac{\partial u}{\partial t}+\frac{\partial^3 u}{\partial x^3}+6u\frac{\partial u}{\partial x}\right)+3\sigma^2\frac{\partial^2 u}{\partial y^2}=0, \tag{1.1}$$

where $u=u(x,y,t)$ and $\sigma^2=\pm 1$, is one of the prototypical $(2+1)$-dimensional integrable nonlinear partial differential equations. The case $\sigma^2=-1$ is known as the KPI equation, and $\sigma^2=1$ as the KPII equation. Originally derived[11] as a model for small-amplitude, long-wavelength, weakly two-dimensional (y-variation much slower than the x-variation) solitary waves in a weakly dispersive medium, the KP equation arises in disparate physical settings including water waves and plasmas, astrophysics, cosmology, optics, magnetics, anisotropic two-dimensional lattices, and Bose-Einstein condensation. The remarkably rich mathematical structure underlying the KP equation, its integrability and large classes of exact solutions have been studied extensively for the past 30 years, and are documented in several monographs.[1,3,8,15,18,21]

In this paper we study a large class of solitary wave solutions of the KPII equation. It is well known (e.g., see Refs. 5 and 15) that solutions of the KPII equation can be expressed as

$$u(x,y,t)=2\frac{\partial^2}{\partial x^2}\ln\tau(x,y,t), \tag{1.2}$$

where the tau function $\tau(x,y,t)$ is given in terms of the Wronskian determinant[7,15]

[a)]Electronic mail: biondini@buffalo.edu
[b)]Electronic mail: chuck@math.uccs.edu

$$\tau(x,y,t) = \mathrm{Wr}(f_1, \ldots, f_N) = \det\begin{pmatrix} f_1 & f_2 & \cdots & f_N \\ f_1' & f_2' & \cdots & f_N' \\ \vdots & \vdots & & \vdots \\ f_1^{(N-1)} & f_2^{(N-1)} & \cdots & f_N^{(N-1)} \end{pmatrix}. \tag{1.3}$$

with $f^{(i)} = \partial^i f / \partial x^i$, and where the functions $f_1, \ldots, f_N$ are a set of linearly independent solutions of the linear system

$$\frac{\partial f}{\partial y} = \frac{\partial^2 f}{\partial x^2}, \quad \frac{\partial f}{\partial t} = \frac{\partial^3 f}{\partial x^3}. \tag{1.4}$$

Equations (1.2) and (1.3) can also be obtained as the N-fold Darboux transformation for KPII (Ref. 15) starting from a seed solution $u=0$. In fact, the functions $f_1, \ldots, f_N$ in Eqs. (1.3) are precisely N independent solutions of the KPII Lax pair: $\partial_y f - \partial_x^2 f + uf = 0$ and $\partial_t f - \partial_x^3 f + 6u(\partial_x u)f + 3(\partial_x^{-1}\partial_y u)f = 0$, with $u=0$. A one-soliton solution of the KPII equation is obtained by choosing $N=1$ and $f(x,y,t) = e^{\theta_1} + e^{\theta_2}$, where

$$\theta_m(x,y,t) = k_m x + k_m^2 y + k_m^3 t + \theta_{m,0} \tag{1.5}$$

with $k_m, \theta_{m,0} \in \mathbb{R}$, $m=1,2$ and with $k_1 \neq k_2$ for nontrivial solutions. Without loss of generality, one can order the parameters as $k_1 < k_2$. The above choice yields the following traveling-wave solution:

$$u(x,y,t) = \tfrac{1}{2}(k_2 - k_1)^2 \operatorname{sech}^2 \tfrac{1}{2}(\theta_2 - \theta_1) = \Phi(\mathbf{k}\cdot\mathbf{x} + \omega t), \tag{1.6}$$

where $\mathbf{x} = (x,y)$. The wave-vector $\mathbf{k} = (l_x, l_y)$ and the frequency ω are given by

$$\mathbf{k} = (k_1 - k_2, k_1^2 - k_2^2), \quad \omega = k_1^3 - k_2^3, \tag{1.7}$$

and they satisfy the nonlinear dispersion relation

$$-4\omega l_x + l_x^4 + 3l_y^2 = 0. \tag{1.8}$$

The solution in Eq. (1.6) is localized along points satisfying $\theta_1 = \theta_2$, which defines a line in the xy plane, for fixed t. Such solitary wave solutions of the KPII equation are thus called *line solitons*. They are stable with respect to transverse perturbations unlike the KPI [Eq. (1.1) with $\sigma^2 = -1$] line-soliton solutions which are not stable with respect to small transverse perturbations. Equation (1.6) also implies that, apart from the constant $\theta_{1,0} - \theta_{2,0}$ corresponding to an overall translation of the solution, a line soliton of KPII is characterized by either the phase parameters k_1, k_2, or the physical parameters, namely, the *soliton amplitude* a and the *soliton direction* c, defined, respectively, as

$$a = k_2 - k_1, \quad c = k_1 + k_2. \tag{1.9}$$

Note that $c = \tan\alpha$, where α is the angle, measured counterclockwise, between the line soliton and the positive y axis. Hence, the soliton direction c can also be viewed as the "velocity" of the soliton in the xy plane, $c = -\mathrm{d}x/\mathrm{d}y = l_y/l_x$. For any given choice of amplitude and direction of the soliton, one obtains the phase parameters $k_{1,2}$ uniquely as $k_1 = \frac{1}{2}(c-a)$ and $k_2 = \frac{1}{2}(c+a)$.

When $c=0$ (equivalently, $k_1 = -k_2$), the solution in Eq. (1.6) becomes y-independent and reduces to the one-soliton solution of the Korteweg-de Vries (KdV) equation. Similar to KdV, it is also possible to obtain multisoliton solutions of the KPII equation. Each of the multisoliton solutions decay exponentially in the xy plane, except along a number of rays or line solitons as $y \to \pm\infty$. These line solitons are sorted according to their directions, with increasing values of c from left to right as $y \to -\infty$ and increasing values of c from right to left as $y \to \infty$. However, the multisoliton solution space of the KPII equation turns out to be much richer than that of the $(1+1)$-dimensional KdV equation due to the dependence of the KPII solutions on the additional

spatial variable y. It is possible to construct a general family of multisoliton solutions via the Wronskian of Eq. (1.3) by choosing M phases $\theta_1,\ldots,\theta_M$ defined as in Eq. (1.5) with distinct real *phase parameters* $k_1<k_2<\cdots<k_M$ and then defining the functions $f_1,\ldots,f_N$ in Eq. (1.3) by

$$f_n(x,y,t)=\sum_{m=1}^{M} a_{n,m}e^{\theta_m},\quad n=1,2,\ldots,N. \tag{1.10}$$

The constant coefficients $a_{n,m}$ define the $N\times M$ *coefficient matrix* $A:=(a_{n,m})$, which is required to be of full rank [i.e., rank$(A)=N$] and all of whose nonzero $N\times N$ minors must be sign definite. The full rank condition is necessary and sufficient for the functions f_n in Eq. (1.10) to be linearly independent. The sign definiteness of the nonzero minors is sufficient to ensure that the tau function $\tau(x,y,t)$ has no zeros in the xy plane for all t, so that the KPII solution $u(x,y,t)$ resulting from Eq. (1.2) is nonsingular.

One of the main results of this work (cf. Theorem 3.6) is to show that, when the coefficient matrix A satisfies certain conditions (cf. Definition 2.2), Eq. (1.10) leads to a multisoliton configuration with N_- asymptotic line solitons as $y\to-\infty$ and N_+ asymptotic line solitons as $y\to\infty$, where $N_-=M-N$ and $N_+=N$. Furthermore, each of the asymptotic line solitons has the form of a plane wave similar to the one-soliton solution in Eq. (1.6). We refer to these multisoliton configurations the (N_-,N_+)-*soliton solutions* of KPII, and call the asymptotic line solitons as $y\to-\infty$ and as $y\to\infty$ the *incoming* and *outgoing* line solitons, respectively. The amplitudes, directions and even the number of incoming solitons are in general different from those of the outgoing ones, depending on the values of M,N, the phase parameters $k_1,\ldots,k_M$ and the coefficient matrix A. We note that a special family of KPII (N_-,N_+)-soliton solutions which also satisfy the finite Toda lattice hierarchy, was found earlier in Ref. 2. In this paper, we generalize the results of Ref. 2 to the entire class of (N_-,N_+)-soliton solutions of KPII generated by arbitrary coefficient matrices A. These solutions exhibit a variety of spatial interaction patterns which include the formation of intermediate line solitons and web structures in the xy plane.[2,12,16,23] In contrast, the line solitons for the previously known[5,15,24] *ordinary* soliton solutions of KPII (cf. Sec. IV) and the KdV solitons experience only a phase shift after collision. The existence of these nontrivial spatial features was found to be related to the presence of *resonant* soliton interactions in some earlier studies.[4,17,19,22] Several examples of these (N_-,N_+)-soliton solutions of KPII are discussed throughout this work (e.g., see Figs. 1–4). If $M=2N$, it follows from Theorem 3.6 that $N_-=N_+=N$, i.e., the numbers incoming and outgoing asymptotic line solitons are the same. We call the resulting solutions the *N-soliton solutions* of KPII. Among these, there is an important subclass called the *elastic N*-soliton solutions, for which the amplitudes and directions of the out-going line solitons coincide with those of the incoming line solitons. Elastic N-soliton solutions possess a number of interesting features, some of which have been studied in Ref. 12. A detailed study of the specific properties of the elastic N-solutions will be reported in a future presentation.

We note that multisoliton solutions exhibiting nontrivial spatial structures and interaction patterns were also recently found in other $(2+1)$-dimensional integrable equations. For example, solutions with soliton resonance and web structure were presented in Refs. 9 and 10 for a coupled KP system, and similar solutions were also found in Ref. 14 in discrete soliton systems such as the two-dimensional Toda lattice, together with its fully discrete and ultradiscrete analogues. From these works, the existence of these solutions appears to be a rather common feature of $(2+1)$-dimensional integrable systems. Thus, we expect that the scope of the results described in this paper will not be limited to the KP equation alone, but will also be applicable to a variety of other $(2+1)$-dimensional integrable systems.

II. THE TAU FUNCTION AND THE ASYMPTOTIC LINE SOLITONS

In this section we investigate the properties of the tau function given by Eq. (1.3) when the N functions $f_1,\ldots,f_N$ are chosen according to Eq. (1.10) as linear combinations of M exponentials $e^{\theta_1},\ldots,e^{\theta_M}$. We should emphasize that Eq. (1.10) represents the most general form for the functions involving linear combinations of exponential phases. Since the elements of the $N\times M$ coef-

ficient matrix $A=(a_{n,m})$ are the linear combination coefficients of the functions $f_1,\dots,f_N$, one can naturally identify each f_n with one of the rows of A and each phase θ_m with one of the columns of A, and vice versa. Next, we examine the asymptotic behavior of the tau function in the xy plane as $y\to\pm\infty$. It is clear that, with the above choice of functions, the tau function is a linear combination of exponentials. Consequently, the leading order behavior of the tau function as $y\to\pm\infty$ in a given asymptotic sector of the xy plane is governed by those exponential terms which are dominant in that sector. A systematic analysis of the dominant exponential phases allows us to characterize the incoming and outgoing line solitons of (N_-,N_+)-soliton solutions of KPII.

A. Basic properties of the tau function

We present here some general properties of the tau function. Without loss of generality, throughout this work we choose the phase parameters k_m to be distinct and well ordered as $k_1<k_2<\cdots<k_M$.

Lemma 2.1: Suppose $\tau_{N,M}=\mathrm{Wr}(f_1,\dots,f_N)$ *as in Eq.* (1.3) *with the functions* $f_1,\dots,f_N$ *given by Eq.* (1.10). *Then*

$$\tau_{N,M}(x,y,t)=\det(A\Theta K^T), \tag{2.1}$$

where $A=(a_{n,m})$ *is the* $N\times M$ *coefficient matrix,* $\Theta=\mathrm{diag}(e^{\theta_1},\dots,e^{\theta_M})$, *and the* $N\times M$ *matrix* K *is given by*

$$K=\begin{pmatrix} 1 & 1 & \cdots & 1 \\ k_1 & k_2 & \cdots & k_M \\ \vdots & \vdots & & \vdots \\ k_1^{N-1} & k_2^{N-1} & \cdots & k_M^{N-1} \end{pmatrix},$$

where the superscript T *denotes matrix transpose. Moreover,* $\tau_{N,M}$ *can be expressed as*

$$\tau_{N,M}(x,y,t)=\sum_{1\leqslant m_1<m_2<\cdots<m_N\leqslant M} V(m_1,\dots,m_N)A(m_1,\dots,m_N)\exp[\theta_{m_1,\dots,m_N}], \tag{2.2}$$

where $\theta_{m_1,\dots,m_N}$ *denotes the phase combination*

$$\theta_{m_1,\dots,m_N}(x,y,t)=\theta_{m_1}(x,y,t)+\cdots+\theta_{m_N}(x,y,t), \tag{2.3}$$

$A(m_1,\dots,m_N)$ *denotes the* $N\times N$ *minor of* A *obtained by selecting columns* $m_1,\dots,m_N$, *and* $V(m_1,\dots,m_N)$ *denotes the Van der Monde determinant*

$$V(m_1,\dots,m_N)=\prod_{1\leqslant s_1\leqslant s_2\leqslant N}(k_{m_{s_2}}-k_{m_{s_1}}). \tag{2.4}$$

Proof: Equation (2.1) follows by direct computation of the Wronskian determinant (1.3). Next, to prove Eq. (2.2) apply the Binet-Cauchy theorem to expand the determinant in Eq. (2.1) and note that the $N\times N$ minor of K obtained by selecting columns $1\leqslant m_1<\cdots<m_N\leqslant M$ is given by the Van der Monde determinant $V(m_1,\dots,m_N)$. □

From Lemma 2.1 we have the following basic properties of the tau function:

(i) The spatiotemporal dependence of the tau function in Eq. (2.2) is confined to a sum of exponential phase combinations $\theta_{m_1,\dots,m_N}$ which according to Eq. (2.3) are linear in x,y,t. Moreover, all the Van der Monde determinants $V(m_1,\dots,m_N)$ are positive, as the phase parameters $k_1,\dots,k_M$ are well ordered. A sufficient condition for the tau function in Eq. (2.2) to generate a nonsingular solution of KPII is that it is sign-definite for all $(x,y,t)\in\mathbb{R}^3$. In turn, a sufficient condition for the sign-definiteness of the tau-function is that the minors of the coefficient matrix A are either all non-negative or all nonpositive. However,

it is not clear at present whether these conditions are also necessary. If the tau function in Eq. (2.2) is taken as a sum of exponential phase combinations with non-negative coefficients, the solution $u(x,y,t)$ in Eq. (1.2) can be expressed as a ratio of two sums, each containing the *same* set of exponential terms, and with non-negative coefficients. Consequently, the resulting solution of KPII is bounded and positive definite for all $(x,y,t) \in \mathbb{R}^3$.

(ii) Each exponential term in the tau function of Eq. (2.2) contains combinations of N *distinct* phases $\theta_{m_1},\ldots,\theta_{m_N}$ identified by integers $m_1,\ldots,m_N$ chosen from $\{1,\ldots,M\}$. Thus, the maximum number of terms in the tau function is given by the binomial coefficient $\binom{M}{N}$. However, a given phase combination $\theta_{m_1,\ldots,m_N}$ is actually *present* in the tau function if and only if the corresponding minor $A(m_1,\ldots,m_N)$ is nonzero.

(iii) If $M<N$ the functions $f_1,\ldots,f_N$ are linearly dependent; in this case there are no terms in the summation in Eq. (2.2), and therefore the tau function $\tau_{N,M}(x,y,t)$ is identically zero. Also, if $M=N$, there is only one term in the summation corresponding to the determinant of A; then $\tau_{N,M}(x,y,t)$ depends linearly on x and therefore it generates the trivial solution $u(x,y,t)=0$. Finally, if $\text{rank}(A)<N$, all $N\times N$ minors of A vanish identically, leading once again to $\tau_{N,M}(x,y,t)=0$. Therefore, for nontrivial solutions one needs $M>N$ and $\text{rank}(A)=N$.

(iv) The transformation $A\to A'=GA$ with $G\in \text{GL}(N,\mathbb{R})$ (corresponding to elementary row operations on A) amounts to an overall rescaling $\tau(x,y,t)\to\tau'(x,y,t)=\det(G)\tau(x,y,t)$ of the tau function (2.1). Such rescaling leaves the solution $u(x,y,t)$ in Eq. (1.2) invariant. This reflects the fact that N independent linear combinations of the functions $f_1,\ldots,f_N$ in Eq. (1.10) generate equivalent tau functions. This $\text{GL}(N,\mathbb{R})$ gauge freedom can be exploited to choose the coefficient matrix A in Eq. (2.1) to be in reduced row-echelon form (RREF). The $\text{GL}(N,\mathbb{R})$ invariance means that the tau function (2.1) represents a point in the real Grassmannian $\text{Gr}(N,M)$.[12]

(v) Suppose that one of the functions in Eq. (1.10) contains only one exponential term, and is given by $f_p=a_{p,q}e^{\theta_q}$ with $a_{p,m}=0\ \forall m\neq q$. Then, the minors $A(m_1,\ldots,m_N)=0$ whenever $q\notin\{m_1,\ldots,m_N\}$. As a result, the tau function in Eq. (2.2) can be expressed as $\tau_{N,M}(x,y,t)=e^{\theta_q}\tau'(x,y,t)$, and $\tau'(x,y,t)$ is a sum of exponential phase combinations, where each combination consists of $N-1$ distinct phases chosen from all M phases except θ_q. From Eq. (1.2) it is evident that $\tau_{N,M}(x,y,t)$ and $\tau'(x,y,t)$ generate the same solution of KPII. Moreover, the function $\tau'(x,y,t)$ is effectively equivalent to a tau function $\tau_{N-1,M-1}(x,y,t)$ with a coefficient matrix obtained by deleting the pth row and qth column of A. Hence in this case the tau function $\tau_{N,M}(x,y,t)$ is reducible to another tau function $\tau_{N-1,M-1}(x,y,t)$ obtained from a Wronskian of $N-1$ functions with $M-1$ distinct phases.

In accordance with the above remarks, throughout this work we consider the coefficient matrix A to be in RREF. Also, to avoid trivial and singular cases, from now on we assume that $M>N$ and $\text{rank}(A)=N$, and that all nonzero $N\times N$ minors of A are positive. Finally, we assume that A satisfies the following irreducibility conditions.

Definition 2.2 (Irreducibility): A matrix A of rank N is said to be irreducible if, in RREF:

(i) *Each column of A contains at least one nonzero element.*

(ii) *Each row of A contains at least one nonzero element in addition to the pivot.*

Condition (i) in Definition 2.2 requires that each exponential phase appear in at least one of the functions $f_1,\ldots,f_N$. If a particular phase is absent, then the corresponding tau function $\tau_{N,M}$ can be reexpressed in terms of a reduced tau function $\tau_{N,M-1}$. Condition (ii) requires that each function contains at least two exponential phases in order to avoid reducible situations like those in part (v) of the above remarks. Note also that if an $N\times M$ matrix A is irreducible, then $M>N$.

B. Dominant phase combinations and index pairs

We now study the asymptotic behavior of the tau function in the xy-plane for large values of $|y|$ and finite values of t. Let Θ denote the set of all phase combinations $\theta_{m_1,\ldots,m_N}$ such that $A(m_1,\ldots,m_N)\neq 0$, that is, the set of phase combinations that are actually present in the tau function $\tau(x,y,t)$.

Definition 2.3 (Dominant phase): A given phase combination $\theta_{m_1,\ldots,m_N}\in\Theta$ is said to be dominant for the tau function $\tau(x,y,t)$ of Eq. (2.2) *in a region $R\in\mathbb{R}^3$ if $\theta_{m'_1,\ldots,m'_N}(x,y,t)\leqslant\theta_{m_1,\ldots,m_N}(x,y,t)$ for all $\theta_{m'_1,\ldots,m'_N}\in\Theta$ and for all $(x,y,t)\in R$. The region R is called the dominant region of $\theta_{m_1,\ldots,m_N}$.*

The phase combinations $\theta_{m_1,\ldots,m_N}(x,y,t)$ are linear functions of x, y, and t. So, each of the inequalities in Definition 2.3 defines a convex subset of $\mathbb{R}^3$. The dominant region R associated with each phase combination is also convex because it is defined by the intersection of finitely many convex subsets. Furthermore, since the phase combinations are defined globally on $\mathbb{R}^3$, each point $(x,y,t)\in\mathbb{R}^3$ belongs to some dominant region R. As a result, we obtain a partition of the entire $\mathbb{R}^3$ into a finite number of convex dominant regions, intersecting only at points on the boundaries of each region. It is important to note that such boundaries always exist whenever there is more than one phase combination in the tau function, because then there are more than one dominant region in $\mathbb{R}^3$. The significant of the dominant regions lies in the following:

Lemma 2.4: The solution $u(x,y,t)$ of the KPII equation generated by the tau function (2.2) *is exponentially small at all points in the interior of any dominant region. Thus, the solution is localized only at the boundaries of the dominant regions, where a balance exists between two or more dominant phase combinations in the tau function of Eq.* (2.2).

Proof: Let R be the dominant region of $\theta_{m_1,\ldots,m_N}$, which is therefore the *only* dominant phase in the interior of R. Then from Eq. (2.2), $\tau_{N,M}(x,y,t)\sim O(e^{\theta_{m_1,\ldots,m_N}})$ in the interior of R. As a result, $\ln\tau_{N,M}(x,y,t)$ locally becomes a linear function of x apart from exponentially small terms. Hence, it follows from Eq. (1.2) that the solution $u(x,y,t)$ of KPII is exponentially small at all such interior points of R. □

The boundary between any two adjacent dominant regions is the set of points across which *a transition* from one dominant phase combination $\theta_{m_1,\ldots,m_N}$ to another dominant phase combination $\theta_{m'_1,\ldots,m'_N}$ takes place. Such boundary is therefore identified by the equation $\theta_{m_1,\ldots,m_N}=\theta_{m'_1,\ldots,m'_N}$, which defines a line in the xy plane for fixed values of t. The simplest instance of a transition between dominant phase combinations arises for the one-soliton solution (1.6), which is localized along the line $\theta_1=\theta_2$ defining the boundary of the two regions of the xy plane where θ_1 and θ_2 dominate. In the one-soliton case, these two regions are simply half-planes. But in the general case the dominant regions are more complicated, although the solution $u(x,y,t)$ is still localized along the boundaries of these regions, corresponding to similar phase transitions. For example, Fig. 1(a) illustrates a (2,1)-soliton known as a *Miles resonance*[17] (also called a Y junction), generated by the tau function $\tau_{1,2}=e^{\theta_1}+e^{\theta_2}+e^{\theta_3}$. In this case, the xy plane is partitioned into three dominant regions corresponding to each of the dominant phases θ_1, θ_2, and θ_3. Once again, the solution $u(x,y,t)$ is exponentially small in the interior of each dominant regions, and is localized along the phase transition boundaries: here, $\theta_1=\theta_2$, $\theta_1=\theta_3$, and $\theta_2=\theta_3$. It should also be noted that some of these regions have infinite extension in the xy plane, while others are bounded, as in the case of resonant soliton solutions, described in Sec. IV and Ref. 2. Each phase transition which occurs asymptotically as $y\to\pm\infty$ defines an *asymptotic line soliton*, which is infinitely extended in the xy plane.

When studying the asymptotics of the tau function for large $|y|$ it is useful to consider the limit $y\to\pm\infty$ along the straight lines

$$L_c: x+cy=\xi, \tag{2.5}$$

parametrized by the direction c. Note that c increases counterclockwise, namely from the positive x axis to the negative x axis for $y>0$ and from the negative x axis to the positive x axis for y

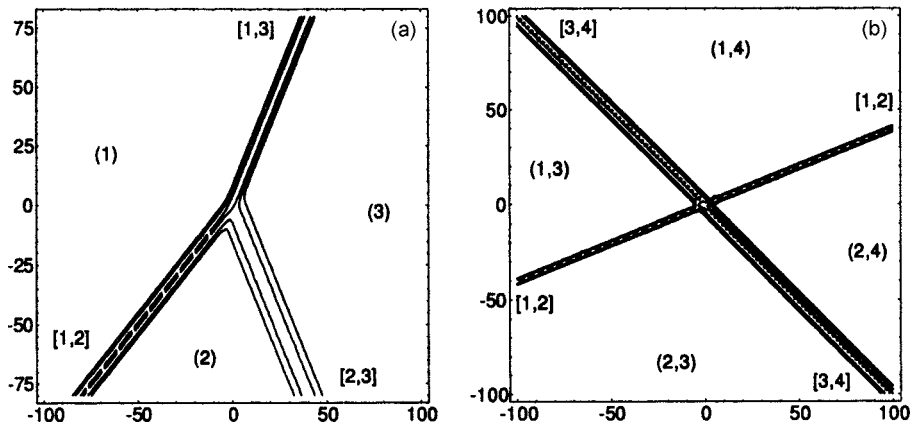

FIG. 1. Dominant phase combinations in the different regions of the xy plane (labeled by the indices in parentheses) and the asymptotic line solitons (labeled by the indices in square braces) for two different line soliton solutions: (a) a fundamental Miles resonance (Y junction) produced by the tau function with $N=1$, $M=3$ and $(k_1,k_2,k_3)=(-1,0,\frac{1}{2})$ at $t=0$; (b) an ordinary two-soliton solution, produced by the coefficient matrix in Example 2.7 with $(k_1,\ldots,k_4)=(-\frac{3}{2},-\frac{1}{2},0,1)$ at $t=0$ (see text for details). Here and in all of the following figures, the horizontal and vertical axes are, respectively, x and y, and the graphs show contour lines of $\ln u(x,y,t)$ at a fixed value of t.

<0. From Eqs. (1.5) and (2.5), each exponential phases along L_c is $\theta_m=k_m(k_m-c)y+k_m\xi+k_m^3t+\theta_{m,0}$. The difference between two such phases along L_c then becomes

$$\theta_m-\theta_{m'}=(k_m-k_{m'})(k_m+k_{m'}-c)y+(k_m-k_{m'})\xi+(k_m^3-k_{m'}^3)t+\theta_{m,0}-\theta_{m',0}, \tag{2.6a}$$

and the difference between any two phase combinations along L_c is given by

$$\theta_{m_1,\ldots,m_N}-\theta_{m'_1,\ldots,m'_N}=\left(\sum_{j=1}^{N}(k_{mj}-k_{m'_j})(k_{m_j}+k_{m'_j}-c)\right)y+\delta(\xi,t), \tag{2.6b}$$

where $\delta(\xi,t)=\Sigma_{j=1}^{N}[(k_{m_j}-k_{m'_j})\xi+(k_{m_j}^3-k_{m'_j}^3)t+\theta_{m_j,0}-\theta_{m'_j,0}]$. In particular, the *single-phase-transition* line $L_{m,m'}:\theta_m=\theta_{m'}$ given by Eq. (2.5) with $c_{m,m'}=k_m+k_{m'}$, will play an important role below.

It is also convenient at this point to introduce the following notations which will be employed throughout this paper. We denote by $A[m]\in\mathbb{R}^N$ the mth column of a matrix A, and we denote by $A[m_1,\ldots,m_r]$ the $N\times r$ submatrix obtained by selecting the r columns $A[m_1],\ldots,A[m_r]$. We also label the N pivot columns of an irreducible, $N\times M$ matrix A by $A[e_1],\ldots,A[e_N]$, with $1=e_1<e_2<\cdots<e_N<M$, and we label the $M-N$ nonpivot columns by $A[g_1],\ldots,A[g_{M-N}]$, where $1<g_1<g_2<\cdots<g_{M-N}=M$. Note that A has N pivot columns because it is rank N; also, $e_1=1$ since A is in RREF, and $e_N<M$ since it is irreducible. We now establish a result that will be useful in order to characterize the asymptotics of the tau function.

Theorem 2.5: *(Single-phase transition) Asymptotically as $y\to\pm\infty$, and for generic values of the phase parameters $k_1,\ldots,k_M$, the dominant phase combinations in the tau function* (2.2) *exhibit the following behaviors in the xy plane.*

(i) *For finite values of t, the set of dominant phase combinations remains invariant in time.*
(ii) *The dominant phase combinations in any two adjacent dominant regions contain $N-1$ common phases.*

We discuss below several consequences of Theorem 2.5 which is proved in the Appendix.

Consider the single-phase transition as $y\to\pm\infty$ in which a phase θ_i from the dominant phase combination in one region is replaced by another phase θ_j to produce the dominant phase combination in the adjacent region. We refer to this transition as an $i\to j$ transition, which takes place along the line $L_{ij}:\theta_i=\theta_j$ whose direction in the xy plane is given by $c_{ij}=k_i+k_j$. As $y\to\infty$, it is clear

from Eq. (2.6a) that, if $k_i < k_j$, the transition $i \to j$ takes place from the left of the line $L_{i,j}$ to its right, while if $k_i > k_j$ the transition $i \to j$ takes place from the right of the line $L_{i,j}$ to its left. Thus, as $y \to \infty$, each dominant phase region R is bounded on the left by the transition line $L_{i,j}$ given by the *minimum* value of $c_{i,j}$ that corresponds to an allowed transition and, on the right by the transition line $L_{i,j}$ given by the *maximum* value of $c_{i,j}$ that corresponds to an allowed transition. Here, an *allowed* transition from one dominant phase combination to another means that the minors associated with those phase combinations in the tau function of Eq. (2.2), are both nonzero. In turn, these nonvanishing minors determine the values of c_{ij} corresponding to the allowed single-phase transitions. A similar statement can be made for transitions occurring as $y \to -\infty$. So, each dominant phase region R as $y \to \pm\infty$ has boundaries defined by a counterclockwise and a clockwise single-phase transitions which can be determined in the following way.

Corollary 2.6: Suppose that $\theta_{m_1,\dots,m_N}$ is the dominant phase combination on a region R asymptotically as $y \to \pm\infty$. Let J be the complement of the set of indices $\{m_1, m_2, \dots, m_N\}$ in $\{1, 2, \dots, M\}$. For each $j \in J$, define $I_j \subseteq \{m_1, m_2, \dots, m_N\}$ as the set of all indices $m_r \in \{m_1, m_2, \dots, m_N\}$ such that the minor $A(m_1, \dots, m_{r-1}, j, m_{r+1}, \dots, m_N) \neq 0$. Then, the following hold.

(i) *As $y \to \infty$, the directions of the counterclockwise and clockwise transition boundaries of R are, respectively, given by*

$$c_+ = \min_{i \in I_j, j \in J} [c_{i,j}] \quad \text{with } k_i > k_j, \quad c_- = \max_{i \in I_j, j \in J} [c_{i,j}] \quad \text{with } k_i < k_j. \tag{2.7a}$$

(ii) *As $y \to -\infty$, the directions of the counterclockwise and clockwise transition boundaries of R are, respectively, given by*

$$c_+ = \min_{i \in I_j, j \in J} [c_{i,j}] \quad \text{with } k_i > k_j, \quad c_- = \max_{i \in I_j, j \in J} [c_{i,j}] \quad \text{with } k_i > k_j. \tag{2.7b}$$

The results of Theorem 2.5 and Corollary 2.6 can be used to determine the asymptotic behavior of the tau function, thereby obtaining an important characterization of the asymptotic line solitons corresponding to (N_-, N_+)-soliton solutions of the KPII equation. Namely, for the tau function $\tau_{N,M}(x, y, t)$ of Eq. (2.2) with generic values of the phase parameters $k_1, \dots, k_M$ we have the following:

(i) As $y \to \pm\infty$, the dominant phase combinations of the tau function in adjacent regions of the xy plane contain $N-1$ common phases and differ by only a single phase. The transition between any two such dominant phase combinations $\theta_{i,m_2,\dots,m_N}$ and $\theta_{j,m_2,\dots,m_N}$ occurs along the line $L_{i,j}: \theta_i = \theta_j$, where a single phase θ_i in the dominant phase combination is replaced by a phase θ_j. Moreover, if the dominant phase combination $\theta_{i,m_2,\dots,m_N}$ in a given region is known, the transition line $L_{i,j}$ and the dominant phase combination $\theta_{j,m_2,\dots,m_N}$ are determined via Corollary 2.6. In particular, Eqs. (2.7) for $c_\pm$ determine explicitly the pair of phase parameters k_i and k_j corresponding to the single-phase transition $i \to j$ across each boundary $L_{i,j}$ of a given dominant phase region.

(ii) As $y \to \pm\infty$ along the line $L_{i,j}$, the asymptotic behavior of the tau function is determined by the balance between the two dominant phase combinations $\theta_{i,m_2,\dots,m_N}$ and $\theta_{j,m_2,\dots,m_N}$, and is given by

$$\tau_{N,M}(x,y,t) \sim V_i A(i, m_2, \dots, m_N) e^{\theta_{i,m_2,\dots,m_N}} + V_j A(j, m_2, \dots, m_N) e^{\theta_{j,m_2,\dots,m_N}},$$

where $V_i := V(i, m_2, \dots, m_N)$ and $V_j := V(j, m_2, \dots, m_N)$ are Van der Monde determinants defined in Eq. (2.4), and where the minors $A(i, m_2, \dots, m_N)$ and $A(j, m_2, \dots, m_N)$ of the coefficient matrix A are both nonzero. The solution $u(x, y, t)$ of the KPII equation in a neighborhood of such a single-phase transition is then obtained from Eq. (1.2) as

$$u(x,y,t) \sim \tfrac{1}{2}(k_i - k_j)^2 \operatorname{sech}^2\left[\tfrac{1}{2}(\theta_i - \theta_j)\right]. \tag{2.8}$$

Moreover, Lemma 2.4 and Theorem 2.5 together imply that the solution of the KPII equation is exponentially small everywhere in the xy-plane except at the locations of such single-phase transitions. Equation (2.8), which is a traveling wave solution satisfying the dispersion relation in Eq. (1.8), coincides with the one-soliton solution in Eq. (1.6). Thus, it defines an asymptotic line soliton associated with the single-phase transition $i \to j$. The phase parameters k_i and k_j associated with the single-phase transition $i \to j$ are determined by Eqs. (2.7). Then, the soliton amplitude is given by $a_{i,j} = |k_i - k_j|$, and the soliton direction is given by the direction of $L_{i,j}$, which is $c_{i,j} = k_i + k_j$.

(iii) All of the asymptotic line solitons resulting from the single-phase transitions described above are invariant in time, in the sense that their number, amplitudes, and directions are constants.

Motivated by these results, *we label each asymptotic line soliton by the index pair* $[i,j]$ *which uniquely identifies the phase parameters* k_i *and* k_j *in the ordered set* $\{k_1, \ldots, k_M\}$. The results summarized in the above remarks can be applied to explicitly delineate the dominant phase combinations and the asymptotic line solitons associated with the tau function of a given (N_-, N_+)-soliton solution of the KPII equation, as illustrated by the following example.

Example 2.7: When $N=2$ and $M=4$, Lemma 2.1 implies that the tau function $\tau(x,y,t)$ is given by

$$\tau(x,y,t) = \operatorname{Wr}(f_1, f_2) = \sum_{1 \leqslant m < m' \leqslant 4} (k_{m'} - k_m) A(m,m') e^{\theta_m + \theta_{m'}}, \tag{2.9}$$

where the phases are given by $\theta_m = k_m x + k_m^2 y + k_m^3 t + \theta_{m,0}$ for $m = 1, \ldots, 4$, as in Eq. (1.5), and where the phase parameters are ordered as $k_1 < \cdots < k_4$. We consider the line-soliton solution constructed from the functions $f_1 = e^{\theta_1} + e^{\theta_2}$ and $f_2 = e^{\theta_3} + e^{\theta_4}$, so that the associated 2×4 coefficient matrix is

$$A = \begin{pmatrix} 1 & 1 & 0 & 0 \\ 0 & 0 & 1 & 1 \end{pmatrix}. \tag{2.10}$$

Then $A(1,2) = A(3,4) = 0$, and the remaining four minors are all equal to 1. We apply Corollary 2.6 to determine the asymptotic line solitons associated with the tau function in Eq. (2.9). First note from the expression $\theta_{m,m'} = (k_m + k_{m'})x + (k_m^2 + k_{m'}^2)y + (k_m + k_{m'}^3)t + (\theta_{m,0} + \theta_{m',0})$ that for every finite value of y the dominant phase combination as $x \to -\infty$ is given by $\theta_{1,3}$, which corresponds to the *minimum* value of $k_m + k_{m'}$ such that $A(m,m') \neq 0$ (cf. Definition 2.3). We denote by $R_{1,3}$ the region of the xy plane where $\theta_{1,3}$ is the dominant phase. The transition boundaries of $R_{1,3}$ are determined by applying Corollary 2.6 as follows: The complement of the index set $\{1,3\}$ is $J = \{2,4\}$. When $j = 2 \in J$, we have $A(1,2) = 0$ but $A(2,3) \neq 0$; hence $I_2 = \{1\}$. Similarly, when $j = 4$ we have $I_4 = \{3\}$ because $A(1,4) \neq 0$ but $A(4,3) = 0$. Thus the possible transitions $i \to j$ from $R_{1,3}$ are $1 \to 2$ and $3 \to 4$. As $y \to \infty$, the second of Eqs. (2.7a) implies that the clockwise transition boundary of $R_{1,3}$ is given by the transition line $L_{3,4}$, whose direction $c_{3,4} = k_3 + k_4$ is greater than the direction $c_{1,2} = k_1 + k_2$ of the line $L_{1,2}$. Across the transition line $L_{3,4}$, the dominant phase combination switches from $\theta_{1,3}$ to $\theta_{1,4}$, onto the corresponding dominant region $R_{1,4}$. Similarly, as $y \to -\infty$, the first of Eqs. (2.7b) implies that the counterclockwise transition boundary of $R_{1,3}$ is given by the transition line $L_{1,2}$, whose direction $c_{1,2}$ is less than the direction $c_{3,4}$ of the line $L_{3,4}$. This implies that the dominant phase combination and dominant region change to $\theta_{2,3}$ and $R_{2,3}$, respectively. Applying Corollary 2.6 again to the region $R_{2,3}$ as $y \to -\infty$, one finds $J = \{1,4\}$ with $I_1 = \{2\}$ and $I_4 = \{3\}$, so the possible transitions from $R_{2,3}$ are $2 \to 1$ and $3 \to 4$. The $2 \to 1$ transition corresponds to a clockwise transition from $R_{2,3}$ back to $R_{1,3}$, whereas the $3 \to 4$ transition corresponds to a counterclockwise transition from $R_{2,3}$ to the region $R_{2,4}$, where $\theta_{2,4}$ is the dominant phase combination. Continuing counterclockwise from $R_{1,3}$ we finally obtain the following dominant phase regions asymptotically as $y \to \pm\infty$, together with the associated single-phase transitions:

$$R_{1,3} \xrightarrow{1\to 2} R_{2,3} \xrightarrow{3\to 4} R_{3,4} \xrightarrow{2\to 1} R_{1,4} \xrightarrow{4\to 3} R_{1,3}. \tag{2.11}$$

It is then clear that there are two asymptotic line solitons as $y\to-\infty$ as well as $y\to\infty$, and in both cases they correspond to the lines $\theta_1=\theta_2$ and $\theta_3=\theta_4$. The dominant phase regions, denoted by indices (m,m'), and the asymptotic line solitons, identified by the index pairs $[i,j]$, are illustrated in Fig. 1(b). The corresponding solution is called an ordinary 2-soliton solution. The ordinary N-soliton solutions are described in Sec. IV.

In the following section we obtain several results that will allow us to identify more precisely the index pairs corresponding to each asymptotic line soliton. In addition, we will prove a general result concerning the numbers of asymptotic line solitons present in an (N_-,N_+)-soliton solution corresponding to the tau function of Eq. (2.2).

III. ASYMPTOTIC LINE SOLITONS AND THE COEFFICIENT MATRIX

In this section we continue our investigation of the tau function in the general setting introduced in Sec. II. We have seen in the preceding section that an asymptotic line soliton corresponds to a dominant balance between two phase combinations in the tau function. But we still need to identify which phase combinations in a given tau function are indeed dominant as $y\to\pm\infty$. This requires a detailed study of the structure of the $N\times M$ coefficient matrix A associated with the tau function. In this section we carry out this analysis, which enables us to explicitly identify all the asymptotic line solitons of a given tau function in an algorithmic fashion. One of our main results of this section will be to establish that, for arbitrary values of N and M, and for irreducible coefficient matrices (cf. Definition 2.2) with non-negative $N\times N$ minors, the tau function (2.2) produces an (N_-,N_+)-soliton solution with $N_-=M-N$ and $N_+=N$, i.e., a solution in which there are $N_-=M-N$ asymptotic line solitons as $y\to-\infty$ and $N_+=N$ asymptotic line solitons as $y\to\infty$.

A. Dominant phases and the structure of the coefficient matrix

We begin by presenting a simple yet useful result (see also Ref. 2, Lemma 2.4) that will be frequently used to determine the dominant phase combinations in the tau function as $y\to\pm\infty$.

Lemma 3.1 (Dominant phase conditions): As $y\to\pm\infty$ along the line $L_{i,j}$: $\theta_i=\theta_j$ with $i<j$, the exponential phases $\theta_1,\dots,\theta_M$ satisfy the following relations.

(i) *As* $y\to\infty$, $\theta_m<\theta_*$, $\forall m\in\{i+1,\dots,j-1\}$, *and* $\theta_m>\theta_*$, $\forall m\in\{1,\dots,i-1,j+1,\dots,M\}$, *where* $\theta_*:=\theta_i=\theta_j$.

(ii) *As* $y\to-\infty$, $\theta_m>\theta_*$, $\forall m\in\{i+1,\dots,j-1\}$, *while* $\theta_m<\theta_*$, $\forall m\in\{1,\dots,i-1,j+1,\dots,M\}$.

Proof: It follows from Eq. (2.6a) that, along the line $L_{i,j}$ whose direction is $c_{i,j}=k_i+k_j$, the difference between any two exponential phases θ_m and $\theta_{m'}$ is given by

$$\theta_m-\theta_{m'}=(k_m-k_{m'})[(k_m+k_{m'})-(k_i+k_j)]y+\delta'(\xi,t), \tag{3.1}$$

where $\delta'(\xi,t)$ is a linear function of ξ and t and which also depends on the constants $\theta_{m,0}$, $\theta_{m',0}$, $\theta_{i,0}$, and $\theta_{j,0}$. It is clear that the sign of $\theta_m-\theta_{m'}$ as $y\to\pm\infty$ and for finite values of ξ and t is determined by the coefficient of y on the right-hand side of Eq. (3.1). Then, setting $m'=i$ (or $m'=j$) in Eq. (3.1) one obtains the desired inequalities. □

Lemma 3.1, which is illustrated in Fig. 2, will be used to obtain a set of conditions that are necessary for a given pair of phase combinations in the tau-function to be dominant. These conditions are given in terms of the vanishing of certain $N\times N$ minors of the coefficient matrix A, and they determine which phase combinations are present (or absent) in the tau function of Eq. (1.3). In order to derive these conditions, it is convenient to introduce two submatrices $P_{i,j}$ and $Q_{i,j}$ associated with any index pair $[i,j]$ with $1\leqslant i<j\leqslant M$, and given by

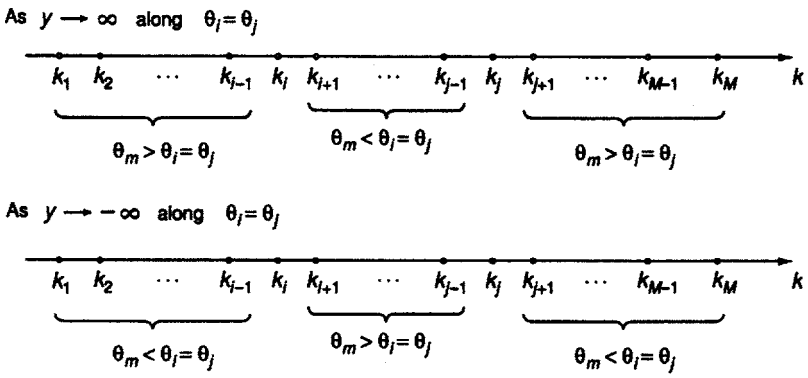

FIG. 2. Relations among the exponential phases as $y \to \pm\infty$ along the direction $L_{i,j}$: $\theta_i = \theta_j$.

$$P_{i,j} = A[1,2,\ldots,i-1,j+1,\ldots,M], \quad Q_{i,j} = A[i+1,\ldots,j-1]. \tag{3.2}$$

The matrix $P_{i,j}$ is formed by the consecutive columns of A to the left of column $A[i]$ and those to the right of column $A[j]$, while $Q_{i,j}$ is formed by the consecutive columns of A between columns $A[i]$ and $A[j]$. Using the matrices $P_{i,j}$ and $Q_{i,j}$ and the dominant phase conditions in Lemma 3.1 we then have the following.

Lemma 3.2 (Vanishing minor conditions): Suppose that the index pair $[i,j]$ *identifies an asymptotic line soliton. Let the two dominant phase combinations along the line* $L_{i,j}$: $\theta_i = \theta_j$ *be given by* $\theta_{i,p_1,\ldots,p_r,q_1,\ldots,q_s}$ *and* $\theta_{j,p_1,\ldots,p_r,q_1,\ldots,q_s}$, *and let* $A(i,p_1,\ldots,p_r,q_1,\ldots,q_s)$, $A(j,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *be the corresponding nonzero minors where* $A[p_1],\ldots,A[p_r] \in P_{i,j}$ *and* $A[q_1],\ldots,A[q_s] \in Q_{i,j}$.

(i) *If* $[i,j]$ *identifies an asymptotic line soliton as* $y \to \infty$, *then*

(a) *all* $N \times N$ *minors obtained by replacing one of the columns* $A[i],A[j],A[q_1],\ldots,A[q_s]$ *from either* $A(i,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *or* $A(j,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *with any column* $A[p] \in P_{i,j}$, *are zero*;

(b) *all* $N \times N$ *minors obtained by replacing one of the columns* $A[q_1],\ldots,A[q_s]$ *from either* $A(i,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *or* $A(j,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *with either* $A[i]$ *or* $A[j]$, *are zero.*

(ii) *If* $[i,j]$ *identifies an asymptotic line soliton as* $y \to -\infty$, *then*

(a) *all* $N \times N$ *minors obtained by replacing one of the columns* $A[i],A[j],A[p_1],\ldots,A[p_r]$ *from either* $A(i,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *or* $A(j,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *with any column* $A[q] \in Q_{i,j}$, *are zero;*

(b) *all* $N \times N$ *minors obtained by replacing one of the columns* $A[p_1],\ldots,A[p_r]$ *from either* $A(i,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *or* $A(j,p_1,\ldots,p_r,q_1,\ldots,q_s)$ *with either* $A[i]$ *or* $A[j]$, *are zero.*

Proof: All of the above conditions follow from the repeated use of the dominant phase conditions in Lemma 3.1. For example, as $y \to \infty$ along the line $L_{i,j}$, Lemma 3.1 implies $\theta_p > \theta_m$ for all $p \in \{1,\ldots,i-1,j+1,\ldots,M\}$ and for all $m \in \{i,j,q_1,\ldots,q_s\}$. Consequently, if condition (b) in part (i) of the Lemma does not hold, each of the phase combinations obtained by replacing θ_m with θ_p in either $\theta_{i,p_1,\ldots,p_r,q_1,\ldots,q_s}$ or $\theta_{j,p_1,\ldots,p_r,q_1,\ldots,q_s}$ will be greater than both $\theta_{i,p_1,\ldots,p_r,q_1,\ldots,q_s}$ and $\theta_{j,p_1,\ldots,p_r,q_1,\ldots,q_s}$. But this contradicts the hypothesis that $\theta_{i,p_1,\ldots,p_r,q_1,\ldots,q_s}$ and $\theta_{j,p_1,\ldots,p_r,q_1,\ldots,q_s}$ are the dominant phase combinations as $y \to \infty$ along $L_{i,j}$. The other conditions follow in a similar fashion. □

We should emphasize that in general, the asymptotic solitons and the index pairs labeling them as $y \to \infty$ are different from those as $y \to -\infty$. Lemma 3.2 allows us to determine the ranks of the submatrices P_{ij} and Q_{ij} associated with each asymptotic line soliton $[i,j]$. This information

will be exploited later in Theorem 3.6 to identify explicitly the asymptotic line solitons produced by any given tau function. The next two results are direct consequences of the conditions specified in Lemma 3.2.

Lemma 3.3 (Span): Let $A[p_1],\dots,A[p_r]\in P_{i,j}$ *and* $A[q_1],\dots,A[q_s]\in Q_{i,j}$ *be the columns in the minors associated with the dominant pair of phase combinations of Lemma 3.2.*

(i) *If* $[i,j]$ *identifies an asymptotic line soliton as* $y\to\infty$, *the columns* $A[p_1],\dots,A[p_r]$ *form a basis for the column space of the matrix* $P_{i,j}$.
(ii) *If* $[i,j]$ *identifies an asymptotic line soliton as* $y\to-\infty$, *the columns* $A[q_1],\dots,A[q_s]$ *form a basis for the column space of the matrix* $Q_{i,j}$.

Proof: We prove part (i). Since $A(i,p_1,\dots,p_r,q_1,\dots,q_s)\neq 0$ by Lemma 3.2, the set of columns $\mathcal{A}=\{A[i],A[p_1],\dots,A[p_r],A[q_1],\dots,A[q_s]\}$ is a basis for $\mathbb{R}^N$. Hence the set $\{A[p_1],\dots,A[p_r]\}\subset\mathcal{A}$ is linearly independent. Moreover, any $A[p]\in P_{i,j}$ can be expanded with respect to the basis $\mathcal{A}$ as

$$A[p]=aA[i]+\sum_{m=1}^{r}b_mA[p_m]+\sum_{m=1}^{s}c_mA[q_m]. \tag{3.3}$$

Replacing one of the columns $A[i],A[q_1],\dots,A[q_s]$ in $A(i,p_1,\dots,p_r,q_1,\dots,q_s)$ with $A[p]\in P_{ij}$, we have from Lemma 3.2(i)(a) that

$$A(p,p_1,\dots,p_r,q_1,\dots,q_s)=0,\quad A(i,p_1,\dots,p_r,q_1,\dots q_{m-1},p,q_{m+1},\dots q_s)=0.$$

Hence in Eq. (3.3) we have $a=0$ and $c_m=0\,\forall\, m=1,\dots,s$. Therefore $A[p]\in\operatorname{span}(\{A[p_1,\dots,A[p_r]\})$ for all $A[p]\in P_{i,j}$. Similarly, part (ii) follows from the conditions in Lemma 3.2(ii)(a). □

Lemma 3.4 (Rank conditions): Let r *be the number of columns from* $P_{i,j}$ *and let* s *be the number of columns from* $Q_{i,j}$ *in the minors associated with the dominant pair of phase combinations of Lemma 3.2.*

(i) *If* $[i,j]$ *identifies an asymptotic line soliton as* $y\to\infty$, *then* $\operatorname{rank}(P_{i,j})=r\leqslant N-1$ *and* $\operatorname{rank}(P_{i,j}|A[i])=\operatorname{rank}(P_{i,j}|A[j])=\operatorname{rank}(P_{i,j}|A[i,j])=r+1$.
(ii) *If* $[i,j]$ *identifies an asymptotic line soliton as* $y\to-\infty$, *then* $\operatorname{rank}(Q_{i,j})=s\leqslant N-1$ *and* $\operatorname{rank}(Q_{i,j}|A[i])=\operatorname{rank}(Q_{i,j}|A[j])=\operatorname{rank}(Q_{i,j}|A[i,j])=s+1$.

Above and hereafter, $(A|B)$ *denotes the matrix* A *augmented by the matrix* B.

Proof: Let us prove part (i). Since the columns $A[p_1],\dots,A[p_r]$ form a basis for the column space of $P_{i,j}$, from Lemma 3.3(i) we immediately have $\operatorname{rank}(P_{i,j})=r$. Moreover, since $\mathcal{A}=\{A[i],A[p_1],\dots,A[p_r],A[q_1],\dots,A[q_s]\}$ is a basis for $\mathbb{R}^N$, the vectors $A[i],A[p_1],\dots,A[p_r]$ are linearly independent, and therefore $\operatorname{rank}(P_{i,j}|A[i])=r+1$. Similarly, replacing $A[i]$ with $A[j]$ in the previous statement we have $\operatorname{rank}(P_{i,j}|A[j])=r+1$. It remains to prove that $\operatorname{rank}(P_{i,j}|A[i,j])=r+1$. Expanding the jth column of A in terms of $\mathcal{A}$ as in Lemma 3.3 we have

$$A[j]=aA[i]+\sum_{m=1}^{r}b_mA[p_m]+\sum_{m=1}^{s}c_mA[q_m]. \tag{3.4}$$

By replacing one of the columns $A[q_1],\dots,A[q_s]$ in $A(i,p_1,\dots,p_r,q_1,\dots,q_s)$ with $A[j]$, we have from Lemma 3.2(i)(b) that $A(i,p_1,\dots,p_r,q_1,\dots,q_{m-1},j,q_{m+1},\dots,q_s)=0$. Therefore $c_m=0$ for all $m=1,\dots,s$. Consequently we have $A[j]\in\operatorname{span}(\{A[i],A[p_1],\dots,A[p_r]\})$, which implies that $\operatorname{rank}(P_{i,j}|A[i,j])=r+1$. Similarly, using Lemma 3.2(ii)(b) one can establish the corresponding results in part (ii) for the asymptotic line solitons as $y\to-\infty$. □

It is important to note that, even though Lemmas 3.3–3.4 were proved by using the vanishing minor conditions in Lemma 3.2, they provide additional information on the structure of the coefficient matrix A. For example, when $r<N-1$ for an asymptotic line soliton as $y\to\infty$, Lemma

3.4 yields $\text{rank}(P_{i,j}|A[i,j]) < N$, and when $s < N-1$ for an asymptotic line soliton as $y \to -\infty$, Lemma 3.4 yields $\text{rank}(Q_{i,j}|A[i,j]) < N$. As a consequence, we immediately have the following additional vanishing minor conditions:

(i) If $[i,j]$ identifies an asymptotic line soliton as $y \to \infty$, then

$$A(i,j,p_1,\ldots,p_r,m_1,\ldots,m_{N-r-2}) = 0 \quad \forall \{m_1,\ldots,m_{N-r-2}\} \subset \{1,\ldots,M\}. \tag{3.5a}$$

(ii) If $[i,j]$ identifies an asymptotic line soliton as $y \to -\infty$, then

$$A(i,j,q_1,\ldots,q_s,m_1,\ldots,m_{N-s-2}) = 0 \quad \forall \{m_1,\ldots,m_{N-s-2}\} \subset \{1,\ldots,M\}. \tag{3.5b}$$

We remark that conditions (3.5) were also introduced (without proof) in Ref. 12 (cf. Definition 4.2) in order to characterize the tau functions of the elastic N-soliton solutions which correspond to the special case $M=2N$. It should also be noted that, when $[i,j]$ identifies an asymptotic line soliton as $y \to \infty$, Lemma 3.4(i) only provides information on $P_{i,j}$, and the only condition on $Q_{i,j}$ is that $\text{rank}(Q_{i,j}) \geqslant s$. Similarly, when $[i,j]$ identifies an asymptotic line soliton as $y \to -\infty$, all is known about $P_{i,j}$ is that $\text{rank}(P_{i,j}) \geqslant r$.

B. Characterization of the asymptotic line solitons from the coefficient matrix

In the preceding section we derived several conditions that an index pair $[i,j]$ must satisfy in order to identify an asymptotic line soliton. Those results are now applied to obtain a complete characterization of the incoming and outgoing asymptotic line solitons of a generic line-soliton solution of the KPII equation.

Lemma 3.5 (Pivots and nonpivots): Consider an index pair $[i,j]$ with $1 \leqslant i < j \leqslant M$.

(i) *If $[i,j]$ identifies an asymptotic line soliton as $y \to \infty$, the index i labels a pivot column of the coefficient matrix A. That is, $A[i]=A[e_n]$ with $1 \leqslant n \leqslant N$.*

(ii) *If $[i,j]$ identifies an asymptotic line soliton as $y \to -\infty$, the index j labels a nonpivot column of the coefficient matrix A. That is, $A[j]=A[g_n]$ with $1 \leqslant n \leqslant M-N$.*

Proof: We first prove part (i). Suppose that $\theta_{i,m_2,\ldots,m_N}$ is one of the dominant phase combinations corresponding to the asymptotic line soliton $[i,j]$ as $y \to \infty$. The corresponding minor $A(i,m_2,\ldots,m_N)$ is nonzero. Since A is in RREF, we have $A[i]=\sum_{r=1}^{n} c_r A[e_r]$ for some $n \leqslant N$, where $e_1 < \cdots < e_n \leqslant i$. Therefore $A(i,m_2,\ldots,m_N)=\sum_{r=1}^{n} c_r A(e_r,m_2,\ldots,m_N)$. If $e_n < i$, we have $A[e_1],\ldots,A[e_n] \in P_{i,j}$, where $P_{i,j}$ is the submatrix of A defined in Eq. (3.2). Then from condition (a) in Lemma 3.2(i) we have $A(e_r,m_2,\ldots,m_N)=0 \; \forall r=1,\ldots,n$, implying that $A(i,m_2,\ldots,m_N)=0$. But this is impossible, since $\theta_{i,m_2,\ldots,m_N}$ is a dominant phase combination. Therefore we must have $i=e_n$, meaning that $A[i]$ is a pivot column.

Part (ii) follows from the rank conditions in Lemma 3.4(ii). In particular, $\text{rank}(Q_{i,j}|A[i]) = \text{rank}(Q_{i,j}|A[i,j]) = s+1$ implies that $A[j] \in \text{span}(\{A[i],\ldots,A[j-1]\})$. Since A is in RREF, none of its pivot column can be spanned by the preceding columns. Hence $A[j]$ is not a pivot column. □

Lemma 3.5 identifies outgoing and incoming asymptotic line solitons, respectively, with the pivot and the nonpivot columns of A. It is then natural to ask if in fact each of the N pivot columns and each of the $M-N$ nonpivot columns identifies an outgoing or incoming line soliton, and whether such identification is unique. Both of these questions can be answered affirmatively by the following theorem which constitutes one of the main results of this work, and is proved in the Appendix.

Theorem 3.6: *(Asymptotic line solitons) Let $\tau_{N,M}(x,y,t)$ be the tau function in Eq. (2.1) associated with a rank N, irreducible coefficient matrix A with non-negative minors.*

(i) *For each pivot index e_n there exists a unique asymptotic line soliton as $y \to \infty$, identified by an index pair $[e_n,j_n]$ with $n=1,\ldots,N$ and $1 \leqslant e_n < j_n \leqslant M$.*

(ii) *For each nonpivot index g_n there exists a unique asymptotic line soliton as $y \to -\infty$, identified by an index pair $[i_n,g_n]$ with $n=1,\ldots,M-N$ and $1 \leqslant i_n < g_n \leqslant M$.*

Thus, the solution of KPII generated by the coefficient matrix A via Eq. (2.1) *has exactly* $N_+=N$ *asymptotic line solitons as* $y\to\infty$ *and* $N_-=M-N$ *asymptotic line solitons as* $y\to-\infty$.

Part (i) of Theorem 3.6 uniquely identifies the asymptotic line solitons as $y\to\infty$ by the index pairs $[e_n,j_n]$ where $e_n<j_n$. The indices $e_1,\dots,e_N$ label the N pivot columns of A, however, the j_n's may correspond to either pivot or nonpivot columns, and indeed both cases appear in examples. Moreover, when the pivot indices are sorted in increasing order $1=e_1<e_2<\cdots<e_N<M$, the indices $j_1,\dots,j_N$ in general *are not sorted* in any specific order. For example, the line solitons as $y\to\infty$ generated by the matrix A in Eq. (4.5) of Sec. IV have $j_1<j_3<j_2$. In fact, the indices $j_1,\dots,j_N$ need not necessarily even be distinct. Similarly, part (ii) of Theorem 3.6 uniquely identifies the asymptotic line solitons as $y\to-\infty$ by index pairs $[i_n,g_n]$, where $i_n<g_n$. In this case, the indices $g_1,\dots,g_{M-N}$ label the $M-N$ nonpivot columns of A, but the i_n's may correspond to either pivot or nonpivot columns. Moreover, when the nonpivot indices are sorted in increasing order $1<g_1<\cdots<g_{M-N}=M$, the indices $i_1,\dots,i_{M-N}$ are not in general sorted, and need not be distinct. Theorem 3.6 yields an important characterization of the solution via the associated coefficient matrix A, and it provides a concrete method to identify the asymptotic line solitons as $y\to\pm\infty$, as illustrated with the examples below. Further examples are discussed in Sec. IV.

Example 3.7: Consider the tau function $\tau_{N,M}$ with $N=2$ and $M=5$ generated by the coefficient matrix

$$A=\begin{pmatrix}1&1&0&-1&-2\\0&0&1&1&1\end{pmatrix}. \tag{3.6}$$

The pivot columns of A are labeled by the indices $\{e_1,e_2\}=\{1,3\}$, and the nonpivot columns by the indices $\{g_1,g_2,g_3\}=\{2,4,5\}$. It follows from Theorem 3.6 that there will be $N_+=N=2$ asymptotic line solitons as $y\to\infty$, identified by the index pairs $[1,j_1]$ and $[3,j_2]$ for some $j_1>1$ and $j_2>3$, and that there will be $N_-=M-N=3$ asymptotic line solitons as $y\to-\infty$, identified by the index pairs $[i_1,2]$, $[i_2,4]$, and $[i_3,5]$, for some $i_1<2$, $i_2<4$, and $i_3<5$. We first determine the asymptotic line solitons as $y\to\infty$ using part (i) of Theorem 3.6 together with the rank conditions in Lemma 3.4(i). The we find the asymptotic line solitons as $y\to-\infty$ using part (ii) of Theorem 3.6 and the rank conditions in Lemma 3.4(ii).

For the first pivot column, $e_1=1$, we start with $j=2$ and consider the submatrix $P_{1,2}=\left(\begin{smallmatrix}0&-1&-2\\1&1&1\end{smallmatrix}\right)$. Since $\operatorname{rank}(P_{1,2})=2>1=N-1$, from Lemma 3.4(i) we conclude that the pair [1,2] cannot identify an asymptotic line soliton as $y\to\infty$. Incrementing j to $j=3,4,5$ and checking the rank of each submatrix $P_{1,j}$ we find that the rank conditions in Lemma 3.4(i) are satisfied when $j=4$, and $P_{1,4}=\left(\begin{smallmatrix}-2\\1\end{smallmatrix}\right)=A[5]$. So, $\operatorname{rank}(P_{1,4})=1$ and $\operatorname{rank}(P_{1,4}|A[1])=\operatorname{rank}(P_{1,4}|A[4])=2$. The condition $\operatorname{rank}(P_{1,4}|A[1,4])=2$ is trivial here, since any three columns are linearly dependent. Thus, the first asymptotic line soliton as $y\to\infty$ is identified by the index pair [1,4]. For the second pivot, $e_2=3$, proceeding in a similar manner we find that $j=4$ does not satisfy the rank conditions because $P_{3,4}$ has rank 2. But $j=5$ satisfies Lemma 3.4(i), since $P_{3,5}=\left(\begin{smallmatrix}1&1\\0&0\end{smallmatrix}\right)$, which yields $\operatorname{rank}(P_{3,5})=1$ and $\operatorname{rank}(P_{3,5}|A[3])=\operatorname{rank}(P_{3,5}|A[5])=2$. Again, $\operatorname{rank}(P_{3,5}|A[3,5])=2$ is trivially satisfied here. So the asymptotic line solitons as $y\to\infty$ are given by the index pairs [1,4] and [3,5], and the associated phase transition diagram (cf. Corollary 2.6) is given by

$$R_{1,3}\xrightarrow{3\to5}R_{1,5}\xrightarrow{1\to4}R_{4,5}.$$

We now consider the asymptotics for $y\to-\infty$. Starting with the nonpivot column $g_1=2$, the only column to its left is $i=1$. We have $Q_{1,2}=\emptyset$, and $\operatorname{rank}(Q_{1,2}|A[1])=\operatorname{rank}(Q_{1,2}|A[2])=\operatorname{rank}(Q_{1,2}|A[1,2])=1$. Consequently, the pair [1,2] identifies an asymptotic line soliton as $y\to-\infty$. For $g_2=4$ we consider $i=1,2,3$ and find that the rank conditions in Lemma 3.4(ii) are satisfied only for $i=2$. In this case, $Q_{2,4}=\left(\begin{smallmatrix}0\\1\end{smallmatrix}\right)=A[3]$, so $\operatorname{rank}(Q_{2,4})=1=N-1$ and $\operatorname{rank}(Q_{2,4}|A[2])=\operatorname{rank}(Q_{2,4}|A[4])=2$, while $\operatorname{rank}(Q_{2,4}|A[2,4])=2$ is trivially satisfied. Hence [2,4] is the unique

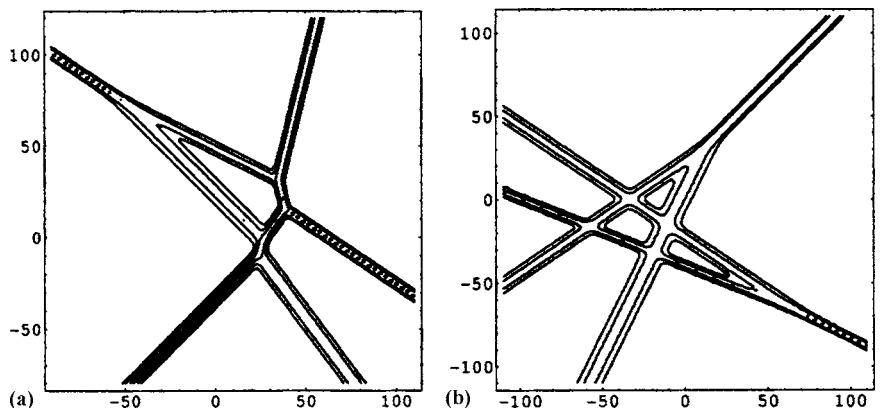

FIG. 3. Line soliton solutions of KPII: (a) the (3,2)-soliton solution generated by the coefficient matrix A in Example 3.7 with $(k_1,\ldots,k_5)=(-1,0,\frac{1}{4},\frac{3}{4},\frac{5}{4})$ at $t=-32$; (b) the inelastic 3-soliton solution generated by the coefficient matrix A in Example 3.8 with $(k_1,\ldots,k_6)=(-1,-\frac{1}{2},0,\frac{1}{2},1,\frac{3}{2})$ at $t=20$ (see text for details).

asymptotic line soliton as $y\to-\infty$ associated to the nonpivot column $g_2=4$. In a similar way we can uniquely identify the last asymptotic line soliton as $y\to-\infty$ as given by the indices [3,5]. The phase transition diagram for $y\to-\infty$ is thus given by

$$R_{1,3}\xrightarrow{1\to2}R_{2,3}\xrightarrow{2\to4}R_{3,4}\xrightarrow{3\to5}R_{4,5}.$$

To summarize, there are $N_+=2$ outgoing line solitons, each associated with one of the pivot columns $e_1=1$ and $e_2=3$, given by the index pairs [1,4] and [3,5], and there are $N_-=3$ incoming line solitons, each associated with one of the nonpivot columns $g_1=2$, $g_2=4$, and $g_3=5$, given by the index pairs [1,2], [2,4], and [3,5]. A snapshot of the solution at $t=-32$ is shown in Fig. 3(a).

Example 3.8: Consider the tau function with $N=3$ and $M=6$ generated by the coefficient matrix in RREF,

$$A=\begin{pmatrix}1&1&1&0&0&0\\0&0&0&1&0&-1\\0&0&0&0&1&2\end{pmatrix}. \tag{3.7}$$

Again, we first determine the asymptotic line solitons as $y\to\infty$, and then the asymptotic line solitons as $y\to-\infty$.

The pivot columns of A are labeled by the indices $e_1=1$, $e_2=4$, and $e_3=5$. Thus, we know that the asymptotic line solitons as $y\to\infty$ will be given by the index pairs $[1,j_1]$, $[4,j_2]$, and $[5,j_3]$ for some $j_1>1$, $j_2>4$, and $j_3>5$. Starting with the first pivot, $e_1=1$, we take $j=2,3,\ldots$ and check the rank of the submatrix $P_{i,j}$ in each case. When $j=2$ we have $P_{1,2}=\begin{pmatrix}1&0&0&0\\0&1&0&-1\\0&0&1&2\end{pmatrix}$, and $\mathrm{rank}(P_{1,2})=3>N-1$. So, by Lemma 3.4(i), the index pair [1,2] does not correspond to an asymptotic line soliton as $y\to\infty$. In fact, using Lemma 3.1 it can be verified that $\theta_{3,5,6}$ is the only dominant phase combination along the line $\theta_1=\theta_2$ as $y\to\infty$. Next, we consider $j=3$. In this case we have $P_{1,3}=\begin{pmatrix}0&0&0\\1&0&-1\\0&1&2\end{pmatrix}$, with $\mathrm{rank}(P_{1,3})=2=:r$ and $\mathrm{rank}(P_{1,3}|A[1])=\mathrm{rank}(P_{1,3}|A[3])=\mathrm{rank}(P_{1,3}|A[1,3])=3=r+1$. So the rank conditions in Lemma 3.4(i) are satisfied. Therefore the index pair [1,3] corresponds to an asymptotic line soliton as $y\to\infty$. Moreover, by considering $j=4,5,6$ one can easily check that the rank conditions are no longer satisfied. Thus [1,3] is the *unique* asymptotic line soliton associated with the pivot index $e_1=1$ as $y\to\infty$, in agreement with Theorem 3.6. Let us now

consider the second pivot column, $e_2=4$. In this case we find that the rank conditions are only satisfied when $j=5$, since $P_{4,5}=\begin{pmatrix}1&1&1&0\\0&0&0&-1\\0&0&0&2\end{pmatrix}$, with $\mathrm{rank}(P_{4,5})=2=:r$ and $\mathrm{rank}(P_{4,5}|A[4])=\mathrm{rank}(P_{4,5}|A[5])=\mathrm{rank}(P_{4,5}|A[4,5])=3=r+1$. Therefore, the index pair [4,5] corresponds to an asymptotic line soliton as $y\to\infty$. Finally, for $e_3=5$, since we know from Theorem 3.6 that $j>e_3$, we immediately find that the third asymptotic line soliton as $y\to\infty$ is given by the index pair [5,6]. From Corollary 2.6, the phase transition diagram as $y\to\infty$ is given by

$$R_{1,4,5}\xrightarrow{5\to6}R_{1,4,6}\xrightarrow{4\to5}R_{1,5,6}\xrightarrow{1\to3}R_{3,5,6}.$$

The nonpivot columns of the coefficient matrix A are labeled by the indices $g_1=2$, $g_2=3$, and $g_3=6$. For $g_1=2$, the only possible value of $i<j$ is $i=1$. In this case $Q_{1,2}=\emptyset$, so $\mathrm{rank}(Q_{1,2})=0$ and $\mathrm{rank}(Q_{1,2}|A[1])=\mathrm{rank}(Q_{1,2}|A[2])=\mathrm{rank}(Q_{1,2}|A[1,2])=1$. Thus the pair [1,2] identifies an asymptotic line soliton as $y\to-\infty$. For $g_2=3$ we consider $i=2,1$. When $i=2$, the rank conditions in Lemma 3.4(ii) are satisfied, leading to the asymptotic line soliton [2,3] as $y\to-\infty$. We can check that the soliton associated with the nonpivot column $g_2=3$ is unique by considering $i=1$ and verifying that the rank conditions are not satisfied. Similarly, it is easy to verify that for $g_3=6$ the index pair [4,6] uniquely identifies the asymptotic line soliton as $y\to-\infty$. The phase transition diagram as $y\to-\infty$ reads as follows:

$$R_{1,4,5}\xrightarrow{1\to2}R_{2,4,5}\xrightarrow{2\to3}R_{3,4,5}\xrightarrow{4\to6}R_{3,5,6}.$$

Summarizing, there are $N_+=3$ asymptotic line solitons as $y\to\infty$ identified by the index pairs [1,3], [4,5], and [5,6], and there are $N_-=3$ asymptotic line solitons as $y\to-\infty$ identified by the index pairs [1,2], [2,3], and [4,6]. A snapshot of the solution at $t=-20$ is shown in Fig. 3(b).

Examples 3.7 and 3.8 illustrate the fact that, starting from any given coefficient matrix A in RREF, the asymptotic line solitons as $y\to\pm\infty$ can be identified in an algorithmic way by applying Theorem 3.6 together with the rank conditions in Lemma 3.4.

IV. FURTHER EXAMPLES

In this section we present a variety of line-soliton solutions of KPII generated by the tau function (2.2) with different choices of coefficient matrices.

Ordinary N-soliton solutions: These are constructed by taking $M=2N$ and choosing the functions $\{f_n\}_{n=1}^N$ in Eq. (1.10) as (e.g., see Refs. 5 and 15)

$$f_n(x,y,t)=e^{\theta_{2n-1}}+e^{\theta_{2n}},\quad n=1,\dots,N. \tag{4.1}$$

The corresponding coefficient matrix is thus given by

$$A=\begin{pmatrix}1&1&0&0&\cdots&0&0\\0&0&1&1&\cdots&0&0\\\vdots&\vdots&\vdots&\vdots&\vdots&\vdots&\vdots\\0&0&0&0&\cdots&1&1\end{pmatrix},$$

with N pairs of identical columns at positions $\{2n-1,2n\}$, $n=1,\dots,N$. There are only 2^N nonzero minors of A, which are given by $A(m_1,m_2,\dots,m_N)=1$ where, for each $n=1,\dots,N$, either $m_n=2n-1$ or $m_n=2n$. The asymptotic analysis of the preceding section implies that the nth asymptotic line soliton as $y\to\pm\infty$ is identified by the index pair $[2n-1,2n]$ for $n=1,\dots,N$, where $i_n=2n-1$ and $j_n=2n$ label, respectively, the pivot and nonpivot columns of A. Therefore the amplitude and direction are given by $a_n=k_{2n}-k_{2n-1}$ and $c_n=k_{2n-1}+k_{2n}$. Moreover, the dominant pair of phase combinations for the nth soliton as $y\to\infty$ is given by $\theta_{1,3,\dots,2n-1,2n+2,2n+4,\dots,2N}$ and $\theta_{1,3,\dots,2n-3,2n,2n+2,\dots,2N}$, while the dominant phase combinations for the same soliton as $y\to-\infty$ by

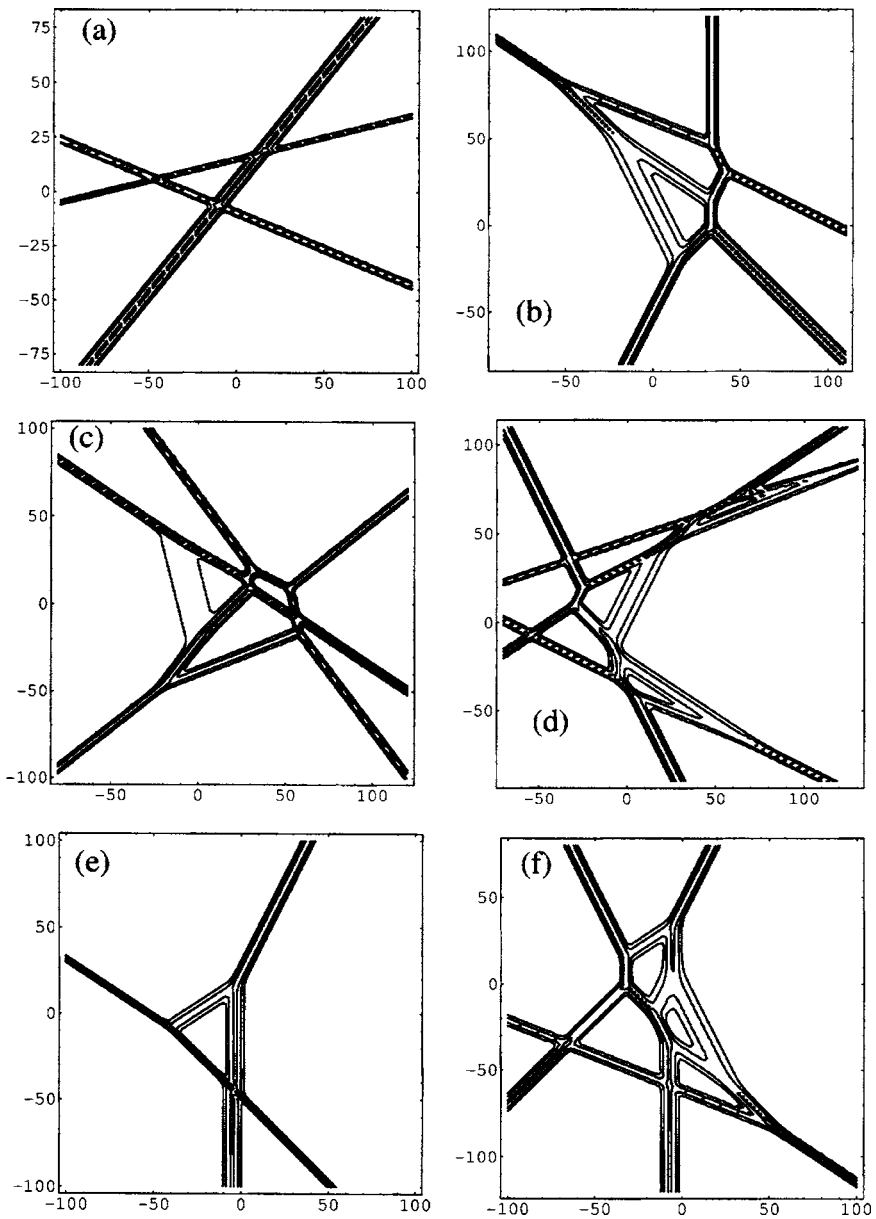

FIG. 4. Line-soliton solutions of KPII: (a) an ordinary 3-soliton solution with $(k_1,\ldots,k_6)=(-3,-2,0,1,\frac{3}{2},2)$ at $t=4$; (b) a fully resonant (3,2)-soliton solution with $(k_1,\ldots,k_5)=(-1,0,\frac{1}{2},1,\frac{3}{2})$ at $t=-32$; (c) an elastic, partially resonant 3-soliton solution with A given by Eq. (4.5) and $(k_1,\ldots,k_6)=(-\frac{3}{2},-1,0,\frac{1}{4},\frac{3}{2},\frac{7}{4})$ at $t=-20$; (d) an elastic, partially resonant 4-soliton solution with A given by Eq. (4.6) and $(k_1,\ldots,k_8)=(-2,-\frac{3}{2},-1,-\frac{1}{2},0,\frac{1}{2},1,\frac{3}{2})$ at $t=20$; (e) an inelastic 2-soliton solution with A given by Eq. (4.7) and $(k_1,\ldots,k_4)=(-1,-\frac{1}{2},\frac{1}{2},2)$ at $t=16$; (f) an inelastic 3-soliton solution with A given by Eq. (4.8) and $(k_1,\ldots,k_6)=(-1,-\frac{1}{2},0,\frac{1}{2},1,\frac{3}{2})$ at $t=32$.

$\theta_{2,4,\ldots,2n,2n+1,2n+3,\ldots,2N-1}$ and $\theta_{2,4,\ldots,2n-2,2n-1,2n+1,\ldots,2N-1}$. Apart from the phase shift of each line soliton, the interaction gives rise to a pattern of N intersecting lines in the xy plane, as shown in Fig. 4(a).

Solutions of KPII which also satisfy the finite Toda lattice hierarchy: Another class of (N_-,N_+)-soliton solutions of KPII is given by the following choice of functions $\{f_n\}_{n=1}^N$ in Eq. (1.10):

$$f_n = f^{(n-1)}, \quad n = 1, \ldots, N. \tag{4.2}$$

In addition to generating solutions of KPII, the set of tau functions $\tau_{N,M}$ for $N=1,\ldots,M$ also satisfy the Plücker relations for the finite Toda lattice hierarchy.[2] Choosing $f(x,y,t)=\sum_{m=1}^{M} e^{\theta_m}$ yields the following coefficient matrix:

$$A = \begin{pmatrix} 1 & 1 & \cdots & 1 \\ k_1 & k_2 & \cdots & k_M \\ \vdots & \vdots & \ddots & \vdots \\ k_1^{N-1} & k_2^{N-1} & \cdots & k_M^{N-1} \end{pmatrix}. \tag{4.3}$$

Note that A in Eq. (4.3) is not in RREF, and coincides with the matrix K in Lemma 2.1. The pivot columns of A are labeled by indices $1,\ldots,N$. Furthermore, all the $N\times N$ minors of A are nonzero, and coincide with the Van der Monde determinants in Eq. (2.4). The corresponding class of KPII solutions was studied in Ref. 2, where it was shown that the N asymptotic line solitons as $y\to\infty$ are identified by the index pairs $[n,n+M-N]$ for $n=1,\ldots,N$, while the $M-N$ asymptotic line solitons as $y\to-\infty$ are identified by the index pairs $[n,n+N]$ for $n=1,\ldots,M-N$. These pairings can also be easily verified using Theorem 3.6. The dominant pair of phase combinations for the nth soliton as $y\to\infty$ is given by $\theta_{1,\ldots,n,M-N+n+1,\ldots,M}$ and $\theta_{1,\ldots,n-1,M-N+n,\ldots,M}$, while the dominant pair of phase combinations for the nth soliton as $y\to-\infty$ by $\theta_{n,\ldots,N+n-1}$ and $\theta_{n+1,\ldots,N+n}$. The solution displays phenomena of soliton resonance and web structure [e.g., see Fig. 4(b)]. More precisely, the interaction of the asymptotic line solitons results in a pattern with $(2N_- -1)N_+$ interaction vertices, $(3N_- -2)N_+$ intermediate interaction segments and $(N_- -1)(N_+ -1)$ "holes" in the xy plane. Each of the intermediate interaction segments can be effectively regarded as a line soliton since it satisfies the dispersion relation (1.8). Furthermore, all of the asymptotic and intermediate line solitons interact via a collection of *fundamental resonances*. A fundamental resonance, also called a Y junction, describes an interaction of three line solitons whose wave numbers $\mathbf{k}_a$ and frequencies ω_a $(a=1,2,3)$ satisfy the three-wave resonance conditions[17,19]

$$\mathbf{k}_1 + \mathbf{k}_2 = \mathbf{k}_3, \quad \omega_1 + \omega_2 = \omega_3. \tag{4.4}$$

Such a solution is shown in Fig. 1(a).

Elastic N-soliton solutions: As mentioned in Sec. I and in the Appendix, the elastic N-soliton solutions are those for which the sets of incoming and outgoing asymptotic line solitons are the same. In this case we necessarily have $M=2N$. Ordinary N-soliton solutions and solutions of KPII which also satisfy the finite Toda lattice hierarchy with $M=2N$ are two special classes of elastic N-soliton solutions. However, a large variety of other elastic N-soliton solutions do also exist, and were recently investigated in Ref. 12. For example, Fig. 4(c) shows an elastic 3-soliton solution generated by the coefficient matrix,

$$A = \begin{pmatrix} 1 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & -2 & -2 & -1 \\ 0 & 0 & 1 & 2 & 1 & 0 \end{pmatrix}. \tag{4.5}$$

In this case the pivot columns are labeled by indices 1, 2, and 3. So, from Lemma 3.5 we know that the asymptotic line solitons as $y\to\infty$ will be identified by index pairs $[1,j_1]$, $[2,j_2]$, and $[3,j_3]$, while those as $y\to-\infty$ by index pairs $[i_1,4]$, $[i_2,5]$, and $[i_3,6]$, for certain values of $i_1,\ldots,i_3$ and $j_1,\ldots,j_3$. Indeed, from the results developed in Sec. III one can verify that both the incoming and the outgoing asymptotic line solitons are given by the *same* index pairs [1,4], [2,6], and [3,5]. The soliton interactions in this case are *partially resonant*, in the sense that the pairwise interaction among solitons [1,4] and [2,6] and that among solitons [1,4] and [3,5] are both resonant, but the pairwise interaction among solitons [2,6] and [3,5] is nonresonant. Similarly, Fig. 4(d) shows an elastic, partially resonant 4-soliton solution generated by the coefficient matrix

$$A = \begin{pmatrix} 1 & 0 & -1 & 0 & 1 & 0 & -1 & -2 \\ 0 & 1 & 2 & 0 & -1 & 0 & 1 & 2 \\ 0 & 0 & 0 & 1 & 2 & 0 & -1 & -2 \\ 0 & 0 & 0 & 0 & 0 & 1 & 2 & 3 \end{pmatrix}. \tag{4.6}$$

In this case the pivot columns are labeled by the indices 1, 2, 4, and 6 and the nonpivot columns by the indices 3, 5, 7, and 8. The asymptotic line solitons as $y \to \pm\infty$ are identified by the index pairs [1,3], [2,5], [4,7], and [6,8]. As can be seen from Fig. 4(f), the pairwise interaction of solitons [1,3] and [2,5], solitons [2,5] and [4,7], and [4,7] and [6,8] are resonant, but the remaining pairwise interactions between solitons [1,3] and [4,7], [1,3] and [6,8], [2,5] and [6,8], are nonresonant. It should be clear from these examples that a large variety of elastic N-soliton solutions with resonant, partially resonant and nonresonant interactions is possible.

Inelastic N-soliton solutions: There also exist a large class of N-soliton solutions that are not elastic. We have already seen such solutions in Examples 3.7 and 3.8 [cf. Figs. 3(a) and 3(b)] of Sec. III. As a further example, Fig. 4(e) shows an inelastic 2-soliton solution generated by the coefficient matrix

$$A = \begin{pmatrix} 1 & 0 & 0 & -1 \\ 0 & 1 & 1 & 1 \end{pmatrix}. \tag{4.7}$$

In this case the pivot columns are labeled by indices 1 and 2. The asymptotic line solitons as $y \to -\infty$ are identified by the index pairs [1,4] and [2,3], while those as $y \to \infty$ by the index pairs [1,3] and [2,4]. Notice that the outgoing solitons interact resonantly via two Y junctions, while the incoming soliton pair interact nonresonantly. This is in contrast with an elastic 2-soliton solution, where both incoming and outgoing pairs of solitons exhibit the same kind of interaction. Similarly, Fig. 4(f) shows inelastic 3-soliton solution generated by the coefficient matrix

$$A = \begin{pmatrix} 1 & 0 & -1 & -1 & 0 & 2 \\ 0 & 1 & 2 & 1 & 0 & -1 \\ 0 & 0 & 0 & 0 & 1 & 1 \end{pmatrix}. \tag{4.8}$$

Here the pivot columns are labeled by indices 1, 2, and 5. The asymptotic line solitons as $y \to \infty$ are identified by the index pairs [1,3], [2,5], and [5,6], while those as $y \to -\infty$ by the index pairs [1,3], [2,4], and [3,6].

Finally, we remark that in the generic case $M \neq 2N$, the numbers of asymptotic line solitons as $y \to \pm\infty$ are different, as in the solutions shown in Figs. 3(a) and 4(b). Also, note that the one-soliton solutions, the ordinary two-soliton solutions and the Y junction solutions have the property that their time evolution is just an overall translation of a fixed spatial pattern. However, for all other solutions discussed above, the interaction patterns formed by the asymptotic line solitons, and the relative positions of the interaction vertices in the xy plane are in general time dependent.

V. CONCLUSIONS

In this paper we have studied a class of line-soliton solutions of the Kadomtsev-Petviashvili II equation by expressing the tau function as the Wronskian of N linearly independent combinations of M exponentials. From the asymptotics of the tau function as $y \to \pm\infty$ we showed that each of these solutions of KPII is composed of asymptotic line solitons which are defined by the transition between two dominant phase combinations with $N-1$ common phases. Moreover, the number, amplitudes and directions of the asymptotic line solitons are invariant in time. We also derived an algorithmic method to identify these asymptotic line solitons in a given solution by examining the $N \times M$ coefficient matrix A associated with the corresponding tau function. In particular, we proved that every $N \times M$, irreducible coefficient matrix A produces an (N_-, N_+)-soliton solution of KPII in which there are $N_+ = N$ asymptotic line solitons as $y \to \infty$, labeled by the pivot columns of A, and $N_- = M - N$ asymptotic line solitons as $y \to -\infty$, labeled by the nonpivot columns of A. Such

solutions exhibit a rich variety of time-dependent spatial patterns which include resonant soliton interactions and web structure. Finally, we discussed a number of examples of such (N_-,N_+)-soliton solutions in order to illustrate the above results.

It is remarkable that the KPII equation possesses such a rich structure of line-soliton solutions generated by a simple form of the tau function. In this work we have primarily focused on the asymptotic behavior of the solutions as $y\to\pm\infty$, but not on their interactions in the xy plane. A full characterization of the interaction patterns of the general (N_-,N_+)-soliton solutions is an important open problem, which is left for further study. Nonetheless, we believe that our results will provide a key step toward that endeavor. We point out that resonant interaction described by the line solitons of KPII is a physical phenomenon that has been observed experimentally in ion-acoustic waves (see e.g., Refs. 20 and 13). Hence, we expect that the resonant solutions considered in this work are likely to be stable with respect to small perturbations and physically relevant. However, a formal stability analysis of these $(2+1)$-dimensional solutions is a highly nontrivial task, and has not yet been carried out to the best of our knowledge. Finally, we note that soliton solutions exhibiting phenomena of soliton resonance and web structure have been found for several other $(2+1)$-dimensional integrable systems, and those solutions can also be described by direct algebraic methods similar to the ones used here. Therefore we expect that the results presented in this work will also be useful to study solitonic solutions in a variety of other $(2+1)$-dimensional integrable systems.

APPENDIX A: PROOF OF THEOREM 2.5

To prove part (i) of Theorem 2.5, it is sufficient to show that, along each line L_c, the sign of the inequalities among the phase combinations in Definition 2.3 remain unchanged in time as $y\to\pm\infty$. For this purpose, note that the sign of $\theta_{m_1,\ldots,m_N}-\theta_{m_1',\ldots,m_N'}$ in Eq. (2.6b) is determined by the coefficient of y on the right-hand side as $y\to\pm\infty$ and for finite ξ and t, if this coefficient is nonzero. For generic values of the phase parameters $k_1,\ldots,k_M$ this coefficient is indeed nonvanishing, and its sign depends only on the direction c of the line L_c. Consequently, the dominant phase combinations asymptotically as $y\to\pm\infty$ are determined only by the constant c for finite time.

Part (ii) of the theorem is proved by showing that the only possible phase transitions are those in which a single phase, say θ_m changes to $\theta_{m'}$ between the two dominant phase combinations across adjacent regions, and that no other type of transitions can occur. We first prove that single-phase transitions are allowed; then we show that no other type of transitions are allowed. In the following, we will assume t to be finite so that the dominant phase combinations remain invariant, according to part (i). Suppose that $\theta_{m_1,\ldots,m_N}$ is the dominant phase combination in a region R asymptotically for large values of $|y|$. Since R is a proper subset of $\mathbb{R}^3$, it *must* have a boundary, across which a transition will take place from $\theta_{m_1,\ldots,m_N}$ to some other dominant phase combination. Since $\theta_{m_1,\ldots,m_N}$ is dominant, $A(m_1,\ldots,m_N)\neq 0$ according to Definition 2.3. Therefore, the columns $A[m_1],\ldots,A[m_N]$ of the coefficient matrix form a basis of $\mathbb{R}^N$, and for all $j\notin\{m_1,\ldots,m_N\}$ we have that $A[j]$ is in the span of $A[m_1],\ldots,A[m_N]$. Thus there exists at least one column $A[m_s]$ such that the coefficient of $A[m_s]$ in the expansion of $A[j]$ is nonzero. We then have $A(m_1,\ldots,m_{s-1},j,m_{s+1},\ldots,m_N)\neq 0$, implying that the phase combination $\theta_{m_1,\ldots,m_{s-1},j,m_{s+1},\ldots,m_N}$ is actually present in the tau function. Then, for *any* $j\notin\{m_1,\ldots,m_N\}$ it is possible to have a single-phase transition from R to the adjacent region R' across the line $\theta_{m_s}=\theta_j$, since the sign of $\theta_{m_s}-\theta_j$ changes across this line, implying that $\theta_{m_1,\ldots,m_{s-1},j,m_{s+1},\ldots,m_N}$ is larger than $\theta_{m_1,\ldots,m_N}$ in R'.

We next show that no *other* type of transitions can occur apart from single-phase transitions; we do so by *reduction ad absurdum*. Suppose that at least two phases $\theta_{m_1}, \theta_{m_2}$ from the dominant phase combination $\theta_{m_1,\ldots,m_N}$ in a region R are replaced with phases $\theta_{m_1'}, \theta_{m_2'}$ during the transition from R to an adjacent region R'. This transition occurs along the common boundary of R and R', which is given by line $L:(\theta_{m_1}+\theta_{m_2})-(\theta_{m_1'}+\theta_{m_2'})=0$. Thus, along L, the differences $\theta_{m_1}-\theta_{m_1'}$ and $\theta_{m_2}-\theta_{m_2'}$ (or, equivalently, the differences $\theta_{m_1}-\theta_{m_2'}$ and $\theta_{m_2}-\theta_{m_1'}$) must have opposite signs or be both zero.

If both differences are zero along L, the lines $\theta_{m_1}=\theta_{m_1'}$ and $\theta_{m_2}=\theta_{m_2'}$ (or, equivalently, the lines $\theta_{m_1}=\theta_{m_2'}$ and $\theta_{m_1'}=\theta_{m_2}$) must both coincide with the line L in the xy plane. This is possible only at a given instant of time *and* if the directions of the two lines are the same, i.e., if $k_{m_1}+k_{m_1'}=k_{m_2}+k_{m_2'}$ (or, equivalently, $k_{m_1}+k_{m_2'}=k_{m_1'}+k_{m_2}$). So for generic values of the phase parameters, or for generic values of time, this exceptional case can be excluded. Hence, we assume that $\theta_{m_1}-\theta_{m_1'}$ and $\theta_{m_2}-\theta_{m_2'}$ are of opposite signs.

Note that $\theta_{m_1}-\theta_{m_1'}=\theta_{m_1,\ldots,m_N}-\theta_{m_1',m_2,\ldots,m_N}$ and $\theta_{m_2}-\theta_{m_2'}=\theta_{m_1,\ldots,m_N}-\theta_{m_1,m_2',m_3\ldots,m_N}$. Moreover, since $\theta_{m_1,\ldots,m_N}$ is the dominant phase in R, both of these phase differences must be *positive* in the interior of R if the minors $A(m_1',m_2,\ldots,m_N)$ and $A(m_1,m_2',m_3\ldots,m_N)$ are nonzero. Hence, we must conclude that $\theta_{m_1}-\theta_{m_1'}$ and $\theta_{m_2}-\theta_{m_2'}$ cannot have opposite signs unless one or both of the phase combinations $\theta_{m_1',m_2,\ldots,m_N}$ and $\theta_{m_1,m_2',m_3,\ldots,m_N}$ is absent from the tau function. This requires that either $A(m_1',m_2,\ldots,m_N)$ or $A(m_1,m_2',m_3\ldots,m_N)$ must be zero. A similar argument applied to the phase differences $\theta_{m_1}-\theta_{m_2'}$ and $\theta_{m_2}-\theta_{m_1'}$ leads to the conclusion that one or both of the minors $A(m_2',m_2,\ldots,m_N)$ and $A(m_1,m_1',m_3\ldots,m_N)$ must vanish. However, from the Plücker relations among the $N\times N$ minors of A we have

$$A(m_1,m_2\ldots,m_N)A(m_1',m_2',\ldots m_N)=A(m_1,m_2',m_3,\ldots m_N)A(m_1',m_2,\ldots,m_N)-A(m_1,m_1',m_3\ldots,m_N)A(m_2',m_2,\ldots,m_N).$$

It follows from above that either $A(m_1,\ldots,m_N)=0$ or $A(m_1',m_2',m_3,\ldots,m_N)=0$. But this is impossible since by assumption both minors on the left-hand-side are associated with dominant phase combinations. Thus, they are both nonzero. Hence we have reached a contradiction which implies that as $y\to\pm\infty$, phase transitions where more than one phase changes simultaneously across adjacent dominant phase regions, are impossible.

APPENDIX B: PROOF OF THEOREM 3.6

First we need to establish the following Lemma that will be useful in proving the theorem.

Lemma B.1: If P_{ij} is the submatrix defined in Eq. (3.2) *and e_n labels the nth pivot column of an irreducible coefficient matrix A, then $N-1\leqslant \mathrm{rank}(P_{e_n e_n+1})\leqslant N$, $\forall n=1,\ldots,N$.*

Proof: Recall that the pivot indices are ordered as $1=e_1<e_2<\cdots<e_N<M$ for an irreducible matrix A. Then it follows from Definition 2.2(ii) that, corresponding to each pivot column $A[e_n]$ of an irreducible matrix A, there exists at least one nonpivot column $A[j_*]$, with $j_*>e_n$, that has a nonzero entry in its nth row. Hence we have $A(e_1,\ldots,e_{n-1},j_*,e_{n+1},\ldots,e_N)\neq 0$. This implies that the matrix $A[1,\ldots,e_n-1,e_n+1,\ldots,M]=(P_{e_n e_n+1}|A[e_n+1])$ which contains the columns $A[e_1],\ldots,A[e_{n-1}],A[j_*],A[e_{n+1}],\ldots,A[e_N]$, has rank N. Thus, the rank of $P_{e_n e_n+1}$ is *at least* $N-1$, and this yields the desired result. □

We are now ready to prove Theorem 3.6. We prove part (i) here; the proof of part (ii) follows similar steps. The proof of part (i) is divided in two parts. First we show that for each pivot index e_n, $n=1,\ldots,N$, there exists an index $j_n>e_n$ with the necessary and sufficient properties for $[e_n,j_n]$ to identify an asymptotic line soliton as $y\to\infty$; then we prove that such a j_n is unique.

Existence: The proof is constructive. For each pivot index e_n, and for any $j>e_n$, we consider the rank of the matrix $P_{e_n,j}=A[1,2,\ldots,e_n-1,j+1,\ldots,M]$ starting from $j=e_n+1$. When $j=e_n+1$ we have $P_{e_n,j}=P_{e_n,e_n+1}$, and therefore $N-1\leqslant\mathrm{rank}(P_{e_n,e_n+1})\leqslant N$ from Lemma B.1. If $\mathrm{rank}(P_{e_n,e_n+1})=N$, then Lemma 3.4(i) implies that the pair $[e_n,e_n+1]$ *does not* identify an

asymptotic line soliton as $y\to\infty$. In this case, we increment the value of j successively from e_n+1, until $\operatorname{rank}(P_{e_n,j})$ decreases from N to $N-1$. Note that a value of j such that $\operatorname{rank}(P_{e_n,j})=N-1$ always exists because if $j=M$, then $\operatorname{rank}(P_{e_n,M})=\operatorname{rank}(A[1,\dots,e_n-1])=n-1\leqslant N-1$, since A is in RREF. Suppose $j=j_*$ is the smallest index such that $\operatorname{rank}(P_{e_n,j_*})=N-1$ and $\operatorname{rank}(P_{e_n,j_*}|A[j_*])=N$. We next check the rank of $\operatorname{rank}(P_{e_n,j_*}|A[e_n])$. Since $\operatorname{rank}(P_{e_n,j_*})=N-1$, two cases are possible: either (a) $\operatorname{rank}(P_{e_n,j_*}|A[e_n])=N$ or (b) $\operatorname{rank}(P_{e_n,j_*}|A[e_n])=N-1$. We discuss these two cases separately.

(a) Suppose that $\operatorname{rank}(P_{e_n,j_*}|A[e_n])=N$. By construction we have $\operatorname{rank}(P_{e_n,j_*}|A[j_*])=N$, and since $N=\operatorname{rank}(A)$ one also has $\operatorname{rank}(P_{i_n,j_*}|A[e_n,j_*])=N$. In this case we set $j_*=j_n$. It follows from Lemma 3.4 that the pair $[e_n,j_n]$ satisfies the necessary rank conditions to identify an asymptotic line soliton as $y\to\infty$. Next we show that these rank conditions are also *sufficient* in order to determine a pair of dominant phase combinations in the tau function corresponding to the single-phase transition $e_n\to j_n$. Since $\operatorname{rank}(P_{e_n,j_n})=N-1$, it is possible to choose $N-1$ linearly independent columns $A[p_1],\dots,A[p_{N-1}]$ from the matrix P_{e_n,j_n} so that for all choices of linearly independent columns $A[l_1],\dots,A[l_{N-1}]\in P_{e_n,j_n}$ one has $\theta_{p_1,\dots,p_{N-1}}\geqslant\theta_{l_1,\dots,l_{N-1}}$ as $y\to\infty$ along the transition line L_{e_n,j_n}. The existence of such a set is guaranteed because part (i) of the dominant phase condition 3.1 implies that, as $y\to\infty$ in the $[e_n,j_n]$ direction, the phases corresponding to the index set P_{e_n,j_n} are ordered as $\theta_1>\theta_2>\cdots>\theta_{e_n-1}$ and $\theta_{j_n+1}<\theta_{j_n+2}<\cdots<\theta_M$. Therefore, it is possible to select the top $N-1$ phases from the above two lists so that the corresponding columns are linearly independent. Furthermore, the conditions $\operatorname{rank}(P_{e_n,j_n}|A[e_n])=\operatorname{rank}(P_{e_n,j_n}|A[j_n])=N$ imply that the minors $A(e_n,p_1,\dots,p_{N-1})$ and $A(j_n,p_1,\dots,p_{N-1})$ are both nonzero, and thus $\theta_{e_n,p_1,\dots,p_{N-1}}$ and $\theta_{j_n,p_1,\dots,p_{N-1}}$ form a dominant pair of phase combinations as $y\to\infty$ along the direction of L_{e_n,j_n}.

(b) Suppose that $\operatorname{rank}(P_{e_n,j_*}|A[e_n])=N-1$. Note that this is possible only for $n<N$, because when $n=N$ the submatrix $P_{e_N,j}$ for any $j>e_N$ contains the pivot columns $A[e_1],\dots,A[e_{N-1}]$. Hence, $\operatorname{rank}(P_{e_N,j})=N-1$ and $\operatorname{rank}(P_{e_N,j}|A[e_N])=N$. Consequently, $n=N$ always belongs to case (a) above and not to case (b). So we consider only the case $n<N$ below.

Since $\operatorname{rank}(P_{e_n,j_*})=\operatorname{rank}(P_{e_n,j_*}|A[e_n])=N-1$, this means that $A[e_n]\in\operatorname{span}(P_{e_n,j_*})$. However, since $A[e_n]$ is a pivot column, it cannot be spanned only by its preceding columns $A[1],\dots,A[e_n-1]$. Hence the spanning set of $A[e_n]$ from P_{e_n,j_*} must contain at least one column from $A[j_*+1],\dots,A[M]$. In this case we continue incrementing the value of j starting from j_* until the pivot column $A[e_n]$ is no longer in the span of the columns of the resulting submatrix $P_{e_n,j}$. Let j_n be the smallest index such that $A[e_n]$ is spanned by the columns of the submatrix $P_{e_n,j_n}|A[j_n]$ but *not* by those of P_{e_n,j_n}. Then, by construction we have $\operatorname{rank}(P_{e_n,j_n})=:r<N-1$, and $\operatorname{rank}(P_{e_n,j_n}|A[e_n])=\operatorname{rank}(P_{e_n,j_n}|A[j_n])=\operatorname{rank}(P_{e_n,j_n}|A[e_n,j_n])=r+1$. The rank conditions in Lemma 3.4(i) are once again satisfied for the index pair $[e_n,j_n]$ thus found. The sufficiency of these conditions can then be established by following similar steps as in case (a). Namely, it is possible to choose a set of linearly independent vectors $A[l_1],\dots,A[l_r]\in P_{e_n,j_n}$ and extend this set to a basis of $\mathbb{R}^N$ as follows: $\{A[e_n],A[l_1],\dots,A[l_r],A[m_1],\dots,A[m_s]\}$, where $A[m_1],\dots,A[m_s]\in Q_{e_n,j_n}$ and $r+s=N-1$. We then have $A(e_n,l_1,\dots,l_r,m_1,\dots,m_s)\neq 0$, which also implies $A(j_n,l_1,\dots,l_r,m_1,\dots,m_s)\neq 0$ since $A[e_n]\in\operatorname{span}(P_{e_n,j_n}|A[j_n])$. As in case (a), we can now maximize the phase combinations over all such sets $\{l_1,\dots,l_r,m_1,\dots,m_s\}$, and find a set of indices $\{p_1,\dots,p_r,q_1,\dots,q_s\}$ such that $\theta_{e_n,p_1,\dots,p_r,q_1,\dots,q_s}$ and $\theta_{j_n,p_1,\dots,p_r,q_1,\dots,q_s}$ form a dominant pair of phase combinations as $y\to\infty$ along the direction of L_{e_n,j_n}. Summarizing, we have shown that for each pivot index $e_n,n=1,2,\dots,N$, there exists at least one asymptotic line soliton $[e_n,j_n]$ with $j_n>e_n$ as $y\to\infty$. Next we prove uniqueness.

Uniqueness: Suppose that $[e_n,j_n]$ and $[e_n,j_n']$ are two asymptotic line solitons identified by the same pivot index e_n as $y\to\infty$. Without loss of generality, assume that $j_n'>j_n$, and consider the line soliton $[e_n,j_n']$. Lemma 3.4(i) implies that $\operatorname{rank}(P_{e_n,j_n'}|A[j_n'])=\operatorname{rank}(P_{e_n,j_n}|A[e_n,j_n'])$. Hence the pivot column $A[e_n]$ is spanned by the columns of the submatrix $(P_{e_n,j_n'}|A[j_n'])$. But by assumption we have $(P_{e_n,j_n'}|A[j_n'])\subseteq P_{e_n,j_n}$, since $j_n'>j_n$. Hence $A[e_n]$ is also spanned by the columns of P_{e_n,j_n}. This however implies that $\operatorname{rank}(P_{e_n,j_n}|A[e_n])=\operatorname{rank}(P_{e_n,j_n})$, which contradicts the necessary rank

conditions in Lemma 3.4(i) for $[e_n, j_n]$ to identify an asymptotic line soliton as $y \to \infty$. Therefore we must have $j_n = j_{n'}$. Thus, it is not possible to have two distinct asymptotic line solitons as $y \to \infty$ associated with the same pivot index e_n. Part (i) of Theorem 3.6 is now proved.

APPENDIX C: EQUIVALENCE CLASSES AND DUALITY OF SOLUTIONS

In this appendix, we investigate the relationship between two classes of KPII multisoliton solutions with complementary sets of asymptotic line solitons. Note that the KPII equation (1.1) is invariant under the inversion symmetry $(x,y,t) \to (-x,-y,-t)$. As a result, if $u(x,y,t)$ is an $(M-N,N)$-soliton solution of KPII with $M-N$ incoming and N outgoing line solitons, then $u(-x,-y,-t)$ is a $(N,M-N)$-soliton solution of KPII where the numbers of incoming and outgoing line solitons are reversed. It follows from Theorem 3.6 that the solution $u(-x,-y,-t)$ should correspond to *some* tau function $\tau_{M-N,M}(x,y,t)$ associated with an $M-N \times M$ coefficient matrix whose pivot and nonpivot columns uniquely identify the asymptotic line solitons of $u(-x,-y,-t)$.

Before proceeding further, we introduce the notion of an equivalence class which plays an important role in subsequent discussions. Let Θ as in Definition 2.3 denote the set of all phase combinations $\theta_{m_1,\ldots,m_N}$ which appear with nonvanishing coefficients in the tau function $\tau(x,y,t)$ of Eq. (2.2).

Definition C.2 (Equivalence class): Two tau functions are defined to be in the same equivalence class if (up to an overall exponential phase factor) the set Θ *is the same for both. The set of* (N_-,N_+)*-soliton solutions of KPII generated by an equivalence class of tau functions defines an equivalence class of solutions.*

It is clear from the above definition that tau functions in a given equivalence class can be viewed as positive-definite sums of the *same* exponential phase combinations but with different sets of coefficients. They are parametrized by the same set of phase parameters $k_1, \ldots, k_M$, but the constants θ_{m0} in the phase θ_m are different. Moreover, the irreducible coefficient matrices associated with the tau functions have exactly the same sets of vanishing and nonvanishing minors, but the magnitudes of the nonvanishing minors are different for different matrices. Thus, it is evident from the remarks following Corollary 2.6 in Sec. II that the asymptotic line solitons of each solution in an equivalence class arise from the *same* $i \to j$ single phase transition, and are therefore labeled by the same index pair $[i,j]$. Theorem 3.6 then implies that the coefficient matrices associated with the tau functions in the same equivalence class have identical sets of pivot and nonpivot indices labeling the asymptotic line solitons as $y \to \infty$ and as $y \to -\infty$, respectively. Thus, solutions in the same equivalence class can differ only in the position of each asymptotic line solitons and in the location of each interaction vertex. As a result, any (N_-,N_+)-soliton solution of KPII can be transformed into any other solution in the same equivalence class by spatio-temporal translations of the individual asymptotic line solitons. We refer to the two tau functions $\tau_{N,M}(x,y,t)$ and $\tau_{M-N,M}(x,y,t)$ as *dual* to each other if the solution $u(-x,-y,-t)$ obtained from the function $\tau_{N,M}(-x,-y,-t)$ and the solution generated by $\tau_{M-N,M}(x,y,t)$ are in the same equivalence class. Note that $\tau_{N,M}(-x,-y,-t)$ is not exactly a tau function according to Eq. (2.2), but it is possible to construct from it a dual tau function $\tau_{M-N,M}(x,y,t)$ whose coefficient matrix B can be derived from the coefficient matrix A associated with the tau function $\tau_{N,M}(x,y,t)$. We describe this construction below.

Since A is of rank N and in RRFF, it can be expressed as $A=[I_N,G]P$, where I_N is the $N \times N$ identify matrix of pivot columns, G is the $N \times (M-N)$ matrix of nonpivot columns, and P denotes the $M \times M$ permutation matrix of M columns of A. We augment A with $M-N$ additional rows to form the invertible $M \times M$ matrix,

$$S = \begin{pmatrix} I_N & G \\ O & I_{M-N} \end{pmatrix} P, \tag{C1}$$

where O is the $(M-N) \times N$ zero matrix and I_{M-N} is the $(M-N) \times (M-N)$ identify matrix. Let A' be the $(M-N) \times M$ matrix obtained by selecting the last $M-N$ rows of $(S^{-1})^T$. The rank of A' is $M-N$, and the following complementarity relation holds between A and A'.

Lemma C.3: The pivot columns of A' are labeled by exactly the same set of indices which label the nonpivot columns of A, and vice versa. Moreover, if A is irreducible then A' is also irreducible.

Proof: From Eq. (C1) and the fact that $P^{-1}=P^T$ for a permutation matrix, we obtain

$$(S^{-1})^T=\begin{pmatrix} I_N & O^T \\ -G^T & I_{M-N} \end{pmatrix}P, \tag{C2}$$

which implies that $A'=[-G^T,I_{M-N}]P$. Then (by performing row reduction in *reverse* order), the pivot columns of $A'P^{-1}$ can be identified with its last $M-N$ columns which correspond to the nonpivot columns of $AP^{-1}=[I_N,G]$, and vice versa. The same correspondence between pivot and nonpivot columns also holds for A and A' because the columns of both matrices are permuted by the same matrix P^{-1}. This proves the first part of the lemma.

To establish that A' is irreducible, note first from Definition 2.2 that the permutation of columns preserves irreducibility of a matrix. Since A is irreducible, Definition 2.2 implies that all rows or columns of G and G^T are nonzero. Therefore the matrix $A'P^{-1}=[-G^T,I_{M-N}]$, and hence A', are both irreducible. □

Note that A' is *not* in the canonical RREF, but can be set in RREF by a GL $(N,\mathbb{R})$ transformation. Next, we define the matrix B which is also of rank $M-N$ and irreducible like A', and whose columns are obtained from A' as

$$B[m]=(-1)^m A'[m], \quad m=1,\ldots,M. \tag{C3}$$

Then using Eqs. (C2) and (C3), the minors of A can be expressed in terms of the complementary minors of B via (see, e.g., Ref. 6, p. 21)

$$A(l_1,\ldots,l_N)=(-1)^\sigma \det(P)B(m_1,\ldots,m_{M-N}), \tag{C4}$$

where $\sigma=M(M+1)/2+N(N+1)/2$, and where the indices $m_1\leqslant m_2\leqslant\cdots\leqslant m_{M-N}$ are the complement of $1\leqslant l_1\leqslant l_2\leqslant\cdots l_N$ in $\{1,2,\ldots,M\}$. The matrix B plays the role of a coefficient matrix for the dual tau function as given by the following lemma.

Lemma C.4 (Duality): If $\tau_{N,M}(x,y,t)$ is the tau function associated with an irreducible $N\times M$ coefficient matrix A, then the matrix B defined via Eq. (C3) *generates a tau function $\tau_{M-N,M}(x,y,t)$ that is dual to $\tau_{N,M}(x,y,t)$.*

Proof: Without loss of generality we choose the tau function $\tau_{N,M}(x,y,t)$ associated with the given equivalence class of solutions such that $\theta_{m,0}=0$ for all $m=1,\ldots,M$ in Eq. (2.2). Then, using Eq. (C4) we can express the tau function as

$$\tau_{N,M}(-x,-y,-t)=(-1)^\sigma \det(P)e^{-\theta_{1,\ldots,M}}\tau'(x,y,t), \tag{C5a}$$

where

$$\tau'(x,y,t)=\sum_{1\leqslant m_1<m_2<\cdots<m_{M-N}\leqslant M} V(l_1,\ldots,l_N)B(m_1,\ldots,m_{M-N})e^{\theta_{m_1,\ldots,m_{M-N}}}, \tag{C5b}$$

with $V(l_1,\ldots,l_N)$ denoting the Van der Monde determinant as in Eq. (2.2) and where the sum is now taken over the complementary indices $m_1,\ldots,m_{M-N}$ instead of $l_1,\ldots,l_N$. [The number of terms in the sum remains the same since $\binom{M}{N}=\binom{M}{M-N}$.] It is clear from Eq. (1.2) that both $\tau_{N,M}(-x,-y,-t)$ and $\tau'(x,y,t)$ in Eq. (C5a) generate the same solution $u(x,y,t)$ of KPII although $\tau'(x,y,t)$ itself is *not* a tau function. Note that all the nonzero minors of B have the same sign, which is determined by the sign of $(-1)^\sigma \det(P)>0$. Thus, by replacing each Van der Monde coefficient $V(l_1,\ldots,l_N)$ by $V(m_1,\ldots,m_{M-N})$ in Eq. (C5b), it is possible to obtain from $\tau'(x,y,t)$, a new tau function $\tau_{M-N,M}(x,y,t)$ associated with the irreducible coefficient matrix B. Since both $\tau'(x,y,t)$ and $\tau_{M-N,M}(x,y,t)$ are sign-definite sums of the *same* exponential phase combinations, they generate solutions that are in the same equivalence class. Therefore, the tau function $\tau_{M-N,M}(x,y,t)$ constructed via the above prescription is dual to the tau function $\tau_{N,M}(x,y,t)$. This

yields the desired result. □

By applying Lemma C.4, it is easy to show that part (i) of Theorem 3.6 implies part (ii) and vice versa. For example, by applying part (i) of Theorem 3.6 to the tau function $\tau_{M-N,M}(x,y,t)$ in Lemma C.4 one can conclude that as $y\to\infty$, $\tau_{M-N,M}(x,y,t)$ generate a solution with exactly $M-N$ line solitons, identified by the *pivot* indices $g_1,\ldots,g_{M-N}$ of the associated coefficient matrix B. One should however note that since the ordering of the pivot and nonpivot columns of B is reversed with respect to that of A, if $[i,j]$ with $i<j$ labels an asymptotic line soliton generated by $\tau_{M-N,M}(x,y,t)$ as $y\to\infty$, then j is the pivot index, not i. The solution generated by $\tau_{M-N,M}(x,y,t)$ is in the same equivalence class as $u(-x,-y,-t)$ because $\tau_{M-N,M}(x,y,t)$ is dual to $\tau_{M,N}(x,y,t)$. Consequently, as $y\to\infty$, $u(-x,-y,-t)$ has $M-N$ asymptotic line solitons labeled by exactly the same indices $g_1,\ldots,g_{M-N}$. Then as $y\to-\infty$, it follows that the solution $u(x,y,t)$ generated by $\tau_{N,M}(x,y,t)$ also has $M-N$ asymptotic line solitons. Furthermore, these line solitons are labeled by the same indices $g_1,\ldots,g_{M-N}$ which are the nonpivot indices of the coefficient matrix A of the tau function $\tau_{N,M}(x,y,t)$. This proves part (ii) of Theorem 3.6. Similarly, one could also prove part (i) of the Theorem using part (ii) and Lemma C.4.

Another consequence of Lemma C.4 is that the dominant pairs of phase combinations for the asymptotic line solitons of $\tau_{M-N,N}(x,y,t)$ as $y\to\infty$ are the complement of those for the asymptotic line solitons of the dual tau function $\tau_{N,M}(x,y,t)$ as $y\to-\infty$. Thus, if the dominant pair of phase combinations for $\tau_{M-N,M}(x,y,t)$ as $y\to\infty$ along the line $L_{i,j}$ is given by $\theta_{i,m_2,\ldots,m_{M-N}}$ and $\theta_{j,m_2,\ldots,m_{M-N}}$, the dominant phase combinations for $\tau_{N,M}(x,y,t)$ as $y\to-\infty$ along $L_{i,j}$ are $\theta_{i,l_2,\ldots,l_N}$ and $\theta_{j,l_2,\ldots,l_N}$, where the index set $\{l_2,\ldots,l_N\}$ is the complement of $\{i,j,m_2,\ldots,m_{M-N}\}$ in $\{1,\ldots,M\}$.

A particularly interesting subclass of (N_-,N_+)-soliton solutions is obtained by requiring the solutions $u(x,y,t)$ and $u(-x,-y,-t)$ to be in the same equivalence class. Thus, this class of solutions is generated tau functions which can be regarded as "self-dual." The corresponding solutions are the elastic N-soliton solutions of KPII, for which the amplitudes and directions of the N incoming line solitons coincide with those of the N outgoing line solitons. Hence, the set of incoming line solitons and the set of outgoing line solitons are both labeled by the same index pairs $\{[i_n,j_n]\}_{n=1}^N$. Clearly, in this case we have $N_+=N_-=N$ and $M=2N$. Some properties of the elastic N-soliton solution have been studied in Ref. 12, and we will discuss several other properties in a future presentation. Here we only mention one result which is a direct consequence of Theorem 3.6 and the above discussions:

Corollary C.5: A necessary condition for a set of index pairs $\{[i_n,j_n]\}_{n=1}^N$ *to describe an elastic N-soliton solution is that the indices* $i_1,\ldots,i_N$ *and* $j_1,\ldots,j_N$ *form a disjoint partition of the integers* $1,\ldots,2N$.

Proof: From part (i) of Theorem 3.6, the indices $i_1,\ldots,i_N$ for the N asymptotic line solitons as $y\to\infty$ label the pivot columns of A, and from part (ii) of Theorem 3.6, the indices $j_1,\ldots,j_N$ for the N asymptotic line solitons as $y\to-\infty$ label the nonpivot columns of A. In order for the N asymptotic line solitons as $y\to-\infty$ to be the same as those as $y\to\infty$, however, the index pairs $[i_n,j_n]$ must obviously be the same as $y\to\pm\infty$ for all $n=1,\ldots,N$. But the sets of pivot and nonpivot indices of any matrix are of course disjoint; hence the desired result. □

Note however that the condition in Corollary C.5 is necessary but *not* sufficient to describe an elastic N-soliton solution. It is indeed possible to have N-soliton solutions where the index pairs labeling the asymptotic line solitons as $y\to\infty$ and as $y\to-\infty$ form two different disjoint partition of integers $\{1,2,\ldots,2N\}$. Such N-soliton solutions are *not* elastic. See, for example, the 2-soliton solution in Fig. 4(e).

A simple procedure is given to transform the Blasius equation into an Abel equation of the second kind. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2176913]

In this Comment, we focus on the nonlinear ode

$$y''' + \alpha y y'' - \beta y'^2 = 0, \tag{1}$$

where the prime denotes derivation with respect to the independent variable x, and α, β are arbitrary constants. This equation describes similarity solutions of the Navier-Stokes equations, corresponding to (axisymmetric) flows caused by the stretching of a flat boundary.[1] For $\beta=0$, it reduces to the Blasius equation.[2]

Equation (1) has been investigated analytically in a recent work by Panayotounakos *et al.*,[3] to which we refer for further details, such as the specification of the boundary conditions. The main results of Ref. 3 are (i) the transformation of (1) into an Abel equation of the second kind; (ii) the definition of a methodology for the construction of exact solutions to the Abel equation, and consequently, of exact solutions to (1). Here we concentrate on the result at point (i). This result involves an elaborate procedure, that relies on first reducing (1), through a sequence of admissible functional transformations, to a generalized Emden-Fowler equation, and then transforming the latter equation into an Abel equation of the second kind. The authors note that this procedure is in fact quite general, and could also be applied to other important equations of mathematical physics, such as those for the Duffing and the Van der Pol nonlinear oscillators, the Kidder equation, etc.

A general approach is always commendable, but sometimes, when dealing with specific problems, simpler ad hoc approaches may be devised. The purpose of this Comment is to provide such an approach for the problem at hand. We first notice that the substitution

$$y' = \frac{\mathrm{d}f(y)}{\mathrm{d}y}, \tag{2}$$

reduces (1) to

$$\frac{\mathrm{d}}{\mathrm{d}y}(\dddot{f}\ddot{f}) + \alpha y \ddot{f} - \beta \dot{f} = 0, \tag{3}$$

with the overdot denoting derivation with respect to y. After a simple manipulation of the middle term on the left-hand side, (3) can be integrated once, yielding

$$\dddot{f}\ddot{f} + \alpha y \dot{f} - (\alpha + \beta) f = C, \tag{4}$$

with C an arbitrary constant. Note that in the special case $\alpha+\beta=0$, (4) already has the form of an Abel equation of the second kind, in the variable $\dot{f}$.

In the general case $\alpha+\beta\neq 0$, a further step is needed to complete the reduction. In this case, we may take $C=0$ in (4) (the addition of a constant to f would not modify y), and set

$$z = y\frac{\dot{f}}{f}, \quad w = A\frac{y^3}{f}, \tag{5}$$

with A an arbitrary constant, to transform (4) into the Abel equation of the second kind

$$[(\alpha+\beta-\alpha z)w - Az^2(z-1)]\frac{\mathrm{d}w}{\mathrm{d}z} = Az(3-z)w. \tag{6}$$

Given a solution $w(z)$ of the Abel equation (6), one may solve (5) to get $f(y)$, and then (2) to obtain $y(x)$. However, finding exact solutions of (5) is likely to be difficult in practical cases, and it is more convenient to construct a parametric representation of the solution, in analogy to what is done in Ref. 3 [see Sec. 3, equations from (3.33) to (3.38)]. It readily follows from (5), (6), and (2) that

$$y = y(z) = \left(\frac{wf}{A}\right)^{1/3}, \tag{7}$$

$$x = x(z) = C_1 + \frac{1}{A^{2/3}}\int \mathrm{d}z \frac{w^{2/3}}{z^2 f^{4/3}}\frac{\mathrm{d}f}{\mathrm{d}z}, \tag{8}$$

with $f(z)$ given by

$$f(z) = \exp\left(C_2 + A\int \frac{z^2\mathrm{d}z}{(\alpha+\beta-\alpha z)w - Az^2(z-1)}\right), \tag{9}$$

and C_1, C_2 integration constants.

The Wigner-Weyl transformation and the quantum path integral

H. Bergeron[a)]
LCAM, Bat. 351, Centre Universitaire Paris-Sud, Orsay, 91405, France

(Received 6 July 2005; accepted 15 February 2006; published online 6 April 2006)

We show that the space of quantum states for a spinless particle possesses a (trivial) fiber bundle structure $\mathcal{B}\times\mathcal{F}$ where $\mathcal{B}$ is the classical phase space. This geometric point of view allows us to define a "quantum path integral" that connects quantum observables with their classical counterparts. We show that this path integral reduces in fact to the Wigner-Weyl transformation. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2184768]

I. INTRODUCTION

Among the different methods that have been developed to link classical and quantum formalisms, one of the most famous is the Wigner-Weyl transformation. This operation defines a one-to-one correspondence between quantum operators $\mathbf{A}$ and functions in phase space $a(p,q)$ in such a way that the quantum evolution of $a(p,q)$ reduces to the classical one when $\hbar$ vanishes.[1,2] In this framework quantization is mathematically a deformation of the Abelian algebra of functions in phase space into a noncommutative algebra.[3]

In this paper we bring to the fore a geometric property of the quantum Hilbert space that allows us to identify a part of the quantum space with the classical phase space. In fact we prove that the quantum space possesses a trivial fiber bundle structure $\mathcal{B}\times\mathcal{F}$. The basis $\mathcal{B}$ is the classical phase space, while the fiber $\mathcal{F}$ contains the quantum effects. The group of translation along the basis $\mathcal{B}$ is the Weyl group: two fibers $\mathcal{F}_\alpha$ and $\mathcal{F}_\beta$ (corresponding to projections α and β on the basis) are linked by a Weyl transformation. Following this picture, we define the classical observable $a(\alpha)$ corresponding to a quantum operator $\mathbf{A}$ as being some "averaged value" of $\mathbf{A}$ over the fiber $\mathcal{F}_\alpha$. To represent this "averaged value," we introduce a "quantum path integral" over the fibers, specifying the rules of calculation. We show that this intuitive definition leads us to the Wigner-Weyl transformation.

The paper is organized as follows:

(i) The first section is devoted to the fiber bundle structure and related questions.
(ii) Then we introduce the "quantum path integral," the rules of calculation and the first consequences.
(iii) We show how this quantum path integral and the Wigner-Weyl transformation are linked and we investigate some consequences.
(iv) Finally we conclude our paper.

Remark: In the following we restrict ourselves to the one dimension case. Moreover bold letters stand for operators.

II. FIBER BUNDLE STRUCTURE

A. Definition

To be able to identify some classical structure into the "quantum world" $\mathcal{H}=L^2(\mathbb{R})$, we need to specify how the basic quantum quantities (observables $\mathbf{Q}$ and $\mathbf{P}=-i\hbar\partial_q$) are connected with classical ones. Since quantum mechanics introduces intrinsic uncertainties, while classical mechanics ignore them, we can say that the classical equivalent of a (normalized) state $|\dot{\psi}\rangle$ is the point of phase space (p,q) with $p=\langle\psi|\mathbf{P}|\psi\rangle$ and $q=\langle\psi|\mathbf{Q}|\psi\rangle$. Of course these quantities do not exist for any square integrable function $\psi\in L^2(\mathbb{R})$, so we restrict the space of functions to $\mathcal{S}$, where $\mathcal{S}$ is the set of C^∞ functions with rapid decrease. Moreover we see that the space of interest is not really the Hilbert space, but rather the set of projectors $\boldsymbol{\pi}_\psi=(1/\|\dot{\psi}\|^2)|\psi\rangle\langle\psi|$. So we define $\mathcal{P}=\{\boldsymbol{\pi}_\psi/\dot{\psi}\in\mathcal{S}\}$. We define the projection Π as

$$\forall\,\pi_\psi\in\mathcal{P},\quad \Pi(\boldsymbol{\pi}_\psi)=(\mathrm{Tr}(\boldsymbol{\pi}_\psi\mathbf{P}),\mathrm{Tr}(\boldsymbol{\pi}_{\dot{\psi}}\mathbf{Q})). \tag{1}$$

So Π is the projection from $\mathcal{P}$ onto the basis $\mathcal{B}$ which is in fact the classical phase space.

Now we define the fiber $\mathcal{F}_0$ as $\mathcal{F}_0=\Pi^{-1}[\{(0,0)\}]$ and more generally $\mathcal{F}_{p,q}=\Pi^{-1}[\{(p,q)\}]$. If we call $\{\mathbf{W}_{p,q}\}$ the Weyl group of unitary transformations

$$\mathbf{W}_{p,q}=\exp[(i/\hbar)(\mathbf{P}q-\mathbf{Q}p)]. \tag{2}$$

We know that

$$\mathbf{W}_{p,q}^\dagger\mathbf{P}\mathbf{W}_{p,q}=\mathbf{P}-p\quad\text{and}\quad\mathbf{W}_{p,q}^\dagger\mathbf{Q}\mathbf{W}_{p,q}=\mathbf{Q}-p. \tag{3}$$

This implies

$$\mathcal{F}_{p,q}=\mathbf{W}_{p,q}^\dagger\mathcal{F}_0\mathbf{W}_{p,q}. \tag{4}$$

We deduce that for any $\boldsymbol{\pi}\in\mathcal{P},\mathbf{W}_{\Pi(\pi)}\boldsymbol{\pi}\mathbf{W}_{\Pi(\pi)}^\dagger\in\mathcal{F}_0$. Then any element $\boldsymbol{\pi}\in\mathcal{P}$ is specified by the pair $(b,\boldsymbol{\pi}_0)$ where $b=(p,q)\in\mathcal{B}$ and $\boldsymbol{\pi}_0\in\mathcal{F}_0$. Then $\mathcal{P}$ is homeomorphic to the Cartesian product $\mathcal{B}\times\mathcal{F}_0$.

B. Remark

This representation of $\mathcal{P}$ is instructive for the study of time evolution. Generally we have a pair $(b(t),\boldsymbol{\pi}_0(t))$, but special cases are interesting.

For example, if the Hamiltonian is $\mathbf{H}=\mathbf{P}^2/2m+V(\mathbf{Q})$ where the potential $V(\mathbf{Q})$ is at the most quadratic, then the equations of motion for the observables $\mathbf{P}(t)$ and $\mathbf{Q}(t)$ are linear. So the expressions of $\mathbf{P}(t)$ and $\mathbf{Q}(t)$ are the classical ones (linear in $\mathbf{P}$ and $\mathbf{Q}$) and the point $(p(t),q(t))$ follows a classical trajectory, while the projector $\boldsymbol{\pi}_0(t)$ evolves as $\boldsymbol{\pi}_0(t)=\mathbf{U}^\dagger(t)\boldsymbol{\pi}_0\mathbf{U}(t)$. Then the evolution of classical quantities (expectation values of $\mathbf{P}$ and $\mathbf{Q}$) does not depend on the evolution of quantum effects represented by $\boldsymbol{\pi}_0(t)$. But if the potential $V(\mathbf{Q})$ is more than quadratic, modifications on the classical behavior of $(p(t),q(t))$ appear due to quantum effects.

Another example is the case of eigenstates. If we start with a bound eigenstate of $\mathbf{H}$ then $(p(t),q(t))=(0,q_0)$ and $\boldsymbol{\pi}_0(t)=\boldsymbol{\pi}_0$. So a bound eigenstate looks like a classical equilibrium point.

III. CLASSICAL OBSERVABLES AND THE QUANTUM PATH INTEGRAL

A. Definition

If $\mathbf{A}$ is a quantum observable and if $\boldsymbol{\pi}_\psi\in\mathcal{P}$ is the state, since classical mechanics ignore quantum uncertainties, we should say that $\mathrm{Tr}(\boldsymbol{\pi}_\psi\mathbf{A})$ is the corresponding classical value of $\mathbf{A}$. But since classical mechanics is only sensitive to the values of p and q, it does not distinguish the states $\boldsymbol{\pi}_\psi\in\mathcal{F}_{p,q}$. So we have in fact an infinity of values for $\mathrm{Tr}(\boldsymbol{\pi}_\psi\mathbf{A})$ corresponding to a unique classical point. So we can think that the true classical value is some "averaged value" of $\mathrm{Tr}(\boldsymbol{\pi}_\psi\mathbf{A})$

over $\mathcal{F}_{p,q}$. To implement this idea we introduce a *symbolic* "quantum path integral" over $\mathcal{P}$ with the notation $\int \mathcal{D}\{\boldsymbol{\pi}\}$ and we give the following axioms:

(i) The classical expression $\mathcal{C}(\mathbf{A})(p,q)=\widetilde{\mathbf{A}}(p,q)$ of the observable $\mathbf{A}$ is given by

$$\widetilde{A}(P,q) = \int \mathcal{D}\{\boldsymbol{\pi}\}\delta(P-\langle \mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{A}\rangle_{\boldsymbol{\pi}}, \tag{5}$$

where $\langle \mathbf{O}\rangle_{\boldsymbol{\pi}}=\mathrm{Tr}(\boldsymbol{\pi}\mathbf{O})$. The distributions δ specify the "integration" over $\mathcal{F}_{p,q}$.

(ii) We assume that the "measure" $\mathcal{D}\{\boldsymbol{\pi}\}$ is real (but not necessarily positive) in order to transform self-adjoint operators into real functions, then $\mathcal{C}(\mathbf{A}^{\dagger})(p,q)=\mathcal{C}(\mathbf{A})(p,q)^{*}$.

(iii) Since the group of symmetry in the quantum space is the unitary group, we assume that the "measure" $\mathcal{D}\{\boldsymbol{\pi}\}$ is invariant under these transformations,

$$\mathcal{D}\{\mathbf{U}^{\dagger}\boldsymbol{\pi}\mathbf{U}\} = \mathcal{D}\{\boldsymbol{\pi}\} \quad \text{if } \mathbf{U}^{\dagger}\mathbf{U} = \mathbf{U}\mathbf{U}^{\dagger} = \mathbf{1}_{\mathcal{H}}. \tag{6}$$

(iv) The condition of "normalization,"

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}}) = 1, \tag{7}$$

stipulates that the "integral" over the fiber $\mathcal{F}_0$ is equal to 1.

Remarks: Following our definition, the path integral over $\mathcal{P}$ is limited to projectors $\boldsymbol{\pi}_{\psi}$ with $\psi\in\mathcal{S}$. So the invariance of the "measure" under unitary transformations must be limited to transformations that leave $\mathcal{S}$ invariant.

Furthermore, in this paper we do not assume that the path integral is really an integral in the mathematical meaning of the word. We think that the symbol $\int \mathcal{D}\{\boldsymbol{\pi}\}$ rather corresponds to a bra-ket of duality as for $\langle \delta,\varphi\rangle=\int \mathrm{d}x\ \delta(x)\varphi(x)$. But this is not a real problem if we understand the symbol $\int \mathcal{D}\{\boldsymbol{\pi}\}$ as a convenient notation and if the axioms are sufficient to give effective rules of calculation (with no contradiction). A rigorous mathematical approach probably involves some generalization of Gleason theorem.[4]

Last, our definition of classical counterparts for quantum observables seems to introduce losses of information since we perform some "average." As we will see later this is not true.

B. Consequences

1. First relations

Introducing the invariance of the "measure" for Weyl transformations ($\mathbf{W}_{p,q}$) into the expression of $\widetilde{A}(p,q)$, and taking into account Eq. (3), we find

$$\widetilde{A}(p,q) = \int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p+p_0-\langle \mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q+q_0-\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{W}^{\dagger}_{p_0,q_0}\mathbf{A}\mathbf{W}_{p_0,q_0}\rangle_{\boldsymbol{\pi}}. \tag{8}$$

We deduce

$$\widetilde{A}(p-p_0,q-q_0) = \int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle \mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{W}^{\dagger}_{p_0,q_0}\mathbf{A}\mathbf{W}_{p_0,q_0}\rangle_{\boldsymbol{\pi}}. \tag{9}$$

We recover that the translation of quantum observables by the Weyl group corresponds to a classical translation in phase space,

$$\mathcal{C}(\mathbf{W}^{\dagger}_{p_0,q_0}\mathbf{A}\mathbf{W}_{p_0,q_0})(p,q) = \mathcal{C}(\mathbf{A})(p-p_0,q-q_0). \tag{10}$$

The same calculation with the parity $\mathbf{K}_P$ gives

$$\widetilde{A}(-p,-q)=\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle\mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle\mathbf{K}_P^{\dagger}\mathbf{A}\mathbf{K}_P\rangle_{\boldsymbol{\pi}}. \tag{11}$$

So,

$$\mathcal{C}(\mathbf{K}_P^{\dagger}\mathbf{A}\mathbf{K}_P)(p,q)=\mathcal{C}(\mathbf{A})(-p,-q). \tag{12}$$

For the unitary group of rescaling $\mathbf{R}_\alpha=\exp[(i\alpha/2\hbar)(\mathbf{PQ}+\mathbf{QP})]$ we obtain

$$\mathcal{C}(\mathbf{R}_\alpha^{\dagger}\mathbf{A}\mathbf{R}_\alpha)(p,q)=\mathcal{C}(\mathbf{A})(e^{\alpha}p,e^{-\alpha}q), \tag{13}$$

since $\mathbf{R}_\alpha^{\dagger}\mathbf{P}\mathbf{R}_\alpha=e^{\alpha}\mathbf{P}$ and $\mathbf{R}_\alpha^{\dagger}\mathbf{Q}\mathbf{R}_\alpha=e^{-\alpha}\mathbf{Q}$.

The invariance for Weyl transformations applied to the condition of normalization gives

$$1=\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle\mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}}). \tag{14}$$

On the one hand, this equation says that the "integral" over each fiber $\mathcal{F}_{p,q}$ is equal to 1, on the other hand, if we notice that $\mathrm{Tr}(\boldsymbol{\pi}\mathbf{1}_{\mathcal{H}})=1$, this equation means that the classical representation of the identity operator $\mathbf{1}_{\mathcal{H}}$ is 1,

$$\mathcal{C}(\mathbf{1}_{\mathcal{H}})(p,q)=1. \tag{15}$$

Now if we replace the general observable $\mathbf{A}$ by $\mathbf{P}$ or $\mathbf{Q}$ and we take into account the δ in the integral, we find

$$\begin{aligned}&\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle\mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle\mathbf{P}\rangle_{\boldsymbol{\pi}}=p,\\ &\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle\mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}}=q.\end{aligned} \tag{16}$$

Then the classical representation of $\mathbf{P}$ is p and the classical representation of $\mathbf{Q}$ is q,

$$\mathcal{C}(\mathbf{P})(p,q)=p \quad \text{and } \mathcal{C}(\mathbf{Q})(p,q)=q. \tag{17}$$

Let us prove that these relations can be extended to more complicated functions of $\mathbf{P}$ or $\mathbf{Q}$.

We define the function $f_\alpha(p,q)=\mathcal{C}(e^{i\alpha\mathbf{P}})(p,q)$. Thanks to Eqs. (3) and (10) we obtain

$$f_\alpha(p-p_0,q-q_0)=e^{-i\alpha p_0}f_\alpha(p,q). \tag{18}$$

The case $p_0=0$ tells us that $f_\alpha(p,q-q_0)=f_\alpha(p,q)$, then f_α is in fact independent of q. So $f_\alpha(p,q)=g_\alpha(p)$ and g_α verifies $g_\alpha(p-p_0)=e^{-i\alpha p_0}g_\alpha(p)$. We deduce that $g_\alpha(p)=C(\alpha)e^{i\alpha p}$, so

$$\mathcal{C}(e^{i\alpha\mathbf{P}})(p,q)=C(\alpha)e^{i\alpha p}. \tag{19}$$

Moreover the rescaling operators $\mathbf{R}_\xi$ give $\mathcal{C}(\mathbf{R}_\xi^{\dagger}e^{i\alpha\mathbf{P}}\mathbf{R}_\xi)=\mathcal{C}(\exp[i\alpha e^{\xi}\mathbf{P}])$, then using Eq. (13), we find that $\mathcal{C}(\alpha)=C(\alpha e^{\xi})$. We deduce $C(\alpha)=\lim_{\xi\to-\infty}C(\alpha e^{\xi})=C(0)$. But $C(0)=1$ because $\mathcal{C}(\mathbf{1}_{\mathcal{H}})=1$ and we obtain

$$\mathcal{C}(e^{i\alpha\mathbf{P}})(p,q)=e^{i\alpha p}. \tag{20}$$

By Fourier transform we can extend this result to any operator $f(\mathbf{P})$,

$$\mathcal{C}[f(\mathbf{P})](p,q)=f(p). \tag{21}$$

The same reasoning is possible for operators $f(\mathbf{Q})$ and

$$\mathcal{C}[f(\mathbf{Q})](p,q)=f(q). \tag{22}$$

Finally, we introduce the self-adjoint operator $\boldsymbol{\rho}$ by the formula

$$\boldsymbol{\rho} = \int \mathcal{D}\{\boldsymbol{\pi}\}\delta(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\boldsymbol{\pi}, \tag{23}$$

and we define $\boldsymbol{\rho}_{p,q}=\mathbf{W}_{p,q}^{\dagger}\boldsymbol{\rho}\mathbf{W}_{p,q}$. The invariance of the measure $\mathcal{D}\{\boldsymbol{\pi}\}$ under Weyl translations shows that

$$\boldsymbol{\rho}_{p,q} = \int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle \mathbf{P}\rangle_{\boldsymbol{\pi}})\delta(q-\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\boldsymbol{\pi}. \tag{24}$$

Then the path integral expression $\mathcal{C}(\mathbf{A})(p,q)$ reduces to

$$\mathcal{C}(\mathbf{A})(p,q) = \mathrm{Tr}(\boldsymbol{\rho}_{p,q}\mathbf{A}). \tag{25}$$

Remark: We notice that the operator $\boldsymbol{\rho}$ must be bounded if we want that $\langle\varphi|\boldsymbol{\rho}|\varphi\rangle=\mathrm{Tr}(\boldsymbol{\rho}|\varphi\rangle\times\langle\varphi|)$ exists for any $\varphi\in\mathcal{H}$.

Furthermore, the invariance of $\mathcal{D}\{\boldsymbol{\pi}\}$ under unitary transformations gives

$$\mathbf{U}^{\dagger}\boldsymbol{\rho}\mathbf{U} = \int \mathcal{D}\{\boldsymbol{\pi}\}\delta(\langle \mathbf{U}^{\dagger}\mathbf{P}\mathbf{U}\rangle_{\boldsymbol{\pi}})\delta(\langle \mathbf{U}^{\dagger}\mathbf{Q}\mathbf{U}\rangle_{\boldsymbol{\pi}})\boldsymbol{\pi}. \tag{26}$$

This implies that $\boldsymbol{\rho}$ must be invariant under different transformations because of the δ distributions. Under parity we have $\mathbf{K}_P^{\dagger}\mathbf{P}\mathbf{K}_P=-\mathbf{P}$ and $\mathbf{K}_P^{\dagger}\mathbf{Q}\mathbf{K}_P=-\mathbf{Q}$, then $\mathbf{K}_P^{\dagger}\boldsymbol{\rho}\mathbf{K}_P=\boldsymbol{\rho}$. Under rescaling we have $\mathbf{R}_{\alpha}^{\dagger}\mathbf{P}\mathbf{R}_{\alpha}=e^{\alpha}\mathbf{P}$, and $\mathbf{R}_{\alpha}^{\dagger}\mathbf{Q}\mathbf{R}_{\alpha}=e^{-\alpha}\mathbf{Q}$ then $\mathbf{R}_{\alpha}^{\dagger}\boldsymbol{\rho}\mathbf{R}_{\alpha}=\boldsymbol{\rho}$ again. Finally under the operators $\mathbf{U}_t=\exp[(-(i\hbar t/2m)\mathbf{P}^2]$ of free evolution, we have $\mathbf{U}_t^{\dagger}\mathbf{P}\mathbf{U}_t=\mathbf{P}$ and $\mathbf{U}_t^{\dagger}\mathbf{Q}\mathbf{U}_t=\mathbf{Q}+\mathbf{P}t/m$, so $\mathbf{U}_t^{\dagger}\boldsymbol{\rho}\mathbf{U}_t=\boldsymbol{\rho}$.

We conclude that $\boldsymbol{\rho}$ must be invariant (at least) under the following family of unitary transformations $\{\mathbf{K}_P,\mathbf{R}_{\alpha},\mathbf{U}_t\}$.

2. Relations with integrals on phase space

If we multiply Eq. (14) by $a(p,q)$ and we perform integration on p and q we obtain

$$\int \mathcal{D}\{\boldsymbol{\pi}\}a(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}}) = \int \mathrm{d}p\,\mathrm{d}q\,a(p,q). \tag{27}$$

Moreover if we have two operators $\mathbf{A}$, $\mathbf{B}$ with their classical counterparts $\widetilde{A}(p,q),\widetilde{B}(p,q)$, and if we multiply the expression of $\widetilde{A}(p,q)$ by the function $\widetilde{B}(p,q)$, after an integration on p and q we obtain

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\widetilde{B}(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{A}\rangle_{\boldsymbol{\pi}} = \int \mathrm{d}p\,\mathrm{d}q\,\widetilde{B}(p,q)\widetilde{A}(p,q). \tag{28}$$

Since this expression is invariant by the exchange of $\widetilde{A}$ and $\widetilde{B}$, we deduce

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\widetilde{B}(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{A}\rangle_{\boldsymbol{\pi}} = \int \mathcal{D}\{\boldsymbol{\pi}\}\widetilde{A}(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{B}\rangle_{\boldsymbol{\pi}}. \tag{29}$$

To go further, we must be able to specify the operator $\boldsymbol{\rho}$.

IV. THE QUANTUM PATH INTEGRAL AND THE WIGNER-WEYL TRANSFORMATION

A. The Wigner-Weyl transformation revisited

From the symmetry properties already analyzed, we know that the bounded self-adjoint operator $\boldsymbol{\rho}$ is invariant under the family of unitary transformations $\{\mathbf{K}_P,\mathbf{R}_{\alpha},\mathbf{U}_t\}$. So what are the possible $\boldsymbol{\rho}$? In fact the solution is

$$\boldsymbol{\rho} = Z_1 \mathbf{1}_{\mathcal{H}} + 2Z_2 \mathbf{K}_P, \tag{30}$$

where Z_1 and Z_2 are real numbers. We differ the proof to the appendix since it is rather technical.

The constant Z_1 leads to a constant contribution to $\boldsymbol{\rho}_{p,q}$ that can be eliminated, then we choose $Z_1=0$.

Let us define $\boldsymbol{\Omega}=2\mathbf{K}_P$ and $\boldsymbol{\Omega}_{p,q}=\mathbf{W}_{p,q}^{\dagger}\boldsymbol{\Omega}\mathbf{W}_{p,q}$, then $\boldsymbol{\rho}_{p,q}=Z_2\boldsymbol{\Omega}_{p,q}$. A direct calculation shows that

$$\mathrm{Tr}(\boldsymbol{\Omega}_{p',q'}^{\dagger}\boldsymbol{\Omega}_{p,q}) = \mathrm{Tr}(\boldsymbol{\Omega}_{p',q'}\boldsymbol{\Omega}_{p,q}) = 2\pi\hbar\ \delta(p'-p)\,\delta(q'-q). \tag{31}$$

Moreover for any operator $\mathbf{A}$,

$$\mathrm{Tr}(\boldsymbol{\Omega}_{p,q}\mathbf{A}) = \int \mathrm{d}x\, e^{-(i/\hbar)px}\left\langle q+\frac{x}{2}\middle|\,\mathbf{A}\,\middle|q-\frac{x}{2}\right\rangle. \tag{32}$$

Then $\mathrm{Tr}(\boldsymbol{\Omega}_{p,q}\mathbf{A})$ corresponds to the Wigner-Weyl transformation.

Furthermore our classical mapping $\mathbf{A}\to\mathcal{C}(\mathbf{A})$ verifies $\mathcal{C}(\mathbf{A})(p,q)=\mathrm{Tr}(\boldsymbol{\rho}_{p,q}\mathbf{A})$, then $\mathcal{C}(\mathbf{A})(p,q)=Z_2\,\mathrm{Tr}(\boldsymbol{\Omega}_{p,q}\mathbf{A})$. But we know that $\mathcal{C}(\mathbf{1}_{\mathcal{H}})=1$, so $Z_2^{-1}=\mathrm{Tr}(\boldsymbol{\Omega}_{p,q})$ and we deduce that $Z_2=1$ from $\mathrm{Tr}(\boldsymbol{\Omega}_{p,q})=1$. We conclude that $\boldsymbol{\rho}_{p,q}=\boldsymbol{\Omega}_{p,q}$ and the classical mapping $\mathbf{A}\to\mathcal{C}(\mathbf{A})$ is exactly the Wigner-Weyl transformation.

So our axioms for the path integral uniquely define the symbol $\int\mathcal{D}\{\boldsymbol{\pi}\}$ for "integrals" involving functions $\boldsymbol{\pi}\to b(\langle\mathbf{P}\rangle_{\boldsymbol{\pi}},\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle\mathbf{A}\rangle_{\boldsymbol{\pi}}$.

Moreover, Eq. (24) implies

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle\mathbf{P}\rangle_{\boldsymbol{\pi}})\,\delta(q-\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\,\boldsymbol{\pi} = \boldsymbol{\Omega}_{p,q}. \tag{33}$$

Furthermore, we have the following expression of the path integral:

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\delta(p-\langle\mathbf{P}\rangle_{\boldsymbol{\pi}})\,\delta(q-\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle\mathbf{A}\rangle_{\boldsymbol{\pi}} = \mathrm{Tr}(\boldsymbol{\Omega}_{p,q}\mathbf{A}). \tag{34}$$

In turn these relations induce new properties for the path integral.

B. Consequences for the path integral

Taking into account Eq. (33) we find

$$\mathbf{A} = \frac{1}{2\pi\hbar}\int \mathcal{D}\{\boldsymbol{\pi}\}\widetilde{A}(\langle\mathbf{P}\rangle_{\boldsymbol{\pi}},\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\,\boldsymbol{\pi} \quad \text{with } \widetilde{A}(p,q)=\mathrm{Tr}(\boldsymbol{\Omega}_{p,q}\mathbf{A}). \tag{35}$$

Multiplying Eq. (34) by $\widetilde{B}(p,q)$ associated with the quantum observable $\mathbf{B}$, we find after integration

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\widetilde{B}(\langle\mathbf{P}\rangle_{\pi},\langle\mathbf{Q}\rangle_{\pi})\langle\mathbf{A}\rangle_{\pi} = 2\pi\hbar\ \mathrm{Tr}[\mathbf{BA}]. \tag{36}$$

We can exchange $\mathbf{A}$ and $\mathbf{B}$ so

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\widetilde{A}(\langle\mathbf{P}\rangle\boldsymbol{\pi},\langle\mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle\mathbf{B}\rangle_{\boldsymbol{\pi}} = 2\pi\hbar\ \mathrm{Tr}[\mathbf{BA}]. \tag{37}$$

Specially if $\mathbf{B}$ is the identity, then $b=1$, so

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\langle \mathbf{A}\rangle_{\boldsymbol{\pi}} = \int \mathcal{D}\{\boldsymbol{\pi}\}\tilde{A}(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}}) = 2\pi\hbar\ \mathrm{Tr}[\mathbf{A}]. \tag{38}$$

This implies

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\langle [\mathbf{A},\mathbf{B}]\rangle_{\boldsymbol{\pi}} = 0. \tag{39}$$

Using Eqs. (27) and (28) and Eqs. (36) and (38) we recover the well-known relations

$$\int \frac{\mathrm{d}p\ \mathrm{d}q}{2\pi\hbar}\tilde{A}(p,q) = \mathrm{Tr}\,\mathbf{A} \quad \text{and} \quad \int \frac{\mathrm{d}p\ \mathrm{d}q}{2\pi\hbar}\tilde{A}(p,q)\tilde{B}(p,q) = \mathrm{Tr}(\mathbf{AB}). \tag{40}$$

Always from Eqs. (29), (36), and (38), we have

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\langle \mathbf{AB}\rangle_{\boldsymbol{\pi}} = \int \mathcal{D}\{\boldsymbol{\pi}\}\tilde{A}(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{B}\rangle_{\boldsymbol{\pi}} \tag{41}$$

or

$$\int \mathcal{D}\{\boldsymbol{\pi}\}\langle \mathbf{AB}\rangle_{\boldsymbol{\pi}} = \int \mathcal{D}\{\boldsymbol{\pi}\}\langle \mathbf{A}\rangle_{\boldsymbol{\pi}}\tilde{B}(\langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}}). \tag{42}$$

Finally Eq. (36) presents a special interest when we are looking for expectation values. If we assume that $\mathbf{D}$ is a density operator with a classical counterpart $\tilde{D}(p,q)$ then

$$\mathrm{Tr}(\mathbf{DA}) = \frac{1}{2\pi\hbar}\int \mathcal{D}\{\boldsymbol{\pi}\}\tilde{D}(\ \langle \mathbf{P}\rangle_{\boldsymbol{\pi}},\langle \mathbf{Q}\rangle_{\boldsymbol{\pi}})\langle \mathbf{A}\rangle_{\boldsymbol{\pi}}. \tag{43}$$

The probability law appears thanks to the classical function $\tilde{D}(p,q)$, while the observable is represented by the quantum quantity $\langle \mathbf{A}\rangle_{\boldsymbol{\pi}}$. This expression is very close to a classical formula of expectation value, but with an "integral" over quantum space.

V. CONCLUSION

Thanks to the structure of the fiber bundle, we have introduced an intuitive definition for the classical counterparts of quantum observables, using a "quantum path integral." The path integral formulation reveals hidden properties of the Wigner-Weyl transformation that in turn gives special relations for the path integral. Moreover we remark that while the Feymann path integral allows us to calculate quantum amplitudes by integration over classical trajectories, this new path integral allows us to define classical quantities by integration over quantum states. Of course the mathematical nature of the notation $\int \mathcal{D}\{\boldsymbol{\pi}\}$ remains unspecified and this needs a special study.

APPENDIX

In this appendix we will prove the uniqueness of $\boldsymbol{\rho}$ verifying the conditions: $\boldsymbol{\rho}$ is a bounded self-adjoint operator invariant under $\{\mathbf{K}_P,\mathbf{R}_\alpha,\mathbf{U}_t\}$. To investigate the solutions, we use the Wigner-Weyl transformation (with the notations previously introduced).

Let us assume that $\mathbf{A}$ is a bounded self-adjoint operator invariant under $\mathbf{K}_P$ and $\mathbf{R}_\alpha$ with a classical counterpart $a(p,q)=\mathrm{Tr}(\boldsymbol{\Omega}_{p,q}\mathbf{A})$.

We know that $a(p,q)$ can be a distribution, but since distributions are limits of functions we first investigate the case where $a(p,q)$ is a function. The hypothesis for $\mathbf{A}$ are translated into the following properties of a:

$$a(p,q) \text{ is real and even}, \quad a(e^{\alpha}p,e^{-\alpha}q) = a(p,q). \tag{A1}$$

This implies that

$$a(p,q) = F(pq) \quad \text{with } F \text{ real}. \tag{A2}$$

For convenience, let us write F as a Fourier transform,

$$a_f(p,q) = \int \frac{\mathrm{d}\alpha}{|\alpha|} f(\alpha) \exp\left(-2i\frac{pq}{\alpha\hbar}\right), \tag{A3}$$

with $f(-\alpha)^* = f(\alpha)$.

The corresponding operator $\mathbf{A}_f$ is obtained with the formula due to the Wigner-Weyl transformation

$$\int \frac{\mathrm{d}p\,\mathrm{d}q}{2\pi\hbar} a_f(p,q)\mathbf{\Omega}_{p,q}. \tag{A4}$$

This relation gives

$$\mathbf{A}_f = \int \mathrm{d}\alpha\, f(\alpha) \int \frac{\mathrm{d}k}{2\pi} |(\alpha-1)k\rangle\langle(\alpha+1)k|, \tag{A5}$$

where the kets $|k\rangle$ verify $\mathbf{P}|k\rangle = \hbar k|k\rangle$ and $\langle k|k'\rangle = 2\pi\delta(k-k')$.

Let us introduce the operators $\mathbf{\Delta}_\alpha$ defined as

$$\mathbf{\Delta}_\alpha = \int \frac{\mathrm{d}k}{2\pi} |(1-\alpha)k\rangle\langle(\alpha+1)k|, \tag{A6}$$

we notice that $\mathbf{\Delta}_{1/\alpha} = |\alpha|\mathbf{K}_p\mathbf{\Delta}_\alpha$.

If we divide the α domain into $|\alpha| \leqslant 1$ and $|\alpha| \geqslant 1$ in Eq. (A5) we obtain

$$\mathbf{A}_f = \mathbf{K}_P \int_{|\alpha|\leqslant 1} \mathrm{d}\alpha\, f(\alpha)\mathbf{\Delta}_\alpha + \int_{|\alpha|\geqslant 1} \frac{\mathrm{d}\alpha}{|\alpha|} f(\alpha)\mathbf{\Delta}_{1/\alpha}. \tag{A7}$$

Then if we define the independent functions f_1 and f_2 by $f_1(\alpha) = f(\alpha)$ for $|\alpha| \leqslant 1$ and $f_2(1/\alpha) = |\alpha| f(\alpha)$ for $|\alpha| \geqslant 1$ we obtain

$$\mathbf{A}_f = \mathbf{K}_P \int_{|\alpha|\leqslant 1} \mathrm{d}\alpha\, f_1(\alpha)\mathbf{\Delta}_\alpha + \int_{|\alpha|\leqslant 1} \mathrm{d}\alpha\, f_2(\alpha)\mathbf{\Delta}_\alpha. \tag{A8}$$

Moreover we want $\mathbf{A}_f$ to be invariant under $\mathbf{U}_t = \exp[-(i\hbar t/2m)\mathbf{P}^2]$. This is equivalent to the condition $[\mathbf{P}^2, \mathbf{A}_f] = 0$. But from the previous expression of $\mathbf{\Delta}_\alpha$ we deduce

$$[\mathbf{P}^2, \mathbf{\Delta}_\alpha] = -4\alpha \int \frac{\mathrm{d}k}{2\pi} (\hbar k)^2 |(1-\alpha)k\rangle\langle(\alpha+1)k|. \tag{A9}$$

So the condition $[\mathbf{P}^2, \mathbf{A}_f] = 0$ is equivalent to $\alpha f_1(\alpha) = \alpha f_2(\alpha) = 0$ and then $f_1(\alpha) = C_1\delta(\alpha)$ and $f_2(\alpha) = C_2\delta(\alpha)$. Replacing f_1 and f_2 into the expression of $\mathbf{A}_f$, we find $\mathbf{A}_f = C_1\mathbf{K}_P + C_2\mathbf{1}_\mathcal{H}$ since $\mathbf{\Delta}_0 = \mathbf{1}_\mathcal{H}$. Finally since $\mathbf{A}_f$ is self-adjoint C_1 and C_2 must be real.

(Received 3 November 2005; accepted 13 February 2006; published online 7 April 2006)

We consider a classical Hamiltonian H on $\mathbb{R}^{2d}$, invariant by a finite group of symmetry G, whose Weyl quantization $\hat{H}$ is a self-adjoint operator on $L^2(\mathbb{R}^d)$. If χ is an irreducible character of G, we investigate the spectrum of its restriction $\hat{H}_\chi$ to the symmetry subspace $L^2_\chi(\mathbb{R}^d)$ of $L^2(\mathbb{R}^d)$ coming from the decomposition of Peter-Weyl. We give reduced semiclassical asymptotics of a regularized spectral density describing the spectrum of $\hat{H}_\chi$ near a noncritical energy $E \in \mathbb{R}$. If $\Sigma_E := \{H=E\}$ is compact, assuming that periodic orbits are nondegenerate in Σ_E/G, we get a reduced Gutzwiller trace formula which makes periodic orbits of the reduced space Σ_E/G appear. The method is based upon the use of coherent states, whose propagation was given in the work of Combescure and Robert. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2184890]

I. INTRODUCTION

The purpose of this work is to give a Gutzwiller trace formula for a reduced quantum Hamiltonian in the framework of symmetries given by a finite group G of linear applications of the configuration space $\mathbb{R}^d$. This semiclassical trace formula will link the reduced spectral density to periodic orbits of the dynamical system in the classical reduced space, i.e., the space of G-orbits. [Results of this paper were presented without proof in a Note aux Comptes Rendus (see Ref. 3).]

The role that symmetry plays in quantum dynamics appeared since the beginning of the theory, and was emphasized by Hermann Weyl in the book. "The theory of groups and quantum mechanics" (Ref. 28). Pioneering physical results were given for models having a lot of symmetries. In the mathematical domain, first systematical investigations were done in 1978–1979, mainly for the eigenvalues counting function of the Laplacian on a Riemannian compact manifold simultaneously by Donnelly and Brüning and Heintze (see Refs. 2 and 7). Later, Guillemin and Uribe described the relation with closed trajectories in Refs. 12 and 13. In $\mathbb{R}^d$, a general study was done in the early 1980s for globally elliptic pseudodifferential operators, both in cases of compact finite and Lie groups, by Helffer and Robert (see Refs. 15 and 16) for high energy asymptotics, and later by El Houakmi and Helffer in the semiclassical setting (see Refs. 9 and 10). Main results were then given in terms of reduced asymptotics of Weyl type for a counting function of eigenvalues of the operator. Here, in a semiclassical study with a finite group of symmetry, we want to go one step beyond Weyl formulas, investigating oscillations of the spectral density, and establishing a Gutzwiller formula for the *reduced* quantum Hamiltonian. The case of a compact Lie group will be carried out in another paper (see Ref. 4).

Without symmetry, in 1971, Gutzwiller published for the first time his trace formula linking semiclassically the spectrum of a quantum Hamiltonian $\hat{H}$ near an energy E, to periodic orbits of the classical Hamiltonian system of H on $\mathbb{R}^{2d}$, lying in the energy shell $\Sigma_E := \{H=E\}$. This was one of the strongest illustrations of the so-called correspondence principle. Later, mathematical proofs

[a)]Electronic mail: cassanas@math.univ-nantes.fr

were given (see, for example, Refs. 20, 21, 19, and 8), using various techniques like wave equation, heat equation, microlocal analysis, and more recently wave packets (see Ref. 5).

Coming back to classical dynamics, let $H:\mathbb{R}^{2d}\to\mathbb{R}$ be a smooth Hamiltonian with a finite group of symmetry G, such that H is G-invariant, i.e., suppose that there is an action M from G into $\mathrm{Sp}(d,\mathbb{R})$, the group of symplectic matrices of $\mathbb{R}^{2d}$, such that

$$H(M(g)z)=H(z),\quad \forall\, g\in G,\quad \forall\, z\in\mathbb{R}^{2d}. \tag{1.1}$$

The Hamiltonian system associated to H is

$$\dot{z}_t=J\nabla H(z_t),\quad \text{where } J=\begin{pmatrix}0 & I_d\\ -I_d & 0\end{pmatrix}. \tag{1.2}$$

In the framework of symmetry, specialists in classical dynamics are used to investigate this system in the space of G-orbits: $\mathbb{R}^{2d}/G$, also called the *reduced space*.

Here, for a quantum study with symmetry, it is therefore natural to expect a reduced Gutzwiller formula, linking semiclassically the spectrum of the *reduced* quantum Hamiltonian near the energy E to periodic orbits of the *reduced* classical dynamical system on Σ_E/G.

We now briefly describe our main result. First, we introduce our quantum reduction. We follow the same setting as in papers by Helffer and Robert:[15,16] let $H:\mathbb{R}^{2d}\to\mathbb{R}$ be a smooth Hamiltonian and G a finite subgroup of the linear group $\mathrm{Gl}(d,\mathbb{R})$. If $g\in G$, we set

$$M(g)(x,\xi):=({}^{t}g^{-1}x,{}^{t}g^{-1}\xi) \tag{1.3}$$

and we assume that H is G-invariant as in (1.1). As usual, we make suitable assumptions—see (3.5)—to have nice properties for the Weyl quantization of H (as functional calculus), which is defined as follows: for $u\in\mathcal{S}(\mathbb{R}^d)$,

$$\mathrm{Op}_h^w(H)u(x)=(2\pi h)^{-d}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}e^{(i/h)(x-y)\xi}H\left(\frac{x+y}{2},\xi\right)u(y)\mathrm{d}y\,\mathrm{d}\xi. \tag{1.4}$$

In particular, $\mathrm{Op}_h^w(H)$ is essentially self-adjoint on $\mathcal{S}(\mathbb{R}^d)$ and we denote by $D(\hat{H})$, $\hat{H}$ its self-adjoint extension.

G acts on the quantum space $L^2(\mathbb{R}^d)$ by $\tilde{M}$ defined for $g\in G$ by

$$\tilde{M}(g)(f)(x)=f(g^{-1}x),\quad \forall\, f\in L^2(\mathbb{R}^d),\quad \forall\, x\in\mathbb{R}^d. \tag{1.5}$$

If χ is an irreducible character of G, we set $d_\chi:=\chi(Id)$. Then, we define the symmetry subspace $L^2_\chi(\mathbb{R}^d)$ associated to χ, by the image of $L^2(\mathbb{R}^d)$ by the projector

$$P_\chi:=\frac{d_\chi}{|G|}\sum_{g\in G}\overline{\chi(g)}\tilde{M}(g), \tag{1.6}$$

$L^2(\mathbb{R}^d)$ splits into a Hilbertian sum of $L^2_\chi(\mathbb{R}^d)$'s (Peter-Weyl decomposition), and the property (1.1) implies that each $L^2_\chi(\mathbb{R}^d)$ is stable by $\hat{H}$. Our goal is to give semiclassical trace formulas for the restriction $\hat{H}_\chi$ of $\hat{H}$ to $L^2_\chi(\mathbb{R}^d)$, which will be called the *reduced quantum Hamiltonian*. We define the following *reduced regularized spectral density*:

$$\mathcal{G}_\chi(h):=\mathrm{Tr}\left(\psi(\hat{H}_\chi)f\left(\frac{E-\hat{H}_\chi}{h}\right)\right), \tag{1.7}$$

where ψ is smooth, compactly supported in a neighborhood $]E-\delta E,E+\delta E[$ of $E\in\mathbb{R}(\delta E>0)$ such that $H^{-1}([E-\delta E,E+\delta E])$ is compact [$\psi(\hat{H}_\chi)$ is an energy cutoff which is trace class], f is smooth and $\hat{f}$ (the Fourier transform of f) is compactly supported in $\mathbb{R}$. The case where $\mathrm{Supp}(\hat{f})$ is localized near zero is the one that leads to the Weyl formulas, and gives an asymptotic expansion

of the counting function of $\hat{H}_\chi$ (see Theorem 4.5, Corollary 4.7). Here we want to focus on the oscillating part of $\mathcal{G}_\chi(h)$. Thus we suppose that $0 \notin \mathrm{Supp}(\hat{f})$.

In order to state the theorem in terms of the reduced space, we need a smooth structure on Σ_E/G, and thus we suppose that the group acts freely on Σ_E, so that dynamics of H on Σ_E would descend to the quotient. Note that this is not an essential assumption, since we have proved the asymptotic without this hypothesis (see Theorem 4.8). The following result involves the quantity $\chi(g_{\bar{\gamma}})$, defined as follows.

If π denotes the projection on the quotient and $\bar{\gamma}$ is a periodic orbit in Σ_E/G if $\pi(\gamma)=\bar{\gamma}$, then, there is only one g_γ in G such that, $\forall z \in \gamma$, $M(g_\gamma)\Phi_{T^*_{\bar{\gamma}}}(z)=z$, where $T^*_{\bar{\gamma}}$ is the primitive period of $\bar{\gamma}$. If $\pi(\gamma_1)=\pi(\gamma_2)$ then $g_{\gamma 1}$ and $g_{\gamma 2}$ are conjugate elements of G, and we denote by $\chi(g_{\bar{\gamma}})$ the quantity $\chi(g_{\gamma 1})=\chi(g_{\gamma 2})$.

In order to have a finite number of periodic orbits of the reduced space involved in the trace formula, we will suppose that periodic orbits of Σ_E/G are *non-degenerate*, in the following sense: If $\bar{\gamma}$ is a periodic orbit of Σ_E/G, with primitive period $T^*_{\bar{\gamma}}$, and if $n \in \mathbb{Z}^*$ is such that $nT_{\bar{\gamma}^*} \in \mathrm{Supp}(\hat{f})$, then 1 is not an eigenvalue of the differential of the Poincaré map $P_{\bar{\gamma}}$ of $\bar{\gamma}$ in Σ_E/G at $nT_{\bar{\gamma}^*}$: $\ker[(\mathrm{d}P_{\bar{\gamma}})^n - Id]=\{0\}$. Then we have the following result.

Theorem 1.1: *Under previous assumptions, suppose that the group G acts freely on* Σ_E *and that periodic orbits of* Σ_E/G *are non–degenerate in the sense given above. We then have a complete asymptotic expansion of* $\mathcal{G}_\chi(h)$ *in powers of h, modulo an oscillating factor of the form* $e^{i(\alpha/h)}$ *as* $h \to 0^+$ *(see Theorem 4.8 for details). The first term is given by*

$$\mathcal{G}_\chi(h) = d_\chi \psi(E) \sum_{\substack{\bar{\gamma} \text{ periodic} \\ \text{orbit of } \Sigma_E/G}} \sum_{\substack{n \in \mathbb{Z}^* s.t. \\ nT^*_{\bar{\gamma}} \in \mathrm{Supp} f}} \hat{f}(nT^*_{\bar{\gamma}}) \overline{\chi(g^n_{\bar{\gamma}})} e^{(i/h) n S_{\bar{\gamma}}} \frac{T^*_{\bar{\gamma}} e^{i(\pi/2)\sigma_{\bar{\gamma},n}}}{2\pi \left|\det(\mathrm{d}P_{\bar{\gamma}})^n - Id\right|^{1/2}} + O(h),$$

where $S_{\bar{\gamma}} := \int_0^{T^*_{\bar{\gamma}}} p_s \dot{q}_s \mathrm{d}s$, $P_{\bar{\gamma}}$ *is the Poincaré map of* $\bar{\gamma}$ *in* Σ_E/G, *and* $\sigma_{\bar{\gamma},n} \in \mathbb{Z}$. *Other terms in* $O(h)$ *are distributions at* $\hat{f}$, *with support in the set of periods of orbits in* Σ_E/G.

Remark 1: The case with $0 \in \mathrm{Supp}(\hat{f})$ could have been included in the preceding theorem, and we would get a Weyl term in addition to this oscillating part. This term was already described by El Houakmi (see Ref. 9) for the leading contribution. See also Theorem 4.5, where we obtain slightly more detailed asymptotics for this Weyl part, by calculating the contribution of each g in G.

Remark 2: One could also consider a symmetry directly given in phase space $\mathbb{R}^d \times \mathbb{R}^d$, and set G as a finite subgroup of $\mathrm{Sp}(d,\mathbb{R})$. Then we would have to suppose that there exists a unitary action $\tilde{M}: G \to \mathcal{L}(L^2(\mathbb{R}^d))$ which is metaplectic, i.e., satisfies

$$\tilde{M}(g)^{-1}\, \mathrm{Op}^w_h(H)\tilde{M}(g) = \mathrm{Op}^w_h(H \circ g), \quad \text{for all } g \text{ in } G. \tag{1.8}$$

For a fixed g, there is always some $\tilde{M}(g)$ satisfying (1.8), but it is not unique [multiply $\tilde{M}(g)$ by a complex of modulus 1]. The difficulty is to find a $\tilde{M}$ that is also a group homomorphism.

The method used is close to the one of Ref. 5: unlike papers previously quoted, which used an approximation of the propagator $\exp[-i(t/h)H]$ by some FIO following the WKB method, we will use here the work of Combescure and Robert on the propagation of coherent states. This method avoids problems of caustics and looks simpler to us. Moreover, the symmetry behaves well with coherent states, and we get very pleasant formulas [see (3.10)]. Thanks to these wave packets, we first reduce the problem to an application of the generalized stationary phase theorem (Sec. III). Then we find minimal hypotheses for the critical set to be a smooth manifold, and to ensure that the transverse Hessian of the phase is nondegenerate. These hypotheses will be called G-clean flow conditions, and we get a theoretical asymptotic expansion of $\mathcal{G}_\chi(h)$ under these assumptions

(Theorem 4.4). Finally, as in the particular cases, we will show that these conditions are fulfilled on the one hand when $\hat{f}$ is supported near zero (Weyl term Theorem 4.5), and on the other hand when periodic orbits are nondegenerate (oscillating term, Theorem 4.8). In both cases, we calculate geometrically first terms of the asymptotic expansion, to make quantities of the reduced classical dynamics appear, as the energy level, periodic orbits and the Poincaré map. The symmetry of periodic orbits plays an important part in the result.

We found strong motivation in the work of physicists Lauritzen, Robbins, and Whelan.[17,18,23]

II. QUANTUM REDUCTION

A. Symmetry subspaces

We recall some basic facts on representations (see Refs. 26 and 27 or 22). A representation $\rho: G \to \mathrm{Gl}(E)$ of the group G on a finite dimensional complex vector space E is said to be irreducible if there is no nontrivial subspace of E stable by $\rho(g)$, for all g in G. The character $\chi_\rho: G \to \mathbb{C}$ of a representation is defined by $\chi_\rho(g) := \mathrm{Tr}(\rho(g))$, for $g \in G$. The degree of the representation ρ is denoted by d_{χ_ρ} and is the dimension of E. Two such representations are isomorphic if and only if they have the same character. We will denote by $\hat{G}$ the set of all irreducible characters, that is the set of characters of irreducible representations. Moreover, G finite implies $\hat{G}$ finite.

A representation $\widetilde{M}$ of G on a Hilbert space is said to be unitary if each $\widetilde{M}(g)$ is a unitary operator. This is the case of our representation $\widetilde{M}$ on the Hilbert space $L^2(\mathbb{R}^d)$ defined by (1.5) since $|\det(g)| = 1$. One can easily check that $\widetilde{M}$ is strongly continuous. Then, the Peter-Weyl theorem (see Refs. 27 or 22) says that if one set $L^2_\chi(\mathbb{R}^d) := P_\chi(L^2(\mathbb{R}^d))$, where P_χ is defined by (1.6), then the P_χ's are orthogonal projectors of sum identity, and we have the Hilbertian decomposition,

$$L^2(\mathbb{R}^d) = \overset{\perp}{\underset{\chi \in \hat{G}}{\oplus}} L^2_\chi(\mathbb{R}^d). \tag{2.1}$$

Furthermore, if $\chi \in \widetilde{G}$, then any irreducible subrepresentation of $\widetilde{M}$ in $L^2_\chi(\mathbb{R}^d)$ is of character χ, and a decomposition having such a property is unique. These $L^2_\chi(\mathbb{R}^d)$'s will be called here the *symmetry subspaces*.

One must think of them as a certain class of functions of $L^2(\mathbb{R}^d)$ having a certain symmetry linked to G and χ. For example, if $G = \{\pm Id_{\mathbb{R}^d}\}$, then we have two irreducible characters χ_+ and χ_- such that $L^2_{\chi_+}(\mathbb{R}^d)$ is the set of even functions of $L^2(\mathbb{R}^d)$, and $L^2_{\chi_-}(\mathbb{R}^d)$ is the set of odd functions. More generally, if χ is a character of degree 1, then χ is multiplicative, and we have

$$L^2_\chi(\mathbb{R}^d) = \{f \in L^2(\mathbb{R}^d) : \forall\, g \in G, \widetilde{M}(g)f = \chi(g)f\}.$$

This is in particular the case for Abelian groups. If $G \simeq \sigma_d$ is the symmetric group of permutation matrices acting on $\mathbb{R}^d$, then there is at least two characters of degree 1: χ_0, the trivial character (always equal to 1), and the signature ε. Thus we get

$$L^2_{\chi_0}(\mathbb{R}^d) = \{f \in L^2(\mathbb{R}^d) : \forall\, \sigma \in G,\ f(x_{\sigma(1)}, \ldots, x_{\sigma(d)}) = f(x_1, \ldots, x_d)\},$$

$$L^2_\varepsilon(\mathbb{R}^d) = \{f \in L^2(\mathbb{R}^d) : \forall\, \sigma \in G,\ f(x_{\sigma(1)}, \ldots, x_{\sigma(d)}) = \varepsilon(\sigma) f(x_1, \ldots, x_d)\}.$$

B. Reduced Hamiltonians

It is easy to check on the formula (1.4) that we have on $\mathcal{S}(\mathbb{R}^d)$,

$$\widetilde{M}(g)^{-1}\,\mathrm{Op}_h^w(H)\widetilde{M}(g)=\mathrm{Op}_h^w(H\circ M(g)),\quad \forall\, g\in G. \tag{2.2}$$

Thus we see that the property of G-invariance (1.1) is equivalent to the commutation of $\hat{H}$ with all $\widetilde{M}(g)$. In particular, it implies that $\hat{H}$ commutes with all P_χ's, and thus, $L^2_\chi(\mathbb{R}^d)$ is stable by $\hat{H}$. We can then define the operator that we plan to study: if $\chi\in\hat{G}$, set

$$D(\hat{H}_\chi):=L^2_\chi(\mathbb{R}^d)\cap D(\hat{H}).$$

The restriction $\hat{H}_\chi$ of $\hat{H}$ to $L^2_\chi(\mathbb{R}^d)$ is called the *reduced quantum Hamiltonian*, and is a self-adjoint operator on the Hilbert space $L^2_\chi(\mathbb{R}^d)$. If $f:\mathbb{R}\to\mathbb{C}$ is Borelian, then we have

$$[f(\hat{H}),P_\chi]=0,\quad D(f(\hat{H}_\chi))=D(f(\hat{H}))\cap L^2_\chi(\mathbb{R}^d),\quad f(\hat{H})=\sum_{\chi\in\hat{G}} f(\hat{H}_\chi)P_\chi,$$

$f(\hat{H}_\chi)$ is the restriction of $f(\hat{H})$ to $L^2_\chi(\mathbb{R}^d)$. Last, if $\sigma(A)$ denotes the spectrum of a self-adjoint operator A, then we have $\sigma(\hat{H})=\cup_{\chi\in\hat{G}}\sigma(\hat{H}_\chi)$. Moreover, the following trace formula will be essential for the rest of this paper.

If $f:\mathbb{R}\to\mathbb{R}$ is Borelian, and if $f(\hat{H})$ is trace class on $L^2(\mathbb{R}^d)$, then, for all $\chi\in\hat{G}$, $f(\hat{H}_\chi)$ is trace class on $L^2_\chi(\mathbb{R}^d)$ and

$$\mathrm{Tr}(f(\hat{H}_\chi))=\mathrm{Tr}(f(\hat{H})P_\chi). \tag{2.3}$$

Indeed, by completing a Hilbertian basis of $L^2_\chi(\mathbb{R}^d)$ into one of $L^2(\mathbb{R}^d)$, we have that $|f(\hat{H}_\chi)|^{1/2}$ is Hilbert-Schmidt, i.e., $f(\hat{H}_\chi)$ is trace class. Moreover the equality of traces is easily obtained by noting that if $\lambda\neq 0$, then $\mathrm{Ker}(f(\hat{H})\circ P_\chi-\lambda)=\mathrm{Ker}(f(\hat{H}_\chi)-\lambda)$.

C. Interpretation of the symmetry

The investigation of $\hat{H}_\chi$ provides informations on the spectrum of $\hat{H}$.

Lemma 2.1: If $\chi\in\hat{G}$ then eigenvalues of $\hat{H}_\chi$ have a multiplicity proportional to d_χ.

Indeed, if $F\subset L^2_\chi(\mathbb{R}^d)$ is an eigenspace of $\hat{H}_\chi$, then it is $\widetilde{M}$-invariant. One can decompose it into irreducible representations By the Peter-Weyl theorem, the only irreducible representation appearing is the one of character χ, and thus is of dimension d_χ. In particular, the operator $\hat{H}_\chi$ provides a lower bound for the multiplicity of some eigenvalues of $\hat{H}$.

Another remark: by splitting an eigenfunction of $\hat{H}$ on the symmetry subspaces, we get at least an eigenvector in one $L^2_\chi(\mathbb{R}^d)$. This means that each eigenspace of $\hat{H}$ contains an eigenfunction having a certain symmetry. As it is well known for the double-well potential ($G=\{\pm Id\}$), where eigenspaces are of dimension 1, this leads to an alternance of even/odd eigenspaces related to tunneling effect.

If $N_\chi(I)$ denotes the number of eigenvalues of $\hat{H}_\chi$ (with multiplicity) in an interval I of $\mathbb{R}$, and $N(I)$ the one of $\hat{H}$, then the quantity $N_\chi(I)/N(I)$ can be thought as the proportion of eigenfunctions of symmetry χ among those corresponding to eigenvalues of $\hat{H}$.

D. Examples

We give a few examples of Schrödinger Hamiltonians with a finite group of symmetry:

$$H(x,\xi):=|\xi|^2+V(x).$$

(1) $G=\{\pm Id\}$: Double well $V(x)=(x^2-1)^2$, harmonic or quadratic oscillator $V(x)=x^2$ or x^4, the well on the island $V(x)=(x^2+a)e^{-x^2}$ $(a>0)$. For the two first examples, $V(x)\to_{+\infty}+\infty$, so $\hat{H}$ is essentially self-adjoint on $\mathcal{S}(\mathbb{R})$ and with compact resolvent.
(2) $G\simeq\sigma_2$, $d=2$. Any potential satisfying $V(x,y)=V(y,x)$.
(3) Group of isometries of the triangle, $d=2$: $V(x,y)=\frac{1}{2}\ (x^2+y^2)^2-xy^2+\frac{1}{3}x^3$, which in polar coordinates is $\widetilde{V}(r,\theta)=V(r\cos\theta,r\sin\theta)=\frac{1}{2}r^2+\frac{1}{3}r^3\cos(3\theta)$ [see also the Hénon-Heiles potential: $V(x,y)=\frac{1}{2}(x^2+y^2)-xy^2+\frac{1}{3}x^3$, but one must look for the self-adjointness of this operator].
(4) Group of isometries of the square, $d=2$: $V(x,y)=\frac{1}{2}x^2y^2$.
(5) $G\simeq(\mathbb{Z}/2\mathbb{Z})^d$: harmonic oscillator with distinct frequencies: $V(x)=\langle Sx,x\rangle_{\mathbb{R}^d}$, with S symmetric positive definite matrix with eigenvalues pairwise distincts. In this case, $\hat{H}$ is still essentially self-adjoint on $\mathcal{S}(\mathbb{R}^d)$ and with compact resolvent. This is one of the few cases where we can calculate periodic orbits of the dynamical system.

III. REDUCTION OF THE PROOF BY COHERENT STATES

We adapt here the method of Ref. 5. The essential tool is the use of coherent states. We refer to the Appendix where we recall basic things about it (see also Refs. 5 and 6). Note that, by an averaging argument (see Lemma 4.6), we could suppose that the group G is composed of *isometries*. For the moment, we still use the general expression of (1.3), to keep in mind the symplectic form of $M(g)$. We suppose that ψ and f are in $\mathcal{S}(\mathbb{R})$ such that $\mathrm{Supp}(\psi)\subset\,]E-\delta E,E+\delta E[$ and the Fourier transform $\hat{f}$ of f is with compact support. We know from Refs. 14 and 24, that, under hypothesis (3.5), $\psi(\hat{H})$ is trace class for small h, and, by formula (2.3), we have

$$\mathcal{G}_\chi(h)=\mathrm{Tr}\left(\psi(\hat{H}_\chi)f\left(\frac{E-\hat{H}_\chi}{h}\right)\right)=\frac{d_\chi}{|G|}\sum_{g\in G}\overline{\chi(g)}I_g(h),$$

where

$$I_g(h):=\mathrm{Tr}\left(\psi(\hat{H})f\left(\frac{E-\hat{H}}{h}\right)\widetilde{M}(g)\right).\tag{3.1}$$

Then, by Fourier inversion, we make the h-unitary quantum propagator $U_h(t):=e^{-i(t/h)\hat{H}}$ appear, and write

$$I_g(h)=\frac{1}{2\pi}\int_{\mathbb{R}}e^{i(tE/h)}\hat{f}(t)\mathrm{Tr}(\psi(\hat{H})U_h(t)\widetilde{M}(g))\mathrm{d}t.\tag{3.2}$$

Then we use the trace formula with coherent states—see (5.5)—to write

$$I_g(h)=\frac{(2\pi h)^{-d}}{2\pi}\int_{\mathbb{R}}\int_{\mathbb{R}^{2d}_a}e^{i(tE/h)}\hat{f}(t)m_h(\alpha,t,g)\mathrm{d}\alpha\,\mathrm{d}t,\tag{3.3}$$

where

$$m_h(\alpha,t,g):=\langle U_h(t)\varphi_\alpha;\widetilde{M}(g)^{-1}\psi(\hat{H})\varphi_\alpha\rangle_{L^2(\mathbb{R}^d)}.\tag{3.4}$$

Using an expansion of the type (3.6), with the same proof as in Ref. 5, we get the following lemma.

Lemma 3.1: There exists a compact set K in $\mathbb{R}^{2d}$ *such that*

$$\int_{\mathbb{R}^{2d}\setminus K} |m_h(\alpha,t,g)|\mathrm{d}\alpha = O(h^{+\infty})$$

uniformly with respect to $g \in G$ *and* $t \in \mathbb{R}$.

We can then suppose that $\Sigma_E := \{H=E\}$ is included in K, and choose a real cutoff function χ_1, compactly supported in $\mathbb{R}^{2d}$ and equal to 1 on K. Then, we classically write $1=\chi_1+(1-\chi_1)$ in (3.3), and settle problems at infinity in α. Besides, we want to use the functional calculus of Helffer and Robert[14,24] for the description of $\psi(\hat{H})$. Thus we make the following hypothesis: $\exists C>0$, $\exists C_\alpha>0$, $\exists m>0$ such that

$$\langle H(z)\rangle \leqslant C\langle H(z')\rangle\langle z-z'\rangle^m, \quad \forall\, z,z' \in \mathbb{R}^{2d},$$

$$\left|\partial_z^\alpha H(z)\right| \leqslant C_\alpha\langle H(z)\rangle, \quad \forall\, z \in \mathbb{R}^{2d}, \quad \forall\, \alpha \in \mathbb{N}^{2d}, \tag{3.5}$$

$$H \text{ has a lower bound on } \mathbb{R}^{2d}.$$

Then, we can write for $N_0 \in \mathbb{N}$,

$$\psi(\hat{H}) = \sum_{j=0}^{N_0} h^j \operatorname{Op}_h^w(a_j) + h^{N_0+1}R_{N_0+1}(h), \tag{3.6}$$

where $\mathrm{Supp}(a_j) \subset H^{-1}(]E-\delta E, E+\delta E[)$, $a_0(z)=\psi(H(z))$, with $\|R_{N_{0+1}}(h)\|\mathrm{Tr} \leqslant Ch^{-d}$.

We obtain

$$I_g(h) = \sum_{j=0}^{N_0} h^j I_g^j(h) + O(h^{-d}h^{N_0+1}). \tag{3.7}$$

Now, we are led to give a complete asymptotic expansion for a fixed j_0 in $\mathbb{N}$ of the quantity

$$I_g^{j_0}(h) = \frac{(2\pi h)^{-d}}{2\pi}\int_{\mathbb{R}}\int_{\mathbb{R}^{2d}_\alpha} e^{i(tE/h)}\cdot \hat{f}(t)\chi_1(\alpha)m_h^{j_0}(\alpha,t,g)\mathrm{d}\alpha\,\mathrm{d}t, \tag{3.8}$$

with

$$m_h^{j_0}(\alpha,t,g) := \langle U_h(t)\varphi_\alpha; \widetilde{M}(g)^{-1}\operatorname{Op}_h^w(a_{j_0})\varphi_\alpha\rangle_{L^2(\mathbb{R}^d)}. \tag{3.9}$$

For the right-hand term of the brackets in (3.9), we expand $\operatorname{Op}_h^w(a_{j0})\varphi_\alpha$ in powers of h, by Lemma 3.1 of Ref. 5. Namely, if $N \in \mathbb{N}^*$, then it exists $C_{d,N}>0$, such that for all $\alpha \in \mathbb{R}^{2d}$,

$$\left\| \operatorname{Op}_h^w(a_{j_0})\varphi_\alpha - \sum_{k=0}^{N} h^{h/2} \sum_{\gamma\in\mathbb{N}^{2d},|\gamma|=k} \frac{\partial^\gamma a_{j_0}(\alpha)}{\gamma!}\mathcal{T}_h(\alpha)\Lambda_h \operatorname{Op}_1^w(z^\gamma)\widetilde{\psi}_0 \right\|_{L^2(\mathbb{R}^d)} \leqslant C_{d,N}\cdot h^{(N+1)/2}.$$

Thanks to (2.2), using the definition (5.1) of $\mathcal{T}_h(\alpha)$, we have

$$\widetilde{M}(g)^{-1}\mathcal{T}_h(\alpha) = \mathcal{T}_h(M(g^{-1})\alpha)\widetilde{M}(g)^{-1}. \tag{3.10}$$

For the left-hand term of the brackets in (3.9), we use the theorem of propagation of coherent states given by Combescure and Robert (Refs. 5 and 6 or 25). If $M \in \mathbb{N}$, then we have

$$\left\| U_h(t)\varphi_\alpha - e^{i[\delta(t,\alpha)/h]}\mathcal{T}_h(\alpha_t)\Lambda_h\left[\sum_{j=0}^{M} h^{i/2}b_j(t,\alpha)(x)\cdot e^{(i/2)\langle M_0 x,x\rangle}\right]\right\|_{L^2(\mathbb{R}^d)} \leqslant C_{M,T}(\alpha)\cdot h^{(M+1)/2},$$

where $\alpha_t=\Phi_t(\alpha)$ is the solution of the system (1.2) with initial condition α (see the Appendix for other notations). After all, since there is no problem of control for α at infinity, we get

$$m_h^{j_0}(\alpha,t,g)=\sum_{k=0}^{2N}\sum_{j=0}^{2N-k} h^{j/2}h^{h/2}\sum_{|\gamma|=k}\frac{\partial^\gamma a_{j_0}(\alpha)}{\gamma!}e^{i[\delta(t,\alpha)/h]}\Upsilon_{j,\gamma}(\alpha,t,g,h)+O(h^{-d}h^{N+(1/2)}), \tag{3.11}$$

with

$$\Upsilon_{j,\gamma}(\alpha,t,g,h):=\langle \mathcal{T}_h(\alpha_t)\Lambda_h b_j(t,\alpha)e^{(i/2)\langle M_0 x,x\rangle};\mathcal{T}_h(M(g^{-1})\alpha)\Lambda_h\tilde{M}(g)^{-1}Q_\gamma\tilde{\psi}_0\rangle,$$

where Q_γ is the polynomial in d variables such that

$$\mathrm{Op}_1^w(z^\gamma)\tilde{\psi}_0=Q_\gamma.\,\tilde{\psi}_0. \tag{3.12}$$

In view of the Appendix, we have

$$\Lambda_h^*\mathcal{T}_h(-M(g^{-1})\alpha)\mathcal{T}_h(\alpha_t)\Lambda_h=e^{(i/2h)\langle M(g^{-1})\alpha,J\alpha_t\rangle}\mathcal{T}_1\left(\frac{\alpha_t-M(g^{-1})\alpha}{\sqrt{h}}\right).$$

Thus

$$\Upsilon_{j,\gamma}(\alpha,t,g,h)=e^{(i/2h)\langle M(g^{-1})\alpha,J\alpha_t\rangle}\left\langle \mathcal{T}_1\left(\frac{\alpha_t-M(g^{-1})\alpha}{\sqrt{h}}\right)b_j(t,\alpha)e^{(i/2)\langle M_0 x,x\rangle};\tilde{M}(g)^{-1}Q_\gamma\tilde{\psi}_0\right\rangle_{L^2}.$$

We will use the notation

$$\alpha=(q,p)\in\mathbb{R}^d\times\mathbb{R}^d \quad \text{and } (q_t,p_t):=\alpha_t=\Phi_t(\alpha).$$

Make the change of variable $g^{-1}y:=x-(q_t-g^{-1}q)/\sqrt{h}$ in the previous $\langle;\rangle_{L^2}$. Since G is compact, $|\det(g)|=1$, and we obtain after calculation:

$$\Upsilon_{j,\gamma}(\alpha,t,g,h)=\pi^{-d/4}e^{(i/h)\{[(qp+q_tp_t)/2]-{}^tgpq_t\}+(i/2)|gq_t-q|^2}\int_{\mathbb{R}^d}e^{-(1/2)\langle Ay,y\rangle+By}Q_\gamma\left(y+\frac{gq_t-q}{\sqrt{h}}\right)b_j(\alpha,t)(y)\mathrm{d}y,$$

where

$$A:=I-{}^tg^{-1}M_0g^{-1} \quad \text{and } \beta:=\frac{i}{\sqrt{h}}[(q-gq_t)+i({}^tg^{-1}p_t-p)]. \tag{3.13}$$

Then we set

$$Q_\gamma(x)=:\sum_{|\mu|\leqslant|\gamma|}\kappa_{\mu,\gamma}x^\mu \quad \text{and } b_j(t,\alpha)(x)=:\sum_{|\nu|\leqslant 3j}c_{\nu,j}(t,\alpha)x^\nu$$

(where $c_{\nu,j}$ is smooth in t, α). For the same reasons as in Ref. 5 [parity of Q_γ and $b_j(t,\alpha)$], only integer powers of h have nonzero coefficients. Then, we can expend Q_γ and $b_j(t,\alpha)$ and use the following calculus of the integral of a Gaussian.

Lemma 3.2: Let $A\in M_d(\mathbb{C})$ such that ${}^tA=A$, and that $\Re A$ is a positive definite matrix, $\beta\in\mathbb{C}^d$ and $\alpha\in\mathbb{N}^d$. Then A is invertible and

$$\int_{\mathbb{R}_x^d}e^{-(1/2)\langle Ax,x\rangle+\beta x}x^\alpha\,\mathrm{d}x=(2\pi)^{1/2}\det{}^{-1/2}(A)e^{(1/2)\langle A^{-1}\beta,\beta\rangle}\sum_{\eta\leqslant\alpha}(A^{-1}\beta)^\eta P_\eta(A),$$

where $P_\eta(A)$ *does not depend on* β, *and* $P_0(A)=1$ *(*$det_*^{-1/2}$ *is defined in* Ref. 5, *Theorem 3.3).*

We get

$$e^{i(t/i)E}e^{(i/h)\delta(t,\alpha)}\Upsilon_{j,\gamma}(\alpha,t,g,h)=\sum_{|\nu|\leqslant 3j}\sum_{|\mu|\leqslant|\gamma|}\kappa_{\mu,\gamma}c_{\nu,j}(t,\alpha)\sum_{\eta\leqslant\mu}\binom{\mu}{\nu}(2\pi)^{d/2}$$
$$\times\det{}_*^{-1/2}(I-i^tg^{-1}M_0g^{-1})\sum_{\sigma\leqslant\mu-\eta+\nu}(gq_t-q)^\eta[(I-i^tg^{-1}M_0g^{-1})^{-1}$$
$$\times(\beta_0)]^\sigma P_\sigma(A)h^{-(1/2)(|\sigma|+|\eta|)}\exp\left(\frac{i}{h}\varphi_E(t,\alpha,g)\right),$$

where $\beta_0:=\sqrt{h}\beta$, and

$$\varphi_E(t,\alpha,g)=tE+S(t,\alpha)+qp-{}^tgpq_t+\frac{i}{2}|gq_t-q|^2-\frac{i}{2}\langle A^{-1}\beta_0,\beta_0\rangle. \tag{3.14}$$

Thus, (3.8) and (3.9) give

$$I_g^{j_0}(h)=\frac{(2\pi h)^{-d}}{2\pi}\sum_{k=0}^{2N}\sum_{j=0}^{2N-k}h^{(i+h)/2}\sum_{|\gamma|=k}\sum_{|\nu|\leqslant 3j}\sum_{|\mu|\leqslant|\gamma|}\frac{\kappa_{\mu,\gamma}}{\pi^{d/2}\gamma!}(2\pi)^{d/2}\sum_{\eta\leqslant\mu}\binom{\mu}{\nu}L_{\eta,\nu,\mu,\gamma,j}(h)+O(h^{N+(1/2)-d}),$$

with

$$L_{\eta,\nu,\mu,\gamma,j}(h):=\sum_{\sigma\leqslant\mu-\eta+\nu}h^{-(1/2)(|\sigma|+|\eta|)}$$
$$\times\int_{\mathbb{R}_t}\int_{\mathbb{R}_a^{2d}}\exp\left(\frac{i}{h}\varphi_E(t,\alpha,g)\right)\hat{f}(t)\partial^\gamma a_{j_0}(\alpha)\chi_1(\alpha)D_{\sigma,\eta,\nu,j}(t,\alpha,g)\mathrm{d}\alpha\,\mathrm{d}t, \tag{3.15}$$

where

$$D_{\sigma,\eta,\nu,j}(t,\alpha,g):=c_{\nu,j}(t,\alpha)\det{}_*^{-1/2}(I-i^tg^{-1}M_0g^{-1})P_\sigma(A)[A^{-1}[(q-gq_t)+i({}^tg^{-1}p_t-p)]]^\sigma(gq_t-q)^\eta. \tag{3.16}$$

A tiresome but straightforward computation gives from (3.14) and (3.13),

$$\varphi_E=\varphi_1+i\varphi_2,$$

$$\varphi_1(t,\alpha,g):=(E-H(\alpha))t+\frac{1}{2}<M(g)^{-1}\alpha,J,\alpha>-\frac{1}{2}\int_0^t(\alpha_t-M(g^{-1})\alpha)J\dot{\alpha}_s\,\mathrm{d}s, \tag{3.17}$$

$$\varphi_2(t,\alpha,g):=\frac{i}{4}\langle(I-\hat{W}_t)(M(g)\alpha_t-\alpha);(M(g)\alpha_t-\alpha)\rangle,$$

where $\hat{W}_t:=\begin{pmatrix}W_t & -iW_t\\ -iW_t & -W_t\end{pmatrix}$ with $\frac{1}{2}(I+W_t):=(I-i^tg^{-1}M_0g^{-1})^{-1}$.

Lemma 3.3: We have $\|W_t\|_{\mathcal{L}(\mathbb{C}^d)}<1$.

Proof: We introduce the Siegel half-plane,

$$\Sigma_d:=\{Z\in M_d(\mathbb{C}):{}^tZ=Z,\text{ and }\Im Z\text{ is positive definite}\}.$$

We know from Ref. 11, pp. 202 and 203 that if $Z\in\Sigma_d$, then $\|(I-iZ)^{-1}(I+iZ)\|_{\mathcal{L}(\mathbb{C}^d)}<1$. Now, we can take $Z={}^tg^{-1}M_0g^{-1}$. Indeed M_0 is symmetric, and, since $F_\alpha(t)$ is symplectic, we have

$$\forall X \in \mathbb{R}^d, \quad \Im({}^tX \cdot M_0 X) = |(A+iB)^{-1}X|^2_{\mathbb{C}^d}.$$

Thus $Z \in \Sigma_d$. The proof is clear if we note that $(I - i^t g^{-1} M_0 g^{-1})^{-1}(I + i^t g^{-1} M_0 g^{-1}) = W_t$. □

We are led to use a stationary phase theorem to get an expansion of each $L_{\eta,\nu,\mu,\gamma,j}(h)$ in powers of h. Note that the term $D_{\sigma,\eta,\nu,j}$ in (3.16) and its derivatives are vanishing on the critical set of the phase for derivatives up to $|\sigma|+|\eta|$ [see (4.1)]. Therefore, when applying the stationary phase theorem to $L_{\eta,\nu,\mu,\gamma,j}(h)$, the first terms of the asymptotic will vanish up to $h^{(1/2)(|\sigma|+|\eta|)}$. This fact compensates for the term in $h^{-(1/2)(|\sigma|+|\eta|)}$, at the beginning of the expression of $L_{\eta,\nu,\mu,\gamma,j}(h)$ in (3.15).

IV. THE STATIONARY PHASE PROBLEM

Now, we fix g in G and we want to find the conditions under which we will be able to apply the stationary phase theorem under the form of Ref. 5 (Theorem 3.3) on $L_{\eta,\nu,\mu,\gamma,j}(h)$. A necessary and sufficient condition will be called g-clean flow. Then we will give particular cases for which this criterium is satisfied (see Secs. IV A and IV B). Our method will first consist of calculating the critical set of the phase φ_E and its Hessian. Then we will calculate the kernel of this Hessian, and, under assumption of smoothness of the critical set, we will describe the conditions for this kernel to be equal to the tangent space of the critical set. In this section, since g is fixed in G, we will denote $\varphi_E(t,z,g)$ by $\varphi_{E,g}(t,z)$, for $z \in \mathbb{R}^{2d}$ and $t \in \mathbb{R}$.

A. Computations and *g*-clean flow

Computation of the critical set:

$$\text{Let } \mathcal{C}_{E,g} := \{a \in \mathbb{R} \times \mathbb{R}^{2d} : \Im(\varphi_{E,g}(a)) = 0, \nabla\varphi_{E,g}(a) = 0\}.$$

Proposition 4.1: The critical set is

$$\mathcal{C}_{E,g} = \{(t,z) \in \mathbb{R} \times \mathbb{R}^{2d} : z \in \Sigma_E, M(g)\Phi_t(z) = z\}, \tag{4.1}$$

where $(t,z) \mapsto \Phi_t(z)$ *is the flow of the system (1.2).*

Proof:

$$\Im\varphi_E(t,z,g) = \Re\varphi_2(t,z,g) = 1/4|z_t - M(g^{-1})z|^2 - \tfrac{1}{4}\Re\langle \hat{W}_t(M(g)z_t - z); M(g)z_t - z\rangle_{\mathbb{R}^{2d}}.$$

We note that, if a and b are in $\mathbb{R}^d$, then

$$\langle \hat{W}_t(a,b);(a,b)\rangle_{\mathbb{R}^{2d}} = \langle W_t(a-ib);(a-ib)\rangle_{\mathbb{R}^d}.$$

Thus,

$$\Im\varphi_E(t,z,g) = 0 \Leftrightarrow |z_t - M(g^{-1})z|^2 = \Re\langle W_t\beta,\beta\rangle_{\mathbb{R}^d} = \Re\langle W_t\beta,\bar{\beta}\rangle_{\mathbb{C}^d},$$

where

$$\beta := (gq_t - q) - i({}^tg^{-1}p_t - p).$$

Therefore, by Lemma 3.3, we have $\Im\varphi_E(t,z,g) = 0 \Leftrightarrow \Phi_t(z) = M(g^{-1})z$.

Computation of the gradient of φ_1:

$$\partial_t\varphi_1(t,z,g) = E - H(z) - \tfrac{1}{2}\langle (z_t - M(g^{-1})z); J\dot{z}_t\rangle,$$

$$\nabla_z\varphi_1(t,z,g) = \tfrac{1}{2}({}^tM(g^{-1}) + {}^tF_z(t))J(z_t - M(g^{-1})z).$$

Computation of the gradient of φ_2:

$$4\partial_t\varphi_2(t,z,g) = 2\langle (I-\hat{W}_t)(M(g)z_t - z); M(g)\dot{z}_t\rangle - \langle \partial_t(\hat{W}_t)(M(g)z_t - z); (M(g)z_t - z)\rangle,$$

$$4\nabla_z\varphi_2(t,z,g) = 2({}^tF_z(t){}^tM(g) - I)(I-\hat{W}_t)(M(g)z_t - z) - {}^t[\partial_z(\hat{W}_t)(M(g)z_t - z)](M(g)z_t - z).$$

Thus, we see that $(t,z,g) \in \mathcal{C}_{E,g}$ if and only if $\Phi_t(z) = M(g^{-1})z$ and $H(z) = E$. □

Computation of Hess $\varphi_{E,g}(t,z)$: We first need some formulas coming from the symmetry that will be helpful for the computation. We recall that $F_z(t) = \partial_z(\Phi_t(z))$. By differentiating formula (1.1), we get

$$\nabla H(M(g)z) = {}^tM(g^{-1})\,\nabla H(z), \quad \forall\, z \in \mathbb{R}^{2d}, \quad \forall\, g \in G. \tag{4.2}$$

This formula implies that we have also

$$\Phi_t(M(g)z) = M(g)\Phi_t(z), \quad \forall\, z \in \mathbb{R}^{2d}, \quad \forall\, g \in G, \quad \forall\, t \in \mathbb{R} \text{ such that } \Phi_t(z) \text{ exists}. \tag{4.3}$$

Moreover we recall that, since $M(g)$ is symplectic, we have

$$JM(g) = {}^tM(g^{-1})J \quad \text{and } M(g)J = J{}^tM(g^{-1}). \tag{4.4}$$

Finally, if t and z are such that $M(g)\Phi_t(z) = z$, then we have

$$(M(g)F_z(t) - I)J\nabla H(z) = 0 \quad \text{and } ({}^tF_z(t){}^tM(g) - I)\,\nabla H(z) = 0. \tag{4.5}$$

The second identity comes from the first since $M(g)F_z(t)$ is symplectic. For this first relation, one can differentiate at $s = t$ the equation:

$$\Phi_t(M(g)\Phi_s(z)) = \Phi_s(z).$$

With these formulas, it is easy to find the following.

Proposition 4.2:

$$\text{Hess } \varphi_{E,g}(t,z) = \begin{pmatrix} \frac{i}{2}\langle l(I-\hat{W}_t)J\nabla H(z); J\nabla H(z)\rangle & -{}^t\nabla H(z) + \frac{i}{2}{}^t[({}^tF_z(t){}^tM(g) - I)(I-\hat{W}_t)J\nabla H(z)] \\ -\nabla H(z) + \frac{i}{2}({}^tF_z(t){}^tM(g) - I)(I-\hat{W}_t)J\nabla H(z) & \frac{1}{2}[JM(g)F_z(t) - {}^t(M(g)F_z(t))J] + \frac{i}{2}({}^tF_z(t){}^tM(g) - I)(I-\hat{W}_t)(M(g)F_z(t) - I) \end{pmatrix}.$$

Computation of the real kernel of the Hessian: If $A \in M_n(\mathbb{C})$, then we define $\ker_{\mathbb{R}}(A) := \{x \in \mathbb{R}^n : A(x) = 0\} = \ker(\Re(A)) \cap \ker(\Im(A))$.

Proposition 4.3: Let $(t,z) \in \mathcal{C}_{E,g}$. *Then the real kernel of the Hessian is*

$$\ker_{\mathbb{R}} \text{Hess } \varphi_{E,g}(t,z) = \{(\tau,\alpha) \in \mathbb{R} \times (\mathbb{R}\,\nabla H(z))^{\perp} : \tau J\nabla H(z) + (M(g)F_z(t) - Id)\alpha = 0\}. \tag{4.6}$$

Proof: Let $\tau \in \mathbb{R}$ and $\alpha \in \mathbb{R}^{2d}$. We set

$$x := \tau J\nabla H(z) + (M(g)F_z(t) - I)\alpha.$$

Let us denote by $\hat{W}_1$ and $\hat{W}_2$ the real and imaginary part of $\hat{W}_t$. Then, $(\tau,\alpha) \in \ker_{\mathbb{R}} \text{Hess } \varphi_{E,g}(t,z)$ if and only if

$$\langle \hat{W}_2 J\nabla H(z); x\rangle = 2\langle \nabla H(z); \alpha\rangle, \tag{4.7}$$

$$\langle (I-\hat{W}_1)J\nabla H(z); x\rangle = 0, \tag{4.8}$$

$$({}^tF_z(t){}^tM(g)-I)(I-\hat{W}_1)x=0, \tag{4.9}$$

and

$$-2\tau\nabla H(z)+[JM(g)F_z(t)-{}^t(M(g)F_z(t))J]\alpha+({}^tF_z(t){}^tM(g)-I)\hat{W}_2x=0.$$

We multiply this last identity by $(M(g)F_z(t))J$, we note that $\hat{W}_2=J\hat{W}_1$ and recall that $M(g)F_z(t)$ is symplectic to obtain the equivalent identity,

$$(M(g)F_z(t)-I)(\hat{W}_1-I)x=2x. \tag{4.10}$$

Now, if $(\tau,\alpha)\in\ker_{\mathbb{R}}$ Hess $\varphi_{E,g}(t,z)$, then, by (4.10) and (4.9), we have

$$\langle x,(I-\hat{W}_1)x\rangle=0, \quad \text{i.e., } |x|^2=\langle\hat{W}_1x,x\rangle.$$

By Lemma 3.3, $\|\hat{W}_1\|_{\mathcal{L}(\mathbb{R}^{2d})}<1$, thus $x=0$, and by (4.7), $\nabla H(z)\perp\alpha$.

Conversely, if $x=0$ and $\nabla H(z)\perp\alpha$, then, we have (4.7)–(4.10). Thus $(\tau,\alpha)\in\ker_{\mathbb{R}}$ Hess $\varphi_{E,g}(t,z)$. □

We are now able to describe the conditions under which we can apply the generalized stationary phase theorem on $L_{\eta,\nu,\mu,\gamma,j}(h)$: we easily check the positivity of the imaginary part of the phase $\varphi_{E,g}$ by Lemma 3.3. Moreover, if $\mathcal{C}_{E,g}$ is a union of smooth submanifolds of $\mathbb{R}\times\mathbb{R}^{2d}$, if $X\in\mathcal{C}_{E,g}$, then the Hessian of $\varphi_{E,g}(X)$ is nondegenerate on the normal space $N_X\mathcal{C}_{E,g}$ if and only if $\ker_{\mathbb{R}}$ Hess $\varphi_{E,g}(X)\subset T_X\mathcal{C}_{E,g}$, the tangent space of $\mathcal{C}_{E,g}$ at X. Besides, note that, by the nonstationary phase theorem, we can restrict this hypothesis to points X in $\mathrm{Supp}(\hat{f})\times\mathrm{Supp}(a_{j_0})$.

Definition: Let $g\in G$, $T>0$, such that $\mathrm{Supp}(\hat{f})\subset]-T,T[$, and

$$\Psi_g:=\begin{cases}\,]-T;T[\times\Sigma_E\to\mathbb{R}^{2d}\ ,\\ (t,z)\mapsto M(g)\Phi_t(z)-z.\end{cases}$$

We say that the flow is g-clean on $]-T,T[\times\Sigma_E$ if zero is a weakly regular value of Ψ, i.e.,

$$\Psi_g^{-1}(\{0\})=:\mathcal{C}_{E,g} \text{ is a finite union of smooth submanifolds of } \mathbb{R}\times\mathbb{R}^{2d},$$

$$\forall(t,z)\in\mathcal{C}_{E,g},\quad T_{(t,z)}\mathcal{C}_{E,g}=\ker d_{(t,z)}\Psi_g.$$

We say that the flow is G-clean on $]-T,T[\times\Sigma_E$ if it is g-clean for all g in G.

By Proposition 4.3, we see that if $(t,z)\in\mathcal{C}_{E,g}$, then $\ker d_{(t,z)}\Psi_g=\ker_{\mathbb{R}}$ Hess $\varphi_{E,g}(t,z)$. Thus, if we only know that the support of $\hat{f}$ is in $]-T,T[$, then the g-clean flow condition is the minimal hypothesis under which we can apply the stationary phase theorem to $L_{\eta,\nu,\mu,\gamma,j}(h)$. Therefore, we can state the theorem.

Theorem 4.4: Reduced trace formula with G-clean flow.

Let G be a finite subgroup of $\mathrm{Gl}(\mathbb{R},d)$ *and* $H:\mathbb{R}^{2d}\to\mathbb{R}$ *a smooth Hamiltonian G-invariant. Suppose that $E\in\mathbb{R}$ is such that there exists $\delta E>0$ such that $H^{-1}([E-\delta E,E+\delta E])$ is compact, and $\Sigma_E=\{H=E\}$ has no critical points. Make hypothesis (3.5). Let f* and *ψ be real functions in $\mathcal{S}(\mathbb{R})$ such that $\mathrm{Supp}(\psi)\subset]E-\delta E,E+\delta E[$ and f is compactly supported in $]-T,T[$, where $T>0$. Suppose that the flow is G-clean on $]-T,T[\times\Sigma_E$. Then the spectral density*

$$\mathcal{G}_\chi(h)=\frac{d_\chi}{|G|}\sum_{g\in G}\overline{\chi(g)}I_g(h)$$

has a complete asymptotic expansion as $h\to0^+$ [where the definition of $I_g(h)$ is given by (3.1)]. Moreover, if $g\in G$, and, if $[\mathcal{C}_{E,g}]$ denotes the set of connected components of $\mathcal{C}_{E,g}$, then the quantity $\int_0^t p_sq_s\,\mathrm{d}s$ is constant on each element Y of $[\mathcal{C}_{E,g}]$, denoted by $S_{Y,g}$, and we have the following expansion:

$$I_g(h)\sum_{Y\in[\mathcal{C}_{E,g}]}(2\pi h)^{(1-\dim Y)/2}e^{(i/h)S_{Y,g}}\frac{1}{2\pi}\left(\int_Y \hat{f}(t)\psi(E)d_g(t,z)\mathrm{d}\sigma_Y(t,z)+\sum_{j\geqslant 1}h^j a_{j,Y}\right)+O(h^{+\infty}),$$

where $a_{j,Y}$ *are distributions in* $\hat{f}\otimes(\psi\circ H)$ *with support in* Y, *and the density* $d_g(t,z)$ *is defined by*

$$d_g(t,z):=\det{}_*^{-1/2}\left(\frac{\varphi''_{E,g}(t,z)_{|\mathcal{N}_{(t,z)}Y}}{i}\right)\det{}_*^{-1/2}\left(\frac{A+iB-i(C+iD)}{2}\right). \tag{4.11}$$

$\varphi_{E,g}$ *is given by (3.17) and* A,B,C,D *are the* $d\times d$ *blocks of the matrix* $F_z(t):=\partial_z(\Phi_t(z))$ [*see (A8)*].

Remark: Without symmetry, this theorem can be compared to papers by Paul and Uribe (cf. Refs. 20 and 21) or to the Gutzwiller formula in the Ph.D. thesis of Dozias,[8] see also Ref. 19. A notion of clean flow is also present in Ref. 5. The density $d_g(t,z)$ is difficult to compute in general, even without symmetry. The purpose of the next sections is to calculate it in two special cases: when $\hat{f}$ is supported near zero (Weyl part), and under an assumption of nondegenerate periodic orbits of the classical flow in Σ_E (oscillating part).

Proof: As we have seen before, we can apply the stationary phase theorem on each $L_{\eta,\nu,\mu,\gamma,j}(h)$, which gives an expansion of each $I_g^{j_0}(h)$ and each $I_g(h)$. The first term is given by

$$I_g(h)\underset{h\to 0^+}{\sim}\frac{(2\pi h)^{-d}}{2\pi}\int_{\mathbb{R}_t}\int_{\mathbb{R}^{2d}_\alpha}\chi_2(\alpha)\hat{f}(t)\psi(H(\alpha))\det{}_*^{-1/2}\left(\frac{A+iB-i(C+iD)}{2}\right)e^{(i/h)\varphi_{E,g}(t,\alpha)}\,\mathrm{d}t\,\mathrm{d}\alpha.$$

By definition of $\mathcal{C}_{E,g}$, $\varphi_{E,g}$ is constant on each connected component of $\mathcal{C}_{E,g}$, and equal to

$$\varphi_{E,g}(t,\alpha)=S(\alpha,t)+Et=\int_0^t p_s\dot{q}_s\,\mathrm{d}s,\quad \text{where } (q_s,p_s)=\Phi_s(\alpha).$$

This ends the proof of Theorem 4.4. □

B. The Weyl part

We now deal with one case which leads to an asymptotic expansion at the first order of the counting function of $\hat{H}_\chi$ in an interval of $\mathbb{R}$. Fix g in G and define

$$\mathcal{L}_{E,g}:=\{t\in\mathbb{R}:\exists\, z\in\Sigma_E: M(g)\Phi_t(z)=z\}. \tag{4.12}$$

Theorem 4.5: *Let* G *be a finite subgroup of* $\mathrm{Gl}(\mathbb{R},d)$ *and* $H:\mathbb{R}^{2d}\to\mathbb{R}$ *a smooth* G*-invariant Hamiltonian. Let* $E\in\mathbb{R}$ *be such that* $H^{-1}([E-\delta E,E+\delta E])$ *is compact for some* $\delta E>0$, *and that* $\Sigma_E=\{H=E\}$ *has no critical points. Make hypothesis (3.5). Let* f *and* ψ *be real functions in* $\mathcal{S}(\mathbb{R})$ *with* $\mathrm{Supp}(\psi)\subset]E-\delta E,E+\delta E[$ *and* $\hat{f}$ *compactly supported. For* g *in* G, *we set*

$$\nu_g:=\dim\ker(g-Id_{\mathbb{R}^d}),\quad F_g:=\ker(M(g)-Id_{\mathbb{R}^{2d}})\quad \text{and } \widetilde{F}_g:=\ker(g-Id_{\mathbb{R}^d}).$$

Set

$$I_{g,E}(h):=Tr\left(\psi(\hat{H})f\left(\frac{E-\hat{H}}{h}\right)\widetilde{M}(g)\right).$$

Then, under previous assumptions, we have the following:

IF $\mathrm{Supp}\,\hat{f}\cap\mathcal{L}_{E,g}=\emptyset$, *then* $I_{g,E}(h)=O(h^{+\infty})$.

If $\mathrm{Supp}\,\hat{f}\cap\mathcal{L}_{E,g}=\{0\}$ *then we have the following expansion modulo* $O(h^{+\infty})$:

$$I_{g,\lambda}(h)\asymp h^{1-\nu_g}\sum_{k\geqslant 0}c_k(\hat{f},g)h^k,\quad \text{as } h\to 0^+ \tag{4.13}$$

uniformly in λ *in a small neighborhood of* E, *where* $\hat{f}\mapsto c_k(\hat{f},g)$ *is a distribution in* $\hat{f}$ *with support in* $\{0\}$, *and, if* $d(\Sigma_\lambda\cap F_g)$ *denotes the Euclidian measure on* $\Sigma_\lambda\cap F_g$, *then we have*

$$c_0(\hat{f},g)=\psi(\lambda)\hat{f}(0)\frac{(2\pi)^{-\nu_g}}{\det(\ (Id_{\mathbb{R}^d}-g)|_{\widetilde{F}_g^{\perp}})}\int_{\Sigma_\lambda\cap F_g}\frac{d(\Sigma_\lambda\cap F_g)(z)}{|\nabla H(z)|}. \tag{4.14}$$

Remark 1: The oscillating term of Theorem 4.4 is now vanishing, since, for $g\in G$, $S_{Y,g}=0$ when $Y=\{0\}\times(\Sigma_E\cap F_g)$. Moreover, it is easy to see that, since Σ_E is compact and noncritical, zero is isolated in $\mathcal{L}_{E,g}$. Thus the hypothesis $\mathrm{Supp}\,\hat{f}\cap\mathcal{L}_{E,g}=\{0\}$ is fulfilled if $\hat{f}$ is supported close enough to zero.

Remark 2: Theorem 4.5 slightly improves the previous result of El Houakmi given in Ref. 9, by the computation of (4.14). Note that the leading term of $\mathcal{G}_\chi(h)$ is obtained for $g=Id$, and

$$\mathcal{G}_\chi(h)=\frac{d_\chi^2}{|G|}\psi(E)\hat{f}(0)(2\pi h)^{1-d}\frac{1}{2\pi}\int_{\Sigma_E}\frac{\mathrm{d}\Sigma_E}{|\nabla H|}+O(h^{2-d}),\quad \text{as } h\to 0^+.$$

Proof: If $\mathrm{Supp}\,\hat{f}\cap\mathcal{L}_{E,g}=\emptyset$, then $(\mathrm{Supp}(\hat{f})\times\mathbb{R}^{2d})\cap\mathcal{C}_{E,g}=\emptyset$, and by the nonstationary phase theorem, we get the result.

Now suppose that $\mathrm{Supp}\,\hat{f}\cap\mathcal{L}_{E,g}=\{0\}$. Then we have

$$\mathcal{C}_{E,g}\cap(\mathrm{Supp}(\hat{f})\times\mathbb{R}^{2d})=\{0\}\times(\Sigma_E\cap F_g). \tag{4.15}$$

Lemma 4.6: For the rest of the proof, one can assume that G *is composed of isometries.*

Proof: We recall that, since G is compact, there exists some S_0, symmetric $d\times d$ positive definite matrix, such that

$$G_0:=S_0^{-1}GS_0 \text{ is a subgroup of the orthogonal group } O(d,\mathbb{R}). \tag{4.16}$$

Indeed, classically, the following scalar product on $\mathbb{R}^d$:

$$\langle\langle x,y\rangle\rangle:=\frac{1}{|G|}\sum_{g\in G}\langle gx;gy\rangle,\quad \forall\, x,y\in\mathbb{R}^d,$$

is invariant by G, and one can take S_0 such that $\langle\langle x,y\rangle\rangle=\langle S_0^2x,y\rangle$ for all x,y in $\mathbb{R}^d$. Thus, we can define a new G_0-invariant Hamiltonian,

$$H_0(z):=H(M(S_0)z),\quad \textit{where } M(S_0):=\begin{pmatrix}S_0 & 0\\ 0 & {}^tS_0^{-1}\end{pmatrix}.$$

If $\chi\in\hat{G}$, then one can define $\chi_0: G_0\to\mathbb{C}$ by

$$\chi_0(g_0):=\chi(S_0g_0S_0^{-1}).$$

Then it is easy to check that $\chi_0\in\hat{G}_0$ and that the application $\chi\mapsto\chi_0$ is bijective from $\hat{G}$ to $\hat{G}_0$. Moreover, identity (2.2) implies that

$$\mathrm{Op}_h^w(H_0)=\widetilde{M}(S_0)^{-1}\,\mathrm{Op}_h^w(H)\widetilde{M}(S_0).$$

If $\chi\in\hat{G}$, then we can define

$$\widetilde{P}_{\chi_0}:=\frac{d_{\chi_0}}{|G_0|}\sum_{g_0\in G_0}\overline{\chi_0(g_0)}\widetilde{M}(g_0).$$

Then we have $\widetilde{P}_{\chi 0}=\widetilde{M}(S_0)^{-1}P_\chi\widetilde{M}(S_0)$. Therefore, if $f(\hat{H})$ is trace class, then $f(\hat{H}_0)$ also, and we have

$$\mathrm{Tr}(f(\hat{H}_\chi)) = \mathrm{Tr}(f(\hat{H})P_\chi) = \mathrm{Tr}\ (f(\hat{H}_0)\widetilde{P}_{\chi_0})),$$

by cyclicity of trace. This remark can be applied in particular for the trace (1.7). Moreover, if $g \in G$, if $g_0 := S_0^{-1} g S_0$, then $\mathrm{Tr}(f(\hat{H})\widetilde{M}(g)) = \mathrm{Tr}(f(\hat{H}_0)\widetilde{M}(g_0))$. Finally, it is easy to check that hypotheses for (H,G) hold for (H_0,G_0), and that coefficients of the asymptotic have the same expression in terms of (H_0,G_0) as in (H,G). □

From now on, we suppose that G is composed of isometries, without loss of generality. First, we remark that Σ_E and F_g are transverse submanifolds of $\mathbb{R}^{2d}$. Indeed, if $z \in \Sigma_E \cap F_g$, then, by (4.2), since g is an isometry, we have $\nabla H(z) \in F_g$, thus $F_g + [\mathbb{R}\nabla H(z)]^\perp = \mathbb{R}^{2d}$. Therefore

$$\mathcal{T}_{(0,z)}\mathcal{C}_{E,g} = \{0\} \times [F_g \cap [\mathbb{R}\nabla H(z)]^\perp].$$

If $(\tau,\alpha) \in \ker_{\mathbb{R}} \mathrm{Hess}\ \varphi_E(0,z)$ then by Proposition 4.3, $\tau J\nabla H(z) + (M(g) - I_{2d})\alpha = 0$. Then one can take the scalar product of this equality with $J\nabla H(z)$ to obtain $\tau = 0$ and thus, $\ker_{\mathbb{R}} \mathrm{Hess}\ \varphi_E(0,z) = \mathfrak{T}_{(0,z)}\mathcal{C}_{E,g}$. This means that we have the theoretical asymptotic expansion of Theorem 4.5.

Now, we must compute the leading term of this expansion. Here again, we can suppose that g is an isometry, which simplifies the calculus: in particular, $[M(g),J]=0$, when $t=0$, we have $\hat{W}_t = 0$, and $F_z(0) = Id$. By Proposition 4.2, we obtain

$$\mathrm{Hess}\ \varphi_{E,g}(0,z) = \begin{pmatrix} \dfrac{i}{2}|\nabla H(z)|^2 & -{}^t\nabla H(z) \\ -\nabla H(z) & \dfrac{1}{2}J(M(g) - M(g^{-1})) + \dfrac{i}{2}(I - M(g))(I - M(g^{-1})) \end{pmatrix}.$$

We have $\mathcal{N}_{(0,z)}\mathcal{C}_{E,g} = \mathbb{R} \times [F_g^\perp + \mathbb{R}\nabla H(z)]$. Let β_0 be a basis of $F_g^\perp$. We set

$$e_0 := \frac{\partial}{\partial t} = (1,0), \quad \varepsilon_0 := (0,\nabla H(z)).$$

Let β be the basis of $\mathcal{N}_{(0,z)}\mathcal{C}_{E,g}$ made up of (in this order) e_0, ε_0, and β_0. We note that the linear application $\frac{1}{2}J(M(g) - M(g^{-1})) + (i/2)(I - M(g))(I - M(g^{-1}))$ stabilizes the space $F_g^\perp$. Then by calculating the determinant of the restriction of $\mathrm{Hess}\ \varphi_E(0,z)$ to $\mathcal{N}_{(0,z)}\mathcal{C}_{E,g}$ in this basis, we get (noting $\mathcal{N} := \mathcal{N}_{(0,z)}\mathcal{C}_{E,g}$):

$$\det\left(\frac{\varphi''_{E,g}(0,z)_{|_\mathcal{N}}}{i}\right) = |\nabla H(z)|^2 \det\left[\frac{1}{2i}J(M(g) - M(g^{-1})) + \frac{1}{2}(I - M(g))(I - M(g^{-1}))\right]_{\Big| F_g^\perp}.$$

If Π_g is the orthogonal projector on $\widetilde{F}_g$, then we have

$$\frac{1}{|\nabla H(z)|^2}\det\left(\frac{\varphi''_{E,g}(0,z)_{|_\mathcal{N}}}{i}\right) = \begin{pmatrix} \dfrac{1}{2}(I_d - g)(I_d - g^{-1}) + \Pi_g & \dfrac{1}{2i}(g - g^{-1}) \\ -\dfrac{1}{2i}(g - g^{-1}) & \dfrac{1}{2}(I_d - g)(I_d - g^{-1}) + \Pi_g \end{pmatrix}.$$

Then, since g is an isometry, we can suppose that g is block diagonal with blocks I_{p_1}, $-I_{p_2}, R_{\theta_1}, \ldots, R_{\theta_r}$, where $p_1 + p_2 + 2r = d$, θ_j's are not in $\pi\mathbb{Z}$, and $R_\theta := \left(\begin{smallmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{smallmatrix}\right)$. We then use the fact that g commutes with Π_g, and that when $[C,D]=0$, then $\det\left(\begin{smallmatrix} A & B \\ C & D \end{smallmatrix}\right) = \det(AD - BC)$, for any blocks A,B,C,D of same size. A straightforward calculus then gives

$$\det\left(\frac{\varphi''_{E,g}(0,z)_{|\mathcal{N}_{(0,x)}e_{E,g}}}{i}\right)=|\nabla H(z)|^2\det[(I_d-g)_{|\tilde{F}_g^{\perp}}]^2.$$

Since $[\det_*^{-1/2}]^2=\det$, we have

$$\det_*^{-1/2}\left(\frac{\varphi''_{E,g}(0,z)_{|\mathcal{N}_{(0,x)}e_{E,g}}}{i}\right)=\pm|\nabla H(z)||\det(I_d-g)_{|\tilde{F}_g^{\perp}}|.$$

We can prove that the factor ±1 is in fact equal to 1, either by coming back to the calculus of $\det_*^{-1/2}$ with Gaussians, or, classically, by using a weak asymptotic, i.e., by calculating the asymptotic of $\mathrm{Tr}(\varphi(\hat{H})M(g))$, when $\varphi:\mathbb{R}\to\mathbb{R}$ is smooth and $\varphi(\hat{H})$ is trace class.

Using (4.11), the fact that the phase vanishes on $\mathcal{C}_{E,g}$, and that $\dim(\mathcal{C}_{E,g})\cap(\mathrm{Supp}(\hat{f})\times\mathbb{R}^{2d})=2\nu_g-1$, we obtain the result we claimed. This ends the proof of Theorem 4.5. □

As a consequence of Theorem 4.5 near $t=0$, using a well-known Tauberian argument (see Ref. 24), we get the following.

Corollary 4.7: Let G be a finite group of $\mathrm{Gl}(d,\mathbb{R})$, $H:\mathbb{R}^{2d}\to\mathbb{R}$ *be a G-invariant smooth Hamiltonian satisfying (3.5). Let $E_1<E_2$ in $\mathbb{R}$, and $I:=[E_1,E_2]$. Suppose that there exists $\varepsilon>0$ such that $H^{-1}([E_1-\varepsilon,E_2+\varepsilon])$ is compact. Furthermore suppose that E_1 and E_2 are not critical values of H. If $\chi\in\hat{G}$, then the spectrum of H_χ is discrete in I, and we have*

$$N_{1,\chi}(h)=\frac{d_\chi^2}{|G|}(2\pi h)^{-d}\,\mathrm{Vol}[H^{-1}(I)]+O(h^{1-d}),$$

where $N_{I,\chi}(h)$ is the number of eigenvalues of $\hat{H}_\chi$ in I counted with multiplicity.

Remark: One can interpret this result by saying that, semiclassically, the proportion of eigenfunctions of $\hat{H}$ having symmetry χ is $d_\chi^2/|G|$. In particular, the same proportion of eigenvalues has multiplicity greater than d_χ. The more d_χ is high, the more $L^2_\chi(\mathbb{R}^d)$ plays a role in the spectrum of $\hat{H}$.

C. The oscillatory part

If $g\in G$ and γ is a periodic orbit of Σ_E globally stable by $M(g)$, we set

$$\mathcal{L}_{g,\gamma}:=\{t\in\mathrm{Supp}\,\hat{f}:\exists\, z\in\gamma: M(g)\Phi_t(z)=z\}.$$

If $t_0\in\mathcal{L}_{g,\gamma}$, $z\in\gamma$, then P_{γ,g,t_0} denotes the Poincaré map of γ between z and $M(g^{-1})z$ at time t_0, restricted to Σ_E. The characteristic polynomial of $\mathrm{d}P_{\gamma,g,t_0}$ does not depend on $z\in\gamma$. Note that, by iterating formula (4.3), since G is finite, if we have $M(g)\Phi_t(z)=z$, then for all k in $\mathbb{N}$, we have $M(g^k)\Phi_{kt}(z)=z$, and with $k=|G|$, we obtain that z is a periodic point of the Hamiltonian system (1.2).

Theorem 4.8: *Make the same assumptions as in Theorem 4.5, but suppose that $0\notin$ Supp $\hat{f}$. Make the following hypothesis of nondegeneracy: if $\gamma\subset\Sigma_E$, is such that $\exists g\in G$ and $\exists t_0\in\mathcal{L}_{g,\gamma}$, $t_0\neq0$, then 1 is not an eigenvalue of $M(g)\mathrm{d}P_{\gamma,g,t_0}$. Then the set of such γ's is finite and the following expansion holds true modulo $O(h^{+\infty})$, as $h\to0^+$:*

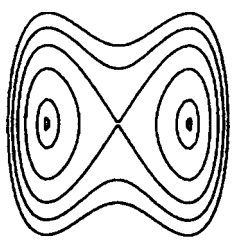
$$\mathcal{G}_\chi(h)\asymp\frac{d_\chi}{|G|}\sum_{\substack{\gamma\text{ periodic}\\ \text{orbit of }\Sigma_E}}\sum_{\substack{g\in G\text{ s.t.}\\ M(g)\gamma=\gamma}}\overline{\chi(g)}\sum_{\substack{t_0\in\mathcal{L}_{g,\gamma}\\ t_0\neq0}}e^{(i/h)S_\gamma(t_0)}\sum_{k\geqslant0}d_k^{\gamma,g,t_0}(\hat{f})h^k. \tag{4.17}$$

The coefficients $\hat{f}\mapsto d_k^{\gamma,g,t_0}(\hat{f})$ define distributions with support in $\{t_0\}$, $S_\gamma(t_0):=\int_0^{t_0}p_s\dot{q}_s\,\mathrm{d}s$, $((q_s,p_s):=\Phi_s(z)$ with $z\in\gamma)$, and

$$d_0^{\gamma,g,t_0}(\hat{f}) = \frac{\psi(E)T_\gamma^* e^{i(\pi/2)\sigma_\gamma(g,t_0)}}{2\pi|\det(M(g)\mathrm{d}P_{\gamma,g,t_0} - Id)|^{1/2}}\hat{f}(t_0),$$

where T_γ^* *is the primitive period of* γ *and* $\sigma_\gamma(g,t_0) \in \mathbb{Z}$.

Example 1: If $d=1$, periodic orbits are always nondegenerate. For example, in the case of a double-well Schrödinger Hamiltonian, one can illustrate the sum of Theorem 4.8 in the diagram below, picturing the classical flow in $\mathbb{R}^2$: some periodic orbits appear only for $g=Id$ in the sum, and others arise for both $g=\pm Id$. One can also fold the picture to compare with the periodic orbits of the reduced space as in Theorem 1.1.



Double-well phase portrait

Example 2: If H is a Schrödinger operator on $\mathbb{R}^d$ with potential $V(x)=\langle Sx,x\rangle$, where S is the diagonal matrix with diagonal nonvanishing $w_1^2,\ldots,w_d^2$, if one assumes that $\forall i \neq j$, $w_i/w_j \notin \mathbb{Q}$, then periodic orbits appear as a union of d planes, with primitive periods $T_j^* = \pi/w_j$ and are all nondegenerate.

As a particular case of this theorem, we get Theorem 1.1.

Proof of Theorem 1.1: If we suppose that G acts freely on Σ_E, then Σ_E/G inherits a structure of smooth manifold such that the canonical projection $\pi:\Sigma_E \twoheadrightarrow \Sigma_E/G$ is smooth, and the dynamical system restricted to Σ_E descends to quotient. If $t_0 \in \mathbb{R}^*$, $g \in G$, and $z \in \Sigma_E$, with orbit γ, are such that $M(g)\Phi_{t_0}(z)=z$, then γ and $\pi(\gamma)$ are periodic. If $P_{\pi(\gamma),\pi(z)}(t_0)$ denotes the Poincaré map of $\pi(\gamma)$ at time t_0, then we have

$$\det(M(g)d_z P_{\gamma,g,t_0} - Id) = \det(d_{\pi(z)}P_{\pi(\gamma),\pi(z)}(t_0) - Id). \tag{4.18}$$

Indeed, if $\tilde{\Phi}_t$ denotes the flow in Σ_E/G, then one can differentiate the following identity on Σ_E with variable z:

$$\pi(M(g)\Phi_{t_0}(z)) = \tilde{\Phi}_{t_0}(\pi(z)),$$

to get the identity:

$$d_z\pi \circ M(g)F_z(t_0) = \tilde{F}_{\pi(z)}(t_0) \circ d_z\pi,$$

where $\tilde{F}_{\pi(z)}(t_0)$ is the differential of $x \mapsto \tilde{\Phi}_{t_0}(x)$ at $\pi(z)$. Moreover, π is a submersion, and by an argument of dimensions it is also an immersion. Thus we have (4.18).

Therefore, the assumptions of Theorem 1.1 imply those of Theorem 4.8. If $z \in \Sigma_E$ is such that the orbit of $\pi(z)$ is periodic with period $t_0 \neq 0$, then there is only one $g = g_\gamma \in G$ such that $M(g)\Phi_{t_0}(z) = z$. If $\mathcal{L}_{\text{red}}$ denotes the set of periods of Σ_E/G, then we resume (4.17) as

$$\sum_{\substack{\gamma \text{ periodic} \\ \text{orbit of } \Sigma_E}} \sum_{\substack{g \in G \text{ s.t.} \\ M(g)\gamma = \gamma}} \sum_{\substack{t_0 \in \mathcal{L}_{g,\gamma} \\ t_0 \neq 0}} \cdots = \sum_{t_0 \in \mathcal{L}_{\text{red}}} \sum_{\substack{\gamma \subset \Sigma_E : \pi(\gamma) \text{ periodic} \\ \text{with } t_0 \text{ for period}}} \sum_{g = g_\gamma} \cdots .$$

If we denote $\text{Stab}(\gamma) := \{g \in G : M(g)\gamma = \gamma\}$, then we have $\text{Stab}(\gamma) = \langle g_\gamma \rangle$ and it is easy to see that $T^*_{\pi(\gamma)} = T^*_\gamma / |\text{Stab}(\gamma)|$. If we denote by $N_{\pi(\gamma)}$ the number of orbits of Σ_E with image $\pi(\gamma)$ by π, then we have $N_{\pi(\gamma)} = |G| / |\text{Stab}(\gamma)|$. Thus we have

$$\mathcal{G}_\chi(h) = d_\chi \sum_{t_0 \in \mathcal{L}_{\text{red}}} \hat{f}(t_0) \sum_{\substack{\gamma \subset \Sigma_E : \pi(\gamma) \text{ periodic} \\ \text{with } t_0 \text{ for period}}} \overline{\chi(g_{\pi(\gamma)}(t_0))} \frac{T^*_{\pi(\gamma)}}{N_{\pi(\gamma)}} \frac{e^{(i/h)S_\gamma(t_0)} e^{i(\pi/2)\sigma_\gamma(g,t_0)}}{2\pi |\det(d_{\pi(z)} P_{\pi(\gamma),\pi(z)}(t_0) - Id)|^{1/2}} + O(h).$$

Then one can show that quantities appearing on the right-hand side do not depend on γ but only on $\pi(\gamma)$, and this proves Theorem 1.1 □

Proof of Theorem 4.8: We fix g in G. If $t_0 \in \mathbb{R}^*$, we set

$$\Gamma_{E,g,t_0} := \{\gamma \text{ orbit of } \Sigma_E : \exists\, z \in \gamma : M(g)\Phi_{t_0}(z) = z\}.$$

Lemma 4.9: Under the nondegeneracy assumptions of Theorem 4.8, $\mathcal{L}_{E,g} \cap \text{Supp}(\hat{f})$ is finite and we have

$$\mathcal{C}_{E,g} \cap (\text{Supp}(\hat{f}) \times \mathbb{R}^{2d}) = \bigcup_{\substack{t_0 \in \mathcal{L}_{E,g} \\ t_0 \neq 0}} \bigcup_{\gamma \in \Gamma_{E,g,t_0}} \{t_0\} \times \gamma. \tag{4.19}$$

Proof: One can adapt the proof of the cylinder theorem of Ref. 1. □

Note that periodic orbits appearing in this critical set are the ones stable by g.

We see that $\mathcal{C}_{E,g} \cap (\text{Supp}(\hat{f}) \times \mathbb{R}^{2d})$ is a submanifold of $\mathbb{R} \times \mathbb{R}^{2d}$ and if $(t_0, z) \in \mathcal{C}_{E,g}$, then we have

$$T_{(t_0,z)}\mathcal{C}_{E,g} = \{0\} \times \mathbb{R} J \nabla H(z).$$

To apply the stationary phase theorem, we must show that $\ker_{\mathbb{R}} \text{Hess}\, \varphi_{E,g}(t_0, z) \subset T_{(t_0,z)}\mathcal{C}_{E,g}$. Let $(\tau, \alpha) \in \ker_{\mathbb{R}} \text{Hess}\, \varphi_{E,g}(t_0, z)$. By Proposition 4.3, we have $\alpha \perp \nabla H(z)$ and

$$\tau J \nabla H(z) + (M(g)F_z(t_0) - I)\alpha = 0. \tag{4.20}$$

If $\lambda \in \mathbb{R}$, we denote by $E_\lambda := \Sigma_{k=1}^{2d} \ker(M(g)F_z(t_0) - Id)^k$. Let γ be the orbit of z. Since 1 is not an eigenvalue of $M(g)\mathrm{d}P_{\gamma,g,t_0}$, 1 is an eigenvalue of $M(g)F_z(t_0)$ of multiplicity 2. Thus $\dim E_1 = 2$. Using (4.5) and (4.20), we have $\alpha \in E_1$. Let $u_2 \in \mathbb{R}^{2d}$ such that $(J\nabla H(z), u_2)$ is a basis of E_1. Note that $\langle u_2, \nabla H(z) \rangle \neq 0$, otherwise we would have $u_2 \in (JE_1)^\perp$, which is equal to $\oplus_{\lambda \neq 1} E_\lambda$ since $M(g)F_z(t_0)$ is symplectic. Since $\alpha \in E_1$ we have λ_1, λ_2 in $\mathbb{R}$ such that

$$\alpha = \lambda_1 J \nabla H(z) + \lambda_2 u_2.$$

Then, using the fact that $\langle \alpha, \nabla H(z)\rangle = 0$, we get $\lambda_2 = 0$ [since $\langle u_2, \nabla H(z)\rangle \neq 0$]. Thus coming back to (4.20), we get $\tau = 0$ and $\alpha \in \mathbb{R}J\nabla H(z)$. Thus $(\tau, \alpha) \in T_{(t_0,z)}\mathcal{C}_{E,g}$.

This shows that we can apply the stationary phase theorem and get a theoretical expansion of $I_g(h)$ and $\mathcal{G}_\chi(h)$. We must now compute the first term of this expansion. We suppose that $(t_0, z) \in \mathcal{C}_{E,g}$. We denote by Π the orthogonal projector on $\mathbb{R}J\nabla H(z)$. We set $F := M(g)F_z(t_0)$ and $W := \hat{W}_{t_0}$. Then we have

$$\det\left(\frac{\varphi''_{E,g}(t_0,z)_{|\mathcal{N}_{(t_0,z)}\mathcal{C}_{E,g}}}{i}\right) = \det\begin{pmatrix} \frac{1}{2}\langle (1-W)J\nabla H(z); J\nabla H(z)\rangle & -\frac{1}{i}{}^t\nabla H(z) + \frac{1}{2}{}^t[({}^tF - I)(I-W)J\nabla H(z)] \\ -\frac{1}{i}\nabla H(z) + \frac{1}{2}({}^tF - I)(I-W)J\nabla H(z) & \frac{1}{2i}[JF + {}^t(JF)] + \frac{1}{2}({}^tF - I)(I-W)(F-I) + \Pi \end{pmatrix}.$$

Since F is symplectic, we have $JF + {}^t(JF) = ({}^tF + I)J(F - I)$. Set

$$K := \frac{1}{2i}({}^tF + I)J + \frac{1}{2}({}^tF + I)(I - W). \tag{4.21}$$

Then, the fourth block is equal to $K(F-I) + \Pi$.

Using (4.5), we note that the third block is equal to $KJ\nabla H(z)$. Let us set

$$X_1 := \tfrac{1}{2}(I - W)J\nabla H(z). \tag{4.22}$$

We then have

$$\det\left(\frac{\varphi''_{E,g}(t_0,z)_{|\mathcal{N}_{(t_0,z)}\mathcal{C}_{E,g}}}{i}\right) = \det\begin{pmatrix} {}^tX_1 J\nabla H(z) & i{}^t\nabla H(z) + {}^tX_1(F-I) \\ KJ\nabla H(z) & K(F-I) + \Pi \end{pmatrix}.$$

The following technical lemma is due to Combescure (see Ref. 5 for the proof).

Lemma 4.10: *K is invertible and* $K^{-1} = \frac{1}{2}[(F-I) + i(F+I)J]$.

Moreover, if we set $F = \begin{pmatrix} \tilde{A} & \tilde{B} \\ \tilde{C} & \tilde{D} \end{pmatrix}$, *then* $\det(K) = (-1)^d \det\left(\frac{1}{2}(\tilde{A} + i\tilde{B} - i(\tilde{C} + i\tilde{D}))\right)^{-1}$ Since

$$\det\left(\frac{\varphi''_{E,g}(t_0,z)_{|\mathcal{N}_{(t_0,z)}Y}}{i}\right) = \det\begin{pmatrix} 1 & 0 \\ 0 & K \end{pmatrix}\begin{pmatrix} {}^tX_1 J\nabla H(z) & i{}^t\nabla H(z) + {}^tX_1(F-I) \\ J\nabla H(z) & (F-I) + K^{-1}\Pi \end{pmatrix},$$

and using (4.11) and the preceding lemma, we get

$$d_g(t,z)^{-2} = (-1)^d \det(g^{-1})\det\begin{pmatrix} {}^tX_1 J\nabla H(z) & i{}^t\nabla H(z) + {}^tX_1(F-I) \\ J\nabla H(z) & (F-I) + K^{-1}\Pi \end{pmatrix}. \tag{4.23}$$

We denote by $\alpha := \langle X_1, J\nabla H(z)\rangle$ [note that $\alpha \neq 0$ since $I - W$ is invertible and $J\nabla H(z) \neq 0$] and we use the line operation $L_2 \leftarrow L_2 - (1/\alpha)J\nabla H(z)L_1$, to get

$$d_g(t,z)^{-2} = (-1)^d \alpha \det(D)\det(g^{-1}), \tag{4.24}$$

where

$$D := (F-I) + K^{-1}\Pi - \frac{1}{\alpha}J\nabla H(z)[i{}^t\nabla H(z) + {}^tX_1(F-I)].$$

Then, we compute $\det(D)$ in the basis $\beta_0 := (v_1, \ldots, v_{2d})$ where $v_1 := J\nabla H(z)$, v_2 is such that $v_2 \perp J\nabla H(z)$ and (v_1, v_2) is a basis of $\ker(F-I)^2$. Last $(v_3, \ldots, v_{2d})$ is a basis of $V_z := \oplus_{\lambda \neq 1} E_\lambda$. Let us set $w := (i/2)(F+I)\nabla H(z)$. We have $Dv_1 = -w$ and, using Lemma 4.10,

$$((F-I)+K^{-1}\Pi)v_2=(F-I)v_2, \tag{4.25}$$

$$\frac{1}{\alpha}J\nabla H(z)[i^t\nabla H(z)+{}^tX_1(F-I)]v_2=\frac{1}{\alpha}(i\langle\nabla H(z),v_2\rangle+\langle X_1,(F-I)v_2\rangle)J\nabla H(z). \tag{4.26}$$

Using the fact that $(F-I)v_2\in E_1$, one easily gets that there exists $\lambda_1\in\mathbb{R}$ such that $(F-I)v_2=\lambda_1 J\nabla H(z)$. Thus $\langle X_1,(F-I)v_2\rangle=\lambda_1\alpha$. We obtain, using (4.25) and (4.26):

$$Dv_2=-\frac{i}{2}\langle\nabla H(z),v_2\rangle J\nabla H(z). \tag{4.27}$$

Note that $(F-I)V_z\subset V_z$. Moreover $K^{-1}\Pi$ is of rank 1. Hence, since its image is equal to $K^{-1}\Pi v_1=-w\neq 0$, we can neglect it on others columns than the first column. The same idea holds for $(1/\alpha)J\nabla H(z)[i^t\nabla H(z)+{}^tX_1(F-I)]$, which we neglect in other columns than the second one [since $(1/\alpha)J\nabla H(z)[i^t\nabla H(z)+{}^tX_1(F-I)]v_2\neq 0$]. Therefore

$$\det(D)=\det\begin{pmatrix}-w_1 & -\frac{i}{\alpha}\langle\nabla H(z),v_2\rangle & 0\\ -w_2 & 0 & \\ -w_3 & 0 & \\ \vdots & \vdots & (F-I)_{|V_z}\\ -w_{2d} & 0 & \end{pmatrix},$$

where $(w_1,\ldots,w_{2d})$ are the coordinates of w in the basis β_0.

Hence $\det(D)=-(i/\alpha)w_2\langle\nabla H(z),v_2\rangle\det((F-I)_{|V_z})$.

We write

$$w=\frac{i}{2}(F+I)\nabla H(z)=w_1J\nabla H(z)+w_2v_2+v,$$

where $v\in V_z$, then we take the scalar product with $\nabla H(z)$. Since $E_1=(JV_z)^{\perp}$, we have $\langle v,\nabla H(z)\rangle=0$ and $i|\nabla H(z)|^2=w_2\langle v_2;\nabla H(z)\rangle$. Thus we get

$$\det(D)=\frac{1}{\alpha}|\nabla H(z)|^2\det((F-I)_{|V_x}).$$

Therefore, according to (4.24)

$$d_g(t,z)^{-2}=(-1)^d|\nabla H(z)|^2\det((F-I)_{|V_x})\det(g^{-1}). \tag{4.28}$$

Since $\det(g^{-1})=\pm 1$, there exists $k\in\mathbb{Z}$, depending on g, such that

$$d_g(t,z)=\frac{e^{ik(\pi/2)}}{|\nabla H(z)||\det((F-I)_{|V_z})|^{1/2}}.$$

Moreover, d_g being continuous, k does not depend on $z\in\gamma$. Thus by Theorem 4.4, we have, if $\mathcal{L}_{E,g}:=\{t\in\mathbb{R}:\exists z\in\Sigma_E: M(g)\Phi_t(z)=z\}$,

$$I_g(h)=\sum_{t_0\in\mathcal{L}_{E,g}\cap\mathrm{Supp}(\hat{f})}\sum_{\gamma\in\Gamma_{E,g,t_0}}e^{(i/h)S_\gamma(t_0)}\frac{\psi(E)\hat{f}(t_0)e^{ik(\pi/2)}}{2\pi|\det((F-I)_{|V_z})|^{1/2}}\int_\gamma\frac{\mathrm{d}\gamma}{|\nabla H|}+O(h).$$

Moreover, if $z\in\gamma$, then

$$\int_\gamma \frac{\mathrm{d}\gamma}{|\nabla H|} = \int_0^{T_\gamma^*} |J\nabla H(\phi_t(z))| \frac{\mathrm{d}t}{|\nabla H(\phi_t(z))|} = T_\gamma^*.$$

Last, we sum on $g \in G$ to get the expansion of $\mathcal{G}_\chi(h)$. This ends the proof of Theorem 4.8. □

APPENDIX: COHERENT STATES

We recall some basic things on coherent states on $\mathbb{R}^{2d}$ in Schrödinger representation. We mainly follow the presentation of Combescure and Robert (cf. Refs. 6, 25, and 5).

Notations: The h-scaling unitary operator $\Lambda_h : L^2(\mathbb{R}^d) \to L^2(\mathbb{R}^d)$ is defined by

$$\Lambda_h \psi(x) = h^{-d/4} \psi(h^{-1/2}x).$$

The phase translation unitary operator associated to $\alpha = (q,p) \in \mathbb{R}^d \times \mathbb{R}^d$ is given by

$$\mathcal{T}_h(\alpha) := \exp\left[\frac{i}{h}(px - qhD_x)\right]. \tag{A1}$$

We classically have $\mathcal{T}_h(\alpha)^* = \mathcal{T}_h(\alpha)^{-1} = \mathcal{T}_h(-\alpha)$ and

$$\mathcal{T}_h(\alpha) f(\alpha) = \exp\left(i\frac{p}{h}\left(x - \frac{q}{2}\right)\right) f(x-q). \tag{A2}$$

The ground state of the harmonic oscillator $-\Delta + |x|^2$ is given by

$$\tilde{\psi}_0(x) := \frac{1}{\pi^{d/4}} \exp\left(-\frac{|x|^2}{2}\right).$$

We set

$$\psi_0(x) := \Lambda_h \tilde{\psi}_0(x) = \frac{1}{(h\pi)^{d/4}} \exp\left(-\frac{|x|^2}{2h}\right). \tag{A3}$$

Then the coherent state associated to $\alpha \in \mathbb{R}^{2d}$ is given by $\varphi_\alpha := \mathcal{T}_h(\alpha)\psi_0$. By (A2), we have

$$\varphi_\alpha(x) = \frac{1}{(h\pi)^{d/4}} \exp\left(i\frac{p}{h}\left(x - \frac{q}{2}\right)\right) \exp\left(-\frac{|x-q|^2}{2h}\right), \tag{A4}$$

and we get easily from (A2) the following formulas:

$$\Lambda_h^* \mathcal{T}_h(\alpha) \Lambda_h = \mathcal{T}_1\left(\frac{\alpha}{\sqrt{h}}\right) \quad \text{and } \Lambda_h^* \operatorname{Op}_h^w(a) \Lambda_h = \operatorname{Op}_1^w(a_h), \quad \text{where } a_\hbar(z) := a(\sqrt{h}z),$$

$$\mathcal{T}_h(\alpha)\mathcal{T}_h(\beta) = e^{(1/2h)\langle J\alpha;\beta\rangle} \mathcal{T}_h(\alpha+\beta) \quad \text{and } \mathcal{T}_h(\alpha)^* \operatorname{Op}_h^w(a) \mathcal{T}_h(\alpha) = \operatorname{Op}_h^w[a(\alpha + \cdot)].$$

A trace formula: If $A \in \mathcal{L}(L^2(\mathbb{R}^d))$ is trace class, then $\int_{\mathbb{R}^{2d}_\alpha} |\langle A\varphi_\alpha; \varphi_\alpha\rangle_{L^2(\mathbb{R}^d)}| \mathrm{d}\alpha < +\infty$, and we have (see Ref. 5)

$$\operatorname{Tr}(A) = (2\pi h)^{-d} \int_{\mathbb{R}^{2d}_\alpha} \langle A\varphi_\alpha; \varphi_\alpha\rangle_{L^2(\mathbb{R}^d)} \, \mathrm{d}\alpha. \tag{A5}$$

Propagation of coherent states: For $z=(q,p)\in\mathbb{R}^d\times\mathbb{R}^d$, let $z_t=(q_t,p_t):=\Phi_t(z)$ be the solution of the Hamiltonian system (1.2) with initial condition z. We introduce the notations

$$S(t,z):=\int_0^t (p_s\cdot\dot{q}_s-H(z_s))\mathrm{d}s, \tag{A6}$$

$$\delta(t,z):=S(t,z)-\frac{q_tp_t-qp}{2}, \tag{A7}$$

where $F_\alpha(t)=\partial_z\Phi_t(\alpha)\in \mathrm{Sp}(d,\mathbb{R})$. We set

$$F_\alpha(t)=\begin{pmatrix} A & B\\ C & D\end{pmatrix} \quad \text{where } A,B,C,D\in M_d(\mathbb{R}). \tag{A8}$$

Theorem 5.1: *Semiclassical propagation of coherent states (Combescure-Robert)* (Refs. 6 and 25). *Let $T>0$. Let $H:\mathbb{R}^{2d}\to\mathbb{R}$ be a smooth Hamiltonian satisfying, for all $\alpha\in\mathbb{N}^{2d}$:*

$$\left|\partial^\alpha H(z)\right|\leqslant C_\alpha\langle x\rangle^{m_\alpha},\quad \textit{where } m_\alpha>0,\quad C_\alpha>0. \tag{A9}$$

Let $\alpha\in\mathbb{R}^{2d}$ be such that the solution with initial condition α of the system $\dot{z}_t=J\nabla H(z_t)$ is defined for $t\in\,]-T,T[$. We denote by $U_h(t):=e^{-i(t/h)H}$ the quantum propagator.

Then, $\forall M\in\mathbb{N}$, $\exists C_{M,T}(\alpha)>0$, independent of h and of $t\in[-T,T]$ such that

$$\left\| U_h(t)\varphi_\alpha-e^{i[(t,\alpha)/h]}\mathcal{T}_h(\alpha_t)\Lambda_h\left[\sum_{j=0}^{M}h^{i/2}b_j(t,\alpha)(x)\cdot e^{(i/2)\langle M_0x,x\rangle}\right]\right\|_{L^2(\mathbb{R}^d)}\leqslant C_{M,T}(\alpha)\cdot h^{(M+1)/2},$$

where $M_0:=(C+iD)(A+iB)^{-1}$, for all $t\in\,]-T,T[$, $b_j(t,\alpha):\mathbb{R}^d\to\mathbb{C}$ is a polynomial independent of h, with degree lower than $3j$, with same parity as j, and smoothly dependent on (t,α). In particular, $b_0(t,\alpha)(x)=\pi^{-d/4}(\det(A+iB))_c^{-1/2}$. Moreover, if the solutions of the Hamiltonian classical system are defined on $[-T,T]$ for initial conditions α in a compact K, then $\alpha\mapsto C_{M,T}(\alpha)$ is upper bounded on K by $\widetilde{C}_{M,T,K}$ independent of $\alpha\in K$.

(Received 31 December 2005; accepted 14 February 2006; published online 10 April 2006)

We prove reverse hypercontractivity inequalities as well as reverse log-Sobolev inequalities in the context of a space of holomorphic functions, which is called the μ-deformed Segal-Bargmann space and arises in the works of Wigner, Rosenblum, and Marron. To achieve this we define μ-deformations of energy and entropy. Our principle results generalize earlier works of Carlen and Sontz. We also show that the semigroup of this theory is L^p bounded, and we conjecture that it is L^p contractive and, even more strongly, that it is hypercontractive. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2186257]

I. INTRODUCTION

Wigner in the very title of his article[29] asked: "Do the equations of motion determine the quantum mechanical commutation relations?" In response to his own question, Wigner gave in that article a parametrized family of inequivalent representations by operators of the equations of motion with the property that the quantum mechanical (i.e., canonical) commutation relation does not hold in those representations for nonzero values of the parameter, which we will denote by μ. Rosenblum in Ref. 20 has extensively studied these representations, which act in an L^2 space of the configuration space and generalize the study of the harmonic oscillator in one dimension in quantum mechanics.

Then in Ref. 14 Marron, a student of Rosenblum, presented in detail a family of Hilbert spaces of holomorphic functions parametrized by the same parameter μ and which carry representations unitarily equivalent to those of Wigner mentioned above. We call these the μ-deformed Segal-Bargmann spaces. These holomorphic Hilbert spaces are proper closed subspaces of an L^2 space associated with the phase space. However, a brief description of these spaces also appears more or less simultaneously in Ref. 21, an unpublished work of Rosenblum. See also Refs. 15 and 17 for earlier related work.

For $\mu=0$, one recovers the usual Segal-Bargmann space. (See Refs. 2 and 22.) In this, the usual context of quantum mechanics, one constructs a number operator N (which is essentially the Hamiltonian of the harmonic oscillator) and its associated contraction semigroup e^{-tN} for $t\geqslant 0$, defined by spectral theory. In this case one finds the following inequalities, called *complex hypercontractivity* or sometimes, more simply, *hypercontractivity*. This says that for $0<p\leqslant q$, $q\leqslant pe^{2t}$ and $f\in\mathcal{B}_0^p$ the operator e^{-tN} satisfies

$$\|e^{-tN}f\|_q \leqslant \|f\|_p$$

and that e^{-tN} is not bounded from $\mathcal{B}_0^p$ to $\mathcal{B}_0^q$ for $q>pe^{2t}$. (Here $\mathcal{B}_0^p$ and $\mathcal{B}_0^q$ are spaces of holomorphic functions, which we will define later. $\mathcal{B}_0^p$ is a subspace of an L^p space and is equipped with its

b)Research partially supported by Grants Nos. 32146-E and P-42227-F, CONACyT (Mexico). Electronic mail: sontz@cimat.mx

norm $\|\cdot\|_p$.) This result is first due to Janson in Ref. 11. Other proofs have been given by Carlen in Ref. 4, Zhou in Ref. 30, Janson in Ref. 12 and Gross in Ref. 9. In the real variable case, Nelson in Ref. 16 has a similar, though not identical, result. It is the work of Nelson that initiated interest in hypercontractivity.

Moreover, Carlen in Ref. 4 obtained another related result, known as *reverse hypercontractivity*. This says that for $0<q<p$, $q<pe^{2t}$, and $f\in\mathcal{B}_0^p$ we have that

$$\|e^{-tN}f\|_q \leqslant C(t,p,q)\|f\|_p,$$

where $C(t,p,q)$ is a finite positive constant. For a discussion about the unknown optimal value of this constant, see Ref. 6. We note that hypercontractivity says that the operator e^{-tN} maps $\mathcal{B}_0^p$ to $\mathcal{B}_0^q$ contractively for $q\geqslant p$ for certain positive values of t. However, reverse hypercontractivity says that the operator e^{-tN} maps $\mathcal{B}_0^p$ to $\mathcal{B}_0^q$ boundedly for $q<p$ for certain values of t, including some negative values. This indicates in what sense the second result is the reverse of the first result. (We will define e^{-tN} for all $t<0$ later on.)

In the context of real variable theory Gross studied in Ref. 8 an inequality known as the *log-Sobolev inequality*. In the case of complex variable theory this says that for all holomorphic functions f in an appropriate space (which is $\mathcal{B}_0^2$ and which will be defined later) we have that

$$S_{\mathcal{B}_0^2}(f) \leqslant \langle f,Nf\rangle,$$

where the entropy $S_{\mathcal{B}_0^2}(f)$ of f will also be defined later on. The term $\langle f,Nf\rangle$ is known as the energy of f.

The second author in Ref. 25 proved an inequality that is known as a *reverse log-Sobolev inequality*. Specifically, this says that for every $c>1$ there exists a number $K(c)>0$ such that

$$\langle f,Nf\rangle \leqslant cS_{\mathcal{B}_0^2}(f) + K(c)\|f\|_2^2$$

for all $f\in\mathcal{B}_0^2$. Note that there is an interchange in the roles of the entropy and the energy in these two types of inequality. The log-Sobolev inequality tells us that finite energy implies finite entropy, while the reverse log-Sobolev inequality tells us precisely the converse.

This paper is a continuation of the works previously mentioned in that we prove reverse hypercontractivity (originally studied by Carlen in Ref. 4) and reverse log-Sobolev inequalities (originally studied by the second author in Ref. 25), but now we do this in the context of the μ-deformed holomorphic function spaces introduced by Rosenblum[21] and Marron[14] in their studies of the works of Rosenblum[20] and Wigner.[29] See Ref. 5 for a study of these reverse inequalities in the context of complex manifolds without μ-deformation. For further studies of μ-deformed Segal-Bargmann analysis, see Refs. 1, 18, and 27.

For the undeformed case $\mu=0$ the relation between log-Sobolev inequalities and hypercontractivity inequalities has been studied extensively, beginning with Ref. 8. Loosely speaking, either one implies the other. Of course, they both involve the number operator N. A similar relation for the case $\mu=0$ between a reverse log-Sobolev inequality and reverse hypercontractivity is to be expected, since again they are both based on the same operator N. But this does not work out as one might wish. (See Ref. 25.) The μ-deformed inequalities are defined in terms of the same μ-deformed number operator (defined later), but as far as we know there is no straightforward relation between the two reverse inequalities. We present them together in this paper, since in a more general approach to deformations of quantum mechanics we would hope to see some underlying connection between them.

An outline of the paper is as follows. In Sec. II we introduce the basic notation and definitions used throughout. In Sec. III we define the basic operators of this theory, namely the μ-deformed number operator N_μ and its associated semigroup e^{-tN_μ}. Then we enter the principle part of the paper in Sec. IV where we discuss reverse hypercontractivity as well as the L^p boundedness of the semigroup. We continue in Sec. V with reverse log-Sobolev inequalities, where we also define μ-deformations of energy and entropy. Then in an Appendix we discuss the relation between the

energy of the μ-deformed harmonic oscillator (described there) and the μ-deformed energy introduced in this paper. Finally, we conclude with a discussion of some problems that remain open.

II. NOTATION AND DEFINITIONS

Let $\mathcal{H}(\mathbb{C})$ denote the space of holomorphic functions $\psi:\mathbb{C}\to\mathbb{C}$, where $\mathbb{C}$ is the field of complex numbers. We also denote by $\mathcal{H}_e(\mathbb{C})$ and $\mathcal{H}_o(\mathbb{C})$ the subspaces of $\mathcal{H}(\mathbb{C})$ of even and odd functions, respectively. We note that $\mathcal{H}(\mathbb{C})=\mathcal{H}_e(\mathbb{C})\oplus\mathcal{H}_o(\mathbb{C})$, where $\oplus$ is the internal direct sum. This is a consequence of the fact that any $\psi\in\mathcal{H}(\mathbb{C})$ can be uniquely written as a sum of an even and an odd function, namely of its even part (notation, ψ_e) and of its odd part (notation, ψ_o). We use this notation throughout without further comment. We also note that μ will always denote a real parameter satisfying $-1/2<\mu<\infty$. One can find an explanation in Ref. 20 of why the region $\mu\leqslant -1/2$ is excluded from this analysis.

We now define the three basic scales of spaces which we will work with in this paper. But before doing so, we comment that we use the usual notation $L^p(\Omega,\nu)$ for the vector space of pth power absolutely integrable functions defined on a measure space Ω with measure ν as well as $\|f\|_p := \|f\|_{L^p(\Omega,\nu)} := (\int_\Omega |f|^p \mathrm{d}\nu)^{1/p}$. We will consider this for $0<p<\infty$. For any $r>1$ we define its *dual index* by $r' := r/(r-1)$.

Definition 2.1: For $0<p<\infty$ we define

$$\mathcal{B}^p_\mu := \{\psi\in\mathcal{H}(\mathbb{C}):\psi_e\in L^p(\mathbb{C},\nu_{e,\mu}),\ \psi_o\in L^p(\mathbb{C},\nu_{o,\mu})\},$$

$$P^p_\mu := \mathcal{H}_e(\mathbb{C})\cap L^p(\mathbb{C},\nu_{e,\mu}) = \mathcal{H}_e(\mathbb{C})\cap\mathcal{B}^p_\mu,$$

$$I^p_\mu := \mathcal{H}_o(\mathbb{C})\cap L^p(\mathbb{C},\nu_{o,\mu}) = \mathcal{H}_o(\mathbb{C})\cap\mathcal{B}^p_\mu.$$

Here

$$\mathrm{d}\nu_{e,\mu}(z) := \kappa_\mu K_{\mu-(1/2)}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y$$

is a probability measure on $\mathbb{C}$,

$$\mathrm{d}\nu_{o,\mu}(z) := \kappa_\mu K_{\mu+(1/2)}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y$$

is a finite measure on $\mathbb{C}$, $\kappa_\mu := 2^{1/2-\mu}/(\pi\Gamma(\mu+1/2))$ *is introduced to simplify notation,* $\Gamma(z)$ *is the Euler gamma function and* $K_\alpha(z)$ *is the Macdonald function of order* α. (*See Ref. 7 or Ref. 13 for information on these special functions.) Finally,* $z\in\mathbb{C}$ *and* $\mathrm{d}x\,\mathrm{d}y$ *is Lebesgue measure on* $\mathbb{C}$.

Proofs that $\mathrm{d}\nu_{e,\mu}$ is a probability measure and that $\mathrm{d}\nu_{o,\mu}$ is a finite measure are given in Refs. 1 and 18. Actually, in Ref. 1 it is shown that $\mathrm{d}\nu_{o,\mu}$ is *not* a probability measure when $\mu\neq 0$. The Macdonald function of order α is characterized by the integral formula

$$K_\alpha(z) = \int_0^\infty e^{-z\cosh u}\cosh(\alpha u)\mathrm{d}u$$

for $\mathrm{Re}(z)>0$ and arbitrary $\alpha\in\mathbb{C}$. This can be found in Lebedev[13] (p. 119), for example. From this integral representation it follows that $K_\alpha(x)>0$ for $x>0$ and that K_α is a monotone decreasing function on $(0,\infty)$. In particular, K_α has no zeros in $(0,\infty)$. A more general definition and discussion of the basic properties of the Macdonald function is given in Refs. 13 and 28. An explanation of how the Macdonald function arises naturally in the context of μ-deformed Segal-Bargmann analysis is given in Ref. 27.

We will be interested in the Macdonald function $K_\alpha(z)$ in the case when z is real and positive and α is real. The asymptotic behavior of the Macdonald function $K_\alpha(x)$ for $x>0$ when $x\to 0^+$ and when $x\to+\infty$ is given as follows. (See Ref. 13, pp. 110 and 136.)

$$K_\alpha(x) \approx \frac{2^{|\alpha|-1}\Gamma(|\alpha|)}{x^{|\alpha|}}, \quad x \to 0^+, \quad \alpha \neq 0, \tag{2.1}$$

$$K_0(x) \approx \log \frac{2}{x}, \quad x \to 0^+, \tag{2.2}$$

$$K_\alpha(x) \approx \left(\frac{\pi}{2x}\right)^{1/2} e^{-x}, \quad x \to +\infty, \quad \text{for all} \quad \alpha \in \mathbb{R}. \tag{2.3}$$

Here we use the standard notation $f(x) \approx g(x)$ when $x \to a$ [and say that $f(x)$ and $g(x)$ are asymptotic when $x \to a$] provided that $\lim_{x\to a} f(x)/g(x) = 1$. Another useful result says that for real α, β satisfying $\beta > |\alpha|$ we have that

$$\int_0^\infty K_\alpha(s) s^{\beta-1}\, \mathrm{d}s = 2^{\beta-2}\Gamma\left(\frac{\beta-\alpha}{2}\right)\Gamma\left(\frac{\beta+\alpha}{2}\right). \tag{2.4}$$

See Eq. (8) on p. 388 in Ref. 28 or Eq. 6.561.16 in Ref. 7.

Definition 2.2: For $\psi \in \mathcal{B}^p_\mu$ and $p > 0$ we define

$$\|\psi\|_{\mathcal{B}^p_\mu} := (\|\psi_e\|^p_{P^p_\mu} + \|\psi_o\|^p_{I^p_\mu})^{1/p},$$

where

$$\|\psi_e\|_{P^p_\mu} := \left(\int_{\mathbb{C}} |\psi_e|^p \, \mathrm{d}\nu_{e,\mu}\right)^{1/p} = \|\psi_e\|_{L^p(\mathbb{C},\nu_{e,\mu})}$$

and

$$\|\psi_o\|_{I^p_\mu} := \left(\int_{\mathbb{C}} |\psi_o|^p \, \mathrm{d}\nu_{o,\mu}\right)^{1/p} = \|\psi_o\|_{L^p(\mathbb{C},\nu_{o,\mu})}.$$

An immediate consequence of these definitions is that these spaces are in fact Banach spaces when they should be, namely, when $p \geqslant 1$. We also include the case $0 < p < 1$ as is usual in the study of holomorphic spaces. Explicitly, we have the following.

Proposition 2.1: If $p \geqslant 1$, then $\|\cdot\|_{\mathcal{B}^p_\mu}$ is a norm and $\mathcal{B}^p_\mu$ equipped with this norm is a Banach space.

Since we will not use this result, we only comment on its proof. First, $\|\cdot\|_{\mathcal{B}^p_\mu}$ is clearly a norm when $p \geqslant 1$. To show that the space is complete in this case, we can adapt an argument for the case $p=2$ and $\mu=0$ from Hall.[10] This identifies $\mathcal{B}^p_\mu$ as a closed subspace of the Banach space $L^p(\mathbb{C}, \nu_{e,\mu}) \oplus L^p(\mathbb{C}, \nu_{o,\mu})$, where $\oplus$ is the external direct sum, and thereby shows $\mathcal{B}^p_\mu$ to be complete. See Ref. 1 for a detailed proof of this result.

Note that for $p=2$ the Banach space $\mathcal{B}^2_\mu$ is actually a Hilbert space with inner product defined by

$$\langle \psi, \phi \rangle_{\mathcal{B}^2_\mu} := \langle \psi_e, \phi_e \rangle_{P^2_\mu} + \langle \psi_o, \phi_o \rangle_{I^2_\mu}.$$

We call this the *μ-deformed Segal-Bargmann space*; it appears in Refs. 14 and 21. When we set $\mu=0$ (as well as $p=2$) we obtain the usual Segal-Bargmann space introduced by Segal[22] and Bargmann.[2]

We warn the reader that in the case $\mu=0$ while the spaces $\mathcal{B}^p_\mu$ are equal to the spaces in Refs. 4 and 25, the norms we have defined are not identical when $p \neq 2$ to the norms used by those authors. However, they are equivalent norms. Since these comments have no bearing on the rest of this paper, we leave their elementary proof to the interested reader.

Definition 2.3: Let (X,ω) *be a finite measure space, that is,* $0<\omega(X)<\infty$. *We define the entropy of any* $f\in L^2(X,\omega)$ *by*

$$S_{L^2(X,\omega)}(f) := \int_X |f(x)|^2 \log|f(x)|^2 \, d\omega(x) - \|f\|_2^2 \log\|f\|_2^2.$$

Here, and in the following, we let log denote the natural logarithm (base e) and set $0\log 0 := 0$. This definition of entropy is due to Shannon in Ref. 23. An application of Jensen's inequality shows that

$$S_{L^2(X,\omega)}(f) \geqslant (-\log \omega(X))\|f\|^2_{L^2(X,\omega)} > -\infty.$$

However, note that $S_{L^2(X,\omega)}(f)=+\infty$ is not excluded. If $f\in\mathcal{H}$, where $\mathcal{H}$ is some closed subspace of $L^2(X,\omega)$ under consideration, we write $S_{\mathcal{H}}(f)$ for this entropy. The first use of Shannon entropy in Segal-Bargmann analysis appears in Ref. 24.

As is usual in analysis, we indifferently use the symbol C for a positive, finite constant whose value can change with each occurrence.

III. THE BASIC OPERATORS

In this section we will define the μ-deformed number operator N_μ and its associated semigroup e^{-tN_μ} in the context of the μ-deformed Segal-Bargmann space $\mathcal{B}^2_\mu$. Our objective is to extend this definition to $\mathcal{H}(C)$. (See Definition 3.5.)

We will start with the following definition, which comes from Rosenblum,[20] p. 372, in order to define later on the canonical orthonormal basis of $\mathcal{B}^2_\mu$.

Definition 3.1: The μ-deformed factorial $\gamma_\mu(n)$ *is defined recursively for integers* $n\geqslant 0$ *by* $\gamma_\mu(0) := 1$ *and by*

$$\gamma_\mu(n) := (n+2\mu\theta_n)\gamma_\mu(n-1) \quad \text{for } n\geqslant 1.$$

Here θ_n *is the characteristic function of the odd integers, that is,* $\theta_n=1$ *if* n *is odd and* $\theta_n=0$ *if* n *is even.*

Note that the standing hypothesis $\mu>-1/2$ implies that $\gamma_\mu(n)>0$. We note that

$$\gamma_\mu(2j) = \frac{2^{2j}\Gamma(j+1)\Gamma(\mu+j+1/2)}{\Gamma(\mu+1/2)} \tag{3.1}$$

and

$$\gamma_\mu(2j+1) = \frac{2^{2j+1}\Gamma(j+1)\Gamma(j+\mu+3/2)}{\Gamma(\mu+1/2)}, \tag{3.2}$$

which can be found in Ref. 20 and are easily checked by induction.

For each integer $n\geqslant 0$ we define the function Ψ^μ_n (actually, holomorphic monomial) by

$$\Psi^\mu_n(z) := \frac{z^n}{(\gamma_\mu(n))^{1/2}}$$

for all $z\in\mathbb{C}$. By direct evaluation of the integrals, using (2.4), (3.1), and (3.2), we have that $\|\Psi^\mu_n\|_{\mathcal{B}^2_\mu}=1$ for all integers $n\geqslant 0$. Next, $\langle\Psi^\mu_n,\Psi^\mu_m\rangle=0$ for $n\neq m$ is quite straightforward. Finally, the set of all these functions forms an orthonormal basis of $\mathcal{B}^2_\mu$ by an argument that closely parallels the proof in Ref. 2 for the case $\mu=0$.

We denote by $\mathcal{D}^2_\mu$ the dense subspace of $\mathcal{B}^2_\mu$ consisting of all finite linear combinations of the Ψ^μ_n. Clearly, $\mathcal{D}^2_\mu$ is the space of all holomorphic polynomials in z.

The following definition is based on formulas in Ref. 20, p. 381.

Definition 3.2: We define the μ-deformed annihilation operator A_μ *as well as the* μ-deformed

creation operator $A_\mu^\star$, *both with domain of definition equal to* $\mathcal{D}_\mu^2$, *by setting for* $n \geqslant 0$,

$$A_\mu \Psi_n^\mu := (n + 2\mu\theta_n)^{1/2} \Psi_{n-1}^\mu,$$

$$A_\mu^\star \Psi_n^\mu := (n + 1 + 2\mu\theta_{n+1})^{1/2} \Psi_{n+1}^\mu,$$

where $\Psi_{-1}^\mu \equiv 0$, *and then extending linearly to all of* $\mathcal{D}_\mu^2$.

The next proposition can be found in Ref. 20, p. 381, though in the context of a different Hilbert space. Since the proof is identical and we will not be needing it, we merely state the result without proving it. The point of this proposition is that the μ-deformed canonical commutation relation, originally given by Wigner in Ref. 29, holds here. (Also see Refs. 14 and 20.) But first, we define the *parity operator* J acting in $\mathcal{B}_\mu^2$ by $J\psi(z) := \psi(-z)$ for all $\psi \in \mathcal{B}_\mu^2$ and all $z \in \mathbb{C}$.

Proposition 3.1: Considered as operators defined with the common domain $\mathcal{D}_\mu^2$ *we have the* μ-deformed canonical commutation relation

$$[A_\mu, A_\mu^\star] = I + 2\mu J \quad \text{or, equivalently,} \quad i[\widetilde{P}_\mu, \widetilde{Q}_\mu] = I + 2\mu J,$$

where $\widetilde{Q}_\mu := 2^{-1/2}(A_\mu + A_\mu^\star)$ *is the definition of the* μ-deformed position operator, $\widetilde{P}_\mu := -i2^{-1/2}(A_\mu - A_\mu^\star)$ *is the definition of the* μ-deformed momentum operator, I *is the identity operator and* J *is the parity operator*.

Note that $\mathcal{D}_\mu^2$ is invariant under the actions of all of A_μ, $A_\mu^\star$, $\widetilde{P}_\mu$, and $\widetilde{Q}_\mu$ so that the commutators are well defined as operators acting on $\mathcal{D}_\mu^2$. Of course, we are using the usual definition $[S,T] := ST - TS$ of the *commutator* of two operators S and T.

We would merely like to note here that the presence of the parity operator J at this basic level of the theory indicates how it comes about that the various function spaces of this theory are defined in terms of the even and odd parts of the functions, which are simply the eigenfunctions of J. More comments about this appear in Ref. 27.

The following definition also is based on Ref. 20 (p. 392), though again in the context of another Hilbert space.

Definition 3.3: We define the μ-deformed number operator N_μ *with domain* $\mathcal{D}_\mu^2$ *by* $N_\mu := A_\mu^\star A_\mu$.

Here the invariance of $\mathcal{D}_\mu^2$ under the action of A_μ tells us that N_μ is well defined. We immediately have for $n \geqslant 0$ that

$$N_\mu \Psi_n^\mu = A_\mu^\star A_\mu \Psi_n^\mu = A_\mu^\star((n + 2\mu\theta_n)^{1/2} \Psi_{n-1}^\mu) = (n + 2\mu\theta_n)\Psi_n^\mu. \tag{3.3}$$

Since the orthonormal basis Ψ_n^μ diagonalizes N_μ, we can use that basis to define functions of N_μ. In particular, this motivates the next definition.

Definition 3.4: For every $t \geqslant 0$, *we define a linear operator* $e^{-tN_\mu}: \mathcal{B}_\mu^2 \to \mathcal{B}_\mu^2$ *as follows. First, we define the operator in the domain* $\mathcal{D}_\mu^2$ *by setting*

$$e^{-tN_\mu} \Psi_n^\mu := e^{-t(n+2\mu\theta_n)} \Psi_n^\mu$$

for every integer $n \geqslant 0$ *and then extending linearly to* $\mathcal{D}_\mu^2$. *Then we can show that* $\|e^{-tN_\mu}\Psi\|_{\mathcal{B}_\mu^2} \leqslant \|\Psi\|_{\mathcal{B}_\mu^2}$ *holds for every* $t \geqslant 0$ *and* $\Psi \in \mathcal{D}_\mu^2$. *Finally, this implies that there is a unique linear extension (still denoted by* e^{-tN_μ}*) to the closure of* $\mathcal{D}_\mu^2$, *namely to* $\mathcal{B}_\mu^2$, *with the same operator norm*.

Let us remark that this definition is what the functional calculus of an unbounded self-adjoint operator also gives. We first note that N_μ with domain $\mathrm{Dom}(N_\mu) = \mathcal{D}_\mu^2$ is a symmetric operator, since the eigenvalues in (3.3) are real. Another straightforward consequence of (3.3) is that each $\Psi_n^\mu \in \mathrm{Ran}(N_\mu \pm i)$, which implies that $\mathrm{Ran}(N_\mu \pm i)$ are dense subspaces in $\mathcal{B}_\mu^2$. So basic functional analysis (Ref. 19, p. 257) tells us that N_μ is essentially self-adjoint. Therefore the functional calculus allows us to evaluate $f_t(\lambda) = e^{-t\lambda}$, where $\lambda \in \mathbb{R}$ and $t \geqslant 0$, on the unique self-adjoint extension $\bar{N}_\mu$ of N_μ. (First, one identifies the spectrum σ of $\bar{N}_\mu$ in order to verify that f_t is bounded

on σ.) By the spectral mapping theorem this bounded operator $f_t(\bar{N}_\mu)$ agrees on the basis elements Ψ_n^μ with the bounded operator e^{-tN_μ} defined above, and so is the same operator acting on $\mathcal{B}_\mu^2$. Alternatively, one can construct $\bar{N}_\mu$ as the Friedrichs extension of N_μ.

The statement and proof of the next proposition are adaptations to this context of a result given by Bargmann in Ref. 2. We present this in detail since we will use this result.

Proposition 3.2: Let $\psi \in \mathcal{H}(\mathbb{C})$ have Maclaurin series (i.e., Taylor series with center at $z=0$),

$$\psi(z) = \sum_{n=0}^{\infty} a_n \Psi_n^\mu(z)$$

written in terms of the monomials Ψ_n^μ. Then

$$\|\psi\|_{\mathcal{B}_\mu^2}^2 = \sum_{n=0}^{\infty} |a_n|^2.$$

In particular, $\psi \in \mathcal{B}_\mu^2$ if and only if $\Sigma_{n=0}^{\infty} |a_n|^2 < \infty$.

Proof: The result is given by the following computation, whose steps are justified afterwards:

$$\begin{aligned}
\|\psi\|_{\mathcal{B}_\mu^2}^2 &= \int_{\mathbb{C}} d\nu_{e,\mu}(z) |\psi_e(z)|^2 + \int_{\mathbb{C}} d\nu_{o,\mu}(z) |\psi_o(z)|^2 = \lim_{R\to\infty} \int_{|z|\le R} d\nu_{e,\mu}(z) \left| \sum_{k=0}^{\infty} a_{2k} \Psi_{2k}^\mu(z) \right|^2 \\
&+ \lim_{R\to\infty} \int_{|z|\le R} d\nu_{o,\mu}(z) \left| \sum_{l=0}^{\infty} a_{2l+1} \Psi_{2l+1}^\mu(z) \right|^2 = \lim_{R\to\infty} \sum_{k,k'=0}^{\infty} a_{2k}^* a_{2k'} \int_{|z|\le R} d\nu_{e,\mu}(z) \Psi_{2k}^\mu(z)^* \Psi_{2k'}^\mu(z) \\
&+ \lim_{R\to\infty} \sum_{l,l'=0}^{\infty} a_{2l+1}^* a_{2l'+1} \int_{|z|\le R} d\nu_{o,\mu}(z) \Psi_{2l+1}^\mu(z)^* \Psi_{2l'+1}^\mu(z) = \lim_{R\to\infty} \sum_{k=0}^{\infty} |a_{2k}|^2 \int_{|z|\le R} d\nu_{e,\mu}(z) \\
&\times |\Psi_{2k}^\mu(z)|^2 + \lim_{R\to\infty} \sum_{l=0}^{\infty} |a_{2l+1}|^2 \int_{|z|\le R} d\nu_{o,\mu}(z) |\Psi_{2l+1}^\mu(z)|^2 = \sum_{k=0}^{\infty} |a_{2k}|^2 \int_{\mathbb{C}} d\nu_{e,\mu}(z) |\Psi_{2k}^\mu(z)|^2 \\
&+ \sum_{l=0}^{\infty} |a_{2l+1}|^2 \int_{\mathbb{C}} d\nu_{o,\mu}(z) |\Psi_{2l+1}^\mu(z)|^2 = \sum_{k=0}^{\infty} |a_{2k}|^2 + \sum_{l=0}^{\infty} |a_{2l+1}|^2 = \sum_{n=0}^{\infty} |a_n|^2.
\end{aligned}$$

The first equality is the definition of the norm. The second equality is by monotone convergence and a simple substitution. The interchange of infinite sum and integral in the third equality is justified by the uniform convergence in the domain of integration. The fourth equality is due to the fact that the off-diagonal integrals vanish as a change of variables to polar coordinates shows. The fifth equality is monotone convergence, while the sixth uses the fact that the functions Ψ_n^μ are normalized. ■

Proposition 3.3: For every $\psi \in \mathcal{B}_\mu^2$ we have

$$e^{-tN_\mu} \psi(z) = \psi_e(e^{-t} z) + e^{-2\mu t} \psi_o(e^{-t} z), \tag{3.4}$$

where $t \ge 0$ and $z \in \mathbb{C}$.

Here $\psi = \psi_e + \psi_o$ is the decomposition of ψ into its even and odd parts.

Proof: We first note for all $n \ge 0$ and $t \ge 0$ that

$$e^{-tN_\mu} \Psi_n^\mu(z) = e^{-t(n+2\mu\theta_n)} \Psi_n^\mu(z) = e^{-t(n+2\mu\theta_n)} z^n / (\gamma_\mu(n))^{1/2} = e^{-2\mu t\theta_n} \Psi_n^\mu(e^{-t} z)$$

follows from the definitions of e^{-tN_μ} and Ψ_n^μ. This is exactly the identity (3.4) we wish to show in the special case when $\psi = \Psi_n^\mu$ for some $n \ge 0$. The rest of the argument consists of an extension of the result to all $\psi \in \mathcal{B}_\mu^2$.

So we let $\psi=\Sigma_{n=0}^{\infty}a_n\Psi_n^{\mu}$ be the Maclaurin series of $\psi\in\mathcal{B}_{\mu}^2$ as before. By the previous proposition we have that $\|\psi\|_{\mathcal{B}_{\mu}^2}^2=\Sigma_{n=0}^{\infty}|a_n|^2$. Since $\psi-\Sigma_{n=0}^{N}a_n\Psi_n^{\mu}=\Sigma_{n=N+1}^{\infty}a_n\Psi_n^{\mu}$ is an element in $\mathcal{B}_{\mu}^2$, the expressions in this computation are finite:

$$\left\|\psi-\sum_{n=0}^{N}a_n\Psi_n^{\mu}\right\|_{\mathcal{B}_{\mu}^2}^2=\left\|\sum_{n=N+1}^{\infty}a_n\Psi_n^{\mu}\right\|_{\mathcal{B}_{\mu}^2}^2=\sum_{n=N+1}^{\infty}|a_n|^2\to 0 \tag{3.5}$$

as $N\to\infty$. Here the second equality is the evaluation of the norm in $\mathcal{B}_{\mu}^2$ by using the previous proposition, but now applied to the function $\Sigma_{n=N+1}^{\infty}a_n\Psi_n^{\mu}\in\mathcal{B}_{\mu}^2$, which is a Maclaurin series. The convergence to zero in (3.5) follows from the fact that $\psi\in\mathcal{B}_{\mu}^2$ and the previous proposition. Therefore (3.5) says that the Maclaurin series $\Sigma_{n=0}^{\infty}a_n\Psi_n^{\mu}$, which is known by complex analysis to converge to ψ uniformly on compact subsets of $\mathbb{C}$, converges to ψ *also* in the norm topology of the Hilbert space $\mathcal{B}_{\mu}^2$. Using this second sense of the convergence of the Maclaurin series to ψ, we immediately see that

$$e^{-tN_{\mu}}\psi=\sum_{n=0}^{\infty}a_ne^{-tN_{\mu}}\Psi_n^{\mu}$$

since $e^{-tN_{\mu}}$ is a bounded operator on the Hilbert space $\mathcal{B}_{\mu}^2$. So we have that

$$\begin{aligned}e^{-tN_{\mu}}\psi(z)&=\sum_{n=0}^{\infty}a_ne^{-tN_{\mu}}\Psi_n^{\mu}(z)=\sum_{n=0}^{\infty}a_ne^{-2\mu t\theta_n}\Psi_n^{\mu}(e^{-t}z)=\sum_{k=0}^{\infty}a_{2k}\Psi_{2k}^{\mu}(e^{-t}z)+\sum_{l=0}^{\infty}a_{2l+1}e^{-2\mu t}\Psi_{2l+1}^{\mu}(e^{-t}z)\\&=\psi_e(e^{-t}z)+e^{-2\mu t}\psi_o(e^{-t}z)\end{aligned}$$

as desired. Here we used the fact that the even (respectively, odd) terms of the Maclaurin series give us the even (respectively, odd) part of the function. ■

Now we extend the definition of $e^{-tN_{\mu}}$, using the previous proposition as our guide.

Definition 3.5: We define $e^{-tN_{\mu}}:\mathcal{H}(\mathbb{C})\to\mathcal{H}(\mathbb{C})$ *by*

$$e^{-tN_{\mu}}\psi(z):=\psi_e(e^{-t}z)+e^{-2\mu t}\psi_o(e^{-t}z), \tag{3.6}$$

where $\psi\in\mathcal{H}(\mathbb{C})$, $z\in\mathbb{C}$, *and* $t\in R$.

Several comments are in order here. First, the previous definition defines the linear operator $e^{-tN_{\mu}}$ with domain given by any of the spaces P_{μ}^p, I_{μ}^p, and $\mathcal{B}_{\mu}^p$ for $0<p<\infty$, and this is what interests us in this paper. By the previous proposition, this generalizes the definition of $e^{-tN_{\mu}}$ for $t\geqslant 0$ given on $\mathcal{B}_{\mu}^2$ in two ways, namely to a larger space and to *all* values $t\in\mathbb{R}$. Actually, the definition also makes sense for all $t\in\mathbb{C}$.

The operator $e^{-tN_{\mu}}$ defined above maps $\mathcal{H}(\mathbb{C})$ to itself continuously (with respect to the topology of uniform convergence on compact subsets) as well as leaving invariant the subspaces $\mathcal{H}_e(\mathbb{C})$ and $\mathcal{H}_o(\mathbb{C})$. The action of $e^{-tN_{\mu}}$ on $\mathcal{H}_e(\mathbb{C})$ is induced exactly by the flow $z\mapsto e^{-t}z$ on $\mathbb{C}$, which is independent of μ. Moreover, on $\mathcal{H}_o(\mathbb{C})$ it is almost induced by the same flow, except that a constant multiplier (depending on μ as well as on t) also appears. Another immediate consequence of the definition is that $e^{-tN_{\mu}}$ for $t\in\mathbb{R}$ is a group of operators acting on $\mathcal{H}(\mathbb{C})$.

Also, let us note that this definition makes sense for *any* function ψ, not just for holomorphic functions. However, in that generality the connection with the operator N_{μ} is obscured. In particular, the proof of Proposition 3.3 depends on the representation of an entire holomorphic function by its Maclaurin series, and the action term by term of $e^{-tN_{\mu}}$ on that series. Another way to understand this is to note that the action of $e^{-tN_{\mu}}$ on the holomorphic polynomials is the starting point of its definition and that these polynomials are dense in $\mathcal{H}(\mathbb{C})$ in its topology of uniform convergence on compact sets. So the extension of the domain of definition of $e^{-tN_{\mu}}$ to $\mathcal{H}(\mathbb{C})$ as given is more or less immediate, while its extension to larger spaces of functions is rather arbitrary.

IV. REVERSE HYPERCONTRACTIVITY

In this section our main goal is to prove reverse hypercontractivity inequalities on the scale of spaces $\mathcal{B}_\mu^p$ for $0<p<\infty$. In order to achieve this goal we will first prove such reverse hypercontractivity inequalities for the even and odd subspaces of $\mathcal{B}_\mu^p$, namely P_μ^p and I_μ^p. This is a technical consideration due to the fact that the definitions of $\mathcal{B}_\mu^p$ and its norm depend on the decomposition of a function into its even and odd parts. And this, as we have noted, comes about from the role that the parity operator plays in this theory.

So, we will prove reverse hypercontractivity inequalities on three scales of spaces: P_μ^p, I_μ^p, and $\mathcal{B}_\mu^p$ where $0<p<\infty$. Specifically, this means we will restrict the action of e^{-tN_μ} for $t\in\mathbb{R}$ to one of these spaces and will ask if the result is a bounded linear map to another one of these spaces indexed by $q<p$. (It need not be a contraction, as is the case in hypercontractivity.) Since e^{-tN_μ} preserves parity and holomorphicity, the problem reduces to finding $q<p$ and $C>0$ for a given value of p such that $\|e^{-tN_\mu}f\|_q\leq C\|f\|_p$ for all f in one of the spaces P_μ^p, I_μ^p or $\mathcal{B}_\mu^p$.

For all the results of this section we use the hypotheses $0<q<p$ and $(1/2)\log(q/p)<t$. We note that they do not depend on the parameter μ. In other words, they are the same hypotheses that appear in the work of Carlen in Ref. 4 on reverse hypercontractivity in the case $\mu=0$. Also, we note that under these hypotheses t can be a negative number.

The method we use originally appeared in Ref. 6 and is also used in Ref. 5.

Theorem 4.1 *(Reverse hypercontractivity for the scale of spaces P_μ^p, $0<p<\infty$):* *For $0<q<p$ and $(1/2)\log(q/p)<t$ we have*

$$\|e^{-tN_\mu}\psi_e\|_{P_\mu^q}\leq A(t,p,q,\mu)\|\psi_e\|_{P_\mu^p} \tag{4.1}$$

for all $\psi_e\in P_\mu^p$, where

$$A(t,p,q,\mu):=e^{(2\mu+3)t/q}\left\{\int_{\mathbb{C}}\left|\frac{K_{\mu-(1/2)}(e^{2t}|w|^2)}{K_{\mu-(1/2)}(|w|^2)}\right|^{p/(p-q)}\mathrm{d}\nu_{e,\mu}(w)\right\}^{(p-q)/pq}<\infty.$$

Remark: Since any $\psi\in P_\mu^p$ is even, $\psi=\psi_e$ holds. So we use the notation ψ_e to denote an arbitrary element in P_μ^p. Similarly, we use ψ_o to denote an arbitrary element in I_μ^p.

Proof: We calculate

$$\begin{aligned}
\|e^{-tN_\mu}\psi_e\|_{P_\mu^q}^q &= \int_{\mathbb{C}}|e^{-tN_\mu}\psi_e(z)|^q\,\mathrm{d}\nu_{e,\mu}(z)=\int_{\mathbb{C}}|\psi_e(e^{-t}z)|^q\kappa_\mu K_{\mu-(1/2)}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y\\
&=\int_{\mathbb{C}}|\psi_e(w)|^q\kappa_\mu K_{\mu-(1/2)}(e^{2t}|w|^2)e^{(2\mu+1)t}|w|^{2\mu+1}e^{2t}\,\mathrm{d}u\,\mathrm{d}v\\
&=e^{(2\mu+3)t}\int_{\mathbb{C}}|\psi_e(w)|^q\frac{K_{\mu-(1/2)}(e^{2t}|w|^2)}{K_{\mu-(1/2)}(|w|^2)}\kappa_\mu K_{\mu-(1/2)}(|w|^2)|w|^{2\mu+1}\,\mathrm{d}u\,\mathrm{d}v\\
&\leq e^{(2\mu+3)t}\||\psi_e|^q\|_{P_\mu^r}\left\{\int_{\mathbb{C}}\left|\frac{K_{\mu-(1/2)}(e^{2t}|w|^2)}{K_{\mu-(1/2)}(|w|^2)}\right|^{r'}\kappa_\mu K_{\mu-(1/2)}(|w|^2)|w|^{2\mu+1}\,\mathrm{d}u\,\mathrm{d}v\right\}^{1/r'},
\end{aligned}$$

where we have used $K_{\mu-(1/2)}(|w|^2)>0$ for $w\neq 0$, $w=u+iv=e^{-t}z$ and Hölder's inequality for $1<r<\infty$. Taking $r=p/q>1$ [implying that its dual index is $r'=r/(r-1)=p/(p-q)$] and then evaluating the $1/q$ power, we obtain

$$\|e^{tN_\mu}\psi_e\|_{P_\mu^q}\leq e^{(2\mu+3)t/q}\|\psi_e\|_{P_\mu^p}\left\{\int_{\mathbb{C}}\left|\frac{K_{\mu-(1/2)}(e^{2t}|w|^2)}{K_{\mu-(1/2)}(|w|^2)}\right|^{p/(p-q)}\mathrm{d}\nu_{e,\mu}(w)\right\}^{(p-q)/pq}$$

which is the inequality (4.1). Next, to prove that $A(t,p,q,\mu)<\infty$, it is necessary and sufficient to show for $r=p/q$ that

$$\int_{\mathbb{C}} \left| \frac{K_{\mu-(1/2)}(e^{2t}|w|^2)}{K_{\mu-(1/2)}(|w|^2)} \right|^{r'} K_{\mu-(1/2)}(|w|^2)|w|^{2\mu+1}\, du\, dv = \pi \int_0^\infty \left| \frac{K_{\mu-(1/2)}(e^{2t}s)}{K_{\mu-(1/2)}(s)} \right|^{r'} K_{\mu-(1/2)}(s) s^{\mu+(1/2)}\, ds$$

is finite. And this is equivalent to proving the integrability of the integrand on the right-hand side near 0 and near ∞, since the integrand is a continuous function of $s \in (0,\infty)$. To show the integrability near 0, we use (2.1) which implies that for all $s \in (0,\delta)$ for $\delta > 0$ sufficiently small we have that

$$\left| \frac{K_{\mu-(1/2)}(e^{2t}s)}{K_{\mu-(1/2)}(s)} \right|^{r'} K_{\mu-(1/2)}(s) \leqslant \frac{C}{s^{|\mu-1/2|}},$$

provided that $\mu \neq 1/2$. When $\mu < 1/2$ this yields

$$\int_0^\delta \left| \frac{K_{\mu-(1/2)}(e^{2t}s)}{K_{\mu-(1/2)}(s)} \right|^{r'} K_{\mu-(1/2)}(s) s^{\mu+(1/2)}\, ds \leqslant \int_0^\delta \frac{C}{s^{(1/2)-\mu}} s^{\mu+(1/2)}\, ds = C \int_0^\delta s^{2\mu}\, ds < \infty,$$

using the standing hypothesis $\mu > -1/2$. And when $\mu > 1/2$ it gives us

$$\int_0^\delta \left| \frac{K_{\mu-(1/2)}(e^{2t}s)}{K_{\mu-(1/2)}(s)} \right|^{r'} K_{\mu-(1/2)}(s) s^{\mu+(1/2)}\, ds \leqslant \int_0^\delta \frac{C}{s^{\mu-(1/2)}} s^{\mu+(1/2)}\, ds = C \int_0^\delta s\, ds < \infty.$$

Finally, for $\mu = 1/2$ we take $s \in (0,\delta)$ where $\delta < 2$. We then use (2.2) to obtain that

$$\begin{aligned} \left| \frac{K_0(e^{2t}s)}{K_0(s)} \right|^{r'} K_0(s) &\leqslant C\left(\log \frac{2}{s}\right) \left(\frac{\log \dfrac{2}{e^{2t}s}}{\log \dfrac{2}{s}} \right)^{r'} \\ &= C\left(\log \frac{2}{s}\right) \left(\frac{\log 2/s - 2t}{\log \dfrac{2}{s}} \right)^{r'} \\ &= C\left(\log \frac{2}{s}\right) \left(1 - \frac{2t}{\log \dfrac{2}{s}} \right)^{r'} \leqslant C \log \frac{2}{s}. \end{aligned}$$

Here we used for $t \geqslant 0$ that $\log(2/s) > 0$ and $1 - 2t/\log(2/s) \leqslant 1$, while for $t < 0$ we used $1 - 2t/\log(2/s) < 2$ for δ sufficiently small. Then by elementary calculus we have

$$\int_0^\delta \left| \frac{K_0(e^{2t}s)}{K_0(s)} \right|^{r'} K_0(s) s\, ds \leqslant C \int_0^\delta s \log(2/s) ds < \infty.$$

To show the integrability near ∞ we use (2.3) to show that

$$\left| \frac{K_{\mu-(1/2)}(e^{2t}s)}{K_{\mu-(1/2)}(s)} \right|^{r'} K_{\mu-(1/2)}(s) \leqslant C \frac{1}{s^{1/2}} e^{-[1-r'(1-e^{2t})]s}$$

for all $s \in (M,\infty)$ for M sufficiently large. Then we get the estimate

$$\int_M^\infty \left| \frac{K_{\mu-(1/2)}(e^{2t}s)}{K_{\mu-(1/2)}(s)} \right|^{r'} K_{\mu-(1/2)}(s) s^{\mu+(1/2)}\, ds \leqslant C \int_M^\infty e^{-[1-r'(1-e^{2t})]s} s^{\mu}\, ds < \infty,$$

since $1-r'(1-e^{2t})>0$ is equivalent to the hypothesis $(1/2)\log(q/p)<t$ given that $r'=p/(p-q)$. ■

Remark: The previous theorem holds for all even functions in $L^p(\mathbb{C},\nu_{e,\mu})$, not just the holomorphic elements, provided that we use the definition in (3.6) for such functions. But, as we commented earlier, such a generalization of the theorem, even though it is true, has nothing to do really with the operator N_μ of interest here. However, we did use the fact that ψ_e is even in the step where we evaluated $e^{-tN_\mu}\psi_e(z)$. The previous theorem also holds with only a slightly modified proof for $0<q<p$ and complex t satisfying $(1/2)\log(q/p)<\mathrm{Re}(t)$. As we also noted before, formula (3.6) defines e^{-tN_μ} for any $t\in\mathbb{C}$. Similar comments hold for the next result, which is about the spaces I^p_μ, and for Theorem 4.3, which is about the spaces $\mathcal{B}^p_\mu$.

Theorem 4.2 *(Reverse hypercontractivity for the scale of spaces I^p_μ, $0<p<\infty$):* *For $0<q<p$ and $(1/2)\log(q/p)<t$ we have that*

$$\|e^{-tN_\mu}\psi_o\|_{I^q_\mu}\leqslant B(t,p,q,\mu)\|\psi_o\|_{I^p_\mu} \tag{4.2}$$

for all $\psi_o\in I^p_\mu$, where

$$B(t,p,q,\mu):=e^{\{[2\mu(1-q)+3]/q\}t}\left\{\int_{\mathbb{C}}\left|\frac{K_{\mu+(1/2)}(e^{2t}|w|^2)}{K_{\mu+(1/2)}(|w|^2)}\right|^{p/(p-q)}\mathrm{d}\nu_{o,\mu}(w)\right\}^{(p-q)/pq}<\infty.$$

Proof: We have that

$$\begin{aligned}\|e^{-tN_\mu}\psi_o\|^q_{I^q_\mu}&=\int_{\mathbb{C}}|e^{-tN_\mu}\psi_o(z)|^q\,\mathrm{d}\nu_{o,\mu}(z)=\int_{\mathbb{C}}|e^{-2\mu t}\psi_o(e^{-t}z)|^q\kappa_\mu K_{\mu+(1/2)}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y\\&=\int_{\mathbb{C}}e^{-2q\mu t}|\psi_o(w)|^q\kappa_\mu K_{\mu+(1/2)}(e^{2t}|w|^2)e^{(2\mu+1)t}|w|^{2\mu+1}e^{2t}\,\mathrm{d}u\,\mathrm{d}v\\&=e^{\{2\mu(1-q)+3\}t}\int_{\mathbb{C}}|\psi_o(w)|^q\frac{K_{\mu+(1/2)}(e^{2t}|w|^2)}{K_{\mu+(1/2)}(|w|^2)}\kappa_\mu K_{\mu+(1/2)}(|w|^2)|w|^{2\mu+1}\,\mathrm{d}u\,\mathrm{d}v\\&\leqslant e^{\{2\mu(1-q)+3\}t}\|\,|\psi_o|^q\|_{I^r_\mu}\left(\int_{\mathbb{C}}\left|\frac{K_{\mu+(1/2)}(e^{2t}|w|^2)}{K_{\mu+(1/2)}(|w|^2)}\right|^{r'}\kappa_\mu K_{\mu+(1/2)}(|w|^2)|w|^{2\mu+1}\,\mathrm{d}u\,\mathrm{d}v\right)^{1/r'},\end{aligned}$$

where we have used $K_{\mu+(1/2)}(|w|^2)>0$ for $w\neq 0$, $w=u+iv=e^{-t}z$ and Hölder's inequality for $1<r<\infty$. Taking $r=p/q>1$ and then raising to the $1/q$ power we obtain the desired estimate (4.2):

$$\|e^{-tN_\mu}\psi_o\|_{I^q_\mu}\leqslant e^{\{[2\mu(1-q)+3]/q\}t}\|\psi_o\|_{I^p_\mu}\left\{\int_{\mathbb{C}}\left|\frac{K_{\mu+(1/2)}(e^{2t}|w|^2)}{K_{\mu+(1/2)}(|w|^2)}\right|^{p/(p-q)}\mathrm{d}\nu_{o,\mu}(w)\right\}^{(p-q)/pq}.$$

To show that this bound is finite is equivalent to showing that

$$\int_{\mathbb{C}}\left|\frac{K_{\mu+(1/2)}(e^{2t}|w|^2)}{K_{\mu+(1/2)}(|w|^2)}\right|^{r'}K_{\mu+(1/2)}(|w|^2)|w|^{2\mu+1}\,\mathrm{d}u\,\mathrm{d}v=\pi\int_0^\infty\left|\frac{K_{\mu+(1/2)}(e^{2t}s)}{K_{\mu+(1/2)}(s)}\right|^{r'}K_{\mu+(1/2)}(s)s^{\mu+(1/2)}\,\mathrm{d}s$$

is finite, where $r=p/q$. As in the previous theorem, it is now a matter of checking that the integrand on the right-hand side is in fact integrable near 0 and near ∞. For $s\in(0,\delta)$ with δ sufficiently small we have that

$$\left| \frac{K_{\mu+(1/2)}(e^{2t}s)}{K_{\mu+(1/2)}(s)} \right|^{r'} K_{\mu+(1/2)}(s) \leqslant C \frac{1}{s^{\mu+(1/2)}},$$

where we have used (2.1) together with the standing hypothesis $\mu+(1/2)>0$. This gives the desired estimate,

$$\int_0^\delta \left| \frac{K_{\mu+(1/2)}(e^{2t}s)}{K_{\mu+(1/2)}(s)} \right|^{r'} K_{\mu+(1/2)}(s) s^{\mu+(1/2)} \, \mathrm{d}s \leqslant \int_0^\delta C \, \mathrm{d}s < \infty.$$

Next, for $s \in [M,\infty)$ with M sufficiently large we apply (2.3) to get

$$\left| \frac{K_{\mu+(1/2)}(e^{2t}s)}{K_{\mu+(1/2)}(s)} \right|^{r'} K_{\mu+(1/2)}(s) \leqslant C \frac{e^{-[1-r'(1-e^{2t})]s}}{s^{1/2}}.$$

Just as in the last estimate in the proof of Theorem 4.1, this then implies that

$$\int_M^\infty \left| \frac{K_{\mu+(1/2)}(e^{2t}s)}{K_{\mu+(1/2)}(s)} \right|^{r'} K_{\mu+(1/2)}(s) s^{\mu+(1/2)} \, \mathrm{d}s \leqslant C \int_M^\infty e^{-[1-r'(1-e^{2t})]s} s^{\mu} \, \mathrm{d}s < \infty,$$

where we have used the inequality $1-r'(1-e^{2t})>0$ which is equivalent to the hypothesis $(1/2)\log(q/p)<t$ together with the fact that $r'=p/(p-q)$. ■

Having shown reverse hypercontractivity for the two scales of spaces P_μ^p and I_μ^p, we now can quickly prove the main goal of this section.

Theorem 4.3 *(Reverse hypercontractivity for the scale of spaces $\mathcal{B}_\mu^p$, $0<p<\infty$):* *For $0<q<p$ and $(1/2)\log(q/p)<t$ we have that*

$$\|e^{-tN_\mu}\psi\|_{\mathcal{B}_\mu^q} \leqslant C(t,p,q,\mu)\|\psi\|_{\mathcal{B}_\mu^p}$$

for every $\psi \in \mathcal{B}_\mu^p$, where

$$C(t,p,q,\mu) := ([A(t,p,q,\mu)]^q + [B(t,p,q,\mu)]^q)^{1/q}$$

and $A(t,p,q,\mu)$ and $B(t,p,q,\mu)$ are defined in Theorems 4.1 and 4.2, respectively.

Proof: For brevity, we write A instead of $A(t,p,q,\mu)$ and so forth. Using the fact that e^{-tN_μ} preserves parity in the second equality, we calculate

$$\begin{aligned}\|e^{-tN_\mu}\psi\|_{\mathcal{B}_\mu^q}^q &= \|(e^{-tN_\mu}\psi)_e\|_{P_\mu^q}^q + \|(e^{-tN_\mu}\psi)_o\|_{I_\mu^q}^q = \|e^{-tN_\mu}\psi_e\|_{P_\mu^q}^q + \|e^{-tN_\mu}\psi_o\|_{I_\mu^q}^q \leqslant A^q\|\psi_e\|_{P_\mu^p}^q + B^q\|\psi_o\|_{I_\mu^p}^q \\ &\leqslant A^q\|\psi\|_{\mathcal{B}_\mu^p}^q + B^q\|\psi\|_{\mathcal{B}_\mu^p}^q = (A^q+B^q)\|\psi\|_{\mathcal{B}_\mu^p}^q = C^q\|\psi\|_{\mathcal{B}_\mu^p}^q.\end{aligned}$$

The first inequality follows from Theorems 4.1 and 4.2, while the first equality and the second inequality follow from the definition of $\|\cdot\|_{\mathcal{B}_\mu^p}$. ■

We conclude this section with a result that is somewhat tangential to the topic of reverse inequalities, but which follows immediately from the results we have just presented. We called this property L^p boundedness before, but we now can give it a more accurate name.

Theorem 4.4 *(Boundedness of the semigroup e^{-tN_μ} on $\mathcal{B}_\mu^p$):* *For $0<p<\infty$ and $t\geqslant 0$ we have that $e^{-tN_\mu}: \mathcal{B}_\mu^p \to \mathcal{B}_\mu^p$ boundedly. Explicitly, we have for all $\psi \in \mathcal{B}_\mu^p$ that*

$$\|e^{-tN_\mu}\psi\|_{\mathcal{B}_\mu^p} \leqslant e^{(2\mu+3)t/p}\|\psi\|_{\mathcal{B}_\mu^p}.$$

Proof: For $\psi_e \in P_\mu^p$ we have from the proof of Theorem 4.1 that

$$\|e^{-tN_\mu}\psi_e\|^p_{P^p_\mu} = e^{(2\mu+3)t}\int_{\mathbb{C}} |\psi_e(w)|^p \kappa_\mu K_{\mu-(1/2)}(e^{2t}|w|^2)|w|^{2\mu+1}\,\mathrm{d}u\,\mathrm{d}v.$$

This holds for $0<p<\infty$ and $t\geqslant 0$. But $K_{\mu-(1/2)}(e^{2t}|w|^2)\leqslant K_{\mu-(1/2)}(|w|^2)$ since the Macdonald function is monotone decreasing and $t\geqslant 0$. Applying this to the previous, we immediately get

$$\|e^{-tN_\mu}\psi_e\|^p_{P^p_\mu} \leqslant e^{(2\mu+3)t}\|\psi_e\|^p_{P^p_\mu}$$

for all $\psi_e \in P^p_\mu$. Similarly, from the identity at the beginning of the proof of Theorem 4.2 and the monotonicity of $K_{\mu+(1/2)}$, we see that for $0<p<\infty$ and $t\geqslant 0$ we have

$$\|e^{-tN_\mu}\psi_o\|^p_{I^p_\mu} \leqslant e^{(2\mu(1-p)+3)t}\|\psi_o\|^p_{I^p_\mu}$$

for all $\psi_o \in I^p_\mu$. The result for general $\psi \in \mathcal{B}^p_\mu$ now follows immediately. ■

This result is far from being sharp. For example, when $\mu=0$, it is known that the semigroup e^{-tN_0} for $t\geqslant 0$ acts contractively on $\mathcal{B}^p_0$. After all, contractivity is just a special case of hypercontractivity. But the bound we get in this case is $e^{3t/p}$. We conjecture that e^{-tN_μ} acts contractively on $\mathcal{B}^p_\mu$ and, even stronger, hypercontractively. This seems reasonable, since it is known to be true for $\mu=0$. Of course, if it is false, then we would have a nice mathematical property that would single out the usual quantization with $\mu=0$ from the deformations with $\mu\neq 0$.

Also note that this result quickly gives us reverse hypercontractivity for $t\geqslant 0$, since then e^{-tN_μ} acting on $\mathcal{B}^p_\mu$ maps its domain to itself boundedly and $\mathcal{B}^p_\mu$ is continuously contained in $\mathcal{B}^q_\mu$ for any $q<p$ by Hölder's inequality. Similar remarks apply to P^p_μ and I^p_μ. So the nontrivial case of reverse hypercontractivity is for negative t, specifically for $t\in((1/2)\log(q/p),0)$.

V. REVERSE LOG-SOBOLEV INEQUALITIES

In this section the goal is to prove a reverse log-Sobolev inequality in the Hilbert space $\mathcal{B}^2_\mu$. As in the preceding section, technical considerations lead us to proving such inequalities first in the Hilbert spaces P^2_μ and I^2_μ. The upshot is that the result for $\mathcal{B}^2_\mu$ is not what one might have expected and, in fact, leads us to a new definition of entropy that is appropriate for $\mathcal{B}^2_\mu$.

The method we use is due to Gross and first appeared in Ref. 26. Also, see Ref. 5 for another use of this method. We start with a definition of a quantity that arises in the next theorem.

Definition 5.1: We define the μ-deformed energy *for* $\psi_e \in P^2_\mu$ *by*

$$E_{e,\mu}(\psi_e) := \int_{\mathbb{C}} |\psi_e(z)|^2|z|^2\,\mathrm{d}\nu_{e,\mu}(z).$$

While we can consider this definition for larger classes of functions, we will comment in detail in an Appendix why we are interested in this quantity in the case that $\psi_e \in P^2_\mu$ and why it is called an energy in that case.

Theorem 5.1 *(Reverse log-Sobolev inequality in the space* P^2_μ*)*: *For* $c>1$ *and* $\psi_e \in P^2_\mu$ *we have that*

$$E_{e,\mu}(\psi_e) \leqslant cS_{P^2_\mu}(\psi_e) + \left(c\log\int_{\mathbb{C}} e^{|z|^2/c}\,\mathrm{d}\nu_{e,\mu}(z)\right)\|\psi_e\|^2_{P^2_\mu}, \tag{5.1}$$

where $S_{P^2_\mu}(\psi_e)$ *is the entropy of* ψ_e *as given in Definition 2.3. Moreover, for* $c>1$ *we have that*

$$1 < \int_{\mathbb{C}} e^{|z|^2/c}\,\mathrm{d}\nu_{e,\mu}(z) < \infty,$$

so that the coefficient of the norm term is positive and finite.

We note that the hypothesis $c>1$ in this and the subsequent theorems in this section does not depend on the parameter μ. In particular, it is the same condition as found by the second author in Ref. 25, where the case $\mu=0$ is studied.

Proof: Consider Young's inequality

$$st \leqslant s \log s - s + e^t,$$

where $s \geqslant 0$ and t are real numbers.

We take $c>1$ and $\psi_e \in P_\mu^2$ and then set $s=c|\psi_e(z)|^2$ and $t=|z|^2/c$ in Young's inequality. Next, we integrate to get

$$E_{e,\mu}(\psi_e) = \int_{\mathbb{C}} |\psi_e(z)|^2 |z|^2 \, \mathrm{d}\nu_{e,\mu}(z) \leqslant \int_{\mathbb{C}} c|\psi_e(z)|^2 \log c|\psi_e(z)|^2 \, \mathrm{d}\nu_{e,\mu}(z) - c\|\psi_e\|_{P_\mu^2}^2 + \int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z)$$

$$= cS_{P_\mu^2}(\psi_e) + (c \log c - c + c \log \|\psi_e\|_{P_\mu^2}^2)\|\psi_e\|_{P_\mu^2}^2 + \int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z),$$

using the definitions of $E_{e,\mu}(\psi_e)$ and $S_{P_\mu^2}(\psi_e)$. Now we replace ψ_e with $\lambda\psi_e$ for $\lambda>0$ and divide by λ^2 to get

$$E_{e,\mu}(\psi_e) \leqslant cS_{P_\mu^2}(\psi_e) + (c \log c - c + c \log \|\psi_e\|_{P_\mu^2}^2 + c \log \lambda^2)\|\psi_e\|_{P_\mu^2}^2 + \frac{1}{\lambda^2}\int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z).$$

Minimizing the right-hand side by varying λ, we obtain the optimal value

$$\lambda^2 = \frac{1}{c\|\psi_e\|_{P_\mu^2}^2}\int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z),$$

if $\psi_e \neq 0$. Substituting this value into the previous inequality and simplifying we get (5.1) in the case when $\psi_e \neq 0$. But (5.1) trivially holds if $\psi_e = 0$.

We still must discuss the integral $\int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z)$. But the integrand is bounded below by 1 and $\nu_{e,\mu}$ is a probability measure, so that $\int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z) > 1$ holds. It remains for us to show that this integral is finite. Since the integrand is continuous, we only must show its integrability near infinity (in the complex plane). We note that by the definition of $\nu_{e,\mu}$ and a simple change of variables we have

$$\int_{\mathbb{C}} e^{|z|^2/c} \, \mathrm{d}\nu_{e,\mu}(z) = \kappa_\mu \int_{\mathbb{C}} e^{|z|^2/c} K_{\mu-(1/2)}(|z|^2)|z|^{2\mu+1} \, \mathrm{d}x \, \mathrm{d}y = \pi\kappa_\mu \int_0^\infty e^{s/c} K_{\mu-(1/2)}(s) s^{\mu+(1/2)} \, \mathrm{d}s. \tag{5.2}$$

So what we must prove is the convergence of this last integral near ∞. But (2.3) implies that for all $s \in [M, \infty)$ for some M sufficiently large, we have that $K_{\mu-1/2}(s) \leqslant Cs^{-1/2}e^{-s}$. Applying this, we find that

$$\int_M^\infty e^{s/c} K_{\mu-(1/2)}(s) s^{\mu+(1/2)} \, \mathrm{d}s \leqslant C \int_M^\infty e^{-(1-1/c)s} s^\mu \, \mathrm{d}s < \infty, \tag{5.3}$$

where we used $c>1$ to conclude that the last integral is finite. ■

Note the the integral on the right-side of (5.2) is exactly calculable as an infinite series by expanding the exponential factor in its Maclaurin series and then using (2.4). This is also given in terms of the hypergeometric function in Eq. 6.621.3 in Ref. 7. We do not present this exact result here, since it seems to be of little interest, unless it should happen to give the unknown optimal coefficient of the norm term in (5.1). So we only present the asymptotic analysis of the integral. This exact result also shows that the integral (5.2) converges if and only if $c>1$, which is

something that an asymptotic analysis gives us as well. In the case $\mu=0$, it is known that the condition $c>1$ in the inequality (5.1) cannot be improved. (See Ref. 25.) It is natural to conjecture that this should be true for all μ. Similar comments apply to Theorem 5.2.

For the subspace of odd holomorphic functions, we have similar results. We start with the definition of the μ-deformation of the energy for this case.

Definition 5.2: We define the μ-deformed energy *for* $\psi_o \in I_\mu^2$ *by*

$$E_{o,\mu}(\psi_o) := \int_{\mathbb{C}} |\psi_o(z)|^2 |z|^2 \, d\nu_{o,\mu}(z).$$

Again, we refer to the Appendix for more details about this concept. It arises in the following theorem, which corresponds to Theorem 5.1 for the space I_μ^2.

Theorem 5.2 *(Reverse log-Sobolev inequality in the space* I_μ^2*)***:** *For* $c>1$ *and* $\psi_o \in I_\mu^2$ *we have*

$$E_{o,\mu}(\psi_o) \leqslant c S_{I_\mu^2}(\psi_o) + \left(c \log \int_{\mathbb{C}} e^{|z|^2/c} \, d\nu_{o,\mu}(z) \right) \|\psi_o\|_{I_\mu^2}^2. \tag{5.4}$$

Here $S_{I_\mu^2}(\psi_o)$ *is the entropy of* ψ_o *as given in Definition 2.3. Furthermore, for* $c>1$ *we have that*

$$\nu_{o,\mu}(C) < \int_{\mathbb{C}} e^{|z|^2/c} \, d\nu_{o,\mu}(z) < \infty, \tag{5.5}$$

so that the coefficient of the norm term is finite.

Proof: The proof of formula (5.4) is the same as the proof of (5.1) in Theorem 5.1, and so it will be omitted. The lower bound in (5.5) follows immediately from the fact that 1 is a lower bound on the integrand. For the upper bound in (5.5) we consider

$$\int_{\mathbb{C}} e^{|z|^2/c} \, d\nu_{o,\mu}(z) = \kappa_\mu \int_{\mathbb{C}} e^{|z|^2/c} K_{\mu+(1/2)}(|z|^2) |z|^{2\mu+1} \, dx \, dy = \pi \kappa_\mu \int_0^\infty e^{s/c} K_{\mu+(1/2)}(s) s^{\mu+(1/2)} \, ds.$$

As in the previous theorem, this integral can be exactly evaluated, but we only do an asymptotic analysis. Since the integrand on the left-hand side is integrable near the origin in the complex plane, the integrand on the right-hand side is integrable near 0. For the integrability on the right-hand side near infinity, we use (2.3) to get $K_{\mu+(1/2)}(s) \leqslant C s^{-1/2} e^{-s}$ for s sufficiently large. Now the proof terminates just as in (5.3), except with $K_{\mu+(1/2)}$ instead of $K_{\mu-(1/2)}$. ■

We comment that for $-1/2<\mu<0$ we have $0<\nu_{o,\mu}(\mathbb{C})<1$. (See Ref. 1.) So the above proof does not exclude the possibility of a negative coefficient of the norm term in (5.4) when $-1/2<\mu<0$. In the case $\mu>0$ we have from Ref. 1 that $\nu_{o,\mu}(\mathbb{C})>1$, so that the coefficient of the norm term in (5.4) is positive. However, we do not know for any pair $\mu>-1/2$ and $c>1$ what is the optimal value of the coefficient of that norm term.

We will use the following concept in the next theorem.

Definition 5.3: We define the total μ-deformed energy *by*

$$E_\mu(\psi) := E_{e,\mu}(\psi_e) + E_{o,\mu}(\psi_o)$$

for all $\psi \in \mathcal{B}_\mu^2$.

Having proved reverse log-Sobolev inequalities in the Hilbert spaces P_μ^2 and I_μ^2, we can now achieve the goal of this section, which is an inequality of that type for $\mathcal{B}_\mu^2$. However, we do not get one entropy term as is the case for a usual reverse log-Sobolev inequality, but rather two.

Theorem 5.3 *(Reverse log-Sobolev inequality in the space* $\mathcal{B}_\mu^2$*)***:** *For all* $c>1$ *there exist real numbers* $M(c,\mu)$ *and* $N(c,\mu)$ *such that for* $\psi \in \mathcal{B}_\mu^2$ *we have*

$$E_\mu(\psi) \leqslant c(S_{P_\mu^2}(\psi_e) + S_{I_\mu^2}(\psi_o)) + M(c,\mu)\|\psi_e\|_{P_\mu^2}^2 + N(c,\mu)\|\psi_o\|_{I_\mu^2}^2.$$

If we set $P(c,\mu) := \max(M(c,\mu), N(c,\mu))$, *then it follows for all* $\psi \in \mathcal{B}_\mu^2$ *that*

$$E_\mu(\psi) \leqslant c(S_{P^2_\mu}(\psi_e) + S_{I^2_\mu}(\psi_o)) + P(c,\mu)\|\psi\|^2_{\mathcal{B}^2_\mu}.$$

The proof of this result is an immediate consequence of Theorems 5.1 and 5.2. The definition of the total μ-deformed energy as the sum of two quadratic forms in $\mathcal{B}^2_\mu$ is neither surprising nor extraordinary. On the other hand, Theorem 5.3 presents us with an expression that is a new type of entropy.

Definition 5.4: For any $\psi \in \mathcal{B}^2_\mu$, *we define its* μ-deformed entropy $S_\mu(\psi)$ *by*

$$S_\mu(\psi) := S_{P^2_\mu}(\psi_e) + S_{I^2_\mu}(\psi_o),$$

where $\psi = \psi_e + \psi_o$ *is the decomposition of* ψ *into its even and odd parts.*

Let us note that this definition is not a particular case of Definition 2.3 of Shannon entropy. As far as we know, this is the first occurrence in the literature of a definition of an entropy of a function that depends on its decomposition into its even and odd parts. Of course, the *μ-deformed even entropy* $S_{P^2_\mu}(\psi_e)$ and the *μ-deformed odd entropy* $S_{I^2_\mu}(\psi_o)$ are Shannon entropies. With this definition the last inequality in Theorem 5.3 now has the compact form:

$$E_\mu(\psi) \leqslant cS_\mu(\psi) + P(c,\mu)\|\psi\|^2_{\mathcal{B}^2_\mu}.$$

VI. CONCLUSION

We note that there is a way to generalize this theory to the case of spaces of holomorphic functions on $\mathbb{C}^n$ for finite n in place of $\mathbb{C}$. We thank C. Pita for telling us about his unpublished work on this subject. This is also presented in Ref. 3. It remains an open problem as to how one might formulate such a theory for an infinite dimensional phase space.

Here are some other problems that are still open in this area. First, one can try to find the optimal constants for the various reverse hypercontractivity and the reverse log-Sobolev inequalities that we have proved. We conjecture that optimizing functions exist for all of these inequalities when the optimal constants are introduced into them, though it remains an open problem to identify these functions explicitly. We recall that a function f_{opt} is an *optimizing function* for an inequality (involving a function f) if that inequality becomes an equality when f_{opt} is substituted for f.

At present we do not even know whether e^{-tN_μ} maps $\mathcal{B}^p_\mu$ to itself contractively for $\mu \neq 0$, $p \neq 2$, and $t > 0$. We conjecture that this is true, but we were only able to prove in Theorem 4.4 that this operator is bounded. In addition we repeat the stronger conjecture made earlier that this semigroup is hypercontractive on the scales of spaces $\mathcal{B}^p_\mu$, a result which is known to be true when $\mu = 0$.

ACKNOWLEDGMENTS

The first author (C.A.A.) wishes to thank the two institutions which aided him so much during his doctoral studies, namely his place of work, the Facultad de Ciencias of the Universidad Autónoma de San Luis Potosí, as well as his place of study, the Centro de Investigación en Matemáticas (CIMAT). He also would like to express his gratitude to Fernando Galaz-Fontes of CIMAT for much valuable assistance throughout his doctoral career. Moreover, he thanks PROMEP for the grant for realizing those doctoral studies in the period from February, 1999 to January, 2002. The second author (S.B.S.) warmly thanks Larry Thomas, whose comments and insights over the years have had an integrated effect far in excess of their algebraic sum. Both authors thank Jaime Cruz Sampedro, Fernando Galaz-Fontes, Roberto Quezada Batalla, and Carlos Villegas-Blas for beneficial comments.

APPENDIX

We would like to comment in this Appendix about the relationship between the μ-deformed energy and the expected value of the μ-deformed harmonic oscillator energy, to be described below. We begin with an exact formula for the μ-deformed energy for the even case. Let us note that the proof of this formula uses hypotheses that are weaker than $\psi_e \in P_\mu^2$, though the latter is the case of interest.

Proposition 6.1: Suppose that $\psi_e:\mathbb{C}\to\mathbb{C}$ *is an even, holomorphic function with Maclaurin series* $\psi_e(z)=\sum_{j=0}^{\infty}a_{2j}z^{2j}$. *Then we have*

$$E_{e,\mu}(\psi_e)=\sum_{j=0}^{\infty}|a_{2j}|^2 2^{2j+1}\frac{\Gamma(j+3/2)\Gamma(\mu+j+1)}{\Gamma(\mu+1/2)}.$$

In particular, $E_{e,\mu}(\psi_e)$ *is finite if and only if the infinite series on the right-hand side is convergent*.

Proof: We exhibit first the following chain of equalities and give the justifications subsequently:

$$\begin{aligned}
\int_{\mathbb{C}}|\psi_e(z)|^2|z|^2\,\mathrm{d}\nu_{e,\mu}(z) &= \lim_{R\to\infty}\int_{|z|\leqslant R}\left(\sum_j a_{2j}z^{2j}\right)^{\star}\left(\sum_l a_{2l}z^{2l}\right)z^{\star}z\,\mathrm{d}\nu_{e,\mu}(z)\\
&= \lim_{R\to\infty}\int_{|z|\leqslant R}\sum_{j,l}a_{2j}^{\star}a_{2l}(z^{\star})^{2j+1}z^{2l+1}\,\mathrm{d}\nu_{e,\mu}(z)\\
&= \lim_{R\to\infty}\sum_{j,l}a_{2j}^{\star}a_{2l}\int_{|z|\leqslant R}(z^{\star})^{2j+1}z^{2l+1}\,\mathrm{d}\nu_{e,\mu}(z)\\
&= \lim_{R\to\infty}\sum_j|a_{2j}|^2\int_{|z|\leqslant R}|z|^{2(2j+1)}\,\mathrm{d}\nu_{e,\mu}(z)=\sum_j|a_{2j}|^2\int_{\mathbb{C}}|z|^{2(2j+1)}\,\mathrm{d}\nu_{e,\mu}(z)\\
&= \frac{1}{\Gamma(\mu+1/2)}\sum_j|a_{2j}|^2 2^{2j+1}\Gamma(j+3/2)\Gamma(\mu+j+1).
\end{aligned}$$

The introduction of the limit in the first equality is an application of the monotone convergence theorem. The interchange of the integral with the infinite sum in the third equality is allowed by the uniform convergence of the infinite series on the compact domain of integration. The fourth equality holds since the integrals for $j\neq l$ are zero, as one sees by introducing polar coordinates. The fifth equality is again monotone convergence, applied first to the infinite sum and then to the integral. The sixth equality is the evaluation of a finite integral, which we present in a moment. Notice that this chain of inequalities holds also in the case when the integral being evaluated is equal to infinity. Finally for the sixth equality, we have that

$$\begin{aligned}
\int_{\mathbb{C}}|z|^{2(2j+1)}\,\mathrm{d}\nu_{e,\mu}(z) &= \kappa_\mu\int_0^{2\pi}\left(\int_0^{\infty}K_{\mu-(1/2)}(r^2)r^{2\mu+1}r^{2(2j+1)}r\,\mathrm{d}r\right)\mathrm{d}\theta\\
&= \frac{2^{(1/2)-\mu}}{\Gamma(\mu+1/2)}\int_0^{\infty}K_{\mu-(1/2)}(s)s^{\mu+2j+3/2}\,\mathrm{d}s\\
&= \frac{1}{\Gamma(\mu+1/2)}2^{2j+1}\Gamma(j+3/2)\Gamma(\mu+j+1).
\end{aligned}$$

The last equality is an application of the identity (2.4). ■

We now consider the expected value of the μ-deformed harmonic oscillator energy $\langle\psi_e,H_\mu\psi_e\rangle$ for $\psi_e\in P_\mu^2$, where

$$H_\mu := \tfrac{1}{2}(\widetilde{P}_\mu^2 + \widetilde{Q}_\mu^2) = \tfrac{1}{2}(A_\mu A_\mu^\star + A_\mu^\star A_\mu) = N_\mu + \tfrac{1}{2}I + \mu J \tag{A1}$$

is the μ-deformed harmonic oscillator Hamiltonian. (See Ref. 20 and Proposition 3.1.) For $\mu=0$, the relation between the two energies is

$$E_{e,0}(\psi_e) = \langle \psi_e, N_0 \psi_e \rangle + \|\psi_e\|_{\mathcal{B}_0^2}^2 = \langle \psi_e, H_0 \psi_e \rangle + \tfrac{1}{2}\|\psi_e\|_{\mathcal{B}_0^2}^2,$$

where the first equality is an identity of Bargmann in Ref. 2 We therefore expect a relation for general $\mu > -1/2$. Since the identity of Bargmann is just a simple application of the canonical commutation relation (with $\mu=0$), one would expect that an application of the μ-deformed canonical commutation relation starting from the expression $\langle \psi_e, H_\mu \psi_e \rangle$ would lead to some expression involving $E_{e,\mu}(\psi_e)$. But this is not what happens. Instead, the integral $\int_{\mathbb{C}} |\psi_e(z)|^2 |z|^2 \, \mathrm{d}\nu_{o,\mu}(z)$ arises. See Ref. 1 for more about this integral.

We start the analysis of H_μ by noting that $H_\mu \Psi_{2j}^\mu = (2j+\mu+1/2)\Psi_{2j}^\mu$, so that

$$\langle \psi_e, H_\mu \psi_e \rangle = \sum_{j=0}^{\infty} |a_{2j}|^2 \gamma_\mu(2j)(2j+\mu+1/2),$$

where $\psi_e(z) = \Sigma_{j=0}^\infty a_{2j} z^{2j}$ is the Maclaurin series of ψ_e. So using Proposition 6.1, the *conjecture* that

$$E_{e,\mu}(\psi_e) = a_\mu \langle \psi_e, H_\mu \psi_e \rangle + b_\mu \|\psi_e\|_{P_\mu^2}^2$$

for some constants a_μ and b_μ is equivalent to the *conjecture* that

$$\frac{1}{\Gamma(\mu+1/2)} 2^{2j+1} \Gamma(j+3/2)\Gamma(\mu+j+1) = a_\mu \gamma_\mu(2j)(2j+\mu+1/2) + b_\mu \gamma_\mu(2j) \tag{A2}$$

for all integers $j \geqslant 0$, since $\|\psi_e\|_{P_\mu^2}^2 = \Sigma_j |a_{2j}|^2 \gamma_\mu(2j)$. This leads us to consider the quantities

$$Q_{j,\mu} := 2^{2j+1} \frac{\Gamma(j+3/2)\Gamma(\mu+j+1)}{\Gamma(\mu+1/2)\gamma_\mu(2j)}$$

for every integer $j \geqslant 0$.

In particular, the conjecture (A2) is equivalent to saying $Q_{j,\mu} = A_\mu j + B_\mu$ for some constants A_μ and B_μ. To proceed we apply the identity (3.1) to get

$$Q_{j,\mu} := 2\left(\frac{\Gamma(j+3/2)}{\Gamma(j+1)}\right)\left(\frac{\Gamma(\mu+j+1)}{\Gamma(\mu+j+1/2)}\right). \tag{A3}$$

We would like to evaluate this last expression exactly for all values of the parameters, namely for all integers $j \geqslant 0$ and all reals $\mu > -1/2$. This can be done for the first quotient since we have $\Gamma(j+1) = j!$ and $\Gamma(j+3/2) = \pi^{1/2} 2^{-j-1}(2j+1)!!$ by well-known identities. (See Ref. 7) So the problem reduces to calculating the second quotient in (A3). This can be done in either of the following two special cases, since we can again calculate the numerator and denominator separately: (1) $\mu = n$ where $n \geqslant 0$ is an integer. (2) $\mu = n + (1/2)$ (a half-integer) where $n \geqslant 0$ is an integer. We do not write down these formulas here. However, let us note that calculations in the case $\mu = 1/2$ show that the conjecture (A2) is false.

However, for general μ we do not need formulas for the numerator and for the denominator separately, but we only need one formula for the second quotient itself in (A3). And this has the form $\Gamma(\alpha+1/2)/\Gamma(\alpha)$ for $\alpha > 0$. We note the identity

$$\frac{\Gamma(\alpha)}{\Gamma(\alpha+1/2)} = \frac{2}{\pi^{1/2}} \int_0^{\pi/2} (\sin^{2\alpha-1}\theta) \mathrm{d}\theta$$

provided that $\alpha > 0$, which comes from evaluating the beta function $B(1/2, \alpha)$ first in terms of the gamma function (Eq. 8.384.1 in Ref. 7) and then in terms of its usual integral representation (Eq. 8.380.1 in Ref. 7). However, the intent behind this identity is that it gives us a way of evaluating the integral on the right-hand side in terms of the elementary function Γ. For example, see Eq. 3.621.5 in Ref. 7. But here we are interpreting the identity as a way of evaluating a quotient of two values of the Euler gamma function in terms of an integral that does not seem elementary at all, except when α is an integer or a half-integer. And these are exactly the cases when the quotient can be evaluated directly by using identities of the Euler gamma function Γ.

It seems that there is no simpler identity in general for the second quotient in (A3) and that the only thing we can do is to find its asymptotic behavior as $j \to \infty$ with μ fixed. But this is a straightforward application of Stirling's formula, which tells us that $\Gamma(\alpha+1/2) \approx \alpha^{1/2}\Gamma(\alpha)$ as $\alpha \to \infty$. (See Sec. 8.327 and Sec. 8.328, Eq. 2 in Ref. 7.) Since we are only getting the asymptotic behavior of the second quotient in (A3), we will only concern ourselves with the asymptotic behavior (rather than the exact formula) of the first quotient, which has the same form as the second quotient in (A3). So we find for fixed $\mu > -1/2$ that

$$Q_{j,\mu} \approx 2(j+1)^{1/2}(j+\mu+1/2)^{1/2} \approx 2j \approx 2j+\mu+1/2$$

as $j \to \infty$. So there are constants $0 < C_{1,\mu} < C_{2,\mu}$ so that

$$C_{1,\mu}(2j+\mu+1/2) \leqslant Q_{j,\mu} \leqslant C_{2,\mu}(2j+\mu+1/2)$$

for all integers $j \geqslant 0$. This implies that

$$C_{1,\mu}\langle \psi_e, H_\mu \psi_e \rangle \leqslant E_\mu(\psi_e) \leqslant C_{2,\mu}\langle \psi_e, H_\mu \psi_e \rangle.$$

This says that the expected value of the energy of the μ-deformed harmonic oscillator and the μ-deformed energy $E_e(\psi_e)$ are equivalent as quadratic forms. So any inequality involving one of these quadratic forms implies a similar inequality with the other. This explains why we call $E_\mu(\psi_e)$ an energy. Also by using (A1), the expected value of H_μ can be related to the expected value of N_μ.

The analysis for the odd case is quite similar, and we will not present it in full detail. We start by deriving a closed formula for the μ-deformed energy.

Proposition 6.2: Let $\psi_o : \mathbb{C} \to \mathbb{C}$ *be an odd, holomorphic function with Maclaurin series* $\psi_o(z) = \sum_{j=0}^{\infty} b_{2j+1} z^{2j+1}$. *Then we have*

$$E_{o,\mu}(\psi_o) = \sum_{j=0}^{\infty} |b_{2j+1}|^2 2^{2j+2} \frac{\Gamma(j+3/2)\Gamma(\mu+j+2)}{\Gamma(\mu+1/2)}.$$

In particular, $E_{o,\mu}(\psi_o)$ *is finite if and only if the infinite series on the right-hand side is convergent.*

Proof: We note that

$$\begin{aligned}
\int_{\mathbb{C}} |\psi_o(z)|^2 |z|^2 \, \mathrm{d}\nu_{o,\mu}(z) &= \lim_{R\to\infty} \int_{|z|\leqslant R} \left(\sum_j b_{2j+1} z^{2j+2} \right)^{\star} \left(\sum_l b_{2l+1} z^{2l+2} \right) \mathrm{d}\nu_{o,\mu}(z) \\
&= \lim_{R\to\infty} \int_{|z|\leqslant R} \sum_{j,l} b_{2j+1}^{\star} b_{2l+1} (z^{\star})^{2j+2} z^{2l+2} \, \mathrm{d}\nu_{o,\mu}(z) \\
&= \lim_{R\to\infty} \sum_{j,l} b_{2j+1}^{\star} b_{2l+1} \int_{|z|\leqslant R} (z^{\star})^{2j+2} z^{2l+2} \, \mathrm{d}\nu_{o,\mu}(z)
\end{aligned}$$

$$= \lim_{R\to\infty} \sum_j |b_{2j+1}|^2 \int_{|z|\leq R} |z|^{2(2j+2)}\, \mathrm{d}\nu_{o,\mu}(z) = \sum_j |b_{2j+1}|^2 \int_{\mathbb{C}} |z|^{2(2j+2)}\, \mathrm{d}\nu_{o,\mu}(z)$$

$$= \frac{1}{\Gamma(\mu+1/2)} \sum_j |b_{2j+1}|^2 2^{2j+2} \Gamma(j+3/2)\Gamma(\mu+j+2).$$

The justifications of the first five equalities are the same as in the corresponding calculation in Proposition 6.1. For the last equality we have used the evaluation of this finite integral,

$$\int_{\mathbb{C}} |z|^{2(2j+2)}\, \mathrm{d}\nu_{o,\mu}(z) = \kappa_\mu \int_{\mathbb{C}} K_{\mu+1/2}(|z|^2)|z|^{2\mu+1}|z|^{2(2j+2)}\, \mathrm{d}x\, \mathrm{d}y = \pi\kappa_\mu \int_0^\infty K_{\mu+1/2}(s) s^{\mu+2j+5/2}\, \mathrm{d}s$$

$$= \frac{1}{\Gamma(\mu+1/2)} 2^{2j+2} \Gamma(j+3/2)\Gamma(\mu+j+2),$$

where the last equality is an application of (2.4). ■

For $\psi_o \in I^2_\mu$ with Maclaurin series $\psi_o(z) = \Sigma_{j=0}^\infty b_{2j+1} z^{2j+1}$ we have that

$$\|\psi_o\|^2_{I^2_\mu} = \sum_{j=0}^\infty |b_{2j+1}|^2 \gamma_\mu(2j+1),$$

$$\langle \psi_o, H_\mu \psi_o \rangle = \sum_{j=0}^\infty |b_{2j+1}|^2 \gamma_\mu(2j+1)(2j+\mu+3/2).$$

We next define the quantity

$$R_{j,\mu} := \frac{2^{2j+2}\Gamma(j+3/2)\Gamma(\mu+j+2)}{\Gamma(\mu+1/2)\gamma_\mu(2j+1)}.$$

Then using (3.2) we obtain

$$R_{j,\mu} = 2\frac{\Gamma(j+3/2)\Gamma(\mu+j+2)}{\Gamma(j+1)\Gamma(\mu+j+3/2)}.$$

Again, an exact analysis is possible when μ is an integer or half-integer. But in general we are only able to give the asymptotic behavior, which is

$$R_{j,\mu} \approx 2(j+1)^{1/2}(j+\mu+3/2)^{1/2} \approx 2j \approx 2j+\mu+3/2$$

as $j\to\infty$ with μ fixed. Consequently, there exist constants $0 < D_{1,\mu} < D_{2,\mu}$ such that

$$D_{1,\mu}\langle \psi_o, H_\mu \psi_o \rangle \leq E_{o,\mu}(\psi_o) \leq D_{2,\mu}\langle \psi_o, H_\mu \psi_o \rangle$$

for all $\psi_o \in I^2_\mu$. And this tells us that the quadratic form $E_{o,\mu}(\psi_o)$ is equivalent to $\langle \psi_o, H_\mu \psi_o \rangle$. And so in this case too we see that the μ-deformed energy $E_{o,\mu}(\psi_o)$ is equivalent to the expected value of the μ-deformed harmonic oscillator energy.

Thus, the total μ-deformed energy $E_\mu(\psi)$ is equivalent to the μ-deformed harmonic oscillator energy $\langle \psi, H_\mu \psi \rangle$ for all $\psi \in \mathcal{B}^2_\mu$.

Phase-integral calculation of the phase of the regular Coulomb wave function $F_L(\eta,\rho)$

Staffan Yngve
Department of Theoretical Physics, University of Uppsala, Box 803, S-751 08 Uppsala, Sweden

(Received 31 January 2006; accepted 28 February 2006; published online 19 April 2006)

The phase of the regular Coulomb wave function $F_L(\eta,\rho)$ is calculated by means of the phase-integral approximation of arbitrary order with a convenient choice of the base function. The result agrees with the most accurate asymptotic expansion of the exact expression, $\arg\Gamma(L+1+i\eta)$, for the phase, truncated at an arbitrary order of approximation. It is seldom the case that the phase-integral expression for a physical quantity can be obtained in an arbitrary order of the approximation, and it is remarkable that in the present case this expression is the same as that obtained from the most accurate asymptotic formula for the quantity in question. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2189196]

I. INTRODUCTION

By means of the phase-integral method, which is described in Chap. 1 of Fröman and Fröman (1993) and in Chap. 2 of Fröman and Fröman (2002), one can in general calculate explicitly only the first few terms in the expansion for a physical quantity. A formula for the general term can, however, be obtained for the phase of the regular Coulomb wave function $F_L(\eta,\rho)$. The purpose of the present paper is to derive this phase with the use of an arbitrary order of the phase-integral approximation and to see how the result is related to asymptotic expansions of the exact expression, $\arg\Gamma(L+1+i\eta)$, for the phase under consideration.

For the background of the present paper we refer to the above-mentioned chapters in Fröman and Fröman (1996, 2002) and to a treatment of Coulomb wave functions in Dzieciol, Yngve, and Fröman (1999).

II. TREATMENT OF THE PROBLEM

Consider the differential equation

$$\frac{d^2\psi}{d\rho^2}+R(\rho)\psi=0 \tag{1}$$

with

$$R(\rho)=1-2\eta/\rho-\frac{L(L+1)}{\rho^2}. \tag{2}$$

The solution of (1) along with (2) that is regular at the origin is proportional to the Coulomb wave function $F_L(\eta,\rho)$, which according to Secs. 14.5.1, 14.5.5, 14.5.6, and 14.5.8 in Abramowitz and Stegun (1972) as $\rho\to+\infty$ behaves as

$$F_L(\eta,\rho)\sim\sin\left[\rho-\eta\ln(2\rho)-\frac{1}{2}L\pi+\sigma_L\right],\quad \rho\to+\infty, \tag{3}$$

where the exact expression for the phase σ_L is given by

$$\sigma_L = \arg \Gamma(L+1+i\eta). \tag{4}$$

Choosing, in our notation,

$$Q^2(\rho) = R(\rho) - \frac{1}{4\rho^2}, \tag{5}$$

Fröman and Yngve (1980) have used the phase-integral method in an arbitrary-order approximation to calculate the phase for the regular solution of a differential equation that becomes identical to (1) along with (2) when one in their paper sets $k=1$ and $b=0$. With this particularization one has according to their equations (10) and (10a, b) in the $(2N+1)$th order of the phase-integral approximation the formulas

$$\sigma_L = \sum_{n=0}^{N} \sigma_L^{(2n+1)} \tag{6}$$

with

$$\sigma_L^{(1)} = \frac{1}{2i}\left[\left(L+\frac{1}{2}+i\eta\right)\ln\left(L+\frac{1}{2}+i\eta\right) - \left(L+\frac{1}{2}-i\eta\right)\ln\left(L+\frac{1}{2}-i\eta\right)\right] - \eta, \tag{7a}$$

$$\begin{aligned}\sigma_L^{(2n+1)} &= \frac{(1-1/2^{2n-1})|B_{2n}|}{4n(2n-1)}\left\{\frac{1}{\left[\eta+i\left(L+\frac{1}{2}\right)\right]^{2n-1}} + \frac{1}{\left[\eta+i\left(L+\frac{1}{2}\right)\right]^{2n-1}}\right\} \\ &= \frac{(-1)^n(1-1/2^{2n-1})|B_{2n}|}{4n(2n-1)}\left\{\frac{1}{i\left(L+\frac{1}{2}+i\eta\right)^{2n-1}} - \frac{1}{i\left(L+\frac{1}{2}-i\eta\right)^{2n-1}}\right\}, \quad n \geqslant 1, \end{aligned} \tag{7b}$$

where B_{2n} are Bernouilli numbers. Noting that according to Secs. 23.1.2, 23.1.18, and 23.1.21 in Abramowitz and Stegun (1972),

$$(-1)^n(1-1/2^{2n-1})|B_{2n}| = (-1)^n(1-1/2^{2n-1})|B_{2n}(0)| = -(1-1/2^{2n-1})B_{2n}(0) = B_{2n}\left(\tfrac{1}{2}\right), n \geqslant 1, \tag{8}$$

where $B_{2n}(0)$ and $B_{2n}\left(\frac{1}{2}\right)$ are Bernouilli polynomials with the arguments 0 and 1/2, respectively, one can write (7b) as

$$\sigma_L^{(2n+1)} = \frac{B_{2n}\left(\frac{1}{2}\right)}{4n(2n-1)}\left\{\frac{1}{i\left(L+\frac{1}{2}+i\eta\right)^{2n-1}} - \frac{1}{i\left(L+\frac{1}{2}-i\eta\right)^{2n-1}}\right\}, \quad n \geqslant 1. \tag{7b$'$}$$

Since

$$L+\frac{1}{2} \pm i\eta = \left[\left(L+\frac{1}{2}\right)^2 + \eta^2\right]^{1/2} \exp\left(\pm i \arctan\frac{\eta}{L+\frac{1}{2}}\right) \tag{9}$$

one can write (7a) as

$$\sigma_L^{(1)} = \eta\left\{\ln\left[\left(L+\frac{1}{2}\right)^2 + \eta^2\right]^{1/2} - 1\right\} + \left(L+\frac{1}{2}\right)\arctan\frac{\eta}{L+\frac{1}{2}}, \tag{10a}$$

and (7b$'$) as

$$\sigma_L^{(2n+1)} = -\frac{B_{2n}\left(\frac{1}{2}\right)}{2n(2n-1)} \operatorname{Re}\left[i\left(L+\frac{1}{2}+i\eta\right)^{-(2n-1)} \right]$$
$$= -\frac{B_{2n}\left(\frac{1}{2}\right)}{2n(2n-1)} \operatorname{Re}\, i\left[\left(L+\frac{1}{2}\right)^2+\eta^2 \right]^{-(2n-1)/2} \exp\left[-i(2n-1)\arctan\frac{\eta}{L+\frac{1}{2}} \right]$$
$$= -\frac{B_{2n}\left(\frac{1}{2}\right)}{2n(2n-1)\left[\left(L+\frac{1}{2}\right)^2+\eta^2\right]^{(2n-1)/2}} \sin\left[(2n-1)\arctan\frac{\eta}{L+\frac{1}{2}} \right], \quad n \geqslant 1. \tag{10b}$$

By means of the phase-integral method we have thus for σ_L obtained the formula (6) along with (7a) and (7b) or alternatively along with (10a) and (10b).

The exact formula for σ_L is

$$\sigma_L = \arg\Gamma(L+1+i\eta) = \frac{1}{2i}[\ln\Gamma(L+1+\eta) - \ln\Gamma(L+1-i\eta)], \tag{11}$$

and the most accurate asymptotic expansion of $\ln\Gamma(L+1\pm i\eta)$, when $L+1\pm i\eta$ tends to infinity, can be obtained from Eq. (5) on p. 32 of Luke (1969), and is

$$\ln\Gamma(L+1\pm i\eta) \sim \left(L+\frac{1}{2}\pm i\eta\right)\left[\ln\left(L+\frac{1}{2}\pm i\eta\right)-1\right] + \ln(2\pi)^{1/2}$$
$$+\sum_{n=1}^{\infty} \frac{B_{2n}\left(\frac{1}{2}\right)}{2n(2n-1)\left(L+\frac{1}{2}\pm i\eta\right)^{2n-1}}, \quad \left|L+\frac{1}{2}\pm i\eta\right| \to \infty. \tag{12}$$

With the use of (12) one obtains from (11) the formula

$$\sigma_L \sim \frac{1}{2i}\left[\left(L+\frac{1}{2}+i\eta\right)\ln\left(L+\frac{1}{2}+i\eta\right) - \left(L+\frac{1}{2}-i\eta\right)\ln\left(L+\frac{1}{2}-i\eta\right)\right] - \eta$$
$$+\sum_{n=1}^{\infty} \frac{B_{2n}\left(\frac{1}{2}\right)}{4n(2n-1)}\left[\frac{1}{i\left(L+\frac{1}{2}+i\eta\right)^{2n-1}} - \frac{1}{i\left(L+\frac{1}{2}-i\eta\right)^{2n-1}}\right], \quad \left|L+\frac{1}{2}\pm i\eta\right| \to \infty, \tag{13}$$

which, when truncated, agrees with the formula (6) along with (7a) and (7b), which was obtained by means of the phase-integral method.

With the use of the asymptotic expansion in Sec. 6.1.40 in Abramowitz and Stegun (1972) one obtains the formula

$$\ln\Gamma(L+1\pm i\eta) \sim \left(L+\frac{1}{2}\pm i\eta\right)\ln(L+1\pm i\eta) - (L+1\pm i\eta) + \ln(2\pi)^{1/2}$$
$$+\sum_{n=1}^{\infty} \frac{B_{2n}}{2n(2n-1)(L+1\pm i\eta)^{2n-1}}, |L+1\pm i\eta| \gg 1, \quad \arg(L+1\pm i\eta) \leqslant \varepsilon \leqslant \pi, \tag{14}$$

which is less accurate than (13). To understand how (14) is related to (12), we consider the first few terms in (14), getting

$$
\begin{aligned}
&\ln\Gamma(L+1\pm i\eta)\\
&\quad\sim\left(L+\frac{1}{2}\pm i\eta\right)\ln(L+1\pm i\eta)-(L+1\pm i\eta)+\ln(2\pi)^{1/2}+\frac{B_2}{2(L+1\pm i\eta)}\\
&\quad=\left(L+\frac{1}{2}\pm i\eta\right)\left\{\ln\left(L+\frac{1}{2}\pm i\eta\right)+\ln\left[1+\frac{1}{2\left(L+\frac{1}{2}\pm i\eta\right)}\right]\right\}\\
&\qquad-(L+1\pm i\eta)+\ln(2\pi)^{1/2}+\frac{B_2}{2(L+1\pm i\eta)}\\
&\quad\approx\left(L+\frac{1}{2}\pm i\eta\right)\left[\ln\left(L+\frac{1}{2}\pm i\eta\right)+\frac{1}{2\left(L+\frac{1}{2}\pm i\eta\right)}-\frac{1}{8\left(L+\frac{1}{2}\pm i\eta\right)^2}\right]\\
&\qquad-\left(L+\frac{1}{2}\pm i\eta\right)-\frac{1}{2}+\ln(2\pi)^{1/2}+\frac{B_2}{2\left(L+\frac{1}{2}\pm i\eta\right)}\\
&\quad=\left(L+\frac{1}{2}\pm i\eta\right)\left[\ln\left(L+\frac{1}{2}\pm i\eta\right)-1\right]+\ln(2\pi)^{1/2}+\frac{B_2-\frac{1}{4}}{2\left(L+\frac{1}{2}\pm i\eta\right)},
\end{aligned}
$$

i.e., when we note that according to Secs. 23.1.3 and 23.1.21 in Abramowitz and Stegun (1972) $B_2-1/4=1/6-1/4=-1/12=B_2(1/2)$,

$$
\ln\Gamma(L+1\pm i\eta)\approx\left(L+\frac{1}{2}\pm i\eta\right)\left[\ln\left(L+\frac{1}{2}\pm i\eta\right)-1\right]+\ln(2\pi)^{1/2}+\frac{B_2\left(\frac{1}{2}\right)}{2\left(L+\frac{1}{2}\pm i\eta\right)}.
$$

This formula agrees with (12), when the sum there is truncated after the first term.

(Received 19 December 2005; accepted 24 February 2006; published online 21 April 2006)

In this paper we introduce a periodic Aharonov-Bohm potential, produced by two parallel infinite thin layers. The motion of a quantum charged particle without spin, under the action of this Aharonov-Bohm potential is examined. Finally we introduce a periodic Aharonov-Bohm potential, produced by a system of parallel solenoids and the motion of the charged particle in this field is also examined. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2189199]

I. INTRODUCTION

In the standard interpretation, the Aharonov-Bohm effect is referred to as the phase modification of a quantum particle in the region of space in which the magnetic induction **B** and electric field intensity **E** vanish, but it still exists in a vector potential **A** or an electric potential ϕ.[1–3] The effect was also investigated experimentally.[2]

In a series of recent papers, Audretsch *et al.*,[4,5] Skarzhinsky *et al.*[6] have demonstrated that in an Aharonov-Bohm potential, some other new important effects like the particle electron-positron pair production, bremsstrahlung of relativistic electrons and scattering of neutral atoms with induced electric dipole moments may occur.

It has been found that the action of the Aharonov-Bohm potential produces shift of the energy levels of atoms[7,8] and quantum harmonic oscillators.[9]

In these papers the case of an Aharonov-Bohm potential generated by a magnetic string which produces weak effects has been considered.

Meanwhile, a series of papers were dedicated to the problem of relativistic particles scattering in an Aharonov-Bohm potential, generated by an infinite solenoid,[10,11] or to the time-dependent Aharonov-Bohm potential.[12]

An attempt is made in our paper to define a magnetic structure that produces Aharonov-Bohm potentials more efficient for experimental purposes.

This kind of potential is important because it permits us to obtain more realistic configurations, similar to the free electron laser configurations with undulator magnets.[13]

II. A PERIODIC AHARONOV-BOHM POTENTIAL

Consider a magnetic system consisting in two infinite magnetic layers of thickness δ, lying parallel to the plane *Oyz*. A section of the system in the *Oxy* plane is drawn in Fig. 1. The magnetic layers L_1 and L_2 are situated at a distance *b* from *Oyz* plane.

Consider that the two magnetic layers are magnetized along the *z* axis, and that the magnetic fields have opposite orientations. The magnetic induction will be assumed constant along the *z* axis and having periodic variation along the *y* axis; let λ be the space period and

[a)]Electronic mail: ghed@mec.utt.ro

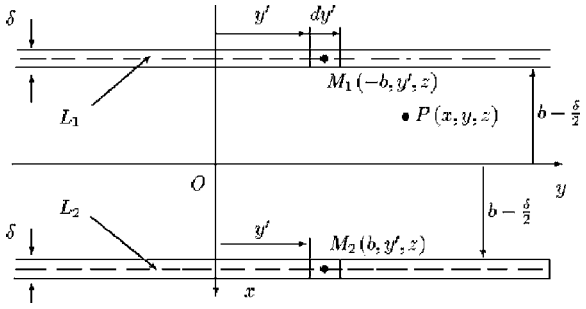

FIG. 1. Magnetic configuration.

$$k = \frac{2\pi}{\lambda},$$

the associated wave vector.

Consider that the magnetic induction in points M_1 and M_2 has the following variation:

$$B_{1z}(x_1, y', z) = -B_0 \cos ky', \quad B_{2z}(x_2, y', z) = B_0 \cos ky',$$

for $x_1 \in [-b-(\delta/2), -b+(\delta/2)]$, $x_2 \in [b-(\delta/2), b+(\delta/2)]$ and that $B_{1j}(-b, y', z) = B_{2j}(b, y', z) = 0$, where $j = x, y$.

Let a pair of magnetic strings, centered in $M_1(-b, y', z)$ and $M_2(b, y', z)$ and directed along the z axis and let $\mathrm{d}S = \delta\, \mathrm{d}y'$ be their cross-section area. These two magnetic strings can be assimilated to a pair of infinite nondispersive solenoids giving rise to the following magnetic fluxes:

$$\mathrm{d}\Phi_1 = B_1 \delta\, \mathrm{d}y', \quad \mathrm{d}\Phi_2 = B_2 \delta\, \mathrm{d}y'.$$

It is known that in an external point $P(x, y, z)$ the vector potential of an infinite nondispersive solenoid, oriented along the z axis is given by[1,2]

$$A_x = -\frac{\Phi}{2\pi} \frac{y}{x^2 + y^2}, \quad A_y = \frac{\Phi}{2\pi} \frac{x}{x^2 + y^2}, \quad A_z = 0,$$

where Φ is the magnetic flux inside the solenoid.

Accordingly, the pair of magnetic strings produces about a point $P(x, y, z)$ (Fig. 1), situated between the magnetic layers, an Aharonov-Bohm vector potential $\mathrm{d}\mathbf{A}$, which has the following components:

$$\mathrm{d}A_x = \frac{B_0 \cos ky' \, \delta\, \mathrm{d}y'}{2\pi} \left[\frac{y - y'}{(x+b)^2 + (y-y')^2} - \frac{y - y'}{(x-b)^2 + (y-y')^2} \right],$$

$$\mathrm{d}A_y = \frac{B_0 \cos ky' \, \delta\, \mathrm{d}y'}{2\pi} \left[\frac{x - b}{(x-b)^2 + (y-y')^2} - \frac{x + b}{(x+b)^2 + (y-y')^2} \right], \tag{1}$$

$$\mathrm{d}A_z = 0.$$

Integrating expressions over $y' \in R$, we obtain the components A_x, A_y, and A_z of the vector potential.

In this view we shall use the Fourier transform after y. Let $\mathcal{F}(k)$ be the Fourier transform of a function $F(y)$. Then, the direct and the inverse Fourier transforms of the function F are

$$\mathcal{F}(k) = \int_{-\infty}^{+\infty} F(y) e^{iky}\, \mathrm{d}y, \quad F(y) = \frac{1}{2\pi} \int_{-\infty}^{+\infty} \mathcal{F}(k) e^{-iky}\, \mathrm{d}y.$$

The relations (1) can be generalized if we replace $\cos ky'$ by $e^{iky'}$,

$$dA'_x = \frac{B_0 \exp(iky')\delta\, dy'}{2\pi}\left[\frac{y-y'}{(x+b)^2+(y-y')^2} - \frac{y-y'}{(x-b)^2+(y-y')^2}\right],$$

$$dA'_y = \frac{B_0 \exp(iky')\delta\, dy'}{2\pi}\left[\frac{x-b}{(x-b)^2+(y-y')^2} - \frac{x+b}{(x+b)^2+(y-y')^2}\right], \tag{2}$$

$$dA'_z = 0.$$

Integrating one can obtain A_x, A_y, and A_z taking the real part of the generalized forms of Eq. (2).

Using the residues theorem, we get

$$\int_R \frac{e^{iky'}y'}{y'^2+(x+b)^2}dy' = \pi i\ \mathrm{sign}(k)e^{-|k|(x+b)}, \tag{3}$$

$$\int_R \frac{e^{iky'}y'}{y'^2+(x-b)^2}dy' = \pi i\ \mathrm{sign}(k)e^{|k|(x-b)}, \tag{4}$$

$$\int_R \frac{e^{iky'}(x+b)}{y'^2+(x+b)^2}dy' = \pi\ \mathrm{sign}(k)e^{-|k|(x+b)}, \tag{5}$$

$$\int_R \frac{e^{iky'}(x-b)}{y'^2+(x-b)^2}dy' = -\pi\ \mathrm{sign}(k)e^{|k|(x-b)}. \tag{6}$$

Using Eqs. (3)–(6) and the properties of the Fourier transform,[14] we can integrate (2) and we obtain A'_x, A'_y, and A'_z. Taking the real part of these integrals, the components (1) result as

$$A_j = \mathrm{Real}\ A'_j, \quad j = x,y,z,$$

which, for $k>0$ are

$$A_x(x,y,z) = B_0\delta e^{-kb}\sinh kx \sin ky = A_0 \sinh kx \sin ky,$$

$$A_y(x,y,z) = B_0\delta e^{-kb}\cosh kx \cos ky = A_0 \cosh kx \cos ky, \tag{7}$$

$$A_z(x,y,z) = 0,$$

where $A_0 = B_0\delta e^{-kb}$. The amplitude A_0 can be written as a function of magnetic flux $\mathcal{F}_0$ in a section of a magnetic foil perpendicular on B_0 and having the length equal to one-half of the period along the y axis [i.e., $y \in [0, \lambda/2)$]:

$$A_0 = B_0\delta e^{-kb} = \frac{k}{2}\mathcal{F}_0 e^{-kb}. \tag{8}$$

It is easy to verify that this periodic potential is also an Aharonov-Bohm (AB) potential in the region between the two magnetic layers ($\nabla\mathbf{A}=0$ and $\nabla\times\mathbf{A}=0$), and we may consider that the particle is excluded from the magnetic layers.

In a similar way it is possible to calculate the vector potential outside the layers, i.e., $x \in [b+(\delta/2), \infty)$, $y \in R$, and $x \in [-b-(\delta/2), -\infty)$, $y \in R$. This potential can be useful for the study of the phase difference in a double connected domain (the AB effect).

III. MOTION OF THE CHARGED PARTICLE IN A PERIODIC AHARONOV-BOHM POTENTIAL

Consider a nonrelativistic particle of charge e, mass m and, moving in the region delimited by the two magnetic layers which produces the periodic Aharonov-Bohm potential (7) defined in the preceding section.

The Hamiltonian of the particle can be written as

$$H = \frac{1}{2m}\left(\mathbf{p} - \frac{e}{c}\mathbf{A}\right)^2, \tag{9}$$

where $\mathbf{A}$ is given by (7).

The stationary states for the Schrödinger equation of the system (9) can be expressed as

$$\left[\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} - 2i\alpha\left(\sinh kx \sin ky \frac{\partial}{\partial x} + \cosh kx \cos ky \frac{\partial}{\partial y}\right) - \alpha^2(\sinh^2 kx \sin^2 ky + \cosh^2 kx \cos^2 ky) + \varepsilon\right]\psi(x,y) = 0, \tag{10}$$

where we used the following notations:

$$\alpha = \frac{eA_0}{c\hbar}, \quad \varepsilon = \frac{2mE}{\hbar^2},$$

in which E is the energy of the stationary states.

Consider that the particle cannot penetrate the magnetic foils domain. Then, it follows that the eigenfunctions $\psi(x,y)$ of (10) must obey the boundary conditions:

$$\psi\left(b - \frac{\delta}{2}, y\right) = 0, \quad \psi\left(-\left(b - \frac{\delta}{2}\right), y\right) = 0. \tag{11}$$

Such a condition was also used in Ref. 15.

In order to find the eigenvalues ε and the eigenfunctions $\psi(x,y)$ of the equation (10) we make the following substitution:

$$u = x + iy, \quad v = x - iy. \tag{12}$$

Accordingly, the Schrödinger equation for the stationary states will be

$$\left[\left(2\frac{\partial}{\partial v} + \alpha \cosh kv\right)\left(2\frac{\partial}{\partial u} - \alpha \cosh ku\right) + \varepsilon\right]\Phi(u,v) = 0, \tag{13}$$

where $\Phi(u,v) = \psi(x,y)$.

The equation (13) is a differential equation with separable variables. Writing the solution under the form

$$\Phi(u,v) = F(u)G(v),$$

we obtain

$$\left[\frac{\left(2\frac{\partial G}{\partial v}+\alpha\cosh kvG\right)}{G}\frac{\left(2\frac{\partial F}{\partial u}-\alpha\cosh kuF\right)}{F}+\varepsilon\right]=0,$$

which, after separation leads to

$$\left(2\frac{\partial}{\partial u}-\alpha\cosh ku\right)F=c_1F,$$

$$\left(2\frac{\partial}{\partial v}+\alpha\cosh kv\right)G=c_2G, \tag{14}$$

$$\varepsilon=-c_1c_2,$$

where c_1 and c_2 are separation constants.

Finally, the solution of Eq. (13),

$$\Phi(u,v)=C\exp\left[\frac{1}{2}(c_1u+c_2v)+\frac{1}{2}\frac{\alpha}{k}(\sinh ku-\sinh kv)\right],$$

where C is the normalization constant. The solution can also be written in terms of variables (x,y) as

$$\psi(x,y)=C\exp\left[\frac{1}{2}(c_1+c_2)x+\frac{1}{2}i(c_1-c_2)y+i\frac{\alpha}{k}\cosh kx\sin ky\right]. \tag{15}$$

Since solution (15) does not comply boundary condition (11) we shall set $c_1=c_2=0$ and examine the more general solution

$$\psi(x,y)=C\exp\left[i\frac{\alpha}{k}\cosh kx\sin ky\right]p(x)q(y), \tag{16}$$

where $p(x)$ and $q(y)$ are unknown functions.

It is noteworthy that the Schrödinger equation (10) is periodic along the y axis with λ and even along the x axis. This implies that the solution $\psi(x,y)$ must fulfill the following conditions:

$$\psi(x,y+\lambda)=\psi(x,y),\quad \psi(-x,y)=\psi(x,y). \tag{17}$$

The factor $\exp[i(\alpha/k)\cosh kx\sin ky]$ in the solution (16) can be expanded in terms of $\exp(iky)$. Due to the property of periodicity it follows from Bloch's theorem that the function $q(y)$ must be periodic with λ.

Finally, we obtain solutions obeying both the conditions (11) and (17), as unbounded states,

$$\psi_{n_1,n_2}(x,y)=N\cos\left(\frac{\pi(2n_1+1)}{2(b-\delta/2)}x\right)\exp\left[in_2ky+i\frac{\alpha}{k}\cosh kx\sin ky\right], \tag{18}$$

where N is the normalization constant. The eigenfunction ψ_{n_1,n_2} is even with respect to the x axis.

The values of n_1, for ψ_{n_1,n_2} must be $n_1=0,1,2,3,\ldots$. The possible values of n_2 are $n_2=0,\pm1,\pm2,\pm3,\ldots$.

Let $|n_1n_2\rangle=\psi_{n_1n_2}$ be the eigenstates (18). It is noteworthy that $|n_1n_2\rangle$ is a set of unbounded states. For this reason, in order to avoid divergent integrals, we can restrict the integration over y to a period, i.e., $y\in[0,2\pi/k]$.

Taking into account this restriction, the scalar product of these states will be

$$\langle n_1 n_2 | n_1' n_2' \rangle = \delta_{n_1,n_1'} \delta_{n_2,n_2'},$$

where δ is the Kronecker symbol. Accordingly, the normalization constant, $N = \sqrt{2/(2b-\delta)}$, and the energy levels will be

$$E_{n_1 n_2} = \frac{\hbar^2}{2m\alpha^2}\left[\left(\frac{\pi}{2b-\delta}\right)^2 (2n_1+1)^2 + k^2 n_2^2\right] = \hbar\,(\omega_x(2n_1+1)^2 + \omega_y n_2^2), \tag{19}$$

where

$$\omega_x = \frac{\hbar c}{ek\mathcal{F}_0}\left(\frac{\pi}{2b-\delta}\right)^2 e^{kb}, \quad \omega_x = \frac{\hbar c}{e\mathcal{F}_0} k e^{kb}.$$

The states ψ_{n_1,n_2} are twofold degenerated with respect to n_1 and n_2, except for $n_2=0$.

Bounded states for Aharonov-Bohm potentials generated by a single solenoid were obtained in a series of previous papers.[7,9,10]

The general solution can also be derived using the variational iteration method of He.[16]

IV. SYSTEM ALGEBRA

We can build the creation and annihilation operators (b_+ and b_-)

$$b_+ = e^{iky}\left[\frac{1}{ik}\left(\frac{\partial}{\partial y} - i\alpha \cosh kx \cos ky\right) + 1\right], \tag{20}$$

$$b_- = \left[\frac{1}{ik}\left(\frac{\partial}{\partial y} - i\alpha \cosh kx \cos ky\right) + 1\right] e^{-iky}, \tag{21}$$

and also a b_0 operator

$$b_0 = \frac{1}{ik}\left(\frac{\partial}{\partial y} - i\alpha \cosh kx \cos ky\right) + \frac{1}{2}, \tag{22}$$

connected to the n_2 quantum number.

The action of these operators on the eigenfunctions $|n_1 n_2\rangle$ is given by

$$\begin{aligned} b_+|n_1,n_2\rangle &= (n_2+1)|n_1,n_2+1\rangle, \\ b_-|n_1,n_2\rangle &= n_2|n_1,n_2-1\rangle, \\ b_0|n_1 n_2\rangle &= \left(n_2+\tfrac{1}{2}\right)|n_1 n_2\rangle. \end{aligned} \tag{23}$$

We also can note that by Hermitian conjugations one can show that

$$b_\pm^\dagger = b_\mp, \quad b_0^\dagger = b_0.$$

These operators obey the commutation relations

$$\begin{aligned} [b_-,b_+] &= 2b_0, \\ [b_0,b_+] &= b_+, \\ [b_0,b_-] &= -b_-. \end{aligned} \tag{24}$$

It is noteworthy that the set of eigenfunctions $|n_1 n_2\rangle$ is separated with respect to n_2 into a set for negative values of n_2 and into a set of positive values of n_2, due to the fact that

$$b_-|n_1 0\rangle = 0, \quad b_+|n_1 - 1\rangle = 0. \tag{25}$$

We can also build a set of creation and annihilation operators $a_\pm$, acting on the quantum number n_1,

$$a_+ = \frac{2b-\delta}{2\pi}\sin\frac{2\pi x}{2b-\delta}\left[\frac{d}{dx} - i\alpha \sinh kx \sin ky\right] + \left(n_1 + \frac{1}{2}\right)\cos\frac{2\pi x}{2b-\delta}, \tag{26}$$

$$a_- = -\frac{2b-\delta}{2\pi}\sin\frac{\pi x}{2b-\delta}\left[\frac{d}{dx} - i\alpha \sinh kx \sin ky\right] + \left(n_1 + \frac{1}{2}\right)\cos\frac{\pi x}{2b-\delta}, \tag{27}$$

and an operator a_0,

$$a_0 = -\left(\frac{2b-\delta}{2\pi}\right)^2\left[\frac{d}{dx} - i\alpha \sinh kx \sin ky\right]^2 - n_1^2 + \frac{1}{4}. \tag{28}$$

It is easy to note that the operators $b_\pm$ are dependent on n_1, i.e., on a state $|n_1 n_2\rangle$ an operator with the same quantum number n_1 must be applied.[17] The action of these operators is given by

$$a_+|n_1,n_2\rangle = \left(n_1 + \tfrac{1}{2}\right)|n_1+1,n_2\rangle, \tag{29}$$

$$a_-|n_1,n_2\rangle = \left(n_1 + \tfrac{1}{2}\right)|n_1-1,n_2\rangle, \tag{30}$$

$$a_0|n_1,n_2\rangle = \left(n_1 + \tfrac{1}{2}\right)|n_1,n_2\rangle. \tag{31}$$

Operators $a_\pm$ and a_0 obey the commutation relations

$$[a_-,a_+] = 2a_0, \tag{32}$$

$$[a_0,a_\pm] = \pm a_\pm. \tag{33}$$

Operators $a_\pm$ can be written in a n_1-independent form using an auxiliary phase type variable ξ ($\xi \in [0,2\pi)$).[18,19] In this representation, the wave functions take the form

$$|n_1 n_2\rangle_\xi = \exp(i n_1 \xi)|n_1 n_2\rangle,$$

and the operators $a_\pm$ (26) and (26) will be

$$a_\pm = \pm e^{\pm i\xi}\frac{2b-\delta}{2\pi}\sin\frac{2\pi x}{2b-\delta}\left[\frac{\partial}{\partial x} - i\alpha \sinh kx \sin ky\right] + e^{\pm i\xi}\cos\frac{2\pi x}{2b-\delta}\left(\frac{1}{i}\frac{\partial}{\partial\xi} + \frac{1}{2}\right), \tag{34}$$

$$a_0 = \left(\frac{1}{i}\frac{\partial}{\partial\xi} + \frac{1}{2}\right). \tag{35}$$

V. COHERENT STATES

We can build the coherent states for the annihilation operator[20,21] as the states $|z_1 z_2\rangle$ (where z_1 and z_2 are complex valued variables, $z_{1,2} \in C$), which are eigenstates for operators a_- and b_-,

$$a_-|z_1 z_2\rangle = z_1|z_1 z_2\rangle, \quad b_-|z_1 z_2\rangle = z_2|z_1 z_2\rangle.$$

These states will be

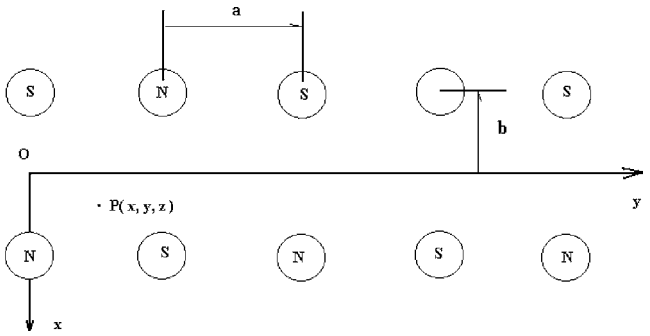

FIG. 2. Periodic structure of solenoids.

$$|z_1 z_2\rangle = d_0 \sum_{n_1=0}^{\infty} \sum_{n_2=-\infty}^{\infty} \frac{z_1^{n_1} z_2^{n_2}}{(3/2)_{n_1} n_2!} |n_1 n_2\rangle, \tag{36}$$

where $(a)_n = a(a+1)(a+2)\cdots(a+n-1)$ and d_0 is a normalization constant equal to

$$d_0 = \left(\sum_{n_1=0}^{\infty} \sum_{n_2=-\infty}^{\infty} \frac{|z_1|^{2n_1} |z_2|^{2n_2}}{(3/2)_{n_1}^2 (n_2\,!)^2} \right)^{-1/2}.$$

We can also build the coherent states for the displacement operators $D_1(\chi_1)$ and $D_2(\chi_2)$ (where $\chi_{1,2} \in C$),

$$D_1(\chi_1) = \exp(\chi_1 a_+ - \chi_1^* a_-), \quad D_2(\chi_2) = \exp(\chi_2 b_+ - \chi_2^* b_-), \tag{37}$$

as[20,21]

$$|\chi_1 \chi_2\rangle = D_1(\chi_1) D_2(\chi_2) |10\rangle. \tag{38}$$

VI. PERIODIC STRUCTURE OF SOLENOIDS

Consider a periodic structure made of solenoids.[22] A section in the plane (x,y) is shown in Fig. 2.

In a point P of the field, situated outside the magnetic flux domain (Fig. 2), the vector potential $\mathbf{A}$ of periodic Aharonov-Bohm structure has the following components:

$$A_x = \frac{F}{2\pi} \sum_{n=-\infty}^{\infty} (-1)^n \left[\frac{y - na}{(x+b)^2 + (y-na)^2} - \frac{y-na}{(x-b)^2 + (y-na)^2} \right],$$

$$A_y = \frac{F}{2\pi} \sum_{n=-\infty}^{\infty} (-1)^n \left[\frac{x-b}{(x-b)^2 + (y-na)^2} - \frac{x+b}{(x+b)^2 + (y-na)^2} \right],$$

$$A_z = 0. \tag{39}$$

In order to put in a restricted form the series expressing the components A_x and A_y of the vector potential, we shall use the Fourier transform with respect to variable y. Then, if $\mathcal{F}(k)$ is the Fourier transform of a function $F(y)$, the Fourier transform of the components A_x and A_y are

$$\mathcal{A}_x(k) = i \frac{F}{4} \operatorname{sign}(k) [e^{-|(x+b)k|} - e^{-|(x-b)k|}] \sum_{n=-\infty}^{+\infty} (e^{in(ka+\pi)} + e^{in(ka-\pi)}), \tag{40}$$

$$\mathcal{A}_y(k) = \frac{F}{4}[\text{sign}(x-b)e^{-|(x-b)k|} - \text{sign}(x+b)e^{-|(x+b)k|}] \sum_{n=-\infty}^{+\infty} (e^{in(ka+\pi)} + e^{in(ka-\pi)}). \tag{41}$$

The above relations contain the following series:

$$S = \sum_{n=-\infty}^{+\infty} (e^{in(ka+\pi)} + e^{in(ka-\pi)}).$$

To express this series, the following identity[14] will be used:

$$\sum_{n=-\infty}^{+\infty} e^{in\omega x} = T \sum_{n=-\infty}^{+\infty} \delta(x - nT). \tag{42}$$

Then, setting $x=[k\pm(\pi/a)]$ and $\omega=2a$, S becomes

$$S = \frac{2\pi}{a} \sum_{n=-\infty}^{+\infty} \left\{ \delta\left[k - (2n+1)\frac{\pi}{a} \right] + \delta\left[k - (2n-1)\frac{\pi}{a} \right] \right\}. \tag{43}$$

Calculating the inverse Fourier transform, observing that $a>0$, and eliminating the negative frequencies, the components of the vector potential can be written as

$$A_x(\mathbf{r}) = \frac{F}{2\pi a} \sum_{n=0}^{+\infty} \left[e^{-2\pi(2n+1)|[(x+b)/2a]|} - e^{-2\pi(2n+1)|[(x-b)/2a]|} \right] \sin\left[2\pi(2n+1)\frac{y}{2a} \right], \tag{44}$$

$$A_y(\mathbf{r}) = \frac{F}{2\pi a} \sum_{n=0}^{+\infty} [\text{sign}(x-b)e^{-2\pi(2n+1)|[(x-b)/2a]|} - \text{sign}(x+b)e^{-2\pi(2n+1)|[(x+b)/2a]|}] \times \cos\left[2\pi(2n+1)\frac{y}{2a} \right], \tag{45}$$

$$A_z(\mathbf{r}) = 0. \tag{46}$$

Taking into account that $x \in [-b, b]$, the components of the vector potential result as

$$A_x(\mathbf{r}) = -\frac{F}{\pi a} \sum_{n=0}^{+\infty} e^{-2\pi(2n+1)(b/2a)} \sinh\left[\frac{2\pi}{2a}(2n+1)x \right] \sin\left[2\pi(2n+1)\frac{y}{2a} \right], \tag{47}$$

$$A_y(\mathbf{r}) = -\frac{F}{\pi a} \sum_{n=0}^{+\infty} e^{-2\pi(2n+1)|(b/2a)|} \cosh\left[\frac{2\pi}{2a}(2n+1)x \right] \cos\left[2\pi(2n+1)\frac{y}{2a} \right]. \tag{48}$$

The *wavelength* (*the spatial period*), of the structure of solenoids, and the corresponding wave number are $\lambda=2a$ and $k=2\pi/\lambda$, respectively.

One can also obtain even harmonics, whose wavelength and wave number are given by

$$\lambda_{2n+1} = \frac{\lambda}{2n+1}, \quad k_{2n+1} = (2n+1)k.$$

The Schrödinger equation for the charged particle under the action of the potential (47) and (48) can be written as

$$\left[\left(\frac{\partial}{\partial x} - \frac{ie}{\hbar c} A_x \right)^2 + \left(\frac{\partial}{\partial y} - \frac{ie}{\hbar c} A_y \right)^2 + \frac{2mE}{\hbar^2} \right] \psi(x,y) = 0. \tag{49}$$

Consider that the particle cannot penetrate the solenoids, i.e., $\psi(x,y)=0$ on the surface of the solenoids.

In terms of variables (u,v), (12), Eq. (49) can be written in a separable form. Then, introducing

$$\epsilon=\frac{2mE}{\hbar^2},\quad \beta=\frac{eF}{\pi a\hbar c},\quad k=\frac{2\pi}{2a},$$

a particular solution $\psi(x,y)$,

$$\psi(x,y)=\exp\left[\frac{1}{2}(c_1+c_2)x+\frac{1}{2}(c_1-c_2)iy-i\frac{\beta}{k}\sum_{n=0}^{\infty}\frac{e^{-kb(2n+1)}}{2n+1}\cosh((2n+1)kx)\sin((2n+1)ky)\right], \tag{50}$$

results.

A more general solution can be written under the form

$$\psi(x,y)=\exp\left[-i\frac{\beta}{k}\sum_{n=0}^{\infty}\frac{e^{-kb(2n+1)}}{2n+1}\cosh((2n+1)kx)\sin((2n+1)ky)\right]h(x,y), \tag{51}$$

where $h(x,y)$ is an unknown function, even with respect to variable x and periodic with respect to variable y, with $\lambda=2a$. Function h must satisfy the differential equation,

$$\frac{\partial^2 h}{\partial x^2}+\frac{\partial^2 h}{\partial y^2}+\epsilon\beta^2 h=0.$$

The general solution cannot be found without knowing the solution outside of the region delimited by the solenoid structure.

VII. CONCLUSIONS

In this paper a periodic Aharonov-Bohm potential of magnetic type, generated by two infinite layers of magnetic foil with periodic magnetization is proposed.

This kind of potential is adequate for experimental purposes.

From Eq. (18) one can see that the charged particle has unbounded states with discrete energy levels.

In the early papers on the subject, it has been considered that the Aharonov-Bohm potential produces only phase shift effects in the wave function.

It is easy to see that our periodic potential (7), (47), and (48) does not give phase shift effects for a particle that crosses an integer number of spatial periods $(n2\pi/k)$ along an axis, parallel to the y axis, i.e.,

$$\phi=\frac{e}{\hbar c}\int_0^{n2\pi/k}A_y\,dy=0,$$

since the phase shift per half period is equal but opposite in sign to the phase shift in the next half period.

We estimate that a study of the relativistic oscillator,[23] or of the atom in the presence of the periodic Aharonov-Bohm potential (7) is also possible.

New multiplicativity results for qubit maps

Christopher King and Nilufer Koldan
Department of Mathematics, Northeastern University, Boston, Massachusetts 02115

(Received 3 January 2006; accepted 10 March 2006; published online 26 April 2006)

Let Φ be a trace-preserving, positivity-preserving (but not necessarily completely positive) linear map on the algebra of complex 2×2 matrices, and let Ω be any finite-dimensional completely positive map. For $p=2$ and $p\geqslant 4$, we prove that the maximal p-norm of the product map $\Phi\otimes\Omega$ is the product of the maximal p-norms of Φ and Ω. Restricting Φ to the class of completely positive maps, this settles the multiplicativity question for all qubit channels in the range of values $p\geqslant 4$. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2191787]

I. INTRODUCTION AND STATEMENT OF RESULTS

Qubit maps provide a useful laboratory for exploring methods and conjectures in quantum information theory. In particular they can serve as a testing ground for approaches to the problem of additivity of minimal entropy, and the related issues of Holevo capacity and entanglement of formation.[18] In this article we will focus on the maximal p-norm and consider the question of its multiplicativity for a product map, when one of the factors in the product is a qubit map. For values of p close to one this question is directly related to the additivity of minimal entropy, and hence to the circle of problems mentioned previously.

Recall first that the Schatten norm of a matrix A is defined for $p\geqslant 1$ as

$$\|A\|_p=(\mathrm{Tr}|A|^p)^{1/p}=(\mathrm{Tr}(A^*A)^{p/2})^{1/p}. \tag{1}$$

Let Φ be a linear map on the matrix algebra $\mathbb{C}^{d\times d}$, then the maximal p-norm of Φ is defined as

$$\nu_p(\Phi)=\sup_{\rho}\|\Phi(\rho)\|_p=\sup_{|\psi\rangle}\|\Phi(|\psi\rangle\langle\psi|)\|_p, \tag{2}$$

where the first sup runs over states in $\mathbb{C}^{d\times d}$, the second sup runs over pure states (normalized vectors in $\mathbb{C}^d$), and the second equality follows by convexity of the p-norm. It is natural to define another norm $||\Phi||_{1\to p}$ by instead taking the sup over all matrices A satisfying $||A||_1=1$, and this has been considered in other works;[19,6] however for the applications in this article we are interested only in the quantity defined in (2). In the case $d=2$ we will refer to Φ as a *qubit* map.

Recall that the map Φ is positivity preserving if $\Phi(A)\geqslant 0$ for every $A\geqslant 0$, and trace preserving if $\mathrm{Tr}\,\Phi(A)=\mathrm{Tr}(A)$. The map is completely positive (CP) if in addition $\Phi\otimes I_{d'}$ is positivity preserving for every dimension d'. A *channel* is a CP, trace-preserving map.

Amosov and Holevo[2] conjectured that the maximal p-norm is multiplicative for products of channels, that is for any channels Φ and Ω and for all $p\geqslant 1$

$$\nu_p(\Phi\otimes\Omega)=\nu_p(\Phi)\nu_p(\Omega). \tag{3}$$

Later Werner and Holevo[20] found a family of d-dimensional channels Ψ for which $\nu_p(\Psi\otimes\Psi)>\nu_p(\Psi)^2$ for p sufficiently large ($p>4.78\ldots$ for $d=3$). No such example is known for $d=2$, and the original conjecture (3) survives for the case where at least one of the channels Φ, Ω is a qubit channel.

In our main result we prove (3) for the case where Φ is a trace-preserving, positivity-preserving qubit map, where Ω is any finite-dimensional completely positive map, and where $p=2$ or $p\geqslant 4$. We do *not* assume that Φ is completely positive. Indeed it is essential for our proof

that we consider the larger class of positivity preserving but not completely positive maps. Previous work on entrywise positive maps[14] has provided other examples where multiplicativity holds for a class of non-CP maps, in the range $p \geqslant 2$.

Theorem 1: *Let* Φ *be a trace-preserving, positivity-preserving qubit map, and* Ω *any finite-dimensional completely positive map. Then for* $p=2$ *and for all* $p \geqslant 4$,

$$\nu_p(\Phi \otimes \Omega) = \nu_p(\Phi)\nu_p(\Omega). \tag{4}$$

There has been a lot of work on the additivity and multiplicativity question for quantum channels, and (4) has been established for special classes of qubit channels, including the depolarizing channel,[5,3,7,1] unital qubit channels,[15,10] and some classes of nonunital qubit channels.[11,12,17,8] Theorem 1 settles the question of multiplicativity for all qubit channels, at least in the range $p \geqslant 4$ (the case $p=2$ was proved in Ref. 11). It should be noted that (4) is false in general for positivity-preserving qubit maps if $p<2$, as can be seen with the example $\Phi \otimes I$ where $\Phi(\rho)=\rho^T$. We are not aware of any counterexamples to (4) for $2<p<4$.

The proof of Theorem 1 uses the following matrix inequality which is of independent interest.

Theorem 2: *Let* $A, B, C, D \in \mathbb{C}^{d\times d}$ *for some* $d \geqslant 1$. *Then for* $p=2$ *and for all* $p \geqslant 4$,

$$\left\| \begin{pmatrix} A & B \\ C & D \end{pmatrix} \right\|_p \leqslant \left\| \begin{pmatrix} \|A\|_p & \|B\|_p \\ \|C\|_p & \|D\|_p \end{pmatrix} \right\|_p \tag{5}$$

Inequality (5) was first derived by Nathanson.[16] It had been known previously in the cases where $A=D$ and $B=C$,[4] where $\begin{pmatrix} A & B \\ C & D \end{pmatrix}$ is positive semidefinite,[12] and where all matrices A, B, C, and D are diagonal.[13] We conjecture that the inequality holds in the interval $2 \leqslant p \leqslant \infty$, and that the reverse inequality holds in the interval $1 \leqslant p \leqslant 2$ (it is easy to see that equality holds at $p=2$). Proving this conjecture would also establish the noncommutative version of Hanner's inequality.[4]

The article is organized as follows. In Sec. II we prove Theorem 1 for a special subclass of qubit maps, making use of the inequality (5). In Sec. III we recall a result of Gorini and Sudarshan[9] on the classification of extreme affine maps on $\mathbb{R}^n$ which map the unit ball into itself. Combining the Gorini-Sudarshan classification with the representation of qubit maps as affine maps on $\mathbb{R}^3$, we derive Lemma 4, which implies that any trace-preserving, positivity-preserving qubit map Φ can be expressed as a convex combination of qubit maps from the subclass of Sec. II, all of which share the same maximal output p-norm as Φ. Using Lemma 4, we then prove Theorem 1 for all qubit maps. Section IV contains the proof of Theorem 2, which makes use of previously known matrix inequalities.[12]

II. PROOF FOR SPECIAL CLASS OF MAPS

In this section we prove Theorem 1 for a special class of positivity-preserving, trace-preserving qubit maps. In order to describe this class we will use the representation of qubit states by points in the Bloch sphere, and qubit maps by affine linear maps on $\mathbb{R}^3$.

A qubit state ρ is represented by a point in the unit ball in $\mathbb{R}^3$ via the relation

$$\rho = \frac{1}{2}\left(I + \sum x_i \sigma_i\right) \mapsto x = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix}, \tag{6}$$

where I is the identity matrix and $\{\sigma_1, \sigma_2, \sigma_3\}$ are the Pauli matrices. Positivity of ρ is equivalent to

$$\sum x_i^2 \leqslant 1. \tag{7}$$

A trace-preserving qubit map Φ sends the state $\rho=\frac{1}{2}(I+\Sigma x_i\sigma_i)$ to the state $\Phi(\rho)=\frac{1}{2}(I+\Sigma y_i\sigma_i)$, where $y \in \mathbb{R}^3$ is obtained from x by applying an affine linear map, that is

$$y = Ax + v \tag{8}$$

for some real 3×3 matrix A, and some vector $v \in \mathbb{R}^3$.

Conjugation by a unitary matrix $U \in \mathrm{SU}(2)$ maps ρ to $U\rho U^*$, and this acts on the Bloch sphere by a rotation, sending $x \mapsto R(U)x$ for some $R(U) \in \mathrm{SO}(3)$. If unitary conjugations by matrices U, V are performed on the domain and range of the map Φ respectively, then representation (8) is replaced by

$$y' = R(V)AR(U)x + R(V)v. \tag{9}$$

Since the map $U \mapsto R(U)$ is onto, the singular value decomposition implies that it is always possible to find unitary matrices U, V so that $R(V)AR(U)$ is diagonal (though the diagonal entries need not be all positive). Spectral properties of the map Φ (in particular its maximal output p-norm) are invariant under unitary conjugations in its domain and range, hence there is no loss of generality in assuming that the matrix A in (8) is diagonal. Using representation (8), we will say that Φ is in *diagonal form* if

$$A = \begin{pmatrix} \lambda_1 & 0 & 0 \\ 0 & \lambda_2 & 0 \\ 0 & 0 & \lambda_3 \end{pmatrix}, \quad v = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix}. \tag{10}$$

Note that Φ is unital if and only if $v=0$ in (8). We now prove Theorem 1 for a special class of maps.

Lemma 3: *Let* Φ *be a positivity-preserving, trace-preserving qubit map in diagonal form* (10), *and suppose that at most one of the numbers* (v_1, v_2, v_3) *is nonzero. Then* (4) *holds for any completely positive map* Ω, *for* $p=2$ *and for* $p \geq 4$.

Proof: By permuting coordinates we can assume that only the third component of v can be nonzero, so that $v_1 = v_2 = 0$. The diagonal entries of A may be positive or negative. However we can change the signs of any two diagonal entries by conjugating with a Pauli matrix, without destroying the diagonal property and without changing the third diagonal entry; for example conjugating with σ_3 changes the signs of λ_1 and λ_2, and leaves λ_3 unchanged. Using this additional freedom we can assume that

$$\lambda_1 \geq 0, \quad \lambda_2 \geq 0. \tag{11}$$

Let ρ_{12} be a bipartite state on $\mathbb{C}^2 \otimes \mathbb{C}^d$ for some d, written in block form

$$\rho_{12} = \begin{pmatrix} X & Y \\ Y^* & Z \end{pmatrix}. \tag{12}$$

Let Ω be a completely positive map on $\mathbb{C}^d$, then

$$(I \otimes \Omega)(\rho_{12}) = \begin{pmatrix} A & B \\ B^* & C \end{pmatrix}, \tag{13}$$

where $A = \Omega(X)$, $B = \Omega(Y)$, and $C = \Omega(Z)$. Since Ω is completely positive, and ρ_{12} is a state, it follows that $(I \otimes \Omega)(\rho_{12})$ is positive semidefinite, and hence $B = A^{1/2} R C^{1/2}$ where R is a contraction. This implies in particular that for all $p \geq 1$

$$\|B\|_p \leq \|A\|_p^{1/2} \|C\|_p^{1/2}. \tag{14}$$

We will encounter the 2×2 matrices of p-norms

$$\begin{pmatrix} \|A\|_p & \|B\|_p \\ \|B\|_p & \|C\|_p \end{pmatrix}, \quad \begin{pmatrix} \|A\|_p & i\|B\|_p \\ -i\|B\|_p & \|C\|_p \end{pmatrix} \tag{15}$$

and we note now that (14) implies the positivity of these matrices, or more generally

$$\begin{pmatrix} \|A\|_p & z\|B\|_p \\ z^*\|B\|_p & \|C\|_p \end{pmatrix} \geqslant 0 \tag{16}$$

for any $z \in \mathbb{C}$ satisfying $|z| \leqslant 1$.

Using the diagonal form (10) and the assumption that v_3 is the only nonzero component of v, we have

$$(\Phi \otimes \Omega)(\rho_{12}) = \begin{pmatrix} c_{++}A + c_{+-}C & \lambda_1 B_1 - i\lambda_2 B_2 \\ \lambda_1 B_1 + i\lambda_2 B_2 & c_{--}A + c_{-+}C \end{pmatrix}, \tag{17}$$

where $B = B_1 - iB_2$ with B_1, B_2 hermitian, and where

$$c_{+\pm} = (1 + v_3 \pm \lambda_3)/2, \quad c_{-\pm} = (1 - v_3 \pm \lambda_3)/2. \tag{18}$$

Since Φ is positivity-preserving, it maps the state $\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ into a positive semidefinite matrix, and this implies that

$$c_{++} \geqslant 0, \quad c_{--} \geqslant 0. \tag{19}$$

Similarly it maps the state $\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ to a positive semidefinite matrix, hence also

$$c_{+-} \geqslant 0, \quad c_{-+} \geqslant 0 \tag{20}$$

A. The case $p=2$

Using representation (17),

$$\mathrm{Tr}((\Phi \otimes \Omega)(\rho_{12}))^2 = \mathrm{Tr}(c_{++}A + c_{+-}C)^2 + 2(\lambda_1^2 \mathrm{Tr}\, B_1^2 + \lambda_2^2 \mathrm{Tr}\, B_2^2) + \mathrm{Tr}(c_{--}A + c_{-+}C)^2. \tag{21}$$

Using the positivity of the coefficients (19), (20) and convexity of the 2-norm gives

$$\mathrm{Tr}((\Phi \otimes \Omega)(\rho_{12}))^2 \leqslant (c_{++}\|A\|_2 + c_{+-}\|C\|_2)^2 + 2(\lambda_1^2 \mathrm{Tr}\, B_1^2 + \lambda_2^2 \mathrm{Tr}\, B_2^2) + (c_{--}\|A\|_2 + c_{-+}\|C\|_2)^2. \tag{22}$$

Define

$$\lambda = \max\{\lambda_1, \lambda_2\} \tag{23}$$

then it follows that

$$\lambda_1^2 \mathrm{Tr}\, B_1^2 + \lambda_2^2 \mathrm{Tr}\, B_2^2 \leqslant \lambda^2 \mathrm{Tr}\, B^* B = \lambda^2 \|B\|_2^2. \tag{24}$$

Using (24) the right-hand side of (22) can be rewritten as the trace squared of a 2×2 matrix, leading to

$$\mathrm{Tr}((\Phi \otimes \Omega)(\rho_{12}))^2 \leqslant \mathrm{Tr}\begin{pmatrix} c_{++}\|A\|_2 + c_{+-}\|C\|_2 & \lambda\|B\|_2 \\ \lambda\|B\|_2 & c_{--}\|A\|_2 + c_{-+}\|C\|_2 \end{pmatrix}^2 = \mathrm{Tr}\left(\Phi\begin{pmatrix} \|A\|_2 & z\|B\|_2 \\ z^*\|B\|_2 & \|C\|_2 \end{pmatrix}\right)^2, \tag{25}$$

where

$$z = \begin{cases} 1 & \text{if} \quad \lambda = \lambda_1 \\ i & \text{if} \quad \lambda = \lambda_2. \end{cases} \tag{26}$$

As noted in (16) the matrix

$$\begin{pmatrix} \|A\|_2 & z\|B\|_2 \\ z^*\|B\|_2 & \|C\|_2 \end{pmatrix}$$

is positive semidefinite, hence by definition of the maximal 2-norm we get

$$\|(\Phi\otimes\Omega)(\rho_{12})\|_2 \leqslant \left\|\Phi\begin{pmatrix} \|A\|_2 & z\|B\|_2 \\ z^*\|B\|_2 & \|C\|_2 \end{pmatrix}\right\|_2 \leqslant \nu_2(\Phi)\mathrm{Tr}\begin{pmatrix} \|A\|_2 & z\|B\|_2 \\ z^*\|B\|_2 & \|C\|_2 \end{pmatrix}$$
$$= \nu_2(\Phi)(\|A\|_2+\|C\|_2). \tag{27}$$

As $A=\Omega(X)$ and $C=\Omega(Z)$, this yields

$$\|(\Phi\otimes\Omega)(\rho_{12})\|_2 \leqslant \nu_2(\Phi)\nu_2(\Omega)(\mathrm{Tr}\,X+\mathrm{Tr}\,Z) = \nu_2(\Phi)\nu_2(\Omega) \tag{28}$$

as $\mathrm{Tr}\,X+\mathrm{Tr}\,Z=\mathrm{Tr}\,\rho_{12}=1$. As this holds for any state ρ_{12} we deduce that

$$\nu_2(\Phi\otimes\Omega) \leqslant \nu_2(\Phi)\nu_2(\Omega). \tag{29}$$

The inequality in the reverse direction follows by restriction to product states, hence this completes the proof for the case $p=2$.

B. The case $p\geqslant 4$

We apply Theorem 2 to (17) to conclude that for $p\geqslant 4$,

$$\|(\Phi\otimes\Omega)(\rho_{12})\|_p \leqslant \left\|\begin{pmatrix} \|c_{++}A+c_{+-}C\|_p & \|\lambda_1B_1-i\lambda_2B_2\|_p \\ \|\lambda_1B_1+i\lambda_2B_2\|_p & \|c_{--}A+c_{-+}C\|_p \end{pmatrix}\right\|_p. \tag{30}$$

Define the 2×2 real symmetric matrix

$$M=\begin{pmatrix} \|c_{++}A+c_{+-}C\|_p & \|\lambda_1B_1-i\lambda_2B_2\|_p \\ \|\lambda_1B_1+i\lambda_2B_2\|_p & \|c_{--}A+c_{-+}C\|_p \end{pmatrix}, \tag{31}$$

so that (30) can be written

$$\|(\Phi\otimes\Omega)(\rho_{12})\|_p \leqslant \|M\|_p. \tag{32}$$

The positivity results (19) and (20) imply that

$$\begin{aligned} \|c_{++}A+c_{+-}C\|_p &\leqslant c_{++}\|A\|_p + c_{+-}\|C\|_p, \\ \|c_{--}A+c_{-+}C\|_p &\leqslant c_{--}\|A\|_p + c_{-+}\|C\|_p. \end{aligned} \tag{33}$$

Further, recall (23) and suppose first that $\lambda=\lambda_1$, so that $\lambda_1-\lambda_2\geqslant 0$. Then

$$\|\lambda_1B_1-i\lambda_2B_2\|_p = \|(\lambda_1-\lambda_2)B_1+\lambda_2B\|_p \leqslant (\lambda_1-\lambda_2)\|B_1\|_p+\lambda_2\|B\|_p \leqslant \lambda\|B\|_p, \tag{34}$$

where in the last inequality we used $\|B_1\|_p=\frac{1}{2}\|B+B^*\|_p\leqslant\|B\|_p$. A similar argument leads to the same conclusion if $\lambda=\lambda_2$.

We would like to replace the entries of M with the bounds on the right-hand sides of (33) and (34), and argue that $\|M\|_p$ must increase under this substitution. However the matrix M may not be positive semidefinite (since Φ is not necessarily completely positive) so this is not immediately obvious. To see that it does in fact increase, let $p=2q$ so that

$$\|M\|_p = (\|M^2\|_q)^{1/2}. \tag{35}$$

Then the matrix $M^2=M^*M$ is positive semidefinite with positive entries, and it is easy to see that this implies $\|M^2\|_q$ is an increasing function of the entries of M^2. Since M is also entrywise positive, the entries of M^2 are increasing functions of the entries of M, and therefore so is $\|M^2\|_q$.

Therefore $\|M\|_p$ increases when the bounds (33), (34) are inserted in the right-hand side of (32), and we get

$$\|(\Phi \otimes \Omega)(\rho_{12})\|_p \leq \left\| \begin{pmatrix} c_{++}\|A\|_p + c_{+-}\|C\|_p & \lambda\|B\|_p \\ \lambda\|B\|_p & c_{--}\|A\|_p + c_{-+}\|C\|_p \end{pmatrix} \right\|_p. \tag{36}$$

Now we note that the right-hand side of (36) is unchanged if the upper-right entry $\lambda\|B\|_p$ is replaced by $z\lambda\|B\|_p$ and the lower left-hand entry by $z^*\lambda\|B\|_p$ for any $|z|=1$. Hence using the notation (26) again, (36) implies

$$\|(\Phi \otimes \Omega)(\rho_{12})\|_p \leq \left\| \Phi \begin{pmatrix} \|A\|_p & z\|B\|_p \\ z^*\|B\|_p & \|C\|_p \end{pmatrix} \right\|_p. \tag{37}$$

We now repeat the arguments used above in the case $p=2$, to conclude that

$$\|(\Phi \otimes \Omega)(\rho_{12})\|_p \leq \nu_p(\Phi)(\|A\|_p + \|C\|_p) \leq \nu_p(\Phi)\nu_p(\Omega)(\mathrm{Tr}\, X + \mathrm{Tr}\, Z) = \nu_p(\Phi)\nu_p(\Omega). \tag{38}$$

As this holds for any state ρ_{12} we again deduce

$$\nu_p(\Phi \otimes \Omega) \leq \nu_p(\Phi)\nu_p(\Omega) \tag{39}$$

and this completes the proof for the case $p \geq 4$.

III. REDUCTION TO SPECIAL FORM

In this section we will show that the general case of Theorem 1 follows from Lemma 3. Recall that a trace-preserving, positivity-preserving qubit map Φ is represented by an affine linear map on $\mathbb{R}^3$ as in (8), sending the Bloch sphere (the closed unit ball in $\mathbb{R}^3$) into an ellipsoid. We will refer to the latter as the *image ellipsoid* of Φ.

For a positivity-preserving, trace-preserving qubit map Φ, the minimal output entropy and maximal output p-norm are all achieved on the same input state. That is, there is a pure state $|\psi\rangle$ such that for all $p \geq 1$

$$\nu_p(\Phi) = \sup_\rho \|\Phi(\rho)\|_p = \|\Phi(|\psi\rangle\langle\psi|)\|_p. \tag{40}$$

Define the function

$$h_p(r) = \left(\left(\frac{1+r}{2} \right)^p + \left(\frac{1-r}{2} \right)^p \right)^{1/p}. \tag{41}$$

The spectrum of $\Phi(|\psi\rangle\langle\psi|)$ is $\{(1\pm r)/2\}$, for some $0 \leq r \leq 1$. Accordingly the value of (40) is

$$\nu_p(\Phi) = h_p(r). \tag{42}$$

We will denote by $\mathcal{C}_r$ the set of all positivity-preserving, trace-preserving qubit maps whose maximal output p-norm is at most $h_p(r)$, that is

$$\mathcal{C}_r = \{\Phi : \nu_p(\Phi) \leq h_p(r)\}. \tag{43}$$

Note that $\mathcal{C}_r$ does not depend on p. Geometrically, $\mathcal{C}_r$ consists of the positivity-preserving qubit maps for which the image ellipsoid lies inside the sphere of radius r centered at the origin.

It is clear that $\mathcal{C}_r$ is a convex set. The next result shows that the extreme points of $\mathcal{C}_r$ have a simple form. Recall the definition (10) of the diagonal form of a qubit map.

Lemma 4: *Let Φ be an extreme point in $\mathcal{C}_r$, represented in diagonal form by the affine map $x \mapsto Ax+v$ on $\mathbb{R}^3$. Then at most one of the components of v is nonzero.*

Lemma 4 is a consequence of the following Theorem of Gorini and Sudarshan,[9] which classifies all extreme affine maps of $\mathbb{R}^n$ sending the closed unit ball into itself.

Theorem 5: *[Gorini-Sudarshan] Let D_n be the set of affine maps of $\mathbb{R}^n$ which send the closed unit ball into itself. Denote by (B,w) the map $x \mapsto Bx+w$, where $w \in \mathbb{R}^n$ and $B \in \mathbb{R}^{n\times n}$. If (B,w) is an extreme point in D_n, then there are orthogonal matrices $Q_1, Q_2 \in O(n)$, and real numbers $0 \leqslant \kappa \leqslant 1$, $0 < \delta \leqslant 1$ such that*

$$Q_1 w = (0, \ldots, 0, \delta(1-\kappa^2)), \quad Q_1 B Q_2 = \mathrm{Diag}(m, \ldots, m, \kappa m), \tag{44}$$

where $m = \sqrt{1+\kappa^2\delta^2-\delta^2}$ and where $\mathrm{Diag}(d_1, d_2, \ldots)$ denotes the diagonal matrix with entries $d_1, d_2, \ldots$.

To derive Lemma 4 from Theorem 5, we identify $\mathcal{C}_r$ with the set of scaled affine maps $rD_3 = \{(rB, rw) : (B,w) \in D_3\}$. Hence every extreme map Φ in $\mathcal{C}_r$ corresponds to an affine map (rB, rw) where (B,w) satisfies (44). Further, the matrix Q_1 in (44) is in $O(3)$, and hence either $Q_1 \in SO(3)$ or $-Q_1 \in SO(3)$; similarly for Q_2. Since every rotation in $SO(3)$ can be implemented by a unitary conjugation in SU(2) [see the discussion leading up to (9)], this shows that Φ can be written in diagonal form with

$$A = \begin{pmatrix} \pm rm & 0 & 0 \\ 0 & \pm rm & 0 \\ 0 & 0 & \pm r\kappa m \end{pmatrix}, \quad v = \begin{pmatrix} 0 \\ 0 \\ \pm r\delta(1-\kappa^2) \end{pmatrix}, \tag{45}$$

and this proves Lemma 4.

In the remainder of this section we will show that Theorem 1 follows from Lemma 3 and Lemma 4. Accordingly, suppose that Φ is a trace-preserving, positivity-preserving qubit map satisfying (42) for some $0 \leqslant r \leqslant 1$, so that

$$\nu_p(\Phi) = h_p(r). \tag{46}$$

Then it is sufficient to show that for any completely positive map Ω,

$$\nu_p(\Phi \otimes \Omega) \leqslant h_p(r)\,\nu_p(\Omega). \tag{47}$$

Now $\mathcal{C}_r$ is a closed bounded convex subset of $\mathbb{R}^{12}$ (since the matrix A and vector v together have 12 entries), hence by Caratheodory's Theorem any element of $\mathcal{C}_r$ can be written as a convex combination of at most 13 of its extreme points. The map Φ is in $\mathcal{C}_r$, hence there are extreme maps $\{\Phi_i\} \in \mathcal{C}_r$ such that

$$\Phi = \sum_i a_i \Phi_i, \tag{48}$$

where $a_i \geqslant 0$ and $\Sigma a_i = 1$. Since $\{\Phi_i\}$ are in $\mathcal{C}_r$ we also have

$$\nu_p(\Phi_i) \leqslant h_p(r). \tag{49}$$

Further, combining Lemmas 4 and 3, we deduce that

$$\nu_p(\Phi_i \otimes \Omega) = \nu_p(\Phi_i)\,\nu_p(\Omega) \leqslant h_p(r)\,\nu_p(\Omega) \tag{50}$$

for all i. By convexity of the p-norm it follows from (48) and (50) that

$$\nu_p(\Phi \otimes \Omega) \leqslant \sum_i a_i \nu_p(\Phi_i \otimes \Omega) = \sum_i a_i \nu_p(\Phi_i)\,\nu_p(\Omega) \leqslant h_p(r)\,\nu_p(\Omega), \tag{51}$$

and this proves (47).

IV. PROOF OF THEOREM 2

Let $p=2q$ and define

$$M=\begin{pmatrix} A & B \\ C & D \end{pmatrix}. \tag{52}$$

Then M^*M is positive semidefinite, and we write it in block form as

$$M^*M=\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}. \tag{53}$$

Now we apply the result of Theorem 1(b) from Ref. 12 to the matrix M^*M to deduce that

$$\|M^*M\|_q \leqslant \left\| \begin{pmatrix} \|M_{11}\|_q & \|M_{12}\|_q \\ \|M_{21}\|_q & \|M_{22}\|_q \end{pmatrix} \right\|_q \tag{54}$$

for all $q \geqslant 2$. Further, $M_{11}=A^*A+C^*C$, hence

$$\|M_{11}\|_q \leqslant \|A^*A\|_q + \|C^*C\|_q = \|A\|_p^2 + \|C\|_p^2. \tag{55}$$

Similarly

$$\|M_{12}\|_q = \|M_{21}\|_q \leqslant \|A\|_p \|B\|_p + \|C\|_p \|D\|_p \tag{56}$$

and

$$\|M_{22}\|_q \leqslant \|B\|_p^2 + \|D\|_p^2. \tag{57}$$

For a positive semidefinite 2×2 matrix the q-norm is an increasing function of the entries. Hence combining (54) with (55)–(57) gives

$$\|M^*M\|_q \leqslant \|m^*m\|_q, \tag{58}$$

where

$$m=\begin{pmatrix} \|A\|_p & \|B\|_p \\ \|C\|_p & \|D\|_p \end{pmatrix}. \tag{59}$$

Taking a square root of both sides gives

$$\|M\|_p \leqslant \|m\|_p \tag{60}$$

which is the stated result.

Superconformal symmetry in the interacting theory of (2,0) tensor multiplets and self-dual strings

Pär Arvidsson[a)]
Department of Fundamental Physics, Chalmers University of Technology, SE-412 96 Göteborg, Sweden

(Received 14 October 2005; accepted 14 February 2006; published online 6 April 2006)

We investigate the concept of superconformal symmetry in six dimensions, applied to the interacting theory of (2,0) tensor multiplets and self-dual strings. The action of a superconformal transformation on the superspace coordinates is found, both from a six-dimensional perspective and by using a superspace with eight bosonic and four fermionic dimensions. The transformation laws for all fields in the theory are derived, as well as general expressions for the transformation of on-shell superfields. Superconformal invariance is shown for the interaction of a self-dual string with a background consisting of on-shell tensor multiplet fields, and we also find an interesting relationship between the requirements of superconformal invariance and those of a local fermionic κ-symmetry. Finally, we try to construct a superspace analogue of the Poincaré dual to the string world-sheet and consider its properties under superconformal transformations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2184810]

I. INTRODUCTION

One of the most interesting discoveries in string/M-theory during the past decade is without doubt the six-dimensional (2,0) theories, named after the supersymmetry algebra under which they are invariant.[1] These are superconformal quantum theories without dynamical gravity, and first appeared in a compactification of Type IIB string theory on a four-dimensional hyper-Kähler manifold.[2] They obey an *ADE* classification (see Ref. 3 for an intrinsically six-dimensional motivation for why the simply laced Lie algebra series A, D, and E appear) but have no other discrete or continuous parameters. However, the theories have a moduli space parametrized by the expectation values of a set of scalar fields.

There is a second origin for the A-series of these theories in terms of M-theory, where they arise as the world-volume theory on a stack of parallel $M5$-branes.[4,5] More specifically, a stack of $r+1$ branes yields the A_r version of (2,0) theory, where r denotes the rank of the associated Lie algebra. The fluctuations of the $M5$-branes are described by r so-called (2,0) tensor multiplets and the $5r$ moduli correspond to the transverse distances between the branes. It is also possible for membranes to stretch between two $M5$-branes;[6–8] the intersections will then appear as self-dual strings from the six-dimensional world-volume perspective on the $M5$-brane. We get in total $r(r+1)/2$ different species of such strings, corresponding to the number of ways to connect the branes. The string tension is proportional to the distance between the branes in question, and is therefore related to the moduli of the theory. Specifically, if the branes coincide, the strings become tensionless. This picture yields in a simple way the different degrees of freedom of (2,0) theory; for a more complete discussion, see, e.g., Ref. 9.

An intrinsically six-dimensional formulation of the (2,0) theories is still lacking, and it is the ultimate goal of our research to find such a definition. In our previous work, we have pursued a program where we consider the theory at a point away from the origin of its moduli space, where

a)Electronic mail: par.arvidsson@chalmers.se

the strings are tensile. This introduces a scale in the theory and breaks the conformal invariance spontaneously, but also provides a basis for doing perturbation theory, since in the limit of large string tension, the theory describes the well understood free (2,0) tensor multiplet and free self-dual strings. The dimensionless expansion parameter will then be the square of some typical energy divided by the string tension. For simplicity, we have chosen to work in the A_1 version of (2,0) theory, which includes a single type of string and a single tensor multiplet.

In this paper, we consider the hitherto uninvestigated superconformal symmetry of our model. It is well known that superconformal field theories cannot exist in space-times with more than six dimensions. Moreover, in six dimensions, the largest possible supersymmetry consistent with superconformal invariance is $\mathcal{N}=(2,0)$. This means that (2,0) theory, regarded as a superconformal theory, has the largest possible supersymmetry in the highest possible dimension. This observation alone provides a motivation for studying these theories.

The aim of the present paper is first to provide a framework for the study of superconformal invariance in six-dimensional (2,0) theory by using superfields. Second, we want to investigate whether our model[10] for a self-dual string interacting with a tensor multiplet background is superconformally invariant, and in what sense. Finally, we would like to use the new superconformal tools to find some clues on how to formulate the full interacting theory, i.e., when the tensor multiplet fields do not obey their free equations of motion.

It is our intention to make the paper self-contained, thereby reviewing and summarizing some well-known results on conformal and superconformal symmetry. We think that it is worthwhile to include these, in order to understand how the superfield transformations work and how they are derived. It is also, in some cases, nontrivial to adapt the known results to our notations and conventions.

The outline of this paper is as follows: Section II is devoted to the study of (bosonic) conformal transformations in six dimensions, as a warm-up exercise preceding the superconformal model. We find explicit expressions for the action of the conformal group on the space-time coordinates, both from a six-dimensional perspective and by considering a projective hypercone in eight dimensions, where the conformal transformations act linearly. We also study how different fields behave under conformal transformations, especially the ones in the bosonic sector of the (2,0) tensor multiplet. The results of Sec. II are not new, but still useful from a pedagogical point of view.

Section III discusses superconformal symmetry. As in the preceding section, we first find how the transformations act on coordinates, this time in a superspace with six bosonic and 16 fermionic dimensions. The coordinate transformations are also found by considering a projective supercone in a higher-dimensional superspace; a method which, to the best of our knowledge, has not appeared previously in the literature. Next, we use a superfield formalism as a way of compactifying and simplifying the notation and derive how superconformal transformations act on the superfields of the complete (2,0) tensor multiplet and on self-dual spinning strings. The explicit transformation laws are used to show that the model describing a string interacting with a tensor multiplet background is superconformally invariant. We find the new and nontrivial result that the requirements of superconformal symmetry and those of a local fermionic κ-symmetry impose similar restrictions on the possible coupling terms, thereby indicating the uniqueness of the theory.

Finally, Sec. IV discusses the construction of a superspace analogue of the Poincaré dual to the string world-sheet and its properties under superconformal transformations.

II. CONFORMAL INVARIANCE IN THE BOSONIC THEORY

Before discussing the issue of superconformal invariance, it is worthwhile to consider a simpler case, which still contains some important aspects of the problem. Therefore, we begin by working with the model describing a spinless self-dual string interacting with the bosonic part of the (2,0) tensor multiplet in six dimensions.[9] The results in this section have appeared previously in the literature, but it is nevertheless useful to review some aspects in order to get a complete picture. We will also refer (for comparison) to formulas in this section later in this paper, to point out similarities and differences between the bosonic and the superconformal models.

A. Conformal coordinate transformations

In this section, we consider the action of conformal transformations on the coordinates x^μ, $\mu=0,\ldots,5$, in a six-dimensional space-time. These transformations are called *passive*, meaning that they act on the coordinates themselves, rather than on the fields of the theory.

Conformal transformations act on space-time in such a way that the *angle* between two intersecting curves is left invariant. This means that the infinitesimal proper time interval

$$\mathrm{d}\tau^2 = -\,\eta_{\mu\nu}\,\mathrm{d}x^\mu\,\mathrm{d}x^\nu \tag{2.1}$$

transforms according to

$$\mathrm{d}\tau^2 \to \Omega^2(x)\mathrm{d}\tau^2, \tag{2.2}$$

where $\eta_{\mu\nu}$ is the flat space-time metric (with "mostly plus" signature) and $\Omega(x)$ denotes a space-time dependent quantity that also involves the parameters of the conformal transformation. For an infinitesimal transformation, such that $\Omega(x)=1+\Lambda(x)$, this yields that

$$\delta(\mathrm{d}\tau^2) = 2\Lambda(x)\mathrm{d}\tau^2, \tag{2.3}$$

where $\Lambda(x)$ is an infinitesimal function.

It is well known that the most general infinitesimal coordinate transformation that respects Eq. (2.3) is given by

$$\delta x^\mu = a^\mu + \omega^{\mu\nu}x_\nu + \lambda x^\mu + c^\mu x^2 - 2c\cdot x x^\mu, \tag{2.4}$$

where $c\cdot x \equiv \eta_{\mu\nu}c^\mu x^\nu = c_\nu x^\nu$. The (constant) parameters a^μ, $\omega^{\mu\nu}$, λ, and c^μ are related to the different transformations of the conformal group according to the following table:

Symmetry	Generator	Parameter
Translations	$P_\mu=\partial_\mu$	a^μ
Rotations and Lorentz boosts	$M_{\mu\nu}=x_{[\nu}\partial_{\mu]}$	$\omega^{\mu\nu}$
Dilatations	$D=x^\mu\partial_\mu$	λ
Special conformal transformations	$K_\mu=x^2\partial_\mu-2x_\mu x^\nu\partial_\nu$	c^μ

where the differential expressions for the generators make the equation

$$\delta x^\mu = (a^\nu P_\nu + \omega^{\nu\rho}M_{\nu\rho} + \lambda D + c^\nu K_\nu)x^\mu \tag{2.5}$$

valid. In total, we have 28 parameters, in agreement with the dimensionality of the conformal group in six dimensions, denoted by SO(6,2).

From Eq. (2.4), it is easily shown that the differential $\mathrm{d}x^\mu$ transforms according to

$$\delta(\mathrm{d}x^\mu) = (\omega^{\mu\nu} + 4c^{[\mu}x^{\nu]})\mathrm{d}x_\nu + (\lambda - 2c\cdot x)\mathrm{d}x^\mu, \tag{2.6}$$

which implies that the proper time interval indeed transforms according to Eq. (2.3) with $\Lambda(x)=\lambda-2c\cdot x$.

Leaving the coordinate transformations aside for a while, we turn to the commutation relations relating the generators of the conformal group to each other. By direct calculation, it is easily verified that the differential operators defined in the table above obey

$$[P_\mu, M_{\nu\rho}] = -\,\eta_{\mu[\nu}P_{\rho]}, \quad [P_\mu, D] = P_\mu,$$

$$[K_\mu, M_{\nu\rho}] = -\,\eta_{\mu[\nu}K_{\rho]}, \quad [K_\mu, D] = -K_\mu,$$

$$[P_\mu, K_\nu] = -4M_{\mu\nu} - 2\eta_{\mu\nu}D, \quad [M_{\mu\nu}, D] = 0,$$

$$[M_{\mu\nu},M^{\rho\sigma}] = 2\delta_{[\mu}{}^{[\rho}M_{\nu]}{}^{\sigma]}. \tag{2.7}$$

This defines the conformal group SO(6,2) in six dimensions. The SO(6,2) structure may be made more explicit by introducing a new set of generators $J_{\hat{\mu}\hat{\nu}}$, $\hat{\mu},\hat{\nu}=0,\ldots,7$, according to

$$M_{\mu\nu} = J_{\mu\nu},$$

$$P_\mu = 2(J_{7\mu} + J_{6\mu}),$$

$$K_\mu = 2(J_{7\mu} - J_{6\mu}),$$

$$D = 2J_{76}. \tag{2.8}$$

These obey the Lorentz-type commutation relations

$$[J_{\hat{\mu}\hat{\nu}},J_{\hat{\rho}\hat{\sigma}}] = \eta_{\hat{\rho}[\hat{\mu}}J_{\hat{\nu}]\hat{\sigma}} - \eta_{\hat{\sigma}[\hat{\mu}}J_{\hat{\nu}]\hat{\rho}}, \tag{2.9}$$

where the metric $\eta_{\hat{\mu}\hat{\nu}}=\mathrm{diag}(-1,1,1,1,1,1,1,-1)$. Thus, the conformal transformations act as rotations in an eight-dimensional space with two timelike directions.

There is a formulation (first suggested by Dirac,[11] whose work was later continued by Kastrup[12] and by Mack and Salam[13]) in which a d-dimensional space-time is regarded as a projective hypercone in a space with one extra spacelike and one extra timelike dimension, just like the one suggested in the preceding paragraph. In the higher-dimensional space, conformal symmetry acts linearly, i.e., as a rotation with the generator $J_{\hat{\mu}\hat{\nu}}$. Denote the coordinates in this space by $y^{\hat{\mu}}$, and define the projective hypercone by

$$y^2 = \eta_{\hat{\mu}\hat{\nu}}y^{\hat{\mu}}y^{\hat{\nu}} = 0. \tag{2.10}$$

This equation is clearly Lorentz invariant in the eight-dimensional space, and therefore conformally invariant from a six-dimensional point of view.

Next, let the infinitesimal rotation parameters be assembled in the matrix $\pi^{\hat{\mu}\hat{\nu}}$, such that

$$\delta y^{\hat{\mu}} = \pi^{\hat{\rho}\hat{\sigma}}J_{\hat{\rho}\hat{\sigma}}y^{\hat{\mu}} = \pi^{\hat{\mu}\hat{\sigma}}y_{\hat{\sigma}}. \tag{2.11}$$

The last equality follows from the obvious definition

$$J_{\hat{\mu}\hat{\nu}} = y_{[\hat{\nu}}\partial_{\hat{\mu}]}, \tag{2.12}$$

where the derivative acts on the y variables.

To make contact with the six-dimensional space-time, we impose that

$$\pi^{\hat{\rho}\hat{\sigma}}J_{\hat{\rho}\hat{\sigma}} = \omega^{\rho\sigma}M_{\rho\sigma} + a^\rho P_\rho + c^\rho K_\rho + \lambda D, \tag{2.13}$$

which when combined with Eq. (2.8) yields that

$$\omega^{\mu\nu} = \pi^{\mu\nu},$$

$$a^\mu = \tfrac{1}{2}(\pi^{7\mu} + \pi^{6\mu}),$$

$$c^\mu = \tfrac{1}{2}(\pi^{7\mu} - \pi^{6\mu}),$$

$$\lambda = \pi^{76}. \tag{2.14}$$

Next, we parametrize the projective hypercone by

$$y^\mu = \gamma x^\mu,$$

$$y^7 - y^6 = \gamma,$$

$$y^7 + y^6 = \gamma \eta_{\rho\sigma} x^\rho x^\sigma, \tag{2.15}$$

where γ is related to the projectiveness of the hypercone and therefore $\gamma \neq 0$.

Under a conformal transformation as in Eq. (2.11), it turns out that the quantity x^μ introduced in Eq. (2.15) must transform exactly as the coordinates x^μ in Eq. (2.4), while γ transforms according to

$$\delta\gamma = (2\eta_{\mu\nu} c^\mu x^\nu - \lambda)\gamma. \tag{2.16}$$

This shows that the surface of the projective hypercone defined in Eq. (2.10) behaves as the six-dimensional space-time we started with. In this way, we have derived the conformal coordinate transformation in Eq. (2.4) from a higher-dimensional perspective, a viewpoint that will be useful later in this paper as well. The eight-dimensional formulation also suggests a way of formulating manifestly conformally invariant quantities, an observation that hopefully will be pursued in future work.

B. Conformal field transformations

Having discussed the conformal group and its action on the six-dimensional space-time thoroughly, we now turn to the question of how the conformal group generators act on fields defined over this space-time. This action consists of two parts: one due to the dependence of the field in question on the space-time coordinate x^μ and one due to specific properties of the field itself. The latter part consists of the action of the stability subgroup of $x=0$ (the little group) on the fields, e.g., the transformation properties of a vector field under Lorentz transformations. We will (in contrast to our convention in the preceding section) adopt the *active* view on conformal transformations, meaning that the space-time coordinates are fixed but the fields change upon such a transformation. By considering the stability subgroup mentioned before, it can be found[13] that a general field $\phi^i(x)$ (where i denotes some index or indices) transforms according to

$$\begin{aligned}\delta_C \phi^i(x) = {} & a^\mu \partial_\mu \phi^i(x) + \omega^{\mu\nu}[x_\nu \partial_\mu \phi^i(x) + (\Sigma_{\mu\nu}\phi)^i(x)] + \lambda[x^\mu \partial_\mu \phi^i(x) + w\phi^i(x)] \\ & + c^\mu[x^2 \partial_\mu \phi^i(x) - 2x_\mu x^\nu \partial_\nu \phi^i(x) + 4x^\nu (\Sigma_{\mu\nu}\phi)^i(x) - 2x_\mu w \phi^i(x) + (k_\mu \phi)^i(x)],\end{aligned} \tag{2.17}$$

where $\Sigma_{\mu\nu}$, w, and k_μ are defined through

$$[M_{\mu\nu}, \phi^i(0)] = (\Sigma_{\mu\nu}\phi)^i(0),$$

$$[D, \phi^i(0)] = w\phi^i(0),$$

$$[K_\mu, \phi^i(0)] = (k_\mu \phi)^i(0). \tag{2.18}$$

Here, $M_{\mu\nu}$, D, and K_μ should not be confused with the differential expressions in the table above; in these equations (when acting on fields), they denote the full generators of Lorentz transformations, dilatations and special conformal transformations, respectively.

Thus, $\Sigma_{\mu\nu}$ and k_μ correspond to the intrinsic properties of the field under space-time rotations and special conformal transformations, respectively, while w is the conformal weight of the field. Together, these generate the stability subgroup of $x=0$. We also note that a *primary* field corresponds to one having $k_\mu = 0$.

It is convenient to summarize the transformation (2.17) in the expression

$$\delta_C \phi^i(x) = \xi^\mu(x)\partial_\mu \phi^i(x) + \Omega^{\mu\nu}(x)(\Sigma_{\mu\nu}\phi)^i(x) + \Lambda(x) w \phi^i(x) + c^\mu (k_\mu \phi)^i(x), \tag{2.19}$$

where the space-time dependent parameter functions are defined by

$$\xi^\mu(x) \equiv a^\mu + \omega^{\mu\nu} x_\nu + \lambda x^\mu + c^\mu x^2 - 2c \cdot x x^\mu, \tag{2.20}$$

$$\Omega^{\mu\nu}(x) \equiv \omega^{\mu\nu} + 4c^{[\mu} x^{\nu]}, \tag{2.21}$$

$$\Lambda(x) \equiv \lambda - 2c \cdot x. \tag{2.22}$$

This expression is also stated in Ref. 14 and will prove to be useful when dealing with superfields and the superconformal group later in this paper. Note that the expression for $\xi^\mu(x)$ in Eq. (2.20) coincides with the expression for δx^μ in Eq. (2.4), indicating that this part corresponds to the change in the field due to its dependence on the space-time coordinates.

When acting on *fields*, the generators obey the same commutation relations as in Eq. (2.7), but with the opposite sign; this is due to the difference between active and passive transformations.

To conclude, the conformal transformation of a general field is specified by stating its conformal weight (w), its behavior under Lorentz transformations ($\Sigma_{\mu\nu}$) and its properties under special conformal transformations (k_μ).

C. The bosonic tensor multiplet

The next step is to apply the results of the preceding section to the fields in the bosonic sector of the (2,0) tensor multiplet, consisting of five scalar fields and a two-form gauge potential. We denote the scalar fields, transforming in the vector representation of the SO(5) R-symmetry group, by the antisymmetric matrix ϕ^{ab}, $a,b=1,\ldots,4$, satisfying the algebraic condition

$$\Omega_{ab}\phi^{ab} = 0, \tag{2.23}$$

where Ω_{ab} is the SO(5) invariant antisymmetric tensor. Obviously, a and b are SO(5) spinor indices. The two-form potential is denoted b and has an associated field strength $h=\mathrm{d}b$, both R-symmetry scalars. Actually, it is only the self-dual part of the field strength that is part of the tensor multiplet, but in order to give a Lagrangian description of the theory,[15] we include the anti-self-dual part as a spectator field. It is essential to keep this part decoupled when adding interactions to the theory. The field content, along with the reality properties, is more thoroughly discussed in Ref. 16.

The fields have the following properties under conformal transformations:

$$(\Sigma_{\mu\nu}\phi^{ab}) = 0, \quad (k_\mu \phi^{ab}) = 0, \quad w_\phi = 2,$$

$$(\Sigma_{\mu\nu} b)_{\rho\sigma} = \eta_{\mu[\rho} b_{\sigma]\nu} - \eta_{\nu[\rho} b_{\sigma]\mu}, \quad (k_\mu b)_{\rho\sigma} = 0, \quad w_b = 2. \tag{2.24}$$

The conformal weights w_ϕ and w_b are bounded from below by a unitarity condition,[17,18] and due to the BPS property of the tensor multiplet representation, this bound is saturated. The weights coincide with the mass dimensions of the fields.

Using the expression (2.19), this means that the fields of the bosonic theory transform according to

$$\delta_C \phi^{ab}(x) = \xi^\mu(x)\partial_\mu \phi^{ab}(x) + 2\Lambda(x)\phi^{ab}(x), \tag{2.25}$$

$$\delta_C b_{\mu\nu}(x) = \xi^\rho(x)\partial_\rho b_{\mu\nu}(x) + 2\Omega_{[\mu}{}^\rho(x) b_{\nu]\rho}(x) + 2\Lambda(x) b_{\mu\nu}(x), \tag{2.26}$$

$$\delta_C h_{\mu\nu\rho}(x) = \xi^\sigma(x)\partial_\sigma h_{\mu\nu\rho}(x) - 3\Omega_{[\mu}{}^\sigma(x) h_{\nu\ \rho]\sigma}(x) + 3\Lambda(x) h_{\mu\nu\rho}(x), \tag{2.27}$$

where we have required the conformal transformation operator to commute with the exterior derivative, in the sense that

$$\mathrm{d}(\delta_C b) = \delta_C(\mathrm{d}b) = \delta_C h. \tag{2.28}$$

Note that this conformal transformation operator is defined in an abstract sense, acting in different ways on different fields. Specifically, its explicit form is different when acting on the derivative of a field than on the field itself. The relation (2.28) may seem evident here, but it is useful to relate to it when we discuss the superconformal transformations later in this paper.

Comparing Eqs. (2.26) and (2.27), we see that both b and its exterior derivative $h=\mathrm{d}b$ are primary fields, meaning that they have no k_μ piece in their transformation laws, cf. Eq. (2.19). It should be noted that, in general, derivatives of primary fields are not necessarily primary, consider, e.g., the variation

$$\delta_C(\partial_\mu \phi^{ab}(x)) = \partial_\mu(\delta_C \phi^{ab}(x)) \tag{2.29}$$

$$= \xi^\nu(x)\partial_\nu\partial_\mu\phi^{ab}(x) - \Omega_\mu{}^\nu(x)\partial_\nu\phi^{ab}(x) + 3\Lambda(x)\partial_\mu\phi^{ab}(x) - 4c_\mu\phi^{ab}(x), \tag{2.30}$$

where we see that the generators of the conformal group act as expected on a field with a subscript vector index and mass dimension 3, apart from the nonprimary piece with parameter c_μ. Thus, although ϕ^{ab} is a primary field, its derivative is not.

The bosonic model also includes self-dual strings, described by an embedding field X^μ, which is a function of the world-sheet coordinates (labelled σ^i, $i=1,2$) and transforms as a Lorentz vector. In particular, since we have adopted the active viewpoint on conformal transformations, it is natural to conclude that X^μ transforms according to

$$\delta_C X^\mu = -\xi^\mu(X) = -a^\mu - \omega^\mu{}_\nu X^\nu - \lambda X^\mu - c^\mu X^2 + 2c\cdot X X^\mu, \tag{2.31}$$

i.e., in the same way as the space-time coordinate x^μ in Eq. (2.4), but with the opposite sign. This expression does not look as nice as the transformations of the tensor multiplet fields found above, but if we instead consider the variation of the differential $\tilde{\mathrm{d}}X^\mu \equiv \mathrm{d}\sigma^i\,\partial_i X^\mu$ (which is what we will need in explicit calculations), we get that

$$\delta_C(\tilde{\mathrm{d}}X^\mu) = -\Omega^\mu{}_\nu(X)\tilde{\mathrm{d}}X^\nu - \Lambda(X)\tilde{\mathrm{d}}X^\mu, \tag{2.32}$$

in accordance with the expected transformation of a field with a vector index, having conformal weight $w_{\tilde{\mathrm{d}}X}=-1$. Note also, from Eqs. (2.19) and (2.31), that all terms apart from those involving $\Sigma_{\mu\nu}$, w, and k_μ vanish manifestly when transforming the pull-back of a space-time field to the world-sheet of the string.

Using the transformation rules found above, it is a straight-forward task to prove that the interaction described in Ref. 9 is conformally invariant. It should be stressed that this model, because of its electromagnetic coupling, suffers from a classical anomaly.[3] This anomaly is cancelled when fermionic degrees of freedom are included in the model in a supersymmetric way.

III. CONFORMAL INVARIANCE IN THE SUPERSYMMETRIC THEORY

In this section we turn to the complete theory, incorporating fermionic degrees of freedom in the model. We take advantage of the superfield notation in order to simplify expressions and keep them similar and comparable to the bosonic results in the preceding section. This section mixes results that have appeared elsewhere in the literature with new findings. It should also be mentioned that, in some cases, our derivation methods are quite different from those that can be found in previous papers on this subject.

A. Including spinors in the model

In this section, we introduce the notations and conventions used for spinors and state the *bosonic* conformal transformations of the *fermionic* tensor multiplet fields. It summarizes old results, but is included for completeness to keep the paper self-contained.

The (2,0) tensor multiplet includes, apart from the scalars and the two-form potential mentioned in the preceding section, four chiral spinors transforming in the spinor representation of the SO(5) *R*-symmetry group. These are denoted as ψ^a_α where $\alpha=1,\ldots,4$ is an SO(5,1) Weyl spinor index. An anti-Weyl spinor is denoted by a superscript α index. The spinor fields obey a symplectic Majorana reality condition.[19]

It is convenient to use spinor indices also for the bosonic representations of the Lorentz group. This means that we let (by contracting with the appropriate gamma matrices)

$$x^\mu \to x^{\alpha\beta} = x^{[\alpha\beta]}, \tag{3.1}$$

$$\partial_\mu \to \partial_{\alpha\beta} = \partial_{[\alpha\beta]}, \tag{3.2}$$

$$\eta_{\mu\nu} \to \tfrac{1}{2}\epsilon_{\alpha\beta\gamma\delta}, \tag{3.3}$$

$$b_{\mu\nu} \to b_\alpha{}^\beta, \quad \text{such that } b_\alpha{}^\alpha = 0, \tag{3.4}$$

$$h_{\mu\nu\rho} + (*h)_{\mu\nu\rho} \to h_{\alpha\beta} = h_{(\alpha\beta)}, \tag{3.5}$$

$$h_{\mu\nu\rho} - (*h)_{\mu\nu\rho} \to h^{\alpha\beta} = h^{(\alpha\beta)}. \tag{3.6}$$

Note that the last two equations conveniently separate the self-dual and anti-self-dual parts of the three-form h into different representations of the Lorentz group.

As is indicated by Eq. (3.3), pairs of antisymmetric indices may be raised and lowered according to

$$\partial^{\alpha\beta} = \tfrac{1}{2}\epsilon^{\alpha\beta\gamma\delta}\partial_{\gamma\delta}. \tag{3.7}$$

Finally, we introduce the dot product between vectors in the same way as before, such that

$$\partial \cdot x \equiv \partial_{\alpha\beta}x^{\alpha\beta} = 6. \tag{3.8}$$

After these preliminaries, let us return to the conformal group and its generators. Naively, the bosonic differential generators of the table in Sec. II A are translated into

Generator	Parameter
$P_{\alpha\beta}=\partial_{\alpha\beta}$	$a^{\alpha\beta}$
$M_{\alpha\beta;\gamma\delta}=\frac{1}{2}(x_{\gamma\delta}\partial_{\alpha\beta}-x_{\alpha\beta}\partial_{\gamma\delta})$	$\omega^{\alpha\beta;\gamma\delta}$
$D=x^{\alpha\beta}\partial_{\alpha\beta}$	λ
$K^{\alpha\beta}=x^2\partial^{\alpha\beta}-2x^{\alpha\beta}x^{\gamma\delta}\partial_{\gamma\delta}$	$c_{\alpha\beta}$

but it is more convenient to introduce a dual notation for the Lorentz generator M and its corresponding parameter ω, according to

$$M_\alpha{}^\beta = \epsilon^{\beta\gamma\delta\varepsilon}M_{\alpha\gamma;\delta\varepsilon}, \tag{3.9}$$

$$\omega_\alpha{}^\beta = \tfrac{1}{2}\epsilon_{\alpha\gamma\delta\varepsilon}\omega^{\beta\gamma;\delta\varepsilon}, \tag{3.10}$$

in analogy with the notation for the two-form b in Eq. (3.4). This yields that

$$\omega_\beta{}^\alpha M_\alpha{}^\beta = \omega^{\alpha\beta;\gamma\delta} M_{\alpha\beta;\gamma\delta}, \tag{3.11}$$

and the differential operator becomes

$$M_\alpha{}^\beta = x^{\beta\gamma}\partial_{\alpha\gamma} - x_{\alpha\gamma}\partial^{\beta\gamma} = 2x^{\beta\gamma}\partial_{\alpha\gamma} - \tfrac{1}{2}\delta_\alpha{}^\beta x\cdot\partial, \tag{3.12}$$

which is traceless as required.

Under a conformal transformation, the spinor field ψ^a_α transforms according to

$$\delta_C\psi^a_\alpha = \xi^{\gamma\delta}(x)\partial_{\gamma\delta}\psi^a_\alpha + \Omega_\alpha{}^\gamma(x)\psi^a_\gamma + \tfrac{5}{2}\Lambda(x)\psi^a_\alpha, \tag{3.13}$$

where the x-dependent parameter functions are the obvious translations from Sec. II A and become

$$\xi^{\alpha\beta}(x) = a^{\alpha\beta} + \omega_\gamma{}^\alpha x^{\gamma\beta} + \omega_\gamma{}^\beta x^{\alpha\gamma} + (\lambda - 2c\cdot x)x^{\alpha\beta} + c^{\alpha\beta}x^2, \tag{3.14}$$

$$\Omega_\alpha{}^\beta(x) = \omega_\alpha{}^\beta - 4c_{\alpha\gamma}x^{\beta\gamma} + c\cdot x\,\delta_\alpha{}^\beta, \tag{3.15}$$

$$\Lambda(x) = \lambda - 2c\cdot x, \tag{3.16}$$

in terms of which the transformations (2.25) and (2.27) are

$$\delta_C\phi^{ab} = \xi^{\gamma\delta}(x)\partial_{\gamma\delta}\phi^{ab} + 2\Lambda(x)\phi^{ab}, \tag{3.17}$$

$$\delta_C h_{\alpha\beta} = \xi^{\gamma\delta}(x)\partial_{\gamma\delta}h_{\alpha\beta} + \Omega_\alpha{}^\gamma(x)h_{\gamma\beta} + \Omega_\beta{}^\gamma(x)h_{\alpha\gamma} + 3\Lambda(x)h_{\alpha\beta}. \tag{3.18}$$

This ends the discussion concerning the conformal group with only bosonic generators. In the next section, we extend the model to incorporate fermionic generators, thereby forming the full superconformal group.

B. Superconformal coordinate transformations

Since we want to treat a supersymmetric model, it is convenient to supplement the six bosonic space-time coordinates $x^{\alpha\beta}$ by a set of 16 fermionic coordinates θ^α_a, see Ref. 10 for a more thorough introduction of these concepts. The fermionic coordinates are anticommuting, i.e., Grassmann odd, as usual and transform as anti-Weyl spinors under Lorentz rotations and as spinors under R-symmetry transformations.

Following the logic of the preceding section, the obvious next step is to find out what the generators of the conformal group SO(6,2) look like in this *superspace* and how they act on the coordinates. Evidently, the generators must change in comparison to the bosonic case, in order to incorporate the nontrivial action of the conformal group on the fermionic coordinates θ^α_a. For example, since θ^α_a transforms as an anti-Weyl spinor under Lorentz rotations, the corresponding generator ($M_\alpha{}^\beta$) must be modified. The commutation relations in Eq. (2.7) are expected to remain unchanged as expressed in terms of abstract generators.

However, we want to go a bit further and also include the R-symmetry group SO(5), generated by $U^{ab} = U^{(ab)}$, and supersymmetry, which is generated by the fermionic Q^a_α. We are then forced to introduce the generators S^α_a of *special supersymmetry* as well, which arise as the commutator of the supersymmetry and the special conformal symmetry generators. Altogether, we have then arrived at the superconformal group $\mathrm{OSp}(8^*|4)$, which is the expected symmetry group of the complete theory. We will denote the parameters of supersymmetry, R-symmetry and special supersymmetry transformations by η^α_a, v_{ab}, and ρ^a_α, respectively. Note that Q^a_α, S^α_a, η^α_a, and ρ^a_α all are fermionic (Grassmann odd) quantities.

In this section, we will content ourselves with the action of the superconformal group on the coordinates in superspace, postponing their action on fields to the next section. Starting from the purely bosonic parts of the generators of SO(6,2) ($P_{\alpha\beta}$, M^β_α, D, and $K^{\alpha\beta}$) obtained above and the well-known generator of supersymmetry (Q^a_α), we can make suitable ansätze for the unknown but

essential additional parts (including fermionic variables and derivatives) of these generators as well as for the newly introduced generators (S_a^α and U^{ab}). By requiring these generators to obey certain of the commutation relations of the $\mathrm{OSp}(8^*|4)$ group (which is related to the requirement that the algebra should close), the unknown coefficients may be determined and the resulting differential generators are found to be

$$P_{\alpha\beta} = \partial_{\alpha\beta}, \tag{3.19}$$

$$M_\alpha{}^\beta = 2x^{\beta\gamma}\partial_{\alpha\gamma} - \tfrac{1}{2}\delta_\alpha{}^\beta x\cdot\partial + \theta_c^\beta \partial_\alpha^c - \tfrac{1}{4}\delta_\alpha{}^\beta \theta\cdot\partial, \tag{3.20}$$

$$D = x\cdot\partial + \tfrac{1}{2}\theta\cdot\partial, \tag{3.21}$$

$$K^{\alpha\beta} = -4x^{\alpha\gamma}x^{\beta\delta}\partial_{\gamma\delta} - \Omega^{ab}\Omega^{cd}\theta_a^\gamma \theta_b^{[\alpha}\,\theta_c^{\beta]}\theta_d^\delta\partial_{\gamma\delta} + 2\theta_c^{[\alpha}\,(2x^{\beta]\gamma} - i\Omega^{ab}\theta_a^{\beta]}\theta_b^\gamma)\partial_\gamma^c, \tag{3.22}$$

$$Q_\alpha^a = \partial_\alpha^a - i\Omega^{ac}\theta_c^\gamma\partial_{\alpha\gamma}, \tag{3.23}$$

$$S_a^\alpha = \Omega_{ac}(2x^{\alpha\gamma} - i\Omega^{bd}\theta_b^\alpha\theta_d^\gamma)\partial_\gamma^c + 2i\theta_a^\gamma\theta_c^\alpha\partial_\gamma^c - i\theta_a^\gamma(2x^{\delta\alpha} - i\Omega^{bd}\theta_b^\delta\theta_d^\alpha)\partial_{\gamma\delta}, \tag{3.24}$$

$$U^{ab} = \tfrac{1}{2}(\Omega^{ac}\theta_c^\gamma\partial_\gamma^b + \Omega^{bc}\theta_c^\gamma\partial_\gamma^a), \tag{3.25}$$

where the dot product between two fermionic quantities a_a^α and b_β^b is defined by

$$a\cdot b \equiv a_c^\gamma b_\gamma^c. \tag{3.26}$$

Note that the fermions involved in this scalar product are required to have opposite SO(5,1) chirality, i.e., one should be a Weyl spinor and the other an anti-Weyl spinor.

The generators of the superconformal group act on the superspace coordinates $x^{\alpha\beta}$ and θ_a^α in the usual way; the resulting transformation laws are (similar transformations but in a different notation, and derived in a different way, also appear in Ref. 20)

$$\begin{aligned}\delta x^{\alpha\beta} = {} & a^{\alpha\beta} + \omega_\gamma{}^\alpha x^{\gamma\beta} + \omega_\gamma{}^\beta x^{\alpha\gamma} + \lambda x^{\alpha\beta} + 4c_{\gamma\delta}x^{\gamma\alpha}x^{\beta\delta} - i\Omega^{ab}\eta_a^{[\alpha}\,\theta_b^{\beta]} + c_{\gamma\delta}\Omega^{ac}\Omega^{bd}\theta_a^{[\alpha}\,\theta_b^{\beta]}\theta_c^\gamma\theta_d^\delta \\ & - 2i\rho_\gamma^{c}\theta_c^{[\alpha}\,x^{\beta]\gamma} - \rho_\gamma^c\Omega^{ab}\theta_c^{[\alpha}\,\theta_a^{\beta]}\theta_b^\gamma,\end{aligned} \tag{3.27}$$

$$\begin{aligned}\delta\theta_a^\alpha = {} & (\omega_\gamma{}^\alpha - 4c_{\gamma\delta}x^{\alpha\delta} - 2ic_{\gamma\delta}\Omega^{cd}\theta_c^\alpha\theta_d^\delta + 2i\rho_\gamma^c\theta_c^\alpha)\theta_a^\gamma + \tfrac{1}{2}\lambda\theta_a^\alpha + \eta_a^\alpha \\ & + 2\Omega_{ca}\rho_\gamma^c x^{\gamma\alpha} + i\Omega_{ac}\Omega^{bd}\rho_\gamma^c\theta_b^\gamma\theta_d^\alpha + \upsilon_{ac}\Omega^{cd}\theta_d^\alpha,\end{aligned} \tag{3.28}$$

which, as in the bosonic case, look rather messy and complicated. However, it is easily shown that the action on the superspace differentials $e^{\alpha\beta} = \mathrm{d}x^{\alpha\beta} + i\Omega^{ab}\theta_a^{[\alpha}d\theta_b^{\beta]}$ and $\mathrm{d}\theta_a^\alpha$ can be written as

$$\delta e^{\alpha\beta} = \Omega_\gamma{}^\alpha(x,\theta)e^{\gamma\beta} + \Omega_\gamma{}^\beta(x,\theta)e^{\alpha\gamma} + \Lambda(x,\theta)e^{\alpha\beta}, \tag{3.29}$$

$$\delta(\mathrm{d}\theta_a^\alpha) = \Omega_\gamma{}^\alpha(x,\theta)\mathrm{d}\theta_a^\gamma + \tfrac{1}{2}\Lambda(x,\theta)\mathrm{d}\theta_a^\alpha + V^c{}_a(\theta)\mathrm{d}\theta_c^\alpha + 2\Xi_{\gamma,a}(\theta)e^{\alpha\gamma}, \tag{3.30}$$

where the superspace-dependent parameter functions

$$\Omega_\alpha{}^\gamma(x,\theta) = \omega_\alpha{}^\gamma - 4c_{\alpha\delta}x^{\gamma\delta} + c\cdot x\delta_\alpha{}^\gamma - 2ic_{\alpha\delta}\Omega^{cd}\theta_c^\gamma\theta_d^\delta + 2i\rho_\alpha^c\theta_c^\gamma - \frac{i}{2}\delta_\alpha{}^\gamma\rho\cdot\theta, \tag{3.31}$$

$$\Lambda(x,\theta) = \lambda - 2c\cdot x + i\rho\cdot\theta \tag{3.32}$$

are extensions of Eqs. (3.15) and (3.16) to the superconformal case, while the functions

$$V^a{}_d(\theta) = -\Omega^{ac}v_{cd} + 4i\Omega^{ac}c_{\gamma\delta}\theta_c^\gamma\theta_d^\delta - 2i\rho_\gamma^a\theta_d^\gamma + 2i\Omega^{ae}\rho_\gamma^f\theta_e^\gamma\Omega_{fd}, \tag{3.33}$$

$$\Xi_{\alpha,a}(\theta) = 2c_{\alpha\beta}\theta_a^\beta + \Omega_{ab}\rho_\alpha^b \tag{3.34}$$

are new. Naturally, Ω_α^β and V_b^a are traceless, i.e., they obey $\Omega_\alpha{}^\alpha = V^a{}_a = 0$. To the best of our knowledge, this way of presenting the superconformal transformations has not appeared previously in the literature. The advantages of using superspace-dependent parameter functions will be made clearer when we consider transformations of *superfields* in Sec. III C.

The transformations (3.29) and (3.30) contain the expected Lorentz, dilatation and R-symmetry parts (with generalized superspace-dependent parameters), but also a term connecting the variation of $\mathrm{d}\theta_a^\alpha$ to $e^{\alpha\beta}$ with the parameter function $\Xi_{\alpha,a}(\theta)$, containing the (constant) parameters $c_{\alpha\beta}$ and ρ_α^a. This separates special conformal and special supersymmetry transformations from the other transformations, which yield no such possibilities. This issue will be further discussed later in this paper and is a superspace analogue to the nontrivial piece k_μ in Eq. (2.19).

It is also interesting to note that the infinitesimal supersymmetric interval length is preserved up to a superspace-dependent scale factor under superconformal transformations, i.e.,

$$\delta\left(\tfrac{1}{2}\epsilon_{\alpha\beta\gamma\delta}e^{\alpha\beta}e^{\gamma\delta}\right) = \Lambda(x,\theta)\epsilon_{\alpha\beta\gamma\delta}e^{\alpha\beta}e^{\gamma\delta}. \tag{3.35}$$

This relation may in fact be seen as a definition of the superconformal transformations, in analogy with Eq. (2.3) in the bosonic case.

Continuing along the path taken in Sec. II, we calculate the commutation relations for the differential generators in Eqs. (3.19)–(3.25). The result is (similar relations appear, e.g., in Refs. 14 and 20)

$$[P_{\alpha\beta}, M_\gamma{}^\delta] = -2\delta_{[\alpha}{}^\delta P_{\beta]\gamma} - \tfrac{1}{2}\delta_\gamma{}^\delta P_{\alpha\beta}, \quad [P_{\alpha\beta}, U^{ab}] = 0,$$

$$[K^{\alpha\beta}, M_\gamma{}^\delta] = 2\delta_\gamma^{[\alpha}K^{\beta]\delta} + \tfrac{1}{2}\delta_\gamma{}^\delta K^{\alpha\beta}, \quad [K^{\alpha\beta}, U^{ab}] = 0,$$

$$[U^{ab}, D] = 0, \quad [M_\alpha{}^\beta, U^{ab}] = 0,$$

$$[U^{ab}, U^{cd}] = -\Omega^{a(c}U^{d)b} - \Omega^{b(c}U^{d)a}, \quad [P_{\alpha\beta}, D] = P_{\alpha\beta},$$

$$[M_\alpha{}^\beta, D] = 0, \quad [K^{\alpha\beta}, D] = -K^{\alpha\beta},$$

$$[M_\alpha{}^\beta, Q_\gamma^a] = -\delta_\gamma{}^\beta Q_\alpha^a + \tfrac{1}{4}\delta_\alpha{}^\beta Q_\gamma^a, \quad [Q_\alpha^a, D] = \tfrac{1}{2}Q_\alpha^a,$$

$$[M_\alpha{}^\beta, S_a^\gamma] = \delta_\alpha{}^\gamma S_a^\beta - \tfrac{1}{4}\delta_\alpha{}^\beta S_a^\gamma, \quad [S_a^\alpha, D] = -\tfrac{1}{2}S_a^\alpha,$$

$$[K^{\alpha\beta}, Q_\gamma^a] = -2\Omega^{ac}\delta_\gamma^{[\alpha}S_c^{\beta]}, \quad [P_{\alpha\beta}, Q_\gamma^c] = 0,$$

$$[P_{\alpha\beta}, S_a^\gamma] = 2\Omega_{ac}\delta_{[\alpha}{}^\gamma Q^c{}_{\beta]}, \quad [K^{\alpha\beta}, S_a^\gamma] = 0,$$

$$[M_\alpha{}^\beta, M_\gamma{}^\delta] = \delta_\alpha{}^\delta M_\gamma{}^\beta - \delta_\gamma{}^\beta M_\alpha{}^\delta, \quad [U^{ab}, Q_\gamma^c] = \Omega^{c(a}Q_\gamma{}^{b)},$$

$$\{Q_\alpha^a, Q_\beta^b\} = -2i\Omega^{ab}P_{\alpha\beta}, \quad [U^{ab}, S_c^\gamma] = \delta_c^{(a}\Omega^{b)d}S_d^\gamma,$$

$$\{S_a^\alpha, S_b^\beta\} = -2i\Omega_{ab}K^{\alpha\beta},$$

$$\{Q^a_\alpha, S^\beta_b\} = i\delta_\alpha{}^\beta(\delta^a{}_b D - 4\Omega_{bc}U^{ac}) + 2i\delta^a{}_b M_\alpha{}^\beta,$$

$$[P_{\alpha\beta}, K^{\gamma\delta}] = -4\delta_{[\alpha}{}^{[\gamma} M_{\beta]}{}^{\delta]} - 2\delta_{[\alpha}{}^{\gamma}\delta_{\beta]}{}^{\delta} D, \tag{3.36}$$

which together define the superconformal group $\mathrm{OSp}(8^*|4)$. It should be noted that these are the relations that apply when the differential operators act on each other, *not* when the generators act on fields. In the latter case, the sign on the right-hand side of every relation should be changed. It is straightforward to verify that the super-Jacobi identities are satisfied.

In the same way as we compactified the notation in the bosonic case in Eq. (2.9) by extending space-time with one extra spacelike and one extra timelike dimension, we may define new generators $J_{\hat\alpha\hat\beta}$, where $\hat\alpha, \hat\beta = 1, \ldots, 8$ are chiral spinor indices in *eight* dimensions. The hatted indices decompose into subscript and superscript indices in six dimensions, corresponding to Weyl ($\hat\alpha = 1, \ldots, 4$) and anti-Weyl ($\hat\alpha = 5, \ldots, 8$) spinors, respectively. We let

$$J_{\alpha\beta} = \tfrac{1}{2} P_{\alpha\beta},$$

$$J_\alpha{}^\beta = \tfrac{1}{2} M_\alpha{}^\beta + \tfrac{1}{4}\delta_\alpha{}^\beta D = -J^\beta{}_\alpha,$$

$$J^{\alpha\beta} = -\tfrac{1}{2} K^{\alpha\beta}, \tag{3.37}$$

and also define new supercharges $\hat Q^a_{\hat\alpha}$ according to

$$\hat Q^a_\alpha = Q^a_\alpha,$$

$$\hat Q^{a,\alpha} = \Omega^{ab} S^\alpha_b, \tag{3.38}$$

together forming a chiral spinor in eight dimensions.

These generators, together with the unaltered R-symmetry generator U^{ab}, obey the commutation relations

$$\{\hat Q^a_{\hat\alpha}, \hat Q^b_{\hat\beta}\} = -4i(\Omega^{ab} J_{\hat\alpha\hat\beta} + I_{\hat\alpha\hat\beta} U^{ab}), \quad [J_{\hat\alpha\hat\beta}, U^{ab}] = 0,$$

$$[J_{\hat\alpha\hat\beta}, J_{\hat\gamma\hat\delta}] = -I_{\hat\alpha[\hat\gamma} J_{\hat\delta]\hat\beta} + I_{\hat\beta[\hat\gamma} J_{\hat\delta]\hat\alpha}, \quad [J_{\hat\alpha\hat\beta}, \hat Q^a_{\hat\gamma}] = I_{\hat\gamma[\hat\alpha}\, \hat Q^a{}_{\hat\beta]},$$

$$[U^{ab}, U^{cd}] = -\Omega^{a(c}\, U^{d)b} - \Omega^{b(c}\, U^{d)a}, \quad [U^{ab}, \hat Q^c_{\hat\alpha}] = \Omega^{c(a}\, \hat Q^{b)}_{\hat\alpha}, \tag{3.39}$$

where the symmetric matrix $I_{\hat\alpha\hat\beta}$ has components

$$I_{\alpha\beta} = 0,$$

$$I_\alpha{}^\beta = \delta_\alpha{}^\beta = I^\beta{}_\alpha,$$

$$I^{\alpha\beta} = 0; \tag{3.40}$$

it transforms in the singlet representation of SO(6,2). The commutation relations (3.39) contain all the information of Eq. (3.36), but in a much more compact notation.

It is possible to compactify the notation further by considering the generators in a superspace with eight bosonic and four fermionic dimensions. This yields the $\mathrm{OSp}(8^*|4)$ structure in a manifest way; this notation appears in Refs. 14 and 21. Introduce a matrix J_{AB}, where $A = (\hat\alpha, a)$ and

$B=(\hat{\beta},b)$ are $\mathrm{OSp}(8^*|4)$ indices. Note that A and B are superindices, meaning that J_{AB} is symmetric if both indices are fermionic, otherwise it is antisymmetric. We denote this in the standard way by

$$J_{AB}=-(-1)^{AB}J_{BA}. \tag{3.41}$$

J_{AB} contains the different generators of the superconformal group, explicitly we take

$$J_{\hat{\alpha}\hat{\beta}}=J_{\hat{\alpha}\hat{\beta}},$$

$$J_{\hat{\alpha}}{}^{b}=\frac{i}{2\sqrt{2}}\hat{Q}^{b}_{\hat{\alpha}},$$

$$J^{a}{}_{\hat{\beta}}=-\frac{i}{2\sqrt{2}}\hat{Q}^{a}_{\hat{\beta}},$$

$$J^{ab}=iU^{ab}. \tag{3.42}$$

These generators obey the (anti)commutation relations

$$[J_{AB},J_{CD}\}=-\tfrac{1}{2}(I_{BC}J_{AD}-(-1)^{AB}I_{AC}J_{BD}-(-1)^{CD}I_{BD}J_{AC}+(-1)^{AB+CD}I_{AD}J_{BC}) \tag{3.43}$$

where the bracket on the left-hand side is an anticommutator if both entries in it are fermionic, otherwise it is a commutator. The superspace metric $I_{AB}=(-1)^{AB}I_{BA}$ is defined by

$$I_{AB}=\begin{pmatrix}0 & \delta_{\alpha}{}^{\beta} & 0\\ \delta^{\alpha}{}_{\beta} & 0 & 0\\ 0 & 0 & i\Omega^{ab}\end{pmatrix}. \tag{3.44}$$

In order to make the relation

$$I_{AB}I^{BC}=\delta^{C}_{A} \tag{3.45}$$

valid (which is essential if want to raise and lower indices), we also need to define the inverse superspace metric as

$$I^{AB}=\begin{pmatrix}0 & \delta^{\alpha}{}_{\beta} & 0\\ \delta_{\alpha}{}^{\beta} & 0 & 0\\ 0 & 0 & -i\Omega_{ab}\end{pmatrix}. \tag{3.46}$$

Note the resemblance between the (anti)commutation relations in Eq. (3.43) and the well-known Lorentz group commutation relations. This suggests that the superconformal transformations act linearly in a superspace with eight bosonic and four fermionic dimensions.

In Sec. II A, we found the conformal transformations of the bosonic coordinates x^{μ} in an indirect way, by looking at a projective hypercone embedded in an eight-dimensional space with two timelike directions. In this higher-dimensional space, the conformal group acts linearly. Guided by the $\mathrm{OSp}(8^*|4)$ covariant notation introduced above, we would like to perform a similar analysis in the superconformal case.

Let the coordinates in superspace be y_A and introduce a projective supercone by the equation

$$I^{AB}y_Ay_B=0. \tag{3.47}$$

We will parametrize the supercone in a more implicit manner than we did when considering the hypercone in Sec. II A. Consider a point on the supercone, with coordinates $y_A=(y_{\alpha},y^{\alpha},y^{a})$. It is always possible to introduce a fermionic field $\theta^{\alpha}_{a}(y)$ such that for any point on the supercone,

$$y^a = \sqrt{2}\Omega^{ab}\theta_b^\beta y_\beta. \tag{3.48}$$

By requiring θ_a^α to transform as an anti-Weyl spinor under SO(5,1), this field is well-defined in all points on the supercone. In the same manner, we introduce the bosonic field $x^{\alpha\beta}(y) = -x^{\beta\alpha}(y)$ such that

$$y^\alpha = (2x^{\alpha\beta} - i\Omega^{ab}\theta_a^\alpha\theta_b^\beta)y_\beta \tag{3.49}$$

for any point on the supercone.

It is easily verified that all points y_A of this form lie on the supercone defined by Eq. (3.47). Obviously, we may always multiply $x^{\alpha\beta}$ or θ_a^α by a constant and still remain on the supercone. This explains the notion *projective* supercone.

The next step is to vary these coordinates. The transformations are generated by

$$J_{AB} = -y_{[A}\partial_{B]} = (-1)^{AB}y_{[B}\partial_{A]}, \tag{3.50}$$

which satisfies the commutation relations (3.43), given that

$$\partial_A y_B = I_{AB}. \tag{3.51}$$

The coordinates y_A transform according to

$$\delta y_A = \pi^{CD}J_{CD}y_A = (-1)^{C(A+D)}I_{AC}\pi^{CD}y_D, \tag{3.52}$$

where the parameter matrix is given by

$$\pi^{AB} = \begin{pmatrix} 2a^{\alpha\beta} & \omega_\beta{}^\alpha + \frac{1}{2}\lambda\delta_\beta{}^\alpha & -i\sqrt{2}\eta_b^\alpha \\ -\omega_\alpha{}^\beta - \frac{1}{2}\lambda\delta_\alpha{}^\beta & -2c_{\alpha\beta} & -i\sqrt{2}\rho_\alpha^c\Omega_{cb} \\ i\sqrt{2}\eta_a^\beta & i\sqrt{2}\rho_\beta^c\Omega_{ca} & -iv_{ab} \end{pmatrix}, \tag{3.53}$$

chosen such that the relation

$$\pi^{AB}J_{AB} = \omega_\alpha{}^\beta M_\beta{}^\alpha + a^{\alpha\beta}P_{\alpha\beta} + c_{\alpha\beta}K^{\alpha\beta} + \lambda D + \eta_a^\alpha Q_\alpha^a + \rho_\alpha^a S_a^\alpha + v_{ab}U^{ab} \tag{3.54}$$

is valid.

Since Eq. (3.47) is invariant under a transformation of this type, we may require the left-hand and the right-hand sides of Eqs. (3.48) and (3.49) to transform equally. The implicated transformation properties of the fields $x^{\alpha\beta}(y)$ and $\theta_a^\alpha(y)$ when the y coordinates are transformed in this way are found to agree exactly with the superconformal transformations of the coordinates $x^{\alpha\beta}$ and θ_a^α in our original superspace (with six bosonic and 16 fermionic dimensions) in Eqs. (3.27) and (3.28) above. This explains the choice of notation and implies that the rather complicated transformation laws for $x^{\alpha\beta}$ and θ_a^α are a mere consequence of a simple rotation in a superspace with eight bosonic and four fermionic dimensions.

This way of introducing the superspace coordinates and deriving their transformation properties has, as far as we know, not appeared previously in the literature. Presumably, the fact that this works points to some underlying structure of the (2,0) superspace in six dimensions, the nature of which is not clear at the moment.

C. Superfields

Having introduced a superspace (in the remainder of this paper, we will work in the usual (2,0) superspace with six bosonic and 16 fermionic dimensions), the next step is to populate it with superfields. The superfield formulation for the (2,0) tensor multiplet first appeared in Ref. 22; a thorough description of its use in our model can be found in Ref. 10. In this paper, we will content ourselves with a short description of the key aspects.

Define a superfield $\Phi^{ab} = \Phi^{ab}(x,\theta)$, obeying the algebraic constraint

$$\Omega_{ab}\Phi^{ab} = 0 \tag{3.55}$$

and the differential constraint

$$D^a_\alpha \Phi^{bc} + \tfrac{2}{5}\Omega_{de} D^d_\alpha \left(\Omega^{ab}\Phi^{ec} + \Omega^{ca}\Phi^{eb} + \tfrac{1}{2}\Omega^{bc}\Phi^{ea}\right) = 0, \tag{3.56}$$

where D^a_α is the covariant superspace derivative, defined according to

$$D^a_\alpha = \partial^a_\alpha + i\Omega^{ac}\theta^\gamma_c \partial_{\alpha\gamma}. \tag{3.57}$$

It is important to note[10] that the differential constraint (3.56) implies that the lowest component of the superfield must obey the free equations of motion for a massless scalar field, i.e., the Klein-Gordon equation. This reflects the fact that we are dealing with an *on-shell* superfield formulation.

It is convenient to define supplementary superfields according to

$$\Psi^a_\alpha = -\frac{2i}{5}\Omega_{bc} D^b_\alpha \Phi^{ca}, \tag{3.58}$$

$$H_{\alpha\beta} = \tfrac{1}{4}\Omega_{ab} D^a_\alpha \Psi^b_\beta, \tag{3.59}$$

but it should be noted that these contain no new degrees of freedom compared to Φ^{ab}.

By definition, a superfield transforms according to

$$\delta_Q \Phi^{ab} = [\eta \cdot Q, \Phi^{ab}] \tag{3.60}$$

under a supersymmetry transformation. Working out this commutator, with Q as in Eq. (3.23), it can be shown (by comparing with the explicit transformations in Ref. 16) that the lowest components of the superfields Φ^{ab}, Ψ^a_α, and $H_{\alpha\beta}$ are the tensor multiplet fields ϕ^{ab}, ψ^a_α, and $h_{\alpha\beta}$, hence the choice of notation. The differential constraint (3.56) yields the usual free equations of motion for these component fields.

The purpose of this section is to find how the rest of the superconformal transformations act on the superfields. The transformations will, as in the bosonic case, contain one piece including the differential expressions in Eqs. (3.19)–(3.25) and some nondifferential pieces. The latter may be derived by requiring that the transformation of Φ^{ab} must satisfy the differential constraint (3.56) when Φ^{ab} itself does. We also require the abstract transformation operator to commute with the covariant derivative in superspace [in the same way as transformations commute with derivatives in the bosonic case, see Eq. (2.28) and the discussion thereafter]. Note that this approach of course requires the superfields to be on shell. The transformation of (2,0) superfields was also discussed in Ref. 23 using a geometric approach, realizing the transformations as derivations in superspace. We will be more explicit and algebraic in our treatment of the problem, trying to take advantage of the superfield formulation. It is our goal to write the transformations of the superfields in a form similar to the one used in the bosonic case in, e.g., Eq. (3.17), inspired by the transformation properties of the superspace differentials in Eqs. (3.29) and (3.30).

After some quite involved computations, it is found that the superfields transform according to (we are still in the active picture, where we transform the fields rather than the coordinates)

$$\delta_C \Phi^{ab} = \xi^{\gamma\delta}(x,\theta)\partial_{\gamma\delta}\Phi^{ab} + \xi^\gamma_c(x,\theta)\partial^c_\gamma \Phi^{ab} + 2\Lambda(x,\theta)\Phi^{ab} + V^a{}_d(\theta)\Phi^{db} + V^b{}_d(\theta)\Phi^{ad}, \tag{3.61}$$

$$\delta_C \Psi^a_\alpha = \xi^{\gamma\delta}(x,\theta)\partial_{\gamma\delta}\Psi^a_\alpha + \xi^\gamma_c(x,\theta)\partial^c_\gamma \Psi^a_\alpha + \Omega_\alpha{}^\gamma(x,\theta)\Psi^a_\gamma + \tfrac{5}{2}\Lambda(x,\theta)\Psi^a_\alpha + V^a{}_c(\theta)\Psi^c_\alpha - 4\Xi_{\alpha,b}(\theta)\Phi^{ab}, \tag{3.62}$$

$$\delta_C H_{\alpha\beta} = \xi^{\gamma\delta}(x,\theta)\partial_{\gamma\delta}H_{\alpha\beta} + \xi_c^{\gamma}(x,\theta)\partial_\gamma^c H_{\alpha\beta} + \Omega_\alpha{}^\gamma(x,\theta)H_{\gamma\beta} + \Omega_\beta{}^\gamma(x,\theta)H_{\alpha\gamma} + 3\Lambda(x,\theta)H_{\alpha\beta} + 3i\Xi_{\alpha,c}(\theta)\Psi_\beta^c + 3i\Xi_{\beta,c}(\theta)\Psi_\alpha^c, \tag{3.63}$$

where the parameter functions $\Omega_\alpha^\beta(x,\theta)$, $\Lambda(x,\theta)$, $V_b^a(\theta)$, and $\Xi_{\alpha,a}(\theta)$ are those defined in Eqs. (3.31)–(3.34), respectively, while $\xi^{\alpha\beta}(x,\theta)=\delta x^{\alpha\beta}$ and $\xi_a^\alpha(x,\theta)=\delta\theta_a^\alpha$, see Eqs. (3.27) and (3.28). In analogy with the notion of primary fields in the purely bosonic case, we see that the superfield Φ^{ab} is *superprimary* (its transformation does not contain any Ξ-part) while the others are not. Note that the transformations (in this notation) are what one would expect by looking at the indices and mass dimensions of the fields, apart from the parts containing $\Xi_{\alpha,a}(\theta)$, where the numerical coefficients are hard to guess *a priori*.

From these transformations, the transformation laws for the component fields may be read off. The SO(6,2) transformations agree, as expected, with Eqs. (3.13), (3.17), and (3.18), while supersymmetry acts according to

$$\delta_Q\phi^{ab} = i\,\eta_c^\alpha\left(\Omega^{ac}\psi_\alpha^b - \Omega^{bc}\psi_\alpha^a - \tfrac{1}{2}\Omega^{ab}\psi_\alpha^c\right),$$

$$\delta_Q\psi_\alpha^a = \Omega^{ab}\eta_b^\beta h_{\alpha\beta} + 2\partial_{\alpha\beta}\phi^{ab}\eta_b^\beta,$$

$$\delta_Q h_{\alpha\beta} = i\,\eta_a^\gamma(\partial_{\gamma\alpha}\psi_\beta^a + \partial_{\gamma\beta}\psi_\alpha^a), \tag{3.64}$$

in agreement with Ref. 16. The special supersymmetry transformations of the component fields are

$$\delta_S\phi^{ab} = -4ix^{\gamma\delta}\rho_\gamma^{[a}\,\psi_\delta^{b]} - i\Omega^{ab}\Omega_{cd}x^{\gamma\delta}\rho_\gamma^c\psi_\delta^d,$$

$$\delta_S\psi_\alpha^a = -2\rho_\gamma^a x^{\gamma\delta}h_{\delta\alpha} - 4\rho_\alpha^b\Omega_{bc}\phi^{ca} + 4\rho_\gamma^b\Omega_{bc}x^{\gamma\delta}\partial_{\alpha\delta}\phi^{ac},$$

$$\delta_S h_{\alpha\beta} = 2i\Omega_{ab}\rho_\gamma^a x^{\gamma\delta}(\partial_{\delta\alpha}\psi_\beta^b + \partial_{\delta\beta}\psi_\alpha^b) - 3i\Omega_{ab}(\rho_\alpha^a\psi_\beta^b + \rho_\beta^a\psi_\alpha^b), \tag{3.65}$$

while R-symmetry acts according to

$$\delta_U\phi^{ab} = -\Omega^{ac}v_{cd}\phi^{db} - \Omega^{bc}v_{cd}\phi^{ad},$$

$$\delta_U\psi_\alpha^a = -\Omega^{ac}v_{cd}\psi_\alpha^d,$$

$$\delta_U h_{\alpha\beta} = 0, \tag{3.66}$$

as suggested by the index structure of the fields.

This completes the analysis of the superconformal transformations of the free tensor multiplet in superspace, but we should also consider the self-dual string. It is, as before, described by a bosonic embedding field $X^{\alpha\beta}(\sigma)$, but we must supplement it by a second (fermionic) field $\Theta_a^\alpha(\sigma)$ describing the embedding in the fermionic coordinates. The superconformal transformations of these fields are

$$\delta_C X^{\alpha\beta} = -a^{\alpha\beta} - \omega_\gamma{}^\alpha X^{\gamma\beta} - \omega_\gamma{}^\beta X^{\alpha\gamma} - \lambda X^{\alpha\beta} - 4c_{\gamma\delta}X^{\gamma\alpha}X^{\beta\delta} + i\Omega^{ab}\eta_a^{[\alpha}\,\Theta_b^{\beta]} - c_{\gamma\delta}\Omega^{ac}\Omega^{bd}\Theta_a^{[\alpha}\,\Theta_b^{\beta]}\Theta_c^\gamma\Theta_d^\delta + 2i\rho_\gamma^c\Theta_c^{[\alpha}\,X^{\beta]\gamma} + \rho_\gamma^c\Omega^{ab}\Theta_c^{[\alpha}\,\Theta_a^{\beta]}\Theta_b^\gamma, \tag{3.67}$$

$$\delta_C\Theta_a^\alpha = -(\omega_\gamma{}^\alpha - 4c_{\gamma\delta}X^{\alpha\delta} - 2ic_{\gamma\delta}\Omega^{cd}\Theta_c^\alpha\Theta_d^\delta + 2i\rho_\gamma^c\Theta_c^\alpha)\Theta_a^\gamma - \tfrac{1}{2}\lambda\Theta_a^\alpha - \eta_a^\alpha - 2\Omega_{ca}\rho_\gamma^c X^{\gamma\alpha} - i\Omega_{ac}\Omega^{bd}\rho_\gamma^c\Theta_b^\gamma\Theta_d^\alpha - v_{ac}\Omega^{cd}\Theta_d^\alpha, \tag{3.68}$$

which coincide with Eqs. (3.27) and (3.28) for the corresponding coordinates but with the *opposite sign*, in the same manner as in the purely bosonic model. These variations do not have the same structure as the variations of the superfields Φ^{ab}, Ψ_α^a, and $H_{\alpha\beta}$, but if we instead consider the

appropriate differentials of these fields, we get something more familiar. The differentials in question are related in an obvious way to the superfield differentials $e^{\alpha\beta}$ and $\mathrm{d}\theta_a^\alpha$ and are $E^{\alpha\beta}=\tilde{\mathrm{d}}X^{\alpha\beta}+i\Omega^{ab}\Theta_a^{[\alpha}\tilde{\mathrm{d}}\Theta_b^{\beta]}$ and $\tilde{\mathrm{d}}\Theta_a^\alpha$, where $\tilde{d}=\mathrm{d}\sigma^i\partial_i$ denotes a differential operator with respect to the world-sheet parameters σ. The variations of these quantities are

$$\delta_C E^{\alpha\beta}=-\Omega_\gamma{}^\alpha(X,\Theta)E^{\gamma\beta}-\Omega_\gamma{}^\beta(X,\Theta)E^{\alpha\gamma}-\Lambda(X,\Theta)E^{\alpha\beta}, \tag{3.69}$$

$$\delta_C(\tilde{\mathrm{d}}\Theta_a^\alpha)=-\Omega_\gamma{}^\alpha(X,\Theta)\tilde{\mathrm{d}}\Theta_a^\gamma-\tfrac{1}{2}\Lambda(X,\Theta)\tilde{\mathrm{d}}\Theta_a^\alpha-V^d{}_a(\Theta)\tilde{\mathrm{d}}\Theta_d^\alpha-2\Xi_{\gamma,a}(\Theta)E^{\alpha\gamma}, \tag{3.70}$$

which are similar to Eqs. (3.29) and (3.30) but again with the opposite sign. We see that $E^{\alpha\beta}$ transforms as a superprimary quantity while $\tilde{\mathrm{d}}\Theta_a^\alpha$ does not.

In retrospect, what we have done in this section is to generalize the superfield formulation, thereby incorporating the full superconformal group in the formalism. This is a must in order to calculate variations of terms involving superfields under such transformations; using the transformation laws for the component fields would lead us nowhere (we do not even know the explicit expressions for the superfields in terms of component fields to all orders). With the superspace generators, we may in a relatively simple and compact way describe the transformations.

We should also comment on the use of superspace-dependent parameter functions in the transformation laws. This also facilitates the calculations, since Lorentz and *R*-symmetry covariance is manifest through the use of tensor notation. They must, however, be applied with care since these parameter functions generally do not commute with derivatives. To the best of our knowledge, this approach to the superconformal transformations of (2,0) superfields has not appeared previously in the literature.

It would be interesting to consider the problem of finding a field theory in the superspace with eight bosonic and four fermionic dimensions discussed at the end of the preceding section. This theory would, presumably, incorporate manifest superconformal symmetry and probably yield some new insights into the properties of the six-dimensional theory.

D. The supersymmetric interaction terms

In this section, we consider the theory describing the supersymmetric coupling of a self-dual string to a (2,0) tensor multiplet background.[10] As usual, background coupling means that the tensor multiplet fields are taken to be on shell, i.e., they obey their free equations of motion.

The interaction is described by the action terms

$$S^{\mathrm{int}}=-\int_\Sigma d^2\sigma\sqrt{\Phi\cdot\Phi}\sqrt{-G}+\int_D F, \tag{3.71}$$

where the first term is a Nambu-Goto term where the string tension has been replaced by an expression in the superfield Φ^{ab} discussed in the preceding section. Explicitly, the SO(5) invariant scalar product is defined by

$$\Phi\cdot\Phi\equiv\tfrac{1}{4}\Omega_{ac}\Omega_{bd}\Phi^{ab}\Phi^{cd}, \tag{3.72}$$

and its appearance can be understood by considering the relation between the moduli parameters and the string tension mentioned in the introduction. Note that the term involves the *pull-back* of the superfield Φ^{ab} to the string world-sheet Σ. In the second factor of the Nambu-Goto term, G denotes the determinant of the induced metric in superspace, which may be written as

$$G=\tfrac{1}{2}\epsilon^{ik}\epsilon^{jl}G_{ij}G_{kl}, \tag{3.73}$$

where

$$G_{ij} = \tfrac{1}{2}\epsilon_{\alpha\beta\gamma\delta}E_i^{\alpha\beta}E_j^{\gamma\delta}. \tag{3.74}$$

Here $E_i^{\alpha\beta}$ is determined by the relation $E^{\alpha\beta}=\mathrm{d}\sigma^i E_i^{\alpha\beta}$. Naturally, Σ denotes the string world-sheet.

The second term in Eq. (3.71) is of Wess-Zumino type and involves the pull-back of a certain super three-form F to the world-volume of a "Dirac membrane" D attached to the string, satisfying $\partial D=\Sigma$. For a more elaborate discussion of the Dirac membrane and its properties, we refer to Refs. 10 and 24. D is described, similarly to the string, by embedding fields $X^{\alpha\beta}$ and Θ_a^α, but these fields are functions of three parameters instead of two. As an embedding, they naturally transform in the same way as the string embedding fields, i.e., according to Eqs. (3.67) and (3.68), under a superconformal transformation.

The super three-form F is expressed as

$$\begin{aligned} F = {} & \frac{1}{6}e^{\gamma_1\gamma_2}\wedge e^{\beta_1\beta_2}\wedge e^{\alpha_1\alpha_2}\epsilon_{\alpha_2\beta_2\gamma_1\gamma_2}H_{\alpha_1\beta_1} - \frac{i}{2}e^{\gamma_1\gamma_2}\wedge e^{\beta_1\beta_2}\wedge d\theta_a^\alpha\epsilon_{\alpha\beta_1\beta_2\gamma_1}\Psi^a_{\gamma_2} \\ & + \frac{i}{2}e^{\gamma_1\gamma_2}\wedge d\theta_b^\beta\wedge d\theta_a^\alpha\epsilon_{\alpha\beta\gamma_1\gamma_2}\Phi^{ab} \end{aligned} \tag{3.75}$$

in terms of the superfields Φ^{ab}, Ψ^a_α, and $H_{\alpha\beta}$. It was used by us in Ref. 10 but has also appeared (in a slightly different notation) in Refs. 23 and 25. The coefficients in the expression for F make it a closed form in superspace, i.e., $dF=0$, where d is the superspace exterior derivative. The last statement is only true if the superfields obey the differential constraint (3.56), but this is always the case on shell.

The relative coefficient in Eq. (3.71) is determined by requiring invariance under a local fermionic κ-symmetry, which also removes half of the degrees of freedom contained in Θ_a^α, as required by supersymmetry.[10] The closure of F is essential for this to work, but it also implies that the choice of Dirac membrane D, given a string world-sheet $\Sigma=\partial D$, should have no physical significance.

Next, let us consider a superconformal variation of the interaction (3.71). The Nambu-Goto term is clearly invariant; this is easily seen from the expressions (3.61) and (3.69) for the variations of Φ^{ab} and $E^{\alpha\beta}$, respectively. Since all fields are superprimary, the only thing we really need to check is that the conformal weights match appropriately.

The variation of the Wess-Zumino term is a bit more involved, mainly because of the terms involving $\Xi_{\alpha,a}(\theta)$ in the transformation laws for $\tilde{d}\Theta_a^\alpha$, Ψ^a_α, and $H_{\alpha\beta}$. It turns out that the pull-back of the super three-form F to the Dirac membrane world-volume D is superconformally invariant if and only if the coefficients are chosen as in Eq. (3.75), i.e., with the same choice of coefficients that makes it a closed three-form in superspace! This means that the interaction in Eq. (3.71) indeed is superconformally invariant, but *only* with the specific three-form in Eq. (3.75). It should also be stressed that, out of all the transformations in the superconformal group, it is only the special conformal and the special supersymmetry transformations that put any restrictions on the coefficients. With another choice, the theory would still be, e.g., supersymmetric. The model is therefore an example of a theory where special conformal invariance does not follow immediately from dilatational, translational and Lorentz invariance.

Summing up, we have found that the requirement of κ-symmetry and that of superconformal invariance impose equivalent restrictions on the coefficients of the super three-form F, but in different ways. Note, however, that κ-symmetry also determines the relative coefficient between the Nambu-Goto term and the Wess-Zumino term. The superconformal symmetry of the theory has no influence on that. The remarkable agreement between superconformal invariance and κ-symmetry indicates the uniqueness of the theory: the model is tightly constrained by its symmetries. This is arguably the most important result of this paper.

IV. THE POINCARÉ DUAL TO THE STRING WORLD-SHEET

In the preceding section, we worked with an on-shell tensor multiplet. This implied that the super three-form F in Eq. (3.75) was closed and lead us to the conclusion that the choice of Dirac membrane, given a specific string world-sheet Σ, should have no physical significance.

In this section, we try to relax the requirement that F should be closed, as a step in the process of finding a theory where the tensor multiplet fields need not be on shell. We will start in the bosonic case, where the motivation for these ideas is found, and then turn to the superconformal model and try to generalize the concepts introduced in the bosonic theory.

A. The bosonic model

A free two-form gauge field b with a three-form field strength h obeys the Bianchi identity

$$\mathrm{d}h = 0 \tag{4.1}$$

and the equations of motion

$$\mathrm{d} * h = 0, \tag{4.2}$$

where $*$ denotes the Hodge duality operator. For a self-dual three-form h, these two equations coincide.

If we want to couple this field electromagnetically to a self-dual string (with both magnetic and electric charge), this is done by changing the right-hand sides of the equations above. Explicitly, we get

$$\mathrm{d}h = \delta_\Sigma,$$

$$\mathrm{d} * h = \delta_\Sigma, \tag{4.3}$$

where δ_Σ denotes a four-form called the Poincaré dual to the string world-sheet Σ. It is defined by the relation

$$\int_\Sigma b \equiv \int_M \delta_\Sigma \wedge b, \tag{4.4}$$

where the left-hand integral is evaluated over the string world-sheet, while the right-hand integral is over the entire six-dimensional Minkowski space. We also note that the self-dual piece of h, expressed as $h_+ = \frac{1}{2}(h + *h)$, obeys an inhomogeneous equation while the anti self-dual piece $h_- = \frac{1}{2}(h - *h)$ is free and therefore decoupled from the theory, as required. It should be emphasized that Eq. (4.3) does not *imply* self-duality, but it is *consistent* with self-duality.

Explicitly, the Poincaré dual is expressed in terms of the string embedding fields X^μ and the space-time coordinates x^μ according to

$$\delta_\Sigma = \frac{1}{4!}\mathrm{d}x^\mu \wedge \mathrm{d}x^\nu \wedge \mathrm{d}x^\rho \wedge \mathrm{d}x^\sigma \int_\Sigma \tilde{\mathrm{d}}X^\tau \wedge \tilde{\mathrm{d}}X^\varepsilon \, \epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(x - X), \tag{4.5}$$

where $\tilde{\mathrm{d}} \equiv \mathrm{d}\sigma^i \partial_i$ again is the differential with respect to the world-sheet variables σ^i, $i = 1, 2$, and $\delta^{(6)}(x - X)$ is a Dirac delta function in six dimensions. This is somewhat analogous to the coupling of a dyonic relativistic particle to a Maxwell field in four dimensions, in that sense δ_Σ is a generalization of the current four-vector.[24] In our model, we couple to a string and δ_Σ is the dual of a current two-form.

In order for this four-form to be consistent with Eq. (4.3), it must be closed. Applying the exterior derivative to δ_Σ, we get that

$$\begin{aligned}
\mathrm{d}\delta_\Sigma &= \frac{1}{4!}\mathrm{d}x^\mu \wedge \mathrm{d}x^\nu \wedge \mathrm{d}x^\rho \wedge \mathrm{d}x^\sigma \wedge \mathrm{d}x^\kappa \int_\Sigma \tilde{\mathrm{d}}X^\tau \wedge \tilde{\mathrm{d}}X^\varepsilon \, \epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\partial_\kappa \delta^{(6)}(x-X) \\
&= -\frac{2}{5!}\mathrm{d}x^\mu \wedge \mathrm{d}x^\nu \wedge \mathrm{d}x^\rho \wedge \mathrm{d}x^\sigma \wedge \mathrm{d}x^\kappa \int_\Sigma \tilde{\mathrm{d}}X^\tau \wedge \tilde{\mathrm{d}}X^\varepsilon \, \epsilon_{\kappa\mu\nu\rho\sigma\tau}\partial_\varepsilon \delta^{(6)}(x-X) \\
&= -\frac{2}{5!}\mathrm{d}x^\mu \wedge \mathrm{d}x^\nu \wedge \mathrm{d}x^\rho \wedge \mathrm{d}x^\sigma \wedge \mathrm{d}x^\kappa \int_\Sigma \tilde{\mathrm{d}}(\tilde{\mathrm{d}}X^\tau \, \epsilon_{\kappa\mu\nu\rho\sigma\tau}\delta^{(6)}(x-X)) = 0, \qquad (4.6)
\end{aligned}$$

where we used the fact that an antisymmetrization over seven vector indices in six dimensions always is zero. The last equality follows since the integrand is a total derivative and the string world-sheet Σ has no boundary.

Next, we are interested in how these relations and quantities behave under (bosonic) conformal transformations. Consider the variation of the three-form h, which according to Eq. (2.27) equals

$$\delta_C h = \frac{1}{3!}\mathrm{d}x^\mu \wedge \mathrm{d}x^\nu \wedge \mathrm{d}x^\rho (\xi^\sigma(x)\partial_\sigma h_{\mu\nu\rho}(x) - 3\Omega_\mu{}^\sigma(x)h_{\sigma\nu\rho}(x) + 3\Lambda(x)h_{\mu\nu\rho}(x)). \qquad (4.7)$$

However, if we compare this with Eq. (2.6), we see that

$$\delta_C h = \delta_x h, \qquad (4.8)$$

where δ_x denotes a *passive* conformal transformation, i.e., one that acts on the space-time coordinates rather than on the fields. This means that, when dealing with h as a differential form, passive and active transformations yield the same result. We will denote such forms as *primary* differential forms. The statement remains true also when exterior derivatives are applied, i.e., $\delta_C(\mathrm{d}h) = \delta_x(\mathrm{d}h)$, but also for the Hodge dual of h, which means that $\delta_C(*h) = \delta_x(*h)$.

Considering Eq. (4.3), we note that the left-hand sides transform as primary four-forms, therefore the right-hand sides should transform in the same way. Since δ_Σ is an expression in terms of the embedding field X^μ, we may calculate its active transformation explicitly. Before doing this, we want to rewrite the transformation of $\tilde{\mathrm{d}}X^\mu$ in Eq. (2.32) so that all parameter functions are expressed in terms of the space-time coordinates x^μ, rather than in terms of the embedding field X^μ. We find that

$$\delta_C(\tilde{\mathrm{d}}X^\mu) = -\Omega^\mu{}_\nu(x)\tilde{\mathrm{d}}X^\nu - \Lambda(x)\tilde{\mathrm{d}}X^\mu - 2c_\nu \tilde{\mathrm{d}}((x-X)^\mu(x-X)^\nu) + c^\mu \tilde{\mathrm{d}}((x-X)\cdot(x-X)), \qquad (4.9)$$

while the passive variation of this quantity obviously vanishes. We will also need the relation

$$\delta_C(\mathrm{d}x^\mu) = 0 = \delta_x \, \mathrm{d}x^\mu - \Omega^\mu{}_\nu(x)\mathrm{d}x^\nu - \Lambda(x)\mathrm{d}x^\mu. \qquad (4.10)$$

Finally, considering the Dirac delta function we find that

$$\delta_C(\delta^{(6)}(x-X)) = -\delta_C X^\mu \partial_\mu \delta^{(6)}(x-X) = \delta_x(\delta^{(6)}(x-X)) + 6\Lambda(x)\delta^{(6)}(x-X), \qquad (4.11)$$

where we have used the relation

$$x^\mu \partial_\nu \delta^{(6)}(x) = -\delta_\nu{}^\mu \delta^{(6)}(x). \qquad (4.12)$$

Putting all this together, again using the properties of the Dirac delta function, we arrive at the conclusion

$$\delta_C(\delta_\Sigma) = \delta_x(\delta_\Sigma), \qquad (4.13)$$

meaning that our expression (4.5) for δ_Σ transforms as a primary four-form. This shows that Eq. (4.3) is a well-defined equation with respect to conformal symmetry.

B. The superconformal model

Having investigated the bosonic case, we try to generalize these concepts to superspace. We note that the on-shell super three-form F in Eq. (3.75) is primary, i.e.,

$$\delta_C F = \delta_{x,\theta} F, \tag{4.14}$$

where $\delta_{x,\theta}$ obviously denotes a passive conformal transformation in superspace. The validity of this equation is most easily seen from the fact that F yields a superconformally invariant Wess-Zumino term, see Sec. III D.

Let us now try to take F off shell, i.e., relax the requirement $\mathrm{d}F=0$. The equation corresponding to Eq. (4.3) is

$$\mathrm{d}\mathcal{F} = \Delta_\Sigma, \tag{4.15}$$

where d is the exterior derivative in superspace and $\mathcal{F}$ is a super three-form, not necessarily equal to F defined in Eq. (3.75). The super four-form Δ_Σ appearing on the right-hand side is supposed to be a generalization of the Poincaré dual δ_Σ. To find such a quantity is nontrivial, since there is no proper analogue of the Poincaré dual in superspace. The best we can hope for is to find a super four-form that reduces to δ_Σ if all fermionic degrees of freedom are removed, and that transforms in a nice way under superconformal transformations.

Guided by our previous experience, we try to formulate this four-form in terms of superfields. The fundamental superfields involving the embedding fields $X^{\alpha\beta}$ and Θ_a^α are

$$s^{\alpha\beta} \equiv x^{\alpha\beta} - X^{\alpha\beta} - i\Omega^{ab}\theta_a^{[\alpha}\,\Theta_b^{\beta]}, \tag{4.16}$$

$$t_a^\alpha \equiv \theta_a^\alpha - \Theta_a^\alpha; \tag{4.17}$$

the superfield properties of these are easily verified. The superfield $s^{\alpha\beta}$ is a vector and we will, when appropriate, use the alternative notation s^μ for this, employing an SO(5,1) vector index as in the bosonic case. Some important quantities will be stated twice, using both conventions.

We will also need the differential

$$\mathrm{d}s^{\alpha\beta} = \mathrm{d}x^{\alpha\beta} - i\Omega^{ab}\,\mathrm{d}\theta_a^{[\alpha}\,\Theta_b^{\beta]} = e^{\alpha\beta} - i\Omega^{ab}(\theta-\Theta)_a^{[\alpha}\,\mathrm{d}\theta_b^{\beta]}, \tag{4.18}$$

where the second equation follows from the definition of the superspace differential $e^{\alpha\beta}$. Similarly, we may differentiate $s^{\alpha\beta}$ with respect to the parameters defining the string world-sheet, yielding

$$\tilde{\mathrm{d}}s^{\alpha\beta} = -\tilde{\mathrm{d}}X^{\alpha\beta} - i\Omega^{ab}\theta_a^{[\alpha}\,\tilde{\mathrm{d}}\Theta_b^{\beta]} = -E^{\alpha\beta} - i\Omega^{ab}(\theta-\Theta)_a^{[\alpha}\,\tilde{\mathrm{d}}\Theta_b^{\beta]}, \tag{4.19}$$

where $E^{\alpha\beta}$ as before is the bosonic superspace differential expressed in terms of the embedding fields $X^{\alpha\beta}$ and Θ_a^α.

Guided by Eq. (4.5), we introduce

$$\Delta_\Sigma = \frac{1}{4!}\int_\Sigma \mathrm{d}s^\mu \wedge \mathrm{d}s^\nu \wedge \mathrm{d}s^\rho \wedge \mathrm{d}s^\sigma\, \tilde{\mathrm{d}}s^\tau \wedge \tilde{\mathrm{d}}s^\varepsilon\, \epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(s) \tag{4.20}$$

$$= \frac{1}{4!}\int_\Sigma \mathrm{d}s^{\delta_1\delta_2} \wedge \mathrm{d}s^{\gamma_1\gamma_2} \wedge \mathrm{d}s^{\beta_1\beta_2} \wedge \mathrm{d}s^{\alpha_1\alpha_2}\, \tilde{\mathrm{d}}s^{\sigma_1\sigma_2} \wedge \tilde{\mathrm{d}}s^{\tau_1\tau_2} \epsilon_{\alpha_1\alpha_2\beta_1\gamma_1}\epsilon_{\gamma_2\delta_1\delta_2\sigma_1}\epsilon_{\sigma_2\tau_1\tau_2\beta_2}\delta^{(6)}(s), \tag{4.21}$$

where the Dirac delta function with a Grassmannian argument containing both "body" and "soul" is defined in terms of its Taylor expansion. It is apparent that this candidate for Δ_Σ reduces to the bosonic δ_Σ in Eq. (4.5) if all fermions are put to zero.

The second requirement on this Δ_Σ is that it should be closed, as is seen immediately from Eq. (4.15). The proof for this is similar to the bosonic case in Eq. (4.6), but slightly more complicated since $\mathrm{d}\,\tilde{\mathrm{d}}s^\mu = \tilde{\mathrm{d}}\,\mathrm{d}s^\mu \neq 0$. However, the changes in the proof are minor and therefore omitted in this text.

We also want to investigate how Δ_Σ transforms under superconformal transformations. As in the bosonic case, we will present the transformations piece by piece. Using the explicit variations of $X^{\alpha\beta}$ and Θ_a^α found above, we find that

$$\delta_C(\mathrm{d}s^{\alpha\beta}) = \delta_{x,\theta}\,\mathrm{d}s^{\alpha\beta} - \tilde{\Lambda}\,\mathrm{d}s^{\alpha\beta} + 2\tilde{\Omega}_\gamma^{\ [\alpha}\,\mathrm{d}s^{\beta]\gamma} + \mathrm{d}\chi^{\alpha\beta}, \tag{4.22}$$

$$\delta_C(\tilde{\mathrm{d}}s^{\alpha\beta}) = \delta_{x,\theta}\,\tilde{\mathrm{d}}s^{\alpha\beta} - \tilde{\Lambda}\,\tilde{\mathrm{d}}s^{\alpha\beta} + 2\tilde{\Omega}_\gamma^{\ [\alpha}\,\tilde{\mathrm{d}}s^{\beta]\gamma} + \tilde{\mathrm{d}}\chi^{\alpha\beta}, \tag{4.23}$$

where we have used the presence of a Dirac delta function in the expression (4.21) to set $s^{\alpha\beta}=0$. Moreover, $\delta_{x,\theta}$ denotes a passive variation in superspace and

$$\tilde{\Omega}_\gamma^{\ \alpha} \equiv \Omega_\gamma^{\ \alpha}(x,\theta) + i\Omega^{cd}\Xi_{c,\gamma}(\theta)t_d^\alpha - \frac{i}{4}\Omega^{cd}\Xi_{c,\delta}(\theta)t_d^\delta\delta_\gamma^{\ \alpha}, \tag{4.24}$$

$$\tilde{\Lambda} \equiv \Lambda(x,\theta) + \frac{i}{2}\Omega^{cd}\Xi_{c,\gamma}(\theta)t_d^\gamma, \tag{4.25}$$

$$\chi^{\alpha\beta} \equiv -\Omega^{ab}\Omega^{cd}\Xi_{a,\gamma}(\theta)t_b^{[\alpha}t_c^{\beta]}t_d^\gamma - c_{\gamma\delta}\Omega^{ab}\Omega^{cd}t_a^\gamma t_b^{[\alpha}t_c^{\beta]}t_d^\delta. \tag{4.26}$$

Alternatively, we may write these variations as

$$\delta_C(\mathrm{d}s^\mu) = \delta_{x,\theta}\,\mathrm{d}s^\mu - \tilde{\Lambda}\,\mathrm{d}s^\mu - \tilde{\Omega}_\nu^\mu\,\mathrm{d}s^\nu + \mathrm{d}\chi^\mu, \tag{4.27}$$

$$\delta_C(\tilde{\mathrm{d}}s^\mu) = \delta_{x,\theta}\,\tilde{\mathrm{d}}s^\mu - \tilde{\Lambda}\,\tilde{\mathrm{d}}s^\mu - \tilde{\Omega}^\mu_{\ \nu}\,\tilde{\mathrm{d}}s^\nu + \tilde{\mathrm{d}}\chi^\mu, \tag{4.28}$$

where we again have introduced a vector index instead of an antisymmetric pair of SO(5,1) spinor indices. We have also introduced $\tilde{\Omega}_\nu^\mu$, the definition of which is apparent from how ω_α^β was defined from $\omega^{\mu\nu}$ in Sec. III A.

The Dirac delta function transforms according to

$$\delta_C(\delta^{(6)}(s)) = \delta_{x,\theta}\delta^{(6)}(s) + 6\tilde{\Lambda}\delta^{(6)}(s) + \chi\cdot\partial\delta^{(6)}(s), \tag{4.29}$$

where we as usual have used the properties of the delta function to set $s^{\alpha\beta}=0$. We have also employed the identity

$$s^{\alpha\gamma}\partial_{\alpha\beta}\delta^{(6)}(s) = -\tfrac{3}{2}\delta_\beta^{\ \gamma}\delta^{(6)}(s), \tag{4.30}$$

which is analogous to Eq. (4.12) in the bosonic model.

Putting all this together, using the vector index notation, we find that the superconformal variation of Δ_Σ is

$$\begin{aligned}\delta_C\Delta_\Sigma = \delta_{x,\theta}\Delta_\Sigma &+ \frac{1}{3!}\int_\Sigma \mathrm{d}s^\mu\wedge\mathrm{d}s^\nu\wedge\mathrm{d}s^\rho\wedge\mathrm{d}\chi^\sigma\,\tilde{\mathrm{d}}s^\tau\wedge\tilde{\mathrm{d}}s^\varepsilon\epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(s)\\ &+ \frac{2}{4!}\int_\Sigma \mathrm{d}s^\mu\wedge\mathrm{d}s^\nu\wedge\mathrm{d}s^\rho\wedge\mathrm{d}s^\sigma\,\tilde{\mathrm{d}}s^\tau\wedge\tilde{\mathrm{d}}\chi^\varepsilon\epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(s)\\ &+ \frac{1}{4!}\int_\Sigma \mathrm{d}s^\mu\wedge\mathrm{d}s^\nu\wedge\mathrm{d}s^\rho\wedge\mathrm{d}s^\sigma\,\tilde{\mathrm{d}}s^\tau\wedge\tilde{\mathrm{d}}s^\varepsilon\epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\,\chi^\kappa\partial_\kappa\delta^{(6)}(s),\end{aligned} \tag{4.31}$$

which may be rewritten as (our conventions for superderivatives may be found in Ref. 10)

$$\delta_C \Delta_\Sigma = \delta_{x,\theta}\Delta_\Sigma + \mathrm{d}\left[\frac{1}{3!}\int_\Sigma \mathrm{d}s^\mu \wedge \mathrm{d}s^\nu \wedge \mathrm{d}s^\rho\, \tilde{\mathrm{d}}s^\tau \wedge \tilde{\mathrm{d}}s^\varepsilon\, \chi^\sigma \epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(s)\right]$$
$$- \frac{2}{4!}\int_\Sigma \tilde{\mathrm{d}}[\mathrm{d}s^\mu \wedge \mathrm{d}s^\nu \wedge \mathrm{d}s^\rho \wedge \mathrm{d}s^\sigma\, \tilde{\mathrm{d}}s^\tau\, \chi^\varepsilon \epsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(s)]$$
$$+ \frac{7}{4!}\int_\Sigma \mathrm{d}s^\mu \wedge \mathrm{d}s^\nu \wedge \mathrm{d}s^\rho \wedge \mathrm{d}s^\sigma\, \tilde{\mathrm{d}}s^\tau \wedge \tilde{\mathrm{d}}s^\varepsilon\, \chi^\kappa \epsilon_{[\mu\nu\rho\sigma\tau\varepsilon}\,\partial_{\kappa]}\delta^{(6)}(s). \tag{4.32}$$

In this expression, the last line vanishes since it is an antisymmetrization over seven vector indices in six dimensions, while the second line is zero since it reduces to a boundary term. We are left with

$$\delta_C \Delta_\Sigma = \delta_{x,\theta}\Delta_\Sigma + \mathrm{d}\Lambda_\Sigma, \tag{4.33}$$

where the super three-form Λ_Σ is given by

$$\Lambda_\Sigma = \frac{1}{3!}\int_\Sigma \mathrm{d}s^\mu \wedge \mathrm{d}s^\nu \wedge \mathrm{d}s^\rho\, \tilde{\mathrm{d}}s^\tau \wedge \tilde{\mathrm{d}}s^\varepsilon\, \chi^\sigma \varepsilon_{\mu\nu\rho\sigma\tau\varepsilon}\delta^{(6)}(s) \tag{4.34}$$

$$= \frac{1}{3!}\int_\Sigma \mathrm{d}s^{\gamma_1\gamma_2} \wedge \mathrm{d}s^{\beta_1\beta_2} \wedge \mathrm{d}s^{\alpha_1\alpha_2}\, \chi^{\varepsilon_1\varepsilon_2}\, \tilde{\mathrm{d}}s^{\sigma_1\sigma_2} \wedge \tilde{\mathrm{d}}s^{\tau_1\tau_2}\delta^{(6)}(s)$$
$$\times\left(\varepsilon_{\varepsilon_1\varepsilon_2\beta_1\gamma_1}\varepsilon_{\gamma_2\alpha_1\alpha_2\sigma_1}\varepsilon_{\sigma_2\tau_1\tau_2\beta_2} - \frac{1}{8}\varepsilon_{\varepsilon_1\varepsilon_2\gamma_1\gamma_2}\varepsilon_{\sigma_1\sigma_2\alpha_1\alpha_2}\varepsilon_{\tau_1\tau_2\beta_1\beta_2}\right), \tag{4.35}$$

but this quantity is obviously only well-defined modulo an exact three-form.

Looking back at Eq. (4.13) for the bosonic model, we see that the introduction of fermionic degrees of freedom has altered the relation by adding a d-exact term to the right-hand side. This means that our candidate (4.20) for Δ_Σ does not transform exactly as one would expect when comparing with the bosonic theory, i.e., an active and a passive transformation do not yield the same result. We note that Λ_Σ vanishes if all fermions are removed and that it is localized (by means of the Dirac delta function) to the world-sheet of the string.

This means that the simple generalization of the bosonic case that we have tried in this section did not work out properly. The most probable reason for this failure is that we are required to add a new ingredient, the matrix $\hat{\phi}^{ab}$, to Δ_Σ. This denotes the vacuum expectation value of the field $\phi^{ab}(x)$, normalized to unit modulus with respect to the scalar product in Eq. (3.72). In other words, $\hat{\phi}^{ab}$ is related to the moduli parameters of the theory, denoting the direction in which R-symmetry is broken by the presence of the tensile string. We have seen the appearance of this quantity previously[16] in the discussion concerning the κ-symmetry of the theory. We will not consider how to formulate a superspace generalization of the Poincaré dual including $\hat{\phi}^{ab}$ in this paper, but we hope to return to the matter in a future presentation.

Friedel theorem for two dimensional relativistic spin-$\frac{1}{2}$ systems

De-Hone Lin
Department of Physics, National Sun Yat-sen University, Kaohsiung, Taiwan

(Received 20 January 2006; accepted 10 March 2006; published online 27 April 2006)

The Friedel sum rule is generalized to relativistic systems of spin-$\frac{1}{2}$ particles in two dimensions. The change in energy due to the presence of an impurity is studied. The relation of the sum rule with the relativistic Levinson theorem is presented. Density oscillations in such systems are discussed. Since the Friedel theorem has been of major importance in understanding the impurity scattering in materials, the present results may be useful to explain some phenomena in two dimensional fermionic many body systems. © *2006 American Institute of Physics.*

I. INTRODUCTION

The Friedel sum rule (FSR)[1–3] is an important theorem in studying the effects of an impurity on the electron structure in solids, which sets up the relation between the change of the number of states ΔN around the impurity and the phase shift at Fermi energy. In three dimensional (3D) systems, the theorem can be described by

$$\Delta N = \frac{2}{\pi}\sum_{l=0}^{\infty}(2l+1)\,\delta_l(E_f), \tag{1}$$

where $\delta_l(E_f)$ denotes the phase shift of scattered state in the angular-momentum channel l with energy at the Fermi surface. The result is one of the most interesting results in the theory of impurity. It states that the change of the number of states caused by the potential of an impurity can be quantified in terms of the scattering phase shift at Fermi energy. The subject was then studied by many authors and generalized to include the internal degree of freedom of particles,[4,5] which provides a powerful method in calculating the residual resistance, diamagnetic susceptibility,[2,3] spectral properties of spin-$\frac{1}{2}$ fermions in the presence of an impurity,[6] and so forth. Recently, based on the Dirac equation, the FSR for relativistic spin-$\frac{1}{2}$ particles in 3D systems is proved to be

$$\Delta N = \frac{1}{\pi}\sum_{\kappa=-\infty,\kappa\neq 0}^{\infty} 2|\kappa|\Bigg\{[\delta_\kappa(E_f)-\delta_\kappa(\mu)+\delta_\kappa(-E_f')-\delta_\kappa(-\mu)] + \epsilon_\kappa\frac{\pi(-1)^{|\kappa|}}{2}[\sin^2\delta_\kappa(\mu)-\sin^2\delta_\kappa(-\mu)]\Bigg\}, \tag{2}$$

where $\delta_\kappa(\pm E_\lambda)$ and $\delta_\kappa(\pm\mu)$, classified by the angular momentum $\kappa=\pm(j+1/2)$ and $\epsilon_\kappa\equiv 1(-1)$ for $\kappa>0$ ($\kappa<0$), are the phase shifts of scattering states at Fermi energies ($E_\lambda=E_f$ and $-E_f'$) and zero-momentum ($E_\lambda=\pm\mu$).[7] The result may provide a basis for exploring the effect of an impurity by the FSR for 3D relativistic systems. For 1D systems, the nonrelativistic FSR is given by[8]

$$\Delta N = \frac{2}{\pi} \sum_{p=e,o} \left(\delta_p(E_f) - \delta_p(0) + \epsilon_p \frac{\pi}{2} \sin^2 \delta_p(0) \right), \tag{3}$$

where $\delta_p(0)$ is the phase shift at zero momentum, and the phase shifts $\delta_p(E_\lambda)$ $(p=e,o)$ are classified by even parity (e) and odd parity (o) of wave functions. Its generalization to relativistic spin-$\frac{1}{2}$ particles is shown to relate to the phase shifts $\delta_p(E_\lambda)$ of scattering states at Fermi energies $(E_\lambda = E_f$ and $-E_f')$ and zero momentum $(E_\lambda = \pm\mu)$ as follows:[8]

$$\Delta N = \frac{1}{\pi} \sum_{p=e,o} \left\{ [\delta_p(E_f) - \delta_p(\mu) + \delta_p(-E_f') - \delta_p(-\mu)] - \epsilon_p \frac{\pi}{2} [\sin^2 \delta_p(\mu) - \sin^2 \delta_p(-\mu)] \right\}. \tag{4}$$

where $\epsilon_p = 1(-1)$ for even parity (odd parity). The result is meaningful in 1D nanostructures since the relativistic spectra appear naturally as a low energy effective spectra for electrons in 1D metals.[9]

Over the past two decades, remarkable phenomena have been observed in the 2D electron gas (2DEG), such as the integer and fractional quantum Hall effect.[10,11] On the other hand, a number of interesting physical systems, the effective quantum theory is expected to be described by the 2D Dirac equation[9,12] rather than the Schrödinger equation. The anticipation recently has been confirmed by experiments in perfect graphene,[13,14] which pose new questions on the nature of the electronic properties in such systems and shows a possibility of studying relativistic phenomena in a tabletop experiment. To my knowledge, as one of the most powerful tools in studying effects of impurities, the FSR for 2D Dirac fermions is still lacking. It is our aim in the paper to establish the FSR for 2D relativistic spin-$\frac{1}{2}$ systems. In two dimensions, based on the Schrödinger equation, the nonrelativistic FSR can be proved to be (see the Appendix)

$$\Delta N = \frac{2}{\pi} \sum_{m=-\infty}^{\infty} [\delta_m(E_f) - \delta_m(0)], \tag{5}$$

where $\delta_m(0)$ is the phase shift at the zero momentum in the angular-momentum channel m $(m = 0, \pm 1, \pm 2, \ldots)$. In this paper, we shall generalize the result to relativistic spin-$\frac{1}{2}$ systems.

This paper is organized as follows. In Sec. II, the 2D FRS is generalized to the relativistic spin-$\frac{1}{2}$ particles moving in a short range potential $|V(r)|$ when $r < a$ and $V(r) = 0$ when $r \geqslant a$. The total change of the number of states ΔN around the potential is shown to relate to the phase shifts $\delta_j(E_\lambda)$ of scattering states at Fermi energies $(E_\lambda = E_f$ and $-E_f')$ and zero-momentum $(E_\lambda = \pm\mu)$ as follows:

$$\Delta N = \frac{1}{\pi} \sum_{j=\pm 1/2, \pm 3/2, \ldots} [\delta_j(E_f) - \delta_j(\mu) + \delta_j(-E_f') - \delta_j(-\mu)] \tag{6}$$

where j $(j = \pm 1/2, \pm 3/2, \ldots)$ is the total angular momentum. Section III is used to discuss the change in energy of a relativistic spin-$\frac{1}{2}$ system in the presence of an impurity. In Sec. IV, the relation between the FSR and the 2D relativistic Levinson theorem[15–18] is presented. Density oscillations of relativistic spin-$\frac{1}{2}$ systems are discussed. The FSR for the massless Dirac fermions is also presented here. Our conclusions are summarized in Sec. V.

II. FRIEDEL SUM RULE FOR RELATIVISTIC SPIN-$\frac{1}{2}$ SYSTEMS IN TWO DIMENSIONS

We consider the 2D model. The Dirac equation of a spin-$\frac{1}{2}$ particle with effective mass μ moving in a cylindrically symmetric potential $V(r)$ specified in the previous is given by

$$[\vec{\alpha} \cdot \hat{\mathbf{p}} + \gamma^0 \mu + V(r)] \Psi_\lambda(\mathbf{r}) = E_\lambda \Psi_\lambda(\mathbf{r}), \tag{7}$$

where $\alpha^i = \gamma^0 \gamma^j$ $(i = 1, 2)$ are Dirac matrices. As usual, they are chosen as the Pauli matrices $\gamma^0 = \sigma^3$, $\gamma^1 = i\sigma^1$, and $\gamma^2 = i\sigma^2$ such that the total angular momentum $\hat{J} = \hat{L} + \hat{S}$ with the spin $\hat{S}$

$=(i\epsilon^{ij}\gamma^i\gamma^j)/4$ is conservative. For our purposes it is very convenient to write the spin wave function in a form

$$\Psi_\lambda(\mathbf{r}) = \sum_{j=\pm 1/2,\pm 3/2,\ldots} c_j \Psi_{\lambda j}(\mathbf{r}) = \sum_{j=\pm 1/2,\pm 3/2,\ldots} c_j \begin{pmatrix} f_{\lambda j}(r)\dfrac{e^{i(j-1/2)\varphi}}{\sqrt{2\pi}} \\ g_{\lambda j}(r)\dfrac{e^{i(j+1/2)\varphi}}{\sqrt{2\pi}} \end{pmatrix}. \tag{8}$$

Here c_j's are coefficients dependent on the particular form required for Ψ_λ and j denotes the quantum number of the total angular momentum $\hat{J}$. With (8), it can be shown that the radial equations for spinors $f_{\lambda j}(r)$ and $g_{\lambda j}(r)$ are

$$\left(\frac{d}{dr} - \frac{j-1/2}{r}\right) f_{\lambda j}(r) + [E_\lambda + \mu - V(r)] g_{\lambda j}(r) = 0, \tag{9}$$

$$\left(\frac{d}{dr} + \frac{j+1/2}{r}\right) g_{\lambda j}(r) - [E_\lambda - \mu - V(r)] f_{\lambda j}(r) = 0. \tag{10}$$

At regions of $V=0$, these equations can be decoupled into

$$\frac{d^2}{dr^2} f_{\lambda j}(r) + \frac{1}{r}\frac{d}{dr} f_{\lambda j}(r) + \left(k^2 - \frac{(j-1/2)^2}{r^2}\right) f_{\lambda j}(r) = 0, \tag{11}$$

$$\frac{d^2}{dr^2} g_{\lambda j}(r) + \frac{1}{r}\frac{d}{dr} g_{\lambda j}(r) + \left(k^2 - \frac{(j+1/2)^2}{r^2}\right) g_{\lambda j}(r) = 0, \tag{12}$$

with $k=\sqrt{E_\lambda^2-\mu^2} \geqslant 0$, which turn out to be the Bessel equations. Thus the solution of scattering state of spinor $f_{\lambda j}$ for positive energy ($E_\lambda > \mu$) and a positive quantum number ($j>0$) is given by

$$f_{\lambda j}(r) = [C_1(k) J_{j-1/2}(kr) + C_2(k) N_{j-1/2}(kr)] = A_j(k)[\sin\,\delta_j(k) J_{j-1/2}(kr) + \cos\,\delta_j(k) N_{j-1/2}(kr)], \tag{13}$$

where $J_{j-1/2}(x)$ and $N_{j-1/2}(x)$ are Bessel functions, $\delta_j(k)$ is the phase shift defined by $C_1/C_2 \equiv \tan\,\delta_j(k)$ and $A_j(k)=C_1(k)/\sin\,\delta_j(k)$. The explicit form of $A_j(k)$ is determined by the normalization condition of $\delta(E_\lambda - E_{\lambda'})$ for free particles, which gives $A_j(k)=\sqrt{(E_\lambda+\mu)/2}$. At large distance $r\to\infty$, the asymptotic representation of the spinor reads as

$$f_{\lambda j}(r) \to \sqrt{\frac{(E_\lambda+\mu)}{\pi k r}} \sin\left(kr - \frac{(j-1/2)\pi}{2} - \frac{\pi}{4} + \delta_j\right). \tag{14}$$

Substituting this expression into (9), one obtains

$$g_{\lambda j}(r) \to -\sqrt{\frac{(E_\lambda-\mu)}{\pi k r}} \cos\left(kr - \frac{(j-1/2)\pi}{2} - \frac{\pi}{4} + \delta_j\right). \tag{15}$$

Similarly, the entire asymptotic solutions for particle (positive energy) and antiparticle (negative energy) are found to be

$$f_{\lambda j}(r) \to \sqrt{\frac{(|E_\lambda| \pm \mu)}{\pi k r}} \sin\left(kr - \frac{\kappa\pi}{2} - \frac{\pi}{4} + \delta_j\right), \tag{16}$$

and

$$g_{\lambda j}(r) \to \mp \sqrt{\frac{(|E_\lambda| \mp \mu)}{\pi k r}} \cos\left(kr - \frac{\kappa\pi}{2} - \frac{\pi}{4} + \delta_j\right). \tag{17}$$

Here $\kappa \equiv |j-1/2|$ and the upper and lower signs indicate the scattering states of the particle (positive energy $E_\lambda > \mu$) and antiparticle (negative energy $E_\lambda < -\mu$), respectively. These asymptotic behaviors of spinors will be used to evaluate the change of the number of states around the potential barrier $V(r)$. To approach our aim, we consider a large 2D circular area, radius R, centered on the potential. By multiplying Eq. (7) through by $\Psi_\lambda^\dagger(\mathbf{r})$ and the corresponding equation for $\Psi_\lambda^\dagger(\mathbf{r})$ by $\Psi_\lambda(\mathbf{r})$, it follows that

$$(E_{\lambda'} - E_\lambda)\Psi_\lambda^\dagger(\mathbf{r})\Psi_{\lambda'}(\mathbf{r}) = -i\,\boldsymbol{\nabla}\cdot[\Psi_\lambda^\dagger(\mathbf{r})\vec{\alpha}\Psi_{\lambda'}(\mathbf{r})]. \tag{18}$$

Integrating over the whole area, and using the divergence theorem, one obtains

$$\int d^2r\, \Psi_\lambda^\dagger(\mathbf{r})\Psi_{\lambda'}(\mathbf{r}) = \frac{R}{(E_{\lambda'} - E_\lambda)} \sum_j [f_{\lambda j}^*(R) g_{\lambda' j}(R) - g_{\lambda j}^*(R) f_{\lambda' j}(R)]. \tag{19}$$

To get the equality, the radial component of $\vec{\alpha}$,

$$\frac{\vec{\alpha}\cdot\mathbf{r}}{r} = \begin{pmatrix} 0 & ie^{-i\varphi} \\ -ie^{i\varphi} & 0 \end{pmatrix} \tag{20}$$

is used and one takes $c_j = 1$; since we are only interested in the difference of states its complex nature is of no interest. For free Dirac particles, the above integral can be expanded as

$$\int d^2r\, \Psi_\lambda^{(0)\dagger}(\mathbf{r})\Psi_{\lambda'}^{(0)}(\mathbf{r}) = \frac{R}{(E_{\lambda'} - E_\lambda)} \sum_j [f_{\lambda j}^{(0)*}(R) g_{\lambda' j}^{(0)}(R) - g_{\lambda j}^{(0)*}(R) f_{\lambda' j}^{(0)}(R)], \tag{21}$$

with $f_{\lambda j}^{(0)} = f_{\lambda j}(\delta_j = 0)$, and $g_{\lambda j}^{(0)} = g_{\lambda j}(\delta_j = 0)$. In solids, the electron (hole) states are occupied up to the Fermi energy E_f $(-E_f')$. So the total change of the number of states ΔN around the potential $V(r)$ is obtained by integrating up to the Fermi energy E_f $(-E_f')$,

$$\Delta N = \lim_{R\to\infty} \lim_{E_{\lambda'}\to E_\lambda} \left(\int_{-E_f'}^{-\mu} + \int_{\mu}^{E_f} \right) dE_\lambda \int d^2r [\Psi_\lambda^\dagger(\mathbf{r})\Psi_{\lambda'}(\mathbf{r}) - \Psi_\lambda^{(0)\dagger}(\mathbf{r})\Psi_{\lambda'}^{(0)}(\mathbf{r})], \tag{22}$$

where the lower bound of the Fermi surface for an antiparticle is denoted by $-E_f'$ for accounting of different levels generally. Since at large distances the wave function $\Psi_\lambda(\mathbf{r})$ must be unchanged, except for the phase shifts in the partial waves, the spinors $f_{\lambda j}$ and $g_{\lambda j}$ in (8) can be replaced by the asymptotic representations of (16) and (17). It follows that

$$\begin{aligned} &\frac{R}{(E_{\lambda'} - E_\lambda)} \sum_j [f_{\lambda j}^*(R) g_{\lambda' j}(R) - g_{\lambda j}^*(R) f_{\lambda' j}(R) - f_{\lambda j}^{(0)*}(R) g_{\lambda' j}^{(0)}(R) + g_{\lambda j}^{(0)*}(R) f_{\lambda' j}^{(0)}(R)] \\ &\quad = \frac{C_\pm}{(E_{\lambda'} - E_\lambda)} \sum_j 2\cos\left((k'-k)R + \frac{1}{2}(\delta_{j'} - \delta_j)\right) \sin\left(\frac{1}{2}(\delta_{j'} - \delta_j)\right) \\ &\qquad + \frac{(-1)^\kappa D_\pm}{(E_{\lambda'} - E_\lambda)} \sum_j \left[2\cos[(k'+k)R] \sin^2\left(\frac{1}{2}(\delta_{j'} + \delta_j)\right) + \sin[(k'+k)R] \sin(\delta_{j'} + \delta_j) \right], \end{aligned} \tag{23}$$

where

$$C_\pm = \frac{\epsilon_E}{2\pi\sqrt{kk'}} \{[(|E_\lambda| \pm \mu)(|E_{\lambda'}| \mp \mu)]^{1/2} + [(|E_\lambda| \mp \mu)(|E_{\lambda'}| \pm \mu)]^{1/2}\}, \tag{24}$$

$$D_{\pm}=\frac{1}{2\pi\sqrt{kk'}}\{\pm[(|E_{\lambda}|\mp\mu)(|E_{\lambda'}|\pm\mu)]^{1/2}\mp[(|E_{\lambda}|\pm\mu)(|E_{\lambda'}|\mp\mu)]^{1/2}\}, \tag{25}$$

with $\epsilon_E\equiv 1(-1)$ for $E_{\lambda}\geqslant\mu$ ($E_{\lambda}\leqslant-\mu$). Here subscript "+" ("−") in $C_{\pm}$ corresponds to the particle (antiparticle). Taking the limit $E_{\lambda'}\to E_{\lambda}$, Eqs. (24) and (25) yield $C_{\pm}\to\epsilon_E/\pi$ and $D_{\pm}/(E_{\lambda'}-E_{\lambda})\to-\epsilon_E(\mu/2\pi k^2)$, such that

$$\lim_{E_{\lambda'}\to E_{\lambda}}\frac{C_{\pm}}{(E_{\lambda'}-E_{\lambda})}2\cos\left((k'-k)R+\frac{1}{2}(\delta_{j'}-\delta_j)\right)\sin\left(\frac{1}{2}(\delta_{j'}-\delta_j)\right)\to\frac{\epsilon_E}{\pi}\frac{d\delta_j}{dE_{\lambda}} \tag{26}$$

and

$$\lim_{E_{\lambda'}\to E_{\lambda}}\frac{(-1)^{\kappa}D_{\pm}}{(E_{\lambda'}-E_{\lambda})}\left[2\cos[(k'+k)R]\sin^2\left(\frac{1}{2}(\delta_{j'}+\delta_j)\right)+\sin[(k'+k)R]\sin(\delta_{j'}+\delta_j)\right]$$
$$\to\epsilon_E\frac{-(-1)^{\kappa}\mu}{2\pi k^2}[2\cos(2kR)\sin^2\delta_j+\sin(2kR)\sin(2\delta_j)]. \tag{27}$$

Since in 2D space $\delta_j(k=0)/\pi$ always take integers,[16,17] and $\lim_{R\to\infty}\cos(2kR)$ oscillates, the integral $\lim_{R\to\infty}\int dE_{\lambda}[\cos(2kR)\sin^2\delta_j]/k^2\to 0$. Moreover, due to the fact that $\lim_{R\to\infty}\sin(2kR)/\pi k=\delta(k)$, the integral in the second term in (27) $\lim_{R\to\infty}\int dE_{\lambda}\sin(2kR)\sin(2\delta_j)/\pi k^2\to 0$. Therefore the difference of the number of states finally can be in terms of the phase shifts at Fermi energies and the critical points $\pm\mu$ of zero momentum,

$$\Delta N=\frac{1}{\pi}\sum_{j=\pm 1/2,\pm 3/2,\ldots}[\delta_j(E_f)-\delta_j(\mu)+\delta_j(-E_f')-\delta_j(-\mu)]. \tag{28}$$

This is the FSR for 2D relativistic fermionic systems. One notice that the zero-momentum behavior is quite different from that in Eqs. (2) and (4) for 3D and 1D systems, where half bound states with phase shifts $\pi/2$ are significant.[16] Comparing with the nonrelativistic FSR (5), the antiparticle turns out to be significant. A positive (negative) ion will attract (repulse) electrons (holes), and repulse (attract) holes such that the variance of states is together with the effect of two kinds of particles.

III. THE CHANGE IN ENERGY DUE TO AN IMPURITY IN RELATIVISTIC 2D SYSTEMS

Equations (16) and (17) shows that the wave functions undergo phase shifts. This fact entails a change of the kinetic energy of particles. It can be quantified by the reasonable requirements $\Psi_{\lambda j}^{(0)}(\mathbf{r})|_{\mathrm{B.C.}}=0$ and $\Psi_{\lambda j}(\mathbf{r})|_{\mathrm{B.C.}}=0$ on boundary of the Dirichlet condition, and give

$$kR-\frac{\kappa\pi}{2}-\frac{\pi}{4}=n\pi,\quad n=1,2,\ldots, \tag{29}$$

for spinor $f_{\lambda j}^{(0)}$ and

$$kR-\frac{\kappa\pi}{2}-\frac{\pi}{4}=\frac{(2n+1)\pi}{2},\quad n=0,1,2,\ldots, \tag{30}$$

for spinor $g_{\lambda j}^{(0)}$. Here R is used to denote the boundary of the 2D system. The number dn of allowed states between k and $k+dk$ is given by differentiating both members of (29) and (30), which yield $R\,dk=\pi\,dn$. Thus, the unperturbed density of states for a definite j reads as

$$D(k)=\frac{dn}{dk}=\frac{R}{\pi}. \tag{31}$$

On the other hand, the boundary condition for perturbed wave functions that vanish at $r=R$ yield

$$kR - \frac{\kappa\pi}{2} - \frac{\pi}{4} + \delta_j(k) = n\pi, \quad n = 1,2, \ldots, \tag{32}$$

for spinor $f_{\lambda j}$ and

$$kR - \frac{\kappa\pi}{2} - \frac{\pi}{4} + \delta_j(k) = \frac{(2n+1)\pi}{2}, \quad n = 0,1,2, \ldots, \tag{33}$$

for spinor $g_{\lambda j}$. From (29), (32), (30), and (33), one finds that the change of the wave number Δk of an electron with angular momentum j is $\Delta k \cdot R = -\delta_j(k)$, and the change in energy is

$$\Delta E|_{e^-} = \frac{k\Delta k}{E_\lambda} = \frac{-k\,\delta_j(k)|_{e^-}}{R\sqrt{k^2+\mu^2}}. \tag{34}$$

Similarly, the change in energy for an antiparticle reads as

$$\Delta E|_{e^+} = \frac{k\Delta k}{E_\lambda} = \frac{k\,\delta_j(k)|_{e^+}}{R\sqrt{k^2+\mu^2}}. \tag{35}$$

Here e^- (e^+) is used to denote the particle (antiparticle). Thus, the change in energy due to the presence of an impurity in 2D relativistic spin-$\frac{1}{2}$ systems is given by

$$\begin{aligned}\Delta E &= \sum_{j=\pm 1/2,\pm 3/2,\ldots} \left(\int_0^{k_f} \Delta E|_{e^-} \frac{R}{\pi} dk - \int_0^{k_f'} \Delta E|_{e^+} \frac{R}{\pi} dk \right) \\ &= -\sum_{j=\pm 1/2,\pm 3/2,\ldots} \left(\int_0^{k_f} \frac{k\,\delta_j(k)|_{e^-}}{R\sqrt{k^2+\mu^2}} \frac{R}{\pi} dk + \int_0^{k_f'} \frac{k\,\delta_j(k)|_{e^+}}{R\sqrt{k^2+\mu^2}} \frac{R}{\pi} dk \right),\end{aligned} \tag{36}$$

where R/π is the density of states for j electrons and holes. This result is a 2D relativistic generalization of Fumi theorem,[19] where the change of the kinetic energy due to the impurity for nonrelativistic systems was studied. It is worthy to note that in the massless limit, the change in energy becomes a more compact representation,

$$\Delta E = -\frac{1}{\pi} \sum_{j=\pm 1/2,\pm 3/2,\ldots} \left(\int_0^{k_f} \delta_j(k)|_{e^-}\, dk + \int_0^{k_f'} \delta_j(k)|_{e^+}\, dk \right), \tag{37}$$

which states the variance of system's energy due to the impurity can be completely ascertained as soon as the phase shifts is decided.

IV. DISCUSSIONS

A. The relation with the relativistic Levinson theorem

In 1949, Levinson established a theorem in nonrelativistic quantum mechanics.[15] Well known as the Levinson theorem, it clarifies the relation between the phase shifts of a quantum particle scattered by a short range potential and the number of bound states therein. In 3D systems, the theorem can be described as

$$\delta_l(0) = N_l\pi, \quad l = 0,1,2, \ldots, \tag{38}$$

where $\delta_l(0)$ denotes the phase shift of scattered state with a momentum k at the threshold ($k=0$) in the angular momentum channel l, and N_l is the total number of bound states in the angular momentum channel l allowed by the short range potential. When the angular momentum $l=0$, the theorem must be modified to

$$\delta_0(0) = (N_0 + 1/2)\pi, \tag{39}$$

due to the existence of a zero-energy resonance (a half-bound state).[16] The theorem is one of the most interesting and beautiful results in nonrelativistic quantum theory. For 2D relativistic spin-$\frac{1}{2}$ systems under consideration, there is a very interesting relation between the Levinson theorem and the Friedel sum rule can be established by noting the relationship of completeness of relativistic states,

$$\sum_{\text{discrete}} \psi_{\lambda j}(\mathbf{r})\psi^{\dagger}_{\lambda j}(\mathbf{r}') + \sum_j \left(\int_{-E_f'}^{-\mu} + \int_{\mu}^{E_f} \right) dE_\lambda \, \Psi_{\lambda j}(\mathbf{r})\Psi^{\dagger}_{\lambda j}(\mathbf{r}') = \delta(\mathbf{r}-\mathbf{r}'). \tag{40}$$

Here $\psi_{\lambda j}(\mathbf{r})$ denotes a discrete bound-state with a definite angular momentum j and energy E_λ allowed by the short range potential. Subtracting the relation from the ones of free particle states $\Psi^{(0)}_{\lambda j}(\mathbf{r})$, setting $\mathbf{r}=\mathbf{r}'$, taking trace, and integrating over the 2D plane, we can find the relation between the total number of bound states N and the difference of scattering states ΔN as follows:

$$N = \sum_j N_j = -\Delta N. \tag{41}$$

The total number of bound states is then given by

$$N = \frac{1}{\pi} \sum_{j=\pm 1/2, \pm 3/2, \ldots} [\delta_j(\mu) - \delta_j(E_f) + \delta_j(-\mu) - \delta_j(-E_f')]. \tag{42}$$

The equality implies the bound-state number for a definite channel of angular momentum j is

$$N_j = \frac{1}{\pi}[\delta_j(\mu) - \delta_j(E_f) + \delta_j(-\mu) - \delta_j(-E_f')]. \tag{43}$$

This result is the Levinson theorem for relativistic spin-$\frac{1}{2}$ particles in 2D many-body systems. Different from the single particle case,[17,18]

$$N_j = \frac{1}{\pi}[\delta_j(\mu) + \delta_j(-\mu)], \tag{44}$$

where the upper bound of the phase is ruled out by the relation $\delta_j(\infty) + \delta_j(-\infty) = 0$. The phase shifts at Fermi energy play an important role here. The relation (41) reflects the completeness of the whole set of states. The total number of states is not altered by an external field, except that some scattering states are pulled down into the bound state region if the external potential is attractive. On the other hand, (41) implies that there is an upper bound on ΔN that depends on the potential $V(r)$. A finite deep potential may have finite bound states such that the change of the number of scattering states is finite.

B. Density oscillation in relativistic systems

Another way to express the change of the number of states that enables us to indicate the variance of the density of states may be expressed as

$$\Delta N = 2\pi \int_0^{\infty} r \, dr[\rho(r) - \rho_0(r)], \tag{45}$$

where $(\rho - \rho_0) \equiv \delta\rho$ is the difference of the density of states given as

$$\delta\rho = \int_{k<k_f} \frac{d^2k}{(2\pi)^2}[|\Psi_\lambda(\mathbf{r})|^2 - |\Psi^{(0)}_\lambda(\mathbf{r})|^2]. \tag{46}$$

At large distances, with (16) and (17), it is shown that

$$\delta\rho = \frac{1}{(2\pi)^2}\sum_j \int_{k<k_f} k\,dk\left((-1)^{\kappa+1}\epsilon_E \frac{2\mu}{\pi k r}\cos(2kr+\delta_j)\sin\,\delta_j\right). \tag{47}$$

The integration about the wave vector is difficult because the phase shifts depend on k. But we can obtain an approximate answer by expending it around the Fermi wave vector as $\delta_j = \delta_j(k_f) + (k - k_f)(d\delta_j/dk)$, which yields

$$\lim_{r\to\infty} \delta\rho = \frac{1}{(2\pi)^2}\sum_j (-1)^{\kappa+1}\frac{\epsilon_E \mu}{\pi}\frac{1}{r^2}\sin[2k_f r + \delta_j(k_f)]\sin\,\delta_j(k_f) + O\left(\frac{1}{r^3}\right). \tag{48}$$

The density oscillates with a period of $2k_f$ and decreases in amplitude as r^{-2}, which describes the density oscillation in 2D systems decay less rapidly than r^{-3} of 3D ones, but more rapidly than r^{-1} of the 1D case.[8] Another remarkable result is that two branches of energy have the opposite oscillating phases. Thus the antiparticle will tend to suppress the oscillation for the same phase shifts.

C. The 2D FSR for massless Dirac fermions

It was pointed out that the Lorentz group often occurs as an approximate symmetry for low energy excitation for 2D fermions in semimetals,[9,12–14] relativistic spectra appear naturally for massless conduction electrons in such systems. It is interesting to discuss the FSR in the condition of the fermion mass tends to zero. From (28), one see that as the effective mass tends to zero, ΔN becomes

$$\Delta N = \sum_{j=\pm 1/2,\pm 3/2,\ldots} [\delta_j(E_f) + \delta_j(-E_f') - 2\delta_j(0)], \tag{49}$$

which indicates the phase shifts of the particle and antiparticle at zero momentum merge to become twice. For systems contain only single carrier type, the Friedel sums become

$$\Delta N_{\text{particle}} = \sum_{j=\pm 1/2,\pm 3/2,\ldots} [\delta_j(E_f) - \delta_j(0)] \tag{50}$$

for the particle and

$$\Delta N_{\text{antiparticle}} = \sum_{j=\pm 1/2,\pm 3/2,\ldots} [\delta_j(-E_f') - \delta_j(0)] \tag{51}$$

for the antiparticle. This is the extreme case of the graphene, where the carrier type can be controlled by the external gate voltage.[13,14] Another interesting result about massless fermions comes from (47). As the effective mass tends to zero, the difference of the density of states at far regions turns into a constant, and is independent of the details of the system. This argument probably enables us to decide the magnitude of effective mass in a nonideal effective relativistic 2D system via Friedel oscillation at far zones.

D. Extension of the potential to the more general case

Although in the procedure of our proof we assume that the potential must be short range, we do not specify the radius a beyond which $V(r)=0$. Hence, we expect that the FSR given in the article should be valid for a very general potential as long as the potential decreases rapidly enough when $r\to\infty$.

E. The control of the change of the total number of states

Since a specified number of bound states in a quantum dot can be realized in the present-day nanotechniques, it seems to us that we can control the number of states around an impurity. This is due to the fact that quantum dots can be carved out of a 2DEG[20] such that the change of the

number of states around them can be counted according to (41). The fact may be very useful in controlling a spin bus (a controllable coupler of many qubits) via Friedel oscillation of spin systems.[20]

V. CONCLUSIONS

In this paper, the 2D Friedel sum rule is generalized to the relativistic spin-$\frac{1}{2}$ systems. The change in energy of the spin-$\frac{1}{2}$ system due to the presence of an impurity is studied. The relation of the rule with the 2D relativistic Levinson theorem is presented. Density oscillation is discussed. Since in 2D semimetals the low energy effective theory for conduction electrons is described by the Dirac's relativistic theory,[9,12–14] we hope that the result is helpful in studying the effects of impurities in the corresponding structures.

APPENDIX

Here we establish the relation between the Friedel sum rule and Levinson theorem for nonrelativistic particles in 2D systems. Consider the 2D Schrödinger equation in the presence of a central potential $V(r)$

$$\hat{H}\Psi = -\frac{\hbar^2}{2\mu}\nabla^2\Psi + V(r)\Psi = E\Psi. \tag{A1}$$

The solution of (A1) may be expanded as

$$\Psi(r,\varphi) = \sum_{m=-\infty}^{\infty} a_m R_{|m|}(r) e^{im\varphi}, \tag{A2}$$

where $R_m(r)$ satisfies the radial equation,

$$\frac{\partial^2}{\partial r^2}R_m + \frac{1}{r}\frac{\partial}{\partial r}R_m + \left(k^2 - \frac{2\mu V}{\hbar^2} - \frac{m^2}{r^2}\right)R_m = 0, \quad m = 0,1,2,\ldots, \tag{A3}$$

with $k=\sqrt{2\mu E/\hbar^2}$ (we preserve $\hbar$ here for the general convention in nonrelativistic quantum mechanics). Here we need the partial derivative, since R_m is also a function of k. For a short range potential $V(r)=0$ when $r \geqslant a$, the independent scattering solution is given by

$$R_m(kr) = AJ_m(kr) + BN_m(kr). \tag{A4}$$

Using the definition of the phase shifts $B/A=-\tan\delta_m(k)$, one can find the asymptotic representation,

$$R_m(kr) \to \sqrt{\frac{2}{\pi r}}\cos\left(kr - \frac{m\pi}{2} - \frac{\pi}{4} + \delta_m(k)\right), \tag{A5}$$

where the normalization constant is chosen as the function for the free particle normalized to $\delta(k-k')$. For simplicity in deriving the FSR, one defines $R_m=\chi_m/\sqrt{r}$ such that Eq. (A3) reduces to

$$\frac{\partial^2}{\partial r^2}\chi_m - \frac{m^2-1/4}{r^2}\chi_m + \left(k^2 - \frac{2\mu V}{\hbar^2}\right)\chi_m = 0. \tag{A6}$$

The total change of the number of states ΔN around the potential $V(r)$ is obtained by integrating $(|\Psi|^2-|\Psi^{(0)}|^2)$ from 0 to R and up to the Fermi wave vector k_f, which yields

$$\Delta N = \lim_{R\to\infty} \sum_{m=-\infty}^{\infty} \int_0^{k_f} dk \int_0^R dr[|\chi_m(r)|^2 - |\chi_m^{(0)}(r)|^2], \tag{A7}$$

where $\chi_m^{(0)}(r)$ denotes the state of a free particle with a definite angular momentum channel m and we have taken $a_m=1$ since we are only interested in the difference of states its complex nature is of no interest. The integration on r can be evaluated by the following procedures. By multiplying (A6) through by χ_m^* and the corresponding equation for χ_m^* by χ_m, it follows that

$$\frac{\partial}{\partial r}\left(\chi_m^*(k',r)\frac{\partial}{\partial r}\chi_m(k,r) - \chi_m(k,r)\frac{\partial}{\partial x}\chi_m^*(k',r)\right) = (k'^2 - k^2)\chi_m^*(k',r)\chi_m(k,r), \tag{A8}$$

where the dependence of χ_m on the variables k,r is expressed explicitly. By taking the limit $k' \to k$, it can be shown that

$$|\chi_m(r)|^2 = \frac{1}{2k}\frac{\partial}{\partial r}\left(\frac{\partial\chi_m}{\partial r}\frac{\partial\chi_m^*}{\partial k} - \chi_m\frac{\partial^2\chi_m^*}{\partial r\,\partial k}\right). \tag{A9}$$

Thus, for large r, making use of Eq. (A5) and the boundary condition $\chi_m^{(0)}(k,0)=0$, $\chi_m(k,0)=0$, since the wave function should be finite at $r=0$; one finds

$$\begin{aligned}
&\sum_{m=-\infty}^{\infty}\int_0^R dr[|\chi_m(r)|^2 - |\chi_m^{(0)}(r)|^2] \\
&\quad= \frac{1}{\pi}\sum_{m=-\infty}^{\infty}\left[\frac{d\delta_m}{dk} + \frac{1}{2k}\sin\left(2kR - m\pi - \frac{\pi}{2} + 2\delta_m\right) - \sin\left(2kR - m\pi - \frac{\pi}{2}\right)\right] \\
&\quad= \frac{1}{\pi}\sum_{m=-\infty}^{\infty}\left(\frac{d\delta_m}{dk} + \frac{(-1)^m}{\pi k}\sin^2\delta_m\cos(2kR) + \frac{(-1)^m}{2}\sin(2\delta_m)\frac{\sin(2kR)}{\pi k}\right).
\end{aligned} \tag{A10}$$

Since $\lim_{R\to\infty}\sin(2kR)/\pi k = \delta(k)$ and $\lim_{R\to\infty}\cos(2kR)$ oscillates, the integration over k in (A7) can be carried out, which yields the 2D Friedel sum rule,

$$\Delta N = \frac{2}{\pi}\sum_{m=-\infty}^{\infty}[\delta_m(E_f) - \delta_m(0)], \tag{A11}$$

where the factor of 2 is spin degeneracy and we have used the fact that $\delta_m(0)/\pi$ always takes integers in 2D space, such that the integration in the second term in (A10)

$$\lim_{R\to\infty}\int_0^{k_f} dk\frac{1}{k}\sin^2\delta_m\cos(2kR) \to 0. \tag{A12}$$

The interesting relation between the number of bound states (LT) and the change in the scattering states ΔN (FSR) can be established by the completeness relationship

$$\sum_{m=-\infty}^{\infty}\sum_{i=1}^{N_m}\psi_{m,E_i}^*(r)\psi_{m,E_i}(r') + \sum_{m=-\infty}^{\infty}\int_0^{k_f} dk\,\chi_m^*(k,r)\chi_m(k,r') = \delta(r-r'). \tag{A13}$$

Here N_m and $\psi_{m,E_i}(r)$ are the bound-state number and eigenfunction for a definite angular momentum channel. Subtracting the relation from the free particles solutions $\chi_m^{(0)}(k,r)$, setting $r=r'$ and integrating from 0 to R, we obtain the equality

$$N = \sum_{m=-\infty}^{\infty} N_m = -\Delta N, \tag{A14}$$

which implies the total number of the bound states

$$N = \frac{2}{\pi} \sum_{m=-\infty}^{\infty} [\delta_m(0) - \delta_m(E_f)], \tag{A15}$$

with

$$N_m = \delta_m(0) - \delta_m(E_f). \tag{A16}$$

This is the Levinson theorem for nonrelativistic particles in 2D many-body systems. Different from the single particle case, the phase shifts at Fermi energy play an important role.

The Cauchy problem is considered for the scalar wave equation in the Schwarzschild geometry. We derive an integral spectral representation for the solution and prove pointwise decay in time. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2186258]

I. INTRODUCTION

Recently pointwise decay was proven for solutions of the scalar wave equation in the Kerr geometry.[1,2] The main difficulties in this proof are due to the fact that the metric is only axisymmetric. In particular, the classical energy density may be negative inside the *ergosphere*, a region outside the event horizon in which the Killing vector corresponding to time translations becomes spacelike. This makes it necessary to apply special methods (spectral theory in Pontrjagin spaces, energy splitting estimates, causality arguments) which are technically demanding and not easily accessible. Therefore, it seems worthwile working out the special case of spherical symmetry (Schwarzschild geometry) separately. This is precisely the purpose of the present paper, where we derive an integral representation for the solution of the Cauchy problem and prove pointwise decay for the scalar wave equation in the Schwarzschild geometry. In this case, the classical energy density is positive everywhere outside the event horizon. This gives rise to a positive definite scalar product, making it possible to apply Hilbert space methods.

Recall that in Schwarzschild coordinates (t,r,ϑ,φ), the Schwarzschild metric takes the form

$$\mathrm{d}s^2 = g_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j = \left(1-\frac{2M}{r}\right)\mathrm{d}t^2 - \left(1-\frac{2M}{r}\right)^{-1}\mathrm{d}r^2 - r^2(\mathrm{d}\vartheta^2+\sin^2\vartheta\,\mathrm{d}\varphi^2) \tag{1.1}$$

with $r>0$, $0\leqslant\vartheta\leqslant\pi$, $0\leqslant\varphi<2\pi$. We often use for the angular variables the short notation $x\in S^2$. Obviously, the metric has two singularities at $r=0$ and $r=2M$. The latter is called the *event horizon* and can be resolved by a simple coordinate transformation. In the following we consider only the region $r>2M$ outside the event horizon. The scalar wave equation in the Schwarzschild geometry is given by

$$\Box\phi := g^{ij}\nabla_i\nabla_j\phi = \frac{1}{\sqrt{-g}}\frac{\partial}{\partial x^i}\left(\sqrt{-g}\,g^{ij}\frac{\partial}{\partial x^j}\right)\phi = 0, \tag{1.2}$$

where g denotes the determinant of the metric g_{ij}. We now state our main result.

Theorem 1.1: *Consider the Cauchy problem of the scalar wave equation in the Schwarzschild geometry*

$$\Box\phi = 0, \quad (\phi, i\partial_t\phi)(0,r,x) = \Phi_0(r,x)$$

for smooth initial data $\Phi_0\in C_0^\infty((2M,\infty)\times S^2)^2$ *which is compactly supported outside the event horizon. Then there exists a unique global solution* $\Phi(t)=(\phi(t),i\partial_t\phi(t))\in C^\infty(\mathbb{R}\times(2M,\infty)\times S^2)^2$

[a)]Electronic mail: johann.kronthaler@mathematik.uni-regensburg.de

which is compactly supported for all times t. Moreover, for fixed (r,x) *this solution decays as* $t\to\infty$.

There has been considerable work on the wave equation in the Schwarzschild geometry. In 1957, Regge and Wheeler[3] investigated the linear stability of this geometry. Kay and Wald[4] proved boundedness for solutions of the Klein-Gordon equation in this space-time outside and on the event horizon. By heuristic arguments, Price[5] got evidence for polynomial decay of solutions of the scalar wave equation. More recently, Dafermos and Rodnianski[6] gave a mathematical proof for this decay for spherical symmetric initial data. For general initial data they derived decay rates,[7] which are however not sharp. Furthermore, Morawetz and Strichartz type estimates for a massless scalar field without charge in a Reissner Nordstrøm background with naked singularity are developed in Ref. 8. And in Ref. 9 a Morawetz-type inequality was proven for the semilinear wave equation in Schwarzschild.

The paper is organized as follows: First, we introduce the Regge-Wheeler variable and rewrite the wave equation as a first-order Hamiltonian system. The resulting Hamiltonian is a symmetric operator with respect to the scalar product arising from the conserved energy. Exploiting the spherical symmetry of the problem, we may consider the problem for fixed angular modes l and m. We then show that the corresponding Hamiltonian is essentially self-adjoint. More precisely, our goal is to apply Stone's formula, which relates the propagator to an integral over the resolvent. Thus in Sec. IV we give an explicit construction for the resolvent. This construction is based on special solutions of the radial equation, which decay exponentially at $\pm\infty$. In Sec. V we prove the existence of these solutions via the formalism of the Jost equation. Moreover, we obtain appropriate regularity results for these solutions, which lead to an integral representation of the solution operators of the Cauchy problem for fixed l and m. According to the theory of symmetric hyperbolic systems, the Cauchy problem has a unique smooth solution. Thus, summing over the angular modes yields the desired representation of this solution. Combining this representation with a Sobolev imbedding argument, we obtain pointwise decay in time.

II. PRELIMINARIES

In this section we reformulate the wave equation as a first order Hamiltonian system. This will make it possible to analyze the dynamics of the waves with Hilbert space methods.

According to (1.1) and (1.2) the scalar wave equation in the Schwarzschild geometry with respect to Schwarzschild coordinates has the explicit form

$$\left[\frac{\partial^2}{\partial t^2}-\left(1-\frac{2M}{r}\right)\frac{1}{r^2}\left(\frac{\partial}{\partial r}(r^2-2Mr)\frac{\partial}{\partial r}+\Delta_{S^2}\right)\right]\phi=0. \tag{2.1}$$

Here Δ_{S^2} denotes the standard Laplacian on the two sphere, which in the coordinates (ϑ,φ) is given by

$$\Delta_{S^2}=\frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2}+\frac{\partial}{\partial(\cos\vartheta)}\sin^2\vartheta\frac{\partial}{\partial(\cos\vartheta)}. \tag{2.2}$$

In order to bring the equation (2.1) into a more convenient form, we first introduce the Regge-Wheeler coordinate u by

$$u(r):=r+2M\log\left(\frac{r}{2M}-1\right). \tag{2.3}$$

The variable u takes values in the whole interval $(-\infty,\infty)$ as r ranges over $(2M,\infty)$. It satisfies the relations

$$\frac{\mathrm{d}u}{\mathrm{d}r} = \frac{1}{1-\frac{2M}{r}}, \quad \frac{\partial}{\partial u} = \left(1-\frac{2M}{r}\right)\frac{\partial}{\partial r}. \tag{2.4}$$

In what follows the variable r is always implicitly given by u. Using the Regge-Wheeler coordinate, the wave equation (2.1) transforms to

$$\left[\frac{\partial^2}{\partial t^2} - \frac{1}{r}\frac{\partial^2}{\partial u^2}r + \left(1-\frac{2M}{r}\right)\left(\frac{2M}{r^3} - \frac{\Delta_{S^2}}{r^2}\right)\right]\phi = 0. \tag{2.5}$$

To simplify this equation we multiply by r and substitute $\psi = r\phi$. This leads us to the Cauchy problem

$$\left[\frac{\partial^2}{\partial t^2} - \frac{\partial^2}{\partial u^2} + \left(1-\frac{2M}{r}\right)\left(\frac{2M}{r^3} - \frac{\Delta_{S^2}}{r^2}\right)\right]\psi(t,u,x) = 0,$$

$$(\psi, i\partial_t\psi)(0,u,x) = \Psi_0(u,x), \tag{2.6}$$

where the initial data $\Psi_0 \in C_0^\infty(\mathbb{R}\times S^2)^2$ is smooth and compactly supported.

The equation in (2.6) can be reformulated as the Euler-Lagrange equation corresponding to the action

$$S = \int_{-\infty}^{\infty}\mathrm{d}t\int_{-\infty}^{\infty}\mathrm{d}u\int_{-1}^{1}d(\cos\vartheta)\int_0^{2\pi}\mathrm{d}\varphi\,\mathcal{L}(\psi,\nabla\psi), \tag{2.7}$$

where the Lagrangian is given by

$$2\mathcal{L} = |\partial_t\psi|^2 - |\partial_u\psi|^2 - \left(1-\frac{2M}{r}\right)\frac{2M}{r^3}|\psi|^2 - \left(1-\frac{2M}{r}\right)\frac{1}{r^2}\left(\frac{1}{\sin^2\vartheta}|\partial_\varphi\psi|^2 + \sin^2\vartheta|\partial_{\cos\vartheta}\psi|^2\right). \tag{2.8}$$

As one sees immediately, the Lagrangian is invariant under time translations, and thus Noether's theorem gives rise to a conserved quantity, the energy E,

$$E[\psi] = \int_{-\infty}^{\infty}\mathrm{d}u\int_{-1}^{1}d(\cos\vartheta)\int_0^{2\pi}\frac{\mathrm{d}\varphi}{\pi}\mathcal{E}, \tag{2.9}$$

where $\mathcal{E}$ is the energy density

$$2\mathcal{E} = 2\left(\frac{\partial\mathcal{L}}{\partial\psi_t}\psi_t - \mathcal{L}\right) = |\partial_t\psi|^2 + |\partial_u\psi|^2 + \left(1-\frac{2M}{r}\right)\left\{\frac{2M}{r^3}|\psi|^2 + \frac{1}{r^2}\left(\frac{1}{\sin^2\vartheta}|\partial_\varphi\psi|^2 + \sin^2\vartheta|\partial_{\cos\vartheta}\psi|^2\right)\right\}. \tag{2.10}$$

It is also easy to check directly that the above energy is conserved in time for all smooth solutions of the wave equation that are compactly supported for all times. Since we consider the wave equation outside the event horizon, i.e., $r>2M$, it is clear that the energy density is positive everywhere.

Next we rewrite the Cauchy problem (2.6) in first-order Hamiltonian form. Letting

$$\Psi = \begin{pmatrix}\psi\\ i\partial_t\psi\end{pmatrix}, \tag{2.11}$$

the Cauchy problem takes the form

$$i\partial_t \Psi = H\Psi, \qquad \Psi|_{t=0} = \Psi_0, \tag{2.12}$$

where H is the Hamiltonian

$$\begin{pmatrix} 0 & 1 \\ A & 0 \end{pmatrix}. \tag{2.13}$$

Here A is the differential operator

$$A = -\partial_u^2 + \left(1 - \frac{2M}{r}\right)\left(\frac{2M}{r^3} - \frac{1}{r^2}\Delta_{S^2}\right). \tag{2.14}$$

We use the energy E in order to introduce a scalar product such that the Hamiltonian H is symmetric with respect to it. More precisely, we endow the space $C_0^\infty(\mathbb{R}\times S^2)^2$ with the *energy scalar product* $\langle .,. \rangle$ by polarizing E, thus

$$\begin{aligned}\langle \Psi, \Phi \rangle := \int_{-\infty}^{\infty} \mathrm{d}u \int_{-1}^{1} d(\cos\vartheta) \int_0^{2\pi} \frac{\mathrm{d}\varphi}{2\pi} \Bigg\{ &\overline{\partial_t \psi} \partial_t \phi + \overline{\partial_u \psi} \partial_u \phi + \left(1 - \frac{2M}{r}\right) \\ &\times \left[\frac{2M}{r^3} \overline{\psi} \phi + \frac{1}{r^2} \left(\frac{1}{\sin^2\vartheta} \overline{\partial_\varphi \psi} \partial_\varphi \phi + \sin^2\vartheta \, \overline{\partial_{\cos\vartheta} \psi} \partial_{\cos\vartheta} \phi \right) \right] \Bigg\},\end{aligned} \tag{2.15}$$

where again $\Psi = (\psi, i\partial_t \psi)^T$ and $\Phi = (\phi, i\partial_t \phi)^T$. Energy conservation implies that for a solution Ψ of the Cauchy problem (2.12) which is compactly supported for all times,

$$0 = \frac{d}{\mathrm{d}t} E[\Psi] = \frac{d}{\mathrm{d}t} \langle \Psi, \Psi \rangle = \langle \dot{\Psi}, \Psi \rangle + \langle \Psi, \dot{\Psi} \rangle = i\langle H\Psi, \Psi \rangle - i\langle \Psi, H\Psi \rangle.$$

Since the initial data $\Psi_0 \in C_0^\infty(\mathbb{R}\times S^2)^2$ can be chosen arbitrarily, polarization yields

$$\langle H\Psi, \Phi \rangle = \langle \Psi, H\Phi \rangle, \quad \text{for all } \Psi, \Phi \in C_0^\infty(\mathbb{R}\times S^2)^2. \tag{2.16}$$

Hence the operator H is symmetric on $C_0^\infty(\mathbb{R}\times S^2)^2$ with respect to $\langle .,. \rangle$.

We will now use the spherical symmetry to simplify the problem. More precisely, we make use of the fact that the angular dependence of the wave equation in the Schwarzschild geometry involves only the Laplacian on the two sphere. It is well known that the spherical harmonics $\{Y_{lm}(\vartheta, \varphi)\}_{l\in\mathbb{N}_0, |m|\leqslant l}$ are smooth eigenfunctions of Δ_{S^2} with the eigenvalues $-l(l+1)$. Moreover, they form an orthonormal basis of the space $L^2(S^2)$. Thus we can decompose an arbitrary $\Psi \equiv (\psi_1, \psi_2)^T \in C_0^\infty(\mathbb{R}\times S^2)^2$ in the following way:

$$\Psi(u, \vartheta, \varphi) = \sum_{l=0}^{\infty} \sum_{|m|\leqslant l} \Psi^{lm}(u) Y_{lm}(\vartheta, \varphi), \tag{2.17}$$

where for each component the sum converges for fixed u in $L^2(S^2)$. Since the $\Psi^{lm} \equiv (\psi_1^{lm}, \psi_2^{lm})^T$ are uniquely determined by $\psi_i^{lm}(u) = \langle Y_{lm}, \psi_i(u) \rangle_{L^2(S^2)}$ it is clear that $\Psi^{lm}(u) \in C_0^\infty(\mathbb{R})^2$ for all l, m. Using this decomposition, we rewrite the norm of Ψ corresponding to the energy scalar product as

$$\begin{aligned}\langle \Psi, \Psi \rangle &= \int_{-\infty}^{\infty} \mathrm{d}u \int_{-1}^{1} d(\cos\vartheta) \int_0^{2\pi} \frac{\mathrm{d}\varphi}{2\pi} \left\{ |\psi_2|^2 + |\partial_u \psi_1|^2 + \overline{\psi_1} \left(1 - \frac{2M}{r}\right)\left(\frac{2M}{r^3} - \frac{1}{r^2}\Delta_{S^2}\right)\psi_1 \right\} \\ &= \sum_{l=0}^{\infty} \sum_{|m|\leqslant l} \int_{-\infty}^{\infty} \mathrm{d}u \left\{ |\psi_2^{lm}(u)|^2 + |\partial_u \psi_1^{lm}(u)|^2 + \left(1 - \frac{2M}{r}\right)\left(\frac{2M}{r^3} + \frac{l(l+1)}{r^2}\right)|\psi_1^{lm}(u)|^2 \right\},\end{aligned} \tag{2.18}$$

where in the first equation we have integrated by parts with respect to (ϑ, φ). The second equation follows from the properties of the Y_{lm}. As one can immediately see, the integrand for every

summand in (2.18) is positive. Hence again by polarizing we obtain for any angular mode l a scalar product $\langle .,. \rangle_l$ on $C_0^\infty(\mathbb{R})^2$ given by

$$\langle \Psi, \Phi \rangle_l = \int_{-\infty}^{\infty} \{\overline{\psi_2}\phi_2 + \overline{\psi_1'}\phi_1' + V_l \overline{\psi_1}\phi_1\} \mathrm{d}u, \tag{2.19}$$

with the potential $V_l(u)$ defined as

$$V_l(u) = \left(1 - \frac{2M}{r}\right)\left(\frac{2M}{r^3} + \frac{l(l+1)}{r^2}\right). \tag{2.20}$$

This definition leads to an isometry

$$(C_0^\infty(\mathbb{R} \times S^2)^2, \langle .,. \rangle) \to \overset{\infty}{\underset{l=0}{\oplus}} \underset{|m|\leqslant l}{\oplus} (C_0^\infty(\mathbb{R})^2, \langle .,. \rangle_l),$$

$$\Psi \mapsto \Psi^{lm}. \tag{2.21}$$

Using (2.17), the Hamiltonian H also decomposes in the following way:

$$H\Psi(u, \vartheta, \varphi) = \sum_{l=0}^{\infty} \sum_{|m|\leqslant l} H_l \Psi^{lm}(u) Y_{lm}(\vartheta, \varphi).$$

Here the H_l act on $C_0^\infty(\mathbb{R})^2$ and are given by

$$H_l = \begin{pmatrix} 0 & 1 \\ -\partial_u^2 + V_l(u) & 0 \end{pmatrix}. \tag{2.22}$$

Thus for fixed angular modes l and m the Cauchy problem (2.12) simplifies to

$$i\partial_t \Psi^{lm} = H_l \Psi^{lm}, \qquad \Psi^{lm}\big|_{t=0} = \Psi_0^{lm}, \tag{2.23}$$

where the initial data is in $C_0^\infty(\mathbb{R})^2$. Moreover, the H_l are symmetric on $C_0^\infty(\mathbb{R})^2$ with respect to $\langle .,. \rangle_l$, because for any $\Psi, \Phi \in C_0^\infty(\mathbb{R})^2$ the functions $\Psi(u)Y_{lm}$ and $\Phi(u)Y_{lm}$ are in $C_0^\infty(\mathbb{R} \times S^2)^2$. Thus

$$\langle H_l \Psi, \Phi \rangle_l = \langle H(\Psi Y_{lm}), \Phi Y_{lm} \rangle = \langle \Psi Y_{lm}, H(\Phi Y_{lm}) \rangle = \langle \Psi, H_l \Phi \rangle_l.$$

In particular, for solutions of (2.23) with compact support in u for all times, the norm with respect to $\langle .,. \rangle_l$ is constant. Therefore we again refer to $\langle .,. \rangle_l$ as the energy scalar product.

Our strategy is to solve for a given inital data $\Psi_0 \in C_0^\infty(\mathbb{R} \times S^2)^2$ the Cauchy problem (2.23) for fixed angular modes l and m, and to sum up the solutions afterwards. Therefore, in what follows we will fix the angular modes l, m and consider the problem (2.23). In order to avoid too many indices, we usually omit the subscript l in the Hamiltonian and energy scalar product.

III. SPECTRAL PROPERTIES OF THE HAMILTONIAN

In the preceding section we introduced the energy scalar product $\langle , \rangle$ on the space $C_0^\infty(\mathbb{R})^2$. Since we cannot expect $C_0^\infty(\mathbb{R})^2$ to be complete with respect to this inner product (and indeed it is not, because the energy scalar product in the second component is just the usual L^2-scalar product), we define the Hilbert space $H^1_{V_l 0}(\mathbb{R})$ as the completion of $C_0^\infty(\mathbb{R})$ within the Hilbert space

$$H^1_{V_l}(\mathbb{R}) = \{u \text{ with } u' \in L^2(\mathbb{R}) \text{ and } V_l^{1/2} u \in L^2(\mathbb{R})\}$$

endowed with the scalar product

$$\langle u,v\rangle_1 := (u',v')_{L^2} + (V_l u, v)_{L^2}.$$

Note that this coincides with the energy scalar product on the first component. Therefore, we choose $\mathcal{H} \equiv H^1_{V_l 0}(\mathbb{R}) \oplus L^2(\mathbb{R})$ endowed with the energy scalar product as the underlying Hilbert space for our Hamiltonian H.

In the preceding section we have seen that the Hamiltonian H is symmetric on $C_0^\infty(\mathbb{R})^2$. Before we can use functional analytic methods, we need to construct a self-adjoint extension of H. In fact, we are able to prove the following lemma.

Lemma 3.1: The operator H with domain $\mathcal{D}(H)=C_0^\infty(\mathbb{R})^2$ is essentially self-adjoint in the Hilbert space $\mathcal{H}$.

In order to prove this lemma, we use the following version of Stone's theorem about strongly continuous one-parameter unitary groups. A proof of this theorem can be found in Ref. 10, Sec. VIII.4. (Also see Ref. 11).

Theorem 3.2: *Let $U(t)$ be a strongly continuous one-parameter unitary group on a Hilbert space $\mathcal{H}$. Then there is a self-adjoint operator A on $\mathcal{H}$ such that $U(t)=e^{itA}$.*

Furthermore, let D be a dense domain which is invariant under $U(t)$ and on which $U(t)$ is strongly differentiable. Then i^{-1} times the strong derivative of $U(t)$ is essentially self-adjoint on D, and its closure is A.

Now we apply this theorem.

Proof of Lemma 3.1: According to the theory of symmetric hyperbolic systems (cf. Ref. 12, Sec. 5.3) the Cauchy problem

$$(\partial_t^2 - \partial_u^2 + V_l(u))\psi(t,u) = 0,$$

$$\psi|_{t=0} = f, \quad i\partial_t\psi|_{t=0} = g$$

with smooth, compactly supported initial data $f,g \in C_0^\infty(\mathbb{R})$ has a unique solution $\psi(t,u) \in C^\infty(\mathbb{R}\times\mathbb{R})$ which is also compactly supported in u for all times. Using this solution, we define for arbitrary $t \in \mathbb{R}$ the operators

$$U(t): C_0^\infty(\mathbb{R})^2 \to C_0^\infty(\mathbb{R})^2,$$

$$\begin{pmatrix} f \\ g \end{pmatrix} \mapsto \begin{pmatrix} \psi(t,.) \\ i\partial_t\psi(t,.) \end{pmatrix},$$

which leave the dense subspace $C_0^\infty(\mathbb{R})^2 \subseteq \mathcal{H}$ invariant for all times t.

Due to the energy conservation, the $U(t)$ are unitary with respect to the energy scalar product and hence extend to unitary operators on the entire Hilbert space $\mathcal{H}$. Furthermore, since the solution is uniquely determined by the initial data, the $U(t)$ have the following properties:

$$U(0) = Id, \quad U(t+s) = U(t)U(s) \quad \text{for all } t,s \in \mathbb{R},$$

and thus they form a one-parameter unitary group. Due to the fact that smooth initial data yields smooth solutions in t and u, this group is strongly continuous on $\mathcal{H}$ and strongly differentiable on the domain $C_0^\infty(\mathbb{R})^2$. Calculating i^{-1} times the strong derivative one gets

$$i^{-1}\lim_{h\searrow 0}\frac{1}{h}\left(U(h)\begin{pmatrix} f \\ g \end{pmatrix} - \begin{pmatrix} f \\ g \end{pmatrix}\right) = i^{-1}\begin{pmatrix} -ig \\ i(\partial_u^2 - V_l)f \end{pmatrix} = -H\begin{pmatrix} f \\ g \end{pmatrix}$$

for all $f,g \in C_0^\infty(\mathbb{R})$, and the lemma follows from Theorem 3.2.

□

For the further investigations of the Hamiltonian H, we consider its self-adjoint closure which, for the sake of simplicity, we again denote by H. For our purposes, it is not important to know the exact domain of definition $\mathcal{D}(H)$ of the self-adjoint extension.

IV. CONSTRUCTION OF THE RESOLVENT

Stone's formula for the spectral projections of a self-adjoint operator A (cf. Ref. 10 Theorem VII.13),

$$\frac{1}{2}[P_{[a,b]}+P_{(a,b)}]=\text{s-}\lim_{\epsilon\searrow 0}\frac{1}{2\pi i}\int_a^b[(A-\omega-i\epsilon)^{-1}-(A-\omega+i\epsilon)^{-1}]\mathrm{d}\omega, \tag{4.1}$$

relates the spectral projections to the resolvent (here s-lim denotes the strong limit of operators). In view of this relation, it is of interest to derive an explicit representation of the resolvent.

In the preceding section we have seen that there is a domain $\mathcal{D}(H)$ such that our Hamiltonian H is self-adjoint in the Hilbert space $(\mathcal{H},\langle,\rangle)$. From this it immediately follows that the spectrum $\sigma(H)\subseteq\mathbb{R}$ is on the real line and therefore the resolvent $(H-\omega)^{-1}:\mathcal{H}\to\mathcal{H}$ exists for every $\omega\in\mathbb{C}\backslash\mathbb{R}$.

Let us now fix $\omega\in\mathbb{C}\backslash\mathbb{R}$. We often denote the ω-dependence by a subscript ω. We begin by reducing the eigenvalue equation $H\Psi=\omega\Psi$ by substituting the equation for the first component in the second equation. We thus obtain the Schrödinger-type equation

$$(-\partial_u^2+V_\omega(u))\phi(u)=0 \tag{4.2}$$

with the potential

$$V_\omega(u)=-\omega^2+V_l(u)=-\omega^2+\left(1-\frac{2M}{r}\right)\left(\frac{2M}{r^3}+\frac{l(l+1)}{r^2}\right). \tag{4.3}$$

In what follows we refer to this equation simply as the Schrödinger equation. It can be regarded as the radial equation associated to the wave equation in (2.6). Our goal is to construct the resolvent $(H-\omega)^{-1}$ out of special solutions of this equation. We introduce fundamental solutions $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$ of the Schrödinger equation (4.2) which satisfy asymptotic boundary conditions at $u=\pm\infty$ (the existence of these solutions will be proved in Sec. V). More precisely, in the case $\mathrm{Im}(\omega)>0$ we impose that

$$\lim_{u\to-\infty}e^{i\omega u}\acute{\phi}_\omega(u)=1,\quad \lim_{u\to-\infty}(e^{i\omega u}\acute{\phi}_\omega(u))'=0, \tag{4.4}$$

$$\lim_{u\to+\infty}e^{-i\omega u}\grave{\phi}_\omega(u)=1,\quad \lim_{u\to+\infty}(e^{-i\omega u}\grave{\phi}_\omega(u))'=0, \tag{4.5}$$

whereas in the case $\mathrm{Im}(\omega)<0$,

$$\lim_{u\to-\infty}e^{-i\omega u}\acute{\phi}_\omega(u)=1,\quad \lim_{u\to-\infty}(e^{-i\omega u}\acute{\phi}_\omega(u))'=0, \tag{4.6}$$

$$\lim_{u\to+\infty}e^{i\omega u}\grave{\phi}_\omega(u)=1,\quad \lim_{u\to+\infty}(e^{i\omega u}\grave{\phi}_\omega(u))'=0. \tag{4.7}$$

Since the resolvent exists, the map $(H-\omega):\mathcal{D}(H)\to\mathcal{H}$ is bijective and in particular the kernel is trivial. Hence the solutions $\acute{\phi}_\omega$, $\grave{\phi}_\omega$ are linearly independent (otherwise they would give rise to a vector in the kernel due to the exponential decay). Thus $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$ are indeed a system of fundamental solutions with nonvanishing Wronskian

$$w(\acute{\phi}_\omega,\grave{\phi}_\omega):=\acute{\phi}_\omega(u)\grave{\phi}_\omega'(u)-\acute{\phi}_\omega'(u)\grave{\phi}_\omega(u). \tag{4.8}$$

Note that the Wronskian is independent of the variable u, as is easily verified by differentiating with respect to u and substituting the Schrödinger equation.

In the next lemma, we use this fundamental system to derive the Green's function corresponding to (4.2).

Lemma 4.1: The function

$$s_\omega(u,v) := -\frac{1}{w(\acute{\phi}_\omega,\grave{\phi}_\omega)} \times \begin{cases} \acute{\phi}_\omega(u)\grave{\phi}_\omega(v), & \text{if } u \leqslant v, \\ \acute{\phi}_\omega(v)\grave{\phi}_\omega(u), & \text{if } u > v, \end{cases} \tag{4.9}$$

satisfies the distributional equations

$$\left(-\frac{\partial^2}{\partial u^2} + V_\omega(u)\right) s_\omega(u,v) = \delta(u-v) = \left(-\frac{\partial^2}{\partial v^2} + V_\omega(v)\right) s_\omega(u,v).$$

Proof: By definition of the distributional derivative we have for every test function $\eta \in C_0^\infty(\mathbb{R})$,

$$\int_{-\infty}^{\infty} \eta(u)[-\partial_u^2 + V_\omega(u)] s_\omega(u,v)\mathrm{d}u = \int_{-\infty}^{\infty} [(-\partial_u^2 + V_\omega(u))\,\eta(u)] s(u,v)\mathrm{d}u.$$

It is obvious from its definition that the function $s(.,v)$ is smooth except at the point $u=v$, where its first derivative has a discontinuity. Thus, after splitting up the integral, we can integrate by parts twice to obtain

$$\begin{aligned} \int_{-\infty}^{\infty} [(-\partial_u^2 + V_\omega(u))\,\eta(u)] s(u,v)\mathrm{d}u &= \int_{-\infty}^{v} \eta(u)(-\partial_u^2 + V_\omega(u)) s(u,v)\mathrm{d}u + \lim_{u \nearrow v}[\eta(u)\partial_u s(u,v)] \\ &\quad + \int_{v}^{\infty} \eta(u)(-\partial_u^2 + V_\omega(u)) s(u,v)\mathrm{d}u - \lim_{u \searrow v}[\eta(u)\partial_u s(u,v)]. \end{aligned}$$

Since for $u \neq v$, s is a solution of (4.2), the obtained integrals vanish. Computing the limits with the definition (4.9), we get

$$\begin{aligned} \int_{-\infty}^{\infty} [(-\partial_u^2 + V_\omega(u))\,\eta(u)] s(u,v)\mathrm{d}u &= (\lim_{u \nearrow v} - \lim_{u \searrow v})\,\eta(u)\partial_u s(u,v) \\ &= -\frac{1}{w(\acute{\phi}_\omega,\grave{\phi}_\omega)}\,\eta(v)[\acute{\phi}'_\omega(v)\grave{\phi}_\omega(v) - \grave{\phi}'_\omega(v)\acute{\phi}_\omega(v)] = \eta(v), \end{aligned}$$

where in the last step we used the definition of the Wronskian (4.8). This yields the first equation. The second equation is proven exactly in the same way.

□

With this function s we are now able to construct the resolvent. More precisely,

Proposition 4.2: For every $\omega \in \mathbb{C}\backslash\mathbb{R}$, the resolvent $(H-\omega)^{-1}: \mathcal{H} \to \mathcal{H}$ can be represented as an integral operator with the integral kernel

$$k_\omega(u,v) = \delta(u-v)\begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} + s_\omega(u,v)\begin{pmatrix} \omega & 1 \\ \omega^2 & \omega \end{pmatrix}. \tag{4.10}$$

Proof: We introduce the integral operator S_ω with the integral kernel $k_\omega(u,v)$ on the domain

$$\mathcal{D}(S_\omega) := \{(H-\omega)\Psi \,|\, \Psi \in C_0^\infty(\mathbb{R})^2\}.$$

Let us verify that $\mathcal{D}(S_\omega)$ is a dense subset of $\mathcal{H}$. Let $\phi \in \mathcal{H}$ be an arbitrary vector. Because of the existence of the resolvent, the operator $H-\omega: \mathcal{D}(H) \to \mathcal{H}$ is onto, and thus there is a vector $\psi \in \mathcal{D}(H)$ with $(H-\omega)\psi = \phi$. Then due to the definition of the closure of H, there is a sequence $\{\psi_n\}_{n\in N} \subseteq C_0^\infty(\mathbb{R})^2$ with $\psi_n \to \psi$ and $H\psi_n \to H\psi$ as $n \to \infty$. This shows that

$\{(H-\omega)\psi_n\}_{n\in N}\subseteq\mathcal{D}(S_\omega)$ converges to $(H-\omega)\psi=\phi$. We conclude that $\mathcal{D}(S_\omega)$ is dense. We now calculate the operator product $S_\omega(H-\omega)$ on $C_0^\infty(\mathbb{R})^2$. For an arbitrary $\Psi=(\psi_1,\psi_2)^T\in C_0^\infty(\mathbb{R})^2$ we have

$$(S_\omega(H-\omega)\psi)(u)=\int_{-\infty}^{\infty}k_\omega(u,v)(H-\omega)\psi(v)\mathrm{d}v$$
$$=\begin{pmatrix}0\\-\omega\psi_1+\psi_2\end{pmatrix}(u)+\int_{-\infty}^{\infty}s_\omega(u,v)\begin{pmatrix}-\partial_v^2+V_\omega(v) & 0\\ \omega(-\partial_v^2+V_\omega(v)) & 0\end{pmatrix}\begin{pmatrix}\psi_1\\\psi_2\end{pmatrix}(v)\mathrm{d}v.$$

Hence, according to Lemma 4.1,

$$S_\omega(H-\omega)=Id\quad\text{on } C_0^\infty(\mathbb{R})^2.$$

This yields that $S_\omega=(H-\omega)^{-1}$ on the dense set $\mathcal{D}(S_\omega)$. Since $(H-\omega)^{-1}$ is a bounded operator, the claim follows.

□

As mentioned at the beginning of this section, we can now apply Stone's formula for the spectral projections of H and get for every $\Psi\in\mathcal{H}$,

$$\frac{1}{2}[P_{[a,b]}+P_{(a,b)}]\Psi=\lim_{\epsilon\searrow 0}\frac{1}{2\pi i}\int_a^b[(H-(\omega+i\epsilon))^{-1}-(H-(\omega-i\epsilon))^{-1}]\Psi\,\mathrm{d}\omega,$$

and this yields together with Proposition 4.2,

$$=\lim_{\epsilon\searrow 0}\frac{1}{2\pi i}\int_a^b\left(\int_{\mathbb{R}}(k_{\omega+i\epsilon}(.,v)-k_{\omega-i\epsilon}(.,v))\Psi(v)\mathrm{d}v\right)\mathrm{d}\omega,\tag{4.11}$$

where the limit is with respect to the norm in $\mathcal{H}$. It is therefore of special interest how the kernels $k_{\omega+i\epsilon}(u,v)$ and $k_{\omega-i\epsilon}(u,v)$ behave as $\epsilon\searrow 0$. Since these kernels are given explicitly in terms of the fundamental solutions $\acute{\phi}_{\omega\pm i\epsilon}$ and $\grave{\phi}_{\omega\pm i\epsilon}$, we will discuss their behavior in the next section.

V. THE JOST SOLUTIONS OF THE RADIAL EQUATION

In this section we want to discuss the existence and the behavior of the solutions $\acute{\phi}_\omega$, $\grave{\phi}_\omega$ of the Schrödinger equation (4.2), which in Sec. IV we used for the construction of the resolvent. We will prove the following theorem.

Theorem 5.1:

(i) *For every* $\omega\in D=\{\omega\in\mathbb{C}|\,\mathrm{Im}\,\omega\leqslant 1/4M\}$, *there exists a unique solution* $\phi_1(\omega,u)$ *of the Schrödinger equation (4.2) satisfying the boundary conditions (4.6) such that for every fixed* $u\in\mathbb{R}$ *the function* $\phi_1(\omega,u)$ *is holomorphic in* $\omega\in\mathring{D}$ *and continuous in* D.

(ii) *For every angular momentum number* l, *the solutions* $\grave{\phi}_\omega$ *of the Schrödinger equation (4.2) with boundary conditions (4.7) are well defined and uniquely determined on the set*

$$E=\{\omega\in\mathbb{C}|\mathrm{Im}\,\omega\leqslant 0,\omega\neq 0\}.$$

For each fixed $u\in\mathbb{R}$, *the function* $\grave{\phi}_\omega(u)$ *is holomorphic in* $\omega\in\mathring{E}$ *and continuous in* E. *Furthermore, in the case* $l=0$, $\grave{\phi}_\omega(u)$ *may be continuously extended to* $\omega=0$.

Once having proven this theorem, we simply set

$$\acute{\phi}_\omega(u):=\begin{cases}\overline{\phi_1(\bar{\omega},u)} & \text{if } \mathrm{Im}\,\omega>0,\\ \phi_1(\omega,u) & \text{if } \mathrm{Im}\,\omega\leqslant 0,\end{cases}\tag{5.1}$$

as well as

$$\overleftarrow{\phi}_\omega(u) := \overline{\overrightarrow{\phi}_{\bar{\omega}}(u)} \quad \text{if } \operatorname{Im}\omega > 0, \tag{5.2}$$

to obtain the solutions of Sec. IV. For $\operatorname{Im}\omega < 0$ this is clear by definition. But in the case of $\operatorname{Im}\omega > 0$ the above defined $\overrightarrow{\phi}_\omega(u)$, $\overleftarrow{\phi}_\omega(u)$ are indeed the unique solutions of the Schrödinger equation (4.2) with the desired boundary conditions (4.4) and (4.5), respectively. This follows immediately by complex conjugation of the Schrödinger equation due to the fact that our potential V_l is real.

For the proof of Theorem 5.1 we will formally manipulate the Schrödinger equation with boundary conditions (4.6) and (4.7) in order to get an appropriate integral equation (which in different contexts is called the Jost or Lipman-Schwinger equation). Then we will perform a perturbation expansion and get estimates for all the terms of the expansion. A reference for this method can be found, e.g., in Ref. 13, Sec. XI.8. Since this reference contains only an outline of the proof, it seems worth working out the details.

To introduce the method, we begin with the solutions $\phi_l(\omega, u)$. First we write the Schrödinger equation (4.2) in the form

$$\left(-\frac{d^2}{\mathrm{d}u^2} - \omega^2\right)\phi_\omega(u) = -W(u)\phi_\omega(u), \tag{5.3}$$

where W is a potential in $L^1(\mathbb{R})$ (later on, W will be replaced by V_l). Next we define for $\omega \in \mathbb{C}$ the function $G_\omega(u)$ by

$$G_\omega(u) := \begin{cases} 0 & \text{if } u \leqslant 0, \\ -\dfrac{1}{\omega}\sin(\omega u) & \text{if } u > 0 \text{ and } \omega \neq 0, \\ -u & \text{if } u > 0 \text{ and } \omega = 0. \end{cases} \tag{5.4}$$

A simple computation shows that $G_\omega(u)$ defines a *Green's function* for the operator on the left-hand side of the equation (5.3) in the sense that the distributional equation

$$\left(-\frac{d^2}{\mathrm{d}u^2} - \omega^2\right)G_\omega(u) = \delta(u)$$

holds. In order to build in the boundary condition (4.6), we make in equation (5.3) the substitution $\phi_\omega(u) = e^{i\omega u} + \tilde{\phi}_\omega(u)$ to obtain

$$\left(-\frac{d^2}{\mathrm{d}u^2} - \omega^2\right)\tilde{\phi}_\omega(u) = -W(u)\phi_\omega(u).$$

Solving this equation formally by convoluting the right-hand side with G_ω, we get the formal solution

$$\tilde{\phi}_\omega(u) = ((-W\phi_\omega) * G_\omega)(u) \equiv -\int_{-\infty}^{\infty} G_\omega(u-v)W(v)\phi_\omega(v)\mathrm{d}v.$$

Hence $\phi_\omega(u)$ satisfies the equation

$$\phi_\omega(u) = e^{i\omega u} - \int_{-\infty}^{u} G_\omega(u-v)W(v)\phi_\omega(v)\mathrm{d}v, \tag{5.5}$$

which is referred to as the *Jost equation with boundary conditions at* $-\infty$. Its significance lies in the fact that we can now easily perform a perturbation expansion in the potential W. Namely, making for ϕ_ω the ansatz as the perturbation series

$$\phi_\omega = \sum_{k=0}^{\infty} \phi_\omega^{(k)}, \tag{5.6}$$

we are led to the iteration scheme

$$\phi_\omega^{(0)}(u) = e^{i\omega u},$$

$$\cdots,$$

$$\phi_\omega^{(k+1)}(u) = -\int_{-\infty}^{u} G_\omega(u-v)W(v)\phi_\omega^{(k)}(v)\mathrm{d}v. \tag{5.7}$$

This iteration scheme can be used to construct solutions of the Jost equation.

We remark that under certain assumptions on W like continuity, the Jost equation is equivalent to the corresponding Schrödinger equation with appropriate boundary conditions. We will show this for our special case $W \equiv V_l$. A systematic method to rewrite second-order differential equations with boundary conditions as integral equations can be found, e.g., in Ref. 13. Sec. XI.8 Appendix 2.

We now state a theorem about solutions of the Jost equation. We consider more general potentials W than we have in our case, because it might be of interest by itself.

Theorem 5.2: *Suppose that W is a measurable function obeying for a given $u_0 < 0$ the condition $\int_{-\infty}^{u_0} |W(v)| \mathrm{d}v < \infty$. Define for $u \leqslant u_0$ the function $P_\omega(u)$ by*

$$P_\omega(u) = \int_{-\infty}^{u} \frac{4|v|}{1+|\omega v|} |W(v)| e^{-(\mathrm{Im}\ \omega + |\mathrm{Im}\ \omega|)v}\, \mathrm{d}v. \tag{5.8}$$

Then

(i) *For each $\omega \in E = \{\omega \in \mathbb{C} \,|\, \mathrm{Im}\ \omega \leqslant 0, \omega \neq 0\}$ the Jost equation (5.5) has a unique solution $\phi_\omega(u)$ obeying $\lim_{u\to-\infty} |e^{-i\omega u}\phi_\omega(u)| < \infty$. Moreover, $\phi_\omega(u)$ is continuously differentiable in u on $(-\infty, u_0)$ with $\lim_{u\to-\infty} e^{-i\omega u}\phi_\omega(u) = 1$ and $\lim_{u\to-\infty} e^{-i\omega u}\phi'_\omega(u) = i\omega$. For each fixed u, the functions $\phi_\omega(u)$ and $\phi'_\omega(u)$ are holomorphic in $\overset{\circ}{E}$ and continuous in E. They satisfy the bounds*

$$|\phi_\omega(u) - e^{i\omega u}| \leqslant e^{-u\ \mathrm{Im}\ \omega} |e^{P_\omega(u)} - 1|, \tag{5.9}$$

$$|\phi'_\omega(u) - i\omega e^{i\omega u}| \leqslant e^{-u\ \mathrm{Im}\ \omega} e^{P_\omega(u)} \int_{-\infty}^{u} |W(v)| \mathrm{d}v. \tag{5.10}$$

(ii) *If $\int_{-\infty}^{u_0} |v||W(v)| \mathrm{d}v < \infty$, for every $u \leqslant u_0$ the function $\phi_\omega(u)$ may be continuously extended to $\omega = 0$. Moreover, (5.9) and (5.10) hold also at $\omega = 0$.*

(iii) *If $\int_{-\infty}^{u_0} e^{-mv} |W(v)| \mathrm{d}v < \infty$, for every $u \leqslant u_0$ the function $\phi_\omega(u)$ can be extended to a holomorphic function in $\{\omega \,|\, \mathrm{Im}\ \omega < \frac{1}{2}m\}$, continuous in $\{\omega \,|\, \mathrm{Im}\ \omega \leqslant \frac{1}{2}m\}$. Moreover, in the interval $0 < \mathrm{Im}\ \omega < \frac{1}{2}m$ the inequalities (5.9) and (5.10) are replaced by*

$$|\phi_\omega(u) - e^{i\omega u}| \leqslant \frac{1}{|\omega|} e^{u\ \mathrm{Im}\ \omega} e^{P_\omega(u)} \int_{-\infty}^{u} e^{-2v\ \mathrm{Im}\ \omega} |W(v)| \mathrm{d}v, \tag{5.11}$$

$$|\phi'_\omega(u) - i\omega e^{i\omega u}| \leqslant e^{u\ \mathrm{Im}\ \omega} e^{P_\omega(u)} \int_{-\infty}^{u} e^{-2v\ \mathrm{Im}\ \omega} |W(v)| \mathrm{d}v, \tag{5.12}$$

In each case, ϕ obeys $\overline{\phi_\omega(u)} \equiv \overline{\phi(\omega, u)} = \phi(-\bar{\omega}, u)$.

We call this solution ϕ the *Jost solution*. For the proof of this theorem we need a good estimate for the Green's function G_ω.

Lemma 5.3: For all $u \in \mathbb{C}$,

$$|\sin u| \leqslant \frac{2|u|}{1+|u|} e^{|\mathrm{Im}\, u|}. \tag{5.13}$$

In particular, if $\omega \neq 0$ *and* $v \leqslant u \leqslant 0$,

$$\left| \frac{1}{\omega} \sin(\omega(u-v)) \right| \leqslant \frac{4|v|}{1+|\omega v|} e^{-v|\mathrm{Im}\, \omega| - u\, \mathrm{Im}\, \omega}. \tag{5.14}$$

Proof: In the case $|u| \geqslant 1$, the inequality (5.13) follows directly from the Euler formula $\sin u = (1/2i)(e^{iu} - e^{-iu})$ and the estimate

$$(1+|u|)|\sin u| \leqslant \tfrac{1}{2}(1+|u|) 2 e^{|\mathrm{Im}\, u|} \leqslant 2|u| e^{|\mathrm{Im}\, u|}.$$

In the remaining case $|u| < 1$, we again use the Euler formula to obtain

$$(1+|u|)|\sin u| = \frac{1}{2}(1+|u|)|e^{iu} - e^{-iu}| = \frac{1}{2}(1+|u|) \left| \int_{-1}^{1} iu e^{iu\tau}\, \mathrm{d}\tau \right|,$$

and hence

$$(1+|u|)|\sin u| \leqslant \frac{1}{2}(|u|+|u|^2) \int_{-1}^{1} |e^{iu\tau}| \mathrm{d}\tau \leqslant \frac{1}{2}(|u|+|u|^2) 2 e^{|\mathrm{Im}\, u|}.$$

Now (5.13) follows by the assumption $|u| < 1$.

In order to show (5.14) we use the identity

$$\frac{1}{\omega} \sin(\omega(u-v)) = \frac{1}{\omega} (\sin(\omega u) e^{i\omega v} - \sin(\omega v) e^{i\omega u})$$

and apply (5.13),

$$\begin{aligned} \left| \frac{1}{\omega} \sin(\omega(u-v)) \right| &\leqslant \frac{1}{|\omega|} (|\sin(\omega u) e^{i\omega v}| + |\sin(\omega v) e^{i\omega u}|) \overset{(5.13)}{\leqslant} \frac{2|u|}{1+|\omega u|} e^{|u\, \mathrm{Im}\, \omega|} e^{-v\, \mathrm{Im}\, \omega} \\ &\quad + \frac{2|v|}{1+|\omega v|} e^{|v\, \mathrm{Im}\, \omega|} e^{-u\, \mathrm{Im}\, \omega}. \end{aligned} \tag{5.15}$$

Due to the assumption $0 \geqslant u \geqslant v$, we know that $|v| \geqslant |u|$ and thus

$$\frac{2|u|}{1+|\omega u|} \leqslant \frac{2|v|}{1+|\omega v|}, \qquad -u|\mathrm{Im}\, \omega| - v\, \mathrm{Im}\, \omega \leqslant -v|\mathrm{Im}\, \omega| - u\, \mathrm{Im}\, \omega.$$

Using these inequalities in (5.15) the claim follows.

□

Note that the estimate (5.14) remains valid in the limit $0 \neq \omega \to 0$, if one replaces $(1/\omega)\sin(\omega(u-v))$ by the function $u-v$.

Now we are ready to prove Theorem 5.2.

Proof of Theorem 5.2: Using the perturbation expansion (5.6) together with the iteration scheme (5.7), one easily sees that we have already found a *formal* solution. So our goal is to show that this series is well defined and has the desired properties. To this end, we shall prove inductively that

$$|\phi_\omega^{(k)}(u)| \leqslant e^{-u \operatorname{Im}\omega} \frac{1}{k!} P_\omega(u)^k \quad \text{for all } k \in \mathbb{N}_0, \quad \text{for all } \omega, u \tag{5.16}$$

such that $P_\omega(u)$ is well defined by (5.8). Due to the integrability conditions on the potential W in the statement of the theorem this is the case for $u \leqslant u_0$ and for all $\omega \in E$ [cf. (i)], $\omega \in \bar{E}$ [cf. (ii)], $\omega \in \{\operatorname{Im}\omega \leqslant \frac{1}{2}m\}$ [cf. (iii)], respectively. Furthermore, $P_\omega(u)$ is continuous in u as well as in ω in these domains. The first statement is obvious while the latter is due to the fact that the integrand in the definition (5.8) is continuous in ω and one directly finds an integrable dominating function such that one can apply Lebegue's dominated convergence theorem.

We start the induction with the case $k=0$ for which (5.16) certainly is satisfied. Thus assume that (5.16) holds for a given k. Then, estimating the integral equation in (5.7) using (5.14) and (5.8), we obtain

$$\begin{aligned}
|\phi_\omega^{(k+1)}(u)| &\leqslant \int_{-\infty}^{u} |G_\omega(u-v)||W(v)||\phi_\omega^{(k)}(v)| \mathrm{d}v \\
&\leqslant \int_{-\infty}^{u} \frac{4|v|}{1+|\omega v|} e^{-v|\operatorname{Im}\omega| - u \operatorname{Im}\omega} |W(v)| e^{-v \operatorname{Im}\omega} \frac{1}{k!} P_\omega(v)^k \, \mathrm{d}v \\
&= e^{-u \operatorname{Im}\omega} \frac{1}{k!} \int_{-\infty}^{u} \frac{\mathrm{d}P_\omega}{\mathrm{d}v}(v) P_\omega(v)^k \, \mathrm{d}v = e^{-u \operatorname{Im}\omega} \frac{1}{(k+1)!} P_\omega(u)^{k+1},
\end{aligned}$$

where in the last step we used that $P_\omega(u)$ vanishes when u goes to $-\infty$. This concludes the proof of (5.16).

Summing over k, (5.16) yields the inequality

$$\sum_{k=0}^{\infty} |\phi_\omega^{(k)}(u)| \leqslant e^{-u \operatorname{Im}\omega} e^{P_\omega(u)}. \tag{5.17}$$

Because of the continuity of $P_\omega(u)$, the series (5.6) converges uniformly for u and ω in compact sets. Using the iteration scheme (5.7), this series can be written as

$$\sum_{k=0}^{\infty} \phi_\omega^{(k)}(u) = e^{i\omega u} - \sum_{k=1}^{\infty} \int_{-\infty}^{u} G_\omega(u-v) W(v) \phi_\omega^{(k-1)}(v) \mathrm{d}v,$$

and the bound (5.17) allows us to apply Lebesgue's dominated convergence theorem and to interchange the sum and the integral. Hence the series is indeed a solution of the Jost equation (5.5).

Next we want to show that a solution of the Jost equation is continuously differentiable with respect to u. To this end, we first compute for an arbitrary $u < u_0$ the difference quotient,

$$\frac{1}{h}(\phi_\omega(u+h) - \phi_\omega(u) - e^{i\omega(u+h)} + e^{i\omega u}) \overset{(5.5)}{=}$$

$$\int_{-\infty}^{u+h} \frac{1}{h\omega} [\sin(\omega(u+h-v)) - \sin(\omega(u-v))] W(v) \phi_\omega(v) \mathrm{d}v \tag{5.18}$$

$$+ \frac{1}{h} \int_{u}^{u+h} \frac{1}{\omega} \sin(\omega(u-v)) W(v) \phi_\omega(v) \mathrm{d}v, \tag{5.19}$$

where $h \neq 0$. We may restrict attention to the case $\operatorname{Im}\omega \leqslant 0$ and $h > 0$ (the other cases are analogous). Using the estimate

$$\left|\partial_u\left(\frac{1}{\omega}\sin(\omega(u-v))\right)\right| = |\cos(\omega(u-v))| \leqslant \frac{1}{2}(e^{-u\ \mathrm{Im}\ \omega}e^{v\ \mathrm{Im}\ \omega} + e^{u\ \mathrm{Im}\ \omega}\, e^{-v\ \mathrm{Im}\ \omega})$$

together with (5.17), we can apply the mean value theorem to the first integrand to obtain the dominating function

$$\frac{1}{2}(e^{-\xi(v)\mathrm{Im}\ \omega}e^{v\ \mathrm{Im}\ \omega} + e^{\xi(v)\mathrm{Im}\ \omega}e^{-v\ \mathrm{Im}\ \omega})|W(v)|e^{-v\ \mathrm{Im}\ \omega}e^{P_\omega(v)},$$

where $\xi(v)\in[u,u+h]$. Due to the integrability conditions on W, it is clear that this function is integrable. Hence Lebesgue's dominated convergence theorem allows us to take the limit $h\to 0$ in (5.18). This gives

$$\int_{-\infty}^{u} \cos(\omega(u-v))W(v)\phi_\omega(v)\mathrm{d}v\,.$$

In order to treat the second integral, we choose $h<h_0$, where h_0 is so small that

$$\max_{v\in[u,u+h]}\left|\frac{1}{\omega h}\sin(\omega(u-v))\right| \leqslant 2 \quad \text{for all } h<h_0.$$

This is possible because $\lim_{h\to 0}(1/\omega h)\sin(\omega h)=1$. Thus we can estimate (5.19) by

$$\left|\frac{1}{h}\int_u^{u+h}\frac{1}{\omega}\sin(\omega(u-v))W(v)\phi_\omega(v)\mathrm{d}v\right| \leqslant 2e^{-(u+h)\mathrm{Im}\ \omega}e^{P_\omega(u+h)}\int_{(-\infty,u_0)}|1_{[u,u+h]}(v)W(v)|\mathrm{d}v\,,$$

and the last integral goes to 0 as $h\to 0$ by Lebesgue's monotone convergence theorem using the fact that $W\in L^1(-\infty,u_0)$. Hence (5.19) vanishes.

Altogether we conclude that $\phi_\omega(u)$ is differentiable with derivative

$$\phi'_\omega(u) = i\omega e^{i\omega u} + \int_{-\infty}^{u}\cos(\omega(u-v))W(v)\phi_\omega(v)\mathrm{d}v\,, \tag{5.20}$$

which is continuous on $(-\infty,u_0)$ because of the estimate (5.17).

The estimate (5.9) is a simple consequence of (5.16) together with the perturbation expansion (5.6). For the proof of (5.10) we use the representation of the derivative (5.20) together with the inequality (5.17):

$$|\phi'_\omega(u)-i\omega e^{i\omega u}| \overset{(5.20)}{\leqslant} \int_{-\infty}^{u}|\cos(\omega(u-v))||W(v)||\phi_\omega(v)|\mathrm{d}v \overset{(5.17)}{\leqslant} \int_{-\infty}^{u}\frac{1}{2}(e^{-u\ \mathrm{Im}\ \omega}e^{v\ \mathrm{Im}\ \omega}+e^{u\ \mathrm{Im}\ \omega}e^{-v\ \mathrm{Im}\ \omega})$$

$$\times|W(v)|e^{-v\ \mathrm{Im}\ \omega}e^{P_\omega(v)}\,\mathrm{d}v \leqslant e^{-u\ \mathrm{Im}\ \omega}e^{P_\omega(u)}\int_{-\infty}^{u}|W(v)|\mathrm{d}v\,,$$

where in the last step we used the fact that $P_\omega(v)$ and $e^{-v\ \mathrm{Im}\ \omega}$ (with $\mathrm{Im}\ \omega\leqslant 0$) are monotone increasing. The estimates (5.11) as well as (5.12) are shown in the same way.

Let us now verify that for any fixed u, the function $\phi_\omega(u)$ is holomorphic in ω, and continuous on the domains as specified in (i), (ii), and (iii). Due to the locally uniform convergence of the perturbation series, it suffices to show that every $\phi_\omega^{(k)}(u)$ has the desired properties. We do this inductively, where the case $k=0$ is trivial. Let us now assume that $\phi_\omega^{(k)}(u)$ is holomorphic in $\mathring{E}$ ($\{\mathrm{Im}\ \omega<\frac{1}{2}m\}$, respectively). In order to prove that $\phi_\omega^{(k+1)}$ is holomorphic, we want to apply Morera's theorem. Thus we must show that $\phi_\omega^{(k+1)}(u)$ is continuous in ω and that the integral

$$\oint_\gamma \phi_\omega^{(k+1)}(u)\mathrm{d}\omega \overset{(5.7)}{=} \oint_\gamma \int_{-\infty}^{u} \frac{1}{\omega}\sin(\omega(u-v))W(v)\phi_\omega^{(k)}(v)\mathrm{d}v\,\mathrm{d}\omega \tag{5.21}$$

vanishes for every closed contour γ in $\mathring{E}$ [or in case (iii), for every contour in $\{\mathrm{Im}\,\omega<\frac{1}{2}m\}$, respectively]. Using the above estimates (5.14) and (5.16) together with the monotonicity of $P_\omega(u)$ in u we get the following bound for the integrand

$$\left|\frac{1}{\omega}\sin(\omega(u-v))W(v)\phi_\omega^{(k)}(v)\right| \leqslant |W(v)|\frac{4|v|}{1+|\omega v|}e^{-u\,\mathrm{Im}\,\omega - v|\mathrm{Im}\,\omega| - v\,\mathrm{Im}\,\omega}\frac{1}{k!}P_\omega(u)^k. \tag{5.22}$$

Due to the induction hypothesis, the integrand is continuous in ω. Moreover, for a compact neighborhood $K(\omega_0)$ of a fixed ω_0 contained in the specified domains, (5.22) yields for the family $(1/\omega)\sin(\omega(u-v))W(v)\phi_\omega^{(k)}(v)$, $\omega\in K(\omega_0)$ the uniformly dominating function

$$|W(v)|\frac{4|v|}{1+|v|\min|\omega|}e^{-u\,\mathrm{Im}\,\omega - v\,\max(|\mathrm{Im}\,\omega|+\mathrm{Im}\,\omega)}\frac{1}{k!}P_\omega(u)^k,$$

where the minimum and the maximum are taken in $K(\omega_0)$. This function is integrable for $K(\omega_0)$ chosen sufficiently small due to the integrability conditions on W. This lets us apply Lebesgue's dominated convergence theorem to show the continuity in ω for $\phi_\omega^{(k+1)}(u)$, which is given by the integral (5.7). Moreover, (5.22) together with the continuity in ω of $P_\omega(u)$ yield that the integral

$$\oint_\gamma \int_{-\infty}^{u}\left|\frac{1}{\omega}\sin(\omega(u-v))W(v)\phi_\omega^{(k)}(v)\right|\mathrm{d}v\,\mathrm{d}\omega<\infty$$

exists for an arbitrary closed contour γ in $\mathring{E}$ (or $\{\mathrm{Im}\,\omega<\frac{1}{2}m\}$, respectively). By the theorem of Fubini, we may interchange the orders of integration in (5.21). Because of the induction hypothesis, the integrand of (5.21) on the right-hand side is holomorphic. Thus the integral vanishes due to the Cauchy integral theorem. We conclude that $\phi_\omega^{(k)}$ is holomorphic for every k. Since $\phi_\omega(u)$ is holomorphic, the same argument together with Eq. (5.20) yields that ϕ_ω' is also holomorphic.

It remains to prove uniqueness. Let $\psi_\omega(u)$ be another solution of the Jost equation obeying $\lim_{u\to-\infty}|e^{-i\omega u}\psi_\omega(u)|<\infty$. Then we can find a $c>0$ with $|\psi_\omega(u)|\leqslant ce^{-u\,\mathrm{Im}\,\omega}$ for all $u\leqslant u_0$. Then as above one shows inductively that

$$\left|\psi_\omega(u)-\sum_{l=0}^{N}\phi_\omega^{(k)}(u)\right| \leqslant ce^{-u\,\mathrm{Im}\,\omega}\frac{1}{(N+1)!}P_\omega(u)^{N+1},$$

and taking $N\to\infty$ we obtain $\psi_\omega=\phi_\omega$.

The uniqueness also implies that $\overline{\phi(\omega,u)}=\phi(-\bar{\omega},u)$, concluding the proof.

□

Remark 5.4: In order to treat the Schrödinger equation (4.2) with boundary conditions at infinity (4.7), we derive the corresponding Jost equation with boundary conditions at $+\infty$ using the same procedure as for the solutions ϕ_1,

$$\phi_\omega(u)=e^{-i\omega u}-\int_u^\infty \frac{1}{\omega}\sin(\omega(u-v))W(v)\phi_\omega(v)\mathrm{d}v. \tag{5.23}$$

It is obvious that the solution $\tilde{\phi}_\omega(u)$ of the Jost equation with boundary conditions at $-\infty$ with potential $W(-v)$ constructed in Theorem 5.2 gives rise to a solution ϕ_ω of (5.23) by defining $\phi_\omega(u):=\tilde{\phi}_\omega(-u)$.

With the results of Theorem 5.2 it is now easy to prove Theorem 5.1.

Proof of Theorem 5.1: Let us apply Theorem 5.2 to the potential $V_l(u)$ given by (2.20), which is obviously a smooth function in u. Furthermore, it vanishes on the event horizon $2M$ with the asymptotics $V_l=\mathcal{O}(r-2M)$. Using the definition of the Regge-Wheeler coordinate u (2.3), this

means that $V_l(u)$ decays exponentially as $u \to -\infty$. More precisely, there is a constant $c > 0$ such that

$$|V_l(u)| \leqslant c e^{u/2M} \quad \text{for small } u.$$

Theorem 5.2 (iii) yields for $u \leqslant u_0 < 0$ a solution $\phi_1(\omega, u)$ of the Jost equation (5.5) with the desired properties. It remains to show that ϕ_1 is also a solution of the Schrödinger equation (4.2) for $u \leqslant u_0$. (Due to the Picard-Lindelöf theorem, this solution of the linear equation can be uniquely extended to $u \in \mathbb{R}$; the resulting function is analytic in ω due to the analytical dependence in ω from the coefficients and initial conditions.) But this follows immediately by differentiating equation (5.20) and using that $V_l \equiv W$ is smooth, so that the whole integrand is at least differentiable with respect to v. We have then proven the existence of $\acute{\phi}_\omega$. For the uniqueness, we show that in our special case every solution of (4.2) with boundary conditions (4.6) is a solution of (5.5). This can be done by integration by parts: let $\psi_\omega(u)$ be such a solution. Then

$$\int_{-\infty}^{u} \frac{1}{\omega} \sin(\omega(u-v)) V_l(v) \psi_\omega(v) \mathrm{d}v = \int_{-\infty}^{u} \frac{1}{\omega} \sin(\omega(u-v))(\partial_v^2 + \omega^2)\psi_\omega(v) \mathrm{d}v = \psi_\omega(u) - e^{i\omega u},$$

where the remaining terms vanish due to the boundary conditions. Since we know that the solution of the Jost equation is uniquely determined, this must be also the case for the solution of the Schrödinger equation. Thus we have proven part (i).

For the proof of (ii) we refer to Remark 5.4. In contrast to the exponential decay at $-\infty$, the potential $V_l(u)$ has only polynomial decay at $+\infty$. More precisely, according to the definition of u, $V_l(u) = \mathcal{O}(l(l+1)/u^2)$ for $l \geqslant 1$, $V_0(u) = \mathcal{O}(2M/u^3)$, respectively, as $u \to \infty$. Thus we can apply the analogs of Theorem 5.2 (i), (ii), respectively. This gives the existence and uniqueness of the solution $\grave{\phi}_\omega$ for the Schrödinger equation with the stated properties.

□

When taking the limit $\epsilon \searrow 0$ in Stone's formula (4.11), the behavior of $\grave{\phi}_\omega(u)$ at $\omega = 0$ still causes problems. While in the case $l = 0$ we know from Theorem 5.1 that $\grave{\phi}_\omega$ can be continuously extended there, we do not yet know what happens for $l \neq 0$. The following theorem settles this problem by showing that, after suitable rescaling, the solutions $\grave{\phi}_\omega$ have a well-defined limit at $\omega = 0$.

Theorem 5.5: *For every angular momentum number l, there is a solution ϕ_0 of the Schrödinger equation (4.2) for $\omega = 0$ with the asymptotics*

$$\lim_{u \to \infty} u^l \phi_0(u) = i^l \frac{2^l \sqrt{\pi}}{\Gamma\left(\frac{1}{2} - l\right)} = (-i)^l (2l-1)!!, \tag{5.24}$$

where

$$(2l-1)!! := \begin{cases} (2l-1) \cdot (2l-3) \cdot \cdots \cdot 3 \cdot 1 & \text{if } l \neq 0, \\ 1 & \text{if } l = 0. \end{cases}$$

This solution can be obtained as a limit of the solutions from Theorem 5.1, in the sense that for all $u \in \mathbb{R}$,

$$\phi_0(u) = \lim_{E \ni \omega \to 0} \omega^l \grave{\phi}_\omega(u) \quad \text{and} \quad \phi_0'(u) = \lim_{E \ni \omega \to 0} \omega^l \grave{\phi}_\omega'(u). \tag{5.25}$$

Note that the above properties of the solution ϕ_0 really coincide in the case $l = 0$ with that of the solution $\grave{\phi}_0$ already constructed in Theorem 5.1 (ii).

For the proof of this theorem we use the same method as in the proof for Theorem 5.1. However, the iteration scheme (5.7) does not work for $l \neq 0$ in the limit $\omega \to 0$, because the integral

$$\phi_0^{(1)}(u) = -\int_u^\infty (u-v)V_l(v)\mathrm{d}v$$

diverges [$V_l(u)$ decays only quadratically at infinity for $l \neq 0$]. We avoid this problem by adding the leading asymptotic term of the potential V_l to the unperturbed equation,

$$\left(-\frac{d^2}{\mathrm{d}u^2} - \omega^2 + \frac{\left(l+\frac{1}{2}\right)^2 - \frac{1}{4}}{u^2}\right)\phi_\omega(u) = -W_l(u)\phi_\omega(u). \tag{5.26}$$

Now the perturbation term $W_l(u) = V_l(u) - [l(l+1)/u^2]$ has the asymptotics $W_l(u) = \mathcal{O}(\log u/u^3)$.

Fortunately, the unperturbed differential equation corresponding to (5.26) can still be solved exactly. The solutions can be expressed in terms of Bessel functions. For our further consideration, the two functions

$$h_1(l,\omega,u) = \sqrt{\frac{\pi\omega u}{2}}J_{l+(1/2)}(\omega u), \quad h_2(l,\omega,u) = \sqrt{\frac{\pi\omega u}{2}}J_{-l-(1/2)}(\omega u) \tag{5.27}$$

play an important role. Here the function $J_\nu(u)$ is the Bessel function of the first kind (a good reference for the theory of the Bessel functions is Ref. 14). It solves Bessel's differential equation

$$u^2y''(u) + uy'(u) + (u^2 - \nu^2)y(u) = 0.$$

In addition, it is an analytic function in ν and u for all values of ν and $u \neq 0$ (if $\mathrm{Re}\,\nu \geqslant 0$, it can be analytically extended even to $u=0$). It has the series expansion

$$J_\nu(u) = \sum_{m=0}^\infty \frac{(-1)^m}{m!\Gamma(\nu+m+1)}\left(\frac{u}{2}\right)^{\nu+2m} \tag{5.28}$$

and the following asymptotics for $|u| \gg 1$ (cf. Ref. 14, 7.21):

$$J_\nu(u) \sim \sqrt{\frac{2}{\pi u}}\left[\cos\left(u - \frac{\pi}{2}\left(\nu+\frac{1}{2}\right)\right)\cdot\sum_{m=0}^\infty \frac{(-1)^m(\nu,2m)}{(2u)^{2m}} - \sin\left(u - \frac{\pi}{2}\left(\nu+\frac{1}{2}\right)\right)\cdot\sum_{m=0}^\infty \frac{(-1)^m(\nu,2m+1)}{(2u)^{2m+1}}\right], \tag{5.29}$$

where we have used the notation

$$(\nu,m) := \frac{\Gamma\left(\nu+m+\frac{1}{2}\right)}{m!\Gamma\left(\nu-m+\frac{1}{2}\right)}.$$

Moreover, the derivatives satisfy the recurrence formulas

$$uJ'_\nu(u) = uJ_{\nu-1}(u) - \nu J_\nu(u),$$

$$uJ'_\nu(u) = \nu J_\nu(u) - uJ_{\nu+1}(u).$$

The Wronskian of the functions J_ν, $J_{-\nu}$ (which both solve the same differential equation, since Bessel's differential equation is symmetric in ν) is given by the formula

$$w(J_\nu(u),J_{-\nu}(u)) = -\frac{2\sin(\nu\pi)}{\pi u}. \tag{5.30}$$

This yields that these functions form a fundamental system for Bessel's differential equation provided that ν is not an integer.

In our applications we choose $\nu = l + \frac{1}{2}$. Thus the functions $h_1(l,\omega,u)$ and $h_2(l,\omega,u)$ have the following asymptotics:

$$h_1(l,\omega,u) \sim \begin{cases} \cos\left(\omega u - (l+1)\dfrac{\pi}{2}\right) & \text{if } |\omega u| \gg 1, \\ \dfrac{\sqrt{\pi}}{\Gamma\left(\dfrac{3}{2}+l\right)}\left(\dfrac{\omega u}{2}\right)^{l+1} & \text{if } |\omega u| \ll 1, \end{cases} \tag{5.31}$$

$$h_2(l,\omega,u) \sim \begin{cases} \cos\left(\omega u + l\dfrac{\pi}{2}\right) & \text{if } |\omega u| \gg 1, \\ \dfrac{\sqrt{\pi}}{\Gamma\left(\dfrac{1}{2}-l\right)}\left(\dfrac{\omega u}{2}\right)^{-l} & \text{if } |\omega u| \ll 1. \end{cases} \tag{5.32}$$

Furthermore, the formula (5.30) for the Wronskian simplifies to

$$w(h_1(l,\omega,u),h_2(l,\omega,u)) = (-1)^{l+1}\omega, \quad \text{if } l \text{ is an integer}, \tag{5.33}$$

and this yields that in the case $\omega \neq 0$ the solutions h_1, h_2 form a fundamental system.

Thus for $\omega \neq 0$ we take as the Green's function for the operator on the left-hand side of (5.26) the standard formula

$$S_\omega(u,v) = \Theta(v-u)\frac{1}{w(h_1,h_2)}(h_1(v)h_2(u) - h_1(u)h_2(v)), \tag{5.34}$$

where $h_{1/2}(u) \equiv h_{1/2}(l,\omega,u)$ and Θ denotes the Heaviside function defined by $\Theta(x)=1$ if $x \geqslant 0$ and $\Theta(x)=0$ otherwise. Note that S_ω is also well defined in the limit $\omega \to 0$. For this we use the asymptotics and the value of the Wronskian and get for very small ω,

$$\begin{aligned} \lim_{\omega\to 0} S_\omega(u,v) &= \lim_{\omega\to 0} \frac{(-1)^{l+1}}{\omega} \cdot \frac{\pi\omega}{2\Gamma\left(\dfrac{3}{2}+l\right)\Gamma\left(\dfrac{1}{2}-l\right)}(v^{l+1}u^{-l} - u^{l+1}v^{-l}) \\ &= \frac{(-1)^{l+1}\pi}{2\left(\dfrac{1}{2}+l\right)\Gamma\left(\dfrac{1}{2}+l\right)\Gamma\left(\dfrac{1}{2}-l\right)}(v^{l+1}u^{-l} - u^{l+1}v^{-l}) = \frac{(-1)^{l+1}\pi\cos(\pi l)}{(2l+1)\pi}(v^{l+1}u^{-l} - u^{l+1}v^{-l}) \\ &= -\frac{1}{2l+1}(v^{l+1}u^{-l} - u^{l+1}v^{-l}), \end{aligned}$$

where we have used some elementary properties of the gamma function. This also shows that the Green's function converges to the Green's function $S_0(u,v)$ given by the above formula for the solutions u^{l+1}, u^{-l} of the unperturbed differential operator on the left-hand side of (5.26) for $\omega = 0$.

We now proceed with the perturbation series ansatz

$$\phi_\omega(u) = \sum_{m=0}^{\infty} \phi_\omega^{(m)}(u), \tag{5.35}$$

which, as at the beginning of this section, leads to the iteration scheme

$$\phi_\omega^{(m+1)}(u) = -\int_u^\infty S_\omega(u,v) W_l(v) \phi_\omega^{(m)}(v) \mathrm{d}v. \tag{5.36}$$

As initial function we take

$$\phi_\omega^{(0)}(u) = \omega^l e^{-i(l+1)(\pi/2)} \sqrt{\frac{\pi\omega u}{2}} H^{(2)}_{l+(1/2)}(\omega u),$$

where $H^{(2)}_\nu$ is another solution of Bessels equation (called Bessel function of the third kind or second Hankel function). It is related to J_ν by

$$H^{(2)}_\nu(u) = \frac{J_{-\nu}(u) - e^{\nu\pi i} J_\nu(u)}{-i \sin(\nu\pi)},$$

and has for large $|u|$ the asymptotics

$$H^{(2)}_\nu(u) \sim \sqrt{\frac{2}{\pi u}} e^{-i\{u-(1/2)\pi[\nu+(1/2)]\}} \sum_{m=0}^{\infty} \frac{(\nu,m)}{(2iu)^m}. \tag{5.37}$$

Thus our initial function $\phi_\omega^{(0)}(u)$ solves the unperturbed equation, and we have the relation

$$\phi_\omega^{(0)}(u) = \omega^l((-i)^{l+1} h_1(l,\omega,u) + i^l h_2(l,\omega,u)) \tag{5.38}$$

together with the asymptotics

$$\phi_\omega^{(0)}(u) = \omega^l e^{-i\omega u}\left(1 + \mathcal{O}\left(\frac{1}{u}\right)\right) \text{ if } |u| \gg 1. \tag{5.39}$$

Moreover, the function $\phi_\omega^{(0)}$ converges in the limit $\omega \to 0$ pointwise for all $u \geqslant u_0 > 0$:

$$\lim_{\omega\to 0} \phi_\omega^{(0)}(u) = i^l \frac{\sqrt{\pi}}{\Gamma\left(\frac{1}{2} - l\right)} \left(\frac{u}{2}\right)^{-l}. \tag{5.40}$$

Since we are interested in statements for $\omega = 0$, it is convenient in what follows to restrict ω to the domain:

$$F := \{\omega \in \mathbb{C} | \mathrm{Im}\ \omega \leqslant 0, |\omega| \leqslant 1\}.$$

The following lemma yields that our perturbation series (5.35) is well defined.

Lemma 5.6: For every $u_0 > 0$, the iteration scheme (5.35), (5.36), and (5.38) *converges locally uniformly for all $u \geqslant u_0$ and $\omega \in F$. In particular, the functions $\phi_\omega(u)$ are for fixed u a continuous family in $\omega \in F$. They satisfy the integral equation*

$$\phi_\omega(u) = \phi_\omega^{(0)}(u) - \int_u^\infty S_\omega(u,v) W_l(v) \phi_\omega(v) \mathrm{d}v. \tag{5.41}$$

Proof: In order to prove the lemma, we need to derive good bounds for the initial function $\phi_\omega^{(0)}(u)$ as well as for the Green's function $S_\omega(u,v)$. To this end, we exploit the asymptotics of h_1, h_2. We thus obtain the bound

$$\frac{1}{C_1} \leqslant |\phi_\omega^{(0)}(u)| e^{-u \operatorname{Im} \omega} \left(\frac{u}{1+|\omega| u} \right)^l \leqslant C_1 . \tag{5.42}$$

Likewise, for the Green's function we have (note that $v \geqslant u > 0$),

$$|S_\omega(u,v)| \leqslant C_2 \left(\frac{u}{1+|\omega| u} \right)^{-l} \left(\frac{v}{1+|\omega| v} \right)^{l+1} \quad \text{if } |\omega v| \ll 1$$

and

$$|S_\omega(u,v)| \leqslant C_3 \frac{v}{1+|\omega| v} e^{v|\operatorname{Im} \omega| + u \operatorname{Im} \omega}, \quad \text{if } |\omega u| \gg 1 .$$

The last inequality follows from the asymptotics

$$|S_\omega(u,v)| \sim \left| \frac{1}{\omega} \sin(\omega(u-v)) \right| \quad \text{if } |\omega u| \gg 1,$$

in the same way as the second inequality of Lemma 5.3. Combining these cases we find a constant such that

$$|S_\omega(u,v)| \leqslant C_4 \left(\frac{u}{1+|\omega| u} \right)^{-l} \left(\frac{v}{1+|\omega| v} \right)^{l+1} e^{v|\operatorname{Im} \omega| + u \operatorname{Im} \omega}. \tag{5.43}$$

Hence defining the function Q_ω by

$$Q_\omega(u) := C_4 \int_u^\infty \frac{v}{1+|\omega| v} |W_l(v)| \mathrm{d}v, \tag{5.44}$$

which is well defined for all $\omega \in F$ and $u \geqslant u_0 > 0$ due to the asymptotic of W_l, it is straightforward to show inductively (cf. proof of Theorem 5.2) that for all $m \in \mathbb{N}$,

$$|\phi_\omega^{(m)}(u)| \leqslant C_1 \left(\frac{u}{1+|\omega| u} \right)^{-l} e^{u \operatorname{Im} \omega} \frac{Q_\omega(u)^m}{m!}. \tag{5.45}$$

Now we proceed exactly as in the proof of Theorem 5.2, where the inequality (5.45) can be considered as the analogue of (5.16). It follows that the series (5.35) converges locally uniformly in ω and u and satisfies the integral equation (5.41). Furthermore, one shows inductively applying Lebesgue's dominated convergence theorem, that for fixed u each $\phi_\omega^{(m)}(u)$ depends continuously of $\omega \in F$. It follows that the same is true for the series due to local uniform convergence.

□

We are now ready to prove Theorem 5.5.

Proof of Theorem 5.5: According to Lemma 5.6, our perturbation series (5.35) satisfies the integral equation (5.41). Using the recurrence formulas for the derivatives of $J_\nu(u)$, one obtains

$$h_1'(l,\omega,u) = -\frac{l}{u} h_1(l,\omega,u) + \omega h_1(l-1,\omega,u),$$

$$h_2'(l,\omega,u) = -\frac{l}{u} h_2(l,\omega,u) - \omega h_2(l-1,\omega,u),$$

respectively. This allows us to estimate the behavior of $\partial_u S_\omega(u,v)$. Exactly as for $S_\omega(u,v)$, we obtain the following asymptotic formulas:

$$|\partial_u S_\omega(u,v)| \leqslant C_5\left(\frac{u}{1+|\omega|u}\right)^{-l-1}\left(\frac{v}{1+|\omega|v}\right)^{l+1} e^{v|\mathrm{Im}\ \omega|+u\ \mathrm{Im}\ \omega}.$$

Following the same arguments of the proofs of Theorems 5.1 and 5.2, and combining them with the above estimates and asymptotic formulas we now have the following results:

(1) One can differentiate $\phi_\omega(u)$ with respect to u, and $\phi'_\omega(u)$ is given by

$$\phi'_\omega(u) = (\phi^{(0)}_\omega)'(u) - \int_u^\infty \partial_u S_\omega(u,v) W_l(v)\phi_\omega(v)\mathrm{d}v.$$

In particular, Lebesgue's dominated convergence theorem yields that for fixed u, $\phi'_\omega(u)$ is continuous in $\omega \in F$.

(2) $\phi_\omega(u)$ and $\phi'_\omega(u)$ obey the following estimates:

$$|\phi_\omega(u) - \phi^{(0)}_\omega(u)| \leqslant C_1\left(\frac{u}{1+|\omega|u}\right)^{-l} e^{u\ \mathrm{Im}\ \omega}(e^{Q_\omega(u)}-1),$$

$$|\phi'_\omega(u) - (\phi^{(0)}_\omega)'(u)| \leqslant C_5\left(\frac{u}{1+|\omega|u}\right)^{-l-1} e^{Q_\omega(u_0)} e^{u\ \mathrm{Im}\ \omega}\int_u^\infty v|W_l(v)|\mathrm{d}v.$$

Thus $\phi_\omega(u) \sim \omega^l e^{-i\omega u}$ and $\phi'_\omega(u) \sim -i\omega^{l+1}e^{-i\omega u}$ as $u \to \infty$.

(3) Differentiating $\phi_\omega(u)$ twice with respect to u shows that $\phi_\omega(u)$ is a solution of the Schrödinger equation (4.2) for all $u \geqslant u_0$. Furthermore, from the asymptotics at infinity combined with the uniqueness statement in Theorem 5.1, we know that

$$\phi_\omega(u) = \omega^l \grave{\phi}_\omega(u), \quad \text{if } \omega \neq 0, u \geqslant u_0. \tag{5.46}$$

Obviously, this extends to all $u \in \mathbb{R}$.

Thus we have proven the continuity statement (5.25) for all $u \geqslant u_0$. On the other hand, we know from the Picard-Lindelöf theorem that for u on compact intervals, the solutions depend continuously on ω. This yields (5.25) for all $u \in \mathbb{R}$.

Finally, the asymptotics (5.24) is a simple consequence of (5.40).

□

VI. AN INTEGRAL SPECTRAL REPRESENTATION

In the preceding section we derived some regularity results for the solutions $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$. We already know (cf. Sec. IV) that these solutions are a system of fundamental solutions of the Schrödinger equation (4.2) in the cases $\mathrm{Im}\ \omega < 0$ and $\mathrm{Im}\ \omega > 0$, respectively. Thus the Wronskian $w(\acute{\phi}_\omega, \grave{\phi}_\omega)$ is nonvanishing in these regions, which implies that the integral kernel $k_\omega(u,v)$ of the resolvent is well defined. Since our next goal is to get the limit in (4.11), we prove in the next lemma that the continuous extension of the solutions $\acute{\phi}_\omega, \grave{\phi}_\omega$ to the real axis again yields a system of fundamental solutions. More precisely we have the following.

Lemma 6.1: The Wronskian $w(\acute{\phi}_\omega, \grave{\phi}_\omega)$ does not vanish for $\omega \in \mathbb{R}\backslash\{0\}$. In particular, $\acute{\phi}_\omega, \grave{\phi}_\omega$ are fundamental solutions for the Schrödinger equation (4.2). *In addition, this remains true for the solutions $\acute{\phi}_0$ and ϕ_0 in the case $\omega = 0$.*

Proof: Let us begin with the statement for $\acute{\phi}_0, \phi_0$.

For $\omega = 0$, the solutions $\acute{\phi}_0(u), \phi_0(u)$ have the asymptotics

$$\lim_{u\to-\infty} \acute{\phi}_0(u) = 1 \quad \text{and} \lim_{u\to\infty} u^l \phi_0(u) = (-i)^l (2l-1)!!.$$

Looking at the construction of these solutions, one sees that $\acute{\phi}_0$ is a real solution, while ϕ_0 is either purely real or imaginary (depending on the value of l). The Schrödinger equation for $\omega=0$ reduces to $\phi''(u)=V_l(u)\phi(u)$ with a everywhere positive potential V_l. Hence, exploiting the special asymptotics, the solution $\acute{\phi}_0$ is convex and Re ϕ_0 (Im ϕ_0, respectively) is either convex or concave depending on l. In any case, we see that $\acute{\phi}_0$ and ϕ_0 are linearly independent, and thus $w(\acute{\phi}_0, \phi_0) \neq 0$.

In order to prove the main part of the lemma, we consider a complex solution $z=z_1+iz_2$ of the Schrödinger equation, where $\{z_1, z_2\}$ is a fundamental system of real solutions, especially $w(z_1, z_2) \equiv c \neq 0$. Setting $y=z'/z$, a simple computation shows that

$$\text{Im } y = \frac{w(z_1, z_2)}{|z|^2},$$

where the right-hand side is well defined because $w(z_1, z_2) \neq 0$ implies that $|z| \neq 0$ everywhere. As a consequence, we have Im $y \neq 0$ everywhere. Thus it follows that for all u either Im $y(u) > 0$ or <0, due to the continuity of the solution z in u.

Applying this result to the solutions $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$, respectively, and exploiting their asymptotics, one sees that Im $\acute{y}_\omega(u)$ and Im $\grave{y}_\omega(u)$ have different signs for all u. Therefore,

$$w(\acute{\phi}_\omega, \grave{\phi}_\omega) = \acute{\phi}_\omega(u)\grave{\phi}'_\omega(u) - \acute{\phi}'_\omega(u)\grave{\phi}_\omega(u) = \acute{\phi}_\omega(u)\grave{\phi}_\omega(u)(\grave{y}_\omega(u) - \acute{y}_\omega(u)) \neq 0.$$

□

As a consequence we have the following.

Corollary 6.2: The function $s_\omega(u,v)$ *given by* (4.9) *is continuous in* (ω,u,v) *for* $\omega \in \{\text{Im } \omega \leqslant 0\}$, $(u,v) \in \mathbb{R}^2$.

Proof: We already know that for fixed $u_0 < 0$, $\acute{\phi}_\omega(u_0)$ is continuous in ω on $\{\text{Im } \omega \leqslant 0\}$. Thus as solutions of the linear differential equation (4.2), which depends analytically on ω and smooth on u, the family $\acute{\phi}_\omega(u)$ is (at least) continuous in (ω,u) in the region $\{\text{Im } \omega \leqslant 0\} \times \mathbb{R}$. Analogously this holds for $\omega^l \grave{\phi}_\omega(u)$ according to Theorems 5.1 and 5.5. Since $s_\omega(u,v)$ is invariant if we substitute $\omega^l \grave{\phi}_\omega(u)$ for $\grave{\phi}_\omega(u)$, the preceding lemma yields the claim.

□

Note that the corollary is also true if ω is in the upper half plane. The essential statement in this corollary is that one can extend $s_\omega(u,v)$ continuously in ω up to the real axis.

From the definitions (5.1) and (5.2), we have for $\omega \in \{\text{Im } \omega \neq 0\}$ the relations

$$\overline{s_\omega(u,v)} = s_{\bar{\omega}}(u,v), \quad \text{hence } \overline{k_\omega(u,v)} = k_{\bar{\omega}}(u,v).$$

This allows us to simplify the expression (4.11). Evaluating for fixed u the right-hand side of (4.11) we obtain for any $\Psi \in \mathcal{H}$ as well as for any bounded interval $[a,b] \subseteq \mathbb{R}$,

$$\lim_{\epsilon \searrow 0} -\frac{1}{\pi} \int_a^b \left(\int_{\mathbb{R}} \text{Im}(k_{\omega - i\epsilon}(u,v)) \Psi(v) \mathrm{d}v \right) \mathrm{d}\omega.$$

According to the above corollary, we know that Im $k_\omega(u,v)$ is continuous in (ω,u,v) for $\omega \in \{\text{Im } \omega \leqslant 0\}$, $(u,v) \in \mathbb{R}^2$. Thus, if we restrict Ψ to the dense set $C_0^\infty(\mathbb{R})^2$, we integrate a continuous integrand over a compact interval. Hence, considering the limit as a pointwise limit for any u, we may interchange the limit and integration. Thus for any $\Psi \in C_0^\infty(\mathbb{R})^2$, $[a,b] \subset \mathbb{R}$ bounded and u the right-hand side of (4.11) converges pointwise to

$$-\frac{1}{\pi}\int_a^b \left(\int_{\text{supp } \psi} \text{Im}(k_\omega(u,v))\psi(v)\mathrm{d}v \right)\mathrm{d}\omega.$$

Hence, together with the norm convergence in (4.11), the spectral projections of H are for every u described by the formula

$$\frac{1}{2}(P_{[a,b]}+P_{(a,b)})\Psi(u) = -\frac{1}{\pi}\int_a^b \left(\int_{\text{supp } \psi} \text{Im}(k_\omega(u,v))\psi(v)\mathrm{d}v \right)\mathrm{d}\omega. \tag{6.1}$$

In particular, this representation yields that $P_{[a,b]} \equiv P_{(a,b)}$.

As an immediate consequence we have the following.

Corollary 6.3: The spectrum $\sigma(H)$ of the operator H is absolutely continuous, i.e., $\sigma(H) \equiv \sigma_{ac}(H)$.

Proof: The corollary is equivalent to the statement that the spectral measure $\langle \Psi, \mathrm{d}P_\omega \Psi\rangle$ of any $\Psi \in \mathcal{H}$ is absolutely continuous. This is clear by (6.1) for any $\Psi \in C_0^\infty(\mathbb{R})^2$. But since this subset is dense, this also holds on the whole Hilbert space $\mathcal{H}$. □

Next we want to write the integrand in (6.1), i.e., $\int_{\text{supp } \Psi} \cdots \mathrm{d}v$, in a more compact way. We first note that for real ω the complex conjugates of $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$ are again solutions of (4.2). Hence, for any $\omega \in \mathbb{R}\backslash\{0\}$ the pair $\{\acute{\phi}_\omega, \overline{\acute{\phi}_\omega}\}$ forms a fundamental system for this equation due to the boundary conditions. Thus we can express $\grave{\phi}_\omega$ as a linear combination of $\acute{\phi}_\omega$ and $\overline{\acute{\phi}_\omega}$,

$$\grave{\phi}_\omega(u) = \lambda(\omega)\acute{\phi}_\omega(u) + \mu(\omega)\overline{\acute{\phi}_\omega(u)} \quad (\omega \in \mathbb{R}\setminus\{0\}),$$

where λ and μ are referred to as *transmission coefficients*. The Wronskian of $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$ can be expressed by

$$w(\acute{\phi}_\omega, \grave{\phi}_\omega) = \mu(\omega) w(\acute{\phi}_\omega, \overline{\acute{\phi}_\omega}) = -2i\omega\mu(\omega),$$

where in the last step we used the asymptotics (4.6). Moreover, we introduce the real fundamental solutions

$$\phi_\omega^1(u) = \text{Re } \acute{\phi}_\omega(u), \quad \phi_\omega^2(u) = \text{Im } \acute{\phi}_\omega(u)$$

and denote the corresponding eigenvectors of the Hamiltonian H by $\Phi_\omega^a(u) = (\phi_\omega^a(u), \omega\phi_\omega^a(u))^T$.

Using the above definitions, a short calculation shows that for $\omega \neq 0$ we can express the imaginary part of the Green's function $s_\omega(u,v)$ by

$$\text{Im } s_\omega(u,v) = -\frac{1}{2\omega}\sum_{a,b=1}^{2} t_{ab}(\omega)\phi_\omega^a(u)\phi_\omega^b(v), \tag{6.2}$$

where the coefficients $t_{ab}(\omega)$ are given by

$$t_{11}(\omega) = 1 + \text{Re}\left(\frac{\lambda}{\mu}(\omega)\right), \quad t_{12}(\omega) = t_{21}(\omega) = -\text{Im}\left(\frac{\lambda}{\mu}(\omega)\right),$$

$$t_{22}(\omega) = 1 - \text{Re}\left(\frac{\lambda}{\mu}(\omega)\right). \tag{6.3}$$

Since we know that $\text{Im } s_\omega(u,v)$ is continuous for $\omega \in \mathbb{R}$ and the expression (6.2) holds for all $\omega \in \mathbb{R}\backslash\{0\}$, it extends to $\omega = 0$. With (6.2), the integrand in (6.1) can be written as

$$-\frac{1}{2\omega}\left(\int_{\text{supp }\Psi}\sum_{a,b=1}^{2} t_{ab}(\omega)\phi^a_\omega(u)\phi^b_\omega(v)\begin{pmatrix}\omega & 1\\ \omega^2 & \omega\end{pmatrix}\Psi(v)\mathrm{d}v\right)$$
$$=-\frac{1}{2\omega^2}\sum_{a,b=1}^{2} t_{ab}(\omega)\Phi^a_\omega(u)\left(\int_{\text{supp }\Psi}\omega^2\phi^b_\omega(v)\psi_1(v)+\omega\phi^b_\omega(v)\psi_2(v)\mathrm{d}v\right),$$

where the ψ_i denote the two components of Ψ.

Using that $\phi^b_\omega(u)$ solves the Schrödinger equation $(-\partial_v^2+V_l(v))\phi^b_\omega(v)=\omega^2\phi^b_\omega(v)$ and integrating by parts, this simplifies to

$$-\frac{1}{2\omega^2}\sum_{a,b=1}^{2} t_{ab}(\omega)\Phi^a_\omega(u)\langle\Phi^b_\omega,\Psi\rangle. \tag{6.4}$$

(Note that in this case the energy scalar product of Φ^b_ω and Ψ is well defined, because Ψ has compact support. Whereas in general this does not exist for arbitrary $\Psi\in\mathcal{H}$, due to the fact that $\Phi^b_\omega\notin\mathcal{H}$.)

With (6.4), we now obtain a more compact representation for the spectral projections. Moreover, we can use (6.4) to express the solution operators e^{-itH}.

Proposition 6.4: Consider the Cauchy problem (2.23) *for compactly supported smooth initial data* $\Psi_0\in C_0^\infty(\mathbb{R})^2$. *Then the solution has the integral representation*

$$\Psi(t)=e^{-itH}\Psi_0=\frac{1}{2\pi}\int_{\mathbb{R}} e^{-i\omega t}\frac{1}{\omega^2}\sum_{a,b=1}^{2} t_{ab}(\omega)\Phi^a_\omega\langle\Phi^b_\omega,\Psi_0\rangle\mathrm{d}\omega. \tag{6.5}$$

Here the integral converges in norm in the Hilbert space $\mathcal{H}$.

Proof: We use the following variation of Stone's formula to obtain for any bounded interval $(c,d)\subseteq\mathbb{R}$,

$$\frac{1}{2}e^{-itH}(P_{[c,d]}+P_{(c,d)})\Psi=\lim_{\epsilon\searrow 0}\int_c^{\mathrm{d}} e^{-i\omega t}[(H-\omega-i\epsilon)^{-1}-(H-\omega+i\epsilon)^{-1}]\Psi\,\mathrm{d}\omega,$$

where the limit is with respect to the norm of $\mathcal{H}$. Since we know that $P_{[c,d]}\equiv P_{(c,d)}$, it follows that this expression is equal to $e^{-itH}P_{(c,d)}\Psi$. Using the explicit formula for the resolvent, for every $u\in\mathbb{R}$ the right-hand side is equal to

$$\lim_{\epsilon\searrow 0}-\frac{1}{\pi}\int_c^{\mathrm{d}} e^{-i\omega t}\left(\int_{\mathbb{R}}\mathrm{Im}(k_{\omega-i\epsilon}(u,v))\Psi(v)\mathrm{d}v\right)\mathrm{d}\omega. \tag{6.6}$$

Due to the continuity of the imaginary part of the kernel $k_\omega(u,v)$, we may take for $\Psi_0\in C_0^\infty(\mathbb{R})^2$ and (c,d) bounded the pointwise limit for any $u\in\mathbb{R}$. Hence, using (6.4) we can simplify (6.6) to

$$\frac{1}{2\pi}\int_c^{\mathrm{d}} e^{-i\omega t}\frac{1}{\omega^2}\sum_{a,b=1}^{2} t_{ab}(\omega)\Phi^a_\omega(u)\langle\Phi^b_\omega,\Psi_0\rangle\mathrm{d}\omega,$$

and together with the norm convergence it follows that this term is equal to $e^{-itH}P_{(c,d)}\Psi_0(u)$. Using the abstract spectral theorem and that e^{-itH} is a unitary operator, it is clear that $e^{-itH}P_{(-n,n)}\Psi_0\to e^{-itH}\Psi_0$ in norm as $n\to\infty$. □

This proposition extends to the following theorem.

Theorem 6.5: *For any fixed* $u\in\mathbb{R}$ *the integrand in the representation* (6.5) *is in* $L^1(\mathbb{R},\mathbb{C}^2)$ *as a function of* ω. *In particular, the representation* (6.5) *of the solutions holds pointwise for every* $u\in\mathbb{R}$, *i.e.*,

$$\Psi(t,u) = \frac{1}{2\pi}\int_{\mathbb{R}} e^{-i\omega t}\frac{1}{\omega^2}\sum_{a,b=1}^{2} t_{ab}(\omega)\Phi^a_\omega(u)\langle\Phi^b_\omega,\Psi_0\rangle \mathrm{d}\omega. \tag{6.7}$$

Moreover, for u fixed, the function $\Psi(t,u)$ *vanishes as* $t\to\infty$.

Proof: Since we know that the integrand is continuous in ω, it is in $L^1([a,b],\mathbb{C}^2)$ for any bounded interval $[a,b]$. Thus it remains to analyze the integrand for large $|\omega|$.

To this end, we must investigate the asymptotic behavior of the fundamental solutions $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$ in ω. We constructed these solutions with the iteration scheme (5.7) as solutions of the Jost equation. For the proof of this, the estimate (5.14) played an essential role. Since in this case we consider real ω with $|\omega|\gg 1$, we can use the simple estimate $|(1/\omega)\sin(\omega(u-v))|\leqslant 1/|\omega|$ instead of (5.14), which now holds for every $u,v\in\mathbb{R}$. Thus, proceeding exactly in the same way as in the proof of Theorem 5.2, we now obtain the following estimates for the several terms in the series expansion (5.6):

$$|\phi^{(k)}_\omega(u)| \leqslant \frac{1}{k!}\hat{P}_\omega(u)^k, \quad \text{where } \hat{P}_\omega(u) := \int_{-\infty}^{u}\frac{1}{|\omega|}V_l(v)\mathrm{d}v,$$

for any $k\in\mathbb{N}$ and $u\in\mathbb{R}$. Thus the solution $\acute{\phi}_\omega(u)$ $(\omega\neq 0)$ is given *for all* $u\in\mathbb{R}$ by this series expansion and obeys the uniform bound

$$|\acute{\phi}_\omega(u) - e^{i\omega u}| \leqslant e^{\hat{P}_\omega(u)} - 1 \leqslant e^{(1/|\omega|)\|V_l\|_{L^1}} - 1,$$

since $V_l\in L^1(\mathbb{R})$. In particular,

$$|\acute{\phi}_\omega(u)| \leqslant 1 + \mathcal{O}\left(\frac{1}{|\omega|}\right) \quad \text{for } |\omega|\gg 1. \tag{6.8}$$

Next we investigate the ω-dependence of $\langle\Phi^b_\omega,\Psi_0\rangle$. We integrate by parts to obtain

$$\langle\Phi^b_\omega,\Psi_0\rangle = \int_{\mathrm{supp}\,\Psi_0}\phi^b_\omega(v)(\omega\psi_2(v) - \psi_1(v)'' + V_l(v)\psi_1(v))\mathrm{d}v,$$

where $\Psi_0=(\psi_1,\psi_2)^T$ [note that the boundary terms drop out, because $\Psi_0\in C^\infty_0(\mathbb{R})^2$]. Since $\phi^b_\omega(u)$ is a solution of the Schrödinger equation (4.2), we substitute $(1/\omega^2)(-\phi^b_\omega(u)''+V_l(u)\phi^b_\omega(u))$ for $\phi^b_\omega(u)$ and integrate by parts twice,

$$= \frac{1}{\omega^2}\int_{\mathrm{supp}\,\Psi_0}\phi^b_\omega(-(\omega\psi_2 - \psi_1'' + V_l\psi_1)'' + V_l(\omega\psi_2 - \psi_1'' + V_l\psi_1))\mathrm{d}v.$$

We can now iterate this procedure as often as we like due to the fact that $\Psi_0\in C^\infty_0(\mathbb{R})^2$ and $V_l\in C^\infty(\mathbb{R})$. Thus using the bound (6.8), we obtain arbitrary polynomial decay in ω for $\langle\Phi^b_\omega,\Psi_0\rangle$.

It remains to control the coefficients $t_{ab}(\omega)$ for large $|\omega|$. According to the definition of the transmission coefficients $\lambda(\omega)$ and $\mu(\omega)$, they satisfy the following relations:

$$w(\grave{\phi}_\omega,\acute{\phi}_\omega) = 2i\mu(\omega) \quad \text{and } w(\grave{\phi}_\omega,\overline{\acute{\phi}_\omega}) = 2i\lambda(\omega).$$

In order to calculate the Wronskians, we substitute the Jost integral equations (5.5) and (5.23) for $\acute{\phi}_\omega$ and $\grave{\phi}_\omega$, respectively, as well as the corresponding integral equations for the derivatives [for instance (5.20) in the case $\acute{\phi}_\omega$] and obtain immediately

$$\mu(\omega) = 1 + \mathcal{O}\left(\frac{1}{\omega}\right), \quad \lambda(\omega) = \mathcal{O}\left(\frac{1}{\omega}\right).$$

Hence the coefficients $t_{ab}(\omega)$ remain (at least) bounded, according to their definition (6.3).

We conclude that the integrand in (6.7) is in $L^1(\mathbb{R},\mathbb{C}^2)$ as a function of ω. Thus the right-hand side in the integral representation (6.5) converges also pointwise and, together with the norm convergence, (6.7) follows.

Since for u fixed, $\Psi(t,u)$ is a Fourier transform of a L^1-function, the Riemann-Lebesgue lemma applies. Hence $\Psi(t,u)$ vanishes as $t\to\infty$.

□

In the next step we extend this proposition to the Cauchy problem (2.6).

Theorem 6.6: *Consider the Cauchy problem (2.6) for smooth and compactly supported initial data. Then there exists a unique smooth solution, which is compactly supported for all times.*

Moreover, decomposing the initial data Ψ_0 *into spherical harmonics, the solution has the representation*

$$\Psi(t,u,\vartheta,\varphi)=\sum_{l=0}^{\infty}\sum_{|m|\leqslant l} e^{-itH_l}\,\Psi_0^{lm}(u)Y_{lm}(\vartheta,\varphi). \tag{6.9}$$

Proof: For the existence and uniqueness of such a solution we apply the theory of linear symmetric hyperbolic systems (cf. Ref. 12). Since the equation in (2.6) is defined on $\mathbb{R}\times\mathbb{R}\times S^2$ we must work in local coordinates for S^2. We demonstrate the idea in the chart $(U,(\vartheta,\varphi))$, where U is an open, relative compact subset of S^2 such that (ϑ,φ) are well defined on $\bar{U}$.

Letting $\Phi=(\partial_t\psi,\partial_u\psi,\partial_{\cos\,\vartheta}\psi,\partial_\varphi\psi,\psi)^T$ we can write the equation as the first order system

$$A^0\partial_t\Phi+A^1\partial_u\Phi+A^2\partial_{\cos\,\vartheta}\Phi+A^3\partial_\varphi\Phi+B\Phi=0,$$

where the matrices A^i,B are given by

$$A^0=\mathrm{diag}\left(1,1,\left(1-\frac{2M}{r}\right)\frac{1}{r^2}\sin^2,\left(1-\frac{2M}{r}\right)\frac{1}{r^2}\frac{1}{\sin^2\vartheta},1\right),$$

$$A^1=(a^1_{ij})\quad\text{with } a^1_{12}=a^1_{21}=-1,$$

$$A^2=(a^2_{ij})\quad\text{with } a^2_{13}=a^2_{31}=-\left(1-\frac{2M}{r}\right)\frac{1}{r^2}\sin^2\vartheta,$$

$$A^3=(a^3_{ij})\quad\text{with } a^3_{14}=a^3_{41}=-\left(1-\frac{2M}{r}\right)\frac{1}{r^2}\frac{1}{\sin^2\vartheta},$$

$$B=(b_{ij})\quad\text{with } b_{13}=\left(1-\frac{2M}{r}\right)\frac{1}{r^2}2\cos\vartheta,$$

$$b_{15}=\left(1-\frac{2M}{r}\right)\frac{2M}{r^3},\quad b_{51}=-1,$$

and all other coefficients vanish. By multiplying this system with $[1-(2M/r)]^{-1}r^2$, we obtain a linear symmetric hyperbolic system on $\mathbb{R}\times\mathbb{R}\times U$ in the sense that the A^i are symmetric and A^0 is uniformly positive definite on $\mathbb{R}\times\mathbb{R}\times U$. Since the initial data Ψ_0 has compact support, we can restrict the system to $\mathbb{R}\times V\times U$, where $V\subseteq\mathbb{R}$ is an open, relative compact set with $\mathrm{supp}\,\Psi_0\subseteq V$. Considering the system on this domain, the matrices A^i,B remain uniformly bounded. Since we can cover S^2 by a finite number of such charts, the theory of symmetric hyperbolic systems yields an $\epsilon_1>0$ such that there is unique and smooth solution $\psi(t,u,x)$ for all $t<\epsilon_1$ on $\mathbb{R}\times V\times S^2$ with initial data Ψ_0.

Moreover, this solution has finite propagation speed, which is independent of u (this is physically clear from causality; it follows mathematically by considering lens-shaped regions for our symmetric hyperbolic systems). Thus there exists an $\epsilon>0$ (possibly smaller than ϵ_1) such that the solution $\psi(t,u,x)$ has compact support in $V\times S^2$ for all times $t\leqslant\epsilon$. Iterating this argument for the Cauchy problem with initial data $(\psi(\epsilon,u,x),i\partial_t\psi(\epsilon,u,x))$ (and choosing $V\subseteq\mathbb{R}$ sufficiently large), we get a unique and smooth solution $\psi(t,u,x)$ with compact support for all $t\leqslant 2\epsilon$ and so forth. Thus we have proven the existence of a global solution $\psi(t,u,x)\in C^\infty(\mathbb{R}\times\mathbb{R}\times S^2)$ which is unique and compactly supported for all times t.

In order to prove the representation (6.9), we consider the restriction of the solution $\Psi(t,u,x)=(\psi(t,u,x),i\partial_t\psi(t,u,x))^T$ of the Cauchy problem (2.12) in Hamiltonian form to fixed modes l,m

$$\Psi^{lm}(t,u)Y_{lm}(\vartheta,\varphi)=\langle\Psi(t,u),Y_{lm}\rangle_{L^2(S^2)}Y_{lm}(\vartheta,\varphi).$$

Then $\Psi^{lm}(t,u)Y_{lm}(\vartheta,\varphi)$ is a solution of (2.12) with initial data $\Psi_0^{lm}(u)Y_{lm}(\vartheta,\varphi)$, which is smooth and compactly supported. Thus $\Psi^{lm}(t,u)$ is a solution of the Cauchy problem (2.23), and due to the uniqueness of such solutions

$$\Psi^{lm}(t,u)=e^{-itH_l}\Psi_0^{lm}(u).$$

Now the uniqueness of the decomposition into spherical harmonics yields (6.9).

□

We are now ready to prove our main theorem.

Proof of Theorem 1.1: The existence and uniqueness of solutions of the Cauchy problem follow directly from Theorem 6.6 after the substitution $\psi=r\phi$. Thus it remains to show the pointwise decay.

The conserved energy for solutions which are compactly supported for all times t implies that for every t,

$$\|\Psi(t,u,\vartheta,\varphi)\|^2=\|\Psi_0(u,\vartheta,\varphi)\|^2=\sum_{l=0}^{\infty}\sum_{|m|\leqslant l}\|\Psi_0^{lm}(u)\|_l^2,$$

where for the second equation we used the isometry (2.21). Hence, defining

$$\Psi^L(t,u,\vartheta,\varphi):=\sum_{l=L}^{\infty}\sum_{|m|\leqslant l}\Psi^{lm}(t,u)Y_{lm}(\vartheta,\varphi),$$

we can find for every $\epsilon>0$ a number L_0 such that

$$\|\Psi^{L_0}(t,u,\vartheta,\varphi)\|^2=\sum_{l=L_0}^{\infty}\sum_{|m|\leqslant l}\|\Psi_0^{lm}(u)\|_l^2<\epsilon.$$

Let us now consider the Cauchy problem (2.6) with initial data

$$H\Psi_0=\sum_{l=0}^{\infty}\sum_{|m|\leqslant l}(H_l\Psi_0^{lm})Y_{lm}.$$

Obviously, this data is also smooth and compactly supported and thus gives rise to the solution

$$\sum_{l=0}^{\infty}\sum_{|m|\leqslant l}(e^{-itH_l}H_l\Psi_0^{lm})Y_{lm}=\sum_{l=0}^{\infty}\sum_{|m|\leqslant l}(H_le^{-itH_l}\Psi_0^{lm})Y_{lm}=H\Psi,$$

where in the second equation we again used the uniqueness of the decomposition into spherical harmonics. Thus for every $\epsilon>0$ there is a L_1 (without restriction $\geqslant L_0$) such that

$$\|H\Psi^{L_1}(t)\| < \epsilon \quad \text{for all times } t.$$

Proceeding inductively, we find for every number N and for every $\epsilon>0$ a number L_N such that

$$\|H^n\Psi^{L_N}(t)\| < \epsilon \quad \text{for all } t \text{ and } n \leqslant N.$$

Let $K\subseteq\mathbb{R}\times S^2$ be an arbitrary compact subset with smooth boundary. Then, due to the definition of the energy, there exists a constant $C_0(K)>0$ such that for $\Psi^{L_N}=(\psi_1^{L_N},\psi_2^{L_N})^T$,

$$\|\psi_1^{L_N}\|_{H^1(K)} + \|\psi_2^{L_N}\|_{L^2(K)} \leqslant C_0(K)\|\Psi^{L_N}\|.$$

Applying the same argument to $H\Psi^{L_N}=(\psi_2^{L_N},A\psi_1^{L_N})^T$, where A is the differential operator given by (2.14), there is a $C_1(K)>0$ such that

$$\|A\psi_1^{L_N}\|_{L^2(K)} + \|\psi_2^{L_N}\|_{H^1(K)} \leqslant C_1(K)\|H\Psi^{L_N}\|.$$

Since the differential operator A is of the form $A=-\Delta+X$, where X is a first order differential operator, it is in particular a second order elliptic partial differential operator. Thus, for $u\in C^\infty(\mathbb{R}\times S^2)$ and for each $U\subset\subset V\subset\subset\mathbb{R}\times S^2$ ($\subset\subset$ denotes relative compact) there is an estimate [cf. Ref. 15, p. 379 (11.3)]

$$\|u\|_{H^{k+2}(U)} \leqslant C\|Au\|_{H^k(V)} + C\|u\|_{H^{k+1}(V)} \quad \text{for all } k\geqslant 0.$$

It follows that there exist new constants $C_0(K),C_1(K)$ such that

$$\|\psi_1^{L_N}\|_{H^2(K)} + \|\psi_2^{L_N}\|_{H^1(K)} \leqslant C_0(K)\|\Psi^{L_N}\| + C_1(K)\|H\Psi^{L_N}\|.$$

Iterating this inequality, we obtain constants $C_0(K),\ldots,C_k(K)$ such that

$$\|\psi_1^{L_N}\|_{H^{k+1}(K)} + \|\psi_2^{L_N}\|_{H^k(K)} \leqslant \sum_{n=0}^{k} C_n(K)\|H^n\Psi^{L_N}\|.$$

In particular, for every $\epsilon>0$ there is a number L such that

$$\|\Psi^L(t)\|_{H^2(K)} < \epsilon \quad \text{for all } t.$$

Thus the Sobolev embedding theorem yields (possibly after enlarging L)

$$\|\Psi^L(t)\|_{L^\infty(K)} < \epsilon \quad \text{for all } t.$$

Furthermore, due to the pointwise decay for fixed modes l,m which was shown in Theorem 6.5, we can find for any $\epsilon>0$ and $(u,x)\in\mathbb{R}\times S^2$ a time t_0 and a number L such that for the solution $\Psi(t,u,x)$ of the Cauchy problem (2.6),

$$|\Psi(t,u,x)| \leqslant \sum_{l=0}^{L-1}\sum_{|m|\leqslant l} |\Psi^{lm}(t,u)Y_{lm}(x)| + |\Psi^L(t,u,x)| < \epsilon \quad \text{for all } t\geqslant t_0.$$

Since $\psi=r\phi$, this concludes the proof.

□

We study a model of power-law inflationary inflation using the space-time-matter theory of gravity for a five-dimensional canonical metric that describes an apparent vacuum. In this approach the expansion is governed by a single scalar (neutral) quantum field. In particular, we study the case where the power of expansion of the universe is $p \gg 1$. This kind of model is more successful than others in accounting for galaxy formation. © *2006 American Institute of Physics.*

I. INTRODUCTION

A standard mechanism for galaxy formation is the amplification of primordial fluctuations by the evolutionary dynamics of space-time. The inflationary cosmology is based on the dynamics of a quantum field undergoing a phase transition.[1] The exponential expansion of the scale parameter naturally gives a scale-invariant spectrum on cosmological scales, in agreement with experimental data. This is one of the many attractive features of the inflationary universe, particulary in regard to the galaxy formation problem[2] and it arises from the fluctuations of the inflaton, the quantum field which induces inflation. This field can be semiclassically expanded in terms of its expectation value plus other fields, which describe the quantum fluctuations.[3] The quantum to classical transition of quantum fluctuations has been studied thoroughly.[4] The infrared matter field fluctuations are classical and can be described by a coarse-grained field which takes into account only wavelengths larger than the Hubble radius. The dynamics of this coarse-grained field is described by a second order stochastic equation, which can be treated using the Fokker-Planck formalism. This issue has been the subject of intense work during the last two decades.[5] Because of the success of this theory to explain the large-scale structure formation, inflation has become a standard ingredient for the description of the early universe. In fact, it is the unique that solves some of the problems of the standard big-bang scenario and also makes predictions about cosmic microwave background (CMBR) anisotropies, which are being measured with increasing precision.

On the other hand, recently, extra dimensional theories of gravity have received much interest, mainly sparked by works in string[6] and supergravity theories.[7] For the most part, four-dimensional (4D) space-time has been extended by the addition of several extra spatial dimensions, usually taken to be compact. Other very interesting approaches, developed by Wesson and co-workers[8,9] have given new impetus to the study of five-dimensional (5D) gravity. None of the standard dimensional reduction techniques imposed to reduce the number of space-time dimensions to four, are adhered to in their approach; indeed, the extra spatial dimension is not necessarily assumed to be compact. The main question they address in whether the 4D properties of matter can be viewed as being purely geometrical in origin. This idea is not new, and was originally introduced by Einstein.[10]

In this work we are interested in studying the early inflationary dynamics of the universe from the STM theory of gravity. In particular, we are aimed to study power-law inflation, where the

[a]Electronic mail: anabitar@mdp.edu.ar
[b]Electronic mail: mbellini@mdp.edu.ar

scale factor of the universe growth as $a \sim t^p$, being $p > 1$ the power of expansion during inflation. To do this, we use the Ponce de Leon metric,[11] in the limital case where the power of expansion is $p \gg 1$, which describe an asymptotic de Sitter expansion of the universe.

II. BASIC STM EQUATIONS

Following the idea suggested by Wesson and co-workers,[8,9] in this section we develop the induced 4D equation of state from the 5D vacuum field equations, $G_{AB}=0 (A,B=0,1,2,3,4)$, which give the 4D Einstein equations $G_{\mu\nu}=8\pi G\, T_{\mu\nu}(\mu,\nu=0,1,2,3)$. In particular, we consider a 5D spatially isotropic and three-dimensional (3D) flat spherically symmetric line element

$$\mathrm{d}S^2 = e^{\alpha(\psi,t)}\,\mathrm{d}t^2 - e^{\beta(\psi,t)}\,\mathrm{d}r^2 - e^{\gamma(\psi,t)}\,\mathrm{d}\psi^2, \tag{1}$$

where $\mathrm{d}r^2=\mathrm{d}x^2+\mathrm{d}y^2+\mathrm{d}z^2$ and ψ is the fifth coordinate. We assume that e^{α}, e^{β}, and e^{γ} are separable functions of the variables ψ and t. The equations for the relevant Einstein tensor elements are

$$G^0{}_0 = -e^{-\alpha}\left[\frac{3\dot{\beta}^2}{4}+\frac{3\dot{\beta}\dot{\gamma}}{4}\right]+e^{-\gamma}\left[\frac{3\overset{\star\star}{\beta}}{2}+\frac{3\overset{\star 2}{\beta}}{2}-\frac{3\overset{\star}{\gamma}\overset{\star}{\beta}}{4}\right], \tag{2}$$

$$G^0{}_4 = e^{-\alpha}\left[\frac{3\overset{\star\cdot}{\beta}}{2}+\frac{3\dot{\beta}\overset{\star}{\beta}}{4}-\frac{3\dot{\beta}\overset{\star}{\alpha}}{4}-\frac{3\overset{\star}{\gamma}\dot{\gamma}}{4}\right], \tag{3}$$

$$\begin{aligned} G^i{}_i = &-e^{-\alpha}\left[\ddot{\beta}+\frac{3\dot{\beta}^2}{4}+\frac{\ddot{\gamma}}{2}+\frac{\dot{\gamma}^2}{4}+\frac{\dot{\beta}\dot{\gamma}}{2}-\frac{\dot{\alpha}\dot{\beta}}{2}-\frac{\dot{\alpha}\dot{\gamma}}{4}\right] \\ &+e^{-\gamma}\left[\overset{\star\star}{\beta}+\frac{3\overset{\star 2}{\beta}}{4}+\frac{\overset{\star\star}{\alpha}}{2}+\frac{\overset{\star 2}{\alpha}}{4}+\frac{\overset{\star}{\beta}\overset{\star}{\alpha}}{2}-\frac{\overset{\star}{\gamma}\overset{\star}{\beta}}{2}-\frac{\overset{\star}{\alpha}\overset{\star}{\gamma}}{4}\right], \end{aligned} \tag{4}$$

$$G^4{}_4 = e^{-\alpha}\left[\frac{3\ddot{\beta}}{2}+\frac{3\dot{\beta}^2}{2}-\frac{3\dot{\alpha}\dot{\beta}}{4}\right]+e^{-\gamma}\left[\frac{3\overset{\star 2}{\beta}}{4}+\frac{3\overset{\star}{\beta}\overset{\star}{\alpha}}{4}\right], \tag{5}$$

where the overstar and the overdot denote, respectively, $\partial/\partial\psi$ and $\partial/\partial t$, and $i=1,2,3$. We shall use the signature $(+,-,-,-)$ for the 4D metric, such that we define $T^0_0=\rho_t$ and $T^1_1=-p$, where ρ_t is the total energy density and p is the pressure. The 5D-vacuum conditions ($G^A_B=0$) are given by[12]

$$8\pi G\rho_t = \tfrac{3}{4}e^{-\alpha}\dot{\beta}^2, \tag{6}$$

$$8\pi G p = e^{-\alpha}\left[\frac{\dot{\alpha}\dot{\beta}}{2}-\ddot{\beta}-\frac{3\dot{\beta}^2}{4}\right], \tag{7}$$

$$e^{\alpha}\left[\frac{3\overset{\star 2}{\beta}}{4}+\frac{3\overset{\star}{\beta}\overset{\star}{\alpha}}{4}\right] = e^{\gamma}\left[\frac{\ddot{\beta}}{2}+\frac{3\dot{\beta}^2}{2}-\frac{\dot{\alpha}\dot{\beta}}{4}\right]. \tag{8}$$

Hence, from Eqs. (6) and (7) and taking $\dot{\alpha}=0$, we obtain the equation of state for the induced matter

$$p = -\left(\frac{4}{3}\frac{\ddot{\beta}}{\dot{\beta}^2} + 1\right)\rho_t. \tag{9}$$

Notice that for $\ddot{\beta}/\dot{\beta}^2 \leqslant 0$ and $|\ddot{\beta}/\dot{\beta}^2| \ll 1$ (or zero), this equation describes an inflationary universe. The particular case $\ddot{\beta}/\dot{\beta}^2 = 0$ corresponds to a 4D de Sitter expansion for the universe.

As in a previous paper,[13] we shall consider power-law inflation, which can be obtained from the metric (1), when α, β, and γ are functions of the following coordinates:

$$\alpha \equiv \alpha(\psi), \quad \beta \equiv \beta(\psi, t), \quad \gamma \equiv \gamma(t). \tag{10}$$

Here, e^{β} is a separable function of ψ and t. The conditions (10) imply that $\dot{\alpha} = \overset{\star}{\gamma} = 0$. Furthermore, we shall consider the case where all the coordinates are independent. The choice (10) implies that only the spatial sphere and the fifth coordinate have squared sizes e^{β} and e^{γ}, respectively, that evolve with time.

III. THE MODEL

In this paper we shall consider the particular case of choosing for the metric (1),

$$e^{\alpha} = \psi^2, \quad e^{\beta} = \left(\frac{t}{t_0}\right)^{2p} \psi^{2p/(p-1)}, \quad e^{\gamma} = \frac{t^2}{(p-1)^2}, \tag{11}$$

which corresponds to the Ponce de Leon metric[11]

$$\mathrm{d}S^2 = \psi^2\,\mathrm{d}t^2 - \left(\frac{t}{t_0}\right)^{2p} \psi^{2p/(p-1)}\,\mathrm{d}r^2 - \frac{t^2}{(p-1)^2}\mathrm{d}\psi^2, \tag{12}$$

for which the absolute value for the determinant of the metric tensor g_{AB} is

$$|^{(5)}g| = \left[\frac{t^{3p+1}\psi^{(4p-1)/(p-1)}}{(p-1)t_0^{3p}}\right]^2.$$

Furthermore, we shall consider an action that describes a free scalar field minimally coupled to gravity

$$I = -\int d^4x\,\mathrm{d}\psi \sqrt{\left|\frac{^{(5)}g}{^{(5)}g_0}\right|}\left[\frac{^{(5)}R}{16\pi G} + {}^{(5)}\mathcal{L}(\varphi, \varphi_{,A})\right], \tag{13}$$

with a Lagrangian

$$L = \sqrt{\frac{^{(5)}g}{^{(5)}g_0}}\mathcal{L}(\varphi, \varphi_{,A}), \tag{14}$$

and the Lagrangian density

$$\mathcal{L} = \tfrac{1}{2}g^{AB}\varphi_{,A}\varphi_{,B}. \tag{15}$$

The scalar $^{(0)}g_0$ in the action (13) is given by $^{(0)}g|_{t=t_0,\psi=\psi_0}$, such that

$$|^{(5)}g_0| = \left(\frac{t_0\psi_0^{(4p-1)/(p-1)}}{(p-1)}\right)^2,$$

where t_0 and ψ_0 are constants. Note that $|^{(5)}g|$ and $|^{(5)}g_0|$ are not well defined for $p=1$. The Lagrange equation is given by

$$\ddot{\varphi}+\frac{3p+1}{t}\dot{\varphi}-\left(\frac{t_0^p\psi^{1/(1-p)}}{t^p}\right)^2\nabla^2\varphi-\psi\frac{(p-1)(4p-1)}{t^2}\varphi_{,\psi}-\psi^2\frac{(p-1)^2}{t^2}\varphi_{,\psi\psi}=0, \tag{16}$$

where the overdot denotes the derivative with respect to the time and $\varphi_{,\psi}=\partial\varphi/\partial\psi$. In order to simplify the structure of this equation we propose the transformation $\varphi=(t_0/t)^{(3p+1)/2}(\psi_0/\psi)^{[(4p-1)/2(p-1)]}\chi$, such that the equation of motion for χ is

$$\ddot{\chi}-\psi^{2/(1-p)}\left(\frac{t_0}{t}\right)^{2p}\nabla^2\chi-\psi^2\frac{(p-1)^2}{t^2}\chi_{,\psi\psi}+\frac{(31p^2-14p+2)}{4t^2}\chi=0. \tag{17}$$

We propose the following Fourier's expansion for χ:

$$\chi(t,\vec{r},\psi)=\frac{1}{(2\pi)^{3/2}}\int d^3k_r\int \mathrm{d}k_\psi[a_{k_rk_\psi}e^{i(\vec{k}_r\cdot\vec{r}+\vec{k}_\psi\cdot\psi)}\xi_{k_rk_\psi}+a^\dagger_{k_rk_\psi}e^{-i(\vec{k}_r\cdot\vec{r}+\vec{k}_\psi\cdot\psi)}\xi^*_{k_rk_\psi}], \tag{18}$$

where the operators $a_{k_rk_\psi}$ and $a^\dagger_{k_rk_\psi}$ describe the algebra

$$[a_{k_rk_\psi},a^\dagger_{k'_rk'_\psi}]=\delta^{(3)}(\vec{k}_r-\vec{k}'_r)\,\delta(\vec{k}_\psi-\vec{k}'_\psi),\quad [a_{k_rk_\psi},a_{k'_rk'_\psi}]=[a^\dagger_{k_rk_\psi},a^\dagger_{k'_rk'_\psi}]=0.$$

The dynamics of the time dependent modes $\xi_{k_rk_\psi}$ is given by

$$\ddot{\xi}_{k_rk_\psi}+\left[\psi^{2/(1-p)}\left(\frac{t_0}{t}\right)^{2p}k_r^2+\frac{\psi^2(p-1)^2}{t^2}\left(k_\psi^2+\frac{(31p^2-14p+2)}{4(p-1)^2\psi^2}-2ik_\psi\frac{\partial}{\partial\psi}-\frac{\partial^2}{\partial\psi^2}\right)\right]\xi_{k_rk_\psi}=0. \tag{19}$$

The commutator between χ and $\dot{\chi}$ is

$$[\chi(t,\vec{r},\psi),\dot{\chi}(t,\vec{r},\psi')]=i\,\delta^{(3)}(\vec{r}-\vec{r})\,\delta(\psi-\psi'), \tag{20}$$

which complies for $\xi_{k_rk_\psi}(t,\psi)\dot{\xi}^*_{k_rk_\psi}(t,\psi')-\xi^*_{k_rk_\psi}(t,\psi')\dot{\xi}_{k_rk_\psi}(t,\psi)=i$, that guarantee the normalization of $\xi_{k_rk_\psi}$. Furthermore, if we make the transformation $\xi_{k_rk_\psi}=e^{-i\vec{k}_\psi\cdot\psi}\tilde{\xi}_{k_rk_\psi}$, we obtain from Eq. (19) the equation of motion for $\tilde{\xi}_{k_rk_\psi}$,

$$\ddot{\tilde{\xi}}_{k_rk_\psi}-\frac{\psi^2}{t^2}(p-1)^2\frac{\partial^2\tilde{\xi}_{k_rk_\psi}}{\partial\psi^2}+\left[\psi^{2/(1-p)}\left(\frac{t_0}{t}\right)^{2p}k_r^2+\frac{(31p^2-14p+1)}{4t^2}\right]\tilde{\xi}_{k_rk_\psi}=0, \tag{21}$$

and the expansion (18) for χ can be rewritten as

$$\chi(t,\vec{r},\psi)=\frac{1}{(2\pi)^{3/2}}\int d^3k_r\int \mathrm{d}k_\psi[a_{k_rk_\psi}e^{i\vec{k}_r\cdot\vec{r}}\tilde{\xi}_{k_rk_\psi}+a^\dagger_{k_rk_\psi}e^{-i\vec{k}_r\cdot\vec{r}}\,\tilde{\xi}^*_{k_rk_\psi}]. \tag{22}$$

4D dynamics of the inflaton field

Now we consider a foliation (choice of a hypersurface) $\psi=\psi_0$ on the metric (12). On this foliation, the effective 4D line element is

$$\mathrm{d}S^2\to\mathrm{d}s^2=\psi_0^2\,\mathrm{d}t^2-\left(\frac{t}{t_0}\right)^{2p}\psi_0^{2p/(p-1)}\,\mathrm{d}r^2, \tag{23}$$

where ψ_0 is a dimensionless constant and the scale factor of the universe is given by $a=a_0(t/t_0)^p$. During inflation $p\gg1$, such that $\ddot{a}>0$ and, for $\dot{\beta}=2H=2\dot{a}/a$ in Eq. (9), the equation of

state describes a quasi-de Sitter (quasivacuum) expansion, $p \simeq \left[\frac{4}{3}(\dot{H}/H^2)+1\right]\rho_t \simeq -\rho_t$. The Lagrangian density (15) can be expanded in the following manner: ${}^{(5)}\mathcal{L} = \frac{1}{2}[g^{\mu\nu}\varphi_{,\mu}\varphi_{,\nu} + g^{\psi\psi}\varphi_{,\psi}\varphi_{,\psi}]$, such that the effective 4D Lagrangian density for the inflaton field on the foliation $\psi = \psi_0$ can be written as

$$ {}^{(4)}\mathcal{L} = \tfrac{1}{2}g^{\mu\nu}\varphi_{,\mu}\varphi_{,\nu} - V(\varphi)\big|_{\psi=\psi_0}, \tag{24}$$

where $V(\varphi)$ is given by

$$ V(\varphi) = -\frac{1}{2}g^{\psi\psi},_{\varphi,\psi}\varphi_{,\psi}\Big|_{\psi=\psi_0} = \frac{(p-1)^2}{2t^2}\left(\frac{\partial\varphi}{\partial\psi}\right)^2\Bigg|_{\psi=\psi_0}. \tag{25}$$

On the other hand, for a foliation $\psi = \psi_0$, the dynamics of the inflaton field holds

$$ \ddot{\varphi} + \frac{(3p+1)}{t}\dot{\varphi} - \left(\frac{t_0}{t}\right)^{2p}\psi^{2/(1-p)}\nabla^2\varphi - \left[\frac{\psi(p-1)(4p-1)}{t^2}\varphi_{,\psi} + \frac{\psi^2(p-1)^2}{t^2}\varphi_{,\psi\psi}\right]\Bigg|_{\psi=\psi_0} = 0, \tag{26}$$

so that we can make the following identification:

$$ V'(\varphi) = \left[\frac{\dot{\varphi}}{t} - \frac{\psi(p-1)(4p-1)}{t^2}\varphi_{,\psi} - \frac{\psi^2(p-1)^2}{t^2}\varphi_{,\psi\psi}\right]\Bigg|_{\psi=\psi_0}. \tag{27}$$

Furthermore, the scalar field χ in Eq. (22) on the foliation $\psi = \psi_0$ now holds

$$ \chi(t,\vec{r},\psi=\psi_0) = \frac{1}{(2\pi)^{3/2}}\int d^3k_r \int \mathrm{d}k_\psi [a_{k_r k_\psi} e^{i\vec{k}_r\cdot\vec{r}}\,\tilde{\xi}_{k_r k_\psi} + \mathrm{c.c.}]\,\delta(k_\psi - k_{\psi_0}). \tag{28}$$

Note that the equation (26) is not separable on the coordinate ψ. However, in the limit $p \gg 1$, which is relevant to study the inflationary expansion of the early universe, the term $(t_0/t)^{2p}\psi^{2/(1-p)}\nabla^2\varphi$ in Eq. (26) tends asymptotically to $(t_0/t)^{2p}\nabla^2\varphi$ as $p \to \infty$. Hence, in this limital case the dynamics for φ is governed by the equation

$$ \ddot{\varphi} + \frac{(3p+1)}{t}\dot{\varphi} - \left(\frac{t_0}{t}\right)^{2p}\nabla^2\varphi - \left[\frac{\psi(p-1)(4p-1)}{t^2}\varphi_{,\psi} + \frac{\psi^2(p-1)^2}{t^2}\varphi_{,\psi\psi}\right]\Bigg|_{\psi=\psi_0} = 0, \tag{29}$$

which is separable on the variable ψ and more easily workable. This particular case will be studied in the next section.

IV. INFLATIONARY EXPANSION ($P \gg 1$)

We consider the case where $p \gg 1$, which describes an inflationary power-law expansion in the very early universe. In this case the equation for the modes, (21), can be approximated to

$$ \ddot{\tilde{\xi}}_{k_r k_\psi} - \frac{\psi^2(p-1)^2}{t^2}\frac{\partial^2\tilde{\xi}_{k_r k_\psi}}{\partial\psi^2} + \left[k_r^2\left(\frac{t_0}{t}\right)^{2p} + \frac{(31p^2-14p+2)}{4t^2}\right]\tilde{\xi}_{k_r k_\psi} \simeq 0. \tag{30}$$

The general solution for this equation on the foliation $\psi = \psi_0$ is

$$ \tilde{\xi}_{k_r k_\psi}(t,\psi) = \alpha\sqrt{\frac{t}{t_0}}\mathcal{H}_\nu^{(1)}[x(t)], \tag{31}$$

where $\nu=\sqrt{(1+4C)}/2(p-1)$, $x(t)=k_r t_0^p t^{1-p}/(p-1)$,

$$\alpha = A_1[M_1\psi_0^{(1/2)+\sqrt{(1/4)+[C/(p-1)^2]}} + M_2\psi_0^{(1/2)-\sqrt{(1/4)+[C/(p-1)^2]}}],$$

$C=C_1+[(31p^2-14p+2)/4]$ and C_1, A_1, M_1, and M_2 are constants of integration. Furthermore, the normalization condition implies that

$$\frac{4(p-1)}{t_0\pi}|\alpha|^2 = 1. \tag{32}$$

To calculate the inflation field fluctuations on the infrared sector, which is relevant for super Hubble scales during inflation, we can make use of the asymptotic representations of the first kind of Hankel function $\mathcal{H}_\nu^{(1)}[x]$ for $x \ll 1$,

$$\mathcal{H}_\nu^{(1)}[x] \simeq \frac{1}{\Gamma(\nu+1)}\left(\frac{x}{2}\right)^\nu + \frac{i}{\pi}\Gamma(\nu)\left(\frac{x}{2}\right)^{-\nu}.$$

With this representation the squared χ fluctuations on cosmological scales are $\langle\chi^2\rangle|_{\mathrm{IR}} = (1/2\pi^2)\int_0^{\epsilon k_0} \mathrm{d}k_r\, k_r^2 \tilde{\xi}_{k_r k_{\psi 0}} \tilde{\xi}^*_{k_r k_{\psi 0}}$ where $k_0(t)=[\sqrt{31p^2-14p+2}/2t_0^p]t^{p-1}$ is the wave number that separates the infrared (IR) and ultraviolet sectors. Making the calculation, we obtain

$$\langle\chi^2\rangle|_{\mathrm{IR}} = \frac{t}{8\pi(p-1)}\left[\frac{1}{\Gamma^2(\nu+1)}\left(\frac{\epsilon^3(31p^2-14p+2)t^{2(p-1)}}{16(p-1)t_0^{2p}}\right)^{2\nu}\frac{1}{(2\nu+3)} - \frac{\Gamma^2(\nu)}{\pi^2(3-2\nu)}\left(\frac{16(p-1)t_0^{2p}t^{-2(p-1)}}{\epsilon^3(31p^2-14p+2)}\right)^{2\nu}\right], \tag{33}$$

and the squared φ fluctuations, which are relevant for us, are

$$\langle\varphi^2\rangle|_{\mathrm{IR}} = \frac{t^{-3p}t_0^{(3p+1)}}{8\pi(p-1)}\left[\frac{1}{\Gamma^2(\nu+1)}\left(\frac{\epsilon^3(31p^2-14p+2)t^{2(p-1)}}{16(p-1)t_0^{2p}}\right)^{2\nu}\frac{1}{(2\nu+3)} - \frac{\Gamma^2(\nu)}{\pi^2(3-2\nu)}\left(\frac{16(p-1)t_0^{2p}t^{-2(p-1)}}{\epsilon^3(31p^2-14p+2)}\right)^{2\nu}\right], \tag{34}$$

which decrease with time as $\langle\varphi^2\rangle|_{\mathrm{IR}} \sim t^{-3p}$. The power spectrum of these fluctuations goes as $\mathcal{P}(k_r) \sim k_r^{3-2\nu}$ which is scale invariant for $C_1=[9(p-1)-2]/8$ and hence for $C=[61p^2-(19p+7)]/8$. This result is very interesting because (with an adequate choice of constant values) we can obtain scale invariance for the power spectrum of $\langle\varphi^2\rangle$ for any $p \gg 1$, independently of some particular value for it.

V. FINAL COMMENTS

In this paper we have studied power-law inflation in the limital case $p \gg 1$ from a STM theory of gravity using the Ponce de Leon metric. In this approach, the inflationary expansion is governed by a single scalar field, that, on a foliation $\psi=\psi_0$ in the 5D metric (12) can be identified as the inflaton field evolving on the effective 4D Friedmann-Robertson-Walker metric (23). In Wesson's theory [called space-time-matter (STM) theory], the, extra dimension is not assumed to be compactified, which is a major departure from earlier multidimensional theories where the cylindricity conditions were imposed. In this theory, the original motivation for assuming the existence of a large extra dimension was to achieve the unification of matter and geometry, i.e., to obtain the properties of matter as a consequence of the extra dimensions. A very important fact in our

approach is that the effective potential $V(\varphi)=-\frac{1}{2}g^{\psi\psi}(\partial\varphi/\partial\psi)^2|_{\psi=\psi_0}$, has a geometrical origin.

In this paper we have studied with major detail the case $p\gg 1$, because this is where the field $\varphi(t,\vec{r},t)$ is separable on the variable ψ and can be more easily treated. However, for cases where the power p is of the order of the unity, the fifth coordinate ψ could play a more important role in the spectrum of the squared φ fluctuations.

(Received 23 November 2005; accepted 23 February 2006; published online 14 April 2006)

Consider, in the domain of outer communication M_+ of a Kerr-Newman black hole, a point p (observation event) and a timelike curve γ (worldline of light source). Assume that γ (i) has no past endpoint, (ii) does not intersect the caustic of the past light cone of p, and (iii) goes neither to the horizon nor to infinity in the past. We prove that then for infinitely many positive integers k there is a past-pointing lightlike geodesic λ_k of (Morse) index k from p to γ, hence an observer at p sees infinitely many images of γ. Moreover, we demonstrate that all lightlike geodesics from an event to a timelike curve in M_+ are confined to a certain spherical shell. Our characterization of this spherical shell shows that in the Kerr-Newman space-time the occurrence of infinitely many images is intimately related to the occurrence of centrifugal-plus-Coriolis force reversal. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2188209]

I. INTRODUCTION

The question of how many images an observer at an event p sees of a light source with worldline γ is equivalent to the question of how many past-pointing lightlike geodesics from p to γ exist. In space-times with many symmetries this question can be addressed, in principle, by directly integrating the geodesic equation. In the space-time around a nonrotating and uncharged black hole of mass m, e.g., which is described by the Schwarzschild metric, all lightlike geodesics can be explicitly written in terms of elliptic integrals; with the help of these explicit expressions, it is easy to verify that in the region outside the horizon, i.e., in the region where $r>2m$, there are infinitely many past-pointing lightlike geodesics from any event p to any integral curve of the Killing vector field ∂_t. This was demonstrated already in 1959 by Darwin.[1] We may thus say that a Schwarzschild black hole acts as a gravitational lens that produces infinitely many images of any static light source. However, already in the Schwarzschild space-time the problem becomes more difficult if we want to consider light sources which are not static, i.e., worldlines γ which are not integral curves of ∂_t.

In this paper we want to investigate this problem for the more general case of a charged and rotating black hole, which is described by the Kerr-Newman metric. More precisely, we want to demonstrate that in the domain of outer communication around a Kerr-Newman black hole, i.e., in the domain outside of the outer horizon, there are infinitely many past-pointing lightlike geodesics from an unspecified event p to an unspecified worldline γ, with as little restrictions on γ as possible. Although the geodesic equation in the Kerr-Newman space-time is completely inte-

[a)]Electronic mail: astrometrie@gmx.de
[b)]Electronic mail: vper0433@itp.physik.tu-berlin.de

grable, the mathematical expressions are so involved that it is very difficult to achieve this goal by explicitly integrating the geodesic equation. Therefore it is recommendable to use more indirect methods.

Such a method is provided by Morse theory. Quite generally, Morse theory relates the number of solutions to a variational principle to the topology of the space of trial maps. Here we refer to a special variant of Morse theory, developed by Uhlenbeck,[2] which is based on a version of Fermat's principle for a globally hyperbolic Lorentzian manifold (M,g). The trial maps are the lightlike curves joining a point p and a timelike curve γ in M, and the solution curves of Fermat's principle are the lightlike geodesics. If (M,g) and γ satisfy additional conditions, the topology of the space of trial maps is determined by the topology of M. Uhlenbeck's work gives criteria that guarantee the existence of infinitely many past- or future-pointing lightlike geodesics from p to γ. In this paper we will apply her results to the domain of outer communication around a Kerr-Newman black hole which is, indeed, a globally hyperbolic Lorentzian manifold. We will show that the criteria for having infinitely many past-pointing timelike geodesics from p to γ are satisfied for every event p and every timelike curve γ in this region, provided that the following three conditions are satisfied. First, γ must not have a past endpoint; it is obvious that we need a condition of this kind because otherwise it would be possible to choose for γ an arbitrarily short section of a worldline such that trivially the number of past-pointing lightlike geodesics from p to γ is zero. Second, γ must not intersect the caustic of the past light-cone of p; this excludes all cases where p sees an extended image, such as an Einstein ring, of γ. Third, in the past the worldline γ must not go to the horizon or to infinity. Under these (very mild) restrictions on the motion of the light source we will see that the Kerr-Newman black hole acts as a gravitational lens that produces infinitely many images. Moreover, we will also show that all (past-directed) lightlike geodesics from p to γ are confined to a certain spherical shell. For the characterization of this shell we will have to discuss a light-convexity property which turns out to be intimately related to the phenomenon of centrifugal (-plus-Coriolis) force reversal. This phenomenon has been discussed, first in spherically symmetric static and then in more general space-times, in several papers by Abramowicz with various coauthors; material which is of interest to us can be found, in particular, in Abramowicz, Carter, and Lasota,[3] Abramowicz,[4] and Abramowicz, Nurowski, and Wex.[5]

The paper is organized as follows. In Sec. II we summarize the Morse-theoretical results we want to use. Section III is devoted to the notions of centrifugal and Coriolis force in the Kerr-Newman space-time; in particular, we introduce a potential Ψ_+ (respectively, Ψ_-) that characterizes the sum of centrifugal and Coriolis force with respect to corotating (respectively, counterrotating) observers whose velocity approaches the velocity of light. In Sec. IV we discuss multiple imaging in the Kerr-Newman space-time with the help of the Morse theoretical result quoted in Sec. II and with the help of the potential $\Psi_\pm$ introduced in Sec. III. Our results are summarized and discussed in Sec. V.

II. A RESULT FROM MORSE THEORY

In this section we briefly review a Morse-theoretical result that relates the number of lightlike geodesics between a point p and a timelike curve γ in a globally hyperbolic Lorentzian manifold to the topology of this manifold. This result was found by Uhlenbeck[2] and its relevance in view of gravitational lensing was discussed by McKenzie.[6] Uhlenbeck's work is based on a variational principle for lightlike geodesics ("Fermat principle") in a globally hyperbolic Lorentzian manifold, and her main method of proof is to approximate trial paths by broken geodesics. With the help of infinite-dimensional Hilbert manifold techniques Giannoni, Masiello, and Piccione were able to rederive Uhlenbeck's result[7] and to generalize it to certain subsets-with-boundary of space-times that need not be globally hyperbolic.[8] In contrast to Uhlenbeck, they start out from a variational principle for lightlike geodesics that is not restricted to globally hyperbolic space-times. (Such a Fermat principle for arbitrary general-relativistic space-times was first formulated by Kovner;[9] the proof that the solution curves of Kovner's variational principle are, indeed, precisely the lightlike geodesics was given by Perlick[10]). Although for our purpose the original Uhlenbeck result is

sufficient, readers who are interested in technical details are encouraged to also consult the papers by Giannoni, Masiello, and Piccione, in particular because in the Uhlenbeck paper some of the proofs are not worked out in full detail.

Following Uhlenbeck,[2] we consider a four-dimensional Lorentzian manifold (M,g) that admits a foliation into smooth Cauchy surfaces, i.e., a globally hyperbolic space-time. (For background material on globally hyperbolic space-times the reader may consult, e.g., Hawking and Ellis.[11] The fact that the original definition of global hyperbolicity is equivalent to the existence of a foliation into *smooth* Cauchy surfaces was completely proven only recently by Bernal and Sánchez.[12]) Then M can be written as a product of a three-dimensional manifold S, which serves as the prototype for each Cauchy surface, and a time axis,

$$M = S \times \mathbb{R}. \tag{1}$$

Moreover, this product can be chosen such that the metric g orthogonally splits into a spatial and a temporal part,

$$g = g_{ij}(x,t)\mathrm{d}x^i\,\mathrm{d}x^j - f(x,t)\mathrm{d}t^2, \tag{2}$$

where t is the time coordinate given by projecting from $M=S\times\mathbb{R}$ onto the second factor, $x=(x^1,x^2,x^3)$ are coordinates on S, and the summation convention is used for italic indices running from 1 to 3. [We write (2) in terms of coordinates for notational convenience only. We do not want to presuppose that S can be covered by a single coordinate system.] We interpret the direction of increasing t as the future direction on M. Again following Uhlenbeck,[2] we say that the splitting (2) satisfies the *metric growth condition* if for every compact subset of S there is a function F with

$$\int_{-\infty}^{0} \frac{\mathrm{d}t}{F(t)} = \infty, \tag{3}$$

such that for $t\leqslant 0$ the inequality

$$g_{ij}(x,t)v^iv^j \leqslant f(x,t)F(t)^2G_{ij}(x)v^iv^j \tag{4}$$

holds for all x in the compact subset and for all $(v^1,v^2,v^3)\in\mathbb{R}^3$, with a time-independent Riemannian metric G_{ij} on S. It is easy to check that the metric growth condition assures that for every (smooth) curve $\alpha:[a,b]\to S$ there is a function $T:[a,b]\to\mathbb{R}$ with $T(a)=0$ such that the curve $\lambda:[a,b]\to M=S\times\mathbb{R}$, $s\mapsto\lambda(s)=(\alpha(s),T(s))$ is past-pointing and lightlike. In particular, the metric growth condition assures that from each point p in M we can find a past-pointing lightlike curve to every timelike curve that is vertical with respect to the orthogonal splitting chosen. In this sense, the metric growth condition prohibits the existence of *particle horizons*, cf. Uhlenbeck[2] and McKenzie.[6] Please note that our formulation of the metric growth condition is the same as McKenzie's which differs from Uhlenbeck's by interchanging future and past (i.e., $t\mapsto -t$). The reason is that Uhlenbeck in her paper characterizes *future-pointing* lightlike geodesics from a point to a timelike curve whereas we, in view of gravitational lensing, are interested in *past-pointing* ones.

For formulating Uhlenbeck's result we have to assume that the reader is familiar with the notion of *conjugate points* and with the following facts (see, e.g., Perlick[13]). The totality of all conjugate points, along any lightlike geodesic issuing from a point p into the past, makes up the *caustic* of the past light-cone of p. A lightlike geodesic is said to have (Morse) index k if it has k conjugate points in its interior; here and in the following every conjugate point must be counted with its multiplicity. For a lightlike geodesic with two endpoints, the index is always finite. It is our goal to estimate the number of past-pointing lightlike geodesics of index k from a point p to a timelike curve γ that does not meet the caustic of the past light-cone of p. The latter condition is generically satisfied in the sense that, for any γ, the set of all points p for which it is true is dense in M. This condition makes sure that the past-pointing lightlike geodesics from p to γ are

countable, i.e., it excludes gravitational lensing situations where the observer sees a continuum of images such as an Einstein ring.

As another preparation, we recall how the *Betti numbers* B_k of the *loop space* $L(M)$ of a connected topological space M are defined. As a realization of $L(M)$ one may take the space of all continuous curves between any two fixed points in M. The kth Betti number B_k is formally defined as the dimension of the kth homology space of $L(M)$ with coefficients in a field $\mathbb{F}$. (For our purpose we may choose $\mathbb{F}=\mathbb{R}$.) Roughly speaking, B_0 counts the connected components of $L(M)$ and B_k, for $k>0$, counts those "holes" in $L(M)$ that prevent a k sphere from being a boundary. If the reader is not familiar with Betti numbers he or she may consult, e.g., Ref. 14.

After these preparations Uhlenbeck's result that we want to use later in this paper can now be phrased in the following way.

Theorem 1 (Uhlenbeck[2]): *Consider a globally hyperbolic space-time* (M,g) *that admits an orthogonal splitting* (1) and (2) *satisfying the metric growth condition. Fix a point* $p\in M$ *and a smooth timelike curve* $\gamma:\mathbb{R}\to M$ *which, in terms of the above-mentioned orthogonal splitting, takes the form* $\gamma(\tau)=(\beta(\tau),\tau)$, *with a curve* $\beta:\mathbb{R}\to S$. *Moreover, assume that* γ *does not meet the caustic of the past light-cone of* p *and that for some sequence* $(\tau_i)_{i\in N}$ *with* $\tau_i\to-\infty$ *the sequence* $(\beta(\tau_i))_{i\in N}$ *converges in* S. *Then the Morse inequalities*

$$N_k \geqslant B_k \quad \text{for all } k\in\mathbb{N}_0 \tag{5}$$

and the Morse relation

$$\sum_{k=0}^{\infty}(-1)^k N_k=\sum_{k=0}^{\infty}(-1)^k B_k \tag{6}$$

hold true, where N_k *denotes the number of past-pointing lightlike geodesics with index* k *from* p *to* γ, *and* B_k *denotes the* kth *Betti number of the loop space of* M.

Proof: See Uhlenbeck,[2] Sec. IV and Proposition 5.2. □

Please note that the convergence condition on $(\beta(\tau_i))_{i\in N}$ is certainly satisfied if β is confined to a compact subset of S, i.e., if γ stays in a spatially compact set.

The sum on the right-hand side of (6) is, by definition, the Euler characteristic χ of the loop space of M. Hence, (6) can also be written in the form

$$N_+ - N_- = \chi, \tag{7}$$

where N_+ (respectively, N_-) denotes the number of past-pointing lightlike geodesics with even (respectively, odd) index from p to γ.

The Betti numbers of the loop space of $M=S\times\mathbb{R}$ are, of course, determined by the topology of S. Three cases are to be distinguished.

Case A: M is not simply connected. Then the loop space of M has infinitely many connected components, so $B_0=\infty$. In this situation (5) says that $N_0=\infty$, i.e., that there are infinitely many past-pointing lightlike geodesics from p to γ that are free of conjugate points.

Case B: M is simply connected but not contractible to a point. Then for all but finitely many $k\in\mathbb{N}_0$ we have $B_k>0$. This was proven in a classical paper by Serre,[15] cf. McKenzie.[6] In this situation (5) implies $N_k>0$ for all but finitely many k. In other words, for almost every positive integer k we can find a past-pointing lightlike geodesic from p to γ with k conjugate points in its interior. Hence, there must be infinitely many past-pointing lightlike geodesics from p to γ and the caustic of the past light-cone of p must be complicated enough such that a past-pointing lightlike geodesic from p can intersect it arbitrarily often.

Case C: M is contractible to a point. Then the loop space of M is contractible to a point, i.e., $B_0=1$ and $B_k=0$ for $k>0$. In this case (7) takes the form $N_+-N_-=1$ which implies that the total number $N_++N_-=2N_-+1$ of past-pointing lightlike geodesics from p to γ is (infinite or) odd.

The domain of outer communication of a Kerr-Newman black hole has topology $S^2 \times \mathbb{R}^2$ which is simply connected but not contractible to a point. So it is Case B we are interested in when applying Uhlenbeck's result to the Kerr-Newman space-time.

III. CENTRIFUGAL AND CORIOLIS FORCE IN THE KERR-NEWMAN SPACE-TIME

The Kerr-Newman metric is given in Boyer-Lindquist coordinates (see, e.g., Misner, Thorne, and Wheeler,[16] p. 877) by

$$g = -\frac{\Delta}{\rho^2}(\mathrm{d}t - a\sin^2\vartheta\,\mathrm{d}\varphi)^2 + \frac{\sin^2\vartheta}{\rho^2}((r^2+a^2)\mathrm{d}\varphi - a\,\mathrm{d}t)^2 + \frac{\rho^2}{\Delta}\mathrm{d}r^2 + \rho^2\,\mathrm{d}\vartheta^2, \tag{8}$$

where ρ and Δ are defined by

$$\rho^2 = r^2 + a^2\cos^2\vartheta \quad \text{and } \Delta = r^2 - 2mr + a^2 + q^2, \tag{9}$$

and m, q, and a are real constants. We shall assume throughout that

$$0 < m, \quad 0 \leqslant a, \quad \sqrt{a^2+q^2} \leqslant m. \tag{10}$$

In this case, the Kerr-Newman metric describes the space-time around a rotating black hole with mass m, charge q, and specific angular momentum a. The Kerr-Newman metric (8) contains the Kerr metric ($q=0$), the Reissner-Nordström metric ($a=0$) and the Schwarzschild metric ($q=0$ and $a=0$) as special cases which are all discussed, in great detail, in Chandrasekhar;[17] for the Kerr metric we also refer to O'Neill.[18]

By (10), the equation $\Delta=0$ has two real roots,

$$r_\pm = m \pm \sqrt{m^2 - a^2 - q^2}, \tag{11}$$

which determine the two horizons. We shall restrict to the region

$$M_+: \quad r_+ < r < \infty, \tag{12}$$

which is usually called the *domain of outer communication* of the Kerr-Newman black hole. On M_+, the coordinates φ and ϑ range over S^2, the coordinate t ranges over $\mathbb{R}$, and the coordinate r ranges over an open interval which is diffeomorphic to $\mathbb{R}$; hence $M_+ \simeq S^2 \times \mathbb{R}^2$.

From now on we will consider the space-time (M_+, g), where g denotes the restriction of the Kerr-Newman metric (8) with (10) to the domain M_+ given by (12). For the sake of brevity, we will refer to (M_+, g) as to the *exterior Kerr-Newman space-time*. As a matter of fact, (M_+, g) is a globally hyperbolic space-time; the Boyer-Lindquist time coordinate t gives a foliation of M_+ into Cauchy surfaces t=constant. Together with the lines perpendicular to these surfaces, we get an orthogonal splitting of the form (2). Observers with worldlines perpendicular to the surfaces t =constant are called *zero-angular-momentum observers* or *locally nonrotating observers*. In contrast to the worldlines perpendicular to the surfaces t=constant, the integral curves of the Killing vector field ∂_t are *not* timelike on all of M_+; they become spacelike inside the so-called *ergosphere* which is characterized by the inequality $\Delta < a^2\sin^2\vartheta$. For $a \neq 0$ it is impossible to find a Killing vector field which is timelike on all of M_+; in this sense, the exterior Kerr-Newman space-time is *not* a stationary space-time.

In the rest of this section we discuss the notions of centrifugal force and Coriolis force for observers on circular orbits around the axis of rotational symmetry in the exterior Kerr-Newman space-time (M_+, g). For background information on these notions we refer to the work of Abramowicz and his collaborators[3–5] which was mentioned already in the introduction. For our discussion it will be convenient to introduce on M_+ the orthonormal basis

$$E_0 = \frac{1}{\rho\sqrt{\Delta}}((r^2+a^2)\partial_t + a\partial_\varphi),$$

$$E_1 = \frac{1}{\rho \sin \vartheta}(\partial_\varphi + a \sin^2 \vartheta \, \partial_t),$$

$$E_2 = \frac{1}{\rho}\partial_\vartheta, \quad E_3 = \frac{\sqrt{\Delta}}{\rho}\partial_r, \tag{13}$$

whose dual basis is given by the covector fields

$$-g(E_0, \cdot) = \frac{\sqrt{\Delta}}{\rho}(\mathrm{d}t - a \sin^2 \vartheta \, \mathrm{d}\varphi),$$

$$g(E_1, \cdot) = \frac{\sin \vartheta}{\rho}((r^2 + a^2)\mathrm{d}\varphi - a \, \mathrm{d}t),$$

$$g(E_2, \cdot) = \rho \, \mathrm{d}\vartheta, \quad g(E_3, \cdot) = \frac{\rho}{\sqrt{\Delta}}\mathrm{d}r. \tag{14}$$

Henceforth we refer to the integral curves of the timelike basis field E_0 as to the worldlines of the *standard observers* in (M_+, g). For later purpose we list all nonvanishing Lie brackets of the E_i,

$$[E_0, E_2] = -\frac{a^2}{\rho^3} \cos \vartheta \sin \vartheta \, E_0,$$

$$[E_0, E_3] = \left(\frac{r-m}{\rho\sqrt{\Delta}} - \frac{r\sqrt{\Delta}}{\rho^3}\right)E_0 + \frac{2ra \sin \vartheta}{\rho^3}E_1,$$

$$[E_1, E_2] = \frac{(\rho^2 + a^2 \sin^2 \vartheta)\cos \vartheta}{\rho^3 \sin \vartheta}E_1 - \frac{2a\sqrt{\Delta} \cos \vartheta}{\rho^3}E_0,$$

$$[E_1, E_3] = \frac{r\sqrt{\Delta}}{\rho^3}E_1,$$

$$[E_2, E_3] = \frac{r\sqrt{\Delta}}{\rho^3}E_2 + \frac{a^2 \cos \vartheta \sin \vartheta}{\rho^3}E_3. \tag{15}$$

For every $v \in [0,1]$, the integral curves of the vector field

$$U = \frac{E_0 \pm vE_1}{\sqrt{1 - v^2}} \tag{16}$$

can be interpreted as the worldlines of observers who circle along the φ-lines around the axis of rotational symmetry of the Kerr-Newman space-time. The number v gives the velocity (in units of the velocity of light) of these observers with respect to the standard observers. For the upper sign in (16), the motion relative to the standard observers is in the positive φ-direction and thus corotating with the black hole (because of our assumption $a \geqslant 0$), for the negative sign it is in the negative φ-direction and thus counter-rotating. Please note that $g(U,U) = -1$, which demonstrates that the integral curves of U are parametrized by proper time.

In general, U is nongeodesic, $\nabla_U U \neq 0$, i.e., one needs a thrust to stay on an integral curve of U. Correspondingly, relative to a U-observer a freely falling particle undergoes an "inertial acceleration" measured by $-\nabla_U U$. To calculate this quantity, we write

$$-g(\nabla_U U, E_i) = -Ug(U,E_i) + g(U,\nabla_U E_i) = -Ug(U,E_i) + g(U,[U,E_i]). \tag{17}$$

The first term on the right-hand side vanishes, and the second term can be easily calculated with the help of (16) and (15), for $i=0,1,2,3$. We find

$$-g(\nabla_U U, \cdot) = A_{\text{grav}} + A_{\text{Cor}} + A_{\text{cent}}, \tag{18}$$

where the covector fields

$$A_{\text{grav}} = \frac{\Delta r - \rho^2(r-m)}{\rho^2\Delta}\mathrm{d}r + \frac{a^2}{\rho^2}\sin\vartheta\cos\vartheta\,\mathrm{d}\vartheta, \tag{19}$$

$$A_{\text{Cor}} = \pm\frac{v}{(1-v^2)}\frac{2a\sqrt{\Delta}}{\rho^2}\left(\frac{r}{\Delta}\sin\vartheta\,\mathrm{d}r + \cos\vartheta\,\mathrm{d}\vartheta\right), \tag{20}$$

$$A_{\text{cent}} = \frac{v^2}{(1-v^2)}\left(\frac{2r\Delta - \rho^2(r-m)}{\rho^2\Delta}\mathrm{d}r + \frac{(\rho^2 + 2a^2\sin^2\vartheta)\cos\vartheta}{\rho^2\sin\vartheta}\mathrm{d}\vartheta\right) \tag{21}$$

give, respectively, the gravitational, the Coriolis, and the centrifugal acceleration of a freely falling particle relative to the U observers. (Multiplication with the particle's mass gives the corresponding "inertial force.") Here the decomposition of the total inertial acceleration into its three contributions is made according to the same rule as in Newtonian mechanics: The gravitational acceleration is independent of v, the Coriolis acceleration is odd with respect to v, and the centrifugal acceleration is even with respect to v. In Ref. 19 it was shown that, according to this rule, gravitational, Coriolis, and centrifugal acceleration are unambiguous whenever a timelike 2-surface with a timelike vector field has been specified; here we apply this procedure to each 2-surface $(r,\vartheta)=$constant with the timelike vector field E_0.

Up to the positive factor $v/(1-v^2)$, the sum of Coriolis and centrifugal acceleration is equal to

$$\begin{aligned} Z_\pm(v) = {} & \pm\frac{2a\sqrt{\Delta}}{\rho^2}\left(\frac{r}{\Delta}\sin\vartheta\,\mathrm{d}r + \cos\vartheta\,\mathrm{d}\vartheta\right) \\ & + v\left(\frac{2r\Delta - \rho^2(r-m)}{\rho^2\Delta}\mathrm{d}r + \frac{(\rho^2 + 2a^2\sin^2\vartheta)\cos\vartheta}{\rho^2\sin\vartheta}\mathrm{d}\vartheta\right). \end{aligned} \tag{22}$$

If we exclude the Reissner-Nordström case $a=0$, the Coriolis force dominates the centrifugal force for small v. To investigate the behavior for v close to the velocity of light, we consider the limit $v\to 1$. By a straightforward calculation we find that

$$Z_\pm(v) \underset{v\to 1}{\to} \frac{\sin\vartheta}{\rho^2\sqrt{\Delta}}(r^2 + a^2 \pm a\sqrt{\Delta}\sin\vartheta)^2\,\mathrm{d}\Psi_\pm, \tag{23}$$

where

$$\mathrm{d}\Psi_\pm = \frac{2r\Delta - (r-m)\rho^2 \pm 2ar\sqrt{\Delta}\sin\vartheta}{\sqrt{\Delta}\sin\vartheta(r^2 + a^2 \pm a\sqrt{\Delta}\sin\vartheta)^2}\mathrm{d}r + \frac{(\rho^2 + 2a^2\sin^2\vartheta \pm 2a\sqrt{\Delta}\sin\vartheta)\sqrt{\Delta}\cos\vartheta}{\sin^2\vartheta(r^2 + a^2 \pm a\sqrt{\Delta}\sin\vartheta)^2}\mathrm{d}\vartheta \tag{24}$$

is the differential of the function

$$\Psi_{\pm} = \frac{-\frac{1}{\sin\vartheta} \mp \frac{a}{\sqrt{\Delta}}}{\frac{r^2+a^2}{\sqrt{\Delta}} \pm a\sin\vartheta}. \tag{25}$$

Because of $\sin\vartheta$ in the denominator, both Ψ_- and Ψ_+ are singular along the axis. Ψ_+ is negative on all of M_+ whereas Ψ_- is negative outside and positive inside the ergosphere.

From (23) we read that, in the limit $v \to 1$, the sum of Coriolis and centrifugal force is perpendicular to the surfaces $\Psi_{\pm}$=constant and points in the direction of increasing $\Psi_{\pm}$. In this limit, we may thus view the function Ψ_+ (or Ψ_-, respectively) as a Coriolis-plus-centrifugal potential for corotating (or counter-rotating, respectively) observers. The surfaces $\Psi_{\pm}$=constant are shown in Fig. 1.

It is not difficult to see that $\Psi_{\pm}$ is independent of the family of observers with respect to which the inertial accelerations have been defined, as long as their 4-velocity is a linear combination of ∂_t and ∂_φ. We have chosen the standard observers; a different choice would lead to different formulas for the inertial accelerations (19)–(21), but to the same $\Psi_{\pm}$. For the sake of comparison, the reader may consult Nayak and Vishveshwara,[20] where the inertial accelerations are calculated with respect to the zero angular momentum observers. Also, it should be mentioned that the potentials Ψ_+ and Ψ_-, or closely related functions, have been used already by other authors. The quantities $\Omega_{c\pm}$, e.g., introduced by de Felice and Usseglio-Tomasset[21] in their analysis of physical effects related to centrifugal force reversal in the equatorial plane of the Kerr metric, are related to our potentials by $\Omega_{c\pm} = \mp\Psi_{\pm}|_{\vartheta=\pi/2}$.

In the Reissner-Nordström case $a=0$, the Coriolis acceleration (20) vanishes identically and

$$\Psi = \Psi_+ = \Psi_- = -\frac{\sqrt{r^2-2mr+q^2}}{r^2\sin\vartheta} \tag{26}$$

is a potential for the centrifugal acceleration in the sense that A_{cent} is a multiple of $\mathrm{d}\Psi$. In this case, the surfaces Ψ=constant coincide with what Abramowicz[4] calls the *von Zeipel cylinders*. Abramowicz's Fig. 1 in Ref. 4, which shows the von Zeipel cylinders in the Schwarzschild space-time, coincides with the $a \to 0$ limit of our Fig. 1, which shows the surfaces Ψ_+=constant and Ψ_-=constant in the Kerr space-time. (The notion of von Zeipel cylinders has also been defined in the Kerr metric, see Ref. 22, for observers of a specified angular velocity. However, these angular-velocity-dependent von Zeipel cylinders are not related to the potentials Ψ_+ and Ψ_- in the Kerr space-time.)

By construction, the function $\Psi_{\pm}$ has the following property. If we send a lightlike geodesic tangential to a φ-line in the positive (respectively, negative) φ-direction, it will move away from this φ-line in the direction of the negative gradient of Ψ_+ (respectively, Ψ_-). Thus, each zero of the differential $\mathrm{d}\Psi_+$ (respectively, $\mathrm{d}\Psi_-$) indicates a corotating (respectively, counter-rotating) circular lightlike geodesic, i.e., a "photon circle." By (24), $\mathrm{d}\Psi_{\pm}$ vanishes if

$$\cos\vartheta = 0 \quad \text{and } 2r\Delta - (r-m)\rho^2 \pm 2ar\sqrt{\Delta}\sin\vartheta = 0. \tag{27}$$

By writing Δ and ρ^2 explicitly, we see that (27) is true at $\vartheta=\pi/2$ and $r=r_{\pm}^{\text{ph}}$, where $r_{\pm}^{\text{ph}}$ is defined by the equation

$$(r_{\pm}^{\text{ph}})^2 - 3mr_{\pm}^{\text{ph}} + 2a^2 + 2q^2 = \mp 2a\sqrt{(r_{\pm}^{\text{ph}})^2 - 2mr_{\pm}^{\text{ph}} + a^2 + q^2}. \tag{28}$$

For $0 < \sqrt{a^2+q^2} < m$, (28) has exactly one solution for each sign which satisfies

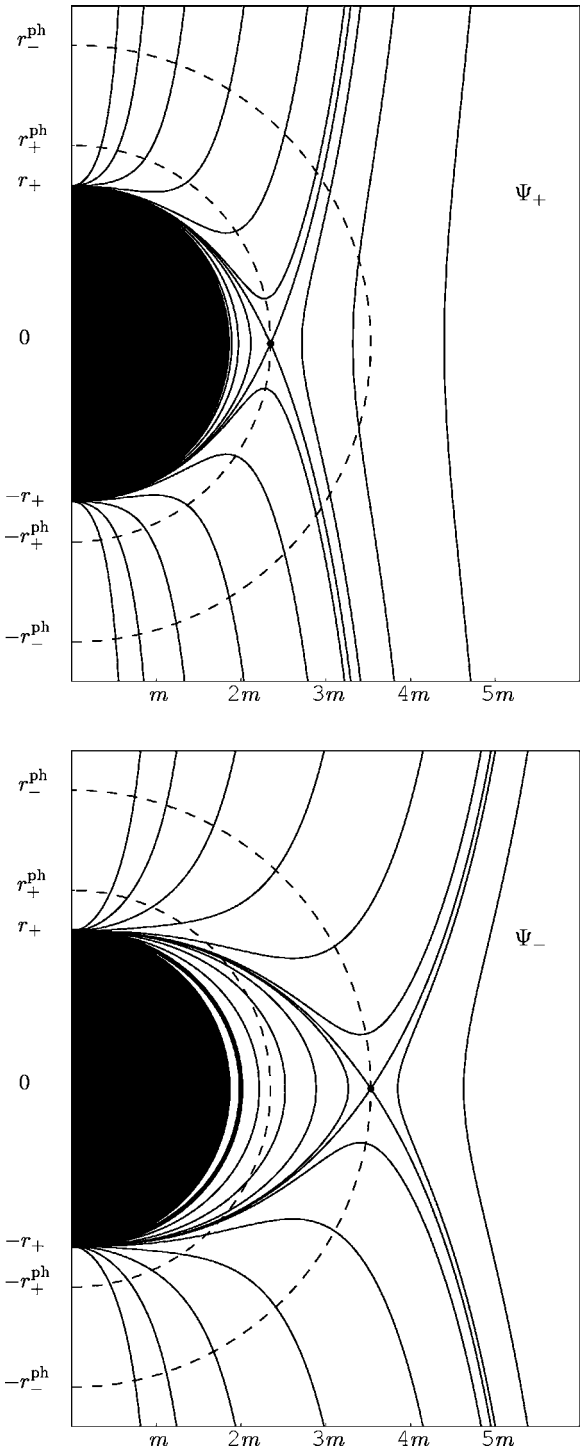

FIG. 1. The surfaces Ψ_+=constant (top) and Ψ_-=constant (bottom) are drawn here for the case $q=0$ and $a=0.5m$. The picture shows the (half-)plane (φ,t)=constant, with $r\sin\vartheta$ on the horizontal and $r\cos\vartheta$ on the vertical axis. The spheres of radius r_+^{ph} and r_-^{ph} are indicated by dashed lines; they meet the equatorial plane in the photon circles. The boundary of the ergosphere coincides with the surface $\Psi_-=0$ and is indicated in the bottom figure by a thick line; it meets the equatorial plane at $r=2m$.

$$r_+ < r_+^{\mathrm{ph}} < \frac{3m}{2} + \sqrt{\frac{9m^2}{4} - 2q^2} < r_-^{\mathrm{ph}} < 2m + 2\sqrt{m^2 - q^2}. \tag{29}$$

So there is exactly one corotating photon circle in M_+, corresponding to the critical point of Ψ_+ at r_+^{ph}, and exactly one counter-rotating photon circle in M_+, corresponding to the critical point of Ψ_- at r_-^{ph}, see Fig. 1. (The relation of photon circles to centrifugal-plus-Coriolis force in the limit $v \to 1$ is also discussed by Stuchlik, Hledik, and Jurán;[23] note, however, that their work is restricted to the equatorial plane of the Kerr-Newman space-time throughout.) In the Reissner-Nordström case, $a=0$, we have

$$r_+^{\mathrm{ph}} = r_-^{\mathrm{ph}} = \frac{3m}{2} + \sqrt{\frac{9m^2}{4} - 2q^2}$$

(cf., e.g., Chandrasekhar,[17] p. 218). If we keep m and q fixed and vary a from 0 to the extreme value $\sqrt{m^2-q^2}$, r_+^{ph} decreases from $\frac{3}{2}m+\sqrt{(9m^2/4)-2q^2}$ to m whereas r_-^{ph} increases from $\frac{3}{2}m+\sqrt{(9m^2/4)-2q^2}$ to $2m+2\sqrt{m^2-q^2}$. As an aside, we mention that, although r_+^{ph} and r_+ both go to m in the extreme case, the proper distance between the corotating photon circle at r_+^{ph} and the horizon at r_+ does not go to zero; for the case $q=0$ this surprising feature is discussed in Ref. 17, p. 340.

From (24) we can read the sign of $\partial_r \Psi_\pm$ at each point. We immediately find the following result.

Proposition 1: Decompose the exterior Kerr space-time into the sets

$$M_{\mathrm{in}}: \quad 2r\Delta - (r-m)\rho^2 < -2ar\sqrt{\Delta}\sin\vartheta, \tag{30}$$

$$K: \quad -2ar\sqrt{\Delta}\sin\vartheta \leqslant 2r\Delta - (r-m)\rho^2 \leqslant 2ar\sqrt{\Delta}\sin\vartheta, \tag{31}$$

$$M_{\mathrm{out}}: \quad 2ar\sqrt{\Delta}\sin\vartheta < 2r\Delta - (r-m)\rho^2, \tag{32}$$

so $M_+ = M_{\mathrm{in}} \cup K \cup M_{\mathrm{out}}$, *see Fig. 2. Then*

$$\partial_r \Psi_+ < 0 \quad \textit{and } \partial_r \Psi_- < 0 \textit{ on } M_{\mathrm{in}}, \tag{33}$$

$$\partial_r \Psi_+ < 0 \quad \textit{and } \partial_r \Psi_- > 0 \textit{ on the interior of } K, \tag{34}$$

$$\partial_r \Psi_+ > 0 \quad \textit{and } \partial_r \Psi_- > 0 \textit{ on } M_{\mathrm{out}}. \tag{35}$$

The inequality $\partial_r \Psi_\pm > 0$ is true for both signs if and only if, for v sufficiently large, the sum of Coriolis and centrifugal force is pointing in the direction of increasing r for corotating and counter-rotating observers. An equivalent condition is that the centrifugal force points in the direction of increasing r and dominates the Coriolis force for v sufficiently large. This is the situation we are familiar with from Newtonian physics. According to Proposition 1, however, in the Kerr-Newman space-time this is true only in the region M_{out}. In the interior of the intermediate region K the direction of centrifugal-plus-Coriolis force for large v is reversed for counter-rotating observers while still normal for corotating observers. In the region M_{in}, finally, it is reversed both for corotating and for counter-rotating observers.

The relevance of the sets M_{out}, M_{in}, and K in view of lightlike geodesics is demonstrated in the following proposition.

Proposition 2: (a) *In the region* M_{out}, *the radius coordinate r cannot have other extrema than strict local minima along a lightlike geodesic.*

(b) *In the region* M_{in}, *the radius coordinate r cannot have other extrema than strict local maxima along a lightlike geodesic.*

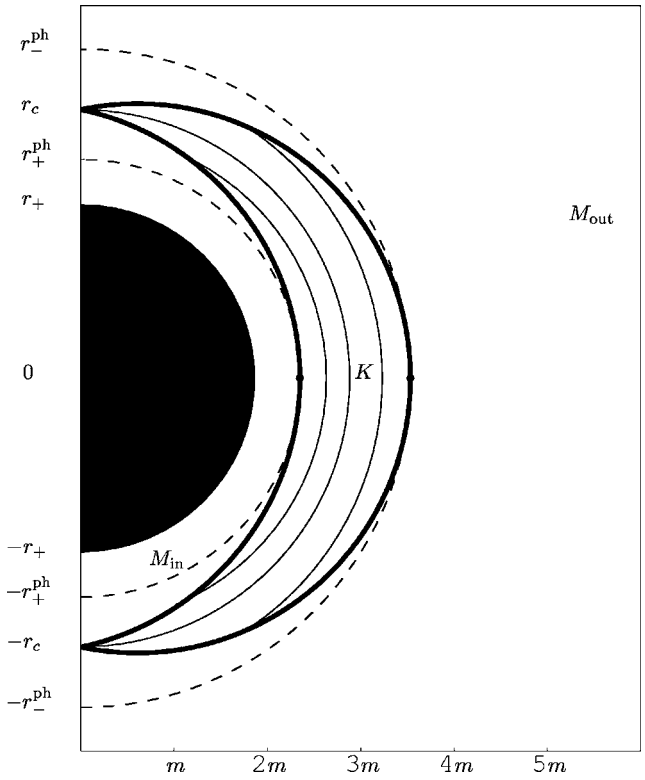

FIG. 2. The regions M_{in}, K, and M_{out} defined in Proposition 1 are shown here for the case $q=0$ and $a=0.5m$. Again, as in Fig. 1, we plot $r\sin\vartheta$ on the horizontal and $r\cos\vartheta$ on the vertical axis. Some of the spherical lightlike geodesics that fill the photon region K are indicated. K meets the equatorial plane in the photon circles at $r=r_+^{\mathrm{ph}}$ and $r=r_-^{\mathrm{ph}}$ and the axis at radius r_c given by $r_c^3-3r_c^2m+r_c(a^2+2q^2)+a^2m=0$. This picture can also be found as Fig. 21 in the online article (Ref. 29).

(c) *Through each point of K there is a spherical lightlike geodesic. (Here "spherical" means that the geodesic is completely contained in a sphere* $r=$constant.)

Proof: Let X be a lightlike and geodesic vector field on (M_+,g), i.e., $g(X,X)=0$ and $\nabla_X X=0$. To prove (a) and (b), we must demonstrate that the implication

$$Xr=0\Rightarrow XXr>0 \tag{36}$$

is true at all points of M_{out} and that the implication

$$Xr=0\Rightarrow XXr<0 \tag{37}$$

is true at all points of M_{in}. Here Xr is to be read as "the derivative operator X applied to the function r." The condition $\nabla_X X=0$ implies

$$XXr=X\,\mathrm{d}r(X)=X\left(\frac{\sqrt{\Delta}}{\rho}g(E_3,X)\right)=\frac{\sqrt{\Delta}}{\rho}g(\nabla_X E_3,X)+\left(X\frac{\sqrt{\Delta}}{\rho}\right)g(E_3,X), \tag{38}$$

where we have used the basis vector field E_3 from (13) and (14). Using these orthonormal basis vector fields, we can write X in the form

$$X=E_0+\cos\alpha\,E_1+\sin\alpha\,E_2 \tag{39}$$

at all points where $Xr=0$. [A nonzero factor of X is irrelevant because X enters quadratically into the right-hand side of (38).] Then (38) takes the form

$$\frac{\rho}{\sqrt{\Delta}}XXr = g(\nabla_{E_0}E_3,E_0) + \sin\alpha\,(g(\nabla_{E_2}E_3,E_0) + g(\nabla_{E_0}E_3,E_2)) + \cos\alpha\,(g(\nabla_{E_1}E_3,E_0) + g(\nabla_{E_0}E_3,E_1))$$
$$+ \sin^2\alpha\, g(\nabla_{E_2}E_3,E_2) + \cos^2\alpha\, g(\nabla_{E_1}E_3,E_1) = g([E_0,E_3],E_0) + \sin\alpha\,(g([E_2,E_3],E_0)$$
$$+ g([E_0,E_3],E_2)) + \cos\alpha\,(g([E_1,E_3],E_0) + g([E_0,E_3],E_1)) + \sin^2\alpha\, g([E_2,E_3],E_2)$$
$$+ \cos^2\alpha\, g([E_1,E_3],E_1). \tag{40}$$

If we insert the Lie brackets from (15) we find

$$\rho^4 XXr = 2r\Delta - (r-m)\rho^2 + 2ar\sqrt{\Delta}\sin\vartheta\cos\alpha. \tag{41}$$

Now we compare this expression with (30)–(32). If $\cos\alpha$ runs through all possible values from -1 to 1, the right-hand side of (41) stays positive on M_{out} and negative on M_{in}. This proves part (a) and part (b). At each point of K there is exactly one value of $\cos\alpha$ such that the right-hand side of (41) vanishes. This assigns to each point of K a lightlike direction such that the integral curves of the resulting direction field are spherical lightlike geodesics. This proves part (c). □

In view of part (c) of Proposition 2 we refer to the closed region K as to the *photon region* of the exterior Kerr-Newman space-time. Along each spherical lightlike geodesic in K the ϑ-coordinate oscillates between extremal values ϑ_0 and $-\vartheta_0$, correponding to boundary points of K, see Fig. 2; the φ-coordinate either increases or decreases monotonically. In the Reissner-Nordström case $a=0$, where (26) is a potential for the centrifugal force, the photon region K shrinks to the *photon sphere* $r=\frac{3}{2}m+\sqrt{(9m^2/4)-2q^2}$ and Proposition 1 reduces to the known fact that centrifugal force reversal takes place at the photon sphere.

We end this section with a word of caution as to terminology. In part (c) of Proposition 2 we have referred to the set $r=$constant as to a sphere. This is indeed justified in the sense that, for each fixed t, fixing the radius coordinate r gives a two-dimensional submanifold of M_+ that is diffeomorphic to the 2-sphere. Moreover, in our Figs. 1 and 2 the sets $r=$constant are represented as (meridional cross sections of) spheres. Note, however, that the Kerr-Newman metric does *not* induce an isotropic metric on these spheres (unless $a=0$), so they are not round spheres in the metrical sense.

IV. MULTIPLE IMAGING IN THE KERR-NEWMAN SPACE-TIME

It is now our goal to discuss multiple imaging in the exterior Kerr-Newman space-time (M_+,g). To that end we fix a point p and a timelike curve γ in M_+ and we want to get some information about the past-pointing lightlike geodesics from p to γ. The following proposition is an immediate consequence of Proposition 2.

Proposition 3: Let p be a point and γ a timelike curve in the exterior Kerr-Newman space-time. Let

$$\Lambda: \quad r_a < r < r_b \tag{42}$$

denote the smallest spherical shell, with $r_+ \leqslant r_a < r_b \leqslant \infty$, such that p, γ and the region K defined by (31) *are completely contained in $\bar{\Lambda}$ (=closure of Λ in M_+). Then all lightlike geodesics that join p and γ are confined within $\bar{\Lambda}$.*

Proof: Along a lightlike geodesic that leaves and reenters $\bar{\Lambda}$ the radius coordinate r must have either a maximum in the region M_{out} or a minimum in the region M_{in}. Proposition 2 makes sure that this cannot happen. □

By comparison with Proposition 1 we see that, among all spherical shells whose closures in M_+ contain p and γ, the shell Λ of Proposition 3 is the smallest shell such that at all points of the boundary of Λ in M_+ the gradient of Ψ_+ and the gradient of Ψ_- are pointing in the direction away from Λ. Based on Proposition 3, we will later see that there is a close relation between multiple imaging and centrifugal-plus-Coriolis force reversal in the Kerr-Newman space-time.

Proposition 3 tells us to what region the lightlike geodesics between p and γ are confined, but it does not tell us anything about the number of these geodesics. To answer the latter question, we now apply Theorem 1 to the exterior Kerr-Newman space-time (M_+,g).

Proposition 4: Consider, in the exterior Kerr-Newman space-time (M_+,g), *a point* p *and a smooth future-pointing timelike curve* $\gamma:]-\infty,\tau_a[\to M_+$, *with* $-\infty<\tau_a\leqslant\infty$, *which is parametrized by the Boyer-Lindquist time coordinate* t, *i.e., the* t*-coordinate of the point* $\gamma(\tau)$ *is equal to* τ. *Assume* (i) *that* γ *does not meet the caustic of the past light-cone of* p, *and* (ii) *that for* $\tau\to-\infty$ *the radius coordinate* r *of the point* $\gamma(\tau)$ *remains bounded and bounded away from* r_+. [*The last condition means that* $\gamma(\tau)$ *goes neither to infinity nor to the horizon for* $\tau\to-\infty$.] *Then there is an infinite sequence* $(\lambda_n)_{n\in\mathbb{N}}$ *of mutually different past-pointing lightlike geodesics from* p *to* γ. *For* $n\to\infty$, *the index of* λ_n *goes to infinity. Moreover, if we denote the point where* λ_n *meets the curve* γ *by* $\gamma(\tau_n)$, *then* $\tau_n\to-\infty$ *for* $n\to\infty$.

Proof: We want to apply Theorem 1 to the exterior Kerr-Newman space-time (M_+,g). To that end, the first thing we must find is an orthogonal splitting of the exterior Kerr-Newman space-time that satisfies the metric growth condition. As in the original Boyer-Lindquist coordinates the t-lines are not orthogonal to the surfaces $t=$constant, we change to new coordinates

$$x^1=r,\quad x^2=\vartheta,\quad x^3=\varphi-u(r,\vartheta)t,\quad t=t, \tag{43}$$

with

$$u(r,\vartheta)=\frac{2mar}{\rho^2\Delta+2mr(r^2+a^2)}. \tag{44}$$

Then the Kerr metric (8) takes the orthogonal splitting form (2), with

$$\begin{aligned} g_{ij}(x,t)\mathrm{d}x^i\,\mathrm{d}x^j=\rho^2&\left(\frac{\mathrm{d}r^2}{\Delta}+\mathrm{d}\vartheta^2\right)\\ &+\frac{\sin^2\vartheta}{\rho^2}((r^2+a^2)^2-\Delta a^2\sin^2\vartheta)\left(t\left(\frac{\partial u(r,\vartheta)}{\partial r}\mathrm{d}r+\frac{\partial u(r,\vartheta)}{\partial\vartheta}\mathrm{d}\vartheta\right)+\mathrm{d}x^3\right)^2 \end{aligned} \tag{45}$$

and

$$f(x,t)=\frac{\rho^2\Delta}{(r^2+a^2)^2-\Delta a^2\sin^2\vartheta}. \tag{46}$$

Clearly, if we restrict the range of the coordinates $x=(x^1,x^2,x^3)$ to a compact set, we can find positive constants A and B such that

$$\frac{g_{ij}(x,t)v^iv^j}{f(x,t)}\leqslant(A+B|t|)^2\delta_{ij}v^iv^j. \tag{47}$$

As $F(t)=A+B|t|$ satisfies the integral condition (3), this proves that our orthogonal splitting satisfies the metric growth condition. Our assumptions on γ guarantee that we can find a curve $\gamma':\mathbb{R}\to M_+$ which, in terms of our orthogonal splitting, is of the form $\gamma'(\tau)=(\beta'(\tau),\tau)$ such that $\gamma'(\tau)=\gamma(\tau)$ for all $]-\infty,\tau_b]$, with some $\tau_b\in\mathbb{R}$. (Introducing γ' is necessary because γ need not be defined on all of $\mathbb{R}$.) As γ does not meet the caustic of the past light-cone of p, we may assure that γ' does not meet the caustic of the past light-cone of p. As γ does not go to the horizon or to infinity for $\tau\to-\infty$, the set $\{\beta'(\tau)\,|-\infty<\tau<\tau_b\}$ is confined to a compact region. Hence, for every sequence $(\tau_i)_{i\in\mathbb{N}}$ with $\tau_i\to-\infty$ the sequence $(\beta'(\tau_i))_{i\in\mathbb{N}}$ must have a convergent subsequence. This shows that all the assumptions of Theorem 1 are satisfied if we replace γ with γ'. Hence, the theorem tells us that $N'_k\geqslant B_k$, where N'_k is the number of past-pointing lightlike geodesics with index k from p to γ' and B_k is the kth Betti number of the loop space of $M_+\simeq S^2\times\mathbb{R}^2$. As $M_+\simeq S^2\times\mathbb{R}^2$ is simply connected but not contractible to a point, the theorem of Serre[15] guarantees

that $B_k > 0$ and, thus, $N_k' > 0$ for all but finitely many $k \in \mathbb{N}$. Hence, for almost all positive integers k there is a past-pointing lightlike geodesic of index k from p to γ'. This gives us an infinite sequence $(\lambda_n)_{n\in\mathbb{N}}$ of mutually different past-pointing lightlike geodesics from p to γ' such that the index of λ_n goes to infinity if $n \to \infty$. We denote the point where λ_n meets the curve γ' by $\gamma'(\tau_n)$. What remains to be shown is that $\tau_n \to -\infty$ for $n \to \infty$; as γ coincides with γ' on $]-\infty, \tau_b]$, this would make sure that all but finitely many λ_n arrive indeed at γ. So we must prove that it is impossible to select infinitely many τ_n that are bounded below. By contradiction, assume that we can find a common lower bound for infinitely many τ_n. As the τ_n are obviously bounded above by the value of the Boyer-Lindquist time coordinate at p, this implies that the τ_n have an accumulation point. Hence, for an infinite subsequence of our lightlike geodesics λ_n the endpoints $\gamma'(\tau_n)$ converge to some point q on γ'. As γ' does not meet the caustic of the past light-cone of p, the past light-cone of p is an immersed three-dimensional lightlike submanifold near q. We have thus found an infinite sequence of points $\gamma'(\tau_n)$ that lie in a three-dimensional lightlike submanifold and, at the same time, on a timelike curve. Such a sequence can converge to q only if all but finitely many $\gamma'(\tau_n)$ are equal to q. So there are infinitely many λ_n that terminate at q. As there is only one lightlike direction tangent to the past light-cone of p at q, all these infinitely many lightlike geodesics must have the same tangent direction at q. As there are no periodic lightlike geodesics in the globally hyperbolic space-time (M_+, g), any two lightlike geodesics from p to q with a common tangent direction at q must coincide. This contradicts the fact that the λ_n are mutually different, so our assumption that there is a common lower bound for infinitely many τ_n cannot be true. □

The proof shows that in Proposition 4 the condition of $\gamma(\tau)$ going neither to infinity nor to the horizon for $\tau \to -\infty$ can be a little bit relaxed. It suffices to require that there is a sequence $(\tau_i)_{i\in\mathbb{N}}$ of time parameters with $\tau_i \to -\infty$ for $i \to \infty$ such that the spatial coordinates of $\gamma(\tau_i)$ converge. This condition is mathematically weaker than the one given in the proposition, but there are probably no physically interesting situations where the former is satisfied and the latter is not.

Proposition 4 tells us that a Kerr-Newman black hole produces infinitely many images for an arbitrary observer, provided that the worldline of the light source satisfies some (mild) conditions. At the same time, this proposition demonstrates that the past light-cone of every point p in the exterior Kerr-Newman space-time must have a nonempty and, indeed, rather complicated caustic; otherwise it would not be possible to find a sequence of past-pointing lightlike geodesics λ_n from p that intersect this caustic arbitrarily often for n sufficiently large. Please note that the last sentence of Proposition 4 makes clear that for the existence of infinitely many images it is essential to assume that the light source exists since arbitrarily early times.

In Proposition 3 we have shown that all lightlike geodesics from p to γ are confined to a spherical shell that contains the photon region K. We can now show that, under the assumptions of Proposition 4, almost all past-pointing lightlike geodesics from p to γ come actually arbitrarily close to K.

Proposition 5: Let U be any open subset of M_+ that contains the region K defined by (31). *Then, if the assumptions of Proposition 4 are satisfied, all but finitely many past-pointing lightlike geodesics from p to γ intersect U.*

Proof: The sequence $(\lambda_n)_{n\in\mathbb{N}}$ of Proposition 4 gives us a sequence $(w_n)_{n\in\mathbb{N}}$ of mutually different lightlike vectors $w_n \in T_pM_+$ with $\mathrm{d}t(w_n) = -1$ and a sequence $(s_n)_{n\in\mathbb{N}}$ of real numbers $s_n \geqslant 0$ such that $\exp_p(s_n w_n)$ is on γ for all $n \in \mathbb{N}$. Here $\exp_p$ denotes the exponential map of the Levi-Civita derivative of the Kerr-Newman metric at the point p. Since the 2-sphere consisting of the lightlike vectors $w \in T_pM_+$ with $\mathrm{d}t(w) = -1$ (which may be regarded as the observer's celestial sphere) is compact, a subsequence of $(w_n)_{n\in\mathbb{N}}$ must converge to some lightlike vector $w_\infty \in T_pM_+$. By Proposition 4, the sequence $(\exp_p(s_n w_n))_{n\in\mathbb{N}}$ cannot have an accumulation point, hence $s_n \to \infty$ for $n \to \infty$. Owing to Proposition 3, the radius coordinate r of all points $\exp_p(s w_n)$ with $s \in [0, s_n]$ is bounded, so the past-pointing past-inextendible lightlike geodesic

$$\lambda_\infty : [0, \infty[\to M_+ \quad ,$$

$$s \mapsto \lambda_\infty(s) = \exp_p(s w_\infty) \tag{48}$$

cannot go to infinity. Let us assume that λ_∞ goes to the horizon. By Proposition 3, this is possible only in the extreme case $a^2+q^2=m^2$. Then along λ_n the radius coordinate r must have local minima arbitrarily close to r_+ for n sufficiently large. As, by Proposition 2, such minima cannot lie in M_{in}, the geodesic λ_n must meet K for n sufficiently large and we are done. Therefore, we may assume for the rest of the proof that λ_∞ does not go to the horizon. So along λ_∞ the coordinate r must either approach a limit value r_∞ or pass through a maximum and a minimum. In the first case, both the first and the second derivative of $s \mapsto r(\lambda_\infty(s))$ must go to zero for $s \to \infty$. This is possible only if λ_∞ comes arbitrarily close to K, because, as we know from the proof of Proposition 2, the implication (36) holds on M_{out} and the implication (37) holds on M_{in}. In the second case, again by Proposition 2, the maximum cannot lie in M_{out} and the minimum cannot lie in M_{in}; hence, both the maximum and the minimum must lie in K. In both cases we have, thus, found that λ_∞ and hence all but finitely many λ_n intersect U. □

V. DISCUSSION AND CONCLUDING REMARKS

We have proven, with the help of Morse theory, in Proposition 4 that a Kerr-Newman black hole acts as a gravitational lens that produces infinitely many images. We emphasize that we made only very mild assumptions on the motion of the light source and that we considered the whole domain of outer communication, including the ergosphere. For the sake of comparison, the reader may consult Sec. 7.2 of Ref. 24 where it is shown, with the help of Morse theory, that a Kerr black hole produces infinitely many images. However, Masiello's work is based on a special version of Morse theory which applies to stationary space-times only; therefore he had to exclude the ergosphere from the discussion, he had to require that the worldline of the light source is an integral curve of the Killing vector field ∂_t, and he had to restrict to the case of slowly rotating Kerr black holes, $0 \leqslant a^2 < a_0^2$ with some a_0 that remained unspecified, instead of the whole range $0 \leqslant a^2 \leqslant m^2$. On the basis of our Proposition 3 one can show that Masiello's a_0 is equal to $m/\sqrt{2}$; this is the value of a where the photon region K reaches the ergosphere (see Fig. 2), i.e., where $r_+^{\text{ph}} = 2m$. For a Kerr space-time with $m \geqslant a \geqslant m/\sqrt{2}$ we can find an event p and a t-line in $M_+ \backslash \{\text{ergosphere}\}$ that can be connected by only finitely many lightlike geodesics in $M_+ \backslash \{\text{ergosphere}\}$.

If an observer sees infinitely many images of a light source, they must have at least one accumulation point on the observer's celestial sphere. This follows immediately from the compactness of the 2-sphere. This accumulation point corresponds to a limit light ray λ_∞. In the proof of Proposition 5 we have demonstrated that λ_∞ comes arbitrarily close to the photon region K and that either λ_∞ approaches a sphere $r=$constant or the radius coordinate along λ_∞ has a minimum and a maximum in K. (In the extreme case $a^2+q^2=m^2$ the ray λ_∞ may go to the inner boundary of M_+.) This is all one can show with the help of Morse theory and the qualitative methods based on the sign of centrifugal-plus-Coriolis force. Stronger results are possible if one uses the explicit first-order form of the lightlike geodesic equation in the Kerr-Newman space-time, making use of the constants of motion which reflect complete integrability. Then one can show that along a lightlike geodesic in M_+ the radius coordinate is either monotonous or has precisely one turning point. (This result can be deduced, e.g., from Calvani and Turolla[25]). Thus, the case that there is a minimum and a maximum in K is, actually, impossible. As a consequence, the limit light ray λ_∞ necessarily approaches a sphere $r=$constant. By total integrability it must then approach a lightlike geodesic with the same constants of motion. Of course, this must be one of the spherical geodesics in K. (In the extreme case $a^2+q^2=m^2$ the limit ray λ_∞ may approach the circular light ray at $r_+^{\text{ph}} = m$ which is outside of M_+.)

Also, it follows from Proposition 4 that the limit curve λ_∞ meets the caustic of the past light cone of p infinitely many times. This gives, implicitly, some information on the structure of the caustic. For the Kerr case, $q=0$, it was shown numerically by Rauch and Blandford[26] that the caustic consists of infinitely many tubes with astroid cross sections. This result was supported by recent analytical results by Bozza, de Luca, Scarpetta, and Sereno.[27]

We have shown, in Proposition 3, that all lightlike geodesics connecting an event p to a timelike curve γ in the exterior Kerr-Newman space-time M_+ are confined to the smallest spherical shell that contains p, γ and the photon region K. If γ satisfies the assumptions of Proposition 4, which guarantees infinitely many past-pointing lightlike geodesics from p to γ, Proposition 5 tells us that all but finitely many of them come arbitrarily close to the photon region K. Thus, our result that a Kerr-Newman black hole produces infinitely many images is crucially related to the existence of the photon region. If we restrict to some open subset of M_+ whose closure is completely contained in either M_{out} or M_{in}, then we are left with finitely many images for any choice of p and γ. In Sec. III we have seen that the decomposition of M_+ into M_{in}, M_{out} and the photon region K plays an important role in view of centrifugal-plus-Coriolis force reversal; if we restrict to an open subset of M_+ that is contained in either M_{out} or M_{in}, then we are left with a space-time on which $\partial_r \Psi_+$ and $\partial_r \Psi_-$ have the same sign, i.e., the centrifugal-plus-Coriolis force for large velocities points either always outwards or always inwards. In an earlier paper[28] we have shown that in a spherically symmetric and static space-time the occurrence of gravitational lensing with infinitely many images is equivalent to the occurrence of centrifugal force reversal. Our new results demonstrate that the same equivalence is true for subsets of the exterior Kerr-Newman space-time, with the only difference that instead of the centrifugal force alone now we must consider the sum of centrifugal and Coriolis force in the limit $v \to 1$. It is an interesting problem to inquire whether this observation carries over to other space-times with two commuting Killing vector fields ∂_t and ∂_φ that span timelike 2-surfaces with cylindrical topology.

ACKNOWLEDGMENTS

During the 1990s a large amount of work was dedicated to studying general relativity coupled to non-Abelian Yang-Mills type theories. Several remarkable results were accomplished. In particular, it was shown that the magnetic monopole, a solution of the Yang-Mills-Higgs equations can indeed be coupled to gravitation. For a low Higgs mass it was found that there are regular monopole solutions, and that for a sufficiently massive monopole the system develops an extremal magnetic Reissner-Nordström quasihorizon with all the matter fields laying inside the horizon. These latter solutions, called quasi-black holes, although nonsingular, are arbitrarily close to having a horizon, and for an external observer it becomes increasingly difficult to distinguish these from a true black hole as a critical solution is approached. However, at precisely the critical value the quasi-black hole turns into a degenerate space-time. On the other hand, for a high Higgs mass, a sufficiently massive monopole develops also a quasi-black hole, but at a critical value it turns into an extremal true horizon, now with matter fields showing up outside. One can also put a small Schwarzschild black hole inside the magnetic monopole, the configuration being an example of a non-Abelian black hole. Surprisingly, Majumdar-Papapetrou systems, Abelian systems constructed from extremal dust (pressureless matter with equal charge and energy densities), also show a resembling behavior. Previously, we have reported that one can find Majumdar-Papapetrou solutions which are everywhere nonsingular, but can be arbitrarily close of being a black hole, displaying the same quasi-black-hole behavior found in the gravitational magnetic monopole solutions. With the aim of better understanding the similarities between gravitational magnetic monopoles and Majumdar-Papapetrou systems, here we study a particular system, namely a system composed of two extremal electrically charged spherical shells (or stars, generically) in the Einstein-Maxwell-Majumdar-Papapetrou theory. We first review the gravitational properties of the magnetic monopoles, and then compare with the gravitational properties of the double extremal electric shell system. These quasi-black-hole solutions can help in the understanding of true black holes, and can give some insight into the nature of the entropy of black holes in the form of entanglement. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2184766]

I. INTRODUCTION

The coupling of general relativity to Yang-Mills SU(2) non-Abelian theories was studied in detail in the 1990s giving rise to a fuller understanding of the systems involved through a series of remarkable results. This effort started after the paper by Bartnick and McKinnon,[1] which showed that Einstein-Yang-Mills theory has one particle solution, the Bartnick-McKinnon particle, in spite of neither pure gravity nor pure Yang-Mills having a particle solution on their own. Further studies inserted a black hole inside this particle[2,3] with the conclusion that, although unstable, the solution could be an instance of no-hair violation, which in turn motivated new works. Similar systems were then studied, such as, the Einstein-Skyrme system,[4–8] the Einstein-Yang-Mills-dilaton system,[5] the Yang-Mills-Proca system,[6,9] the Einstein-Yang-Mills-Higgs sphaleron system,[6,9] Einstein-Yang-Mills in anti-de Sitter space-times,[10] all these systems have in common that their global electromagnetic type charge is zero, a good review is in Ref. 11. There is yet another very interesting system, which concerns us here, the magnetic monopole which is a solution of the Einstein-Yang-Mills-Higgs system. Indeed, the 't Hooft-Polyakov magnetic monopole, is a solution of the pure Yang-Mills-Higgs system (i.e., Einstein-Yang-Mills-Higgs with zero gravity), when the Yang-Mills and the Higgs fields are in the adjoint SO(3) representation (see the review paper of Goddard and Olive[12]). The 't Hooft-Polyakov magnetic monopole, at large distances, has the same structure of the Dirac monopole, however the core is nonsingular.[12,13] When one couples gravitation, at least weakly, the magnetic monopole solution is still there, as was noticed in Ref. 14, now exerting a small gravitational attraction. For strong gravitational fields the system was studied much later, in the wake of the Bartnick-McKinnon particle, notably by Ortiz,[15] Lee, Nair, and Weinberg,[16,17] Breitenlohner, Forgács, and Maison,[18,19] and Aichelburg and Bizon,[20] among others. A distinctive feature of this system is that it has a global magnetic charge, which of course influences the properties of the space-time. In addition, the Einstein-Yang-Mills-Higgs system has two length scales, one due to the mass of the W particle (the Yang-Mills particle that has eaten some mass in the symmetry breaking process), the other due to the mass of the Higgs. For low Higgs mass, the associated large Compton length scale does not interfere much, and the structure of the monopole is characterized in great extent by the W field features. For this system, the one analyzed in Refs. 15–20, it was found that there are regular solutions, and moreover, for a sufficiently massive monopole the system turns into an extremal quasi-black hole, developing an extremal quasihorizon, with all the nontrivial matter fields inside it. A quasi-black hole is a configuration which is nonsingular but on the verge of having a horizon at some radius r_*. More specifically, quasi-black holes are nonsingular solutions arbitrarily close to having a horizon. For an external observer it becomes increasingly difficult to distinguish a quasi-black hole from a true black hole as a critical solution is approached. At the critical value one must distinguish two situations. In the low Higgs mass situation a horizon never forms, when the configuration has radius r_* the space-time is degenerated, where the time dimension disappears altogether from a region of the space-time. The distinction between a quasi-black hole and a true black hole, as well as the appearance of a degenerated space-time, was not clear in the early works. On the other hand, for high Higgs mass the system behaves differently as was shown later by Lue and Weinberg[21,22] (see also Ref. 23). In this case, for a sufficiently massive monopole the system turns into a quasi-black hole, and at the critical value, a real extremal magnetic Reissner-Nordström black hole appears, developing a true extremal horizon inside the monopole core, and moreover, non-Abelian matter fields stick out of the horizon, in gross violation of the no-hair conjecture. It was further found that one could insert a Schwarzschild black hole inside the monopole without perturbing much its structure, forming a non-Abelian black hole. But when the radius of the Schwarzschild black hole achieved a certain value the horizon would jump into another extremal quasihorizon. This happens both in the low Higgs mass case, as was found by the original authors, as well as in the high Higgs mass case, as was shown by Brihaye, Hartmann, and Kunzin[24] where the continuation of the original program has been carried out. Other studies connected with

[a]Electronic mail: lemos@fisica.ist.utl.pt
[b]Electronic mail: zanchin@ccne.ufsm.br

magnetic monopoles in the Einstein-Yang-Mills-Higgs theory can be mentioned: (i) The thermodynamical properties of these monopole black holes were further studied by Maeda *et al.*[25–27] in the low Higgs mass case, and by Lue and Weinberg[22] for high Higgs mass; (ii) Ridgeway and Weinberg found the existence of nonspherically symmetric magnetic monopole configurations;[28] (iii) dyonic solutions were found by Brihaye *et al.*;[29,30] (iv) monopole solutions in other theories were also found, like in a Brans-Dicke theory,[31] and in SU(3), SU(5), and SU(N) gauge theories.[32–34]

Now, in a different context, the study of the Einstein-Maxwell system goes back to the origins of general relativity where Reissner in 1916 and Nordström in 1918 found the Reissner-Nordström solution (see Ref. 35 for the appropriate references), and Weyl studied axisymmetric gravitoelectric vacuum systems in four dimensions.[36] A great development occurred in 1947 when Majumdar[37] and Papapetrou,[38] drawing upon Weyl's results, found new four-dimensional solutions that represent many particles (from one to infinity), each particle with mass equal to charge, located at any desired position, without spatial symmetry in the most generic case [see Ref. 39 for a generalization of Majumdar's[37] and Papapetrou's[38] works to higher dimensional ($d>4$) spacetimes]. The idea is borrowed from Newtonian gravitation: A particle with mass equal to charge is in equilibrium with other mass equal to charge particle, and so with many other such particles, since the gravitational attraction is balanced by the electric repulsion. The Majumdar-Papapetrou solutions are the general relativistic realization of this idea. Now, in Newtonian theory, point particles are point particles, but in general relativity they can be black holes. This was clarified by Hartle and Hawking[40] who showed that the vacuum solution represents extremal Reissner-Nordström black holes at any spatial position. A different development was taken by Das,[41] who relying on the work of Majumdar,[37] put dust particles on the point particles positions, evading the black hole horizons. Several other authors have further analyzed the properties of Majumdar-Papapetrou systems.[42–47] Bonnor and collaborators[48–52] in a series of papers have shown and studied important new solutions of Majumdar-Papapetrou equations and properties of the system. In particular, in Refs. 49–51, spherical extremal matter stars (where extremal matter stars are defined as stars composed of matter with charge density equal to the energy density), with an exterior extremal Reissner-Nordström metric, were found. These are the Bonnor stars. Bonnor stars were further developed by Lemos and Weinberg[53] where new explicit solutions were found. It was also found that these new stars, as well as Bonnor stars, develop a quasi-black-hole behavior, and there are cases that the solution can even display some kind of hair.[53] In addition, in Ref. 54 a thick shell solution was found. In the limit of zero interior radius for this thick shell, the solution is a Bonnor star, in the limit of the thickness going to zero, the solution is a thin shell. These solutions also have quasi-black-hole behavior.

Here we want to explore further the analogy between gravitational magnetic monopoles and Majumdar-Papapetrou stars. In the previous papers,[53,54] the Majumdar-Papapetrou solutions found, although complex did not exhibit the full behavior of the gravitational magnetic monopoles, where there is an interplay between the W-field scale and the Higgs field scale. We construct here a Majumdar-Papapetrou system which shows such a full behavior. Such a system is composed of two infinitesimally thin shells. Majumdar-Papapetrou thin shells have many interesting properties. Let us think first of one thin shell to simplify. We will call it the star, it is a regular solution. Fix the mass of the star, and study the set of formed configurations as one decreases its radius. For a sufficiently small radius the star develops an extremal Reissner-Nordström quasi-black hole. The same happens if instead one fixes the radius and increases the mass. One can go further and put another thin shell inside the thin shell star. One can then ask, when the radii of the system are decreased which shell is going to form a quasihorizon first? The usual case is the outer shell developing a quasihorizon first, the whole system being inside the quasi-black hole. But, depending on the parameters and constraints, the inner shell can develop a quasihorizon first, in which case we have an extremal quasi-black hole in the core of the system, with star matter floating outside. One can also put an extremal Reissner-Nordström true black hole inside the regular star (as was done in the gravitational magnetic monopole case, when one puts a small Schwarzschild black hole inside the magnetic monopole) and then increase the black hole radius

through a set of configurations. At a certain point the whole system jumps into a new extremal Reissner-Nordström quasi-black hole. If we exchange star for monopole, the properties of this Majumdar-Papapetrou system are identical to the properties of the gravitational magnetic monopole system. All these similarities with the gravitational magnetic monopole will be explored in this paper. A similarity which we do not explore, is that both systems permit nonspherically symmetric solutions, in the magnetic monopole case see Ref. 28, in the Majumdar-Papapetrou case see Ref. 52. We note that the Majumdar-Papapetrou solutions, such as the extremal Reissner-Nordström black hole solutions and the Bonnor stars, are also of interest in extensions of general relativity, since the system turns out to be supersymmetric when embedded in a larger theory, such as $N=2$ gauged supergravity (see Ref. 55 for a review of Majumdar-Papapetrou solutions in supergravity and string theories).

The paper is organized as follows. In Sec. II we overview the properties of gravitational magnetic monopoles that most interest us, we give the equations and define the important scales, we review the low Higgs field (low b) case without, and then with, an interior Schwarzschild black hole, and review also the high b case. In Sec. III we study the properties of the Majumdar-Papapetrou two shell system: we give the equations and length scales, assume some constraints for the shells and present the solution, study the equivalent low b behavior without and with an interior extremal Reissner-Nordström true black hole, and then the equivalent high b behavior. A remark: when we write a black hole it means a true extremal Reissner-Nordström black hole, when we write a quasi-black hole it means solutions of matter configurations that are on the verge of being a black hole. In some instances, quasi-black holes turn into degenerated space-times,[16,53] in other instances turn into real black holes.[22]

II. GRAVITATIONAL BEHAVIOR OF MAGNETIC MONOPOLES, AN OVERVIEW

In this section we overview the solutions for gravitational magnetic monopoles. The logical presentation of the material reflects in a unified way the work of the authors on this subject and is suited for comparison with the subsequent analysis on Majumdar-Papapetrou stars.

A. The Einstein-Yang-Mills-Higgs magnetic sector

1. The action and equations of motion

The action of the Einstein-Yang-Mills-Higgs theory is ($G=c=1$)

$$S=\int d^4x\sqrt{-g}\left(-\frac{1}{16\pi}R+\mathcal{L}_{\text{matter}}\right), \tag{1}$$

where R is the scalar curvature, and $\mathcal{L}_{\text{matter}}$ is the Yang-Mills-Higgs Lagrangian given by

$$\mathcal{L}_{\text{matter}}=-\frac{1}{4}F^a_{\mu\nu}F^{a\mu\nu}+\frac{1}{2}D_\mu\phi^a D^\mu\phi^a-\frac{\lambda}{2}(\phi^{a2}-v^2)^2, \tag{2}$$

$$F^a_{\mu\nu}=\partial_\mu A^a_\nu-\partial_\nu A^a_\mu-e\epsilon^a{}_{bc}A^b_\mu A^c_\nu, \tag{3}$$

$$D_\mu\phi^a=\partial_\mu\phi^a-e\epsilon^a{}_{bc}A^b_\mu\phi^c, \tag{4}$$

where e is the gauge coupling constant, λ the Higgs coupling constant, and v the vacuum expectation value of the Higgs field. The Yang-Mills connection A^a and the Higgs field ϕ^a take values on the Lie algebra of the SU(2) group, with a being an internal index. The potential $(\lambda/2)(\phi^{a^2}-v^2)^2$ in the matter Lagrangian has a family of gauge-equivalent minima, given by $\phi^{a2}=v^2$, which breaks spontaneously the SU(2) symmetry down to U(1). One can choose the vacuum to be in the third internal direction $\phi^a=v\delta^{a3}$ (for details see Refs. 12 and 23). The elementary particles of the theory are the electromagnetic U(1) massless gauge field (a photon), two massive W particles with

charge $\pm e$ and mass $m_W = ev$, and the neutral massive field ϕ^3 with mass $m_H = 1/\sqrt{\lambda}v$. There is also the massless graviton.

The monopole configuration is spherically symmetric with metric written generically in terms of two functions $A(r)$ and $B(r)$ as

$$ds^2 = -B(r)dt^2 + A(r)dr^2 + r^2(d\theta^2 + \sin^2\theta\, d\phi^2), \tag{5}$$

with a magnetic Yang-Mills field, written in terms of one function $u(r)$, as

$$A_0 = 0, \quad A_i^a = \epsilon_{iaj}\hat{r}^j \frac{1-u(r)}{er}, \tag{6}$$

and a Higgs field, written in terms of one function $h(r)$, as

$$\phi^a = v\hat{r}^a h(r), \tag{7}$$

where ϵ_{iaj} is the Levi-Civita tensor, and $\hat{r}$ is the unit vector in the radial direction. Putting this ansatz into the Einstein-Yang-Mills-Higgs action and varying the action with relation to the four functions yields four equations, two for the gravitational fields $B(r)$ and $A(r)$, one for the Yang-Mills field $u(r)$, and one for the Higgs field $h(r)$. The equations are, respectively (see Ref. 16),

$$\frac{(AB)'}{AB} = 16\pi r\left(\frac{u'^2}{e^2r^2} + \frac{1}{2}v^2h'^2\right), \tag{8}$$

$$\left[r\left(1-\frac{1}{A}\right)\right]' = 8\pi r^2\left[\frac{1}{A}\left(\frac{u'^2}{e^2r^2} + \frac{1}{2}v^2h'^2\right) + \frac{(u^2-1)^2}{2e^2r^4} + \frac{u^2h^2v^2}{r^2} + \frac{\lambda}{2}v^2(h^2-1)^2\right], \tag{9}$$

$$\frac{1}{\sqrt{AB}}\left[\frac{\sqrt{AB}u'}{A}\right]' = \frac{u(u^2-1)}{r^2} + e^2uh^2v^2, \tag{10}$$

$$\frac{1}{r^2\sqrt{AB}}\left[\frac{r^2\sqrt{AB}h'}{A}\right]' = \frac{2hu^2}{r^2} + 2\lambda h(h^2-1)v^2. \tag{11}$$

Sometimes, instead of $A(r)$ the mass function $m(r) = r(1-[1/A(r)])$ is used. There are four parameters in the theory: G (which we have set equal to one), e, λ, and v. With these parameters one can form two dimensionless parameters, α and β. Since v is dimensionless, it is already a sought parameter, $\alpha = v$. The other dimensionless parameter is $\beta = \sqrt{\lambda}/e$. [In passing, note that in these studies of gravitational magnetic monopoles, G is not usually set to one, but rather $G = m_p^{-2} = l_p^2$ ($\hbar = c = 1$), and m_p and l_p are the Planck mass and the Planck length, respectively. Here we are setting $m_p = 1$ and $l_p = 1$, i.e., we are measuring everything in terms of these scales. It is straightforward to move from one system of units to the other: Every time one finds a mass one should divide by m_p, every time one finds a length one should divide by l_p, in the end collect all m_p's and l_p's, transform l_p into m_p by $l_p = m_p^{-1}$, and put back G from $m_p^{-2} = G$.]

2. Some properties and scales of the magnetic monopole

The magnetic monopole solution can be characterized by its mass and radius, and by a secondary mass and a secondary radius. To understand the effects of gravity it is useful to rewrite the parameters α and β, defined above, in terms of two renewed parameters, a and b, defined through the characteristic masses and radii themselves. Indeed, for a weak gravitational field the magnetic charge of the monopole is $Q_m = 1/e$, its radius is given roughly by the Compton wavelength of the Yang-Mills field, $r_m \simeq 1/ev$, and its mass by the magnetic energy $M_m \simeq Q_m^2/r_m = v/e$. Thus, instead of α given above ($\alpha = v$), we can define a parameter a (with $a \sim v^2$) as

$$a \equiv \frac{M_m}{r_m}, \tag{12}$$

which is a useful characterization when we turn on gravitation, and for later comparison. The other parameter b can also be written in similar terms: Since there is the Higgs mass scale, the monopole solution has secondary mass and radius scales. The secondary radius is given by the Compton wavelength of the Higgs field, $r_{m_2} \simeq 1/\sqrt{\lambda}v$, and the secondary mass is given by $M_{m_2} \simeq Q_m^2/r_{m_2} = \sqrt{\lambda}v/e^2$. Thus, instead of β given above ($\beta = \sqrt{\lambda}/e$), we can define a parameter b (with $b \sim \lambda/e^2$) as

$$b \equiv \frac{M_{m_2}/r_{m_2}}{M_m/r_m}, \tag{13}$$

which displays the coupling between both, mass over radius scales. There are three parameters v, e, λ and four quantities, M_m, r_m, M_{m_2}, r_{m_2}, so there is an equation

$$M_m r_m = M_{m_2} r_{m_2}, \tag{14}$$

which constrains the four quantities. For instance, r_{m_2} can be considered as fixed once the other three quantities are known.

B. The gravitational behavior as a function of *a* (gravitation) for low *b* (low Higgs mass)

Here, we overview the solutions found in Refs. 15–19 keeping in mind that we will later want them for comparison. We present the metric and matter functions as a function of radius, discuss the naked horizon behavior and the Coulomb character of this type of solutions, put a Schwarzschild black hole inside, and resketch some diagrams covering the space of solutions.

From the preceding section, low b indicates a small Higgs mass m_H, or large associated Compton wavelength, which means that the Higgs does not participate in the dynamics, it has very little influence on the monopole structure. Reinterpreted through Eq. (13) one can also see the low b case as a monopole with small secondary mass M_{m_2} or large secondary radius r_{m_2}. Given a low b configuration, we want now to understand how the structure changes as gravity is turned on higher and higher, i.e., as the parameter $a = M_m/r_m$ increases.

1. The regular magnetic monopole solution: from no gravitation to the extremal quasi-black hole

Let us start with a [see Eq. (12)] small. This means a highly dispersed magnetic monopole with small mass M_m and large radius r_m. As a increases the solution gets more general relativistic and eventually should get to a black hole, where $a = a_{\text{crit}} \sim 1$ (for instance, if the configuration formed a Schwarzschild black hole $a_{\text{crit}} = \frac{1}{2}$, or if it formed an extremal Reissner-Nordström black hole $a_{\text{crit}} = 1$). It does not happen exactly like this. The solution in the limit of a_{crit} yields a quasi-black hole as defined in Refs. 22 and 53. To get a grip on the solutions we draw in Fig. 1 diagrams showing the metric functions and the matter field functions as a function of r for two values of a, a small, and a_{crit}.[16] The function A signals the existence of a black hole horizon, the function B is the redshift function, the product function $(AB)^{1/2}$ tells whether a horizon is naked or not, and the function u and h report on the hair or no-hair of the solution. More specifically: (i) The function A, or better $1/A$, indicates how strong the curvature is, and in particular indicates the existence of a black hole horizon. At $r = 0$, $1/A$ should be 1 in order that there are no conical singularities, and at $r \to \infty$ should be again 1 for asymptotically flat space-times. Now, for $a \simeq 0$ space-time is flat and $1/A \simeq 1$ for all r. For small a there is a small dip at intermediate r as shown in Fig. 1. For large a the dip is large, and for $a = a_{\text{crit}}$, $1/A$ is zero, indicating that a black hole horizon might have formed, here an extremal one since $1/A$ gets a double zero. In fact, as was first noticed in Ref. 22, a true extremal black never forms. Instead, for a configuration with a radius

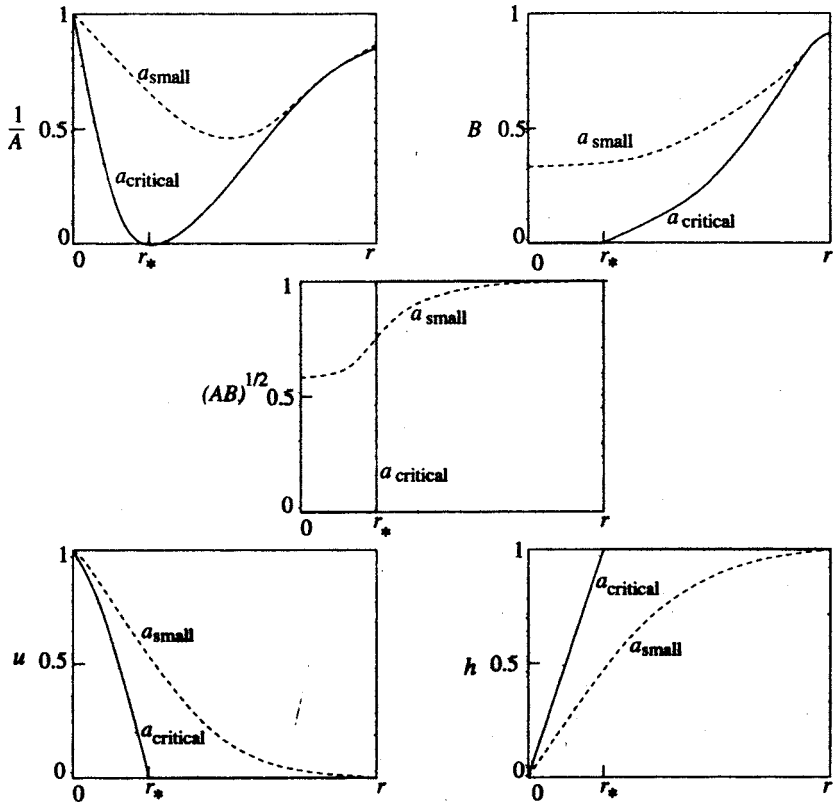

FIG. 1. The graphs of the metric and matter functions, $(1/A, B, (AB)^{1/2}, u, h)$, are plotted as a function of r in the low b case. The curves a small are typical of small gravitational effects, and the curves a critical give the properties of the extremal quasi-black hole. The radius r_* is the radius at which the quasihorizon is formed, see text for details.

arbitrarily near the critical radius, a quasi-black hole forms (i.e., a matter solution whose gravitational properties are virtual indistinguishable from a black hole[22]), and at a_{crit} precisely, a degenerate space-time appears as it is found when one looks to the metric function B. (ii) The metric function B gives the redshift behavior, or the relative behavior of clocks at different spatial positions. It is the function that distinguishes a true black hole from a quasi-black hole, as we will now see. For $a \simeq 0$, one has $B \simeq 1$. For small a, B lowers at the origin showing the existence of a gravitational potential, and goes to 1 at $r \to \infty$. For $a = a_{\text{crit}}$ or very near it, B goes again to one at $r \to \infty$, but now it is zero up to the monopole radius. This is odd, the infinite redshift surface is not a surface it is a three-dimensional region. To be a black hole B should go to zero at a given r only. This means that the solution at $a = a_{\text{crit}}$ does not represent a smooth manifold. Thus, the quasi-black-hole configuration gives rise to a degenerated space-time. For a very near the critical value it is very hard to distinguish the quasi-black-hole solution from a true black hole. The radius of these quasi-black holes is denoted by $r = r_*$, and is arbitrarily near to the radius of the extremal Reissner-Nordström black hole of same mass and charge, see Fig. 1. (iii) One should also pay attention to the behavior of $(AB)^{1/2}$, which says whether the horizon is naked or not, as it will be precised below. For $a \simeq 0$ one has $(AB)^{1/2} \simeq 1$. For a small, $(AB)^{1/2}$ is small at $r = 0$ and 1 at $r \to \infty$. For $a = a_{\text{crit}}$, $(AB)^{1/2}$ is 0 up to $r = r_*$ and then steps into 1, see Fig. 1. It is interesting to comment further on the behavior of $(AB)^{1/2}$ and its consequences. For the Schwarzschild and Reissner-Nordström solutions $(AB)^{1/2}$ is 1 for all radii. However, it is not so here, as can be seen directly in Fig. 1. The fact that $(AB)^{1/2} \to 0$ for $r \leqslant r_*$ at the critical solution implies that the black hole horizon formed has a naked behavior [22]. This means that the components of the Riemann tensor at the horizon in an orthonormal frame blow up at the horizon. It can be understood as follows. Suppose a particle sent in through the monopole, by a distant observer, turns around, and

comes back to the point where it started. Suppose also the monopole is on the verge of forming a horizon, i.e., the monopole surface is a quasihorizon. Due to the very small value of $(AB)^{1/2}$ inside and at the quasihorizon (see Fig. 1), one finds that the proper time the particle takes for the round trip is given by $\Delta\tau \sim r_* \epsilon^q$, where r_* is the radius of the quasihorizon, $\epsilon \equiv (1/A)_{\min}$ is a very small quantity near the critical solution, and q is found by numerical methods to be $\sim 0.7-1.0$.[22] So the particle takes virtual zero time within the quasihorizon. This fact is related to the black hole nakedeness. The Riemann tensor on a particle gives essentially the tidal forces in the particle. It can be shown that the Riemann tensor in these cases is inversely proportional to the square of the proper time it takes the particle to cross the region.[22] Thus if the proper time is zero, the Riemann tensor, and thus the tidal forces are huge, giving rise to a naked behavior, the horizon is exposed. Here $R_{\hat{t}\hat{i}\hat{t}\hat{i}} \sim \epsilon^{-2q}$, where the caret means calculated in the freely falling frame and the indexes i denote spatial indexes. So, these are naked black holes. Note that for the Schwarzschild, Reissner-Nordström, and extremal Reissner-Nordström black holes, the Riemann tensor calculated in the frame falling with the particle is well behaved, so the horizon is well behaved, a result that is known otherwise. The other interesting time to compute in the round trip is the coordinate time. It is given by $\Delta t \sim r_* \epsilon^{-q}$. Thus, for a coordinate observer, the particle takes a long time to return. This coordinate time can be important for entropic considerations.[22] (iv) The function u for the Yang-Mills field shows for a small a $1/r^2$ fall off for large r, and for $a=a_{\text{crit}}$ it disappears for radii greater than $r=r_*$. (v) The function h of the Higgs field for small a is zero and then grows to pick up the Higgs vacuum value at large r. For $a=a_{\text{crit}}$ it grows from 0 at the origin to 1 at the horizon, and stays at 1 up to infinity. This means that there is no hair, outside the horizon, only the trivial magnetic and vacuum Higgs fields. These quasi-black holes have been termed Coulomb type quasi-black holes since they show a Coulomb (no hair) field when they form.[21]

2. Nonregular magnetic monopoles: The Schwarzschild black hole solution inside the monopole

Up to now we have mentioned the behavior of regular gravitating monopoles, i.e., solutions that are regular from the origin to infinity. One can now put a small Schwarzschild black hole, with mass M_{bh} and radius r_{bh}, inside the magnetic monopole. This system is an example of a non-Abelian black hole with hair. One could think that putting a Schwarzschild black hole inside the monopole would disrupt the structure, and turn the monopole solution into a time-dependent one with the Yang-Mills and Higgs fields being accreted onto the black hole. But this is not the case, matter, with energy density ρ and radial pressure component p_{rr}, can coexist with an event horizon at its location as long as $\rho+p_{rr}=0$, a result that follows directly from the conservation equation $T^{\mu\nu}{}_{;\nu}=0$. A well-known example is the Schwarzschild-de Sitter solution, where the cosmological constant term Λ can be seen as a fluid which certainly obeys $\rho+p_{rr}=0$. Following Refs. 16 and 25 one finds that the non-Abelian structure inside the monopole may be approximated as a uniform vacuum energy density ρ_{vac} up to the monopole radius r_m such that the black hole in this region has a metric identical to the Schwarzschild-de Sitter black hole. For small black holes the condition $\rho+p_{rr}=0$ is obeyed and they can inhabit the center of the monopole, i.e., small black holes inside do not perturb much the solution. However, when the Schwarzschild black hole is large enough, such that its mass is of the order of the mass of the system, the system itself collapses giving rise to a magnetically charged extremal Reissner-Nordström quasi-black hole. We note that the literature is not clear whether it forms a true extremal black hole or an extremal quasi-black hole, however by continuity from the regular case one is entitled to infer that it is a quasi-black hole, followed by a degenerated space-time at the critical value. The appearance of this quasi-black hole happens for a critical value of the parameter a, with $a_{\text{crit}} \sim 1$, or alternatively, for a critical value of the total mass M, with $M=M_m+M_{\text{bh}}$. The behavior is thus analogous to the regular monopole in the sense that as one increases gravitation, i.e., as the parameter a or the mass M of the system increases, one finds a a magnetically charged extremal Reissner-Nordström quasi-black hole.

To understand the generic behavior it is helpful to make a plot of the solution space. One such plot is given in a $M_m \times M$, where $M=M_m+M_{\text{bh}}$ is the total mass. This is shown in Fig. 2, see also

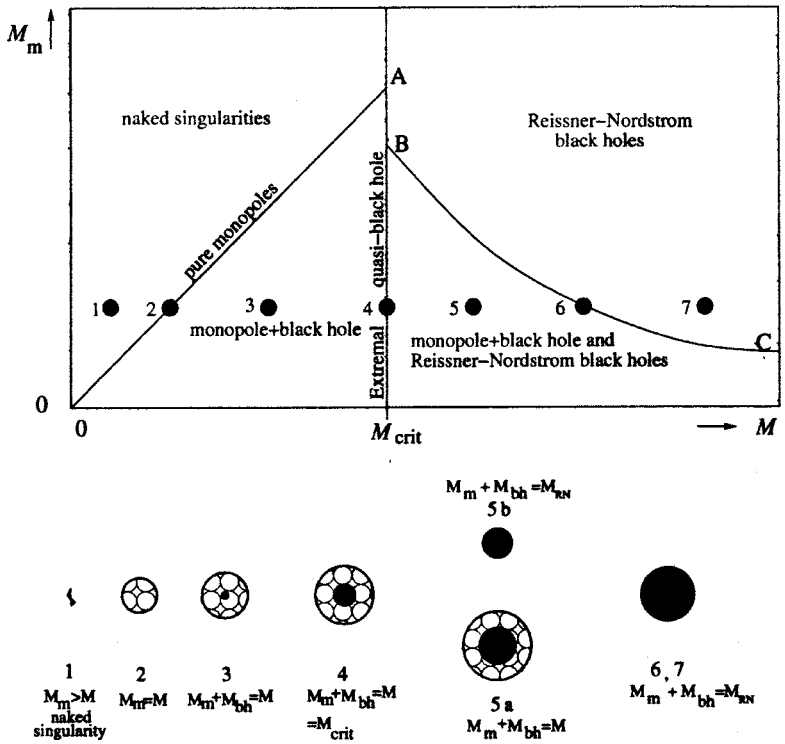

FIG. 2. The space of solutions in a $M_m \times M$, where $M = M_m + M_{\rm bh}$ is the total mass, is plotted (see also Ref. 16). For each point 1–7, along a constant monopole mass, in the diagram, the corresponding configuration is pictorially represented in the bottom part of the figure.

Ref. 16. There are four areas and three lines. The pure monopole line (the regular solutions discussed above) with the total mass equal to the monopole mass, is represented by a line with slope 1. The top-left region represents naked singularities. The center-left area represents monopole+Schwarzschild (non-Abelian) black hole solutions mentioned above. At arbitrarily near the critical mass the solutions are extremal magnetic charged Reissner-Nordström quasi-black holes (and at precisely the critical mass they turn into degenerated solutions). To the right there is a region where monopole+Schwarzschild (non-Abelian) black holes coexist with magnetic (Abelian) Reissner-Nordström black holes. Then to the far right and above there is a region of magnetic (Abelian) Reissner-Nordström black holes alone. In this diagram, solutions with a constant black hole mass are represented by lines parallel to the pure monopole line, i.e., lines of slope 1. Lines of constant monopole mass are horizontal lines. We show pictorially each representative configuration along a constant monopole mass line. Each numbered point (from 1 to 7) in Fig. 2 is represented in the bottom of the figure by a schematic drawing. In this drawing, note that the horizon area of the solution containing a Schwarzschild black hole surrounded by monopole matter (numbered 5a) is larger than the horizon area of the pure magnetic Reissner-Nordström horizon (numbered 5b). Following the area law, the smaller one is prone to be unstable and decay to the larger hairy one. This has interesting implications in the ultimate fate of the black hole through Hawking evaporation.[17]

Another similar but interesting plot is $a \times r_{\rm bh}$ diagram, shown in Fig. 3, see also Ref. 18. There are four areas and four lines. There is the pure monopole line ($r_{\rm bh}=0$), which yields the regular solutions discussed above. The top-left area is the region of no solutions. There is the center-left area of monopole+Schwarzschild (non-Abelian) black hole solutions discussed above, there is the bottom-left area where one finds monopole+Schwarzschild (or non-Abelian) black hole solutions as well as magnetic (Abelian) Reissner-Nordström black holes, and then the right area of magnetic (Abelian) Reissner-Nordström black holes. The other lines are boundaries between these areas.

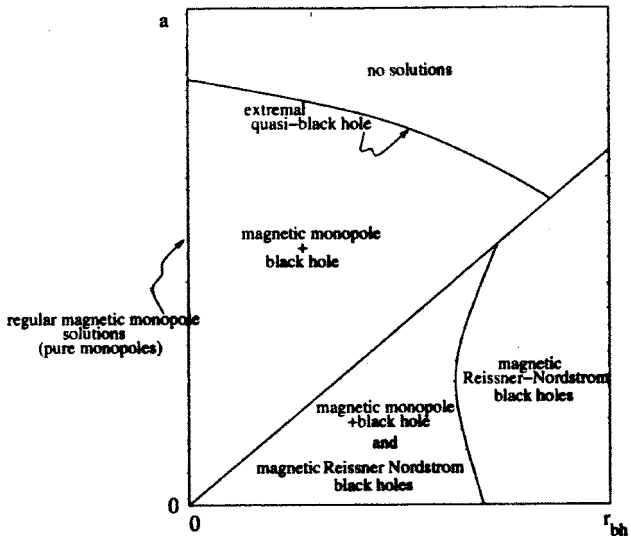

FIG. 3. The space of solutions in a $a \times r_{\rm bh}$ diagram (see also Ref. 18).

C. The gravitational behavior as a function of *a* (gravitation) for high *b* (high Higgs mass)

High Higgs mass reserves surprises. Here we overview the solutions found in Refs. 21 and 22 still keeping in mind that we will later need them for comparison. High b means $b \gtrsim 40$.[21] From Sec. II A, high b indicates a large Higgs mass m_H, or small associated Compton wavelength. This means that the Higgs field does participate in the dynamics, and can have great influence on the monopole structure. Reinterpreted through Eq. (13) one can also see high b as a monopole with large secondary mass M_{m_2}, or small secondary radius r_{m_2}. In order to understand how the structure changes as gravity is turned on higher and higher one must increase the parameter a.

1. The regular magnetic monopole solution: from no gravitation to the extremal black hole

For low a there is not much change in relation to the low b case. Low a represents a highly dispersed magnetic monopole, with small mass M_m and large radius r_m. As a increases the solution gets more general relativistic and eventually gets to a black hole, when $a=a_{\rm crit} \sim 1$. An important difference to the low b case is that instead of passing from a quasihorizon to a degenerate space-time, it passes from a quasihorizon to a true horizon, well inside the core at r_{*2}.[22] To get a grip on the solutions we draw in Fig. 4 diagrams showing the metric functions and the matter field functions as a function of r for two values of a, a small and $a_{\rm crit}$. Specifically the behavior of the functions is (i) The function $1/A$, the metric function that signals the formation of a black hole, shows that very near $a_{\rm crit}$ there are two radial scales, where horizon could be formed, one at r_{*2} (related to the scale set by the Higgs mass), the other at $r=r_*$ (related to the scale set by the W mass), but at $a_{\rm crit}$ the double zero occurs at r_{r^*2}, and an extremal horizon appears there. (ii) The metric function B shows also a zero at r_{*2} signaling the formation of an infinite redshift surface. Note now that B is zero at one point only, r_{r^*2}, not in a whole region as was the case for low b. This means that the configuration quasi-black hole with radius very near r_{*2}, turns into a true extremal black hole rather than to a degenerate space-time as in the low b case. (iii) The behavior of $(AB)^{1/2}$, which tells whether the horizon is naked or not, confirms this behavior. It shows that it is never zero, meaning the horizon is a regular, not a naked one.[22] This means that the components of the Riemann tensor at the horizon in an orthonormal frame are well behaved. In this case a particle that is sent in through the monopole, turns around, and comes back to the point where it started, takes a proper time $\Delta\tau$ which is finite, nonzero. Thus, since the Riemann tensor is pro-

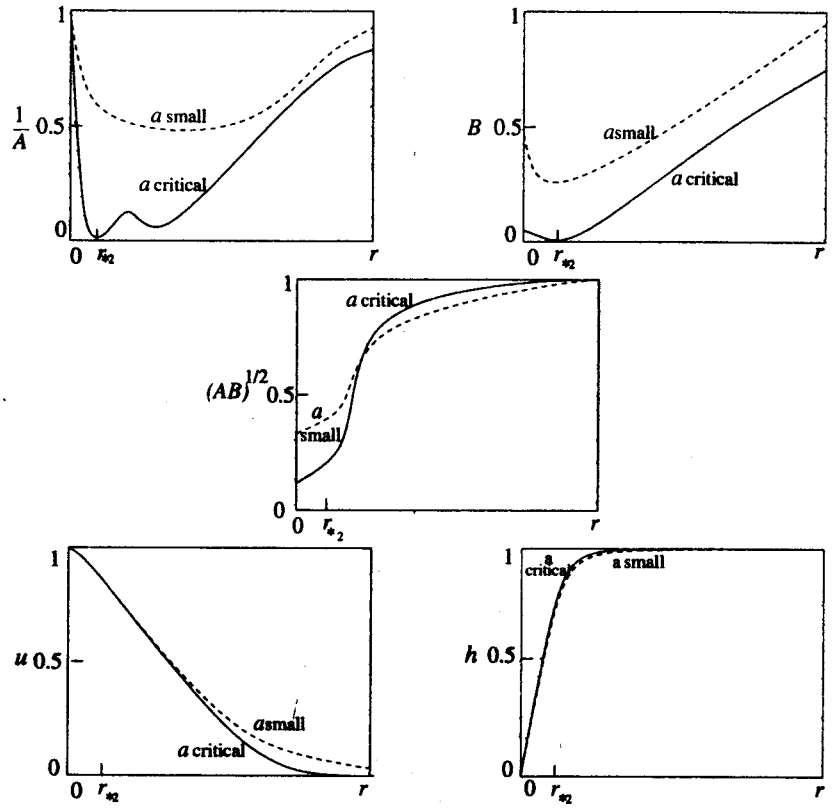

FIG. 4. The graphs of the metric and matter functions, $(1/A, B, (AB)^{1/2}, u, h)$, are plotted as a function of r in the high b case. The curves a small are typical of small gravitational effects, and the curves a critical give the properties of the extremal quasi-black hole. The radius r_* is the radius at which the quasihorizon is formed, see text for details.

portional to $(\Delta\tau)^{-2}$, as discussed in connection to the low b case, there is no funny behavior at the horizon and all behaves well. (iv) The function u for the Yang-Mills field shows that for a_{crit} there is field outside the horizon radius, i.e., there is hair. (v) The function h for the Higgs field, behaves similarly to u. In the critical situation, it only acquires the vacuum value for radii much larger than r_{*2}.

There are three points that are worth commenting. First, we comment further on the behavior of $(AB)^{1/2}$ and its consequences. In terms of the coordinate time, the particle takes for the round trip the time $\Delta t \sim r_{*2}\epsilon^{-1/2}$, where again $\epsilon \equiv (1/A)_{\min}$ is a very small number. Thus the particle takes, as in the low b case, a long time to return to a coordinate observer, and this is important in connection with entropy issues.[22] Indeed, in leading order, this time is determined only from the space-time geometry. An observer finds that the quasi-black hole has an inside which is inaccessible, since probes stay there for an arbitrarily large amount of time, and describes it by a density matrix ρ_{matrix} obtained by tracing over the degrees of freedom inside the quasihorizon, yielding an entropy $S=-\text{Tr}\,(\rho_{\text{matrix}} \ln \rho_{\text{matrix}})$. The calculation of the interior entropy of a field inside a spherical box was performed for a scalar field with the result that $S=\gamma(A/4)$, where γ is an undetermined factor, and A is the area of the box.[56] In this case, the box is the magnetic monopole quasihorizon configuration on the verge of being a black hole. Since one can give a little push from this configuration to the horizon configuration, and in the latter case the entropy is $S=A/4$ one can guess by continuity that the coefficient of proportionality in the quasihorizon case has a dependence on the size of the box $\gamma=\gamma(r_{\text{box}})$ and when a horizon forms, $\gamma(r_{*2})=\frac{1}{4}$.[22] In this sense, the entropy of the extremal black hole is the number of the entangled degrees of freedom inside the horizon. This analysis cannot be applied to the low b case because there is never a true horizon: in the limit, when the object is turning into a black hole it gives a nonsmooth manifold.

Second, another feature of these monopoles is that they have a charge to mass ratio given by $Q/M>1$. Thus if one drops neutral matter onto a regular magnetic monopole one can form an extremal black hole.[22] This is contrary to the case of electric Reissner-Nordström black holes with $Q/M<1$, and where one can drop charged matter, with charge q and mass m obeying $q/m>1$, as much as one wants that one never gets an extremal black hole (this is a version of the third law of black hole mechanics).

Third, one can ask what happens for a higher than the critical value. Following Ref. 22 one finds that there are possibly two branches. One branch is formed of magnetically Abelian charged Reissner-Nordström black holes. The other branch, has non-Abelian matter and hair outside, a horizon, and regular non-Abelian matter inside. Following theorems by Borde[57–59] one finds that these regular solutions may have different inside and outside topologies. This issue should be further explored.

2. The Schwarzschild black hole solution inside the monopole

As in the low b case one can put a Schwarzschild black hole inside. This was done in Ref. 24. The main feature is that again there is hair outside the true horizon. The results are in line with what we have been discussing. Diagrams like those of Figs. 2 and 3 can be drawn, although we have not found them in the literature.

D. Further discussion

Thus, gravitationally there are two distinct behaviors, the low b case and the high b case, the marginal case being at $b\simeq 40$. The low b case has the following main features: when one turns on gravitation (when one increases a) a quasi-black hole appears from the regular monopole, which turns into a degenerate space-time at the critical value $a_{\rm crit}$; it has a naked horizon, and shows no hair, i.e., it is of Coulomb type, the nontrivial fields are hidden inside the horizon. In addition, one can enrich the monopole structure by putting a Schwarzschild black hole inside up to a certain maximum mass. The high b case has also a regular monopole solution which, when one increases the gravitational parameter a, turns into a quasi-black hole, and then at $a_{\rm crit}$ a true extremal black hole appears, with regular horizon and hair. There is a transition between the two cases, a first order type transition. When b is in the transition zone, there is a double double zero, one zero at r_* and the other at r_{*2}. So, the transition is discontinuous in radius, and thus in entropy. It is, however, continuous in mass.[21]

Other features that are also very interesting but not important in our context are the following: (i) For very low b ($b<0.1$ say), the behavior is more complicated near $a_{\rm crit}$.[18] If one increases a from zero, one passes $a_{\rm crit}$ up to an $a_{\rm max}$. But from $a_{\rm crit}$ to $a_{\rm max}$ there are two solutions, one with larger mass M_m (larger radius r_m), the other with smaller values. The one with smaller values is the one that connects continuously with the low mass solutions. The smaller mass solutions are stable, and so the branch which forms black holes is unstable; (ii) for a certain range of the parameters a and b, there are multiple node solutions [nodes appearing in the function $u(r)$ of the Yang-Mills field] of the type found in the Bartnick-Mckinonn solution;[18] (iii) the particular case $b\to\infty$ in the high b sector was analyzed in detail by Aichelburg and Bizon.[20] The solution has a conical singularity at $r=0$ but apart from that it is well behaved. Perhaps, oddly, core behavior in this limit was not found, we will comment on this later on.

This program of studying the gravitational behavior of magnetic monopoles has been continued by Brihaye *et al.*, where the structure of dyonic non-Abelian black holes has been analyzed,[29,30] and gravitational monopoles in SU(3), SU(5), and SU(N) theories have been found.[32–34]

III. GRAVITATIONAL BEHAVIOR OF MAJUMDAR-PAPAPETROU MATTER SYSTEMS: TWO CONCENTRIC SPHERICAL THIN SHELLS

A. The Majumdar-Papapetrou sector of the Einstein-Maxwell-charged dust system

1. The action and equations of motion

We now want to study the Einstein-Maxwell system coupled to some specific electrically charged dust currents as will be described below. By dust one means a fluid with zero pressure. We will compare the configurations found below with the magnetic configurations discussed in Sec. II. A first study in this direction has been done in Ref. 53 (see also Ref. 54). The action for the Einstein-Maxwell-charged dust system is $(G=c=1)$

$$S=\int d^4x\sqrt{-g}\left(\frac{1}{16\pi}R+\mathcal{L}_{\text{matter}}\right), \tag{15}$$

where R is the scalar curvature, and

$$\mathcal{L}_{\text{matter}}=\mathcal{L}_{\text{Maxwell}}+\mathcal{L}_{\text{charged dust}}+\mathcal{L}_{\text{int}}. \tag{16}$$

The Maxwell Lagrangian is

$$\mathcal{L}_{\text{Maxwell}}=-\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}, \tag{17}$$

$$F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu, \tag{18}$$

where $F_{\mu\nu}$ and A_ν are the electromagnetic field strength and potential, respectively. The charged dust Lagrangian, $\mathcal{L}_{\text{charged dust}}$, is such that the action integral, $S_{\text{dust}}=\int d^4x\sqrt{-g}\mathcal{L}_{\text{dust}}$, gives the energy-momentum tensor for charged dust, i.e.,

$$T^{\mu\nu}_{\text{charged dust}}=-\frac{1}{8\pi}\frac{1}{\sqrt{-g}}\frac{\delta S_{\text{charged dust,}}}{\delta g^{\mu\nu}}=\rho u^\mu u^\nu, \tag{19}$$

where ρ is the dust energy density and u^μ its four-velocity. The interaction Lagrangian $\mathcal{L}_{\text{interaction}}$ is given by

$$\mathcal{L}_{\text{interaction}}=A_\mu j^\mu, \tag{20}$$

where $j^\mu=\rho_e u^\mu$, ρ_e being the electric charge density. The elementary particles are then the electromagnetic massless photon, the massless graviton, and the massive charged dust particles with energy density ρ and charge density ρ_e. The charged dust particles may spread over a given three-dimensional region of space, or can be squeezed into a two-dimensional thin membrane, i.e., a shell. In the latter case the action (15) acquires the form of a bulk action plus a membrane action. These bulk plus membrane systems will be treated now.

The configuration we want to discuss is spherically symmetric, a star type configuration, with metric given again by

$$\mathrm{d}s^2=-B(r)\mathrm{d}t^2+A(r)\mathrm{d}r^2+r^2(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2), \tag{21}$$

and with the electric Maxwell field given by

$$A_0=\varphi(r),\quad A_i=0. \tag{22}$$

Putting this ansatz into the Einstein-Maxwell-charged dust action (15) and varying the action with relation to the three functions, yields three equations, two for the gravitational field $B(r)$ and $A(r)$, and one for the Maxwell field $\varphi(r)$. The equations are, respectively,

$$\frac{(AB)'}{AB}=8\pi r\rho A, \tag{23}$$

$$\left[r\left(1-\frac{1}{A}\right)\right]' = 8\pi r^2\rho + \frac{r}{AB}\varphi'^2, \tag{24}$$

$$\frac{\sqrt{B}}{r^2\sqrt{AB}}\left[\frac{r^2}{\sqrt{AB}}\varphi'\right]' = -4\pi\rho_e. \tag{25}$$

There are three parameters in the theory: G which we have set equal to one, ρ and ρ_e. Now, ρ and ρ_e have dimensions of length to minus two. Thus one can form in principle two length scales. The ratio of these length scales yields a parameter without dimensions. One particular class of solutions, the one we want to treat, sets

$$\frac{\rho_e}{\rho} = 1. \tag{26}$$

(Note that the charge density ρ_e can have two signs, so strictly speaking one should set $\rho_e = \pm\rho$. In order to not carry this $\pm$ throughout we drop the minus sign, bearing in mind that a $-$ sign can be floating about.) Matter obeying the condition (26), i.e., matter with mass equal to charge, can be called extremal charged dust in analogy with the extremal Reissner-Nordström black holes. The system of equations (23)–(25) with condition (26) is the Majumdar-Papapetrou system.[37,38]

Now, in order to show a behavior analogous to the magnetic monopole of the Einstein-Yang-Mills-Higgs system the Majumdar-Papapetrou system per se is not enough, the parameters do not give enough structure. In order to get more structure we must add new parameters. First assume a given spherical symmetric solution, which we call a star. Then, a new parameter is the radius of the star, $r_{\rm star}$. So now, one has two parameters ρ and $r_{\rm star}$. It is preferable to swap the star's density ρ for the star's mass $M_{\rm star}$, so that the two parameters are $M_{\rm star}$ and $r_{\rm star}$. Then one can form an adimensional parameter

$$a = \frac{M_{\rm star}}{r_{\rm star}}. \tag{27}$$

This is the equivalent to the parameter a in the Einstein-Yang-Mills-Higgs theory, see (12). To simplify the analysis, and without loss of generality, we can think that the star is made of a thin shell of extremal charged dust, with $M_{\rm star}$ and $r_{\rm star}$ being now the mass and the radius of the thin shell. It is not difficult to see that this thin shell is a solution of the Majumdar-Papapetrou system.[54] One can now further bring into the problem a new extremal charged thin shell, called the secondary shell, with two new parameters, the mass M_2 and the radius r_2. One has then two thin shells, one inside the other, a configuration that is also a solution of the Majumdar-Papapetrou system, as will be displayed below. One can then form a new dimensionless parameter b given by

$$b = \frac{M_2/r_2}{M_{\rm star}/r_{\rm star}}. \tag{28}$$

This is equivalent to the secondary parameter of the Einstein-Yang-Mills-Higgs system appearing in Eq. (13). This double shell solution has four parameters $M_{\rm star}$, $r_{\rm star}$, M_2, r_2. In order to produce the required model one should restrict these four parameters through a constraint equation, as in the magnetic monopole case. Generically, the two shells are indistinguishable, one cannot say whether the outer one is the star or the secondary shell. To be definitive, the inner shell is called the secondary shell, the outer shell is the star, and we keep the secondary shell always inside the star, through the constraint

$$r_{\rm star} = 2r_2. \tag{29}$$

The factor 2 in (29) was chosen for convenience, any real number greater than 1 will do. Equation (29) is the equivalent to the constraint (14) in the magnetic monopole case. Thus the system we are going to work with is a Majumdar-Papapetrou system with two extremal charged shells. This

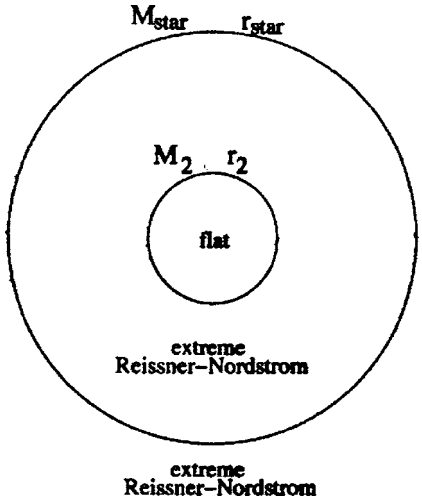

FIG. 5. A schematic drawing of the double shell solution in the Majumdar-Papapetrou system, showing the secondary shell inside the star shell.

simple system mimics a good deal of behavior of the Einstein-Yang-Mills-Higgs system. Instead of working with thin shells, one could work with the thick shell solutions found in Ref. 54 or with the Bonnor stars,[49–51] but this only complicates the technical analysis of the problem without further illuminating it.

2. Some properties and scales of the Majumdar-Papapetrou double shell

We are now ready to put a shell within a shell, and simulate the behavior of the gravitational magnetic monopoles. The star (outer shell) and the secondary shell (inner shell) are considered to be infinitesimally thin, see Fig. 5. Then, the metric valid from $0 \leqslant r < \infty$, for a Majumdar-Papapetrou space-time with two extremal matter thin shells, is given by

$$\mathrm{d}s^2 = -\frac{\left(1-\frac{M}{r_{\mathrm{star}}}\right)^2\left(1-\frac{M_2}{r_2}\right)^2}{\left(1-\frac{M_2}{r_{\mathrm{star}}}\right)^2}\mathrm{d}t^2 + \mathrm{d}r^2 + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2), \quad 0 \leqslant r \leqslant r_2, \tag{30}$$

$$\mathrm{d}s^2 = -\frac{\left(1-\frac{M}{r_{\mathrm{star}}}\right)^2}{\left(1-\frac{M_2}{r_{\mathrm{star}}}\right)^2}\left(1-\frac{M_2}{r}\right)^2\mathrm{d}t^2 + \frac{\mathrm{d}r^2}{\left(1-\frac{M_2}{r}\right)^2} + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2), \quad r_2 \leqslant r \leqslant r_{\mathrm{star}}, \tag{31}$$

$$\mathrm{d}s^2 = -\left(1-\frac{M}{r}\right)^2\mathrm{d}t^2 + \frac{\mathrm{d}r^2}{\left(1-\frac{M}{r}\right)^2} + r^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\phi^2), \quad r_{\mathrm{star}} \leqslant r < \infty, \tag{32}$$

where $M = M_{\mathrm{star}} + M_2$ is the total mass of the system. The constants in the g_{tt} components were chosen so that the metric matches at the shells. The electric field is

$$\varphi = 1 - \frac{\left(1 - \frac{M}{r_{\rm star}}\right)\left(1 - \frac{M_2}{r_2}\right)}{\left(1 - \frac{M_2}{r_{\rm star}}\right)}, \quad 0 \leqslant r \leqslant r_2, \tag{33}$$

$$\varphi = 1 - \frac{\left(1 - \frac{M}{r_{\rm star}}\right)\left(1 - \frac{M_2}{r}\right)}{\left(1 - \frac{M_2}{r_{\rm star}}\right)}, \quad r_2 \leqslant r \leqslant r_{\rm star}, \tag{34}$$

$$\varphi = 1 - \left(1 - \frac{M}{r}\right) = \frac{M}{r}, \quad r_{\rm star} \leqslant r < \infty. \tag{35}$$

The fluid field is given by the surface energy densities of the shells. For the secondary thin shell one has that the surface energy density σ_2 is given by

$$\sigma_2 = \frac{M_2}{4\pi r_2^2}, \tag{36}$$

with the corresponding surface electric charge density of the shell σ_{e_2} given by $\sigma_{e_2} = \sigma_2$. For the thin shell star one has that the surface energy density $\sigma_{\rm star}$ is given by

$$\sigma_{\rm star} = \frac{M_{\rm star}}{4\pi r_{\rm star}^2}, \tag{37}$$

with the corresponding surface electric charge density of the shell $\sigma_{e_{\rm star}}$ given by $\sigma_{e_{\rm star}} = \sigma_{\rm star}$. Note that the g_{rr} component of the metric has a step function at r_2 and $r_{\rm star}$. This is no problem, one can smooth it out by considering a shell with small thickness,[54] but for the problem we are considering it is irrelevant.

One important question is which shell, and in which conditions a shell, forms a horizon. We know that a horizon should form when $1/A = 0$. Suppose a b is given, and one starts to increase a. Then it is meaningfull to ask which shell forms first a horizon, the star or the secondary shell? To answer it note that

$$\left(\frac{1}{A}\right)_{r_2} = 1 - \frac{M_2}{r_2} = 1 - ab, \tag{38}$$

$$\left(\frac{1}{A}\right)_{r_{\rm star}} = 1 - \frac{M}{r_{\rm star}} = 1 - \frac{M_{\rm star}}{\rm r_{star}}\left(1 + \frac{M_2/r_2}{M_{\rm star}/r_{\rm star}}\frac{r_2}{r_{\rm star}}\right) = 1 - a\left(1 + \frac{b}{2}\right). \tag{39}$$

It is then clear that there are three cases:

$b < 2$, when a increases an external horizon forms first at $r_{\rm star} = M$, with $a_{\rm crit} = 1/(1 + b/2)$. This is analogous to the behavior of magnetic monopoles with low b, where an external horizon forms outside the core.

$b > 2$, when a increases an interior horizon forms first at $r_2 = M_2$, with $a_{\rm crit} = 1/b$. This is analogous to behavior of magnetic monopoles with high b, where an external horizon forms within the core.

$b = 2$, when a increases a horizon forms at both shells, interior and exterior with $a_{\rm crit} = 1/2$. This divides the two cases above.

As we will show below the solution does not develop a true horizon. Independently of b, upon increasing a, a quasihorizon appears. Then at the critical value one gets a degenerated space-time, and for values of a above the critical one there is no static solution, the shell collapses (see Ref.

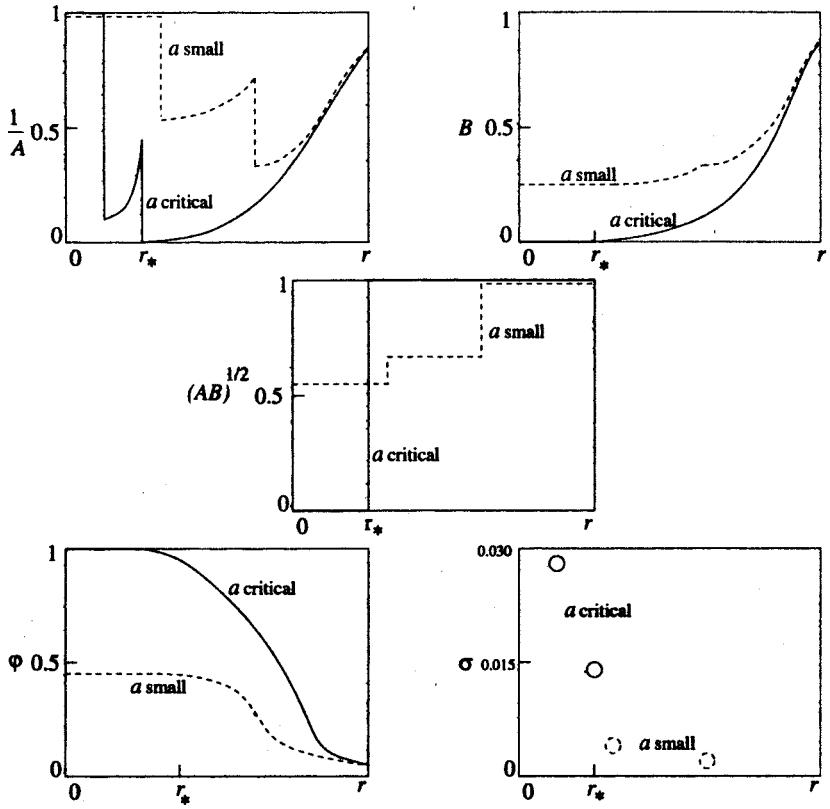

FIG. 6. The graphs of the metric and matter functions, $(1/A, B, (AB)^{1/2}, \varphi, \sigma)$, are plotted as a function of r in the low b ($b<2$) case. The curves a small (dashed lines) are typical of small gravitational effects, and the curves a critical (full lines) give the properties of the extremal electrical quasi-black hole. The radius r_* is r_{star} at the quasihorizon (arbitrarily near the critical radius), see text for details. (In the graphs, we have used $b=1$ as a typical low b case, and have set $M_{\text{star}}=\frac{5}{2}$, $M_2=\frac{5}{4}$, and for a small we have set $r_{\text{star}}=10$, $r_2=5$, while for a critical we have set $r_{\text{star}}=\frac{15}{4}$, $r_2=\frac{15}{8}$.)

60) into a singularity and an extremal Reissner-Nordström black hole forms. In what follows we study each type of configuration. We start with low b, $b<2$, then we do high b, $b>2$.

B. The gravitational behavior as a function of *a* for low *b*

Since $b=(M_2/r_2)/(M_{\text{star}}/r_{\text{star}})$, low b can be seen as a relatively small secondary mass M_2, or large secondary radius r_2, which means that the secondary shell has little influence in the structure. Given a low b configuration, we want to understand how the structure changes as the parameter $a=M_{\text{star}}/r_{\text{star}}$ increases. We present plots giving the behavior of the metric and matter functions as a function of radius for typical cases, discuss the naked horizon behavior and the Coulomb character of these solutions, put an extremal Reissner-Nordström black hole inside, and sketch some diagrams covering the space of solutions.

1. The regular Majumdar-Papapetrou double shell solution: from no gravitation to the extremal quasi-black hole and beyond

We have seen from Eqs. (38) and (39) that for fixed b, with $b<2$, an extremal quasihorizon appears when the parameter a increases, i.e., when one puts more gravitation into the star shell. A small a parameter, i.e., $M_{\text{star}}/r_{\text{star}}$ small, means that the star shell is very dispersed. As a increases, eventually it gets to a stage where a kind of an extremal event horizon forms. Using Eqs. (30)–(39) one can plot the behavior of the metric and matter functions as a function of radius for two values of a, a small, and a arbitrarily near a_{crit}, when a quasihorizon forms, see Fig. 6. Specifically, the behavior of the functions $1/A$, B, $(AB)^{1/2}$, φ, and σ is: (i) the function $1/A$ signals the formation

of a black hole. For a small the function $1/A$ starts at the value 1 (thus there are no conical singularities) drops slightly at the secondary shell, rises and drops again at the star shell, and then rises again to 1 at infinity. When $a=a_{\rm crit}$ (or arbitrarily near it) the function gets a double zero at $r=r_*$ (it would be a double zero had we smoothed out enough of the matter) signaling the formation of a kind of an extremal Reissner-Nordström black hole. (ii) The function B, the redshift function, has the usual behavior for a small. However, for $a_{\rm crit}$ the whole of the region inside r_* gets infinitely redshifted. This means that the manifold is not smooth. Thus the critical case is not a true black hole, it is a degenerated space-time. (iii) The product function $(AB)^{1/2}$ is important to determine whether the forming horizon is naked or not. We find that a particle on a return trip to the star takes a proper time given by $\Delta\tau\sim r_*\epsilon^{1/2}$, where r_* is the radius of the quasihorizon, and, near the critical solution, $\epsilon\equiv(1/A)_{\rm min}$ is a very small quantity.[54] Since this proper time is arbitrarily small, the Riemann tensor diverges at the horizon, and the horizon is naked. For completeness we given the coordinate time Δt taken by the particle in its trip, $\Delta t\sim r_*\epsilon^{-1/2}$, implying that the particle takes a long time to return for a coordinate observer. (iv) The function φ tells whether the solution has hair or not. It starts constant, then decays with $1/r$, with a bump at r_2 and at $r_{\rm star}$. When the horizon forms the field is a pure Coulomb field, showing no-hair. (v) The surface density function σ of the charged dust is also drawn, for completeness. Outside the quasihorizon at r_* there is no matter.

The case $b=0$ is worth discussing because it is the simplest one in the low b sector. There is no secondary shell ($M_2=0$) and so it represents a single thin shell with mass $M_{\rm star}$ and radius $r_{\rm star}$. It is interesting because on one hand it has the same properties of any other low b case, on the other hand, it is easier to figure out what happens above criticality, i.e., for $a>a_{\rm crit}$ ($M_{\rm star}>r_{\rm star}$). We have seen that when the precise equality holds, $a=a_{\rm crit}$, the redshift function B is zero not only at the horizon but also in the whole region inside, meaning that in fact a true black hole does not form, since inside there is no smooth manifold. For $a>a_{\rm crit}$ one has now a shell of matter at $r_{\rm star}$ inside an extremal electrical Reissner-Nordström black hole at $r_{\rm bh}=M_{\rm star}$, the solution being everywhere free from curvature singularities. Following a theorem by Borde,[57] this means that the topology of spacelike slices in this black hole space-time would change from a region where they are noncompact to a region where they are compact, in the interior. In our case this in fact does not happen, there are no solutions with $a>a_{\rm crit}$, i.e., $m>r_{\rm o}$, the shell collapses into a singularity.[60]

2. Nonregular Majumdar-Papapetrou shell solutions: The extremal Reissner-Nordström black hole solution inside the thin shell star

One can put a black hole inside the double thin shell and obtain a structure similar to the one found when one puts a black hole inside a magnetic monopole. For the double thin shell, the extra inner black hole must be an extremal Reissner-Nordström black hole, rather than a Schwarzschild black hole, to keep the solutions within the Majumdar-Papapetrou system. If one puts a nonextremal black hole foreign tensions would develop at the thin shells. So, in order to stick to pure Majumdar-Papapetrou system we stick to an inner extremal Reissner-Nordström black hole. In order to simplify the analysis, we will work with the $b=0$ which is a good simple case for low b. For any other small b, such that $b<2$, the result is analogous. In the $b=0$ case one has $M_2=0$. Thus the system is formed by the star shell with mass $M_{\rm star}$ and radius $r_{\rm star}$, and an inner extremal Reissner-Nordström black hole with mass $M_{\rm bh}$ and radius $r_{\rm bh}$ ($M_{\rm bh}=r_{\rm bh}$). The metric is now

$$ds^2=-\left(1-\frac{M_{\rm bh}}{r}\right)^2\frac{\left(1-\frac{M}{r_{\rm star}}\right)^2}{\left(1-\frac{M_{\rm bh}}{r_{\rm star}}\right)^2}dt^2+\frac{dr^2}{\left(1-\frac{M_{\rm bh}}{r}\right)^2}+r^2(d\theta^2+\sin^2\theta\, d\phi^2),\quad 0\leqslant r\leqslant r_{\rm star},\tag{40}$$

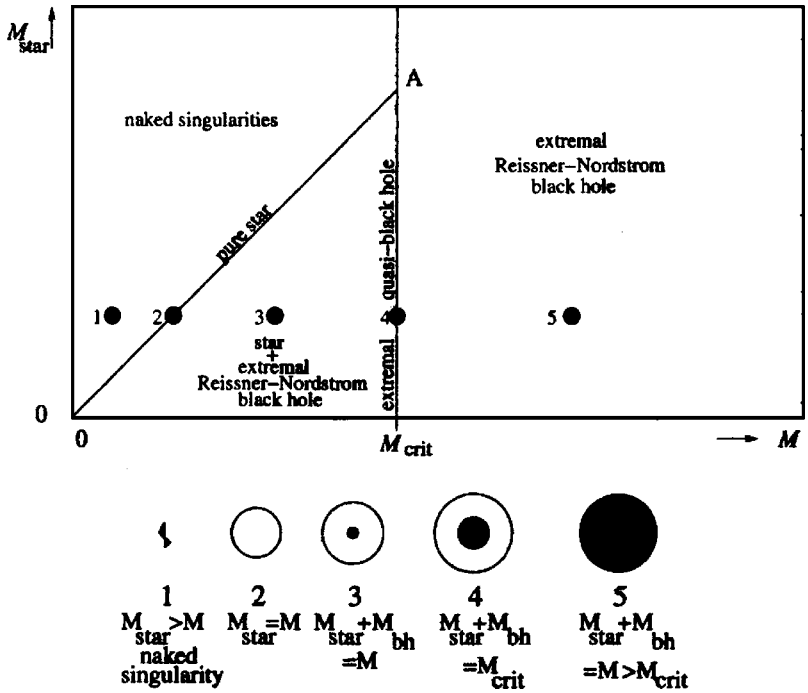

FIG. 7. The space of solutions in a $M_{\text{star}} \times M$, where $M = M_{\text{star}} + M_{\text{bh}}$ is the total mass, is plotted. For each point 1–5, along a constant star mass, in the diagram, the corresponding configuration is pictorially represented in the bottom part of the figure. This is the graph made in Fig. 2 (see also Ref. 16) adapted to the thin shell Majumdar-Papapetrou system.

$$ds^2 = -\left(1 - \frac{M}{r}\right)^2 dt^2 + \frac{dr^2}{\left(1 - \frac{M}{r}\right)^2} + r^2(d\theta^2 + \sin^2\theta\, d\phi^2), \quad r_{\text{star}} \leqslant r, \tag{41}$$

where here $M = M_{\text{star}} + M_{\text{bh}}$ is now the total mass. The electric field $\varphi(r)$ and the charge density field $\rho(r) = \sigma_{\text{star}}(r_{\text{star}})$ profile accordingly.

To understand the generic behavior of this system it is helpful to make a plot of the solution space, similar to the plot made for a Schwarzschild black hole inside the magnetic monopole shown in Fig. 2. We do this in Fig. 7, where we plot the solution space in a $M_{\text{star}} \times M$ diagram for fixed r_{star}. There are three regions and two lines. The pure star line, i.e., the regular solutions discussed above with the total mass equal to the star mass, is represented by a line with slope 1. The top-left region represents extremal charged naked singularities. The center-left region represents star+(extremal Reissner-Nordström black hole) solutions displayed in Eqs. (40) and (41). At values arbitrarily near the critical mass M_{crit} the solutions are extremal electric charged Reissner-Nordström quasi-black holes, which degenerate at the critical value. To the right there is a region of extremal Reissner-Nordström black holes. We show pictorially each representative configuration along a constant star mass line. Each numbered point (from 1 to 5) in Fig. 7 is represented in the bottom of the figure by a schematic drawing. We see that taking M_{star} constant and increasing M we pass through point 1 where M_{star} is greater than M and therefore there is a negative mass at the center, through point 2 where one finds a thin shell solution with $M_{\text{star}} = M$, through point 3 where there is a black hole inside the star, through point 4 which is the case arbitrarily near the critical value where $M_{\text{star}} + M_{\text{bh}} = r_{\text{star}}$, and thus an extremal quasi-black hole appears at r_{star}, finally to point 5 where r_{star} has collapsed inside the horizon radius to form an extremal black hole. Note there is a jump in horizon radius from a point infinitesimally to the left of point 4, to a point infinitesimally to the right of point 4. Note also that this diagram is done for fixed r_{star}. For another value of r_{star}, one gets the same diagram, but with the vertical critical line critical shifted, to the

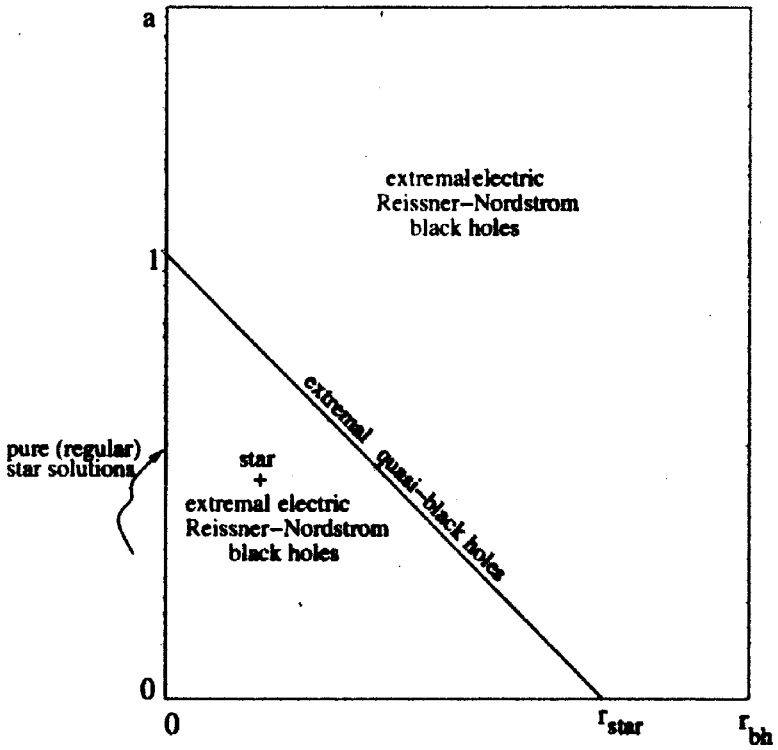

FIG. 8. The space of solutions in an $a \times r_{bh}$ plot. This is the graph made by Fig. 3 (see also Ref. 18) adapted to the thin shell Majumdar-Papapetrou system.

right when the new r_{star} is larger, and to the left when the new r_{star} is smaller than the original value. Comparison of Figs. 2 and 7 shows the similarities between the magnetic monopole and the Majumdar-Papapetrou system.

One can also translate Fig. 3 into this Majumdar-Papapetrou system. This is done in Fig. 8, where we display the important regions in a graph $a \times r_{bh}$ (where again $a = M_{star}/r_{star}$). There are two regions and two lines. There is the vertical line, $r_{bh}=0$, of regular star solutions. There is the region where star+(extremal electric Reissner-Nordström black hole) solutions exist. There is the line where the system forms a quasi-black hole (i.e., a solution arbitrarily near the critical degenerate case). Finally there is the region where an extremal electric black hole exists. These are black holes free from singularities. The naked singularity region, not shown, would appear for negative r_{bh}, i.e., for negative black hole masses, $r_{bh}=M_{bh}<0$.

C. The gravitational behavior as a function of *a* for high *b*

High b can be seen as a relatively large secondary mass M_2, or small secondary radius r_2, which means that the secondary shell has a decisive influence in the structure. Given a high b configuration, we want to understand how the structure changes as the parameter $a = M_{star}/r_{star}$ increases. We present plots giving the behavior of the metric and matter functions as a function of radius for typical cases, discuss the naked horizon behavior and the non-Coulomb character of these solutions, and we briefly comment on putting an extremal Reissner-Nordström black hole inside the high b double shell system.

1. The regular solution: from no gravitation to the extremal quasi-black hole and beyond

In contrast with low b, in the high b case, an extremal quasihorizon forms at the secondary shell r_2, rather than in the star shell. Using Eqs. (30)–(39) one can draw the important field

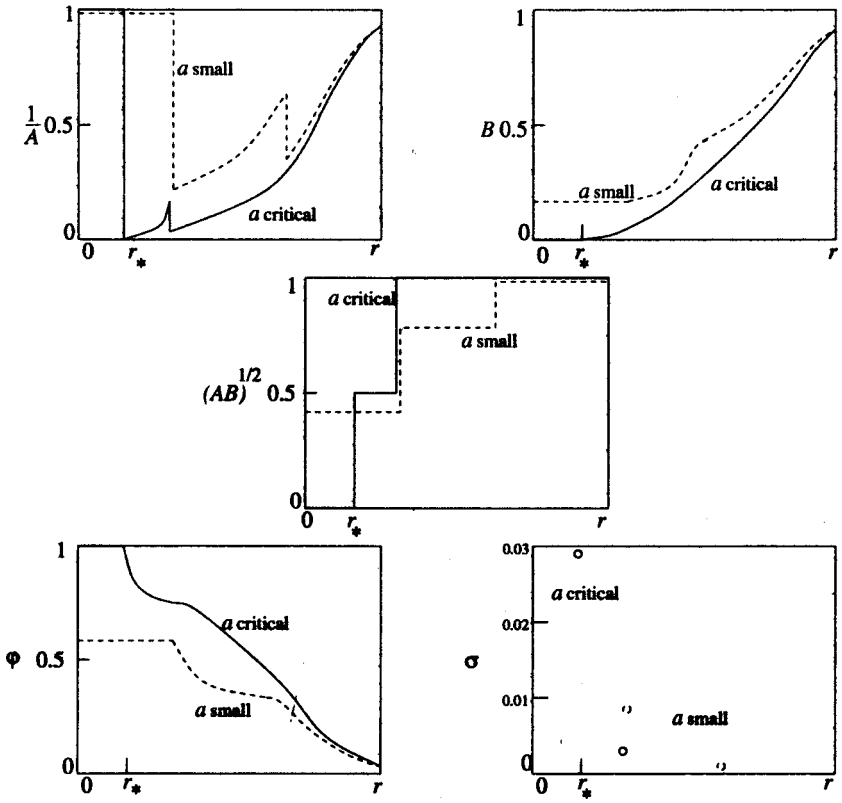

FIG. 9. The graphs of the metric and matter functions, $(1/A, B, (AB)^{1/2}, \varphi, \sigma)$, are plotted as a function of r in the high b ($b>2$) case. The curves a small (dashed lines) are typical of small gravitational effects, and the curves a critical (full lines) give the properties of the extremal quasi-black hole. The radius r_* is now r_2 at the quasihorizon, see text for details. (In the graphs, we have used $b=4$ as a typical high b case, and have set $M_{\text{star}}=\frac{5}{4}$, $M_2=\frac{5}{2}$, and for a small we have set $r_{\text{star}}=10$, $r_2=5$, while for a critical we have set $r_{\text{star}}=5$, $r_2=\frac{5}{2}$.)

functions as a function of r, for a given high b and for two values of a, a small and a critical, see Fig. 9. The behavior of the functions $1/A$, B, $(AB)^{1/2}$, φ, and σ is the following: (i) For a small the function $1/A$ starts at the value 1 drops at the secondary shell, rises and drops slightly at the star shell, and then rises again to 1 at infinity. When a is arbitrarily near a_{crit} the function gets a double zero at $r=r_*$, now situated at the secondary shell r_2, signaling the formation of a quasihorizon. (ii) For a small, the function B has the usual behavior. For a arbitrarily near a_{crit}, B is arbitrarily near zero throughout the region inside r_2. At $a=a_{\text{crit}}$ precisely the manifold is not smooth. Thus again, the critical case is not a true black hole, it is a degenerate manifold. (iii) The function $(AB)^{1/2}$ is zero inside the quasihorizon confirming the existence of a naked behavior. This is not quite the same as the high b behavior for the magnetic monopole, since the magnetic system gets in the high b case a non-naked horizon. (iv) At a arbitrarily near a_{crit}, the function φ does not have a Coulomb type behavior as one can see from Fig. 9, the electric field outside the quasihorizon gets a bump due to the presence of the outer shell. Strictly speaking one cannot talk of a no-hair violation since the no-hair theorem is applied to black holes, not quasi-black holes. (v) The surface density function σ of the charged dust is also drawn, for completeness.

There are two questions that can be asked. The first one is what happens if one increases a past a_{crit}. For $a>a_{\text{crit}}$ one gets an extremal electric Reissner-Nordström black hole outside r_2. This secondary shell then collapses, leaving an extremal black hole with a star shell outside. This is then analogous to the extremal black hole solution inside the star shell discussed previously in the low b case. Upon increasing a further one hits a new critical value, $a_{\text{crit new}}$, where a new horizon forms at the exterior star shell r_{star}.

The second question is what happens when $b \to \infty$. In the magnetic monopole system this case has been analyzed in Ref. 20. When one increases b, keeping a fixed, one finds that r_2 gets relatively smaller and smaller. The behavior is best displayed by looking into the $1/A$ plot of Fig. 9. For a small and fixed, when one increases b the minimum at r_2 is displaced more and more toward $r=0$. Eventually at $b \to \infty$ the minimum hits the $r=0$ line at a point $1/A$ less than 1, which means that the configuration starts at a conical singularity. This example shows why Ref. 20 did not get the high b behavior found in Ref. 21, namely, a smooth black hole formation in the core of the magnetic monopole. What happens is that for $b \to \infty$ a horizon (a kind of singularity) in the inner secondary shell does not form at the core because the initial configuration already possesses at the core ($r=0$) a conical singularity (another kind of singularity which substitutes the horizon in this limit $b \to \infty$). This conical configuration exists for a given typical value of a. Upon increasing a further one hits a critical value for a (corresponding to the $a_{\text{crit new}}$ mentioned above) where a new quasihorizon forms at the exterior star shell r_{star}.

2. The extremal black hole solution inside the system

As in the low b case, where an extremal black hole was put inside the low b shells, one can also put an extremal black hole inside the high b shells. We will not do this here since the behavior is similar to the previous cases. In the magnetic monopole high b case this was done in Ref. 24.

D. Further discussion

(i) *The $b=2$ configuration:* We have treated the cases $b<2$ and $b>2$. The case $b=2$ is also worth commenting as a limiting case. The new feature is that at a_{critical} the function $1/A$ develops two double zeros, one at the secondary shell r_2, the other at the star shell r_{star}. Thus, on going from $b<2$ to $b>2$ the quasihorizon jumps discontinuously in radius at some critical a. If the entropy of this object can be related to the area of the object, as was done in Ref. 22, then the entropy also jumps discontinuously when one passes from $b<2$ to $b>2$. In the transition there is no mass jump, the mass is continuous, so that it is a kind of first order phase transition.

(ii) *More complex configurations:* One can put a third extremal matter shell inside the other two. In this case one has two new parameters, M_3 and r_3, and a new dimensionless parameter c can be given. In analogy with a and b of Eqs. (27) and (28), one finds

$$c = \frac{M_3/r_3}{M_2/r_2}. \tag{42}$$

Assume also as the constraint equation that $r_2=2r_3$. Then, one has

$$\left(\frac{1}{A}\right)_{r_{\text{star}}} = 1 - \frac{M_{123}}{r_{\text{star}}} = 1 - a\left[1 + \frac{b}{2}\left(1 + \frac{c}{2}\right)\right], \tag{43}$$

$$\left(\frac{1}{A}\right)_{r_2} = 1 - \frac{M_{23}}{r_2} = 1 - ab\left(1 + \frac{c}{2}\right), \tag{44}$$

$$\left(\frac{1}{A}\right)_{r_3} = 1 - \frac{M_3}{r_3} = 1 - abc, \tag{45}$$

where $M_{123}=M_{\text{star}}+M_2+M_3$ is the total mass of the system and $M_{23}=M_2+M_3$. Then (I) For $b<4/(2+c)$ and $b<4/(3c-2)$ a quasihorizon forms first at r_{star}, with $a_{\text{crit}}=1/[1+b/2(1+c/2)]$. (II) For $b>4/(2+c)$ and $c<2$ a quasihorizon forms first at r_2, with $a_{\text{crit}}=1/b(1+c/2)$. (III) For the two cases (i) $b<4/(2+c)$ and $b>4/(3c-2)$, and (ii) $b>4/(2+c)$ and $c>2$, a quasihorizon forms first at r_3 with $a_{\text{crit}}=1/(bc)$. Equalities mean that the three quasihorizons form together with $b=1$, $c=2$, and $a_{\text{crit}}=1/2$. Two quasihorizons alone cannot form together.

One can continue to put more shells with the emergence of even more complex behavior in the function $1/A$. This type of behavior should also happen in non-Abelian theories with more Higgs scales.

(iii) *Other configurations:* Other configurations that could be dealt with are a thick shell within a thin shell, with the thick shell being the solution found in Ref. 54. The behavior is similar to what we have been discussing. For the low b case it will give for a_{crit} an extremal naked, Coulomb (no-hair), quasi-black hole. For high b it would give an extremal naked, non-Coulomb (hair), quasi-black hole. One can also put an extremal black hole inside a thick shell, although there is no known exact solution for it.

IV. CONCLUSIONS

We have shown that gravitational magnetic monopoles and Majumdar-Papapetrou stars, in the form of two thin shells, have common properties. We have shown that both systems have extremal quasi-black-hole solutions, some without hair while others developing some type of hair. Both, the monopole system and the two shell Majumdar-Papapetrou system, possess solutions with naked bahavior, i.e., tidal forces tend to infinity at the quasihorizon. At the critical value the interior solution does not give a smooth manifold, indicating a change of topology. For other parameters in the space of solutions of the magnetic monopole system, specifically for high Higgs mass, there are solutions with non-naked behavior, allowing the formation of a true black hole. On the other hand, the two shell Majumdar-Papapetrou system, never shows non-naked behavior, there are only quasi-black-hole solutions. In both systems one can put a black hole inside the configuration without destabilizing the system, for a range of parameters.

(Received 15 December 2005; accepted 23 February 2006; published online 17 April 2006)

The scalar field degree of freedom in Einstein's plus matter field equations is decoupled for Bianchi type I and V general cosmological models. The source, apart from the minimally coupled scalar field with arbitrary potential $V(\Phi)$, is provided by a perfect fluid obeying a general equation of state $p=p(\rho)$. The resulting ODE is, by an appropriate choice of final time gauge affiliated to the scalar field, reduced to first order, and then the system is completely integrated for arbitrary choices of the potential and the equation of state. © *2006 American Institute of Physics.*

I. INTRODUCTION

In the past two decades there has been a growing interest in scalar field cosmological models primarily due to the prominent importance of scalar fields for inflationary scenarios.[1] The importance of the coupling between a scalar field and the gravitational field has been further stressed by Madsen,[2] who has shown that it can have nontrivial consequences for the spontaneous breaking of gauge symmetries. A dynamical systems approach has been extensively used in the study of scalar field cosmologies and their asymptotic behavior.[3] See also Ref. 4 for a concise review.

As far as exact solutions of scalar field cosmologies are concerned, Burd and Barrow[5] have studied homogeneous but anisotropic Bianchi models of types III and VI (as well as Kantowski-Sachs models) and have found exact solutions. Lidsey, and Aguirregabiria *et al.*[6] have found exact solutions for Bianchi type I models. Feinstein and Ibanez[7] have found exact solutions for Bianchi models of type III and VI, Moss and Wright, Madsen, and Abreut, Crawford, and Mimoso[8] have studied exact solutions in the setting of conformal scalar field cosmologies. Paul[9] has obtained exact solutions of a higher derivative theory in the presence of an interacting scalar field. The discovery of the BTZ black hole has motivated the study of analytic solutions in the context of scalar field cosmology in (2+1) dimensions,[10] while Russo[11] has obtained the general solution for

a scalar field cosmology in d dimensions with exponential potentials and a flat Robertson-Walker metric. An early work on exponential potentials has been done by Salopek and Bond[12] while recent treatments are given by Kehagias and Kofinas[13] and Neupane.[14]

Cosmological models containing both a fluid and a scalar field have also been studied. Chimento and Jakubi[15] have given exact solutions of scalar field cosmologies with a perfect fluid and a viscous fluid, respectively. Mendez[16] has obtained an exact solution for the case of an imperfect fluid in a FRW space-time. In the so-called scaling scalar field cosmologies, the energy density due to the scalar field is proportional to the energy density of the perfect fluid. Thus a number of spatially flat, isotropic models in which the energy density of the scalar field is proportional to that of the perfect fluid have been investigated.[17] Billyard, Coley, and van den Hoogen[18] have studied the stability of these scaling solutions within the class of spatially homogeneous cosmological models with a barotropic fluid matter content. Furthermore, they have studied the qualitative behavior of spatially homogeneous models with a barotropic fluid and a noninteracting scalar field with an exponential potential in the class of Bianchi type B models.[19] Saha[20] has obtained exact solutions for a Bianchi type I model with a perfect fluid and dark energy content, while Chimento and Cossarini have studied exact solutions in $1+1$ dimensions using an isotropic perfect fluid source.[21]

In a significant paper, Hawkins and Lidsey[22] have shown that, for a flat FRW geometry, the dynamics of scalar field cosmologies with a perfect fluid matter content can be described by the nonlinear, Ermakov-Pinney equation (which, in turn, leads to tantalizing analogies with the dynamics of Bose-Einstein condensates), while an early work of Barrow also deserves mention in this context. Exact solutions have been obtained in this description.[23] Another kind of decoupling of the scalar field degree of freedom has been initiated in Ref. 24, where a Robertson-Walker background geometry minimally coupled to the scalar field has been investigated. By use of integrals of the motion and of the Klein-Gordon (KG) equation in the quadratic constraint equation, a single, higher-order nonlinear differential equation for the scalar field was obtained.

In the present work we generalize this decoupling for the case of general Bianchi type I and V geometries in the presence of a general perfect fluid source. The advantage is that the resulting ODE is fully integrated and this is achieved for arbitrary choices of the scalar field potential and the fluid equation of state. The paper is organized as follows. In Sec. II the geometry and the matter description as well as the governing equations for the system are presented. In Sec. III the decoupling of the scalar field degree of freedom is performed for Bianchi type I, the reduction of the resulting ODE is given and the system is completely integrated. The corresponding calculations for Bianchi type V are given in Sec. IV. Finally, the conclusions and a discussion of the results obtained are presented in Sec. V.

Throughout we use geometrized units, i.e., $c=8\pi G=1$, while $g_{\mu\nu}$ has the signature $(-,+,+,+)$.

II. THE GOVERNING EQUATIONS AND THE MATTER CONTENT

Our starting point is the line element for a spatially homogeneous geometry,

$$\mathrm{d}s^2=[N^{\alpha}(t)N_{\alpha}(t)-N^2(t)]\mathrm{d}t^2+2N_{\alpha}(t)\sigma_i^{\alpha}(x)\mathrm{d}x^i\,\mathrm{d}t+\gamma_{\alpha\beta}(t)\sigma_i^{\alpha}(x)\sigma_j^{\beta}(x)\mathrm{d}x^i\,\mathrm{d}x^j, \tag{2.1}$$

where $\sigma_i^{\alpha}(x)$ are the basis one-forms satisfying $\sigma_{i,j}^{\alpha}(x)-\sigma_{j,i}^{\alpha}(x)=2C_{\beta\gamma}^{\alpha}\sigma_j^{\beta}(x)\sigma_i^{\gamma}(x)$ (with $C_{\beta\gamma}^{\alpha}$ the structure constants of the Lie algebra of the corresponding three-dimensional isometry group of motion acting simply transitively on the spatial hypersurfaces of simultaneity), $N_{\alpha}(t)$ is the shift vector, $N(t)$ is the lapse function, and $\gamma_{\alpha\beta}(t)$ is the scale factor matrix of the Bianchi type examined.

As explained in Ref. 25 there are special general coordinate transformations mixing space and time in the new space coordinates, whose effect on the line element (2.1) is described by

$$\tilde{\gamma}_{\alpha\beta}(t)=\Lambda_{\alpha}^{\mu}\Lambda_{\beta}^{\nu}a_{\mu\nu}(t),$$

$$\widetilde{N}(t) = N(t)$$

$$\widetilde{N}_\alpha(t) = \Lambda^\beta_\alpha(t)[N_\beta(t) + P^\rho(t)\gamma_{\rho\beta}(t)], \tag{2.2}$$

where $\Lambda^\mu_\nu(t)$, $P^\rho(t)$ satisfy

$$\Lambda^\alpha_\mu C^\mu_{\beta\gamma} = \Lambda^\rho_\beta \Lambda^\sigma_\gamma C^\alpha_{\rho\sigma}, \tag{2.3}$$

$$2P^\mu C^\alpha_{\mu\nu}\Lambda^\nu_\beta = \dot{\Lambda}^\alpha_\beta \tag{2.4}$$

the overdot denoting differentiation with respect to time. Due to (2.3), $\Lambda^\alpha_\beta(t)$ belongs to the automorphism group of the Bianchi type in question and transformations (2.2) describe the gauge freedom of the emanating system of Einstein's field equations in the case of vacuum. So, the three arbitrary functions of time contained in $\Lambda^\alpha_\beta(t)$ and $P^\alpha(t)$ can be used to simplify the line element (2.1) and, thus, also the aforementioned equations. Automorphisms induced by general coordinate transformations have also been considered in Ref. 26, while the rigid gauge symmetries have been analyzed in Ref. 27. Time-dependent automorphisms, seen as tangent space transformations, have also been considered previously,[28,29] while the first (known to us) reference of the relevance of automorphisms to a systematic analysis of Bianchi cosmologies goes back to 1962.[30]

The above result also holds true when the matter content is such that the linear constraints G^0_i do not acquire an extra term T^0_i. For orthogonal perfect fluids and scalar fields depending only on time, T^0_i is indeed zero and therefore we can use the gauge freedom (2.2)–(2.4) to diagonalize $\gamma_{\alpha\beta}(t)$ without losing generality. Therefore, the scale factor matrix is taken to be

$$\gamma_{\alpha\beta}(t) = \mathrm{diag}(a^2, b^2, c^2) \tag{2.5}$$

while for the shift vector we have $N_\alpha(t)=0$. Our choice of time is specified by the gauge condition $N=\sqrt{\det \gamma_{\mu\nu}}$, which is frequently used due to the simplification of the Einstein tensor and whose importance for the decoupling is essential.

The matter content is a minimally coupled scalar field with an arbitrary potential $V(\Phi)$, thus having an energy-momentum tensor

$$T^{(1)}_{\mu\nu} = \Phi_{,\mu}\Phi_{,\nu} - \tfrac{1}{2}g_{\mu\nu}(g^{\kappa\lambda}\Phi_{,\kappa}\Phi_{,\lambda} + 2V(\Phi)) \tag{2.6}$$

and a perfect fluid part

$$T^{(2)}_{\mu\nu} = (p+\rho)u_\mu u_\nu + p g_{\mu\nu}, \tag{2.7}$$

where u^μ is the unit four-velocity vector and a general equation of state $p=p(\rho)$ is adopted. The governing Einstein's field equations are taken to be

$$R^\mu_\nu - \tfrac{1}{2}\delta^\mu_\nu R = T^\mu_\nu, \tag{2.8}$$

where $T_{\mu\nu}=T^{(1)}_{\mu\nu}+T^{(2)}_{\mu\nu}$, while the scalar field equation (Klein-Gordon) is

$$\frac{1}{\sqrt{-g}}\partial_\mu(\sqrt{-g}g^{\mu\nu}\partial_\nu\Phi) - V'(\Phi) = 0 \tag{2.9}$$

the prime, from now onwards, denoting differentiation with respect to the argument.

The "equation of motion" for the perfect fluid is the conservation of its energy-momentum tensor:

$$T^{(2)\mu}_{\nu;\mu} = 0. \tag{2.10}$$

(The scalar field energy-momentum tensor is separately conserved by virtue of the Klein-Gordon equation).

III. DECOUPLING OF THE SCALAR DEGREE AND THE SOLUTION SPACE FOR BIANCHI TYPE I

The basis one-forms are $\sigma_i^\alpha(x)=\delta_i^\alpha$ and, thus, with (2.5), zero shift and the chosen time gauge, the initial form of the metric is given by

$$g_{\mu\nu}=\begin{pmatrix} -a^2b^2c^2 & 0 & 0 & 0 \\ 0 & a^2 & 0 & 0 \\ 0 & 0 & b^2 & 0 \\ 0 & 0 & 0 & c^2 \end{pmatrix}. \tag{3.1}$$

Spatial homogeneity implies that $\Phi=\Phi(t)$ and $\rho=\rho(t)$. The nonzero components of the Einstein tensor G_ν^μ, and the energy-momentum tensors $T_\nu^{(1)\mu}$, $T_\nu^{(2)\mu}$ (all multiplied by $a^2b^2c^2$) are given by

$$G_0^0=-\frac{\dot{a}\dot{b}}{ab}-\frac{\dot{a}\dot{c}}{ac}-\frac{\dot{b}\dot{c}}{bc}, \tag{3.2}$$

$$G_1^1=\frac{\dot{a}\dot{b}}{ab}+\frac{\dot{b}^2}{b^2}+\frac{\dot{a}\dot{c}}{ac}+\frac{\dot{b}\dot{c}}{bc}+\frac{\dot{c}^2}{c^2}-\frac{\ddot{b}}{b}-\frac{\ddot{c}}{c}, \tag{3.3}$$

$$G_2^2=\frac{\dot{a}^2}{a^2}+\frac{\dot{a}\dot{b}}{ab}+\frac{\dot{a}\dot{c}}{ac}+\frac{\dot{b}\dot{c}}{bc}+\frac{\dot{c}^2}{c^2}-\frac{\ddot{a}}{a}-\frac{\ddot{c}}{c}, \tag{3.4}$$

$$G_3^3=\frac{\dot{a}^2}{a^2}+\frac{\dot{a}\dot{b}}{ab}+\frac{\dot{b}^2}{b^2}+\frac{\dot{a}\dot{c}}{ac}+\frac{\dot{b}\dot{c}}{bc}-\frac{\ddot{a}}{a}-\frac{\ddot{b}}{b}, \tag{3.5}$$

$$T_0^{(1)0}=-a^2b^2c^2V(\Phi)-\tfrac{1}{2}\dot{\Phi}^2, \tag{3.6}$$

$$T_1^{(1)1}=T_2^{(1)2}=T_3^{(1)3}=-a^2b^2c^2V(\Phi)+\tfrac{1}{2}\dot{\Phi}^2, \tag{3.7}$$

$$T_0^{(2)0}=-a^2b^2c^2\rho(t), \tag{3.8}$$

$$T_1^{(2)1}=T_2^{(2)2}=T_3^{(2)3}=a^2b^2c^2p(\rho(t)). \tag{3.9}$$

Due to the equalities (3.7) and (3.9), we can subtract the corresponding Einstein's equations $G_\nu^\mu=T_\nu^{(1)\mu}+T_\nu^{(2)\mu}$, i.e., form the differences (all multiplied by $a^2b^2c^2$) $G_2^2-G_1^1=T_2^{(1)2}+T_2^{(2)2}-T_1^{(1)1}-T_1^{(2)1}$ and $G_3^3-G_1^1=T_3^{(1)3}+T_3^{(2)3}-T_1^{(1)1}-T_1^{(2)1}$ and get the following equations involving only the scale factors:

$$\frac{\dot{a}^2}{a^2}-\frac{\dot{b}^2}{b^2}-\frac{\ddot{a}}{a}+\frac{\ddot{b}}{b}=0, \tag{3.10}$$

$$\frac{\dot{a}^2}{a^2}-\frac{\dot{c}^2}{c^2}-\frac{\ddot{a}}{a}+\frac{\ddot{c}}{c}=0. \tag{3.11}$$

These equations provide the following integrals of motion:

$$b(t)=e^{\lambda t}a(t), \tag{3.12}$$

$$c(t) = e^{\mu t} a(t), \tag{3.13}$$

leaving us with just one undetermined scale factor. At this stage the Klein-Gordon equation (2.9) becomes

$$-V'(\Phi) - \frac{e^{-2(\lambda+\mu)t}\ddot{\Phi}(t)}{a^6(t)} = 0. \tag{3.14}$$

Now, the conservation of the fluid energy-momentum tensor (continuity equation) gives

$$3\frac{\dot{a}}{a} + \frac{\dot{\rho}}{p(\rho)+\rho} + \lambda + \mu = 0. \tag{3.15}$$

It is straightforward to check that the time derivative of the quadratic constraint equation $G_0^0 = T_0^{(1)0} + T_0^{(2)0}$ is identically satisfied by virtue of the remaining spatial equation $G_1^1 = T_1^{(1)1} + T_1^{(2)1}$, the Klein-Gordon equation and the continuity equation [solved for $\ddot{a}(t)$, $\ddot{\Phi}(t)$, $\dot{\rho}(t)$], as expected from the consistency between the aforementioned constraint with the spatial Einstein and the matter equations. Therefore, the equations to be solved are the Klein-Gordon equation (3.14), the continuity equation (3.15) and the constraint equation which, upon multiplication by $-2a^6 e^{2(\lambda+\mu)t}$ reads

$$6\left(\frac{\dot{a}}{a}\right)^2 + 4(\lambda+\mu)\frac{\dot{a}}{a} + 2\lambda\mu - \dot{\Phi}^2 - 2e^{2(\lambda+\mu)t}a^6[V(\Phi)+\rho] = 0. \tag{3.16}$$

In order to have a closed form for the integral of the continuity Eq. (3.15), it is convenient to use the parametrization

$$p(\rho) = \frac{g(\rho)}{g'(\rho)} - \rho \tag{3.17}$$

(the prime denoting differentiation with respect to the argument) through the use of which one obtains the integral

$$\rho = h[\rho_0 a^{-3} e^{-(\lambda+\mu)t}] \tag{3.18}$$

with h being the inverse function to g, i.e., satisfying $h(g(x))=x$.

From the Klein-Gordon equation (3.14) the scale factor and its logarithmic derivative is expressed in terms of the scalar field $\Phi(t)$ and its derivatives as well as $V(\Phi)$,

$$a = \left[-\frac{e^{-2(\lambda+\mu)t}\ddot{\Phi}}{V'(\Phi)}\right]^{1/6}, \tag{3.19}$$

$$\frac{\dot{a}}{a} = \frac{1}{6}\left(\frac{\dddot{\Phi}}{\ddot{\Phi}} - \frac{V''(\Phi)}{V'(\Phi)}\dot{\Phi} - 2(\lambda+\mu)\right). \tag{3.20}$$

The promised decoupling of the scalar field dynamics from the geometry occurs upon inserting (3.18)–(3.20) into (3.16). The result is the following nonlinear, third order ODE for $\Phi(t)$:

$$\left(\frac{\dddot{\Phi}}{\ddot{\Phi}} - \frac{V''(\Phi)}{V'(\Phi)}\dot{\Phi}\right)^2 - 4(\lambda+\mu)^2 + 12\lambda\mu - 6\dot{\Phi}^2 + 12\frac{\ddot{\Phi}}{V'(\Phi)}V(\Phi) + 12\frac{\ddot{\Phi}}{V'(\Phi)}h\left[\rho_0\left(-\frac{\ddot{\Phi}}{V'(\Phi)}\right)^{-1/2}\right] = 0. \tag{3.21}$$

At this stage, any solution to this equation determines, through (3.18) and (3.19) a corresponding solution to the full Einstein plus matter system whose entire space of solution is therefore attained

from the solution space of (3.21). Of course, the price paid, for the moment, is the nonlinearity in the highest time derivative, which has also been raised to third order. Furthermore, normally one would expect that the arbitrary functions h, V need first to be specified before hoping to actually get a solution. Nevertheless, it is quite interesting that further reduction of the order of (3.21), and subsequent complete integration of the whole system, is possible. To this end, we first observe that many terms in (3.21), namely all the nontrivial except the fourth and fifth, are functions of the combination $-\ddot{\Phi}/V'(\Phi)$. We thus define

$$\chi = -\frac{\ddot{\Phi}}{V'(\Phi)} \tag{3.22}$$

and write (3.21) as

$$\left(\frac{\dot{\chi}}{\chi}\right)^2 - 4(\lambda+\mu)^2 + 12\lambda\mu - 6f(\chi) - 12\chi h(\rho_0\chi^{-1/2}) = 0, \tag{3.23}$$

where

$$f(\chi) \equiv \dot{\Phi}^2 + 2\chi V(\Phi) \tag{3.24}$$

implicitly reflects the arbitrariness in choosing $V(\Phi)$. Now (3.23) can be integrated and, by judicious choices for f, h, even give $\chi(t)$ in closed form. Suppose $\chi(t)$ does indeed solve (3.23). Then, multiplying (3.22) by $2\dot{\Phi}V'(\Phi)$ and using (3.24) we get the first order linear differential equation for $f(t)$:

$$\frac{\mathrm{d}f(t)}{\mathrm{d}t} = 2\dot{\chi}(t)V(t) \tag{3.25}$$

and consequently $\Phi(t)$ is given by

$$\frac{\mathrm{d}\Phi(t)}{\mathrm{d}t} = \pm\sqrt{f(\chi(t)) - 2\chi(t)V(t)}. \tag{3.26}$$

Finally, a change of time variable from t to χ [defined in (3.22)] permits the presentation of the entire space of solutions to the system under consideration in closed form. Indeed, considering V, f, Φ as functions of χ one gets from (3.25) and (3.26), respectively,

$$\frac{\mathrm{d}f}{\mathrm{d}\chi} = 2V(\chi), \tag{3.27}$$

$$\frac{\mathrm{d}\Phi(\chi)}{\mathrm{d}\chi}\dot{\chi}(t) = \pm\sqrt{f(\chi) - 2\chi V(\chi)}, \tag{3.28}$$

where the time derivative of χ is given by the constraint (3.23). The integration of these two equations is trivial, yielding f, Φ as

$$f(\chi) = \sigma + 2\int V(\chi)\mathrm{d}\chi, \tag{3.29}$$

$$\Phi(\chi) = \kappa \pm \int \frac{1}{\chi}\sqrt{\frac{f(\chi) - 2\chi V(\chi)}{4(\lambda+\mu)^2 - 12\lambda\mu + 6f(\chi) + 12\chi h(\rho_0\chi^{-1/2})}}\mathrm{d}\chi. \tag{3.30}$$

The line element in the new time χ reads

$$ds^2 = -\frac{d\chi^2}{\chi[4(\lambda+\mu)^2 - 12\lambda\mu + 6f(\chi) + 12\chi h(\rho_0\chi^{-1/2})]} + [e^{-2(\lambda+\mu)t(\chi)}\chi]^{1/3}\,dx^2 + [e^{(4\lambda-2\mu)t(\chi)}\chi]^{1/3}\,dy^2 + [e^{(-2\lambda+4\mu)t(\chi)}\chi]^{1/3}\,dz^2 \tag{3.31}$$

with $t(\chi)$ given by the integral form of (3.23),

$$t(\chi) = \pm\int \frac{1}{\chi\sqrt{4(\lambda+\mu)^2 - 12\lambda\mu + 6f(\chi) + 12\chi h(\rho_0\chi^{-1/2})}}d\chi \tag{3.32}$$

while the density and pressure are given as

$$\rho(\chi) = h(\rho_0\chi^{-1/2}), \quad p(\chi) = \rho_0\chi^{-1/2}h'(\rho_0\chi^{-1/2}) - h(\rho_0\chi^{-1/2}) \tag{3.33}$$

the prime denoting differentiation with respect to the argument. Quite independently of the way these solutions were obtained, one can straightforwardly check (through, say, a symbolic computing facility) that they do satisfy all 10 Einstein's equations, the generalized KG and the continuity equation. Furthermore, since no extra ansatz has been involved in the process of integration of the system (2.8)–(2.10), equations (3.29)–(3.33) represent the full space of solutions to the Einstein plus matter system considered. The functions V, h can be freely specified to obtain special case solutions.

IV. DECOUPLING OF THE SCALAR DEGREE AND THE SOLUTION SPACE FOR THE BIANCHI TYPE V

In this case the basis one-forms are $\sigma^1 = e^{-x}\,dy$, $\sigma^2 = e^{-x}\,dz$, $\sigma^3 = dx$. The $G^0_1 = 0$ Einstein equation [due to spatial homogeneity $\Phi = \Phi(t)$ and $\rho = \rho(t)$ and therefore there is no corresponding component of the matter tensor] implies $c = ab$. Thus the initial metric is taken as

$$g_{\mu\nu} = \begin{pmatrix} -a^3b^3 & 0 & 0 & 0 \\ 0 & ab & 0 & 0 \\ 0 & 0 & a^2e^{-2x} & 0 \\ 0 & 0 & 0 & b^2e^{-2x} \end{pmatrix}. \tag{4.1}$$

The nonzero components of the Einstein tensor G^μ_ν, and the energy-momentum tensors $T^{(1)\mu}_\nu$, $T^{(2)\mu}_\nu$, all multiplied by a^3b^3, are given by

$$G^0_0 = 3a^2b^2 - \frac{\dot{a}^2}{2a^2} - \frac{2\dot{a}\dot{b}}{ab} - \frac{\dot{b}^2}{2b^2}, \tag{4.2}$$

$$G^1_1 = a^2b^2 + \frac{3\dot{a}^2}{2a^2} + \frac{2\dot{a}\dot{b}}{ab} + \frac{3\dot{b}^2}{2b^2} - \frac{\ddot{a}}{a} - \frac{\ddot{b}}{b}, \tag{4.3}$$

$$G^2_2 = a^2b^2 + \frac{\dot{a}^2}{a^2} + \frac{2\dot{a}\dot{b}}{ab} + \frac{2\dot{b}^2}{b^2} - \frac{\ddot{a}}{2a} - \frac{3\ddot{b}}{2b}, \tag{4.4}$$

$$G^3_3 = a^2b^2 + \frac{2\dot{a}^2}{a^2} + \frac{2\dot{a}\dot{b}}{ab} + \frac{\dot{b}^2}{b^2} - \frac{3\ddot{a}}{2a} - \frac{\ddot{b}}{2b}, \tag{4.5}$$

$$T^{(1)0}_0 = -a^3b^3V(\Phi) - \tfrac{1}{2}\dot{\Phi}^2, \tag{4.6}$$

$$T_1^{(1)1} = T_2^{(1)2} = T_3^{(1)3} = -a^3b^3V(\Phi) + \tfrac{1}{2}\dot{\Phi}^2, \tag{4.7}$$

$$T_0^{(2)0} = -a^3b^3\rho(t), \tag{4.8}$$

$$T_1^{(2)1} = T_2^{(2)2} = T_3^{(2)3} = a^3b^3p(\rho(t)). \tag{4.9}$$

The situation is similar to the type I case, and thus forming the difference (multiplied by a^3b^3) $G_2^2 - G_1^1 = T_2^{(1)2} + T_2^{(2)2} - T_1^{(1)1} - T_1^{(2)1}$ we get the following equation involving only the scale factors:

$$-\frac{\dot{a}^2}{2a^2} + \frac{\dot{b}^2}{2b^2} + \frac{\ddot{a}}{2a} - \frac{\ddot{b}}{2b} = 0, \tag{4.10}$$

which can be integrated yielding

$$b(t) = e^{\lambda t}a(t). \tag{4.11}$$

The Klein-Gordon equation (2.9) becomes

$$-V'(\Phi) - \frac{e^{-3\lambda t}\ddot{\Phi}(t)}{a^6(t)} = 0 \tag{4.12}$$

while the conservation of the fluid energy-momentum tensor (continuity equation) gives

$$3\frac{\dot{a}}{a} + \frac{\dot{\rho}}{p(\rho)+\rho} + \frac{3}{2}\lambda = 0. \tag{4.13}$$

Again, the only other equation to be solved is the constraint equation which reads

$$6\left(\frac{\dot{a}}{a}\right)^2 + 6\lambda\frac{\dot{a}}{a} + \lambda^2 - 6e^{2\lambda t}a^4 - \dot{\Phi}^2 - 2e^{3\lambda t}a^6(V(\Phi)+\rho) = 0, \tag{4.14}$$

where the fourth term is the only nontrivial difference from the corresponding equation (3.16) and its presence is due to the nonvanishing curvature of the spatial slice.

Integrating (4.13) [in the parametrization (3.17)] and solving (4.12) for $a(t)$, we obtain the following results for the matter density $\rho(t)$, the scale factor $a(t)$ and its logarithmic derivative

$$\rho = h(\rho_0 a^{-3} e^{-(3/2)\lambda t}), \tag{4.15}$$

$$a = \left(-\frac{e^{-3\lambda t}\ddot{\Phi}}{V'(\Phi)}\right)^{1/6}, \tag{4.16}$$

$$\frac{\dot{a}}{a} = \frac{1}{6}\left(\frac{\dddot{\Phi}}{\ddot{\Phi}} - \frac{V''(\Phi)}{V'(\Phi)}\dot{\Phi} - 3\lambda\right). \tag{4.17}$$

Use of these equations in the quadratic constraint equation (4.14) (multiplied by $-2e^{3\lambda t}a^6$) yields

$$\left(\frac{\dddot{\Phi}}{\ddot{\Phi}} - \frac{V''(\Phi)}{V'(\Phi)}\dot{\Phi}\right)^2 - 3\lambda^2 - 36\left(-\frac{\ddot{\Phi}}{V'(\Phi)}\right)^{2/3} - 6\dot{\Phi}^2 + 12\frac{\ddot{\Phi}}{V'(\Phi)}V(\Phi) + 12\frac{\ddot{\Phi}}{V'(\Phi)}h\left(\rho_0\left(-\frac{\ddot{\Phi}}{V'(\Phi)}\right)^{-1/2}\right) = 0 \tag{4.18}$$

which, with the same definition of χ, translates into

$$\left(\frac{\dot{\chi}}{\chi}\right)^2 - 3\lambda^2 - 36\chi^{2/3} - 6f(\chi) - 12\chi h(\rho_0\chi^{-1/2}) = 0. \tag{4.19}$$

By arguments completely analogous to the previous type I case, the final form of the solution is, in this case

$$f(\chi) = \sigma + 2\int V(\chi)\mathrm{d}\chi, \tag{4.20}$$

$$\Phi(\chi) = \kappa \pm \int \frac{1}{\chi}\sqrt{\frac{f(\chi) - 2\chi V(\chi)}{3\lambda^2 + 36\chi^{2/3} + 6f(\chi) + 12\chi h(\rho_0\chi^{-1/2})}}\mathrm{d}\chi, \tag{4.21}$$

$$\mathrm{d}s^2 = -\frac{\mathrm{d}\chi^2}{\chi[3\lambda^2 + 36\chi^{2/3} + 6f(\chi) + 12\chi h(\rho_0\chi^{-1/2})]} + \chi^{1/3}\,\mathrm{d}x^2 + e^{-\lambda t(\chi)-2x}\chi^{1/3}\,\mathrm{d}y^2 + e^{\lambda t(\chi)-2x}\chi^{1/3}\,\mathrm{d}z^2 \tag{4.22}$$

with $t(\chi)$ given by the integral form of (4.19),

$$t(\chi) = \pm\int \frac{1}{\chi\sqrt{3\lambda^2 + 36\chi^{2/3} + 6f(\chi) + 12\chi h(\rho_0\chi^{-1/2})}}\mathrm{d}\chi, \tag{4.23}$$

while the density and pressure are given as

$$\rho(\chi) = h(\rho_0\chi^{-1/2}), \quad p(\chi) = \rho_0\chi^{-1/2}h'(\rho_0\chi^{-1/2}) - h(\rho_0\chi^{-1/2}). \tag{4.24}$$

The remarks at the end of the preceding section apply also here.

V. DISCUSSION AND CONCLUSIONS

We have discussed the dynamics of a scalar field with an arbitrary potential, minimally coupled to a general (anisotropic) Bianchi type I and V geometry, in the presence of a perfect fluid source obeying a general equation of state. In the case of vacuum, the rich structure of outer automorphisms for these two symmetry groups entails the existence of some integrals of motion: Indeed, consider the generators of the rigid symmetries (2.3), i.e., the vector fields in the space of dependent variables $X_I = \lambda^\rho_{I\alpha}\gamma_{\rho\beta}(\partial/\partial\gamma_{\alpha\beta})$ where λ^α_β satisfy $\lambda^\alpha_{I\rho}C^\rho_{\beta\gamma} = \lambda^\rho_{I\beta}C^\alpha_{\rho\gamma} + \lambda^\rho_{I\gamma}C^\alpha_{\beta\rho}$. If one performs the appropriate change of variables $\gamma_{\alpha\beta} \to z_{\alpha\beta}$ which brings one (or more, if possible) generator into each canonical form, say $\partial/\partial z_{11}$, then Einstein's field equations written in the new variables do not explicitly depend on z_{11}. Thus the system becomes of first order in the variable $\dot{z}_{11}$ and therefore an integral of motion arises.

The initial choice of the time gauge in which the lapse is equal to the determinant of the scale factor matrix has a twofold advantage: First, it enables the corresponding integrals of motion (in the presence of the matter content chosen) to be revealed. Second, it makes the Klein-Gordon equation purely algebraic in the scale factor variables. As a result, when the utilization of the integrals of motion has reduced the number of these variables to one, this equation gives this last scale factor as a function of the second derivative of the scalar field, the derivative of the potential with respect to the scalar field, and of time. Substitution of this form of the scale factor into the only equation remaining to be solved, i.e., the quadratic constraint, results in a single ODE for the scalar field (without any explicit time dependence). The utilization of a final time gauge adapted to the scalar field enables the reduction of this equation to first order and subsequently leads to the complete integration of the entire system of Einstein plus matter field equations. The description of the space of solutions contains, in an integral form, the arbitrary functions of the final time χ, $V(\chi)$, and $h(\rho_0\chi^{-1/2})$. The presence of this twofold arbitrariness corresponds to the fact that we have not specified either the form of the potential (as a function of the scalar field) or the equation of state. It is evident that prescribing $V(\chi)$ and $h(\rho_0\chi^{-1/2})$ implicitly corresponds to a choice of

potential form and equation of state. For example, the choice $h=A(\rho_0\chi^{-1/2})^{1+\gamma}$ gives through (4.24) $p=\gamma\rho$, i.e., the barotropic equation of state. For the scalar field, if we take the particular case $\lambda=\mu=\sigma=h(\rho_0\chi^{-1/2})=0$ (i.e., flat Robertson-Walker with no fluid) the choice $V(\chi)=C/\sqrt{\chi}$ corresponds to the functional form $V=\pm Ce^{\sqrt{3}(\kappa-\Phi)}$. If, on the other hand, someone insists in prescribing $V(\Phi)$ and $p(\rho):=p(h)$ then the situation must be dealt with in the following manner: As far as the density is concerned, the equation giving the pressure becomes the holonomic, first order differential equation $p(h)=wh'(w)-h(w)$ with w standing for $\rho_0\chi^{-1/2}$ which can be straightforwardly integrated. For example, a barotropic equation $p:=\gamma\rho$ gives $\rho=A(\rho_0\chi^{-1/2})^{1+\gamma}$. As far as the matter field is concerned, the situation is somewhat more complicated as the results of choosing a particular form $V(\Phi)$ are influenced by the choice of the density h. As an example consider again the case $\lambda=\mu=\sigma=h(\rho_0\chi^{-1/2})=0$ and an arbitrary potential form $V(\Phi)$. Relaxing for a moment (3.30), we get the following Klein-Gordon equation

$$-\frac{V'(\Phi)}{V(\Phi)}+\frac{6\chi}{6\chi^2\Phi'^2(\chi)}[2\chi\Phi''(\chi)-6\chi^2\Phi'^3(\chi)+3\Phi'(\chi)]=0,$$

which may be difficult to solve depending on the choice of $V(\Phi)$. This is the price paid for insisting on prescribing $V(\Phi)$ and not $V(\chi)$ in which case the solution would be given by (3.29)–(3.33) or (4.20)–(4.24) correspondingly. The particular choice $V=V_0e^{-\lambda\Phi}$ corresponds to the case considered in Ref. 11 and the equation above can be dealt with by choosing a new time $\chi=e^{3\tau/2}$, in which the equation becomes the following first order in the derivative $\omega\equiv d\Phi/d\tau$:

$$48\frac{d\omega}{d\tau}-96\omega^3+24\lambda\omega^2-9\lambda=0.$$

Finally, there are two cases which, at first sight, need to be separately examined. The first concerns the case of a constant potential $V(\Phi)\equiv V_0$, i.e., a cosmological constant term. Then, $V'(\Phi)=0$ and the definition of the final time χ in Eq. (3.32) seems to be precarious. However, the Klein-Gordon Eq. (3.14) then implies that also $\ddot{\Phi}=0$ and, surprisingly enough, χ does exist. Indeed, substituting $V(\Phi)\equiv V_0$ in the solutions (3.29)–(3.33) or (4.20)–(4.24) one can see that the solution is still valid. This holds true even for $V_0=0$. The second case arises when the ratio $\ddot{\Phi}/V'(\Phi)=-1/c^6$, for, then, the change of time from t to χ is not valid. In this case, the remaining scale factor is given by $a(t)=ce^{-(\lambda+\mu)t/3}$ in the type I case or $a(t)=ce^{-\lambda t/2}$ in the type V case. The continuity equation [(3.15) or (4.12), respectively] implies that the pressure and density are constants, say, p_0 and ρ_0. The remaining equations dictate $\Phi(t)=At+B$ and $V(\Phi)=V_0$ and there exists a relation between c, p_0, ρ_0, A, and B due to the quadratic constraint.

The general properties of the space of solutions found for both type I and type V cases, e.g., isotropization, attractors and self-similarity, and quintessence, will be examined in a forthcoming paper, in which also particular cases of high interest are to be explicitly elaborated. Possible applications of the method exhibited here can be the cases of $D+1$ spatially homogeneous spacetimes, in which the outer automorphisms are rich enough to provide sufficient integrals of motion. Then the method will be applicable if the matter content is such that the integrals of motion persist.

A technique is provided that allows to associate to a Hamiltonian another, ω-modified, Hamiltonian, which reduces to the original one when the parameter ω vanishes, and for $\omega>0$ features an *open*, hence *fully dimensional*, region in its phase space where *all* its solutions are *isochronous*, i.e., *completely periodic* with the *same* period. The class of Hamiltonians to which this technique is applicable is large: it includes for instance the Hamiltonian characterizing the classical many-body problem with potentials that are *translation-invariant* but otherwise *completely arbitrary*, which is largely used in this paper to illustrate these findings. We also discuss variants of this technique that yield *partially isochronous* Hamiltonians, which also feature a region in their phase space where *all* solutions are *isochronous*, that region having however a bit less than full dimensionality (for instance codimension one or two) in phase space. © *2006 American Institute of Physics*. [DOI: 10.1063/1.2188211]

I. INTRODUCTION AND OUTLINE OF MAIN FINDINGS

Not too long ago a (so-called) "trick" was introduced,[2] characterized by a *real* parameter ω and capable of transforming an *autonomous* dynamical system (belonging to a fairly large class, see below) into another, as well *autonomous*, system. The ω-modified dynamical system thereby obtained, while reducing to the original system for $\omega=0$, features for $\omega>0$ in its phase space an *open*, hence *fully dimensional*, region in which *all* motions are *completely periodic* with the fixed period

$$T=\frac{2\pi}{\omega}, \tag{1}$$

or possibly with a (generally small) *integer* multiple of this period. Here and hereafter by *completely periodic* we mean that the periodicity property is shared by *all* the dependent variables. Systems featuring such a periodicity property—with a period independent of the initial data provided the initial data belong to some *open, fully dimensional* set of such data—are here called *isochronous*; and we call *partially isochronous* the dynamical systems for which the *complete periodicity* property with a fixed period obtains for a set of initial data having a bit less than full dimensionality in phase space (for instance, for a set of initial data belonging to a manifold in phase space of codimension one or two, see below).

This trick has been extensively exploited to identify and investigate *isochronous* systems.[1–38]

Here, to illustrate our main findings, we focus mainly on the dynamical system describing an N-body problem, as characterized by the Hamiltonian

$$H(\underline{p},\underline{q}) = \frac{1}{2}\sum_{n=1}^{N} p_n^2 + V(\underline{q}) + C, \tag{2}$$

where the *arbitrary* constant C has been introduced for convenience (see below) and the potential $V(\underline{q}) \equiv V(q_1, q_2, \ldots, q_N)$ shall generally be assumed *translation invariant*,

$$V(\underline{q} + a) \equiv V(q_1 + a, q_2 + a, \ldots, q_N + a) = V(\underline{q}), \tag{3a}$$

with a an arbitrary constant, entailing (for infinitesimal a)

$$\sum_{n=1}^{N} \frac{\partial V(\underline{q})}{\partial q_n} = 0. \tag{3b}$$

This is the standard Hamiltonian for the nonrelativistic N-body problem, entailing the standard Hamiltonian equations of motion

$$\dot{q}_n = p_n, \quad \dot{p}_n = -\frac{\partial V(q)}{\partial q_n}, \tag{4}$$

as well as the corresponding Newtonian equations of motion

$$\ddot{q}_n = -\frac{\partial V(\underline{q})}{\partial q_n}, \tag{5}$$

the total momentum conservation formula,

$$P(\underline{p}) = \sum_{n=1}^{N} p_n, \tag{6a}$$

$$\dot{P} = 0, \tag{6b}$$

and the "center-of-mass" evolution

$$Q(\underline{q}) = \frac{1}{N}\sum_{n=1}^{N} q_n, \tag{7a}$$

$$Q(t) = Q(0) + \frac{P}{N}t. \tag{7b}$$

Notation: Here and always below N is a positive integer ($N \geqslant 2$), the (*real*) independent variable t has the significance of *physical time*, superimposed dots indicate differentiations with respect to this variable, indices such as n, m run from 1 to N unless otherwise indicated, underlined symbols denote N-vectors, for instance $\underline{q} \equiv (q_1, \ldots, q_N)$, and of course we use (here and below) the short-hand notation according to which $Q(t) \equiv Q[\underline{q}(t)]$. Note that, for simplicity, we assume here all the particles to have the same mass, and the motions to occur in one-dimensional space; but these restrictions can be dispensed with, see Sec. IV.

In the context of this N-body problem the trick consists of the following change of dependent and independent variables:

$$\breve{q}_n(t) = \exp(i\lambda\omega t) q_n(\tau), \tag{8a}$$

$$\tau = \frac{\exp(i\omega t) - 1}{i\omega}, \tag{8b}$$

where λ is a constant to be chosen appropriately (see below). Note that this change of variables entails the following relations among the initial data for the "old" dependent variables q_n and the "new" dependent variables $\breve{q}_n$:

$$q_n(0) = \breve{q}_n(0), \quad q_n'(0) = \dot{\breve{q}}(0) - i\lambda\omega\breve{q}_n(0). \tag{9}$$

Here and hereafter primes denote differentiations with respect to the argument of the function they are appended to, and of course $q_n'(0)$ denotes the value of $q_n'(\tau) \equiv \mathrm{d}q_n(\tau)/\mathrm{d}\tau$ at $\tau = 0$.

The insertion of this change of variables, (8), in the (*autonomous*) dynamical system characterized by the Newtonian equations of motion (5) yields, as it can be easily verified, the (*autonomous*) dynamical system

$$\ddot{\breve{q}}_n - (2\lambda + 1)i\omega\dot{\breve{q}}_n - \lambda(\lambda + 1)\omega^2\breve{q}_n = -\frac{\partial V(\underline{\breve{q}})}{\partial \breve{q}_n}, \tag{10a}$$

provided the potential $V(\underline{q})$ satisfies the scaling property

$$V(c\underline{q}) = c^{\gamma}V(\underline{q}) \tag{10b}$$

(where c is an arbitrary constant and γ is the exponent characterizing the scaling property) and correspondingly the parameter λ is assigned as follows:

$$\lambda = \frac{2}{\gamma - 2}. \tag{10c}$$

This new system of ODEs (10), determining the time evolution of the new dependent variables $\breve{q}_n \equiv \breve{q}_n(t)$, is the ω-dependent dynamical system and, as we now show, it is generally *isochronous* provided the parameter λ is *real* and *rational*. Note that λ is indeed *real* and *rational* provided γ, see (10b), is itself *real* and *rational* [and different from 2, $\gamma \neq 2$; see (10c)]. Also note that the dynamical variables $\breve{q}_n(t)$ are now necessarily evolving in the *complex* $\breve{q}$-plane; this shall be the case as well for all the evolutions considered hereafter. Of course in order that derivatives with respect to *complex* variables [such as τ, see (8b)] make good sense, one must deal (as we shall always do) with *analytic* functions. On the other hand, any evolution of the N *complex* coordinates $\breve{q}_n(t)$ is completely equivalent to the evolution of the $2N$ coordinates that obtain by considering separately the *real* and the *imaginary* parts of these coordinates; and there are cases (see for instance Chap. 4 of Ref. 3) when such an evolution can, as it were "more physically," be interpreted—by identifying the *complex* plane with a *real* plane—as the evolution of N "physical" pointlike particles in a plane [say, N particles the positions of which are identified by *real* vectors in the *horizontal* plane, $\vec{r}_n(t) \equiv (\mathrm{Re}[\breve{q}_n(t)], \mathrm{Im}[\breve{q}_n(t)], 0)$].

To show that the time evolution entailed by the equations of motion (10) (with λ *real* and *rational*) is indeed *isochronous* we point out to begin with that the change of dependent variable (8b) entails that, as the (*real*) "physical time" variable t evolves from $t = 0$ onwards, the (*complex*) timelike variable τ goes round and round, in the *complex* τ-plane, on the circle C centered at i/ω and having radius $1/\omega$ (draw diagram), traveling a full circle in every time interval T, see (1). Hence, if the functions $q_n(\tau)$ of the *complex* variable τ are *holomorphic* in the (closed) disk D enclosed by the circle C, the corresponding variables $\breve{q}_n(t)$ [see (8) and (1)] are λ-*periodic* with period T,

$$\breve{q}_n(t + T) = \exp(2i\pi\lambda)\breve{q}_n(t), \tag{11}$$

and this entails that they are indeed *periodic* with period T if λ is an *integer*, or with a period which is an *integer multiple* of T if λ is a (*real* and) *rational* number (as we hereafter assume). On

the other hand, the functions $q_n(\tau)$ are just the analytic continuation for *complex time* of the solutions of the Newtonian equations of motion (5)—corresponding to the formal replacement of the *real* variable t by the *complex* variable τ, or equivalently to the replacement of the equations of motion (5) with the analogous equations

$$q_n'' = -\frac{\partial V(q)}{\partial q_n}, \tag{12}$$

where $q_n \equiv q_n(\tau)$ and of course appended primes indicate differentiations with respect to the new (*complex*) independent variable τ. It is then clear that, provided the initial data [see (9)] for these equations of motion are so assigned as to avoid that their right-hand sides be *singular* (at $\tau=0$)—as we shall hereafter assume—their solutions $q_n(\tau)$ are certainly *holomorphic* functions of the *complex* variable τ for $|\tau|<R$ for some $R>0$, namely (at least) inside a circle of *positive* radius R, centered at the origin ($\tau=0$) in the *complex* τ-plane—as implied by the standard theorem guaranteeing the existence, uniqueness and analyticity of the solutions of analytic (systems of) ODEs. The (minimum) value of R depends on the *initial* values of the right-hand sides of the equations (of motion in the *complex* timelike variable τ) (12), on the distances in the (*complex*) q-plane of the *initial* assignments $q_n(0)$ of the dependent variables from the values of these variables that cause the right-hand sides of the ODEs (12) to become *singular*, and on the (moduli of) the *initial* assignments $q_n'(0)$ of the derivatives [see (9)]. But it stands to reason (see examples below, and in the literature quoted above) that there generally exist an *open* set of initial data $\breve{q}_n(0)$ and $\breve{q}_n(0)$ having *full dimensionality* in the (phase) space of these dependent variables such that [via (9)]

$$R > \frac{2}{\omega}. \tag{13}$$

Clearly the analysis we just made implies then that the time evolution of the dependent variables $\breve{q}_n(t)$ resulting from such initial data is *completely periodic*, since this inequality, (13), implies that the circle of radius R centered at the origin in the *complex* τ-plane *encloses* the circular disk D, implying the *holomorphic* character of the functions $q_n(\tau)$ in this (closed) disk.

The development reported so far has tersely reproduced—in the specific context of the standard many-body problem, characterized by the Newtonian equations of motion (5)—the argument associating to a given dynamical system an ω-modified system—in this case, characterized by the Newtonian equations of motions (10)—that has the remarkable property to be *isochronous*. As indicated by the argument reviewed above, the main condition required to obtain such an *isochronous* system is the validity of the scaling property (10b) with γ *real* and *rational* ($\gamma \neq 2$). And let us reemphasize that, as implied by the above argument and as discussed in detail in the literature (see for instance Refs. 8 and 11), in order that the ω-modified system of Newtonian equations (10) be *isochronous* it is by no means required that the original system from which it was obtained [namely, the system of Newtonian equations of motion (5) corresponding to (10) with $\omega=0$] be itself *isochronous* or *integrable*.

But note that it is *far from obvious*—and indeed often *not true*—that the new ω-modified Newtonian equations of motion (10) be *Hamiltonian*, i.e., obtainable from a Hamiltonian.

The main contribution of the present paper is to introduce a technique producing, from a given *Hamiltonian* H, an ω-modified *Hamiltonian* $\tilde{H}$ yielding *isochronous* equations of motion. The main requirement on the original Hamiltonian H for the applicability of this technique is that the dynamics it entails allow the identification of a "collective variable," explicitly defined in terms of the Hamiltonian canonical coordinates and momenta, the time evolution of which is essentially identical to *time* itself. If we denote such a variable as $\Theta(\underline{p},\underline{q})$, it will be characterized by the formula

$$[\Theta(\underline{p},\underline{q}),H(\underline{p},\underline{q})] = 1. \tag{14}$$

Notation: Here and hereafter the *Poisson bracket* $[F,G]$ of two functions $F(\underline{p},\underline{q}),G(\underline{p},\underline{q})$ of the canonical coordinates and momenta is defined in the standard manner,

$$[F(\underline{p},\underline{q}),G(\underline{p},\underline{q})]=\sum_{n=1}^{N}\left[\frac{\partial F(\underline{p},\underline{q})}{\partial q_n}\frac{\partial G(\underline{p},\underline{q})}{\partial p_n}-\frac{\partial F(\underline{p},\underline{q})}{\partial p_n}\frac{\partial G(\underline{p},\underline{q})}{\partial q_n}\right]. \tag{15}$$

The ω-modified Hamiltonian $\widetilde{H}$ yielding *isochronous* motions is then defined as follows:

$$\widetilde{H}(\underline{p},\underline{q};\omega)=u(\underline{p},\underline{q};\omega)H(\underline{p},\underline{q}), \tag{16a}$$

$$u(\underline{p},\underline{q};\omega)=1+i\omega\Theta(\underline{p},\underline{q}). \tag{16b}$$

Let us emphasize that hereafter we only consider the time evolution yielded by this ω-modified Hamiltonian $\widetilde{H}(\underline{p},\underline{q};\omega)$, and therefore the time evolution of functions of the Hamiltonian variables p_n and q_n—such as $H(\underline{p},\underline{q}),P(\underline{p}),Q(\underline{q}),u(\underline{p},\underline{q};\omega)$, see (2), (6a), (7a), and (16b)—obtains via the time dependence of these Hamiltonian variables $p_n\equiv p_n(t),q_n\equiv q_n(t)$ implied by the standard Hamiltonian equations (see below) associated with the Hamiltonian $\widetilde{H}(\underline{p},\underline{q};\omega)$; hence the time evolution of these collective variables is given by the standard formula characterizing the Hamiltonian evolution of any function $F(t)=F[\underline{p}(t),\underline{q}(t)]$ of the Hamiltonian variables,

$$\dot{F}=[F,\widetilde{H}]. \tag{17}$$

In particular it is crucial to note that—as implied by this formula via (16) and (14)—the collective quantities $H(t)$, respectively, $u(t;\omega)$ evolve now as follows:

$$\dot{H}=-i\omega H \tag{18a}$$

entailing

$$H(t)=H(0)\exp(-i\omega t), \tag{18b}$$

respectively,

$$\dot{u}=i\omega u \tag{19a}$$

entailing

$$u(t;\omega)=u(0;\omega)\exp(i\omega t). \tag{19b}$$

Note the consistency, via (16a), of the time evolutions (18b) and (19b) with the obvious fact that the Hamiltonian $\widetilde{H}$ is a constant of motion.

To illustrate our findings in a specific context we now focus again on the (unmodified) N-body Hamiltonian (2), taking advantage of the fact that, as a consequence of its *Galilean invariance*, see (2) and (3), a collective variable Θ satisfying (14) is provided by the following explicit formula:

$$\Theta(\underline{p},\underline{q})=\frac{NQ(\underline{q})}{P(\underline{p})}, \tag{20}$$

see (6a) and (7a). Of course to this quantity one could add an arbitrary function of P, and also of other quantities, if any, which Poisson commute with the (unmodified) Hamiltonian H and are therefore constants of motion for the evolution determined by this Hamiltonian; but for simplicity we refrain from doing so in the following.

In the following Sec. II we demonstrate, for this specific case, the *isochronous* character of the ω-modified Hamilton $\widetilde{H}$, as given by (16) with (2) and (20), (6a) and (7a). Let us emphasize that, quite remarkably, to prove the *isochronous* character of this ω-modified Hamiltonian *no* additional

property of the original N-body Hamiltonian H besides *Galilean invariance* is required, in particular *no* scaling property such as that entailed by the condition (10b)—which was instead essential to allow the transformation via the trick (8) from the (*autonomous*) *Newtonian* equations of motion (5) to the (as well *autonomous*) ω-modified *Newtonian* equations of motion (10). On the other hand the *Newtonian* equations of motion entailed by the ω-modified Hamiltonian $\widetilde{H}$, while having the appealing property to be themselves evidently *Hamiltonian* (which opens the possibility to study the quantized versions of the corresponding N-body problems) and of course to be *isochronous*, seem somewhat less susceptible of a "physical interpretation" than the equations, see (10), yielded by the standard approach based on the application of the trick (8); indeed these novel *Newtonian* equations of motion cannot be generally written in quite explicit form, although the corresponding *Hamiltonian* equations can be quite explicitly exhibited and are indeed relatively neat, see below.

In Sec. III we tersely discuss some specific examples of many-body problems, characterized by specific assignments of the potential $V(\underline{q})$. In Sec. IV we outline various generalizations of our approach, still in the context of nonrelativistic N-body problems: to the case with different masses, and to multidimensional space. In Sec. V we indicate how our approach to generate *isochronous* Hamiltonian systems can be applied in the context of more general Hamiltonian systems than those characterizing the nonrelativistic many-body problem. In Sec. VI we consider (different) variants of our technique [as applied again to the standard many-body problem, see (2), (3), (4) and (5)], yielding (*partially isochronous*) modified Hamiltonians characterized by a time evolution that features a set of initial data—having however a bit less than full generality in phase space, being restricted to lie on a manifold of nonvanishing (but generally small, and in any case N-independent) codimension—out of which emerge motions *all* of which are again *completely periodic* with the *same*, *fixed* period. The paper is concluded by a Sec. VII entitled Outlook, in which we mention further developments (to be pursued in future publications) suggested by the results reported in this paper.

II. THE ISOCHRONOUS *N*-BODY HAMILTONIAN

In this section we demonstrate the *isochronous* character of the time evolution entailed by the ω-modified N-body Hamiltonian $\widetilde{H}(\underline{p},\underline{q};\omega)$ associated to the classical N-body problem, as defined in the preceding section by (16) with (2), (20), (6a), and (7a).

The time evolution associated with the Hamiltonian $\widetilde{H}(\underline{p},\underline{q};\omega)$ is given by the following formulas:

$$\dot{q}_n = [q_n, \widetilde{H}] = \frac{\partial \widetilde{H}}{\partial p_n} = u p_n + \frac{(1-u)H}{P}, \tag{21}$$

$$\dot{p}_n = [p_n, \widetilde{H}] = -\frac{\partial \widetilde{H}}{\partial q_n} = -u\frac{\partial V(\underline{q})}{\partial q_n} - \frac{i\omega H}{P}. \tag{22}$$

From the latter Hamiltonian equations, (22), we get [via (6a) and (3b)]

$$\dot{P} = [P, \widetilde{H}] = -\frac{Ni\omega H}{P}, \tag{23a}$$

entailing, via (18b),

$$P(t) = P(0)\left[\frac{1-\alpha\exp(-i\omega t)}{1-\alpha}\right]^{1/2}. \tag{23b}$$

Here and often below we use the short-hand notation

$$\alpha = \frac{2NH(0)}{2NH(0) - P^2(0)}. \tag{24}$$

Likewise, from the Hamiltonian equations of motion (21) and (7a) we get

$$\dot{Q} = \frac{uP}{N} + \frac{(1-u)H}{P}, \tag{25a}$$

and, via (16b), (20), and (19b),

$$Q(t) = \left[\frac{Q(0)\exp(i\omega t)}{P(0)} + \frac{\exp(i\omega t) - 1}{Ni\omega} \right] P(t), \tag{25b}$$

as well as [from (25a), (16b), and (20)]

$$H = -\frac{P^2\left(\dot{Q} - i\omega Q - \frac{P}{N}\right)}{Ni\omega Q}. \tag{26}$$

Finally we recall that the time evolution of $H(t)$ and $u(t;\omega)$ is provided by the explicit expressions (18) and (19), of course with

$$H(0) = \frac{1}{2}\sum_{n=1}^{N} p_n^2(0) + V(\underline{q}(0)) + C, \tag{27}$$

$$u(0;\omega) = 1 + Ni\omega\frac{Q(0)}{P(0)} = 1 + i\omega\frac{\sum_{n=1}^{N} q_n(0)}{\sum_{n=1}^{N} p_n(0)}. \tag{28}$$

It clearly follows from its explicit expression (23b) that $P(t)$ has (primitive) period T if $|\alpha| < 1$ and has period $2T$ if $|\alpha| > 1$:

$$P(t+T) = P(t) \quad \text{if } |\alpha| < 1, \tag{29a}$$

$$P(t+2T) = P(t) \quad \text{if } |\alpha| > 1. \tag{29b}$$

Note that in the special case when the modulus of α is just unity, $|\alpha| = 1$, clearly $P(t)$, see (23b), vanishes at some finite (*real*) value $t = t_s, P(t_s) = 0$, and clearly at this time t_s the equations of motion (21) and (22) become *singular* due to the blow-up of their right-hand sides. This is not surprising, in view of the appearance of P in the *denominator* in the definition of our Hamiltonian $\tilde{H}(\underline{p}, \underline{q}; \omega)$, see (16) with (20). And of course the periodicity properties of $P(t)$ are as well shared by the center-of-mass coordinate $Q(t)$, see (25b),

$$Q(t+T) = Q(t) \quad \text{if } |\alpha| < 1, \tag{30a}$$

$$Q(t+2T) = Q(t) \quad \text{if } |\alpha| > 1. \tag{30b}$$

Hence we conclude that the motion of the center of mass of our system is *isochronous*, the *isochronicity period* being T or $2T$ depending whether the initial data entail that the modulus of the quantity α, see (24), is smaller or larger than unity [but recall that $H(t)$ and $u(t;\omega)$ are always *periodic* with period T, see (18) and (19)].

Let us now turn to the *relative* motion. To this end let us set

$$p_{n,m} = p_n - p_m, \quad q_{n,m} = q_n - q_m. \tag{31}$$

One then notes by a routine computation [see (20)] that

$$[p_{n,m}, \Theta] = 0, \quad [q_{n,m}, \Theta] = 0, \tag{32}$$

from which it immediately follows that

$$\dot{q}_{n,m} = [q_{n,m}, \widetilde{H}] = [q_{n,m}, H]u = u(0)[q_{n,m}, H]\exp(i\omega t), \tag{33a}$$

$$\dot{p}_{n,m} = [p_{n,m}, \widetilde{H}] = [p_{n,m}, H]u = u(0)[p_{n,m}, H]\exp(i\omega t). \tag{33b}$$

Note that we have more ODEs than independent unknowns. However, these ODEs all follow from the same equations of motion and are hence necessarily consistent: of course only $N-1$ of the ODEs (33b) are independent, and likewise only $N-1$ of the ODEs (33a). To analyze the time evolution of these dependent variables $p_{n,m}(t)$ and $q_{n,m}(t)$ it is now convenient to perform the following change of (independent and dependent) variables [namely, essentially again the trick, see (8), but in the simpler version with $\lambda = 0$]:

$$q_{n,m}(t) = \xi_{n,m}(\tau), \quad p_{n,m}(t) = \pi_{n,m}(\tau), \tag{34a}$$

where the new (*complex*) timelike variable τ is again defined as above [see (8b)],

$$\tau = \frac{\exp(i\omega t) - 1}{i\omega}. \tag{34b}$$

Note that this definition, (34b), entails that $\tau = 0$ for $t = 0$, so that, via (34a), the initial data for the new dependent variables $\xi_{n,m}$ and $\pi_{n,m}$ coincide with the initial data for the original problem:

$$\xi_{n,m}(0) = q_{n,m}(0), \quad \pi_{n,m}(0) = p_{n,m}(0). \tag{35}$$

The time evolution of the dependent variables $\xi_{n,m}(\tau)$ and $\pi_{n,m}(\tau)$ is now given, from (33) via (34), by the following (*autonomous*) equations of motion:

$$\xi'_{n,m} = u(0;\omega)\,\pi_{n,m}, \tag{36a}$$

$$\pi'_{n,m} = -u(0;\omega)\frac{\partial V(\underline{\xi})}{\partial \xi_{n,m}}, \tag{36b}$$

where of course appended primes indicate differentiations with respect to the new (*complex*) independent variable τ. [We hope the attentive reader will pardon the abuse entailed by our use of the notation $\partial V(\underline{\xi})/\partial \xi_{n,m}$ on the right-hand side of the last equation, and will understand the significance of this notation, which is of course permissible thanks to the *translation-invariant* character of the potential $V(\underline{q})$, see (3), entailing that $V(\underline{q})$ is only a function of the difference of the particle coordinates, see (31) and (34a)]. And now, by the standard argument associated with the trick—as tersely reviewed in the preceding section, see the discussion following (12), the adaptation of which to the present circumstances is too obvious to require a detailed treatment—one easily concludes that the (*nonautonomous*) dynamical system characterized by the equations of motion (33) is *isochronous*, there being an open set of initial data $q_{n,m}(0)$, $p_{n,m}(0)$, having full dimensionality in the space of these data, such that the resulting motions are *completely periodic* with period T,

$$q_{n,m}(t+T) = q_{n,m}(t), \quad p_{n,m}(t+T) = p_{n,m}(t). \tag{37}$$

To formulate our final result we need coordinates to describe the *relative* motion. Finding *canonical* coordinates that do this is notoriously awkward, but also not necessary for us here. Let us therefore introduce

$$\tilde{p}_n = p_n - P, \quad \tilde{q}_n = q_n - Q, \tag{38}$$

which are *noncanonical* coordinates describing the *relative* motion. It then follows from (37) that $\tilde{p}_n$ and $\tilde{q}_n$ are all *isochronous*, as they are easily expressed in terms of the $q_{n,m}$ and the $p_{n,m}$:

$$\tilde{q}_n(t+T) = \tilde{q}_n(t), \quad \tilde{p}_n(t+T) = \tilde{p}_n(t). \tag{39}$$

And from this formula, via (38), (29), and (30), we arrive at our fundamental conclusion, namely that the time evolution entailed by the ω-modified Hamiltonian (16) possesses an *open*, hence fully dimensional, set of initial data $\underline{p}(0), \underline{q}(0)$ such that the solutions of the corresponding initial-value problem are *isochronous,*

$$q_n(t+T) = q_n(t), \quad p_n(t+T) = p_n(t) \quad \text{if } |\alpha| < 1, \tag{40a}$$

$$q_n(t+2T) = q_n(t), \quad p_n(t+2T) = p_n(t) \quad \text{if } |\alpha| > 1, \tag{40b}$$

with the constant α defined in terms of the initial data by (24).

Let us end this section by also exhibiting the *Newtonian* equations of motion associated with our *isochronous* dynamical system, that are of course obtained by time differentiating the first of the two Hamiltonian equations, (21), by then using the second, (22), as well as (20), (18b), and (23a), to get rid of all time-differentiated terms on the right-hand side of the resulting equations, and by finally using again (21) to get rid (to the extent possible, see below) of p_n so as to get Newtonian equations of motion that feature on their left-hand sides the "accelerations" $\ddot{q}_n$ and on their right-hand sides the corresponding "forces" expressed in terms of the positions q_m and the velocities $\dot{q}_m$ of the "particles" (moving in the *complex* q-plane). We thus obtain the following equations of motion:

$$\ddot{q}_n - i\omega\dot{q}_n = -\left(1 + Ni\omega\frac{Q}{P}\right)^2 \frac{\partial V(\underline{q})}{\partial q_n} + F, \tag{41a}$$

$$F = -\frac{2i\omega H}{P}\left(1 + \frac{N^2 i\omega Q H}{2P^3}\right) = \ddot{Q} - i\omega\dot{Q}. \tag{41b}$$

Note that the "collective force" F acts equally on *all* the coordinates q_n, and it is moreover easily seen from the results reported above that the time dependence of this force is *periodic* [with period T or $2T$, see (18), (23b), and (25b)]. Moreover, this collective force F induces a collective, *periodic*, motion $Q(t)$ of *all* the canonical coordinates $q_n(t)$, and likewise a collective *periodic* motion $P(t)$ of *all* the canonical momenta $p_n(t)$, the explicit time dependence of which is exhibited above [see (25a) and (23b)].

It should however be noted that these equations, (41), do not quite have yet the *Newtonian* form, because the right-hand sides of (41a), namely, the "forces," are not yet expressed just in terms of the coordinates q_m and the velocities $\dot{q}_m$: a dependence on the canonical momenta p_m still lingers, albeit only via the collective coordinates $P \equiv P(\underline{p})$ and $F \equiv F(\underline{p}, \underline{q})$, see (6a) and (41b) with (2). Actually the second of this collective coordinates can be rather neatly expressed in terms of the first [via (26) and (41)],

$$F = \frac{P^2 - [N(\dot{Q} - i\omega Q) - 2P]^2}{N^2 Q}. \tag{42}$$

But in order to express P in terms of the coordinates q_n and of the velocities $\dot{q}_n$—the first of which actually only enter via $Q(\underline{q})$ and $V(\underline{q})$, see (7a) and (2), while the second enter via $\dot{Q} = Q(\underline{\dot{q}})$ and the collective coordinate K,

$$K \equiv K(\dot{\underline{q}}) = \frac{1}{2}\sum_{n=1}^{N} (\dot{q}_n)^2, \tag{43}$$

see below—one should solve the following algebraic equation (of *fifth* degree in P), obtained from (2) via (21) with (16b) and (20) (to obtain p_n in terms of $\dot{q}_n, Q, P, H$) and then via (26) (to express H in terms of P,Q, and $\dot{Q}$):

$$P^2\left\{-\frac{NS^2}{2} + Ni\omega Qs(s-1)S + K\right\} = (N\omega sQ)^2(V+C), \tag{44a}$$

$$S = \dot{Q} - i\omega sQ = \dot{Q} - i\omega Q - \frac{P}{N}, \tag{44b}$$

$$s = 1 + \frac{P}{Ni\omega Q}. \tag{44c}$$

But let us note that, if the initial data entail that

$$H(0) \equiv H(\underline{p}(0), \underline{q}(0)) = 0, \tag{45a}$$

yielding via (18),

$$H(t) = 0, \tag{45b}$$

the Newtonian equations of motion take instead the much simpler, completely explicit, form

$$\ddot{q}_n - i\omega\dot{q}_n = -\left[\frac{\sum_{n=1}^{N}\dot{q}_n}{\sum_{n=1}^{N}(\dot{q}_n - i\omega q_n)}\right]^2 \frac{\partial V(q)}{\partial q_n}, \tag{46}$$

as entailed by (41a) [with $F=0$, see (41b) with (45) and (25a)] [with (45), (16b) and (20) yielding $P=N(\dot{Q}-i\omega Q)$]; while in the special examples in which the original Hamiltonian H reduces to the free Hamiltonian (i.e., $V+C=0$, see examples below), the Eq. (44) for P becomes a *cubic*.

In view of the significant simplification that obtains (here, and see also below) when the initial data entail the condition (45a), let us note that the requirement that this condition holds restricts the initial data to a hypersurface in the *complex* phase space of (*complex*) codimension one. But this hypersurface can be shifted at will by varying the parameter C in the definition (2) of the original Hamiltonian H. One way to justify this is by considering C itself as an additional dynamical variable rather than a given constant; then the absence in the Hamiltonian $\tilde{H}(\underline{p}, \underline{q}; \omega)$ of the corresponding canonical momentum entails that this quantity C is indeed time independent, namely that C maintains for all time its initial value; which can then be assigned, together with the assignment of all the other initial data, so that (45a) holds. But let us emphasize that, while varying C does not affect the dynamics generated by the original Hamiltonian H, see (2), it does instead modify the dynamics yielded by the ω-modified Hamiltonian $\tilde{H}$, see (16).

III. EXAMPLES

In this section we discuss tersely the results reported above for some cases characterized by specific choices for the potentials $V(\underline{q})$, see (2).

A. No potential

The very simplest case obtains for the choice

$$V(\underline{q}) = 0, \tag{47a}$$

i.e., for the original Hamiltonian

$$H(\underline{p},\underline{q}) = \frac{1}{2}\sum_{n=1}^{N} p_n^2 + C, \tag{47b}$$

and the ω-modified Hamiltonian

$$\tilde{H}(\underline{p},\underline{q};\omega) = \left[1 + Ni\omega\frac{Q(\underline{q})}{P(\underline{p})}\right]\left[\frac{1}{2}\sum_{n=1}^{N} p_n^2 + C\right]. \tag{47c}$$

Here and always below the collective coordinates Q and P are of course defined by (7a) and (6a).

The Hamiltonian, respectively, Newtonian equations of motions yielded by this ω-modified Hamiltonian, (47c), read

$$\dot{q}_n = \left[1 + Ni\omega\frac{Q}{P}\right]p_n - \frac{Ni\omega QH}{P^2}, \tag{48a}$$

$$\dot{p}_n = -\frac{i\omega H}{P}, \tag{48b}$$

respectively,

$$\ddot{q}_n - i\omega\dot{q}_n = \frac{P^2 - [N(\dot{Q} - i\omega Q) - 2P]^2}{N^2 Q}. \tag{48c}$$

Also, it is easily seen that the solution of the corresponding initial-value problem reads

$$p_n(t) = p_n(0) + \frac{P(0)}{N}\left\{\left[\frac{1 - \alpha\exp(-i\omega t)}{1 - \alpha}\right]^{1/2} - 1\right\}, \tag{49a}$$

$$q_n(t) = q_n(0) + \frac{NQ(0)}{P(0)}[\exp(i\omega t)p_n(t) - p_n(0)] + p_n(t)\frac{\exp(i\omega t) - 1}{i\omega}, \tag{49b}$$

with α given by (24) and of course [see (48a)] with

$$p_n(0) = \left[1 + Ni\omega\frac{Q(0)}{P(0)}\right]^{-1}\left[\dot{q}_n(0) + \frac{Ni\omega Q(0)H(0)}{P^2(0)}\right] \tag{49c}$$

in the context of the initial-value problem for the Newtonian equation of motions (48c).

The *isochronous* character of this Hamiltonian many-body problem is now evident: its phase space is divided into two parts, that characterized by $|\alpha| < 1$ and by solutions *completely periodic* with period T, see (1), and that characterized by $|\alpha| > 1$ and by solutions *completely periodic* with period $2T$, as stated in (40), while on the *separatrix* between these two phase-space regions, characterized by the formula

$$|\alpha| = 1, \quad \alpha = \exp(i\vartheta), \quad \mathrm{Im}(\vartheta) = 0, \tag{50}$$

the equations of motion become *singular* at the (*real*) time $t_s = (\vartheta/\omega)\mathrm{mod}(T)$ due to the vanishing at that time of the collective coordinate $P, P(t_s) = 0$, see (23b) and (48).

B. Two-body homogeneous potential

Next, let us consider the standard many-body problem characterized by the following *two-body* potentials:

$$V(\underline{q}) = \frac{1}{2} \sum_{n,m=1,n\neq m}^{N} V_{nm}(q_n - q_m), \quad V_{nm}(q) = \frac{g_{nm} q^{2k}}{2k}, \tag{51}$$

where the "coupling constants" g_{nm} satisfy the symmetry condition $g_{nm}=g_{mn}$ and k is an arbitrary *integer* (positive or negative, but *nonvanishing,* and *different from unity* to exclude the uninteresting "harmonic oscillator" case). This choice allows a comparison with the *isochronous* equations of motion of Newtonian type (10)—obtained via the application of the standard trick to the Newtonian equations yielded by the original Hamiltonian H, see (2) with (51)—that in this case read as follows:

$$\ddot{\breve{q}}_n - \left(\frac{k+1}{k-1}\right) i\omega \dot{\breve{q}}_n - \left[\frac{k}{(k-1)^2}\right] \breve{q}_n = -\sum_{m=1,m\neq n}^{N} g_{nm}(\breve{q}_n - \breve{q}_m)^{2k-1}. \tag{52}$$

The (*autonomous*) Newtonian equations of motion (41) yielded by our approach read instead

$$\ddot{q}_n - i\omega \dot{q}_n = -u^2 \sum_{m=1,m\neq n}^{N} g_{nm}(q_n - q_m)^{2k-1} + F, \tag{53}$$

with u, respectively, F expressed in terms of $Q \equiv Q(\underline{q}), P \equiv P(\underline{q})$ and $H \equiv H(\underline{p},\underline{q})$, see (7a), (6a), and (2) with (51), by the formulas (16b) with (20), respectively, (41b) (except that these are not really Newtonian equations of motion, as discussed above; the display of such equations, to the extent it is possible, see above, can be left to the diligent reader).

In this case it is possible to provide explicit conditions on the initial data that are *sufficient* (but of course not *necessary*) to guarantee the *isochronous* behavior of the corresponding solution. The task to exhibit them can be left to the diligent reader, who will find—if need be—guidance in the literature [see for instance Refs. 4, 8, 11, 16, 22, 28, and 32, where analogous computations have been often performed, in particular explicit formulas providing a lower bound to the radius R, see the discussion before and after (13)].

IV. GENERALIZATIONS

In the following two sections we indicate tersely how the treatment of the many-body problem given above can be extended to the cases with different masses and with more dimensions.

A. Different masses

In this section we tersely indicate how the results reported above can be extended to the case with different masses M_n. Since this extension is quite trivial, we simply limit our presentation here to exhibiting, for a few of the key equations of our treatment, their corresponding, extended versions (which of course reduce to the previous equations by setting all the particle masses M_n to unity).

The definition of the unmodified many-body Hamiltonian [see (2)] now reads

$$H(\underline{p},\underline{q}) = \sum_{n=1}^{N} \frac{p_n^2}{2M_n} + V(\underline{q}) + C, \tag{54}$$

and correspondingly the Hamiltonian, respectively, Newtonian equations of motion [see (4), respectively, (5)] read now

$$\dot{q}_n = \frac{p_n}{M_n}, \quad \dot{p}_n = -\frac{\partial V(\underline{q})}{\partial q_n}, \tag{55}$$

respectively,

$$M_n \ddot{q}_n = -\frac{\partial V(\underline{q})}{\partial q_n}. \tag{56}$$

The definition (7a) of the quantity Q is now replaced by

$$Q(\underline{q}) = \frac{\sum_{n=1}^{N} M_n q_n}{\sum_{n=1}^{N} M_n}. \tag{57}$$

We trust the alert reader will have no difficulty to identify which, and how, other equations written above, and below, should be analogously modified, hence we do not devote additional space to this issue.

B. More dimensions

The generalization of the results reported above, and below, to the case with more (say, S) space dimensions is sufficiently simple not to require a detailed treatment: the Hamiltonian coordinates q_n are replaced by S-vectors $\vec{q}_n$, and likewise the corresponding Hamiltonian momenta p_n are replaced by S-vectors $\vec{p}_n$. Again, we trust the alert reader will have no difficulty to see how the standard equations written above, and below, shall be correspondingly modified. But there is one issue in this more general context that warrants some discussion, namely the possibility to introduce a more general definition of the collective variable Θ, see (20), characterized by the validity of the relation (14).

Let us therefore indicate, without many comments, the relevant generalization of our treatment (limiting consideration, for simplicity, to the equal masses case). We generalize (2) to read

$$H(\underline{\vec{p}}, \underline{\vec{q}}) = \frac{1}{2} \sum_{n=1}^{N} (\vec{p}_n \cdot \vec{p}_n) + V(\underline{\vec{q}}) + C \tag{58}$$

[of course always with the translation invariant property (3)], and likewise we generalize (16) to read

$$\tilde{H}(\underline{\vec{p}}, \underline{\vec{q}}; \underline{\vec{a}}; \omega) = u[\vec{P}(\underline{\vec{p}}), \vec{Q}(\underline{\vec{q}}); \underline{\vec{a}}; \omega] H(\underline{\vec{p}}, \underline{\vec{q}}), \tag{59a}$$

$$u(\vec{P}, \vec{Q}; \underline{\vec{a}}; \omega) = 1 + i\omega\Theta(\vec{P}, \vec{Q}; \underline{\vec{a}}) \tag{59b}$$

with [see (20)]

$$\Theta(\vec{P}, \vec{Q}; \underline{\vec{a}}) = \frac{N}{S} \sum_{s=1}^{S} \frac{Q_s}{P_s}, \tag{60}$$

where

$$Q_s = \vec{a}_s \cdot \vec{Q}, \quad P_s = \vec{a}_s \cdot \vec{P}, \tag{61}$$

and of course [see (7a) and (6a)]

$$\vec{Q}(\underline{\vec{q}}) = \frac{1}{N} \sum_{n=1}^{N} \vec{q}_n, \quad \vec{P}(\underline{\vec{p}}) = \sum_{n=1}^{N} \vec{p}_n. \tag{62}$$

The S constant S-vectors $\vec{a}_s$ [see (61)] are *arbitrary*, except for the orthogonality condition (quite useful to simplify the following formulas)

$$\vec{a}_s \cdot \vec{a}_{s'} = a_s^2 \delta_{ss'}. \tag{63}$$

It is then easy to verify that the definition (60) is compatible with the requirement (14). Therefore the properties (18) and (19) continue to hold.

Let us now discuss, as we did in Sec. II, first, the time evolution of the center-of-mass coordinates $\vec{Q}$ and $\vec{P}$, and then the *relative* motions.

To discuss the time evolutions of $\vec{Q}$ and $\vec{P}$ we note first of all that the definitions (61) entail the following formulas, as can be easily verified using the orthogonality relation (63):

$$\vec{Q} = \sum_{s=1}^{S} \frac{Q_s \vec{a}_s}{a_s^2}, \quad \vec{P} = \sum_{s=1}^{S} \frac{P_s \vec{a}_s}{a_s^2}, \tag{64}$$

$$[Q_s, Q_{s'}] = \delta_{ss'} a_s^2, \tag{65}$$

$$\left[\frac{NQ_s}{P_s}, H \right] = 1. \tag{66}$$

It is then easy, following the treatment given in the one-dimensional case (see Sec. II), to obtain the following explicit expressions detailing the time evolution of the quantities $P_s(t)$ and $Q_s(t)$:

$$P_s(t) = P_s(0) \left[\frac{1 - \alpha_s \exp(-i\omega t)}{1 - \alpha_s} \right]^{1/2}, \tag{67a}$$

$$\alpha_s = \frac{2a_s^2 H(0)}{1 - 2a_s^2 H(0)}, \tag{67b}$$

$$Q_s(t) = \left\{ \frac{Q_s(0)}{P_s(0)} + \frac{u(0)[\exp(i\omega t) - 1]}{Ni\omega} \right\} P_s(t). \tag{68}$$

It is thereby seen that the quantities $P_s(t)$ and $Q_s(t)$ are both *periodic*, with period T, respectively, $2T$ if $|\alpha_s| < 1$, respectively, $|\alpha_s| > 1$. Hence we conclude [see (64)] that the quantities $\vec{P}(t)$ and $\vec{Q}(t)$ are both *periodic* with period T if *all* the quantities α_s have modulus less than unity,

$$\vec{Q}(t+T) = \vec{Q}(t), \quad \vec{P}(t+T) = \vec{P}(t) \quad \text{if} \max_{s=1,\ldots,S} |\alpha_s| < 1, \tag{69a}$$

and are *periodic* with period $2T$ otherwise,

$$\vec{Q}(t+2T) = \vec{Q}(t), \quad \vec{P}(t+2T) = \vec{P}(t) \text{ if } \max_{s=1,\ldots,S} |\alpha_s| > 1. \tag{69b}$$

The discussion of the relative motions can then be done just as in the one-dimensional case, see Sec. II, since it is easy to verify that the definition (60) entails the vanishing of the following Poisson brackets:

$$[\vec{q}_n - \vec{q}_m, \Theta(\vec{P}, \vec{Q}; \underline{\vec{a}})] = 0, \quad [\vec{p}_n - \vec{p}_m, \Theta(\vec{P}, \vec{Q}; \underline{\vec{a}})] = 0. \tag{70}$$

Hence, following exactly the same reasoning as in Sec. II one arrives at the formulas:

$$\vec{q}_n(t+T)=\vec{q}_n(t),\quad \vec{p}_n(t+T)=\vec{p}_n(t)\quad \text{if } \max_{s=1,\ldots,S}|\alpha_s|<1, \tag{71a}$$

$$\vec{q}_n(t+2T)=\vec{q}_n(t),\quad \vec{p}_n(t+2T)=\vec{p}_n(t)\quad \text{if } \max_{s=1,\ldots,S}|\alpha_s|>1. \tag{71b}$$

We thereby see that our fundamental conclusion about the *isochronous* character of the dynamics entailed by the ω-modified Hamiltonian (59) is confirmed.

V. GENERAL HAMILTONIANS

In this section we indicate how the approach introduced above can be applied to more general Hamiltonians than that describing the nonrelativistic many-body problem, see (2). This discussion allows a more explicit display of the essential aspects of our technique to manufacture modified Hamiltonians yielding an *isochronous* dynamics.

Let us therefore consider again an ω-modified Hamiltonian defined by (16) with the collective variable $\Theta(\underline{p},\underline{q})$ satisfying (14), but now without making any assumption on the original Hamiltonian H and therefore without being able to provide an explicit form for the dependence of Θ on the Hamiltonian variables. It is nevertheless clear that the time evolution of H and of u is again given by (18) and (19), and therefore that the Hamiltonian equations can now be written in the following (*nonautonomous*) version:

$$\dot{q}_n=i\omega H(0)\exp(-i\omega t)\frac{\partial\Theta(\underline{p},\underline{q})}{\partial p_n}+u(0)\exp(i\omega t)\frac{\partial H(\underline{p},\underline{q})}{\partial p_n}, \tag{72a}$$

$$\dot{p}_n=-i\omega H(0)\exp(-i\omega t)\frac{\partial\Theta(\underline{p},\underline{q})}{\partial q_n}-u(0)\exp(i\omega t)\frac{\partial H(\underline{p},\underline{q})}{\partial q_n}. \tag{72b}$$

Now the first observation is that, if one restricts attention to initial data such that $H(0)$ vanishes, see (45), one gets again an *isochronous* behavior, since then these Hamiltonian equations of motion, (72), take the simpler form

$$\dot{q}_n=u(0)\exp(i\omega t)\frac{\partial H(\underline{p},\underline{q})}{\partial p_n}, \tag{73a}$$

$$\dot{p}_n=-u(0)\exp(i\omega t)\frac{\partial H(\underline{p},\underline{q})}{\partial q_n}, \tag{73b}$$

to which the by now familiar trick can be applied, entailing *isochronicity*. This is however a case of *partial isochronicity* (see Sec. I for this terminology), because the initial data must be restricted to satisfy the condition (45a).

Let us emphasize that this observation—possibly associated with the general possibility to add a constant C to the original Hamiltonian [and see in this respect the discussion at the end of Sec. II of how this possibility can facilitate the implementation of this restriction, (45a)]—entails that the class of Hamiltonians to which our technique can be successfully applied is indeed extremely large, at least as regards manufacturing ω-modified Hamiltonians which are *partially isochronous*.

In the more general case when $H(0)$ does *not* vanish, we conjecture that the motion will be *isochronous* in quite general circumstances, but we do not try to prove this in this paper. We rather restrict attention to systems such that there exists a collective function Θ satisfying (14) that depends on the Hamiltonian coordinates *only* via the two "center of mass" coordinates P and Q, see (6a) and (7a):

$$\Theta(\underline{p},\underline{q}) = \Theta[P(\underline{p}),Q(\underline{q})] \tag{74}$$

(this of course limits substantially the class of Hamiltonians to which this approach is applicable). Then one easily sees that there hold the relations (32) [with (31)], hence proceeding as in Sec. II one concludes that the relative motions are *isochronous.*

To proceed further it is necessary to gain some knowledge on the time evolution of the global "center of mass" quantities $Q(t)$ and $P(t)$. This requires additional information on the explicit form of the function $\Theta(P,Q)$, and moreover on the specific form of the original Hamiltonian, because the time evolution of these quantities, $Q(t)$ and $P(t)$, is determined by the evolution equations [clearly implied by (72)],

$$\dot{Q} = i\omega H(0)\exp(-i\omega t)\Theta_P(P,Q) + \frac{u(0)\exp(i\omega t)}{N}\sum_{n=1}^{N}\frac{\partial H(\underline{p},\underline{q})}{\partial p_n}, \tag{75a}$$

$$\dot{P} = -\frac{i\omega H(0)\exp(-i\omega t)\Theta_Q(P,Q)}{N} - u(0)\exp(i\omega t)\sum_{n=1}^{N}\frac{\partial H(\underline{p},\underline{q})}{\partial q_n}. \tag{75b}$$

VI. PARTIALLY ISOCHRONOUS VARIANTS OF THE MANY-BODY HAMILTONIAN

In this section we discuss—again in the context of the many-body problem characterized by the Hamiltonian (2)—variants of our technique, yielding modified Hamiltonians with enough *completely periodic* solutions to justify calling them *partially isochronous* (see the definition of this term given in Sec. I).

Let us take as starting point of our treatment the modified Hamiltonian

$$\tilde{H}(\underline{p},\underline{q}) = U(P,Q)H(\underline{p},\underline{q}). \tag{76}$$

Notation: largely the same as above, see Secs. I and II, in particular (2), (6a), and (7a). The novelty is that, for the time being, we do not commit ourselves to a specific form of the "modifying multiplicative coefficient" U, except for the assumption that it depend on the Hamiltonian variables *only* via the collective coordinates $P \equiv P(\underline{p})$ and $Q \equiv Q(\underline{q})$; of course for the special choice $U=u$ [see (16) with (20), (6a), and (7a)] the treatment of this section reduces to that given in Secs. I and II. And let us again emphasize, as we did in Sec. I, that hereafter we consider the time evolution entailed by the Hamiltonian $\breve{H}$, both for the Hamiltonian coordinates $q_n(t)$ and $p_n(t)$ and for any collective coordinate—such as P,Q,H,U—the time evolution of which obtains via the time dependence of the Hamiltonian coordinates.

The following evolution equations are then yielded by this modified Hamiltonian (76):

$$\dot{H} = -\frac{PU_Q H}{N}, \tag{77}$$

$$\dot{U} = \frac{PU_Q U}{N}, \tag{78}$$

$$\dot{P} = -U_Q H, \tag{79}$$

$$\dot{Q} = \frac{UP}{N} + U_P H, \tag{80}$$

$$\dot{q}_n = Up_n + U_P H, \tag{81}$$

$$\dot{p}_n = -U\frac{\partial V(\underline{q})}{\partial q_n} - \frac{U_Q H}{N}. \tag{82}$$

Note that here and hereafter we use the short-hand notation U_Q and U_P to denote the (partial) derivatives of the (yet to be assigned) function $U(P,Q)$ with respect to its two arguments:

$$U_Q \equiv \frac{\partial U}{\partial Q}, \quad U_P \equiv \frac{\partial U}{\partial P}. \tag{83}$$

From (79) and (77) we get

$$\dot{P}P = \dot{H}, \tag{84}$$

entailing

$$P = (2H - B^2)^{1/2}, \tag{85a}$$

$$B^2 = 2H(0) - P^2(0). \tag{85b}$$

To proceed further one must make a specific choice for the function $U(P,Q)$. We consider below various possibilities.

A. A simple variant

The first modified Hamiltonian we now consider is characterized by the following "β-modified" variant of the N-body Hamiltonian (2):

$$\breve{H}(\underline{p},\underline{q};\beta) = [1 + i\beta Q(\underline{q})]H(\underline{p},\underline{q}), \tag{86}$$

corresponding to (76) with

$$U(P,Q) \equiv U(Q;\beta) = 1 + i\beta Q \tag{87a}$$

implying

$$U_Q = i\beta, \quad U_P = 0. \tag{87b}$$

Our main result is to show that there exists a set of initial data $q_n(0)$ and $p_n(0)$—having a bit less than full dimensionality in phase space, being restricted by the requirement

$$H(0) \equiv H[\underline{p}(0),\underline{q}(0)] = 0 \tag{88}$$

(and see in this connection the discussion at the end of Sec. II)—yielding motions *all* of which are *completely periodic* with the period

$$\breve{T} = \frac{2\pi}{\Omega}, \quad \Omega = \frac{\beta P(0)}{N} \equiv \frac{\beta P[\underline{p}(0)]}{N}. \tag{89}$$

In this formula $P(\underline{p})$ is of course defined by (6a). Note that this formula entails that the period $\breve{T}$ does depend on the initial data, albeit only via the collective variable $P(\underline{p})$, and of course that we must restrict the initial data so that this period $\breve{T}$, as well as the corresponding circular frequency Ω, be *real*. This entails an *additional* restriction of the initial data $p_n(0)$ to a hypersurface of *real* codimension one. And one can repeat in this respect a completely analogous discussion to that given after (45), up to replacing the role played in that context by the parameter C with the role played in the present context by the parameter β. Note moreover that in this manner—adjusting at one's convenience the value of β [as it were *a posteriori*, after the initial data $p_n(0)$ have been

assigned]—one can in fact even impose that $\breve{T}$ have a given, preassigned value, thereby restoring the property of yielding *isochronous* motions—albeit for a set of initial data having a bit less than full dimensionality in phase space, being restricted to lie on a manifold of (*complex*) codimension *two* in phase space [i.e., the intersection of *two* hypersurfaces each of which of *complex* codimension *one*, that characterized by (88) and that characterized by the requirement that the period $\breve{T}$, or equivalently the circular frequency Ω, see (89), have a *preassigned* real value].

To prove this result we note that the Hamiltonian $\breve{H}(\underline{p},\underline{q};\beta)$, see (86), entails the following time-evolution equations [see (81), (82), (80), (79), and (77) with (87)]:

$$\dot{q}_n = (1 + i\beta Q)p_n, \tag{90a}$$

$$\dot{p}_n = -(1 + i\beta Q)\frac{\partial V(\underline{q})}{\partial q_n} - i\beta H, \tag{90b}$$

$$\dot{Q} = \frac{(1 + i\beta Q)P}{N}, \tag{90c}$$

$$\dot{P} = -i\beta H, \tag{90d}$$

$$\dot{H} = -\frac{i\beta HP}{N}. \tag{90e}$$

The preceding three equations can be easily integrated for general initial data, but we restrict attention here only to the case characterized by the condition (88), in which case the outcome is particularly simple,

$$H(t) = H(0) = 0, \tag{91a}$$

$$P(t) = P(0) \equiv P[\underline{p}(0)], \tag{91b}$$

$$1 + i\beta Q(t) = [1 + i\beta Q(0)]\exp(i\Omega t). \tag{91c}$$

Insertion of the first and last of these formulas in (90a) and (90b) yields the equations that determine the time evolution of the dependent variables $q_n(t)$ and $p_n(t)$,

$$\dot{q}_n = [1 + i\beta Q(0)]\exp(i\Omega t)p_n, \tag{92a}$$

$$\dot{p}_n = -[1 + i\beta Q(0)]\exp(i\Omega t)\frac{\partial V(q)}{\partial q_n}. \tag{92b}$$

From these evolution equations, via the, by now usual, argument based on the trick, one easily concludes that the assertions made at the beginning of this section are valid.

Let us end this section by pointing out that the Hamiltonian $\breve{H}(\underline{p},\underline{q};\beta)$, see (86), is perhaps more susceptible to a "physical interpretation" than the Hamiltonian $\tilde{\tilde{H}}(\underline{p},\underline{q};\omega)$, see (16), inasmuch as $\breve{H}(\underline{p},\underline{q};\beta)$, in contrast to $\tilde{H}(\underline{p},\underline{q};\omega)$, does *not* feature momentum variables in the denominator. This observation is underscored by the possibility to write in this case quite explicitly the *Newtonian* equations of motion that correspond to the *Hamiltonian* equations (90a) and (90b):

$$\ddot{q}_n = \frac{i\beta\dot{Q}\dot{q}_n}{1+i\beta Q} - (1+i\beta Q)^2 \frac{\partial V(\underline{q})}{\partial q_n} - \frac{i\beta(1+i\beta Q)H}{N}, \tag{93}$$

where of course $Q \equiv Q(\underline{q})$ [see (7a)] and $H \equiv H(\underline{p},\underline{q})$ [see (2)] with

$$p_n = \frac{\dot{q}_n}{1+i\beta Q} \tag{94}$$

[see (90a)]. And note moreover that the last term on the right-hand side of the *Newtonian* equations of motion (93) is altogether missing when (88) holds, see (91a).

B. A more general variant

A more general variant—that includes as a special case those treated above—is associated with the observation that—quite generally—the evolution equation (77) with (88) entails the vanishing of H for all time, see (91a), and that—again quite generally, see (79)—the vanishing of H entails that P is time independent, see (91b). This we assume in this section, as in the previous one, hence we consider again a modified Hamiltonian defined by (76) [with (2)], and initial data restricted so that (88) holds. But now we note that (91c) does not generally follow from (91a) and (91b); all that one can assert is that, if (91a) and (91b) hold, then (78) and (80) take the following simpler form:

$$\dot{U} = -\frac{P(0)U_Q U}{N}, \quad \dot{Q} = \frac{P(0)U}{N}. \tag{95}$$

To proceed further, an assumption must again be introduced on the assignment of $U(P,Q)$, although the time-independence of P entails that we can manage with an *ansatz* that allows a certain generality as regards the dependence on this collective variable. For instance let us set

$$U = 1 + \Phi(P)Q + \Psi(P)Q^2, \tag{96a}$$

entailing

$$U_Q = \Phi(P) + 2\Psi(P)Q \tag{96b}$$

[of course the results of the preceding section would be reproduced for $\Phi(P)=i\beta$, $\Psi(P)=0$, although this might involve a nontrivial limiting process; and those of Secs. I and II—with (45)—would be reproduced for $\Phi(P)=Ni\beta/P$, $\Psi(P)=0$]. Then one can easily obtain the following results:

$$U(t) = A\left\{\sin\left[\frac{\Omega(t-t_0)}{2}\right]\right\}^{-2}, \tag{97a}$$

$$A = 1 - \frac{\Phi^2(P)}{4\Psi(P)}, \tag{97b}$$

$$\Omega = \frac{P}{N}[-\Phi^2(P) + 4\Psi(P)]^{1/2}, \tag{97c}$$

$$\sin(t_0) = \left[\frac{A}{1+\Phi(P)Q(0)+\Psi(P)Q^2(0)}\right]^{1/2}. \tag{97d}$$

We then note that, via (91a) and (97), the Hamiltonian equations (81) and (82) now read

$$\dot{q}_n = A\left\{\sin\left[\frac{\Omega(t-t_0)}{2}\right]\right\}^{-2} p_n, \tag{98a}$$

$$\dot{p}_n = -A\left\{\sin\left[\frac{\Omega(t-t_0)}{2}\right]\right\}^{-2} \frac{\partial V(q)}{\partial q_n}, \tag{98b}$$

or equivalently

$$\dot{q}_n = \dot{\tau} p, \quad \dot{p}_n = -\dot{\tau}\frac{\partial V(\underline{q})}{\partial q_n}, \tag{99}$$

provided we set

$$\tau(t) = -\left(\frac{2A}{\Omega}\right)\cot\left[\frac{\Omega(t-t_0)}{2}\right]. \tag{100}$$

It is now clear from (99)—via a generalized version of the trick, the details of which can be easily filled in by the interested reader, being based on the change of independent variables

$$q_n(t) = \breve{q}_n(\tau), \quad p_n(t) = \breve{p}_n(\tau), \tag{101}$$

with the new (*complex*) variable τ related to the (*real*) time variable t by (100)—that this modified Hamiltonian system is *partially isochronous* [with period $2\pi/\Omega$, see (97c)], the initial data having to be restricted, in order to entail *complete periodicity* of the corresponding solutions, by the requirement that (88), hence as well (91a), hold (a restriction of *complex* codimension *one*; but see the remark at the end of Sec. II) and moreover so that Ω be *real* (a restriction of *real* codimension *one*) or have a *preassigned* fixed value (a restriction of *complex* codimension *one*). This last restriction could however be lifted for special choices of the functions $\Phi(P)$ and $\Psi(P)$ that guarantee that Ω have a *fixed real* value independent of P, which is clearly the case if

$$-\Phi^2(P) + 4\Psi(P) = \left(\frac{N\omega}{P}\right)^2, \tag{102}$$

yielding $\Omega = \omega$, see (97c). Note that this restriction, (102), is compatible with $\Phi(P)$ and $\Psi(P)$ being both *real* functions (that yield *real* values whenever their argument, P, is *real*), provided $\Psi(P)$ does not vanish identically [as it instead did in the treatment of Secs. I and II, which indeed involved the *imaginary* function $\Phi(P) = i\omega/P$]. In addition—in order to avoid that the equations of motion run into a *singularity* as the (*real*) time t evolves—the initial data should of course *exclude* that the quantity t_0 be *real* [see (97d) and (98)].

C. Simple examples (no potential)

In this section we exhibit the explicit solutions of the initial-value problems for the models that correspond to the cases treated in the two preceding sections, when the potential is altogether missing, $V(\underline{q}) = 0$. The derivation of these findings is quite straightforward and is therefore left as an exercise for the diligent reader.

The modified Hamiltonian of the first of the two preceding sections reads now as follows:

$$\breve{H}(\underline{p},\underline{q};\beta) = \left[1 + \frac{i\beta}{N}\sum_{n=1}^{N} q_n\right]\left[\frac{1}{2}\sum_{n=1}^{N} p_n^2 + C\right], \tag{103}$$

and, for all initial data satisfying the condition

$$\frac{1}{2}\sum_{n=1}^{N} p_n^2(0) + C = 0, \tag{104}$$

it yields the solution

$$p_n(t) = p_n(0), \quad q_n(t) = q_n(0) + \left[1 + \frac{i\beta}{N}\sum_{n=1}^{N} q_n(0) \right] p_n(0) \frac{\exp(i\Omega t) - 1}{i\Omega}, \tag{105a}$$

$$\Omega = \frac{\beta}{N}\sum_{n=1}^{N} p_n(0), \tag{105b}$$

which is clearly *completely periodic* with period $2\pi/\Omega$ provided Ω is *real* (and *nonvanishing*).

The modified Hamiltonian of the second of the two preceding sections reads now as follows:

$$\tilde{H}(\underline{p},\underline{q};\beta) = [1 + \Phi(P)Q + \Psi(P)Q^2] \left[\frac{1}{2}\sum_{n=1}^{N} p_n^2 + C \right], \tag{106}$$

where of course $P \equiv P(\underline{p})$ and $Q \equiv Q(\underline{q})$, see (6a) and (7a). For all initial data satisfying the condition (104) it yields the solution

$$p_n(t) = p_n(0), \quad q_n(t) = q_n(0) - \frac{2A}{\Omega} p_n(0) \left\{ \cot\left[\frac{\Omega(t - t_0)}{2} \right] + \cot\left[\frac{\Omega t_0}{2} \right] \right\}. \tag{107a}$$

In these formulas we are of course using the notation of the second of the two preceding sections, in particular A, Ω, and t_0 are defined by (97b)–(97d) with $P = P(0)$. This solution is clearly *completely periodic* with period $2\pi/\Omega$ provided Ω is *real* (and *nonvanishing*) and t_0 is instead *not real*.

VII. OUTLOOK

Let us note first of all that the results reported in this paper, see in particular Secs. I, II, V, and VI, do justify the assertion contained in its title, inasmuch as we have shown the existence of a universal procedure applicable to a very broad class of Hamiltonians and yielding *isochronous* dynamics. Indeed let us underline that our treatment entails that the ω-modified Hamiltonian $\tilde{H}(\underline{p},\underline{q};\omega)$, see (16), is *isochronous* [for $\omega > 0$, with basic period T, see (1)] irrespective of any requirement that the original Hamiltonian $H(\underline{p},\underline{q}) = \tilde{H}(\underline{p},\underline{q};0)$ (namely, the unmodified one, corresponding to $\omega = 0$) be special (for instance, *integrable*): the only essential requirement is that there exist a collective variable $\Theta(\underline{p},\underline{q})$ satisfying (14). And conversely, the fact that the solutions of the modified Hamiltonian (with $\omega > 0$) display an *isochronous* behavior generally entails no information on the behavior of the solutions of the unmodified system, at least whenever the *isochronous* character of the solutions of the modified system [with $\omega > 0$, and basic period T, see (1)] prevails only in a subregion (having however full dimensionality, as required in order that the system be indeed classified as *isochronous*) of the phase space, but not in the *entire* phase space (or in the *entire* phase space except for a region of *vanishing* measure, namely having *positive* codimensionality). Only if the *isochronous* character of the solutions of the ω- modified Hamiltonian were to prevail [possibly with a period which is a *finite integer* multiple of the basic period T, see (1)] in the *entire* phase space (or at least in the *entire* phase space except for a region of *vanishing* measure, namely having *positive* codimensionality), then one might well conjecture that the original Hamiltonian be special, perhaps indeed *integrable*.

Two general directions of further research are suggested by the findings reported in this paper.

A first direction, probably of *theoretical* rather than *applicative* relevance, is the investigation of *quantized* versions of modified Hamiltonian models manufactured via the procedure introduced in this paper: in particular the simpler systems, such as those discussed in Secs. III A and VI B that

feature solutions *all* of which are *isochronous* (with the possible exception of a set of solutions of *vanishing* measure in phase space), as well as other, less trivial, systems that are also *isochronous* in the entire phase space (with the possible exception of a set of solutions of *vanishing* measure in phase space) such as those obtained by ω-modifying *integrable* Hamiltonian systems (many such examples can now be easily manufactured). It will be of interest to see whether the *hunch* that there always exist quantized versions of these models that feature *equispaced* spectra is confirmed, and, if so, whether the corresponding eigenfunctions can be *explicitly* exhibited. These investigations are likely to yield some further insight on the quantization issue, which would be further illuminated by the discovery of new *solvable* models, especially such models involving an *arbitrary* number of degrees of freedom.

A second direction of research points instead towards the *applicative* relevance of the findings reported in this paper, as well as in other recent papers which have emphasized that *isochronous dynamical systems are not rare*.[11,17,16,18] It is however likely that such applications be more relevant in other disciplines than physics, and therefore that they will not necessarily involve *Hamiltonian* systems: indeed the domain of natural philosophy that appears to feature the most striking instances of *isochronicity* is *biology*, including key phenomena of human life such as the regular beating of our hearts and the Circadian clocks that subtend the tempo of our biological lives.[39] Whether *mathematical physics* results such as those presented in this paper and in previous ones[2,38] will shed any light on this phenomenology remains to be seen; it certainly does point to an appealing direction of further study.

ACKNOWLEDGMENTS

Low-frequency currents induced in adjacent spherical cells

Dionisios Margetis and Nikos Savva
Department of Mathematics, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

(Received 4 September 2005; accepted 3 March 2006; published online 21 April 2006)

The currents induced inside cells by external electric fields in the frequency range 50–60 Hz are studied analytically by accounting for thin cell membranes with transverse conductivity that is small compared to the conductivity of the saline fluid. A general perturbation scheme is formulated and applied to two adjacent spherical cells of equal radii by using a reflection principle and solving a nonlinear difference equation. The presence of the second cell is found to cause a no more than 10% increase to the current induced in an isolated spherical cell. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2190333]

I. INTRODUCTION

Concerns about the possible health effects of electromagnetic fields generated by power lines have stimulated theoretical studies of the currents induced in the human body when this is exposed to external, extremely-low-frequency fields, in the frequency range 50–60 Hz.[1–11] Over a decade ago Adair[2] asserted that the current induced inside an isolated cell is negligible, because the resistive cell membrane appears to shield the cell interior from incident low-frequency fields.

More recently, King and Wu[4] pointed out that Adair's conclusion, although correct for spherical cells, may not be valid for elongated, cylindrical cells. In the latter case the induced current depends on the length of the cell and the polarization of the incident electric field, so that shielding effects can be significantly reduced as the cell length increases or the incident field becomes parallel to the cell axis. For a typical spherical cell with radius 1 μm, membrane thickness $\delta \approx 5$ nm, membrane conductivity $\sigma_m \approx 10^{-6}$ S/m, and protoplasm (saline-fluid) conductivity $\sigma_0 \approx 0.5$S/m, King and Wu[4] calculated the electric field to be reduced by a factor 10^{-4} inside the cell. By contrast, the electric field inside the elongated, myelinated cell was calculated[4] to be almost equal to the incident field if the length of the cell roughly exceeds 5 mm and the external field is along the cell axis.

The purpose of the present study is to extend previous works[2,4] to more realistic cases where the current induced inside a cell is affected by the presence of neighboring cells. As a starting point, we treat the geometry with two spherical cells by an analytical technique which is directly applicable, although increasingly cumbersome, to many-cell geometries. Our formulation considers disconnected cells and therefore differs from that of Ref. 5 where cells are connected through suitable gap junctions.

The main assumptions underlying our analysis are that the cell membrane thickness is small compared to (i) the cell radius of curvature, and (ii) the length over which the cell curvature varies. So, elongated cells with sharp ends may not be included in the analysis. In addition, the cell curvature is assumed to be a sufficiently smooth and slowly varying function of the surface coordinates. Following Ref. 4 we also assume that the cell membrane is homogeneous and isotropic, with a scalar conductivity σ_m in the range 10^{-5}–10^{-6} S/m. This assumption may pose a limitation on our model, especially because membranes of actual cells have ion channels[12] and thus act as anisotropic media. To avoid complications due to anisotropies and yet preserve the essential physical features of thin membranes we replace the membrane by an "effective" boundary condition that accounts for its thickness and conductivity in the direction transverse to the cell

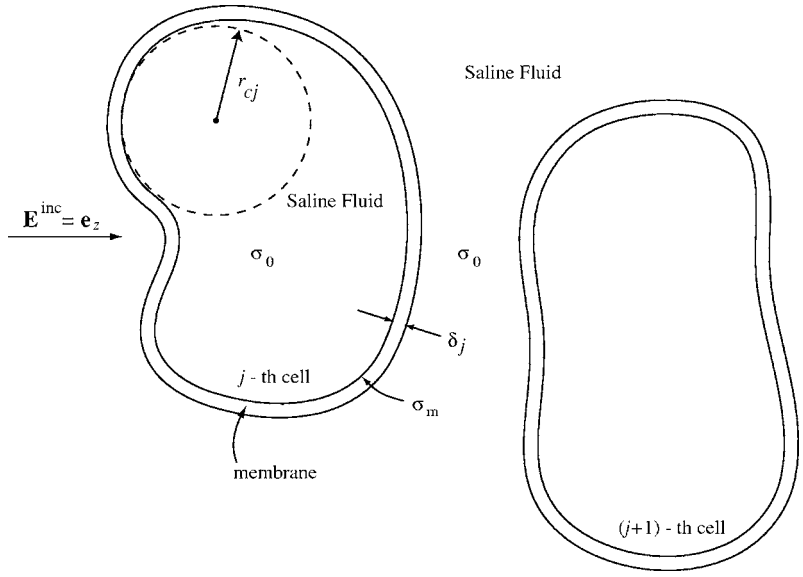

FIG. 1. Schematic of the geometry of arbitrarily shaped cells. The jth cell has radius of curvature r_{cj} and membrane thickness δ_j. The conductivities of the saline fluid and cell membrane are σ_0 and σ_m, respectively. The incident electric field is polarized along the **z** axis.

surface;[4] cf. Eq. (9) below. Similarly, the cell interior is considered as homogeneous and isotropic with conductivity σ_0, typically in the range $0.5-0.8$ S/m, which is taken to be equal to the conductivity of the surrounding saline fluid.

One can argue that the reduction of the electric field in the interior of a cell of reasonably arbitrary shape can be estimated by dimensional analysis. More precisely, the fraction of the penetrating field is expected to be proportional to the *small* factor $\tilde{\epsilon}=(\bar{r}_c/\delta)(\sigma_m/\sigma_0)$, where $\bar{r}_c$ is the cell mean radius of curvature, typically in the range $1-10$ μm, and δ is the membrane thickness, $\delta=2-5$ nm; cf. Fig. 1. This observation motivates the perturbation analysis of this paper because it indicates the dependence of the induced current on the small dimensionless parameter $\tilde{\epsilon}$. A similar technique is described in Ref. 13 for the cell response to a delta-function excitation. The application of perturbation theory, as described below, transcends dimensional analysis because it provides (i) a general mathematical framework to treat systematically problems of low-frequency scattering by cells; and (ii) a closed-form formula for the geometry-dependent prefactor for the field reduction inside a cell for the practically appealing case with two spherical cells of equal radii.

The paper is organized as follows. In Sec. II we describe the general formulation based on perturbation theory to determine currents induced inside cells exposed to uniform electric fields. In Sec. III we apply this formulation to the case with two neighboring spherical cells and derive simple, closed-form formulas for the electric field in the interior of each of the cells. In Sec. IV we discuss other cell geometries where the present framework may serve as a basis of detailed studies. The $e^{-i\omega t}$ time dependence is suppressed throughout the analysis.

II. PERTURBATION THEORY

A. General formulation

We consider a uniform electric field $\mathbf{E}^{\mathrm{inc}}$ parallel to the **z** axis, $\mathbf{E}^{\mathrm{inc}}=E_0\mathbf{e}_z$, and incident upon N cells of reasonably arbitrary shape, where $\mathbf{e}_z$ is the **z**-directed unit vector of the Cartesian coordinate system, and we take $E_0=1$ without loss of generality; cf. Fig. 1. The cells are immersed in saline fluid, an isotropic and homogeneous medium with conductivity σ_0. The interior $\mathcal{R}_j$ of the jth cell[14] is also assumed to be isotropic and homogeneous with a conductivity σ_0, equal to that of the ambient medium. The membrane is sufficiently thin and in principle anisotropic; we take the

membrane conductivity in the direction normal to the boundary to be σ_m, which is small compared to σ_0, $\sigma_m \ll \sigma_0$. At sufficiently low frequencies the effective dielectric constant, ϵ_{eff}, in each medium is dominated by the corresponding conductivity σ,

$$\epsilon_{\text{eff}} \sim \frac{i\sigma}{\omega}, \tag{1}$$

where ω is the radial frequency of the incident field.

The electric field inside each cell depends on the *relative* effective dielectric constant of the membrane because the requisite boundary conditions for the field on the cell surfaces, through which the conductivities enter, are homogeneous; see Appendix A where the problem of a single spherical cell is revisited. Therefore, for later notational convenience we introduce the dimensionless parameter ϵ by

$$\epsilon = \frac{\sigma_m}{\sigma_0}, \tag{2}$$

where ϵ is a small positive number, $0 < \epsilon \ll 1$.

The local radius of curvature, r_{cj}, of the jth cell is assumed to be a positive, sufficiently smooth function of the surface coordinates, and large compared to the membrane thickness δ_j,[15]

$$\tilde{r} = \frac{r_{cj}}{\delta_j} \gg 1. \tag{3}$$

Effective boundary conditions at the boundaries of cells with thin membranes involve the parameter $\tilde{r}\epsilon$.[4] In many cell configurations of interest this parameter is small,

$$\tilde{r}\epsilon \ll 1. \tag{4}$$

Condition (4) is enforced throughout the paper, and enables the application of regular perturbation theory as described below; see also Appendix A where, by virtue of (4), a simplified formula is derived for the current in the interior of an isolated spherical cell.

When the frequency of the incident electromagnetic field is sufficiently low, for instance in the range 50–60 Hz, a mathematically convenient quantity to use is the scalar potential, $\Phi(\mathbf{r})$, which satisfies to a good approximation the Laplace equation,

$$\nabla^2 \Phi(\mathbf{r}) = 0. \tag{5}$$

The electric field $\mathbf{E}(\mathbf{r})$ is approximately decoupled from the magnetic field, and is described by

$$\mathbf{E} = -\nabla\Phi. \tag{6}$$

For the incident field $\mathbf{E}^{\text{inc}} = \mathbf{e}_z$ the condition for $\Phi(\mathbf{r})$ at infinity reads

$$\Phi(\mathbf{r}) \sim -z, \quad r = |\mathbf{r}| \to \infty. \tag{7}$$

Despite the simple form of (5) and (6), mathematical complications may arise because of the special boundary conditions at the membrane separating the cell interior from the saline fluid. Following Ref. 4 we replace the membrane by an effective boundary condition that stems from treating the membrane thickness, δ_j, as properly small compared to the membrane radius of curvature. Next, we rederive briefly and interpret the related result of Ref. 4 by relaxing mathematical elaboration. By integration of (6) across the membrane, the restriction Φ^+ of Φ on the cell boundary from outside the cell and the corresponding restriction Φ^- from inside the cell should satisfy $\Phi^+ - \Phi^- = -E_{m,\perp}\delta_j$; $E_{m,\perp}$ is an appropriate value of the electric field normal to the boundary *inside* the membrane and $\Phi^{\pm}$ are boundary values of Φ *outside* the membrane. For suitably thin membrane, $E_{m,\perp}$ satisfies $\sigma_m E_{m,\perp} = \sigma_0 E_\perp^+ = \sigma_0 E_\perp^-$ by Gauss's law in the absence of surface charge,

where $E_{\perp}^{\pm}$ denote the boundary values of the transverse electric field outside the membrane. The relations of this paragraph yield

$$\frac{\partial\Phi^{+}}{\partial\eta}=\frac{\partial\Phi^{-}}{\partial\eta}\equiv\left.\frac{\partial\Phi}{\partial\eta}\right|_{\partial\mathcal{R}_j}, \tag{8}$$

$$\left.\frac{\partial\Phi}{\partial\eta}\right|_{\partial\mathcal{R}_j}=\frac{1}{\xi_j}[\Phi^{+}(\mathbf{r})-\Phi^{-}(\mathbf{r})], \tag{9}$$

where $\partial\mathcal{R}_j$ is the boundary of region $\mathcal{R}_j$, $\partial\Phi/\partial\eta=\mathbf{e}_\eta\cdot\nabla\Phi$ and $\mathbf{e}_\eta$ is the unit vector normal to the boundary $\partial\mathcal{R}_j$ pointing outward; $\Phi^{+}(\mathbf{r})$ and $\partial\Phi^{+}/\partial\eta$ are the values of Φ and $\partial\Phi/\partial\eta$ as $\mathbf{r}$ approaches $\partial\mathcal{R}_j$ from outside the cell ($\mathbf{r}\to\partial\mathcal{R}_j^{+}$), and $\Phi^{-}(\mathbf{r})$ and $\partial\Phi^{-}/\partial\eta$ are the corresponding values as $\mathbf{r}$ approaches $\partial\mathcal{R}_j$ from inside the cell ($\mathbf{r}\to\partial\mathcal{R}_j^{-}$). The parameter ξ_j has dimensions of length and is defined by

$$\xi_j=\frac{\delta_j}{\epsilon}. \tag{10}$$

Condition (4) ensures that the ξ_j entering boundary condition (9) is large compared to the radius of cell curvature, r_{cj},

$$r_{cj}\ll\xi_j. \tag{11}$$

Next, we describe a perturbation scheme for calculating Φ. The starting point is the expansion[16]

$$\Phi=\Phi_0+\Phi_1+\cdots+\Phi_n+\cdots,\quad n=0,1,\ldots, \tag{12}$$

where the subscript, n, denotes the perturbation order[17] and the ratio of two successive terms is assumed to be[18]

$$\frac{\Phi_n}{\Phi_{n-1}}=O\left(\frac{r_{c1}}{\xi_1},\ldots,\frac{r_{cN}}{\xi_N}\right). \tag{13}$$

Each term Φ_n in expansion (12) is determined iteratively as described below.

1. Zeroth-order approximation, n=0

In the zeroth-order approximation the right-hand side of (9) is set equal to zero. With $\Phi(\mathbf{r})\sim\Phi_0(\mathbf{r})$, Φ_0 satisfies Laplace's equation and the Neumann boundary condition on the cell boundaries, $\partial\mathcal{R}_j$. The boundary-value problem for the cell exterior thus reads

$$\nabla^2\Phi_0(\mathbf{r})=0,\quad \mathbf{r}\in\Omega,\qquad \left.\frac{\partial\Phi_0}{\partial\eta}\right|_{\partial\mathcal{R}_j^{+}}=0,\quad j=1,2,\ldots,N, \tag{14}$$

along with condition (7), where $\Omega=\mathbb{R}^3-\cup_j\mathcal{R}_j-\cup_j\partial\mathcal{R}_j$ is the exterior of all cells ($\mathcal{R}_j$) with exclusion of every $\partial\mathcal{R}_j$; $\mathbb{R}^3$ is the Euclidean space. This problem admits a unique solution for $\Phi_0(\mathbf{r})$.[19] The corresponding problem for the cell interior $\mathcal{R}_j$ has solution

$$\Phi_0(\mathbf{r})=\varphi_{0j},\quad \mathbf{r}\in\mathcal{R}_j, \tag{15}$$

where φ_{0j} ($j=1,2,\ldots,N$) are constants to be determined below. Each of these constants enters the boundary conditions for $\Phi_1(\mathbf{r})$ (in the first-order approximation) and is evaluated as an appropriate surface integral of $\Phi_0(\mathbf{r})$; cf. (19) below.

2. First-order approximation, $n=1$

In this approximation the right-hand side of (9) is replaced by $(\Phi_0^+ - \Phi_0^-)/\xi_j$, and $\Phi(\mathbf{r}) \sim \Phi_0(\mathbf{r}) + \Phi_1(\mathbf{r})$ where $\Phi_0(\mathbf{r})$ is known from (14) above. The boundary-value problem for the cell interior is described by

$$\nabla^2 \Phi_1(\mathbf{r}) = 0, \quad \mathbf{r} \in \mathcal{R}_j, \qquad \left.\frac{\partial \Phi_1}{\partial \eta}\right|_{\mathbf{r} \in \partial \mathcal{R}_j^-} = \frac{1}{\xi_j}(\Phi_0^+ - \varphi_{0j}), \tag{16}$$

along with the condition that $\Phi_1(\mathbf{r})$ be finite in $\mathcal{R}_j$. The Laplace equation with the same boundary conditions on $\partial \mathcal{R}_j$ also apply to the exterior problem. The requisite condition for Φ_1 at infinity becomes

$$\Phi_1(\mathbf{r}) \to 0, \quad r \to \infty. \tag{17}$$

Because the constant φ_{0j} enters the Neumann condition (16), its value must be consistent with the Laplace equation.[19] By integrating $\nabla^2 \Phi_1 = 0$ over $\mathcal{R}_j$ we obtain

$$\oint_{\partial \mathcal{R}_j^-} d\mathbf{r}\, \frac{\partial \Phi_1}{\partial \eta} = 0. \tag{18}$$

By virtue of condition (16),

$$\varphi_{0j} = \frac{1}{\|\partial \mathcal{R}_j\|} \oint_{\partial \mathcal{R}_j} d\mathbf{r}\, \Phi_0^+(\mathbf{r}), \tag{19}$$

where $\|\partial \mathcal{R}_j\|$ denotes the area of the closed surface $\partial \mathcal{R}_j$.

3. nth-order approximation, $n=1,2,\ldots$

It is reasonably straightforward to generalize the first-order approximation in order to carry out the calculations to the next orders in r_{cj}/ξ_j. With $\Phi(\mathbf{r}) \sim \Sigma_{i=0}^{n} \Phi_i(\mathbf{r})$ and $n \geqslant 1$ the boundary-value problem for $\Phi_n(\mathbf{r})$ follows from the preceding discussions of the zeroth- and first-order approximations via the replacements $0 \to n-1$ and $1 \to n$ in the subscripts for Φ. In the cell interior, Φ_n satisfies the boundary-value problem

$$\nabla^2 \Phi_n(\mathbf{r}) = 0, \quad \mathbf{r} \in \mathcal{R}_j, \qquad \left.\frac{\partial \Phi_n}{\partial \eta}\right|_{\partial \mathcal{R}_j^-} = \frac{1}{\xi_j}(\Phi_{n-1}^+ - \Phi_{n-1}^-), \tag{20}$$

where $\Phi_n(\mathbf{r})$ must be bounded everywhere for $n \geqslant 1$. The same differential equation and conditions on $\partial \mathcal{R}_j$ hold for the exterior problem. The condition at infinity reads

$$\Phi_n(\mathbf{r}) \to 0, \quad r \to \infty, \quad n \geqslant 1. \tag{21}$$

In the following we restrict the analysis to the zeroth- and first-order approximations for Φ.

B. Example: Single spherical cell

Next, for comparison and validation purposes we apply the general perturbation scheme of Sec. II A to a single spherical cell with radius a exposed to a uniform field $E^{\mathrm{inc}} = \mathbf{e}_z$. This prototypical case was studied in Refs. 2 and 4. Here, we derive the same result as in Ref. 4 for the electric field inside the cell within the framework of our Sec. II A. For the sake of completeness, the derivation of Ref. 4 for a single cell is revisited in our Appendix A, via the full set of boundary conditions by which the cell membrane is taken to have a finite thickness.

1. Zeroth-order approximation

The potential Φ_0 of the exterior problem satisfies

$$\nabla^2\Phi_0(\mathbf{r}) = 0, \quad r > a, \tag{22}$$

and

$$\frac{\partial\Phi_0}{\partial r} = 0 \quad \text{at } r = a, \quad \Phi_0(r,\theta) \sim -z, \quad r \to \infty. \tag{23}$$

The solution to (22) and (23) is obtained via a reflection principle in Appendix B. The result is

$$\Phi_0(r,\theta) = -\left(r + \frac{a^3}{2r^2}\right)\cos\theta, \quad r > a. \tag{24}$$

In particular, for $r \to a^+$,

$$\Phi_0(a^+,\theta) = \Phi_0^+ = -\frac{3a}{2}\cos\theta. \tag{25}$$

It follows from (15) and (19) that the potential Φ_0 vanishes for $r < a$,

$$\Phi_0(r < a, \theta) \equiv \varphi_0 = 0. \tag{26}$$

2. First-order approximation

In the next order the interior problem is described by

$$\nabla^2\Phi_1(\mathbf{r}) = 0, \quad r < a, \tag{27}$$

$$\frac{\partial\Phi_1}{\partial r} = \frac{1}{\xi}\Phi_0^+ = -\frac{1}{\xi}\frac{3a}{2}\cos\theta \quad \text{at } r = a, \quad \Phi_1(0,\theta)\text{: finite}. \tag{28}$$

Recall that the parameter ξ is defined by (10). Because of rotational symmetry, we apply separation of variables and write $\Phi_1(r,\theta) = g(r)\cos\theta$ where, by (27) and (28), $g(r)$ satisfies

$$r^2\frac{d^2g}{dr^2} + 2r\frac{dg}{dr} - 2g = 0 \quad \text{for } r < a, \quad g(0)\text{: finite}, \quad g(a) = -\frac{3a}{2\xi}, \tag{29}$$

with solution $g(r) = -(3a/2\xi)r$. Hence,

$$\Phi_1(r,\theta) = -\frac{3a}{2\xi}r\cos\theta, \quad r < a, \tag{30}$$

in agreement with (A9) of Appendix A. The electric field $\mathbf{E}$ inside the sphere follows by $\mathbf{E} = -\nabla\Phi$,

$$\mathbf{E}(r,\theta) = \frac{3a}{2\xi}\mathbf{e}_z, \quad r < a. \tag{31}$$

This formula shows that the incident field is reduced by the factor $3a/2\xi$ inside the cell.[2,4]

III. PAIR OF SPHERICAL CELLS

In this section we apply the perturbation scheme introduced in Sec. II to two spherical cells, denoted A and B, with equal radii; cf. Fig. 2 for the geometry of the problem. The radius of each sphere is a and the distance between their centers, O_1 and O_2, is $2d$. The z axis passes through $O_1(0,0,-d)$ and $O_2(0,0,d)$. The extension of our treatment to two spherical cells with different radii, or to three or more spherical cells, is straightforward yet increasingly cumbersome and lies beyond the scope of this paper.

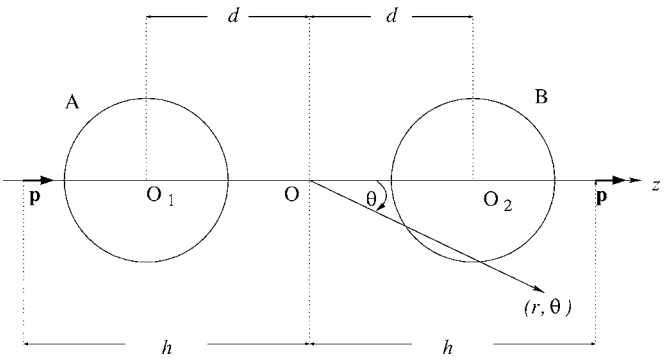

FIG. 2. The geometry of two spherical cells with equal radii, a. The incident, uniform electric field is polarized along the **z** axis. Two dipoles of moment $\mathbf{p}=\mathbf{e}_z$ are placed symmetrically with respect to the origin O in order to produce the incident field in the limit $h\to\infty$.

A. Zeroth-order approximation

The zeroth-order potential Φ_0 satisfies the Neumann boundary condition

$$\frac{\partial\Phi_0}{\partial\eta}=0, \quad \mathbf{r}\in\partial\mathcal{R}_A\cup\partial\mathcal{R}_B, \tag{32}$$

where $\partial\mathcal{R}_A$ and $\partial\mathcal{R}_B$ are the boundaries of spheres $\mathcal{R}_A$ and $\mathcal{R}_B$. In addition, $\Phi_0\sim -r\cos\theta$ as $r\to\infty$. We apply the reflection principle of Appendix B to the boundary-value problem for Φ_0 in the exterior of the cells by replacing the incident electric field by two electric dipoles (sources) of unit moment, $\mathbf{p}=\mathbf{e}_z$, located symmetrically with respect to O, at positions $(0,0,-h)$ and $(0,0,h)$; cf Fig. 2. The uniform incident field of unit amplitude, $\mathbf{E}^{\text{inc}}=\mathbf{e}_z$, is reproduced by taking the limit $h\to\infty$ after multiplying each (unit) dipole moment by πh^3; cf. (B10) of Appendix B. For finite h, the source dipoles generate an infinite number of image dipoles, all lying in the z axis, that are needed to sustain condition (32) on each spherical surface.

Next, we describe the location of image dipoles and their corresponding moments needed to satisfy the Neumann condition on the surface of each sphere, applying the results of Appendix B. Because each time an image dipole is placed inside a sphere the Neumann condition on the other sphere no longer holds, the procedure of placing image dipoles must be repeated *ad infinitum* leading to appropriate sequences of image dipoles inside each sphere. The source dipole at $(0,0,-h)$ induces image dipoles inside sphere A at positions $(0,0,-d-b)$, $(0,0,-d+a_2),\ldots,(0,0,-d+a_{2j})$, and at $(0,0,-d+b_2),\ldots,(0,0,-d+b_{2j})$, and inside sphere B at positions $(0,0,d-a_1),\ldots,(0,0,d-a_{2j-1})$ and at $(0,0,b_1),\ldots,(0,0,d-b_{2j-1})$, where j here is a positive integer and $j\to\infty$. By symmetry, the dipole at $(0,0,h)$ induces images of equal corresponding moments inside sphere B at $(0,0,d+b)$, $(0,0,d-a_2),\ldots,(0,0,d-a_{2j})$ and at $(0,0,d-b_2),\ldots,(0,0,d-b_{2j})$, and inside sphere A at $(0,0,-d+a_1),\ldots,(0,0,-d+a_{2j+1})$ and at $(0,0,-d+b_1),\ldots,(0,0,-d+b_{2j+1})$. According to (B5) of Appendix B, the distance b is defined by

$$b=\frac{a^2}{h-d}. \tag{33}$$

The distances a_m and b_m, where $a_0=d-h$ and $b_0=-b$, separately satisfy the recursion relation

$$\alpha_m=\frac{a^2}{2d-\alpha_{m-1}}, \quad m=1,2,\ldots, \tag{34}$$

where $\alpha_0=a_0$ or $\alpha_0=b_0=-b$. It follows from (B7) of Appendix B that the moments of the image dipoles located at distances a_m from O_1 or O_2 are

$$p_m = (-1)^m \left(\frac{\prod_{i=1}^{m} a_i}{a^m} \right)^3, \quad m = 1,2, \ldots . \tag{35}$$

The dipole moments corresponding to distances b_m from O_1 or O_2 are

$$q_m = (-1)^{m+1} \left(\frac{b\prod_{i=1}^{m} b_i}{a^{m+1}} \right)^3, \quad m = 1,2, \ldots ; \quad q_0 = -(b/a)^3. \tag{36}$$

The difference equation (34) is solved in Appendix C to yield

$$\alpha_m = a \frac{\sinh[m\kappa - \zeta(\alpha_0)]}{\sinh[(m+1)\kappa - \zeta(\alpha_0)]}, \tag{37}$$

where

$$\kappa = \ln \lambda, \quad \lambda = \frac{d + \sqrt{d^2 - a^2}}{a}, \tag{38}$$

$$\zeta(\alpha) = \frac{1}{2} \ln \left[\frac{1 - \lambda a^{-1} \alpha}{1 - (\lambda a)^{-1} \alpha} \right]. \tag{39}$$

It follows from Eqs. (35) and (36) that the strengths of the image dipoles are given explicitly by

$$p_m = (-1)^m \left\{ \frac{\sinh[\kappa - \zeta(a_0)]}{\sinh[(m+1)\kappa - \zeta(a_0)]} \right\}^3, \quad m = 1,2, \ldots , \tag{40}$$

$$q_m = (-1)^{m+1} \left\{ \frac{\sinh \zeta(b_0)}{\sinh[(m+1)\kappa - \zeta(b_0)]} \right\}^3, \quad m = 0,1,2, \ldots . \tag{41}$$

Thus, the zeroth-order potential in the exterior of the cells is furnished by[20]

$$\begin{aligned} 4\pi\Phi^{\mathrm{d}}(\mathbf{r};h) = {} & \frac{\mathbf{e}_z \cdot (h\mathbf{e}_z + \mathbf{r})}{|h\mathbf{e}_z + \mathbf{r}|^3} + \frac{\mathbf{e}_z \cdot (-h\mathbf{e}_z + \mathbf{r})}{|-h\mathbf{e}_z + \mathbf{r}|^3} - \frac{b^3}{a^3} \frac{\mathbf{e}_z \cdot [(d+b)\mathbf{e}_z + \mathbf{r}]}{|(d+b)\mathbf{e}_z + \mathbf{r}|^3} - \frac{b^3}{a^3} \frac{\mathbf{e}_z \cdot [-(d+b)\mathbf{e}_z + \mathbf{r}]}{|-(d+b)\mathbf{e}_z + \mathbf{r}|^3} \\ & + \sum_{m=1}^{\infty} p_m \left[\frac{(d-a_m) + \mathbf{e}_z \cdot \mathbf{r}}{|(d-a_m)\mathbf{e}_z + \mathbf{r}|^3} + \frac{-(d-a_m) + \mathbf{e}_z \cdot \mathbf{r}}{|-(d-a_m)\mathbf{e}_z + \mathbf{r}|^3} \right] + \sum_{m=1}^{\infty} q_m \left[\frac{(d-b_m) + \mathbf{e}_z \cdot \mathbf{r}}{|(d-b_m)\mathbf{e}_z + \mathbf{r}|^3} \right. \\ & \left. + \frac{-(d-b_m) + \mathbf{e}_z \cdot \mathbf{r}}{|-(d-b_m)\mathbf{e}_z + \mathbf{r}|^3} \right] = \sum_{m=0}^{\infty} (-1)^m \left\{ \frac{\sinh[\kappa - \zeta(a_0)]}{\sinh[(m+1)\kappa - \zeta(a_0)]} \right\}^3 \left[\frac{(d-a_m) + \mathbf{e}_z \cdot \mathbf{r}}{|(d-a_m)\mathbf{e}_z + \mathbf{r}|^3} \right. \\ & \left. + \frac{-(d-a_m) + \mathbf{e}_z \cdot \mathbf{r}}{|-(d-a_m)\mathbf{e}_z + \mathbf{r}|^3} \right] + \sum_{m=0}^{\infty} (-1)^{m+1} \left\{ \frac{\sinh \zeta(b_0)}{\sinh[(m+1)\kappa - \zeta(b_0)]} \right\}^3 \left[\frac{(d-b_m) + \mathbf{e}_z \cdot \mathbf{r}}{|(d-b_m)\mathbf{e}_z + \mathbf{r}|^3} \right. \\ & \left. + \frac{-(d-b_m) + \mathbf{e}_z \cdot \mathbf{r}}{|-(d-b_m)\mathbf{e}_z + \mathbf{r}|^3} \right], \end{aligned} \tag{42}$$

where $a_0 = d - h$ and $b_0 = -b$. Recall that b is defined by (33).

In the limit $h \to \infty$ we obtain $a_0 \to -\infty$ and $b_0 \to 0$, and in view of (37) and (39) we find

$$\zeta(a_0) \sim \kappa - \frac{a}{h}\sinh\kappa, \quad \zeta(b_0) \sim \frac{a}{h}\sinh\kappa, \tag{43}$$

and

$$a_{m+1} \sim a\,\frac{\sinh(m\kappa)}{\sinh[(m+1)\kappa]} \equiv \chi_m, \quad b_m \sim \chi_m. \tag{44}$$

After some rearrangement of terms in (42), the potential for $h\to\infty$ reduces to

$$4\pi\Phi^{\mathrm{d}}(\mathbf{r};h) \sim -\frac{4}{h^3}z - 2\frac{a^3}{h^3}(\sinh\kappa)^3\sum_{m=0}^{\infty}\frac{(-1)^m}{[\sinh(m+1)\kappa]^3}\left\{\frac{d-\chi_m+z}{[(d-\chi_m)^2+r^2+2(d-\chi_m)z]^{3/2}}\right.$$
$$\left.+\frac{-(d-\chi_m)+z}{[(d-\chi_m)^2+r^2-2(d-\chi_m)z]^{3/2}}\right\}. \tag{45}$$

The zeroth-order potential $\Phi_0(\mathbf{r})$ is obtained via multiplying Φ^{d} above by πh^3 so that the potential at infinity becomes $-z$:

$$\Phi_0(\mathbf{r}) = \lim_{h\to\infty}(\pi h^3\Phi^{\mathrm{d}}) = -z - \frac{a^3}{2}(\sinh\kappa)^3\sum_{m=0}^{\infty}\frac{(-1)^m}{[\sinh(m+1)\kappa]^3}\left\{\frac{d-\chi_m+z}{[(d-\chi_m)^2+r^2+2(d-\chi_m)z]^{3/2}}\right.$$
$$\left.+\frac{-(d-\chi_m)+z}{[(d-\chi_m)^2+r^2-2(d-\chi_m)z]^{3/2}}\right\}. \tag{46}$$

For nontouching spheres ($d>a$) the terms of the preceding series approach zero exponentially fast as $m\to\infty$.

Equation (46) is simplified considerably when the spheres touch ($d\to a$). With

$$\kappa \sim \sqrt{2}\left(1-\frac{a}{d}\right)^{1/2} \to 0 \quad \text{as } d\to a, \tag{47}$$

(44) furnishes

$$\chi_m = a\,\frac{m}{m+1}. \tag{48}$$

Accordingly, (46) entails

$$\Phi_0(\mathbf{r}) = -z - \frac{a^3}{2}\sum_{m=0}^{\infty}\left\{\frac{z+\dfrac{a}{m+1}}{\left[r^2+\dfrac{a^2}{(m+1)^2}+\dfrac{2az}{m+1}\right]^{3/2}} + \frac{z-\dfrac{a}{m+1}}{\left[r^2+\dfrac{a^2}{(m+1)^2}-\dfrac{2az}{m+1}\right]^{3/2}}\right\}\frac{(-1)^m}{(m+1)^3}. \tag{49}$$

It is worthwhile noting that as $m\to\infty$ terms of this series behave as $O(m^{-3})$, ensuring fast, absolute convergence.

B. First-order approximation

1. Formulas for nontouching spheres, d>a

With $\Phi\sim\Phi_0+\Phi_1$ everywhere the boundary condition for Φ_1 on each spherical surface reads

$$\left.\frac{\partial\Phi_1}{\partial r'}\right|_{r'=a} = \frac{1}{\xi}\,(\Phi_0 - \varphi_0)|_{r'=a}, \tag{50}$$

where (r', θ', ϕ') is the coordinate system with origin at the center of each sphere and φ_0 is given by (19). By expanding Φ_0 in spherical harmonics according to (D1) and (D2) of Appendix D, condition (50) reads

$$\left.\frac{\partial\Phi_1}{\partial r'}\right|_{r'=a} = \frac{1}{\xi}\left[-a\cos\theta' - \frac{a}{2}\sum_{l=1}^{\infty} D_l P_l(\cos\theta)\right], \tag{51}$$

where

$$D_l = D_l^A = (\sinh\kappa)^3 l \sum_{m=0}^{\infty} \frac{(-1)^m}{[\sinh(m+1)\kappa]^3}\left[\left(\frac{\chi_m}{a}\right)^{l-1} + \left(1+\frac{1}{l}\right)\left(\frac{2d-\chi_m}{a}\right)^{-l-2}\right] \tag{52}$$

for sphere A, and

$$D_l = D_l^B = (\sinh\kappa)^3(-1)^{l-1} l \sum_{m=0}^{\infty} \frac{(-1)^m}{[\sinh(m+1)\kappa]^3}\left[\left(\frac{\chi_m}{a}\right)^{l-1} - \left(1+\frac{1}{l}\right)\left(\frac{2d-\chi_m}{a}\right)^{-l-2}\right] \tag{53}$$

for sphere B.

Therefore, Φ_1 is expanded inside each sphere as

$$\Phi_1 = -\frac{a}{\xi} r' \cos\theta' - \frac{a^2}{2\xi}\sum_{l=1}^{\infty}\frac{D_l}{l}\left(\frac{r'}{a}\right)^l P_l(\cos\theta') + \mathcal{C}, \tag{54}$$

where $\mathcal{C}$ is an immaterial constant which is henceforth set to zero, $\mathcal{C}=0$. In view of (52) and (53) along with (D1)–(D3) of Appendix D, carrying out the summation over l gives

$$\begin{aligned}\Phi_1 = -\frac{a}{\xi} z' - \frac{a^2}{2\xi}\sum_{m=0}^{\infty}(-1)^m \frac{(\sinh\kappa)^3}{[\sinh(m+1)\kappa]^3}\left[\frac{r'}{a} T_m\left(\mp\beta_m\frac{r'}{a}, \theta'\right) \pm \gamma_m^3 \frac{r'}{a} T_m\left(\mp\gamma_m\frac{r'}{a}, \theta'\right)\right.\\ \left. + \gamma_m^2 S_m\left(\mp\gamma_m\frac{r'}{a}, \theta'\right)\right],\end{aligned} \tag{55}$$

where the upper (lower) sign corresponds to cell A (B),

$$\beta_m = \frac{\sinh(m\kappa)}{\sinh[(m+1)\kappa]}, \quad \gamma_m = \left(\frac{2d-\chi_m}{a}\right)^{-1}, \tag{56}$$

$$T_m(s,\theta') = \frac{2\cos\theta' + s}{\sqrt{1+2s\cos\theta'+s^2}}\,\frac{1}{1+\sqrt{1+2s\cos\theta'+s^2}}, \tag{57}$$

$$S_m(s,\theta') = \ln\left|\frac{2}{\sin^2\theta'}\frac{1}{s}\right| + \ln\left|\frac{s+\cos\theta' - \cos\theta'\sqrt{1+2s\cos\theta'+s^2}}{1+\sqrt{1+2s\cos\theta'+s^2}}\right|, \tag{58}$$

and χ_m is defined by (44).

The electric field, which is proportional to the current, inside each cell is

$$\mathbf{E}_1 = -\mathbf{e}_{r'}\frac{\partial\Phi_1}{\partial r'} - \mathbf{e}_{\theta'}\frac{1}{r'}\frac{\partial\Phi_1}{\partial\theta'}, \tag{59}$$

where

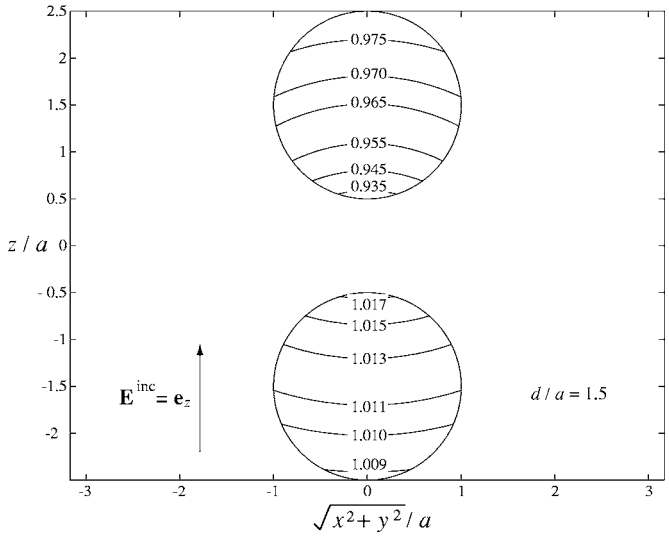

FIG. 3. Contour plots of the magnitude of the normalized electric field, $(3a/2\xi)^{-1}|\mathbf{E}_1|$, inside each cell. Maximum magnitudes are attained at $\theta'=0$; (x,y,z) is the usual Cartesian coordinate system.

$$-\frac{\partial\Phi_1}{\partial r'} = \frac{a}{\xi}\cos\theta' + \frac{a}{2\xi}\sum_{m=0}^{\infty}(-1)^m\frac{(\sinh\kappa)^3}{[\sinh(m+1)\kappa]^3} \times\left[V_m\left(\mp\beta_m\frac{r'}{a},\theta'\right)\pm\gamma_m^3 V_m\left(\mp\gamma_m\frac{r'}{a},\theta'\right)\pm\gamma_m^3 T_m\left(\mp\gamma_m\frac{r'}{a},\theta'\right)\right], \tag{60}$$

and

$$\frac{1}{r'}\frac{\partial\Phi_1}{\partial\theta'} = \frac{a}{\xi}\sin\theta' + \frac{a}{2\xi}\sin\theta'\sum_{m=0}^{\infty}(-1)^m\frac{(\sinh\kappa)^3}{[\sinh(m+1)\kappa]^3} \times\left[U_m\left(\mp\beta_m\frac{r'}{a},\theta'\right)\pm\gamma_m^3 U_m\left(\mp\gamma_m\frac{r'}{a},\theta'\right)\pm\gamma_m^3 W_m\left(\mp\gamma_m\frac{r'}{a},\theta'\right)\right]. \tag{61}$$

In the above,

$$U_m(s,\theta') = \frac{1}{(1+2s\cos\theta'+s^2)^{3/2}}, \tag{62}$$

$$V_m(s,\theta') = \frac{\cos\theta'+s}{(1+2s\cos\theta'+s^2)^{3/2}}, \tag{63}$$

$$W_m(s,\theta') = \frac{1}{\sqrt{1+2s\cos\theta'+s^2}}\,\frac{2\cos\theta'+s}{\cos\theta'(1+\sqrt{1+2s\cos\theta'+s^2})+s}. \tag{64}$$

In Fig. 3 we show contour plots for the magnitude of $\mathbf{E}_1$, normalized by the field $3a/2\xi$ inside an isolated spherical cell of equal radius (cf. Appendix A), inside cells A and B for a fixed value of d/a. In Fig. 4 we show plots for the maximum normalized magnitudes as functions of d/a. Two comments are in order: (i) As expected by close inspection of (59)–(64), for any $d>a$ the maximum $|\mathbf{E}_1|$ is attained for $\theta'=0$ for both spheres. (ii) This maximum value increases with d in sphere A and decreases with d in sphere B; cf. Fig. 4.

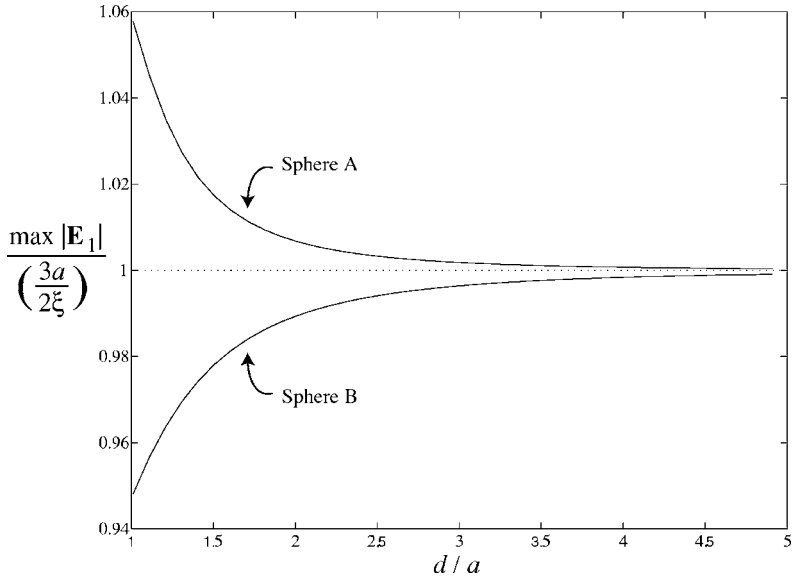

FIG. 4. Plots of the maximum magnitudes of the normalized electric fields inside cells A and B as functions of their normalized distance, d/a; $3a/2\xi$ is the electric field inside an isolated spherical cell of equal radius.

2. Touching spheres, $d \to a$

As mentioned above, a close examination of Eqs. (60) and (61) reveals that for fixed distance d the field magnitude attains its maximum at $\theta' = 0$ inside sphere A (as r' approaches a from left, $r' \to a^-$). A similar situation arises in fluid mechanics.[21] This maximum increases as d approaches a when the spheres tend to touch. In this case, $d \to a$, approximation (47) yields

$$\Phi_1 = -\frac{a}{\xi} z' - \frac{a}{2\xi} \sum_{m=0}^{\infty} \frac{(-1)^m}{(m+1)^3} \left[\frac{r'}{a} T_m\left(\mp \frac{m}{m+1} \frac{r'}{a}, \theta' \right) \pm \frac{(m+1)^3}{(m+2)^3} \frac{r'}{a} T_m\left(\mp \frac{m+1}{m+2} \frac{r'}{a}, \theta' \right) + \frac{(m+1)^2}{(m+2)^2} S_m\left(\mp \frac{m+1}{m+2} \frac{r'}{a}, \theta' \right) \right]. \tag{65}$$

The corresponding electric field is derived by invoking

$$-\frac{\partial \Phi_1}{\partial r'} = \frac{a}{\xi} \cos\theta' + \frac{a}{2\xi} \sum_{m=0}^{\infty} \frac{(-1)^m}{(m+1)^3} \left[V_m\left(\mp \frac{m}{m+1} \frac{r'}{a}, \theta' \right) \pm \frac{(m+1)^3}{(m+2)^3} V_m\left(\mp \frac{m+1}{m+2} \frac{r'}{a}, \theta' \right) \pm \frac{(m+1)^3}{(m+2)^3} T_m\left(\mp \frac{m+1}{m+2} \frac{r'}{a}, \theta' \right) \right], \tag{66}$$

and

$$\frac{1}{r'} \frac{\partial \Phi_1}{\partial \theta'} = \frac{a}{\xi} \sin\theta' + \frac{a}{2\xi} \sin\theta' \sum_{m=0}^{\infty} \frac{(-1)^m}{(m+1)^3} \left[U_m\left(\mp \frac{m}{m+1} \frac{r'}{a}, \theta' \right) \pm \frac{(m+1)^3}{(m+2)^3} U_m\left(\mp \frac{m+1}{m+2} \frac{r'}{a}, \theta' \right) \pm \frac{(m+1)^3}{(m+2)^3} W_m\left(\mp \frac{m+1}{m+2} \frac{r'}{a}, \theta' \right) \right]. \tag{67}$$

It follows that for $d \to a$ the electric field in sphere A along the z axis becomes $\mathbf{E} = (a/\xi)\mathcal{E}_1(z')\mathbf{e}_z$, where $\mathcal{E}_1$ is the positive quantity

$$\mathcal{E}_1(z') = 1 + \frac{1}{2}\sum_{m=0}^{\infty} \frac{(-1)^m}{(m+1)^3}\left(1 - \frac{|z'|}{a}\frac{m}{m+1}\right)^{-2} + \frac{1}{2}\sum_{m=0}^{\infty} \frac{(-1)^m}{(m+2)^3}\left(1 - \frac{|z'|}{a}\frac{m+1}{m+2}\right)^{-2}$$
$$+ \frac{1}{2}\sum_{m=0}^{\infty} \frac{(-1)^m}{(m+2)^3}\left(1 - \frac{|z'|}{a}\frac{m+1}{m+2}\right)^{-1}. \tag{68}$$

Hence, $\mathcal{E}_1$ attains its maximum for $z'=a$,

$$\mathcal{E}_{1,\max} = 1 + \frac{1}{2}\sum_{m=0}^{\infty} (-1)^m\left(\frac{1}{m+1} + \frac{1}{m+2} + \frac{1}{(m+2)^2}\right) = 2 - \frac{\pi^2}{24} \approx 1.5888, \tag{69}$$

which is 6% higher than the corresponding value inside the isolated spherical cell of equal radius; compare with (31) of Sec. II.

IV. CONCLUSION

By use of perturbation theory we studied analytically a mathematical model for the scattering of extremely low frequency, uniform electric fields from cells of arbitrary shapes. Two main assumptions in our derivations were that the cell radius of curvature is a slowly varying function of surface coordinates and the cell interior is an isotropic and homogeneous medium. Our results for two spherical cells suggest that the presence of a neighboring cell causes only a small increase to the electric field inside a single cell of reasonably arbitrary shape.

Our analysis, based on suitable application of regular perturbations along with a reflection principle and exact solution of a nonlinear difference equation, can be extended to geometries of many cells but becomes increasingly cumbersome with the number of cells. In this case the solution for the electrostatic potential is obtained by solving a system of tractable difference equations. It is expected, however, that the presence of additional cells will cause only a minor increase in the induced electric field, being sufficiently bounded in the number of cells. This problem is subject of work in progress.

ACKNOWLEDGMENTS

The authors are indebted to Professor T. T. Wu for suggesting the problem.

APPENDIX A: REVISITING THE SINGLE SPHERICAL CELL

In this appendix we review the case with a uniform electric field incident on a single spherical cell, which is also studied in Refs. 2 and 4. The cell interior consists of two concentric spheres of radii a and b, where $b>a$. The effective dielectric constant in the regions $0<r<a$ and $r>b$ is taken to be 1 without loss of generality; the region $a<r<b$ corresponds to the cell membrane and has dielectric constant equal to the ϵ defined by (2). The real parameter ϵ expresses the *relative* dielectric constant for the two media, membrane and protoplasm, and is equal to the ratio of their conductivities, which enter the equations only through the homogeneous boundary conditions given in Eqs. (A5) and (A6) below. For an incident field $\mathbf{E}^{\text{inc}}=\mathbf{e}_z$ the scalar potential Φ at infinity is

$$\Phi(r,\theta) \sim -r\cos\theta, \quad r\to\infty, \tag{A1}$$

where (r,θ,ϕ) are the usual spherical coordinates. The boundary conditions at $r=a,b$ dictate continuity of Φ and $\epsilon(\partial\Phi/\partial r)$ across the spherical boundaries. The scalar potential Φ is thus independent of the azimuthal angle, ϕ, while it satisfies Laplace's equation in free space. With

$$\Phi(r,\theta) = f(r)\cos\theta, \tag{A2}$$

we obtain the equation

$$\left(\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}-\frac{2}{r^2}\right)f(r)=0, \tag{A3}$$

with general solution $f(r)=Ar+Br^{-2}$. More precisely,

$$f(r)=\begin{cases} A_1 r, & r<a, \\ A_2 r+\dfrac{B_2}{r^2}, & a<r<b, \\ -r+\dfrac{B_3}{r^2}, & r>b, \end{cases} \tag{A4}$$

where the boundary condition (A1) has been used. In order to determine the constants A_1, A_2, B_2, and B_3 we apply the boundary conditions at $r=a$ and $r=b$, and thus obtain the equations

$$A_1 a=A_2 a+\frac{B_2}{a^2}, \quad A_1=\epsilon\left(A_2-\frac{2B_2}{a^3}\right), \tag{A5}$$

$$A_2 b+\frac{B_2}{b^2}=-b+\frac{B_3}{b^2}, \quad \epsilon\left(A_2-\frac{2B_2}{b^3}\right)=-1-\frac{2B_3}{b^3}. \tag{A6}$$

The electric field inside the cell is $-A_1\mathbf{e}_z$, where

$$-A_1=\frac{9\epsilon}{(1+2\epsilon)(2+\epsilon)-2(1-\epsilon)^2(a/b)^3}. \tag{A7}$$

Specifically, if ϵ is small and $a=b-\delta$, $\delta\ll a$, then

$$-A_1\sim\frac{1}{1+\dfrac{2}{3}\dfrac{\delta}{a\epsilon}}=\frac{1}{1+\dfrac{2\xi}{3a}}, \tag{A8}$$

where $\xi=\delta/\epsilon$. The right-hand side of the above equation is small if $\xi\gg a$, and can be expanded as a (convergent) geometric series for $3a/(2\xi)<1$. Specifically,

$$-A_1\sim\frac{3a}{2\xi}, \quad \frac{a}{\xi}\ll 1. \tag{A9}$$

APPENDIX B: REFLECTION PRINCIPLE WITH NEUMANN CONDITION

In this appendix (i) we derive a reflection principle, involving image dipoles, for the problem with a source dipole in the presence of a sphere with Neumann boundary conditions, extending the known analysis with a source charge and Dirichlet boundary conditions;[20] and (ii) we apply this principle to determine the potential Φ for the case with an insulating sphere and incident uniform electric field (cf. Appendix A).

We consider a $\mathbf{z}$-directed electric dipole of moment $\mathbf{p}=p\mathbf{e}_z$ located at $\mathbf{r}_0=(0,0,h)$ in the presence of a sphere with radius a centered at O. In units where $\epsilon_{\text{eff}}=1$, where ϵ_{eff} is the effective dielectric constant of the infinite medium, the ensuing scalar potential $\Phi(\mathbf{r};\mathbf{r}_0|\mathbf{p})$ satisfies the Poisson equation

$$\nabla^2\Phi=p\frac{\partial}{\partial z}\delta(\mathbf{r}-\mathbf{r}_0), \quad r>a, \tag{B1}$$

along with the prescribed Neumann boundary condition

$$\left.\frac{\partial\Phi}{\partial r}\right|_{r=a}=0, \tag{B2}$$

and $\Phi(\mathbf{r};\mathbf{r}_0|\mathbf{p})\to 0$ as $r\to\infty$. The potential Φ is thus determined uniquely in the region $r>a$. Recall that the potential generated by a dipole of moment $\mathbf{p}$ located at the origin is $\mathbf{p}\cdot\mathbf{r}/4\pi r^3$. We next express Φ for $r>a$ as a superposition of the (primary) potential Φ^{pr} generated by the source dipole at $\mathbf{r}_0$ in the absence of the sphere and the (scattered) potential Φ^{sc} of an image dipole with moment $\mathbf{p}'=\nu p\mathbf{e}_z$ at $\mathbf{r}_1=(0,0,h')$ where $h'<a$; ν and h' are to be determined.

Because of condition (B2) it is advantageous to work directly with the electric field $\mathbf{E}=-\nabla\Phi$. For $r>a$ and $|\mathbf{r}-\mathbf{r}_0|>0$,

$$\begin{aligned}\mathbf{E}(\mathbf{r})=\mathbf{E}^{\mathrm{pr}}(\mathbf{r})+\mathbf{E}^{\mathrm{sc}}(\mathbf{r})&=\frac{3[\mathbf{p}\cdot(\mathbf{r}-\mathbf{r}_0)](\mathbf{r}-\mathbf{r}_0)-(\mathbf{r}-\mathbf{r}_0)^2\mathbf{p}}{4\pi|\mathbf{r}-\mathbf{r}_0|^5}+\nu\frac{3[\mathbf{p}'\cdot(\mathbf{r}-\mathbf{r}_1)](\mathbf{r}-\mathbf{r}_1)-(\mathbf{r}-\mathbf{r}_1)^2\mathbf{p}'}{4\pi|\mathbf{r}-\mathbf{r}_1|^5}\\&=p\frac{3(r\cos\theta-h)(r\mathbf{e}_r-h\mathbf{e}_z)-(r^2+h^2-2rh\cos\theta)\mathbf{e}_z}{4\pi(r^2+h^2-2rh\cos\theta)^{5/2}}\\&\quad+\nu p\frac{3(r\cos\theta-h')(r\mathbf{e}_r-h'\mathbf{e}_z)-(r^2+h'^2-2rh'\cos\theta)\mathbf{e}_z}{4\pi(r^2+h'^2-2rh'\cos\theta)^{5/2}}.\end{aligned} \tag{B3}$$

Hence,

$$-\left.\frac{\partial\Phi(\mathbf{r})}{\partial r}\right|_{r=a}=p\frac{2(a^2+h^2)\cos\theta-ah(3+\cos^2\theta)}{4\pi(a^2+h^2-2ah\cos\theta)^{5/2}}+\nu p\frac{2(a^2+h'^2)\cos\theta-ah'(3+\cos^2\theta)}{4\pi(a^2+h'^2-2ah'\cos\theta)^{5/2}}. \tag{B4}$$

The substitution

$$\frac{h'}{a}=\frac{a}{h} \tag{B5}$$

yields $|\mathbf{r}-\mathbf{r}_1|=(a/h)|\mathbf{r}-\mathbf{r}_0|$ and reduces (B4) to

$$-\left.\frac{\partial\Phi(\mathbf{r})}{\partial r}\right|_{r=a}=p\left[1+\nu\left(\frac{h}{a}\right)^3\right]\frac{2(a^2+h^2)\cos\theta-ah(3+\cos^2\theta)}{4\pi(a^2+h^2-2ah\cos\theta)^{5/2}}. \tag{B6}$$

Condition (B2) is satisfied if

$$\nu=-\frac{a^3}{h^3}. \tag{B7}$$

This equation concludes the derivation of the reflection principle for a source dipole and Neumann boundary condition on a neighboring sphere.

Next, we apply this principle in order to derive the electrostatic potential for the case with an insulating sphere immersed in a uniform electric field, $E^{\mathrm{inc}}=E_0\mathbf{e}_z$; cf. Appendix A. This potential satisfies the Laplace equation and condition (B2), while the condition at infinity reads

$$\Phi(\mathbf{r})\sim -E_0 r\cos\theta \quad \text{as } r\to\infty. \tag{B8}$$

The uniform incident field is now viewed as the total field of two dipoles located at $(0,0,h)$ and $(0,0,-h)$ in the limit $h\to\infty$, where each dipole has moment $\mathbf{p}=p\mathbf{e}_z$.[22] The scalar potential due to these dipoles in the presence of the insulating sphere and for $r>a$ is

$$\Phi(\mathbf{r}) = \frac{p}{4\pi h^3}\Bigg[\frac{r\cos\theta - h}{\left(1 - \frac{2r}{h}\cos\theta + \frac{r^2}{h^2}\right)^{3/2}} - \frac{a^3}{r^3}\frac{r\cos\theta - \frac{a^2}{h}}{\left(1 - \frac{2a^2}{hr}\cos\theta + \frac{a^4}{r^2h^2}\right)^{3/2}} + \frac{r\cos\theta + h}{\left(1 + \frac{2r}{h}\cos\theta + \frac{r^2}{h^2}\right)^{3/2}}$$
$$- \frac{a^3}{r^3}\frac{r\cos\theta + \frac{a^2}{h}}{\left(1 + \frac{2a^2}{hr}\cos\theta + \frac{a^4}{r^2h^2}\right)^{3/2}}\Bigg] = -\frac{p}{\pi h^3}\left[r + \frac{a^3}{2r^2} + O\left(\frac{a^5}{r^5}\frac{a^2}{h^2}\right)\right]\cos\theta$$
$$\equiv -E_0\left(r + \frac{a^3}{2r^2}\right)\cos\theta, \quad h \to \infty, \tag{B9}$$

in view of (B8), where

$$p = \pi h^3 E_0, \quad h \to \infty. \tag{B10}$$

APPENDIX C: SOLUTION OF NONLINEAR DIFFERENCE EQUATION

In this appendix, the difference equation

$$x_n = \frac{\tilde{a}^2}{1 - x_{n-1}}, \quad n = 1,2,\ldots, \tag{C1}$$

where $0 < \tilde{a} \leqslant 1/2$ and $x_0 < 0$, is solved exactly. The solution is subsequently simplified for $|x_0| \ll 1$.

The substitution $x_n = \tilde{a}(y_n/y_{n+1})$ recasts (C1) to

$$y_n = \tilde{a}(y_{n+1} + y_{n-1}), \quad n = 1,2,\ldots. \tag{C2}$$

This equation is linear and can be solved via the replacement $y_n = \varrho^n$. The variable ϱ satisfies the equation $\tilde{a}\varrho^2 - \varrho + \tilde{a} = 0$ with solutions

$$\varrho = \varrho_\pm = \frac{1 \pm \sqrt{1 - 4\tilde{a}^2}}{2\tilde{a}}. \tag{C3}$$

Note that $\varrho_+\varrho_- = 1$ and $\varrho_+ + \varrho_- = 1/\tilde{a}$. It is inferred that $\varrho_+ \geqslant 1$ and $0 < \varrho_- \leqslant 1$. The solution to (C2) thus reads

$$y_n = c_1\varrho_+^n + c_2\varrho_-^n, \tag{C4}$$

where c_1 and c_2 are constants. Accordingly,

$$x_n = \tilde{a}\lambda\frac{\tilde{c}\lambda^{2n} - 1}{\tilde{c}\lambda^{2(n+1)} - 1}, \quad \lambda = \varrho_+, \quad \tilde{c} = -\frac{c_1}{c_2}. \tag{C5}$$

It follows that

$$\tilde{c} = \frac{\tilde{a} + \lambda^{-1}|x_0|}{\tilde{a} + \lambda|x_0|}, \quad 0 < \tilde{c} < 1. \tag{C6}$$

Let

$$\tilde{c} = e^{-2\zeta}, \quad \lambda = e^{\kappa}, \quad \zeta > 0, \quad \kappa > 0. \tag{C7}$$

Equation (C5) then becomes

$$x_n = \tilde{a}\frac{\sinh(n\kappa - \zeta)}{\sinh[(n+1)\kappa - \zeta]}, \quad n = 0,1,2,\ldots . \tag{C8}$$

It remains to derive an approximation for x_n when $\tilde{a}^{-1}|x_0| \ll 1$. From (C6),

$$\tilde{c} \sim (1 - \tilde{a}^{-1}\lambda^{-1}x_0)(1 + \tilde{a}^{-1}\lambda x_0) \sim 1 + (1 - \lambda^{-2})\tilde{a}^{-1}\lambda x_0, \tag{C9}$$

which in turn leads to

$$x_n \sim \tilde{a}\frac{[1 - (1 - e^{-2\kappa})\tilde{a}^{-1}\lambda|x_0|]e^{n\kappa} - e^{-n\kappa}}{[1 - (1 - e^{-2\kappa})\tilde{a}^{-1}\lambda|x_0|]e^{(n+1)\kappa} - e^{-(n+1)\kappa}} \sim \tilde{a}\frac{\sinh n\kappa}{\sinh(n+1)\kappa}\left(1 - e^{n\kappa}\frac{\sinh\kappa}{\sinh n\kappa}\tilde{a}^{-1}|x_0|\right)$$
$$\times\left[1 + \tilde{a}^{-1}|x_0|e^{(n+1)\kappa}\frac{\sinh\kappa}{\sinh(n+1)\kappa}\right] \sim \tilde{a}\frac{\sinh n\kappa}{\sinh(n+1)\kappa} - \left[\frac{\sinh\kappa}{\sinh(n+1)\kappa}\right]^2|x_0|. \tag{C10}$$

This expression becomes a trivial equality for $n=0$. Note that the coefficient of the correction term $O(x_0)$ is bounded uniformly with n.

APPENDIX D: ELEMENTARY EXPANSION IN LEGENDRE POLYNOMIALS

It is known that[23]

$$(1 + 2\beta x + \beta^2)^{-1/2} = \sum_{l=0}^{\infty}(-1)^l \mathrm{P}_l(x)\begin{cases}\beta^l, & |\beta| < 1,\\ \beta^{-l-1}, & |\beta| > 1,\end{cases} \tag{D1}$$

where $x = \cos\theta$ and $\mathrm{P}_l(x)$ are Legendre polynomials. It follows by differentiation that

$$\frac{x+\beta}{(1 + 2\beta x + \beta^2)^{3/2}} = \sum_{l=0}^{\infty}(-1)^l \mathrm{P}_l(x)\begin{cases}(-l)\beta^{l-1},\\ (l+1)\beta^{-l-2},\end{cases} \tag{D2}$$

for $|\beta| < 1$ or $|\beta| > 1$, respectively.

The term-by-term integration of (D1) yields

$$\sum_{l=1}^{\infty}\frac{\beta^l}{l}\mathrm{P}_l(x) = \int_0^{\beta}\frac{\mathrm{d}t}{t}\left(\frac{1}{\sqrt{1 - 2tx + t^2}} - 1\right), \tag{D3}$$

where $|\beta| < 1$. This integral is elementary; by changing the variable to w according to $t - x = \sqrt{1 - x^2}\sinh w$ we find

$$\sum_{l=1}^{\infty}\frac{\beta^l}{l}\mathrm{P}_l(x) = \ln\left|\frac{2}{1-x^2}\frac{1}{\beta}\frac{\beta - x + x\sqrt{1 - 2\beta x + \beta^2}}{1 + \sqrt{1 - 2\beta x + \beta^2}}\right|. \tag{D4}$$

In the limit $x \to 1^-$ the right-hand side of this formula approaches $-\ln(1-\beta)$, as it should.

(Received 6 January 2006; accepted 23 February 2006; published online 28 April 2006)

This paper presents some developments related to the idea of covariance in elasticity. The geometric point of view in continuum mechanics is briefly reviewed. Building on this, regarding the reference configuration and the ambient space as Riemannian manifolds with their own metrics, a Lagrangian field theory of elastic bodies with evolving reference configurations is developed. It is shown that even in this general setting, the Euler-Lagrange equations resulting from horizontal (referential) variations are equivalent to those resulting from vertical (spatial) variations. The classical Green-Naghdi-Rivilin theorem is revisited and a material version of it is discussed. It is shown that energy balance, in general, cannot be invariant under isometries of the reference configuration, which in this case is identified with a subset of $\mathbb{R}^3$. Transformation properties of balance of energy under rigid translations and rotations of the reference configuration is obtained. The spatial covariant theory of elasticity is also revisited. The transformation of balance of energy under an arbitrary diffeomorphism of the reference configuration is obtained and it is shown that some nonstandard terms appear in the transformed balance of energy. Then conditions under which energy balance is materially covariant are obtained. It is seen that material covariance of energy balance is equivalent to conservation of mass, isotropy, material Doyle-Ericksen formula and an extra condition that we call configurational inviscidity. In the last part of the paper, the connection between Noether's theorem and covariance is investigated. It is shown that the Doyle-Ericksen formula can be obtained as a consequence of spatial covariance of Lagrangian density. Similarly, it is shown that the material Doyle-Ericksen formula can be obtained from material covariance of Lagrangian density. [DOI: 10.1063/1.2190827]

I. INTRODUCTION

Invariance plays an important role in mechanics and in physics. In any continuum theory one has some conservation laws; i.e., quantities that are constant in time, such as mass and energy or balance laws, such as balance of linear and angular momentum. One way of building a continuum theory is to postulate these conservation or balance laws. On the other hand, as we shall recall later, conservation laws and even balance laws can be obtained as a result of postulating invariance of a quantity such as energy or Lagrangian density, under some group of transformations.

Traditionally, continuum mechanics is developed using Euclidean space as the ambient space. This has been motivated by the engineering applications of continuum mechanics and the general tendency of the engineering community to work with the simplest possible spaces. This is of

[a)]Author to whom correspondence should be addressed. Electronic mail: arash.yavari@ce.gatech.edu

course useful and the implicit simplifying assumptions of continuum mechanics have made it applicable to many problems of practical importance. However, being restricted to the misleading and rigid structure of Euclidean space, one should expect to lose important geometric information. For example, for many years there were debates on different stress rates and whether one stress rate is "more objective" than the other one. Putting continuum mechanics in the right geometric setting, one can clearly see that different stress rates in the literature are simply different representations of the same Lie derivative.[28]

Another basic example of the lack of geometry in the traditional formulation of continuum mechanics is the dependence of the well-known balance of linear and angular momenta on the linear structure of Euclidean space. These laws are written in terms of integrals of some vector fields. Of course, integrating a vector field has no intrinsic meaning and is dependent on a linear structure or a specific coordinate choice. One can argue that a geometric point of view has proven useful in, for example, building systematic numerical schemes as well as in bridging length and time scales. For example, geometry has proven useful in Refs. 25, 6, and 3, although much remains to be done in the future.

Following Einstein's idea that physical laws should not depend on any particular choice of coordinate representation of ambient spaces, Marsden and Hughes[28] developed a covariant theory of elasticity building on ideas originated from the work of Naghdi, Green and Rivilin.[19] This work starts from balance of energy, which makes sense intrinsically as it is written in terms of integrals of scalar fields (or more precisely 3-forms). Then they postulate that balance of energy is invariant under arbitrary diffeomorphisms of the ambient space. They observe that this invariance assumption gives all the usual balance laws *plus* the Doyle-Ericksen formula that relates the stress and the metric tensor.

Our motivation for studying spatial and material covariant balance laws was to gain a better understanding of the geometry of configurational forces, which are forces that act in the reference configuration. One may ask the following question. What are the consequences of postulating that balance of energy is *materially* covariant? In the process of answering this question we discovered that such invariance cannot hold in general and this led us to obtain formulas for the way in which balance of energy transforms under material diffeomorphisms. In this paper we also study the connection between spatial and material covariance with Noether's theorem. It will be shown that spatial and material covariance of a Lagrangian density lead to the spatial and material forms of the Doyle-Ericksen formula, respectively.

As was mentioned, one of our motivations for this study was to initiate a geometric study of configurational forces. These forces and their balance laws are important in formulating the evolution of defects in solids in the setting of continuum mechanics. Driving (configurational, material and so forth) forces in continuum mechanics were introduced by Eshelby,[13–15] and many researchers have studied them from different points of view. We mention the work of Knowles,[22] Abeyaratneh and Knowles[1,2] on driving force on a phase interface, Gurtin's work[20,21] on configurational forces by postulating new balance laws, the work of Maugin[31,32] and Maugin and Trimarco[33] on pull-back of balance of standard linear momentum to the reference configuration, etc. However, even after more than five decades after Eshelby's original work there does not seem to be a consensus on the nature of configurational forces and their exact role in continuum mechanics and there are still some controversies in the literature. We believe that the geometric ideas in this paper may be helpful in this direction.

This paper is organized as follows. The geometry of continuum mechanics is reviewed in Sec. II. The Lagrangian field theory of elastic bodies with evolving reference configurations is presented in Sec. III, where deformed bodies and their reference configurations are treated as Riemannian manifolds. Using this setting, the classical Green-Naghdi-Rivilin theorem and a new material version of it are discussed in Sec. IV. Spatial covariant energy balance is revisited in Sec. V. In Sec. VI we obtain the transformation (push-forward) of energy balance under an arbitrary material diffeomorphism. Then, we investigate the consequences of material covariance of energy balance. Section VII studies the connection between covariance and Noether's theorem. It is

shown that spatial and material covariance of a Lagrangian density result in spatial and material versions of the Doyle-Ericksen formula, respectively. Conclusions and future directions are given in Sec. VIII.

II. GEOMETRY OF CONTINUUM MECHANICS

This section recalls some notation from the geometric approach to continuum mechanics that will be needed. It is assumed that the reader is familiar with the basic ideas; refer to, for example, Marsden and Hughes[28] for details. See also Refs. 30 and 29.

If M is a smooth n-manifold, the tangent space to M at a point $p \in M$ is denoted T_pM, while the whole tangent bundle is denoted TM.

We denote by $\mathfrak{B}$ a reference manifold for our body and by $\mathcal{S}$ the space in which the body moves. We assume that $\mathfrak{B}$ and $\mathcal{S}$ are Riemannian manifolds with metrics denoted by $\mathbf{G}$ and $\mathbf{g}$, respectively. Local coordinates on $\mathfrak{B}$ are denoted by X^I and those on $\mathcal{S}$ by x^i. The material body $\mathcal{B}$ is a subset of the material manifold, i.e., $\mathcal{B} \subset \mathfrak{B}$.

A *deformation* of the body is, for purposes of this paper, a C^1 embedding $\varphi: \mathcal{B} \to \mathcal{S}$. The tangent map of φ is denoted $\mathbf{F} = T\varphi: T\mathcal{B} \to T\mathcal{S}$; in the literature it is often called the deformation gradient. In local charts on $\mathcal{B}$ and $\mathcal{S}$, the tangent map of φ is given by the Jacobian matrix of partial derivatives of the components of φ, which we write as

$$\mathbf{F} = T\varphi: T\mathcal{B} \to T\mathcal{S}, \quad T\varphi(X, \mathbf{V}) = (\varphi(X), \mathbf{D}\varphi(X) \cdot \mathbf{V}). \tag{2.1}$$

If $F: \mathcal{B} \to \mathbb{R}$ is a C^1 scalar function, $X \in \mathcal{B}$ and $\mathbf{V}_X \in T_X\mathcal{B}$, then $\mathbf{V}_X[F]$ denotes the derivative of F at X in the direction of $\mathbf{V}_X$, i.e., $\mathbf{V}_X[F] = \mathbf{D}F(X) \cdot \mathbf{V}$. In local coordinates $\{X^I\}$ on $\mathcal{B}$,

$$\mathbf{V}_X[F] = \frac{\partial F}{\partial X^I} V^I. \tag{2.2}$$

For $f: \mathcal{S} \to \mathbb{R}$, the *pull-back* of f by φ is defined by

$$\varphi^* f = f \circ \varphi. \tag{2.3}$$

If $F: \mathcal{B} \to \mathbb{R}$, the *push-forward* of F by φ is defined by

$$\varphi_* F = F \circ \varphi^{-1}. \tag{2.4}$$

If $\mathbf{Y}$ is a vector field on $\mathcal{B}$, then $\varphi_* \mathbf{Y} = T\varphi \circ \mathbf{Y} \circ \varphi^{-1}$, or using the $\mathbf{F}$ notation, $\varphi_* \mathbf{Y} = \mathbf{F} \circ \mathbf{Y} \circ \varphi^{-1}$ is a vector field on $\varphi(\mathcal{B})$ called the *push-forward* of $\mathbf{Y}$ by φ. Similarly, if $\mathbf{y}$ is a vector field on $\varphi(\mathcal{B}) \subset \mathcal{S}$, then $\varphi^* \mathbf{y} = T(\varphi^{-1}) \circ \mathbf{y} \circ \varphi$ is a vector field on $\mathcal{B}$ and is called the pull-back of $\mathbf{y}$ by φ.

The cotangent bundle of a manifold M is denoted T^*M and the fiber at a point $p \in M$ (the vector space of one-forms at p) is denoted by T_p^*M. If β is a one form on $\mathcal{S}$ (that is, a section of the cotangent bundle $T^*\mathcal{S}$), then the one-form on $\mathcal{B}$ defined as

$$(\varphi^* \beta)_X \cdot \mathbf{V}_X = \beta_{\varphi(X)} \cdot (T\varphi \cdot \mathbf{V}_X) = \beta_{\varphi(X)} \cdot (\mathbf{F} \cdot \mathbf{V}_X) \tag{2.5}$$

for $X \in \mathcal{B}$ and $\mathbf{V}_X \in T_X\mathcal{B}$, is called the *pull-back* of β by φ. Likewise, the *push-forward* of a one-form α on $\mathcal{B}$ is the one form on $\varphi(\mathcal{B})$ defined by $\varphi_* \alpha = (\varphi^{-1})^* \alpha$.

We can associate a vector field $\beta^\sharp$ to a one-form β on a Riemannian manifold M through the equation

$$\langle \beta_x, \mathbf{v}_x \rangle = \langle\langle \beta_x^\sharp, \mathbf{v}_x \rangle\rangle_x, \tag{2.6}$$

where $\langle , \rangle$ denotes the natural pairing between the one-form $\beta_x \in T_x^*M$ and the vector $\mathbf{v}_x \in T_xM$ and where $\langle\langle \beta_x^\sharp, \mathbf{v}_x \rangle\rangle_x$ denotes the inner product between $\beta_x^\sharp \in T_xM$ and $\mathbf{v}_x \in T_xM$. In coordinates, the components of $\beta^\sharp$ are given by $\beta^i = g^{ij}\beta_i$.

Traditionally force is thought of as a vector field in the deformed configuration. For example, body force $\mathbf{B}$ per unit undeformed mass is a vector field on $\mathcal{S}$ and its associated one-form can be defined as

$$\langle \beta_x, \delta\mathbf{w}\rangle = \langle\langle \mathbf{B}, \delta\mathbf{w}\rangle\rangle_x \tag{2.7}$$

for all $\delta\mathbf{w} \in T_x\mathcal{S}$. The pull-back of β is defined as

$$\langle (\varphi^* \beta)_X, \delta\mathbf{W}\rangle_X = \langle \beta_x, \mathbf{F}\,\delta\mathbf{W}\rangle_X = \langle\langle \mathbf{B}, \mathbf{F}\,\delta\mathbf{W}_X\rangle\rangle_X = \langle\langle \mathbf{F}^{\mathsf{T}}\mathbf{B}, \delta\mathbf{W}_X\rangle\rangle_X. \tag{2.8}$$

Therefore $\mathbf{F}^{\mathsf{T}}\mathbf{B}$ is the vector field associated with the pull-back of the one-form associated with $\mathbf{B}$.

A type $\binom{p}{q}$-tensor at $X \in \mathcal{B}$ is a multilinear map,

$$\mathbf{T}: \underbrace{T_X^*\mathcal{B} \times \cdots \times T_X^*\mathcal{B}}_{p \text{ copies}} \times \underbrace{T_X\mathcal{B} \times \cdots \times T_X\mathcal{B}}_{q \text{ copies}} \to \mathbb{R}. \tag{2.9}$$

$\mathbf{T}$ is said to be contravariant of order p and covariant of order q. In a local coordinate chart,

$$\mathbf{T}(\alpha^1, \ldots, \alpha^p, \mathbf{V}_1, \ldots, \mathbf{V}_q) = T^{i_1\cdots i_p}{}_{j_1\cdots j_q}\alpha^1_{i_1}\cdots\alpha^p_{i_p}V^{j_1}_1\cdots V^{j_q}_q, \tag{2.10}$$

where $\alpha^k \in T_X^*\mathcal{B}$ and $\mathbf{V}^k \in T_X\mathcal{B}$.

Suppose $\varphi: \mathcal{B} \to \mathcal{S}$ is a regular map and $\mathbf{T}$ is a tensor of type $\binom{p}{q}$. Push-forward of $\mathbf{T}$ by φ is denoted $\varphi_*\mathbf{T}$ and is a $\binom{p}{q}$-tensor on $\varphi(\mathcal{B})$ defined by

$$(\varphi_*\mathbf{T})(x)(\alpha^1, \ldots, \alpha^p, \mathbf{v}_1, \ldots, \mathbf{v}_q) = \mathbf{T}(X)(\varphi^*\alpha^1, \ldots, \varphi^*\alpha^p, \varphi^*\mathbf{v}_1, \ldots, \varphi^*\mathbf{v}_q), \tag{2.11}$$

where $\alpha^k \in T_x^*\mathcal{S}, \mathbf{v}_k \in T_x\mathcal{S}, X = \varphi^{-1}(x), \varphi^*(\alpha^k)\cdot\mathbf{v}_l = \alpha^k\cdot(T\varphi\cdot\mathbf{v}_l)$ and $\varphi^*(\mathbf{v}_l) = T(\varphi^{-1})\mathbf{v}_l$. Similarly, pull-back of a tensor $\mathbf{t}$ defined on $\varphi(\mathcal{B})$ is given by $\varphi^*\mathbf{t} = (\varphi^{-1})_*\mathbf{t}$. In the setting of continuum mechanics push-forward and pull-back of tensors will have the following forms:

$$(\varphi_*\mathbf{T})^{i_1\cdots i_p}{}_{j_1\cdots j_q}(x) = F^{i_1}{}_{I_1}(X)\cdots F^{i_p}{}_{I_p}(X)T^{I_1\cdots I_p}{}_{J_1\cdots J_q}(F^{-1})^{J_1}{}_{j_1}(x)\cdots(F^{-1})^{J_q}{}_{j_q}(x),$$

$$(\varphi^*\mathbf{t})^{I_1\cdots I_p}{}_{J_1\cdots J_q}(X) = (F^{-1})^{I_1}{}_{i_1}(x)\cdots(F^{-1})^{I_p}{}_{i_p}(x)t^{i_1\cdots i_p}{}_{j_1\cdots j_q}F^{j_1}{}_{J_1}(X)\cdots F^{j_q}{}_{J_q}(X).$$

A *two-point tensor* $\mathbf{T}$ of type $\begin{pmatrix} q & q' \\ p & p' \end{pmatrix}$ at $X \in \mathcal{B}$ over a map $\varphi: \mathcal{B} \to \mathcal{S}$ is a multilinear map,

$$T: \underbrace{T_X^*\mathcal{B} \times \cdots \times T_X^*\mathcal{B}}_{p \text{ copies}} \times \underbrace{T_X\mathcal{B} \times \cdots \times T_X\mathcal{B}}_{q \text{ copies}} \times \underbrace{T_x^*\mathcal{S} \times \cdots \times T_x^*\mathcal{S}}_{p \text{ copies}} \times \underbrace{T_x\mathcal{S} \times \cdots \times T_x\mathcal{S}}_{q \text{ copies}} \to \mathbb{R}, \tag{2.12}$$

where $x = \varphi(X)$.

Let $\mathbf{w}: \mathcal{U} \to T\mathcal{S}$ be a vector field, where $\mathcal{U} \subset \mathcal{S}$ is open. A curve $\mathbf{c}: I \to \mathcal{S}$, where I is an open interval, is an *integral curve* of $\mathbf{w}$ if

$$\frac{\mathrm{d}\mathbf{c}}{\mathrm{d}t}(r) = \mathbf{w}(\mathbf{c}(r)) \quad \forall\, r \in I. \tag{2.13}$$

If $\mathbf{w}$ depends on time variable explicitly, i.e., $\mathbf{w}: \mathcal{U} \times (-\varepsilon, \varepsilon) \to T\mathcal{S}$, an integral curve is defined by

$$\frac{\mathrm{d}\mathbf{c}}{\mathrm{d}t} = \mathbf{w}(\mathbf{c}(t), t). \tag{2.14}$$

Let $\mathbf{w}:\mathcal{S}\times I\to T\mathcal{S}$ be a vector field. The collection of maps $F_{t,s}$ such that for each s and x, $t\mapsto F_{t,s}(x)$ is an integral curve of $\mathbf{w}$ and $F_{s,s}(x)=x$ is called the flow of $\mathbf{w}$. Let $\mathbf{w}$ be a C^1 vector field on $\mathcal{S}$, $F_{t,s}$ its flow, and $\mathbf{t}$ a C^1 tensor field on $\mathcal{S}$. The *Lie derivative* of $\mathbf{t}$ with respect to $\mathbf{w}$ is defined by

$$\mathbf{L}_{\mathbf{w}}\mathbf{t} = \left.\frac{d}{dt}(F_{t,s}^{*}\mathbf{t})\right|_{t=s}. \tag{2.15}$$

If we hold t fixed in $\mathbf{t}$ then we denote

$$\pounds_{\mathbf{w}}\mathbf{t} = \left.\frac{d}{dt}(F_{t,s}^{*}\mathbf{t})\right|_{t=s}, \tag{2.16}$$

which is called the *autonomous Lie derivative*. Hence

$$\mathbf{L}_{\mathbf{w}}\mathbf{t} = \frac{\partial}{\partial t}\mathbf{t} + \mathfrak{L}_{\mathbf{w}}\mathbf{t}. \tag{2.17}$$

Let $\mathbf{v}$ be a vector field on $\mathcal{S}$ and $\varphi:\mathcal{B}\to\mathcal{S}$ a regular and orientation preserving C^1 map. The *Piola transform* of $\mathbf{v}$ is

$$\mathbf{V} = J\varphi^{*}\mathbf{v}, \tag{2.18}$$

where J is the Jacobian of φ. If $\mathbf{Y}$ is the Piola transform of $\mathbf{y}$, then the *Piola identity* holds,

$$\operatorname{Div}\mathbf{Y} = J(\operatorname{div}\mathbf{y})\circ\varphi. \tag{2.19}$$

A k-form on a manifold M is a skew-symmetric $\binom{0}{k}$-tensor. The space of k-forms on M is denoted $\Omega^k(M)$. If $\varphi:M\to N$ is a regular and orientation preserving C^1 map and $\alpha\in\Omega^k(\varphi(M))$, then

$$\int_{\varphi(M)}\boldsymbol{\alpha} = \int_{M}\varphi^{*}\boldsymbol{\alpha}. \tag{2.20}$$

Geometric continuum mechanics: We next review a few of the basic notions of continuum mechanics from the geometric point of view.

A *body* $\mathcal{B}$ is a submanifold of a Riemannian manifold $\mathfrak{B}$ and a *configuration* of $\mathcal{B}$ is a mapping $\varphi:\mathcal{B}\to\mathcal{S}$, where $\mathcal{S}$ is another Riemannian manifold. The set of all configurations of $\mathcal{B}$ is denoted $\mathcal{C}$. A *motion* is a curve $c:\mathbb{R}\to\mathcal{C};t\mapsto\varphi_t$ in $\mathcal{C}$.

For a fixed t, $\varphi_t(X)=\varphi(X,t)$ and for a fixed X, $\varphi_X(t)=\varphi(X,t)$, where X is position of material points in the undeformed configuration $\mathcal{B}$. The *material velocity* is the map $\mathbf{V}_t:\mathcal{B}\to\mathbb{R}^3$ given by

$$\mathbf{V}_t(X) = \mathbf{V}(X,t) = \frac{\partial\varphi(X,t)}{\partial t} = \frac{d}{dt}\varphi_X(t). \tag{2.21}$$

Similarly, the *material acceleration* is defined by

$$\mathbf{A}_t(X) = \mathbf{A}(X,t) = \frac{\partial\mathbf{V}(\mathbf{X},t)}{\partial t} = \frac{d}{dt}\mathbf{V}_X(t). \tag{2.22}$$

In components

$$A^a = \frac{\partial V^a}{\partial t} + \gamma^a_{bc}V^bV^c, \tag{2.23}$$

where γ^a_{bc} is the Christoffel symbol of the local coordinate chart $\{x^a\}$.

Here it is assumed that φ_t is invertible and regular. The *spatial velocity* of a regular motion φ_t is defined as

$$\mathbf{v}_t:\varphi_t(\mathcal{B}) \to \mathbb{R}^3, \quad \mathbf{v}_t = \mathbf{V}_t \circ \varphi_t^{-1}, \tag{2.24}$$

and the *spatial acceleration* $\mathbf{a}_t$ is defined as

$$\mathbf{a} = \dot{\mathbf{v}} = \frac{\partial \mathbf{v}}{\partial t} + \nabla_{\mathbf{v}}\mathbf{v}. \tag{2.25}$$

In components

$$a^a = \frac{\partial v^a}{\partial t} + \frac{\partial v^a}{\partial x^b}v^b + \gamma^a_{bc}v^b v^c. \tag{2.26}$$

Let $\varphi:\mathcal{B}\to\mathcal{S}$ be a C^1 configuration of $\mathcal{B}$ in $\mathcal{S}$, where $\mathcal{B}$ and $\mathcal{S}$ are manifolds. Recall that the deformation gradient is denoted $\mathbf{F}=T\varphi$. Thus, at each point $X\in\mathcal{B}$, it is a linear map

$$\mathbf{F}(X):T_X\mathcal{B} \to T_{\varphi(X)}\mathcal{S}. \tag{2.27}$$

If $\{x^i\}$ and $\{X^I\}$ are local coordinate charts on $\mathcal{S}$ and $\mathcal{B}$, respectively, the components of $\mathbf{F}$ are

$$F^i{}_J(X) = \frac{\partial \varphi^i}{\partial X^J}(X). \tag{2.28}$$

The deformation gradient may be viewed as a two-point tensor,

$$\mathbf{F}(X):T^*_x\mathcal{S} \times T_X\mathcal{B} \to \mathbb{R}; \quad (\alpha,\mathbf{V}) \mapsto \langle \alpha, T_X\varphi \cdot \mathbf{V}\rangle. \tag{2.29}$$

Suppose $\mathcal{B}$ and $\mathcal{S}$ are Riemannian manifolds with inner products $\langle\langle,\rangle\rangle_X$ and $\langle\langle,\rangle\rangle_x$ based at $X\in\mathcal{B}$ and $x\in\mathcal{S}$, respectively.

Recall that the transpose of $\mathbf{F}$ is defined by

$$\mathbf{F}^{\mathsf{T}}:T_x\mathcal{S} \to T_X\mathcal{B}, \quad \langle\langle \mathbf{F}\mathbf{V},\mathbf{v}\rangle\rangle_x = \langle\langle \mathbf{V},\mathbf{F}^{\mathsf{T}}\mathbf{v}\rangle\rangle_X \tag{2.30}$$

for all $\mathbf{V}\in T_X\mathcal{B}, \mathbf{v}\in T_x\mathcal{S}$. In components,

$$(F^{\mathsf{T}}(X))^J{}_i = g_{ij}(x)F^j{}_K(X)G^{JK}(X), \tag{2.31}$$

where $\mathbf{g}$ and $\mathbf{G}$ are metric tensors on $\mathcal{S}$ and $\mathcal{B}$, respectively. On the other hand, the *dual* of $\mathbf{F}$, a metric independent notion, is defined by

$$\mathbf{F}*(x):T^*_x\mathcal{S} \to T^*_X\mathcal{B}; \quad \langle \mathbf{F}^*(x)\cdot\alpha,\mathbf{W}\rangle = \langle \alpha,\mathbf{F}(X)\mathbf{W}\rangle \tag{2.32}$$

for all $\alpha\in T^*_x\mathcal{S}, \mathbf{W}\in T_X\mathcal{B}$.

Considering bases $\mathbf{e}_a$ and $\mathbf{E}_A$ for $\mathcal{S}$ and $\mathcal{B}$, respectively, one can define the corresponding dual bases $\mathbf{e}^a$ and $\mathbf{E}^A$. The matrix representation of $\mathbf{F}^*$ with respect to the dual bases is the transpose of $F^a{}_A$. $\mathbf{F}$ and $\mathbf{F}^*$ have the following local representations:

$$\mathbf{F} = F^j{}_K\frac{\partial}{\partial x^j}\otimes \mathrm{d}X^K, \quad \mathbf{F}^* = F^j{}_K\,\mathrm{d}X^K \otimes \frac{\partial}{\partial x^j}. \tag{2.33}$$

The *right Cauchy-Green deformation tensor* is defined by

$$\mathbf{C}(X):T_X\mathcal{B} \to T_X\mathcal{B}, \quad \mathbf{C}(X) = \mathbf{F}(X)^T\mathbf{F}(X). \tag{2.34}$$

In components,

$$C^I{}_J = (F^T)^I{}_k F^k{}_J. \tag{2.35}$$

It is straightforward to show that

$$\mathbf{C}^\flat = \varphi^*(\mathbf{g}), \quad \text{i . e . , } C_{IJ} = (g_{ij} \circ \varphi) F^i{}_I F^j{}_J. \tag{2.36}$$

From now on, by $\mathbf{C}$ we mean the tensor with components C_{IJ}. The Finger tensor is defined as $\mathbf{b} = \varphi_{t*}\mathbf{G}$, where $\mathbf{G}$ is the metric of the reference configuration.

To make ideas more concrete, a comment is in order. In the geometric treatment of continuum mechanics one assumes that the material body is a Riemannian manifold $(\mathcal{B}, \mathbf{G})$. Here $\mathcal{B}$ is an embedding of the material body, i.e., material points are identified with their positions in the reference configuration. A deformation of the material body is represented by a mapping $\varphi: \mathcal{B} \to \mathcal{S}$, where $(\mathcal{S}, \mathbf{g})$ is the ambient space, which is another Riemannian manifold. If $\varphi = \mathrm{Id}$, the reference configuration is a trivial embedding of the material body in the ambient space. Physically, in the deformation process the relative distance of material points change in general. In other words, in terms of material points $\mathbf{X}, \mathbf{X} + d\mathbf{X}$ and their positions in the deformed configuration $\mathbf{x}, \mathbf{x} + d\mathbf{x}$ we have

$$d\mathbf{x} \cdot d\mathbf{x} = \mathbf{C}\, d\mathbf{X} \cdot d\mathbf{X} \neq d\mathbf{X} \cdot d\mathbf{X}. \tag{2.37}$$

This means that in general

$$\mathbf{g} \neq \varphi_{t*}\mathbf{G}. \tag{2.38}$$

The following identities will be used frequently in this paper.

$$\frac{\partial g_{ab}}{\partial x^c} = g_{ad}\gamma^d_{bc} + g_{bd}\gamma^d_{ac}, \tag{2.39}$$

$$\frac{\partial G_{AB}}{\partial X^C} = G_{AD}\Gamma^D_{BC} + G_{BD}\Gamma^D_{AC}, \tag{2.40}$$

where γ^d_{bc} and Γ^D_{BC} are the Christoffel symbols associated to the metric tensors $\mathbf{g}$ and $\mathbf{G}$, respectively. The covariant derivative of two-point tensors will also be used frequently in this paper. The following two examples would be useful to clarify the idea. For definition for an arbitrary two-point tensor the reader may refer to Marsden and Hughes,[28]

$$P^{aA}{}_{|B} = \frac{\partial P^{aA}}{\partial X^B} + P^{aC}\Gamma^A_{CB} + P^{bA}F^c{}_A\gamma^a_{bc}, \tag{2.41}$$

$$Q_a{}^A{}_{|B} = \frac{\partial Q_a{}^A}{\partial X^B} + Q_a{}^C\Gamma^A_{CB} - Q_b{}^A F^c{}_A\gamma^b_{ca}. \tag{2.42}$$

Let $\varphi_t: \mathcal{B} \to \mathcal{S}$ be a regular motion of $\mathcal{B}$ in $\mathcal{S}$ and $\mathcal{P} \subset \mathcal{B}$ a k-dimensional submanifold. The *transport theorem* says that for any k-form α on $\mathcal{S}$,

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{P})} \alpha = \int_{\varphi_t(\mathcal{P})} \mathbf{L}_\mathbf{v}\alpha, \tag{2.43}$$

where $\mathbf{v}$ is the spatial velocity of the motion. In a special case when $\alpha = f\, dv$ and $\mathcal{P} = \mathcal{U}$ is an open set,

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{P})} f\, dv = \int_{\varphi_t(\mathcal{P})} \left[\frac{\partial f}{\partial t} + \mathrm{div}(f\mathbf{v})\right] dv. \tag{2.44}$$

We say that a body $\mathcal{B}$ satisfies *balance of linear momentum* if for every nice open set $\mathcal{U} \subset \mathcal{B}$,

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{U})} \rho\mathbf{v}\, dv = \int_{\varphi_t(\mathcal{U})} \rho\mathbf{b}\, dv + \int_{\partial\varphi_t(\mathcal{U})} \mathbf{t}\, da, \tag{2.45}$$

where $\rho=\rho(\mathbf{x},t)$ is mass density, $\mathbf{b}=\mathbf{b}(\mathbf{x},t)$ is body force vector field and $\mathbf{t}=\mathbf{t}(\mathbf{x},\hat{\mathbf{n}},t)$ is the traction vector. Note that Cauchy's stress theorem tells us that there is a contravariant second-order tensor $\boldsymbol{\sigma}=\boldsymbol{\sigma}(\mathbf{x},t)$ (Cauchy stress tensor) with components σ^{ij} such that $\mathbf{t}=\langle\langle\boldsymbol{\sigma},\hat{\mathbf{n}}\rangle\rangle$. Note that $\langle\langle,\rangle\rangle$ is the inner product induced by the Riemmanian metric $\mathbf{g}$. Equivalently, balance of linear momentum can be written in the undeformed configuration as

$$\frac{d}{dt}\int_{\mathcal{U}} \rho_0\mathbf{V}\, dV = \int_{\mathcal{U}} \rho_0\mathbf{B}\, dV + \int_{\partial\mathcal{U}} \langle\langle\mathbf{P},\hat{\mathbf{N}}\rangle\rangle dA, \tag{2.46}$$

where, $\mathbf{P}=J\varphi^{*}\boldsymbol{\sigma}$ (the first Piola-Kirchhoff stress tensor) is the Piola transform of Cauchy stress tensor. Note that $\mathbf{P}$ is a two-point tensor with components P^{iJ}. Note also that this is the balance of linear momentum in the deformed (physical) space written in terms of some quantities that are defined with respect to the reference configuration.

As was mentioned before, balance of linear momentum has no intrinsic meaning because integrating a vector field is geometrically meaningless. As is standard in continuum mechanics, this balance law makes use of the linear (or affine) structure of Euclidean space.

A body $\mathcal{B}$ is said to satisfy *balance of angular momentum* if for every nice open set $\mathcal{U}\subset\mathcal{B}$,

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{U})} \rho\mathbf{x}\times\mathbf{v}\, dv = \int_{\varphi_t(\mathcal{U})} \rho\mathbf{x}\times\mathbf{b}\, dv + \int_{\partial\varphi_t(\mathcal{U})} \mathbf{x}\times\langle\langle\boldsymbol{\sigma},\hat{\mathbf{n}}\rangle\rangle da. \tag{2.47}$$

As with balance of linear momentum, balance of angular momentum makes use of the linear structure of Euclidean space and this does *not* transform in a covariant way under a general change of coordinates.

One says that *balance of energy* holds if, for every nice open set $\mathcal{U}\subset\mathcal{B}$,

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{U})} \rho\left(e+\frac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle\right) dv = \int_{\varphi_t(\mathcal{U})} \rho(\langle\langle\mathbf{b},\mathbf{v}\rangle\rangle + r) dv + \int_{\partial\varphi_t(\mathcal{U})} (\langle\langle\mathbf{t},\mathbf{v}\rangle\rangle + h) da, \tag{2.48}$$

where $e=e(\mathbf{x},t)$, $r=r(\mathbf{x},t)$ and $h=h(\mathbf{x},\hat{\mathbf{n}},t)$ are internal energy per unit mass, heat supply per unit mass and heat flux, respectively.

The geometry of inverse motions: The study of inverse motions in continuum mechanics was started by Shield[38] and further extended by Ericksen[10] and Steinmann.[43,42] Here the idea is to fix spatial points and look at the evolution of material points under the inverse of the deformation mapping. It is known that in inverse motion, Eshelby's tensor has a role similar to that of stress tensor in direct motion. One should note that formulating continuum mechanics in terms of the inverse motion is simply a change in describing the same physical system and so, in general, cannot have any profound consequences. However, in the general relativistic setting, in which it is desireable to have the fields to be defined on space-time and take values in a bundle over space-time, inverse configurations are preferred; see Ref. 5 and references therein.

III. LAGRANGIAN FIELD THEORY OF ELASTIC BODIES WITH EVOLVING REFERENCE CONFIGURATIONS

Suppose the reference configuration evolves in time and assume that this evolution can be represented by a one-parameter family of mappings that map $\mathcal{B}\subset\mathfrak{B}$ (reference configuration at $t=0$) to $\mathcal{B}_t\subset\mathfrak{B}$ (the reference configuration at time t),

$$\Xi_t:\mathcal{B}\to\mathcal{B}_t. \tag{3.1}$$

We call these maps the *configurational deformation maps*. Note that this is not the most general form of reference configuration evolution. In general, one should look at the reference configura-

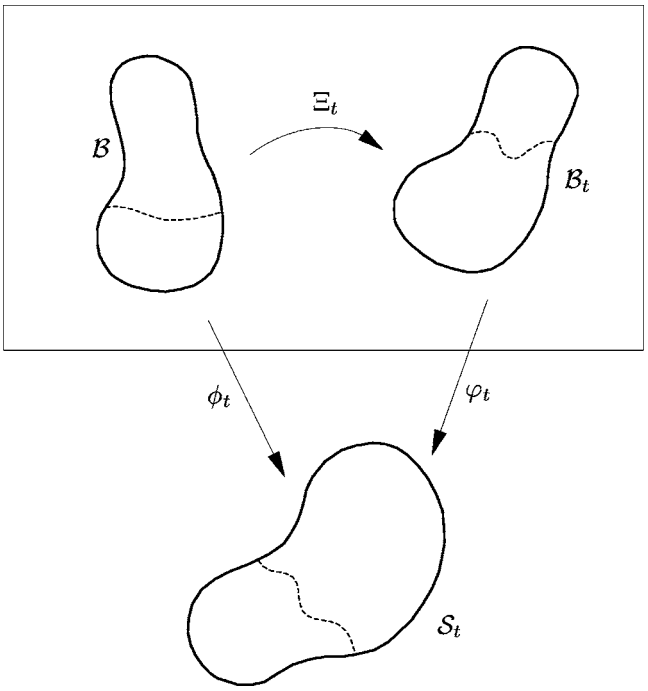

FIG. 1. Configurational and standard deformation maps.

tion evolution locally (see Refs. 9 and 8 for some discussions on this). For the sake of simplicity, we assume a global reference configuration evolution. The *configuration space* for the evolution of the reference configuration is

$$\mathcal{C}^{\text{conf}} = \{\Xi | \Xi : \mathcal{B} \to \mathcal{B}_t\}. \tag{3.2}$$

An *evolution of the reference configuration* is a curve $c : I \to \mathcal{C}^{\text{conf}}$ in $\mathcal{C}^{\text{conf}}$. It is important to put the right restrictions on Ξ_t. It does not seem necessary for Ξ_t to be invertible, in general. Here, we assume that Ξ_t is a diffeomorphism. A standard deformation is represented by a one-parameter family of mappings,

$$\varphi_t : \mathcal{B}_t \to \mathcal{S}. \tag{3.3}$$

The standard configuration space is defined by

$$\mathcal{C} = \{\varphi | \varphi : \mathcal{B}_t \to \mathcal{S}\}. \tag{3.4}$$

Again, a standard deformation is a curve in the standard configuration space. The total deformation map is the composition of standard and configurational deformation maps,

$$\phi_t = \varphi_t \circ \Xi_t : \mathcal{B} \to \mathcal{S}; \tag{3.5}$$

that is, the following diagram commutes:

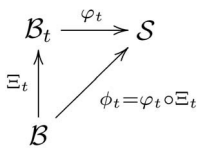

Figure 1 below shows the same idea schematically.

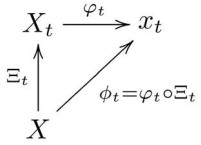
In terms of mapping the material points, $x_t=\varphi_t(X_t)=\varphi_t\circ\Xi_t(X)$, as is shown in the following commutative diagram:



The *configuration space* for the total deformation is defined as

$$\mathcal{C}^{\text{tot}}=\{\phi|\phi=\varphi\circ\Xi,\varphi\in\mathcal{C},\Xi\in\mathcal{C}^{\text{conf}}\}=\mathcal{C}\circ\mathcal{C}^{\text{conf}}. \tag{3.6}$$

A *deformation* is a curve $c:I\to\mathcal{C}^{\text{tot}}$ in the total configuration space. Note that $\Xi_t=\text{Id}$ (identity map) in most of classical continuum mechanics.

Notice that there are two independent deformation mappings φ_t and Ξ_t when reference configuration evolves in time (see Fig. 1). These separate mappings represent independent kinematical processes and hence may correspond to two separate systems of forces, in general.

Definition 3.1 (configurational velocity): The configurational velocity is defined by

$$\mathbf{V}_0(X,t)=\frac{\partial\Xi_t(X)}{\partial t}. \tag{3.7}$$

Definition 3.2: The total material velocity is defined by

$$\tilde{\mathbf{V}}(\mathbf{X},t)=\left.\frac{\partial\phi_t(\mathbf{X}_t)}{\partial t}\right|_{\mathbf{X}\text{ fixed}}=\frac{\partial\varphi_t}{\partial t}+\mathbf{F}\mathbf{V}_0=\mathbf{V}+\mathbf{F}\mathbf{V}_0, \tag{3.8}$$

where, as before, $\mathbf{F}=\partial\varphi_t/\partial\mathbf{X}_t$ *is the deformation gradient* (*holding t fixed*). Note that

$$T\phi_t=T\varphi_t\circ T\Xi_t \quad\text{or}\quad \tilde{\mathbf{F}}=\mathbf{F}\mathbf{F}_0. \tag{3.9}$$

Thus

$$\mathbf{F}_0=\mathbf{F}^{-1}\circ\tilde{\mathbf{F}}. \tag{3.10}$$

Now we may think about postulating the conservation of configurational mass and balance of linear and angular configurational momenta.

Conservation of mass is defined in terms of conservation of mass for deformation mappings Ξ_t and φ_t separately or equivalently for Ξ_t and ϕ_t separately. This makes sense as Ξ_t and φ_t correspond to configurational and standard deformations and should preserve the mass of an arbitrary sub-body.

Definitiion 3.3 (conservation of mass): Suppose $\mathcal{B}$ *is a body and* $\phi_t=\varphi_t\circ\Xi_t$ *is a deformation map. We say that the deformation mapping is mass conserving if for every* $\mathcal{U}\subset\mathcal{B}$,

$$\frac{d}{dt}\int_{\Xi_t(\mathcal{U})}\rho_0(\mathbf{X}_t,t)dV=0 \quad \textit{and} \quad \frac{d}{dt}\int_{\phi_t(\mathcal{U})}\rho(\mathbf{x},t)dv=0, \tag{3.11}$$

where $\rho_0(\mathbf{X}_t,t)$ *is the mass density at point* $X_t\in\mathcal{B}_t$ *and* $\rho(\mathbf{x},t)$ *is the mass density at the point* $\mathbf{x}\in\mathcal{S}$.

Localization of the above equations gives the local form of conservation of mass, namely

$$R_0(\mathbf{X})=\rho_0(\mathbf{X}_t,t)J_0=\rho(\mathbf{x},t)\tilde{J}, \tag{3.12}$$

where $J_0=\det(\mathbf{F}_0)(\sqrt{\det\mathbf{G}}/\sqrt{\det\mathbf{G}_0})$, $\mathbf{F}_0=T\Xi_t$ is the *configurational deformation gradient*, $\mathbf{G}_0$ is the fixed metric of $\mathcal{B}$, $\mathbf{G}$ is the metric of $\mathcal{B}_t$ and R_0 is the mass density at $\mathbf{X}\in\mathcal{B}$ and $\tilde{J}=\det(\tilde{\mathbf{F}})\times(\sqrt{\det\mathbf{g}}/\sqrt{\det\mathbf{G}})=JJ_0$. Note that this is equivalent to

$$R_0 = \rho_0 J_0 \quad \text{and} \quad \rho_0 = \rho J. \tag{3.13}$$

One may be tempted to postulate a balance of configurational linear momentum as follows. A body $\mathcal{B}$ satisfies the balance of configurational linear momentum if for any $\mathcal{U}' \subset \mathcal{B}_t$,

$$\frac{d}{dt}\int_{\mathcal{U}'} \rho_0 \mathbf{V}_0 \, dV = \int_{\mathcal{U}'} \rho_0 \mathbf{B}_0 \, dV + \int_{\partial\mathcal{U}'} \mathbf{P}_0 \mathbf{N} \, dA. \tag{3.14}$$

Localization of this balance law and using Cauchy's theorem gives the following local form of the balance of configurational linear momentum

$$\text{Div}\, \mathbf{P}_0 + \rho_0 \mathbf{B}_0 = \rho_0 \mathbf{A}_0. \tag{3.15}$$

Thinking of configurational deformation mapping Ξ_t as a deformation of a fixed reference configuration, this balance law is similar to the standard balance of linear momentum written in the deformed configuration. Note that postulating such a balance law requires the introduction of two new quantities, namely $\mathbf{P}_0$ and $\mathbf{B}_0$ and does not seem to be of any use at this point.

It should be noted that a configurational change need not be volume preserving. An example is a phase transformation from cubic to tetragonal which has the following configurational deformation gradient (this is called Bain strain or matrix in martensitic phase transformations),

$$\mathbf{F}_0 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \dfrac{c}{a} \end{pmatrix} \tag{3.16}$$

where $a=b$ and $c>a$ are the tetragonal lattice parameters.

The Lagrangian may be regarded as a map $L: T\mathcal{C} \to \mathbb{R}$, where $\mathcal{C}$ is the space of some sections (for technical details see Ref. 28), associated to the Lagrangian density $\mathcal{L}$ and a volume element $dV(X)$ on $\mathcal{B}$ and is defined as

$$L(\varphi, \dot{\varphi}) = \int_{\mathcal{B}} \mathcal{L}(X, \varphi(X), \dot{\varphi}(X), \mathbf{F}(X), \mathbf{G}(X), \mathbf{g}(\varphi(X))) dV(X). \tag{3.17}$$

Note that here we have assumed an explicit dependence of $\mathcal{L}$ on the material and spatial metrics $\mathbf{G}$ and $\mathbf{g}$. Let us first revisit the classical Lagrangian field theory of elasticity using the above Lagrangian density with explicit dependence on material and spatial metrics. The *action function* is defined as

$$S(\varphi) = \int_{t_0}^{t_1} L(\varphi, \dot{\varphi}) dt. \tag{3.18}$$

Hamilton's principle states that the physical configuration φ is the critical point of the action, i.e.,

$$\mathbf{d}S(\varphi) \cdot \delta\varphi = 0. \tag{3.19}$$

Note that variation in φ leaves the material metric unchanged. The statement of Hamilton's principle can be simplified to read

$$\int_{t_0}^{t_1} \int_{\mathcal{B}} \left(\frac{\partial \mathcal{L}}{\partial \varphi} \cdot \delta\varphi + \frac{\partial \mathcal{L}}{\partial \dot{\varphi}} \cdot \delta\dot{\varphi} + \frac{\partial \mathcal{L}}{\partial \mathbf{F}} : \delta\mathbf{F} + \frac{\partial \mathcal{L}}{\partial \mathbf{g}} : \delta\mathbf{g} \right) dV(X) dt = 0. \tag{3.20}$$

After some manipulations the above integral statement results in

$$\frac{\partial \mathcal{L}}{\partial \varphi^a} - \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}}\right)_a - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A} - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b^{\ A} F^c{}_A \gamma^b_{ac} + 2\frac{\partial \mathcal{L}}{\partial g_{cd}} g_{bd}\gamma^b_{ac} = 0. \tag{3.21}$$

Noting that

$$\frac{d}{\mathrm{d}t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}}\right)_a = \rho_0 (g_{ab}A^b + g_{bc}\gamma^c_{ad}\dot{\varphi}^b\dot{\varphi}^d), \tag{3.22}$$

$$\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a^{\ A} = -P_a{}^A, \tag{3.23}$$

$$2\frac{\partial \mathcal{L}}{\partial g_{cd}} = \rho_0 \dot{\varphi}^c\dot{\varphi}^d - J\sigma^{cd}, \tag{3.24}$$

Eq. (3.21) can be written as

$$P_a{}^A{}_{|A} + \frac{\partial \mathcal{L}}{\partial \varphi^a} + (F^c{}_A P_b{}^A - J\sigma^{cd}g_{bd})\gamma^b_{ac} = \rho_0 g_{ab}A^b. \tag{3.25}$$

Note that if $\mathcal{L}$ depends on $\mathbf{F}$ and $\mathbf{g}$ through $\mathbf{C}$, then the term in the parentheses would be zero and hence

$$P_a{}^A{}_{|A} + \frac{\partial \mathcal{L}}{\partial \varphi^a} = \rho_0 g_{ab}A^b, \tag{3.26}$$

which is nothing but the familiar equations of motion. [Also note that in (3.25) use was made of Doyle-Ericksen formula (3.24). However, for arriving at (3.26) there is no need for using Doyle-Ericksen formula.]

Now suppose that during the process of deformation the continuum undergoes a continuous material evolution. This means that the deformation mapping φ is the composition of a total deformation mapping and a referential mapping, i.e.,

$$\varphi = \phi \circ \Xi^{-1} \quad \text{or} \quad \phi = \varphi \circ \Xi. \tag{3.27}$$

Note that defining such a composition is ambiguous because there are infinitely many possibilities for decomposing a given deformation mapping ϕ into two mappings φ and Ξ. The new mappings can represent part of the standard deformation and material evolution. To make sure that φ is the standard part of total deformation mapping, the Lagrangian is written as an integral on the current reference configuration $\mathcal{B}_t$

$$L(\varphi, \dot{\varphi}) = \int_{\mathcal{B}_t} \mathcal{L}(X, \varphi(X), \dot{\varphi}(X), \mathbf{F}(X), \mathbf{G}(X), \mathbf{g}(\varphi(X)))\mathrm{d}V(X). \tag{3.28}$$

It would be more convenient to write the Lagrangian as a functional on $\mathcal{B}$ (the fixed initial reference configuration). Let us denote points on $\mathcal{B}$ by U. Note that

$$\dot{\phi}(U) = (\dot{\varphi}\circ\Xi)(U) + T\varphi(\Xi(U))\cdot\dot{\Xi}(U) \quad \text{or} \quad (\dot{\varphi}\circ\Xi)(U) = \dot{\phi}(U) - \mathbf{F}(\Xi(U))\cdot\dot{\Xi}(U). \tag{3.29}$$

Also

$$\mathbf{F}(\Xi(U)) = \mathbf{F}_\phi(U)\mathbf{F}_\Xi^{-1}(\Xi(U)). \tag{3.30}$$

Thus,

$$\mathcal{L} = \mathcal{L}(\Xi(U), \phi(U), \dot{\phi}(U) - \mathbf{F}_\phi(U)\mathbf{F}_\Xi^{-1}(\Xi(U)) \cdot \dot{\Xi}(U), \mathbf{F}_\phi(U)\mathbf{F}_\Xi^{-1}(\Xi(U)), \mathbf{G}(\Xi(U)), \mathbf{g}(\phi(U)))J_\Xi(U), \tag{3.31}$$

where

$$J_\Xi = \det(T\Xi)\frac{\sqrt{\det \mathbf{G}}}{\sqrt{\det \mathbf{G}_0}}, \tag{3.32}$$

and where $\mathbf{G}_0$ is the fixed metric of the fixed reference configuration and $\mathbf{G}$ is the metric of $\mathcal{B}_t$. As before, the action is defined as

$$S(\Xi, \phi) = \int_{t_0}^{t_1} L(\Xi, \dot{\Xi}, \phi, \dot{\phi})\mathrm{d}t. \tag{3.33}$$

Hamilton's principle states that the physical configurations Ξ and ϕ are the critical points of the action, i.e.,

$$\mathbf{d}S(\Xi, \phi) \cdot (\delta\Xi, \delta\phi) = 0. \tag{3.34}$$

For the sake of clarity, we look at the two independent variations separately.

A. Vertical variations

Let us first look at *vertical variations*; that is, we assume that $\delta\Xi = 0$ and see if we can recover the classical Euler-Lagrange equations.

Proposition 3.4: Allowing only vertical variations in Hamilton's principle, one obtains the following equations of motion

$$\frac{\partial \mathcal{L}}{\partial \varphi^a} - \frac{d}{\mathrm{d}t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi} \circ \Xi}\right)_a - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |B}^{B} - F^c{}_B \gamma^b_{ac}\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b^B + \frac{\partial \mathcal{L}}{\partial g^{bc}}\frac{\partial g^{bc}}{\partial x^a} = 0. \tag{3.35}$$

Proof: The derivative of the action with respect to vertical variations is computed as follows:

$$\begin{aligned}\mathbf{d}S(\Xi, \phi) \cdot (0, \delta\phi) = \int_{t_0}^{t_1}\int_{\mathcal{B}} \Bigg\{ &\frac{\partial \mathcal{L}}{\partial \varphi \circ \Xi} \cdot \delta\phi + \frac{\partial \mathcal{L}}{\partial \dot{\varphi} \circ \Xi} \cdot (\delta\dot{\phi} - \delta[\mathbf{F}_\phi(U)\mathbf{F}_\Xi^{-1}(\Xi(U)) \cdot \dot{\Xi}(U)]) \\ &+ \frac{\partial \mathcal{L}}{\partial \mathbf{F}} : \delta[\mathbf{F}_\phi(U)\mathbf{F}_\Xi^{-1}(\Xi(U))] + \frac{\partial \mathcal{L}}{\partial \mathbf{g}} : \delta\mathbf{g} \circ \phi \Bigg\} J_\Xi(U)\mathrm{d}V(U)\mathrm{d}t = 0.\end{aligned} \tag{3.36}$$

Note that

$$\begin{aligned}\delta(\mathbf{F}_\phi\mathbf{F}_\Xi^{-1} \circ \Xi) &= \delta(\mathbf{F}_\phi\mathbf{F}_\Xi^{-1}) \circ \Xi = T(\delta(\phi \circ \Xi^{-1})) \circ \Xi = T(\delta\phi \circ \Xi^{-1}) \circ \Xi \\ &= (T\delta\phi T\Xi^{-1}) \circ \Xi = D\delta\phi\mathbf{F}_\Xi^{-1} \circ \Xi.\end{aligned} \tag{3.37}$$

Let us assume coordinates $\{U^\alpha\}$, $\{X^A\}$, and $\{x^a\}$ and basis vectors $\mathbf{E}_\alpha$, $\mathbf{e}_A$, and $\mathbf{f}_a$ on $\mathcal{B}$, $\mathcal{B}_t$, and $\mathcal{S}$, respectively. Thus, in coordinates

$$D\delta\phi = \frac{\partial \delta\phi^a}{\partial U^\alpha}\mathbf{f}_a \otimes \mathbf{E}^\alpha. \tag{3.38}$$

The first part of the second term is simplified as

$$\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\delta\dot{\phi}J_{\Xi}(U)\mathrm{d}V(U)=-\int_{t_0}^{t_1}\int_{\mathcal{B}}\left[\frac{d}{\mathrm{d}t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a+\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}_a W^B{}_{|B}\right]\delta\phi^a J_{\Xi}\,\mathrm{d}V(U)\mathrm{d}t, \tag{3.39}$$

where

$$\mathbf{W}(U)=\frac{d}{\mathrm{d}t}\Xi(U). \tag{3.40}$$

The second part of the second term in (3.36) can be simplified to

$$\begin{aligned}
&-\int_{t_0}^{t_1}\int_{\mathcal{B}}J_{\Xi}\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}D\delta\phi\mathbf{F}_{\Xi}^{-1}\circ\Xi\cdot\mathbf{W}\,\mathrm{d}V(U)\mathrm{d}t\\
&\quad=\int_{t_0}^{t_1}\int_{\mathcal{B}}\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a J_{\Xi}(\mathbf{F}_{\Xi}^{-1}\circ\Xi)^{\beta}{}_B W^B\right]_{|\beta}\delta\phi^a\,\mathrm{d}V(U)\mathrm{d}t\\
&\qquad+\int_{t_0}^{t_1}\int_{\mathcal{B}}\left[J_{\Xi}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_b(\mathbf{F}\circ\Xi)^c{}_A\gamma_{ac}^b W^A\right]\delta\phi^a\,\mathrm{d}V(U)\mathrm{d}t.
\end{aligned} \tag{3.41}$$

Using the Piola identity we have

$$\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a J_{\Xi}(\mathbf{F}_{\Xi}^{-1}\circ\Xi)^{\beta}{}_B W^B\right]_{|\beta}=J_{\Xi}\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a W^A\right]_{|A}. \tag{3.42}$$

Also

$$\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a W^A\right]_{|A}=\frac{\partial}{\partial X^A}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a W^A+\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a W^A{}_{|A}-\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_b W^A\gamma_{ac}^b F_A^c. \tag{3.43}$$

Therefore (3.41) is simplified to

$$\int_{t_0}^{t_1}\int_{\mathcal{B}}\left[\frac{\partial}{\partial X^A}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a W^A+\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a W^A{}_{|A}\right]\delta\phi^a J_{\Xi}\mathrm{d}V(U)\mathrm{d}t. \tag{3.44}$$

Note that

$$\frac{\partial}{\partial t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a=\frac{\partial}{\partial t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a\circ\Xi^{-1}-\frac{\partial}{\partial X^A}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a\circ\Xi^{-1}W^A. \tag{3.45}$$

Hence adding (3.39) and (3.44) the term corresponding to $\delta\dot{\phi}$ is simplified to

$$\int_{t_0}^{t_1}\int_{\mathcal{B}_t}-\frac{\partial}{\partial t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a\delta\phi^a\circ\Xi^{-1}\,\mathrm{d}V(X)\,\mathrm{d}t. \tag{3.46}$$

After some lengthy manipulations, the third term in (3.36) can be written as

$$-\int_{t_0}^{t_1}\int_{\mathcal{B}}\left[\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}\circ\Xi}\right)_a{}_{|B}^{B}+F^c{}_B\circ\Xi\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}\circ\Xi}\right)_a^B\gamma_{ac}^b\right]\delta\phi^a J_{\Xi}(U)\mathrm{d}V(U)\mathrm{d}t. \tag{3.47}$$

The last term is simplified as

$$\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial\mathbf{g}\circ\phi}:\delta\mathbf{g}\circ\phi J_{\Xi}\,\mathrm{d}V(U)\mathrm{d}t=\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial g^{bc}\circ\phi}\frac{\partial g^{bc}}{\partial x^a}\delta\phi^a J_{\Xi}\,\mathrm{d}V(U)\mathrm{d}t=\int_{t_0}^{t_1}\int_{\mathcal{B}_t}\frac{\partial\mathcal{L}}{\partial g^{bc}}\frac{\partial g^{bc}}{\partial x^a}\delta\phi^a$$
$$\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t=-\int_{t_0}^{t_1}\int_{\mathcal{B}_t}\frac{\partial\mathcal{L}}{\partial g^{bc}}(g^{cd}\gamma^b_{ad}+g^{bd}\gamma^c_{ad})\delta\phi^a\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t. \tag{3.48}$$

Therefore, adding the above four simplified terms, we obtain

$$\mathbf{d}S(\Xi,\phi)\cdot(0,\delta\phi)=\int_{t_0}^{t_1}\int_{\mathcal{B}_t}\left[\frac{\partial\mathcal{L}}{\partial\varphi^a}-\frac{d}{\mathrm{d}t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a-\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)^B_{a\ |B}-F^c{}_B\gamma^b_{ac}\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)^B_b+\frac{\partial\mathcal{L}}{\partial g^{bc}}\frac{\partial g^{bc}}{\partial x^a}\right]\delta\phi^a$$
$$\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t. \tag{3.49}$$

As $\delta\phi^a$ is arbitrary we conclude that

$$\frac{\partial\mathcal{L}}{\partial\varphi^a}-\frac{d}{\mathrm{d}t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a-\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)^B_{a\ |B}-F^c{}_B\gamma^b_{ac}\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)^B_b+\frac{\partial\mathcal{L}}{\partial g^{bc}}\frac{\partial g^{bc}}{\partial x^a}=0, \tag{3.50}$$

which gives the stated result. □

B. Horizontal variations

Now let us try to find the Euler-Lagrange equations resulting from *horizontal variations*; that is, variations of the configurational deformation mapping Ξ.

Proposition 3.5: Allowing only horizontal variations in Hamilton's principle, one obtains the following configurational equations of motion:

$$\frac{\partial\mathcal{L}}{\partial X^A}+\frac{\partial}{\partial t}\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a F^a{}_A\right]-\left[\mathcal{L}\delta^B{}_A-\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)^B_a F^a{}_A\right]_{|B}+\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)^B_a F^a{}_C\Gamma^C_{AB}+2G_{CD}\Gamma^D_{AB}\frac{\partial\mathcal{L}}{\partial G_{BC}}=0, \tag{3.51}$$

where Γ^C_{AB} is the Christoffel symbol of a local chart in $\mathcal{B}_t$.

Proof: The derivative of the action with respect to horizontal variations is computed as follows:

$$\mathbf{d}S(\Xi,\phi)\cdot(\delta\Xi,0)=\int_{t_0}^{t_1}\int_{\mathcal{B}}\left(\left[\frac{\partial\mathcal{L}}{\partial\Xi}\cdot\delta\Xi-\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\cdot\delta(\mathbf{F}_{\phi}\mathbf{F}^{-1}_{\Xi}\circ\Xi\cdot\dot{\Xi})+\frac{\partial\mathcal{L}}{\partial\mathbf{F}\circ\Xi}:\delta(\mathbf{F}_{\phi}\mathbf{F}^{-1}_{\Xi}\circ\Xi)\right]J_{\Xi}\right.$$
$$\left.+\frac{\partial\mathcal{L}}{\partial\mathbf{G}\circ\Xi}:\delta\mathbf{G}\circ\Xi+\mathcal{L}\delta J_{\Xi}\right)\mathrm{d}V(U)\mathrm{d}t=0. \tag{3.52}$$

Note that

$$\delta(\mathbf{F}_{\phi}\mathbf{F}^{-1}_{\Xi}\circ\Xi)=\mathbf{F}_{\phi}\delta(\mathbf{F}^{-1}_{\Xi}\circ\Xi). \tag{3.53}$$

But

$$\delta(\mathbf{F}^{-1}_{\Xi}\circ\Xi)=-\mathbf{F}^{-1}_{\Xi}D(\delta\Xi)\mathbf{F}^{-1}_{\Xi}\circ\Xi. \tag{3.54}$$

Thus

$$\delta(\mathbf{F}_{\phi}\mathbf{F}^{-1}_{\Xi}\circ\Xi)=-\mathbf{F}_{\phi}\mathbf{F}^{-1}_{\Xi}D(\delta\Xi)\mathbf{F}^{-1}_{\Xi}\circ\Xi=-\mathbf{F}D(\delta\Xi)\mathbf{F}^{-1}_{\Xi}\circ\Xi. \tag{3.55}$$

Similarly

$$\delta(\mathbf{F}_\phi\mathbf{F}_\Xi^{-1}\circ\Xi\cdot\dot{\Xi}) = -\mathbf{F}D(\delta\Xi)\mathbf{F}_\Xi^{-1}\circ\Xi\cdot\mathbf{W}+\mathbf{F}\circ\Xi\cdot\frac{d}{dt}(\delta\Xi). \tag{3.56}$$

In coordinates,

$$D(\delta\Xi) = \frac{\partial\delta\Xi^A}{\partial U^\beta}\mathbf{e}_A\otimes\mathbf{E}^\beta. \tag{3.57}$$

The second term in (3.52) has two parts which are simplified as follows. The first part is

$$\int_{t_0}^{t_1}\int_{\mathcal{B}}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\right)_a F^a{}_A\circ\Xi\frac{\partial\delta\Xi^A}{\partial U^\beta}(\mathbf{F}_\Xi^{-1}\circ\Xi)^\beta{}_B W^B J_\Xi\,\mathrm{d}V(U)\mathrm{d}t = -\int_{t_0}^{t_1}\int_{\mathcal{B}'}\frac{\partial}{\partial X^B}\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a F^a{}_A\right]W^B\delta\Xi^A$$
$$\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t - \int_{t_0}^{t_1}\int_{\mathcal{B}'}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a F^a{}_A W^B{}_{|B}\delta\Xi^A\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t. \tag{3.58}$$

Similarly, the second part is simplified as

$$-\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\cdot\mathbf{F}\circ\Xi\cdot\frac{d}{dt}(\delta\Xi)J_\Xi\,\mathrm{d}V(U)\mathrm{d}t = \int_{t_0}^{t_1}\int_{\mathcal{B}_t}\frac{d}{dt}\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a F^a{}_A\right]\delta\Xi^A\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t$$
$$+\int_{t_0}^{t_1}\int_{\mathcal{B}_t}\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a F^a{}_A W^B{}_{|B}\delta\Xi^A\,\mathrm{d}V(X)\mathrm{d}t. \tag{3.59}$$

Adding (3.58) and (3.59), the second term of (3.52) can be written as

$$-\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial\dot{\varphi}\circ\Xi}\delta(\mathbf{F}_\phi\mathbf{F}_\Xi^{-1}\circ\Xi\cdot\dot{\Xi})J_\Xi\,\mathrm{d}V(U)\mathrm{d}t = \int_{t_0}^{t_1}\int_{\mathcal{B}_t}\frac{d}{dt}\left[\left(\frac{\partial\mathcal{L}}{\partial\dot{\varphi}}\right)_a F^a{}_A\right]\delta\Xi^A\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t. \tag{3.60}$$

After some lengthy manipulations, the third term of (3.52) is simplified to

$$\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial\mathbf{F}\circ\Xi}:\delta(\mathbf{F}_\phi\mathbf{F}_\Xi^{-1}\circ\Xi)J_\Xi\,\mathrm{d}V(U)\mathrm{d}t$$
$$=\int_{t_0}^{t_1}\int_{\mathcal{B}_t}\left[\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)_a{}^B F^a{}_A\right]_{|B}\delta\Xi^A\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t$$
$$+\int_{t_0}^{t_1}\int_{\mathcal{B}_t}\left(\frac{\partial\mathcal{L}}{\partial\mathbf{F}}\right)_a{}^B F^a{}_C\Gamma^C_{AB}\delta\Xi^A\circ\Xi^{-1}\,\mathrm{d}V(X)\mathrm{d}t. \tag{3.61}$$

The fourth term of (3.52) is simplified to

$$\int_{t_0}^{t_1}\int_{\mathcal{B}}\frac{\partial\mathcal{L}}{\partial\mathbf{G}\circ\Xi}:\delta\mathbf{G}\circ\Xi J_\Xi\,\mathrm{d}V(U)\mathrm{d}t = \int_{t_0}^{t_1}\int_{\mathcal{B}_t}2G_{CD}\Gamma^D_{AB}\frac{\partial\mathcal{L}}{\partial G_{BC}}\mathrm{d}V(X)\mathrm{d}t. \tag{3.62}$$

Note that

$$J_\Xi = (\det\mathbf{F}_\Xi)\sqrt{\frac{\det\mathbf{G}}{\det\mathbf{G}_0}}, \tag{3.63}$$

where $\mathbf{G}_0$ is the fixed Riemannian metric of the fixed reference configuration. Thus,

$$\delta J_\Xi = \delta(\det \mathbf{F}_\Xi)\sqrt{\frac{\det \mathbf{G}}{\det \mathbf{G}_0}} + (\det \mathbf{F}_\Xi)\frac{\delta \det \mathbf{G}}{\det \mathbf{G}_0} = J_\Xi(\mathbf{F}_\Xi^{-1})^\beta{}_B \frac{\partial \delta \Xi^B}{\partial U^\beta} + (\det \mathbf{F}_\Xi)\frac{1}{\sqrt{\det \mathbf{G}_0}}\frac{\partial \sqrt{\det \mathbf{G}}}{\partial \mathbf{X}}\delta\Xi. \tag{3.64}$$

Note that

$$\frac{\partial \sqrt{\det \mathbf{G}}}{\partial \mathbf{X}} = \frac{1}{2}\sqrt{\det \mathbf{G}}\mathbf{G}^{-1}\frac{\partial \mathbf{G}}{\partial \mathbf{X}} = \sqrt{\det \mathbf{G}}\Gamma^B_{AB}\delta\Xi^A. \tag{3.65}$$

Hence

$$\delta J_\Xi = J_\Xi(\mathbf{F}_\Xi^{-1})^\beta{}_B \frac{\partial \delta \Xi^B}{\partial U^\beta} + J_\Xi \Gamma^B_{AB}. \tag{3.66}$$

Thus the last term of (3.52) is simplified to

$$\int_{t_0}^{t_1}\int_{\mathcal{B}} \mathcal{L}\delta J_\Xi \, \mathrm{d}V(U)\mathrm{d}t = -\int_{t_0}^{t_1}\int_{\mathcal{B}_t} (\mathcal{L}\delta_A{}^B)_{|B}\delta\Xi^A \circ \Xi^{-1}\, \mathrm{d}V(X)\mathrm{d}t. \tag{3.67}$$

Now substituting the above five simplified terms into (3.52), we have

$$\begin{aligned}\mathbf{d}S(\Xi,\phi)\cdot(\delta\Xi,0) = \int_{t_0}^{t_1}\int_{\mathcal{B}_t}\left\{\frac{\partial \mathcal{L}}{\partial X^A} + \frac{\partial}{\partial t}\left[\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}}\right)_a F^a{}_A\right] - \left[\mathcal{L}\delta_A{}^B - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^B F^a{}_A\right]_{|B}\right\}\delta\Xi^A \\ \circ \Xi^{-1}\, \mathrm{d}V(X)\mathrm{d}t + \int_{t_0}^{t_1}\int_{\mathcal{B}_t}\left\{\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^B F^a{}_C\Gamma^C_{AB} + 2G_{CD}\Gamma^D_{AB}\frac{\partial \mathcal{L}}{\partial G_{BC}}\right\}\delta\Xi^A \\ \circ \Xi^{-1}\, \mathrm{d}V(X)\mathrm{d}t = 0.\end{aligned} \tag{3.68}$$

Because $\delta\Xi^A$ is arbitrary, we conclude that

$$\frac{\partial \mathcal{L}}{\partial X^A} + \frac{\partial}{\partial t}\left[\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}}\right)_a F^a{}_A\right] - \left[\mathcal{L}\delta_A{}^B - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^B F^a{}_A\right]_{|B} + \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^B F^a{}_C\Gamma^C_{AB} + 2G_{CD}\Gamma^D_{AB}\frac{\partial \mathcal{L}}{\partial G_{BC}} = 0. \tag{3.69}$$

□

We now show that this is equivalent to the classical Euler-Lagrange equations and does not give us any new information. After some lengthy manipulations, it can be shown that

$$\begin{aligned}\frac{\partial \mathcal{L}}{\partial X^A} + \frac{\partial}{\partial t}\left[\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}}\right)_a F^a{}_A\right] - \left[\mathcal{L}\delta_A{}^B - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^B F^a{}_A\right]_{|B} = \left[\frac{\partial \mathcal{L}}{\partial \varphi^a} - \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}}\right)_a - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^A{}_{|A}\right. \\ \left. - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b{}^A F^c{}_A\gamma^b_{ac} + 2\frac{\partial \mathcal{L}}{\partial g_{cd}}g_{bd}\gamma^b_{ac}\right]F^a{}_A - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^B F^a{}_C\Gamma^C_{AB} - 2G_{CD}\Gamma^D_{AB}\frac{\partial \mathcal{L}}{\partial G_{BC}}.\end{aligned} \tag{3.70}$$

□

[It will be seen in Sec. VI that material covariance of internal energy density implies that the sum of the last two terms is zero. In Sec. VII, it will be shown that material covariance of Lagrangian density results in the same identity. However, at this point there is no such relation and the variational principle does not give us any new information.] This result is known for the case where the underlying metrics are trivial.[25] In conclusion, we have proved the following proposition.

Proposition 3.6: In the absence of discontinuities, i.e., when all the fields are smooth, the configurational and the standard equations of motion are equivalent, even if one is allowed to vary the referential and spatial metrics.

IV. THE GREEN-NAGHDI-RIVILIN THEOREM

Green, Rivilin, and Naghdi[19] realized that conservation of mass and balance of linear and angular momenta can be obtained as a result of postulating invariance of energy balance under isometries of $\mathbb{R}^3$, i.e., rigid translations and rotations in the deformed configuration. Later Marsden and Hughes[28] extended this idea to Riemannian manifolds and diffeomorphisms of the deformed configuration showing that this covariant approach gives the Doyle-Ericksen formula for Cauchy stress as well as conservation of mass and balance of linear and angular momenta. In another relevant work, Šilhavý[39] considered all the densities in the energy balance to be volume densities and assuming (i) invariance of energy balance under Galilean transformations and (ii) boundedness of energy from below, proved the existence of mass, its conservation, balance of linear and angular momenta, transformation of body forces and the splitting of total energy into internal and kinetic energies.

Before discussing the covariant approach to elasticity, let us first discuss the classical Green-Naghdi-Rivilin (GNR) theorem and a nonconventional material form of it. We consider two cases: (i) material energy balance invariance under spatial isometries of $\mathbb{R}^3$ and (ii) material energy balance invariance under material isometries of $\mathbb{R}^3$. We call (i) and (ii) the spatial-material and material-material GNR theorems, respectively.

A. The spatial-material GNR theorem

Consider the material energy balance for a nice subset $\mathcal{U}\subset\mathcal{B}$,

$$\frac{d}{\mathrm{d}t}\int_{\mathcal{U}}\rho_0\left(\Psi+\frac{1}{2}\mathbf{V}\cdot\mathbf{V}\right)\mathrm{d}V=\int_{\mathcal{U}}\rho_0(\mathbf{B}\cdot\mathbf{V}+R)\mathrm{d}V+\int_{\partial\mathcal{U}}(\mathbf{T}\cdot\mathbf{V}+H)\mathrm{d}A, \tag{4.1}$$

where $\Psi=\Psi(t,\mathbf{X},\mathbf{F})$ is the free energy density per unit mass of the undeformed configuration. Now consider an isometry $\xi_t:\mathbb{R}^3\to\mathbb{R}^3$ of $\mathbb{R}^3$. We postulate that the material energy balance is invariant under ξ_t. For the sake of simplicity we consider translations and rotations separately.

(i) (*Rigid translations*) A spatial rigid translation is defined by

$$\xi_t(\mathbf{x})=\mathbf{x}+(t-t_0)\mathbf{c}, \tag{4.2}$$

where $\mathbf{c}$ is some constant vector field. We now postulate that the material balance of energy holds for the deformation mapping $\varphi_t'=\xi_t\circ\varphi_t$ as well. This balance law is still written on $\mathcal{U}$ but with different fields (primed fields) in general,

$$\frac{d}{\mathrm{d}t}\int_{\mathcal{U}}\rho_0'\left(\Psi'+\frac{1}{2}\mathbf{V}'\cdot\mathbf{V}'\right)\mathrm{d}V=\int_{\mathcal{U}}\rho_0'(\mathbf{B}'\cdot\mathbf{V}'+R')\mathrm{d}V+\int_{\partial\mathcal{U}}(\mathbf{T}'\cdot\mathbf{V}'+H')\mathrm{d}A. \tag{4.3}$$

Using Cartan's space-time theory, the primed fields are related to the unprimed quantities through the following relations:

$$\rho_0'(\mathbf{X})=\rho_0(\mathbf{X}),\quad R'(\mathbf{X})=R(\mathbf{X}),\quad H'(\mathbf{X})=H(\mathbf{X}),$$

$$\mathbf{V}'|_{t=t_0}=\left.\frac{\partial}{\partial t}\varphi_t'\right|_{t=t_0}=(T\xi_t\mathbf{V}+\mathbf{c})_{t=t_0}=\mathbf{V}+\mathbf{c},$$

$$\mathbf{T}'(\mathbf{X},\mathbf{N})=\mathbf{T}(\mathbf{X},\mathbf{N}). \tag{4.4}$$

Also because

$$\mathbf{b}' - \mathbf{a}' = \xi_{t*}(\mathbf{b} - \mathbf{a}) \quad \text{and} \quad \mathbf{B} - \mathbf{A} = (\mathbf{b} - \mathbf{a}) \circ \varphi_t. \tag{4.5}$$

We have

$$\mathbf{B}' - \mathbf{A}' = \xi_t^*(\mathbf{b} - \mathbf{a}) \circ \varphi_t'. \tag{4.6}$$

Hence

$$(\mathbf{B}' - \mathbf{A}')_{t=t_0} = (\mathbf{b} - \mathbf{a}) \circ \varphi_t = (\mathbf{B} - \mathbf{A}). \tag{4.7}$$

It can be easily shown that

$$\mathbf{F}'(\mathbf{X}) = \mathbf{F}(\mathbf{X}). \tag{4.8}$$

The free energy density would have the following transformation:

$$\Psi'(t, \mathbf{X}, \mathbf{F}'(\mathbf{X})) = \Psi(t, \mathbf{X}, \mathbf{F}(\mathbf{X})). \tag{4.9}$$

Thus,

$$\frac{d}{\mathrm{d}t}\Psi'(t, \mathbf{X}, \mathbf{F}'(\mathbf{X})) = \frac{\partial \Psi}{\partial t}. \tag{4.10}$$

Balance of energy for $\mathcal{U} \subset \mathcal{B}$ for the new deformation mapping at $t = t_0$ can be written as

$$\begin{aligned} &\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(\Psi + \frac{1}{2}(\mathbf{V} + \mathbf{c}) \cdot (\mathbf{V} + \mathbf{c})\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0\left(\frac{\partial \Psi}{\partial t} + (\mathbf{V} + \mathbf{c}) \cdot \mathbf{A}'|_{t=t_0}\right)\mathrm{d}V \\ &\quad = \int_{\mathcal{U}} \rho_0(\mathbf{B}'|_{t=t_0} \cdot (\mathbf{V} + \mathbf{c}) + R)\mathrm{d}V + \int_{\partial \mathcal{U}} (\mathbf{T} \cdot (\mathbf{V} + \mathbf{c}) + H)\mathrm{d}A, \end{aligned} \tag{4.11}$$

where Div $\mathbf{c} = 0$ was used. Subtracting the material energy balance of the deformation φ_t for $\mathcal{U} \subset \mathcal{B}$ from the above equation and using (4.7) we obtain

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(\mathbf{c} \cdot \mathbf{V} + \frac{1}{2}\mathbf{c} \cdot \mathbf{c}\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0 \mathbf{A} \cdot \mathbf{c}\, \mathrm{d}V = \int_{\mathcal{U}} \rho_0 \mathbf{B} \cdot \mathbf{c}\, \mathrm{d}V + \int_{\partial \mathcal{U}} \mathbf{T} \cdot \mathbf{c}\, \mathrm{d}A. \tag{4.12}$$

Because $\mathcal{U}$ and $\mathbf{c}$ are arbitrary one concludes that

$$\frac{\partial \rho_0}{\partial t} = 0, \tag{4.13}$$

$$\mathrm{Div}\, \mathbf{P} + \rho_0 \mathbf{B} = \rho_0 \mathbf{A}. \tag{4.14}$$

(ii) (*Rigid rotations*) Now let us consider a rigid rotation in the ambient space, i.e., $\xi_t : \mathcal{S} \to \mathcal{S}$, where

$$\xi_t(\mathbf{x}) = e^{(t-t_0)\mathbf{\Omega}}\mathbf{x}, \tag{4.15}$$

for some constant skew-symmetric matrix $\mathbf{\Omega}$. Note that

$$T\xi_t|_{t=t_0} = e^{(t-t_0)\mathbf{\Omega}}|_{t=t_0} = \mathrm{Id} \quad \text{and} \quad \left.\frac{\partial}{\partial t}\right|_{t=t_0} \xi_t(\mathbf{x}) = \mathbf{\Omega}\mathbf{x}. \tag{4.16}$$

Also

$$\mathbf{V}'(\mathbf{X})|_{t=t_0} = \mathbf{V} + \mathbf{\Omega}\mathbf{x}(\mathbf{X}). \tag{4.17}$$

Subtracting the balance of energy for $\mathcal{U}$ for deformation mapping φ_t from that of $\varphi'_t = \xi_t \circ \varphi_t$ at time $t=t_0$ results in

$$\int_{\mathcal{U}} \rho_0 \mathbf{\Omega}\mathbf{x}(\mathbf{X}) \cdot (\mathbf{A} - \mathbf{B}) \mathrm{d}V = \int_{\partial\mathcal{U}} \mathbf{T}\mathbf{\Omega}\mathbf{x}(\mathbf{X}) \mathrm{d}A. \tag{4.18}$$

But

$$\int_{\partial\mathcal{U}} \mathbf{T}\mathbf{\Omega}\mathbf{x}(\mathbf{X}) \mathrm{d}A = \int_{\mathcal{U}} (\mathrm{Div}\, \mathbf{P} \cdot \mathbf{\Omega}\mathbf{x} + \mathbf{P}\mathbf{F}^{\mathsf{T}} : \mathbf{\Omega}) \mathrm{d}V. \tag{4.19}$$

Thus

$$\mathbf{P}\mathbf{F}^{\mathsf{T}} = \mathbf{F}\mathbf{P}^{\mathsf{T}}, \tag{4.20}$$

where use was made of balance of linear momentum.

B. The material-material GNR theorem

To our best knowledge, there is no study of invariance of energy balance under isometries of the reference configuration in the literature. It turns out that such an invariance does not hold in general, even in Euclidean space. In this section we study the transformation of balance of energy under rigid translations and rotations of the reference configuration in the Euclidean space context. It will be shown that balance of energy is invariant under translations and rotations of the reference configuration for isotropic materials that satisfy an internal constraint that we call material inviscidity.

Again we consider rigid translations and rigid rotations of the reference configuration separately.

(i) (*Rigid translations*) Consider a time-dependent rigid translation of the reference configuration $\Xi_t : \mathcal{B} \to \mathcal{B}'$. Let

$$\mathbf{X}' = \mathbf{X}_t = \Xi_t(\mathbf{X}) = \mathbf{X} + (t - t_0)\mathbf{W}, \tag{4.21}$$

for some constant vector field $\mathbf{W}$. Note that

$$T\Xi_t = \mathrm{Id}, \quad \mathbf{X} = \Xi_t^{-1}(\mathbf{X}_t) = \mathbf{X}_t - (t - t_0)\mathbf{W}. \tag{4.22}$$

Deformation gradient with respect to the new reference configuration is denoted $\mathbf{F}'$ and,

$$\mathrm{d}\mathbf{x} = \mathbf{F}\, \mathrm{d}\mathbf{X} = \mathbf{F}'\, \mathrm{d}\mathbf{X}'. \tag{4.23}$$

But, $\mathrm{d}\mathbf{X}' = \mathrm{d}\mathbf{X}$ and hence

$$\mathbf{F}\, \mathrm{d}\mathbf{X} = \mathbf{F}'\, \mathrm{d}\mathbf{X} \quad \forall\, \mathrm{d}\mathbf{X}. \tag{4.24}$$

This means that

$$\mathbf{F}'(\mathbf{X}_t) = \mathbf{F}(\mathbf{X}) \quad \text{or} \quad \mathbf{F}' = \mathbf{F} \circ \Xi_t^{-1}. \tag{4.25}$$

In the differential geometry language this means that

$$\mathbf{F}' = \Xi_{t*}\mathbf{F} = \mathbf{F} \circ \Xi_t^{-1}. \tag{4.26}$$

The material velocity with respect to the new reference configuration is

$$\mathbf{V}'(\mathbf{X}_t) = \frac{\partial}{\partial t}\varphi_t \circ \Xi_t^{-1}(\mathbf{X}') = \mathbf{V} \circ \Xi_t^{-1}(\mathbf{X}') - \mathbf{F}\mathbf{W}. \tag{4.27}$$

Thus at $t=t_0$,

$$\mathbf{V}' = \mathbf{V} - \mathbf{F}\mathbf{W}. \tag{4.28}$$

Free energy density is assumed to have the following transformation:

$$\Psi'(\mathbf{X}', \mathbf{F} \circ \Xi_t^{-1}) = \Psi(\mathbf{X}, \mathbf{F}). \tag{4.29}$$

Or

$$\Psi'(\mathbf{X}', \mathbf{F}) = \Psi(\mathbf{X}, \mathbf{F} \circ \Xi_t). \tag{4.30}$$

[Note that this does not put any restrictions on the material properties as here all we assume is that under a change of frame the 3-form $\rho_0\Psi\, \mathrm{d}V$ is transformed to a 3-form $\rho_0'\Psi'\, \mathrm{d}V' = \Xi_{t*}(\rho_0\Psi\, \mathrm{d}V)$.] More precisely,

$$\Xi_t^*\Psi'(\mathbf{X}', \mathbf{F}) = \Psi(\mathbf{X}, \mathbf{F} \circ \Xi_t). \tag{4.31}$$

Thus

$$\frac{d}{\mathrm{d}t}\Psi'(\mathbf{X}', \mathbf{F}) = \frac{\partial \Psi}{\partial t} + \frac{\partial \Psi}{\partial (\mathbf{F} \circ \Xi_t)} : \frac{\partial \mathbf{F}}{\partial \Xi_t(\mathbf{X})} \cdot \mathbf{W}. \tag{4.32}$$

Hence at $t=t_0$

$$\frac{d}{\mathrm{d}t}\Psi'(\mathbf{X}', \mathbf{F}) = \frac{\partial \Psi}{\partial t} + \frac{\partial \Psi}{\partial \mathbf{F}} : \frac{\partial \mathbf{F}}{\partial \mathbf{X}} \cdot \mathbf{W}. \tag{4.33}$$

Material balance of energy for $\mathcal{U} \subset \mathcal{B}$ reads

$$\begin{aligned} &\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(\Psi + \frac{1}{2}\langle\langle \mathbf{V}, \mathbf{V}\rangle\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0\left(\frac{d}{\mathrm{d}t}\Psi + \langle\langle \mathbf{V}, \mathbf{A}\rangle\rangle\right)\mathrm{d}V \\ &\quad = \int_{\mathcal{U}} \rho_0(\mathbf{B} \cdot \mathbf{V} + R)\mathrm{d}V + \int_{\partial\mathcal{U}} (\mathbf{T} \cdot \mathbf{V} + H)\mathrm{d}A. \end{aligned} \tag{4.34}$$

Let us assume that material balance of energy for $\mathcal{U}' \subset \mathcal{B}'$ reads

$$\begin{aligned} \frac{d}{\mathrm{d}t}\int_{\mathcal{U}'} \rho_0'\left(\Psi' + \frac{1}{2}\mathbf{V}' \cdot \mathbf{V}'\right)\mathrm{d}V' &= \int_{\mathcal{U}'} \rho_0(\mathbf{B}' \cdot \mathbf{V}' + R')\mathrm{d}V' + \int_{\mathcal{U}'} \mathbf{B}_0' \cdot \mathbf{W}_t\, \mathrm{d}V' \\ &\quad + \int_{\partial\mathcal{U}'} (\mathbf{T}' \cdot \mathbf{V}' + H')\mathrm{d}A', \end{aligned} \tag{4.35}$$

for some vector field $\mathbf{B}_0'$ which will be determined shortly. Note that thinking of the integrand of the left-hand side of balance of energy as a 3-form α, we have

$$\frac{d}{\mathrm{d}t}\int_{\mathcal{U}'} \alpha' = \int_{\mathcal{U}} \frac{d}{\mathrm{d}t}(\Xi_t^*\alpha'). \tag{4.36}$$

But $\Xi_t^*\alpha' = \rho_0(\mathbf{X})\Psi(\mathbf{X}, \mathbf{F} \circ \Xi_t)\mathrm{dV}$, thus material balance of energy for $\mathcal{U}' \subset \mathcal{B}'$ at $t=t_0$ reads

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(\Psi + \frac{1}{2}\langle\langle \mathbf{V}-\mathbf{FW}, \mathbf{V}-\mathbf{FW}\rangle\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0\left(\left.\frac{d}{\mathrm{d}t}\right|_{t=t_0} \Psi' + \langle\langle \mathbf{V}-\mathbf{FW}, \mathbf{A}'|_{t=t_0}\rangle\rangle\right)\mathrm{d}V$$
$$= \int_{\mathcal{U}} \rho_0\left(\mathbf{B}'|_{t=t_0}\cdot(\mathbf{V}-\mathbf{FW}) + R\right)\mathrm{d}V + \int_{\partial\mathcal{U}} (\mathbf{T}\cdot(\mathbf{V}-\mathbf{FW}) + H)\mathrm{d}A + \int_{\mathcal{U}} \mathbf{B}_0\cdot\mathbf{W}\,\mathrm{d}V, \tag{4.37}$$

where $\mathbf{B}_0$ is an unknown vector field at this point. Note that

$$(\mathbf{B}'-\mathbf{A}')_{t=t_0} = \mathbf{B}-\mathbf{A}. \tag{4.38}$$

Now subtracting the material balance of energy for $\mathcal{U}\subset\mathcal{B}$ from that of $\mathcal{U}'\subset\mathcal{B}'$ at time $t=t_0$ yields

$$\int_{\mathcal{U}} \left(\mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}} + \rho_0\mathbf{F}^{\mathrm{T}}(\mathbf{B}-\mathbf{A}) - \mathbf{B}_0\right)\cdot\mathbf{W}\,\mathrm{d}V + \int_{\partial\mathcal{U}} \mathbf{F}^{\mathrm{T}}\mathbf{T}\cdot\mathbf{W}\mathrm{d}A = 0 \quad \forall\,\mathbf{W}. \tag{4.39}$$

Localization leads to the following conclusion:

$$\mathbf{B}_0 = \mathrm{Div}(\mathbf{F}^{\mathrm{T}}\mathbf{P}) + \rho_0\mathbf{F}^{\mathrm{T}}(\mathbf{B}-\mathbf{A}) + \mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}}. \tag{4.40}$$

Note that

$$\mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}} = \mathrm{Div}(\Psi\mathbf{I}) - \frac{\partial \Psi}{\partial \mathbf{X}}, \tag{4.41}$$

and

$$\mathrm{Div}(\mathbf{F}^{\mathrm{T}}\mathbf{P}) = \mathbf{F}^{\mathrm{T}}\,\mathrm{Div}\,\mathbf{P} + \mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}}. \tag{4.42}$$

Thus (4.40) is equivalent to

$$\mathbf{B}_0 = \mathbf{F}^{\mathrm{T}}[\mathrm{Div}\,\mathbf{P} + \rho_0(\mathbf{B}-\mathbf{A})] + 2\mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}} = 2\mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}}. \tag{4.43}$$

Therefore, the transformed balance of energy is (4.35) with $\mathbf{B}_0' = \Xi_{t*}(\mathbf{B}_0)$.
Invariance of balance of energy under rigid translations of the reference configuration is equivalent to $\mathbf{B}_0 = \mathbf{0}$, i.e.,

$$\mathbf{P}:\frac{\partial \mathbf{F}}{\partial \mathbf{X}} = \mathbf{0}, \tag{4.44}$$

which is equivalent to

$$\mathrm{Div}(\mathbf{F}^{\mathrm{T}}\mathbf{P}) = \mathbf{F}^{\mathrm{T}}\,\mathrm{Div}(\mathbf{P}). \tag{4.45}$$

Obviously, if $\mathbf{F}$ is independent of $\mathbf{X}$, i.e., if the deformation gradient is uniform then this condition is satisfied but as we will see in the sequel this is not necessary. Note that (4.43) is independent of balance of linear momentum. It is seen that an additional constraint must be satisfied for the material energy balance to be invariant under time-dependent rigid referential translations. This shows the very different natures of material and spatial manifolds. We will show at the end of Sec. VI that (4.45) implies that configurational stress tensor is hydrostatic. For this reason we call (4.45) the configurational inviscidity constraint.
Example: Consider a Neo-Hookean rod in uniaxial tension. The deformation gradient is

$$\mathbf{F} = \begin{pmatrix} \lambda^{-1/2} & 0 & 0 \\ 0 & \lambda^{-1/2} & 0 \\ 0 & 0 & \lambda \end{pmatrix}. \tag{4.46}$$

It can be easily shown that the first Piola-Kirchhoff stress tensor has the following representation:

$$\mathbf{P} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & \mu\lambda - \dfrac{\mu}{\lambda^2} \end{pmatrix}, \tag{4.47}$$

where $\mu = \mu(\mathbf{X})$. It is now an easy exercise to show that (4.45) is satisfied only if λ is constant, i.e., only if the deformation gradient is uniform. Thus in this case the only possibility would be a uniform deformation gradient for balance of energy to be invariant under rigid translations of the reference configuration.

Example: We know that for an isotropic material

$$S_{AB} = \alpha_0 G_{AB} + \alpha_1 C_{AB} + \alpha_2 C_A^D C_{DB}, \tag{4.48}$$

where α_0, α_1, and α_2 are scalar functions of $\mathbf{X}$ and S_{AB} are components of the second Piola-Kirchhoff stress tensor. For the sake of simplicity, suppose $\alpha_1 = \alpha_2 = 0$. In terms of $\mathbf{P}$ and $\mathbf{F}$ we have

$$P^{aA} = \alpha_0 G^{AB} F^a{}_B. \tag{4.49}$$

When the reference configuration and ambient space are Euclidean the condition $\mathrm{Div}(\mathbf{F}^\mathsf{T}\mathbf{P}) = \mathbf{F}^\mathsf{T}\,\mathrm{Div}(\mathbf{P})$ is equivalent to

$$\alpha_0 F^a{}_B \frac{\partial F^a{}_B}{\partial X^A} = 0. \tag{4.50}$$

Or

$$F^a{}_B \frac{\partial F^a{}_B}{\partial X^A} = F^a{}_B \frac{\partial F^a{}_A}{\partial X^B} = 0. \tag{4.51}$$

Note that, in general, this does not imply that the deformation gradient is uniform and it is simply an internal constraint.

Example: Consider an incompressible perfect fluid (ideal fluid) for which

$$\sigma^{ab} = -pg^{ab} \quad \text{and} \quad J = 1. \tag{4.52}$$

Thus

$$P^{aA} = -J(\mathbf{F}^{-1})^A{}_b p g^{ab}. \tag{4.53}$$

Using Piola identity we have

$$(\mathrm{Div}(\mathbf{F}^\mathsf{T}\mathbf{P}))^A = (-pJG^{AB})_{|B} = -J\frac{\partial p}{\partial x^b} F^b{}_B G^{AB}. \tag{4.54}$$

Also

$$(\mathbf{F}^\mathsf{T}\,\mathrm{Div}(\mathbf{P}))^A = -g_{ab} F^b{}_B G^{AB} J(pg^{ad})_{|d} = -J\frac{\partial p}{\partial x^b} F^b{}_B G^{AB}. \tag{4.55}$$

Thus (4.45) is satisfied for an ideal fluid.

(ii) (*Rigid rotations*) Consider a time-dependent rigid rotation of the reference configuration $\Xi_t:\mathcal{B}\to\mathcal{B}'$ defined as

$$\mathbf{X}'=\mathbf{X}_t=e^{(t-t_0)\mathbf{\Omega}}\mathbf{X}, \tag{4.56}$$

for some constant skew-symmetric matrix $\mathbf{\Omega}$. Note that

$$\mathbf{V}'=V-\mathbf{F}\mathbf{\Omega}\mathbf{X},\quad \mathbf{F}'=\mathbf{F}\circ\Xi_t^{-1}. \tag{4.57}$$

Let us assume that material balance of energy for $\mathcal{U}'\subset\mathcal{B}'$ has the following form:

$$\frac{d}{\mathrm{d}t}\int_{\mathcal{U}'}\rho_0'\left(\Psi'+\frac{1}{2}\mathbf{V}'\cdot\mathbf{V}'\right)\mathrm{d}V'=\int_{\mathcal{U}'}\rho_0(\mathbf{B}'\cdot\mathbf{V}'+R')\mathrm{d}V'+\int_{\partial\mathcal{U}'}(\mathbf{T}'\cdot\mathbf{V}'+H')\mathrm{d}A'$$
$$+\int_{\mathcal{U}'}(\mathbf{B}_0'\cdot\mathbf{\Omega}\mathbf{X}+\mathbf{C}_0':\mathbf{\Omega})\mathrm{d}V', \tag{4.58}$$

where $\mathbf{C}_0'=\Xi_{t*}\mathbf{C}_0$ and $\mathbf{C}_0$ is an unknown vector field at this point. Material balance of energy for $\mathcal{U}'\subset\mathcal{B}'$ at $t=t_0$ reads

$$\int_{\mathcal{U}}\frac{\partial\rho_0}{\partial t}\left(\Psi+\frac{1}{2}\langle\langle\mathbf{V}-\mathbf{F}\mathbf{\Omega}\mathbf{X},\mathbf{V}-\mathbf{F}\mathbf{\Omega}\mathbf{X}\rangle\rangle\right)\mathrm{d}V$$
$$+\int_{\mathcal{U}}\rho_0\left(\left.\frac{d}{\mathrm{d}t}\right|_{t=t_0}\Psi'+\langle\langle\mathbf{V}-\mathbf{F}\mathbf{\Omega}\mathbf{X},\mathbf{A}'|_{t=t_0}\rangle\rangle\right)\mathrm{d}V$$
$$=\int_{\mathcal{U}}\rho_0(\mathbf{B}'|_{t=t_0}\cdot(\mathbf{V}-\mathbf{F}\mathbf{\Omega}\mathbf{X})+R)\mathrm{d}V+\int_{\partial\mathcal{U}}(\mathbf{T}\cdot(\mathbf{V}-\mathbf{F}\mathbf{\Omega}\mathbf{X})+H)\mathrm{d}A$$
$$+\int_{\mathcal{U}}(\mathbf{B}_0\cdot\mathbf{\Omega}\mathbf{X}+\mathbf{C}_0:\mathbf{\Omega})\mathrm{d}V. \tag{4.59}$$

Subtracting the material balance of energy for $\mathcal{U}\subset\mathcal{B}$ from that of $\mathcal{U}'\subset\mathcal{B}'$ at time $t=t_0$ and considering the relation for $\mathbf{B}_0$ coming from rigid translations of the reference configuration yields

$$\int_{\mathcal{U}}(\mathbf{F}^{\mathsf{T}}\mathbf{P}-\mathbf{C}_0):\Omega\,\mathrm{d}V=0. \tag{4.60}$$

This means that

$$\mathbf{F}^{\mathsf{T}}\mathbf{P}-\mathbf{C}_0=(\mathbf{F}^{\mathsf{T}}\mathbf{P}-\mathbf{C}_0)^{\mathsf{T}}. \tag{4.61}$$

Thus $\mathbf{C}_0=-\mathbf{P}^{\mathsf{T}}\mathbf{F}+\mathbf{S}$ for some symmetric tensor $\mathbf{S}$. This symmetric tensor does not contribute to balance of energy and we can choose it to be $\mathbf{S}=\mathbf{0}$. Thus the transformed balance of energy under rigid rotations of the reference configuration is (4.58) where $\mathbf{C}_0'=\Xi_{t*}(\mathbf{C}_0)$ and $\mathbf{C}_0=-\mathbf{P}^{\mathsf{T}}\mathbf{F}$.

In conclusion, we have proved the following proposition.

Proposition 4.1: Balance of energy is invariant under time-dependent translations and rotations of the reference configuration if $\mathbf{B}_0=\mathbf{C}_0=\mathbf{0}$, i.e., if the reference configuration is both configurationally inviscid and isotropic.

Thus, balance of energy is invariant under material isometries of the reference configuration only under some constraints. As an example, it is seen that balance of energy is invariant under material isometries in the case of ideal fluids.

V. COVARIANT SPATIAL ENERGY BALANCE

In this section we start by a reappraisal of the concept of covariance in elasticity and its consequences. We revisit Marsden and Hughes' theorem[28] and clarify some details in their proof. We then show that the same conclusions can be reached if one assumes that mass density is a 3-form instead of a scalar. A proof is then given for converse of Marsden and Hughes' theorem, i.e., assuming conservation of mass, balance of linear and angular momenta and Doyle-Ericksen formula, balance of energy is invariant under arbitrary spatial diffeomorphisms. At the end of this section, we show that assuming spatial covariance for material energy balance yields results that are identical to those obtained by assuming spatial covariance for spatial energy balance.

A. Covariance and the Doyle-Ericksen formula

First recall that the general notion of covariance of a set of equations is as follows.

Definition 5.1 (Covariance): Suppose a theory has some tensor fields $\mathbf{U},\mathbf{V},\ldots$ *defined on a space* $\mathcal{A}$ *and the governing equations of the theory have the form* $F(\mathbf{U},\mathbf{V},\ldots)=0$. *These governing equations are called covariant if for any diffeomorphism* $\xi:\mathcal{A}\to\mathcal{A}$, $\xi^*(F(\mathbf{U},\mathbf{V},\ldots))=F(\xi^*\mathbf{U},\xi^*\mathbf{V},\ldots)$. *A theory is covariant if all its governing equations are covariant.*

The Doyle-Ericksen formula: Doyle and Ericksen[7] showed the following interesting relation:

$$\boldsymbol{\sigma}=2\rho\frac{\partial e}{\partial \mathbf{g}}, \tag{5.1}$$

i.e., Cauchy's stress tensor is proportional to the partial derivative of the free energy density with respect to the Riemannian metric in the deformed configuration. [Note that (see Ref. 28, p. 198)

$$\frac{\partial e}{\partial \mathbf{g}}=\frac{\partial \psi}{\partial \mathbf{g}}. \tag{5.2}$$

In other words, in Doyle-Ericksen formula internal energy density can be replaced by free energy density because

$$e=\psi+\theta s, \tag{5.3}$$

where θ is absolute temperature and s is entropy density. Thus

$$\frac{\partial e}{\partial \mathbf{g}}=\frac{\partial \psi}{\partial \mathbf{g}}+\frac{\partial \psi}{\partial \theta}\frac{\partial \theta}{\partial \mathbf{g}}+\frac{\partial \theta}{\partial \mathbf{g}}s=\frac{\partial \psi}{\partial \mathbf{g}}, \tag{5.4}$$

as $\partial\psi/\partial\theta=-s$].

Doyle and Ericksen[7] looked at changes of spatial frame passively, i.e., as changes of coordinates while Marsden and Hughes[28] chose the active point of view. The Doyle-Ericksen formula is known to be the essential condition for covariance of energy balance. Later Simo and Marsden[40] found a material version of Doyle-Ericksen formula, which we discuss next. Here by "material version" they mean an analogue of the usual Doyle-Ericksen formula that ensures covariance of material energy balance under spatial diffeomorphisms. [An interesting question to ask would be the condition(s) that ensures covariance of material energy balance under diffeomorphisms of the reference configuration. This will be discussed in Sec. VI.] Simo and Marsden consider a general form of polar decomposition theorem by first associating two Riemannian metrics $\mathbf{G}_0$ and $\mathbf{G}$ to $\mathcal{B}$, where $\mathbf{G}_0$ does not change under spatial diffeomorphisms while $\mathbf{G}$ does change. The polar decomposition theorem states that

$$\mathbf{F}=\mathbf{R}\mathbf{U}, \tag{5.5}$$

where

$$\mathbf{U}(\mathbf{X}):(T_{\mathbf{X}}\mathcal{B},\mathbf{G}_0)\rightarrow(T_{\mathbf{X}}\mathcal{B},\mathbf{G}) \tag{5.6}$$

is the material stretch tensor (a positive-definite symmetric linear map with respect to the given metrics) and

$$\mathbf{R}(\mathbf{X}):(T_{\mathbf{X}}\mathcal{B},\mathbf{G})\rightarrow(T_{\varphi_t(\mathbf{X})}\mathcal{S},\mathbf{g}) \tag{5.7}$$

is, for each $X\in\mathcal{B}$, a $(\mathbf{G},\mathbf{g})$-orthogonal linear transformation. The metric $\mathbf{G}$ is arbitrary and can change under spatial diffeomorphisms,

$$\mathbf{G}=\mathbf{R}^{*}(\mathbf{g}). \tag{5.8}$$

The internal energy density per unit mass of the deformed configuration is

$$e=e(\mathbf{x},t,\mathbf{g}(\mathbf{x})). \tag{5.9}$$

Now define

$$E(\mathbf{X},t,\mathbf{G})=e(\varphi_t(\mathbf{X}),t,\mathbf{R}_{*}(\mathbf{G})). \tag{5.10}$$

Simo and Marsden[40] show that

$$\mathbf{\Sigma}=2\rho\frac{\partial E}{\partial\mathbf{G}}, \tag{5.11}$$

where $\mathbf{\Sigma}$ is the rotated stress tensor defined as

$$\mathbf{\Sigma}=\mathbf{R}^{*}\boldsymbol{\sigma}\quad\text{or}\quad\Sigma^{AB}=(\mathbf{R}^{-1})^{A}{}_{a}\sigma^{ab}(\mathbf{R}^{-1})^{B}{}_{b}. \tag{5.12}$$

In this paper we prove a similar theorem by postulating a balance of energy for an arbitrary reframing of the reference configuration for a special class of materials. It should be noted that there are four possibilities for a covariant energy balance law.

(i) Spatial energy balance law for any reframing of the deformed configuration: This gives the usual Doyle-Ericksen formula.
(ii) Material energy balance law for any reframing of the deformed configuration: This gives the Doyle-Ericksen formula in terms of Kirchhoff stress tensor.
(iii) Material energy balance law for any reframing of the reference configuration: This should give a material form of Doyle-Ericksen formula for Eshelby's stress tensor.
(iv) Spatial energy balance for any reframing of the reference configuration: This should give a spatial form of Doyle-Ericksen formula for Eshelby's stress tensor.

Note that cases (i) and (ii) and also cases (iii) and (iv) are equivalent as the important thing here is the type of the diffeomorphism.

B. Revisiting Marsden and Hughes' theorem

Let us first revisit Marsden and Hughes' covariant energy balance theory.[28] These authors postulate a covariant spatial energy balance, i.e., they consider a motion $\varphi_t:\mathcal{B}\rightarrow\mathcal{S}$ and postulate that balance of energy still holds for any spatial change of frame. Marsden and Hughes consider arbitrary changes of frame for the deformed configuration and postulate that energy balance is invariant under these framings. For a given nice subset $\mathcal{U}\subset\mathcal{B}$, the (spatial) balance of energy reads

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{U})}\rho\left(e+\frac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle\right)dv=\int_{\varphi_t(\mathcal{U})}\rho(\langle\langle\mathbf{b},\mathbf{v}\rangle\rangle+r)dv+\int_{\partial\varphi_t(\mathcal{U})}(\langle\langle\mathbf{t},\mathbf{v}\rangle\rangle+h)da, \tag{5.13}$$

where e,r, and h are the internal energy function per unit mass, the heat supply per unit mass and the heat flux, respectively. Marsden and Hughes then consider an arbitrary reframing of the deformed configuration, which can be regarded as a motion of $\mathcal{S}$ in $\mathcal{S}$, i.e., $\xi_t:\mathcal{S}\rightarrow\mathcal{S}$. Postulating

the balance of energy (5.13) for such a reframing and considering it for $t=t_0$ they obtain (i) conservation of mass, (ii) balance of linear momentum, (iii) balance of angular momentum, and (iv) the Doyle-Ericksen formula. Conversely, if (i), (ii), (iii), (iv) and balance of energy hold, then balance of energy would hold for any change of spatial frame. We will give a proof for the converse of the theorem in the sequel.

Proposition 5.2 (Transport theorem in a reframing of the deformed configuration): Suppose $f'=\xi_{t*}f$ *is a scalar quantity defined on* $\varphi_t'(\mathcal{U})$, *i.e.*, $f':\varphi_t'(\mathcal{U})\to\mathbb{R}$ *and* $f:\varphi_t(\mathcal{U})\to\mathbb{R}$. [Marsden and Hughes have the following transport theorem on p. 166 of Ref. 28 in the second equation after their Eq. (2), which needs to be corrected:

$$\frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})} f\,\mathrm{d}v=\int_{\varphi_t'(\mathcal{U})}(\dot{f}+f\,\mathrm{div}\,\mathbf{v})\mathrm{d}v'. \tag{5.14}$$

In fact, the first $\mathrm{d}v$ should read $\mathrm{d}v'$.] *Then*,

$$\frac{d}{\mathrm{d}t}\bigg|_{t=t_0}\int_{\varphi_t'(\mathcal{U})} f'\,\mathrm{d}v'=\int_{\varphi_t(\mathcal{U})}(\dot{f}+f\,\mathrm{div}\,\mathbf{v})\mathrm{d}v. \tag{5.15}$$

Proof: The usual transport theorem can be written as

$$\frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})} f'\,\mathrm{d}v'=\int_{\varphi_t'(\mathcal{U})}(\dot{f}'+f'\,\mathrm{div}'\,\mathbf{v}')\mathrm{d}v', \tag{5.16}$$

where

$$\dot{f}'=\frac{\partial f'}{\partial t}+\frac{\partial f'}{\partial \mathbf{x}'}\cdot\mathbf{v}'=\frac{\partial f'}{\partial t}+\mathrm{d}f'\cdot\mathbf{v}', \tag{5.17}$$

and

$$\mathbf{v}'=\xi_{t*}\mathbf{v}+\mathbf{w}. \tag{5.18}$$

Therefore,

$$\frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})} f'\,\mathrm{d}v'=\int_{\varphi_t'(\mathcal{U})}\left[\frac{\partial f'}{\partial t}+\mathrm{d}f'\cdot(\xi_{t*}\mathbf{v}+\mathbf{w})+f'\,\mathrm{div}'\,\mathbf{v}'\right]\mathrm{d}v'. \tag{5.19}$$

Note that

$$\frac{\partial}{\partial \mathbf{x}}=\frac{\partial}{\partial \mathbf{x}'}\circ(T\xi_t)\quad\text{or}\quad\frac{\partial}{\partial \mathbf{x}'}=(T\xi_t)^{-1}\circ\frac{\partial}{\partial \mathbf{x}}. \tag{5.20}$$

This means that

$$\frac{\partial}{\partial \mathbf{x}'}\bigg|_{t=t_0}=\frac{\partial}{\partial \mathbf{x}}. \tag{5.21}$$

Lemma 5.3: If $\xi_t:\mathcal{S}\to\mathcal{S}$ *is a diffeomorphism with the properties*,

$$\xi_t\big|_{t=t_0}=\mathrm{Id},\quad T\xi_t\big|_{t=t_0}=\mathrm{Id}. \tag{5.22}$$

Then

$$(\mathrm{div}'\,\mathbf{v}'\,\mathrm{d}v')\big|_{t=t_0}=\mathrm{div}\,\mathbf{v}\,\mathrm{d}v. \tag{5.23}$$

Proof: We prove the lemma when $\mathcal{S}$ is equipped with an arbitrary volume form μ. This will imply the particular case of a Riemannian manifold with the volume form induced by the Rie-

mannian metric. Recall that the divergence of a vector field $\mathbf{X}$ with respect to μ is defined as

$$\mathbf{L}_{\mathbf{X}}\mu = (\mathrm{div}_{\mu}\,\mathbf{X})\mu. \tag{5.24}$$

Under the spatial change of frame $\mathbf{v}' = \xi_{t*}\mathbf{X} + \mathbf{w}$, $\mu' = \xi_{t*}\mu$. Thus,

$$(\mathrm{div}_{\mu'}\,\mathbf{v}')\mu' = \mathbf{L}_{\mathbf{v}'}(\xi_{t*}\mu) = \xi_{t*}(\mathbf{L}_{\mathbf{v}}\mu), \tag{5.25}$$

where use was made of Theorem 6.19 of Marsden and Hughes[28]. Therefore,

$$(\mathrm{div}'\,\mathbf{v}'\,\mathrm{d}v')\big|_{t=t_0} = \mathrm{div}\,\mathbf{v}\,\mathrm{d}v. \tag{5.26}$$

□

One should be careful with partial time derivatives as $\partial f'/\partial t$ is not equal to $\partial f/\partial t$ at $t=t_0$ because the former is partial time derivative for fixed $\mathbf{x}'$ while the latter is a partial time derivative for fixed $\mathbf{x}$. Note that

$$\left.\frac{\partial f'}{\partial t}\right|_{\mathbf{x}\ \text{fixed}} = \left.\frac{\partial f'}{\partial t}\right|_{\mathbf{x}'\ \text{fixed}} + \mathrm{d}f'\cdot\mathbf{w}_t. \tag{5.27}$$

Hence,

$$\left(\left.\frac{\partial f'}{\partial t}\right|_{\mathbf{x}'\ \text{fixed}}\right)_{t=t_0} = \frac{\partial f}{\partial t} - \mathrm{d}f\cdot\mathbf{w}. \tag{5.28}$$

Therefore (5.19) is simplified to

$$\left.\frac{d}{\mathrm{d}t}\right|_{t=t_0}\int_{\varphi_t'(\mathcal{U})} f'\,\mathrm{d}v' = \int_{\varphi_t(\mathcal{U})}(\dot{f} + f\,\mathrm{div}\,\mathbf{v})\mathrm{d}v. \tag{5.29}$$

□

Now let us take a more natural approach and assume that we are transporting a 3-form. Note that this is more general in the sense that we have not chosen a volume form $\mathrm{d}v$ *a priori*.

Proposition 5.4: Suppose $\alpha' = \xi_{t*}\alpha$ *is a* 3*-form defined on* $\varphi_t'(\mathcal{U})$. *Then*,

$$\left.\frac{d}{\mathrm{d}t}\right|_{t=t_0}\int_{\varphi_t'(\mathcal{U})}\alpha' = \int_{\varphi_t(\mathcal{U})}\mathbf{L}_{\mathbf{v}}\alpha. \tag{5.30}$$

Proof: Using the usual transport theorem for forms we have

$$\frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})}\alpha' = \int_{\varphi_t'(\mathcal{U})}\mathbf{L}_{\mathbf{v}'}\alpha'. \tag{5.31}$$

Assuming that α transforms objectively, i.e., $\alpha' = \xi_{t*}\alpha$, using Theorem 6.19 of Marsden and Hughes[28] we have

$$\mathbf{L}_{\mathbf{v}'}\alpha' = \xi_{t*}\mathbf{L}_{\mathbf{v}}\alpha. \tag{5.32}$$

Thus,

$$\frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})}\alpha' = \int_{\varphi_t'(\mathcal{U})}\xi_{t*}\mathbf{L}_{\mathbf{v}}\alpha. \tag{5.33}$$

Therefore,

$$\left.\frac{d}{dt}\right|_{t=t_0}\int_{\varphi_t'(\mathcal{U})}\alpha' = \int_{\varphi_t(\mathcal{U})}\mathbf{L}_{\mathbf{v}}\alpha. \tag{5.34}$$

□

Now substitute $\alpha = f\,dv$, where f is a scalar. Note that

$$f'\,dv' = f'\wedge dv' = (\xi_{t*}f)\wedge(\xi_{t*}\,dv) = \xi_{t*}(f\wedge dv) = \xi_{t*}(f\,dv). \tag{5.35}$$

The above proposition now reads

$$\left.\frac{d}{dt}\right|_{t=t_0}\int_{\varphi_t'(\mathcal{U})}f'\,dv' = \int_{\varphi_{t_0}(\mathcal{U})}\mathbf{L}_{\mathbf{v}}(f\,dv). \tag{5.36}$$

Note that $\mathbf{L}$ is a derivation and hence

$$\mathbf{L}_{\mathbf{v}}(f\,dv) = (\mathbf{L}_{\mathbf{v}}f)dv + f(\mathbf{L}_{\mathbf{v}}\,dv) = (\dot{f} + \operatorname{div}\mathbf{v})dv. \tag{5.37}$$

Therefore

$$\left.\frac{d}{dt}\right|_{t=t_0}\int_{\varphi_t'(\mathcal{U})}f'\,dv' = \int_{\varphi_{t_0}(\mathcal{U})}(\dot{f} + f\operatorname{div}\mathbf{v})dv. \tag{5.38}$$

Thus, this approach recovers the same transport equation (5.15).

C. Energy balance in terms of differential forms

In this section we regard ρ as a 3-form and write the energy balance equation as

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{U})}\rho\left(e + \frac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle\right) = \int_{\varphi_t(\mathcal{U})}\rho(\langle\langle\mathbf{b},\mathbf{v}\rangle\rangle + r) + \int_{\partial\varphi_t(\mathcal{U})}(\langle\langle\mathbf{t},\mathbf{v}\rangle\rangle + h)da. \tag{5.39}$$

[Traction can be thought of as a covector-valued 2-form. There are some technical details involved and we choose to stick to the usual definition of traction.] Under a spatial diffeomorphism $\xi_t:\mathcal{S}\to\mathcal{S}$ we postulate that

$$\frac{d}{dt}\int_{\varphi_t'(\mathcal{U})}\rho'\left(e' + \frac{1}{2}\langle\langle\mathbf{v}',\mathbf{v}'\rangle\rangle\right) = \int_{\varphi_t'(\mathcal{U})}\rho'(\langle\langle\mathbf{b}',\mathbf{v}'\rangle\rangle + r') + \int_{\partial\varphi_t'(\mathcal{U})}(\langle\langle\mathbf{t}',\mathbf{v}'\rangle\rangle + h')da'. \tag{5.40}$$

Let f be the scalar multiplying the density 3-form in the first integrand, i.e., $f := e + \frac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle$. Thus

$$\frac{d}{dt}\int_{\varphi_t(\mathcal{U})}\rho f = \int_{\varphi_t(\mathcal{U})}\mathbf{L}_{\mathbf{v}}(\rho f) = \int_{\varphi_t(\mathcal{U})}(\rho\mathbf{L}_{\mathbf{v}}f + f\mathbf{L}_{\mathbf{v}}\rho). \tag{5.41}$$

But

$$\begin{aligned}\mathbf{L}_{\mathbf{v}}f &= \mathbf{L}_{\mathbf{v}}e + \mathbf{L}_{\mathbf{v}}\left(\tfrac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle\right) = \dot{e} + \frac{\partial}{\partial t}\left(\frac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle\right) + d\left(\frac{1}{2}\langle\langle\mathbf{v},\mathbf{v}\rangle\rangle\right)\cdot\mathbf{v}\\ &= \dot{e} + \left\langle\left\langle\frac{\partial\mathbf{v}}{\partial t},\mathbf{v}\right\rangle\right\rangle + \langle\langle\mathbf{v},\nabla_{\mathbf{v}}\mathbf{v}\rangle\rangle = \dot{e} + \langle\langle\mathbf{v},\mathbf{a}\rangle\rangle.\end{aligned} \tag{5.42}$$

Also,

$$\frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})}\rho' f' = \int_{\varphi_t(\mathcal{U})}\mathbf{L}_{\mathbf{v}'}(\rho' f') = \int_{\varphi_t'(\mathcal{U})}(\rho'\mathbf{L}_{\mathbf{v}'}f' + f'\mathbf{L}_{\mathbf{v}'}\rho'). \tag{5.43}$$

Note that $\mathbf{v}' = \xi_{t*}\mathbf{v} + \mathbf{w}_t$ and thus

$$\mathbf{L}_{\mathbf{v}'}\rho' = \xi_{t*}(\mathbf{L}_{\mathbf{v}}\rho). \tag{5.44}$$

Also,

$$\mathbf{L}_{\mathbf{v}'}f' = \dot{e'} + \left\langle\!\left\langle \mathbf{v}', \frac{\partial \mathbf{v}'}{\partial t} + \nabla_{\mathbf{v}'}\mathbf{v}' \right\rangle\!\right\rangle = \dot{e'} + \langle\langle \mathbf{v}', \mathbf{a}' \rangle\rangle. \tag{5.45}$$

Thus

$$(\mathbf{L}_{\mathbf{v}'}f')\big|_{t=t_0} = \dot{e} + \frac{\partial e}{\partial \mathbf{g}} : \mathfrak{L}_{\mathbf{w}}\mathbf{g} + \langle\langle \mathbf{v}+\mathbf{w}, \mathbf{a}'\big|_{t=t_0}\rangle\rangle, \tag{5.46}$$

$$(\mathbf{L}_{\mathbf{v}'}\rho')\big|_{t=t_0} = \mathbf{L}_{\mathbf{v}}\rho. \tag{5.47}$$

Therefore

$$\begin{aligned}\frac{d}{\mathrm{d}t}\bigg|_{t=t_0}\int_{\varphi_t'(\mathcal{U})}\rho' f' = \int_{\varphi_t(\mathcal{U})}\rho\left(\dot{e} + \frac{\partial e}{\partial \mathbf{g}} : \mathfrak{L}_{\mathbf{w}}\mathbf{g} + \left\langle\!\left\langle \mathbf{v}+\mathbf{w}, \mathbf{a}'\big|_{t=t_0}\right\rangle\!\right\rangle\right) \\ + \int_{\varphi_t(\mathcal{U})}\left(f + \langle\langle \mathbf{v}, \mathbf{w}\rangle\rangle + \frac{1}{2}\langle\langle \mathbf{w}, \mathbf{w}\rangle\rangle\right)\mathbf{L}_{\mathbf{v}}\rho.\end{aligned} \tag{5.48}$$

Now subtracting the balance of energy equation for $\varphi_t(\mathcal{U})$ from that of $\varphi_t'(\mathcal{U})$ at $t=t_0$ we obtain

$$\begin{aligned}&\int_{\varphi_t(\mathcal{U})}\rho\left(\frac{\partial e}{\partial \mathbf{g}} : \mathcal{L}_{\mathbf{w}}\mathbf{g} + \langle\langle \mathbf{v}, \mathbf{a}'\big|_{t=t_0} - \mathbf{a}\rangle\rangle + \langle\langle \mathbf{w}, \mathbf{a}'\big|_{t=t_0}\rangle\rangle\right) + \int_{\varphi_t(\mathcal{U})}\left(\langle\langle \mathbf{v}, \mathbf{w}\rangle\rangle + \frac{1}{2}\langle\langle \mathbf{w}, \mathbf{w}\rangle\rangle\right)\mathbf{L}_{\mathbf{v}}\rho \\ &= \int_{\varphi_t(\mathcal{U})}(\langle\langle \mathbf{v}, \mathbf{b}'\big|_{t=t_0} - \mathbf{b} + \langle\langle \mathbf{w}, \mathbf{b}'\big|_{t=t_0}\rangle\rangle) + \int_{\partial\varphi_t(\mathcal{U})}\langle\langle \mathbf{w}, \mathbf{t}\rangle\rangle \mathrm{d}a.\end{aligned} \tag{5.49}$$

Using the identity $(\mathbf{b}' - \mathbf{a}')\big|_{t=t_0} = \mathbf{b} - \mathbf{a}$ we have

$$\int_{\varphi_t(\mathcal{U})}\rho\left(\frac{\partial e}{\partial \mathbf{g}} : \mathcal{L}_{\mathbf{w}}\mathbf{g} + \langle\langle \mathbf{w}, \mathbf{a} - \mathbf{b}\rangle\rangle\right) + \int_{\varphi_t(\mathcal{U})}\left(\langle\langle \mathbf{v}, \mathbf{w}\rangle\rangle + \frac{1}{2}\langle\langle \mathbf{w}, \mathbf{w}\rangle\rangle\right)\mathbf{L}_{\mathbf{v}}\rho = \int_{\partial\varphi_t(\mathcal{U})}\langle\langle \mathbf{w}, \mathbf{t}\rangle\rangle \mathrm{d}a. \tag{5.50}$$

We know that

$$\int_{\partial\varphi_t(\mathcal{U})}\langle\langle \mathbf{w}, \mathbf{t}\rangle\rangle \mathrm{d}a = \int_{\varphi_t(\mathcal{U})}\left(\langle\langle \operatorname{div}\boldsymbol{\sigma}, \mathbf{w}\rangle\rangle + \boldsymbol{\sigma} : \frac{1}{2}\mathcal{L}_{\mathbf{w}}\mathbf{g} + \boldsymbol{\sigma} : \boldsymbol{\omega}\right)\mathrm{d}v, \tag{5.51}$$

where $\boldsymbol{\omega}$ has the coordinate representation $\omega_{ab} = \frac{1}{2}(w_{a|b} - w_{b|a})$. Let us replace ρ by $\rho\,\mathrm{d}v$ in the first integral of Eq. (5.50),

$$\int_{\varphi_t(\mathcal{U})} \rho\left(\frac{\partial e}{\partial \mathbf{g}}:\mathcal{L}_{\mathbf{w}}\mathbf{g} + \langle\langle \mathbf{w}, \mathbf{a}-\mathbf{b}\rangle\rangle\right)\mathrm{d}v + \int_{\varphi_t(\mathcal{U})}\left(\langle\langle \mathbf{v},\mathbf{w}\rangle\rangle + \frac{1}{2}\langle\langle \mathbf{w},\mathbf{w}\rangle\rangle\right)\mathbf{L}_{\mathbf{v}}\rho$$
$$= \int_{\varphi_t(\mathcal{U})}\left(\langle\langle \operatorname{div}\boldsymbol{\sigma},\mathbf{w}\rangle\rangle + \boldsymbol{\sigma}:\frac{1}{2}\mathcal{L}_{\mathbf{w}}\mathbf{g} + \boldsymbol{\sigma}:\boldsymbol{\omega}\right)\mathrm{d}v. \tag{5.52}$$

Since $\mathbf{w}$ is arbitrary we conclude that

$$\mathbf{L}_{\mathbf{v}}\rho = 0, \tag{5.53}$$

$$\boldsymbol{\sigma} = 2\rho\frac{\partial e}{\partial \mathbf{g}}, \tag{5.54}$$

$$\operatorname{div}\boldsymbol{\sigma} + \rho\mathbf{b} = \rho\mathbf{a}, \tag{5.55}$$

$$\boldsymbol{\sigma}^{\mathsf{T}} = \boldsymbol{\sigma}. \tag{5.56}$$

D. Proof of the converse of Marsden and Hughes' theorem

Marsden and Hughes[28] do not give a proof for the converse of the covariant energy balance theorem, i.e., when Eqs. (5.53)–(5.56) are satisfied then energy balance is invariant under $\xi_t:\mathcal{S}\to\mathcal{S}$. Such a proof is nontrivial and is given here.

Let us assume that Eqs. (5.53)–(5.56) are satisfied and define

$$\Delta E(\xi_t) = \frac{d}{\mathrm{d}t}\int_{\varphi_t'(\mathcal{U})}\rho'\left(e' + \frac{1}{2}\langle\langle \mathbf{v}',\mathbf{v}'\rangle\rangle_{\mathbf{g}}\right) - \int_{\varphi_t'(\mathcal{U})}\rho'\left(\langle\langle \mathbf{b}',\mathbf{v}'\rangle\rangle_{\mathbf{g}} + r'\right) - \int_{\partial\varphi_t'(\mathcal{U})}\left(\langle\langle \mathbf{t}',\mathbf{v}'\rangle\rangle_{\mathbf{g}} + h'\right)\mathrm{d}a'. \tag{5.57}$$

Note that balance of energy for $\varphi_t(\mathcal{U})$ can be written as $\Delta E(\mathrm{Id})=0$. We need to prove that for any diffeomorphism ξ_t, $\Delta E(\xi_t)=0$. We know that

$$e'(x',t,\mathbf{g}) = e(x,t,\xi_t^*(\mathbf{g})). \tag{5.58}$$

Let us denote

$$\mathbf{w}_t := \frac{d}{\mathrm{d}t}\xi_t, \quad \mathbf{W}_t = \xi_t^*(\mathbf{w}_t), \quad \mathbf{g}_t = \xi_t^*(\mathbf{g}). \tag{5.59}$$

Note that by definition

$$\int_{\varphi_t'(\mathcal{U})}\rho' r' = \int_{\varphi_t(\mathcal{U})}\rho r, \quad \int_{\partial\varphi_t'(\mathcal{U})} h'\,\mathrm{d}a' = \int_{\partial\varphi_t(\mathcal{U})} h\,\mathrm{d}a. \tag{5.60}$$

Also note that

$$\int_{\partial\varphi_t'(\mathcal{U})}\langle\langle \mathbf{t}',\mathbf{v}'\rangle\rangle_{\mathbf{g}}\,\mathrm{d}a' = \int_{\partial\varphi_t'(\mathcal{U})}\langle\langle \xi_{t*}\mathbf{t}, \xi_{t*}\mathbf{v}+\mathbf{w}_t\rangle\rangle_{\mathbf{g}}\,\mathrm{d}a' = \int_{\partial\varphi_t(\mathcal{U})}\langle\langle \mathbf{t},\mathbf{v}+\mathbf{W}_t\rangle\rangle_{\mathbf{g}_t}\,\mathrm{d}a. \tag{5.61}$$

A straightforward computation shows that

$$\frac{d}{dt}\int_{\varphi_t'(\mathcal{U})}\left(\frac{1}{2}\rho'\langle\langle\mathbf{v}',\mathbf{v}'\rangle\rangle_{\mathbf{g}}-\rho'\langle\langle\mathbf{b}',\mathbf{v}'\rangle\rangle_{\mathbf{g}}\right)=\int_{\varphi_t'(\mathcal{U})}\rho'\langle\langle\xi_{t*}(\mathbf{a}-\mathbf{b}),\xi_{t*}\mathbf{v}+\mathbf{w}_t\rangle\rangle_{\mathbf{g}}=\int_{\varphi_t(\mathcal{U})}\rho\langle\langle\mathbf{a}-\mathbf{b},\mathbf{v}\rangle\rangle_{\mathbf{g}_t}$$
$$+\int_{\varphi_t(\mathcal{U})}\rho\langle\langle\mathbf{a}-\mathbf{b},\mathbf{W}_t\rangle\rangle_{\mathbf{g}_t}, \tag{5.62}$$

where use was made of $\mathbf{L}_{\mathbf{v}}\rho=0$. Note that

$$\frac{d}{dt}\int_{\varphi_t'(\mathcal{U})}\rho'e'=\int_{\varphi_t'(\mathcal{U})}[\rho'\mathbf{L}_{\mathbf{v}'}e'+e'\xi_{t*}(\mathbf{L}_{\mathbf{v}}\rho)]=\int_{\varphi_t'(\mathcal{U})}\rho'\mathbf{L}_{\mathbf{v}'}e'=\int_{\varphi_t'(\mathcal{U})}\rho\xi_t^*(\mathbf{L}_{\mathbf{v}'}e'). \tag{5.63}$$

But

$$\xi_t^*(\mathbf{L}_{\mathbf{v}'}e')=\dot{e}+\frac{\partial e}{\partial\mathbf{g}_t}:\mathcal{L}_{\mathbf{W}_t}\mathbf{g}_t. \tag{5.64}$$

Therefore

$$\Delta E(\xi_t)=\Delta E(\mathrm{Id})+\int_{\varphi_t(\mathcal{U})}\left[\left(2\rho\frac{\partial e}{\partial\mathbf{g}_t}-\boldsymbol{\sigma}\right):\frac{1}{2}\mathcal{L}_{\mathbf{W}_t}\mathbf{g}_t+\boldsymbol{\sigma}:\boldsymbol{\omega}_t\right]dv-\int_{\varphi_t(\mathcal{U})}\langle\langle\mathrm{div}\,\boldsymbol{\sigma}+\rho(\mathbf{b}-\mathbf{a}),\mathbf{W}_t\rangle\rangle_{\mathbf{g}_t}dv$$
$$=0. \tag{5.65}$$

□

E. Spatial covariant material energy balance

Let us consider the material balance of energy

$$\frac{d}{dt}\int_{\mathcal{U}}\rho_0\left(E+\frac{1}{2}\langle\langle\mathbf{V},\mathbf{V}\rangle\rangle\right)=\int_{\mathcal{U}}\rho_0\left(\langle\langle\mathbf{B},\mathbf{V}\rangle\rangle+R\right)+\int_{\partial\mathcal{U}}\left(\langle\langle\mathbf{T},\mathbf{V}\rangle\rangle+H\right)dA, \tag{5.66}$$

where we have assumed that ρ_0 is a 3-form. Physically this is equivalent to the spatial energy balance; material energy balance is simply the spatial energy balance expressed in terms of quantities defined with respect to the reference configuration. Let us postulate that the material energy balance is invariant with respect to diffeomorphisms $\xi_t:\mathcal{S}\to\mathcal{S}$. This is physically equivalent to the postulate of covariant spatial energy balance. The material energy balance for $\varphi_t'(\mathcal{U})\subset\mathcal{S}$ is written as

$$\frac{d}{dt}\int_{\mathcal{U}}\rho_0'\left(E'+\frac{1}{2}\langle\langle\mathbf{V}',\mathbf{V}'\rangle\rangle\right)=\int_{\mathcal{U}}\rho_0'\left(\langle\langle\mathbf{B}',\mathbf{V}'\rangle\rangle+R'\right)+\int_{\partial\mathcal{U}}\left(\langle\langle\mathbf{T}',\mathbf{V}'\rangle\rangle+H'\right)dA. \tag{5.67}$$

Note that for both deformations balance of energy is written for the same subset $\mathcal{U}\subset\mathcal{B}$. The material velocity $\mathbf{V}'$ is related to $\mathbf{V}$ by the following relation:

$$\mathbf{V}'(\mathbf{X})=T\xi_t\circ\mathbf{V}_t+\mathbf{w}_t\circ\varphi_t(\mathbf{X}). \tag{5.68}$$

Thus

$$\mathbf{V}'\big|_{t=t_0}=\mathbf{V}+\mathbf{w}\circ\varphi_{t_0}. \tag{5.69}$$

We know that

$$R=J_{\varphi_t}r\circ\varphi_t,\quad R'=J_{\varphi_t'}r'\circ\varphi_t',\quad r=J_{\xi_t}r'\circ\xi_t. \tag{5.70}$$

Hence

$$J_{\varphi_t'} r' \circ \varphi_t' = (J_{\xi_t} r' \circ \xi_t) \circ \varphi_t J_{\varphi_t} = J_{\varphi_t} r \circ \varphi_t. \tag{5.71}$$

Thus

$$R' = R. \tag{5.72}$$

Similarly

$$H' = H. \tag{5.73}$$

Note that looking at densities as 3-forms

$$\rho_0(\mathbf{X},t) = \varphi_t^* \rho(\mathbf{x},t), \quad \rho_0'(\mathbf{X},t) = (\varphi_t')^* \rho'(\mathbf{x}',t). \tag{5.74}$$

But

$$(\varphi_t')^* \rho'(\mathbf{x}',t) = (\xi_t \circ \varphi_t)^* \rho'(\mathbf{x}',t) = (\varphi_t^* \circ \xi_t^*) \circ \xi_{t*} \rho(\mathbf{x},t) = \varphi_t^* \rho(\mathbf{x},t). \tag{5.75}$$

Thus

$$\rho_0'(\mathbf{X},t) = \rho_0(\mathbf{X},t). \tag{5.76}$$

Because balance of energy is written for the same subset $\mathcal{U} \subset \mathcal{B}$ the same equality holds for densities as scalar fields, i.e., one can replace ρ_0' and ρ_0 by $\rho_0' \, \mathrm{d}V$ and $\rho_0 \, \mathrm{d}V$, respectively. Define

$$E(\mathbf{X},t,\mathbf{g}) = e(\varphi_t(\mathbf{X}),t,\mathbf{g} \circ \varphi_t(\mathbf{X})). \tag{5.77}$$

We know that

$$e'(\mathbf{x}',t,\mathbf{g}) = e(\mathbf{x},t,\xi_t^* \mathbf{g}). \tag{5.78}$$

Thus

$$E'(\mathbf{X},t,\mathbf{g}) = e'(\mathbf{x}',t,\mathbf{g}) = e(\mathbf{x},t,\xi_t^* \mathbf{g}) = E(\mathbf{X},t,\xi_t^* \mathbf{g}). \tag{5.79}$$

Therefore

$$\left. \frac{d}{\mathrm{d}t} \right|_{t=t_0} E' = \frac{\partial E}{\partial t} + \frac{\partial E}{\partial \mathbf{g}} : \mathfrak{L}_{\mathbf{w} \circ \varphi_t} (\mathbf{g} \circ \varphi_t). \tag{5.80}$$

Now the material energy balance for the motion φ_t' at $t = t_0$ can be written as

$$\begin{aligned} &\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t} \left(E + \frac{1}{2} \left\langle \left\langle \mathbf{V} + \mathbf{w} \circ \varphi_{t_0}, \mathbf{V} + \mathbf{w} \circ \varphi_{t_0} \right\rangle \right\rangle \right) \mathrm{d}V + \int_{\mathcal{U}} \left[\rho_0 \left(\frac{\partial E}{\partial t} + \frac{\partial E}{\partial \mathbf{g}} : \mathfrak{L}_{\mathbf{w} \circ \varphi_t} (\mathbf{g} \circ \varphi_t) \right) \right. \\ &\qquad \left. + \rho_0 \langle \langle \mathbf{V} + \mathbf{w} \circ \varphi_{t_0}, \mathbf{A}' |_{t=t_0} \rangle \rangle \right] \mathrm{d}V \\ &= \int_{\mathcal{U}} \rho_0 (\langle \langle \mathbf{B}' |_{t=t_0}, \mathbf{V} + \mathbf{w} \circ \varphi_{t_0} \rangle \rangle + R) \, \mathrm{d}V + \int_{\partial \mathcal{U}} \left(\left\langle \left\langle \mathbf{T}, \mathbf{V} + \mathbf{w} \circ \varphi_{t_0} \right\rangle \right\rangle + H \right) \mathrm{d}A. \end{aligned} \tag{5.81}$$

Subtracting the balance of energy for the motion φ_t from (5.81) one arrives at the following identity:

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(\left\langle\left\langle \mathbf{V}, \mathbf{w}\circ\varphi_{t_0}\right\rangle\right\rangle + \frac{1}{2}\left\langle\left\langle \mathbf{w}\circ\varphi_{t_0}, \mathbf{w}\circ\varphi_{t_0}\right\rangle\right\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0\left(\frac{\partial E}{\partial \mathbf{g}}:\mathfrak{L}_{\mathbf{w}\circ\varphi_t}(\mathbf{g}\circ\varphi_t) + \left\langle\left\langle \mathbf{w}\circ\varphi_{t_0}, \mathbf{A}\right\rangle\right\rangle\right)\mathrm{d}V$$
$$= \int_{\mathcal{U}} \langle\langle \rho_0 \mathbf{B}, \mathbf{w}\circ\varphi_{t_0}\rangle\rangle \mathrm{d}V + \int_{\partial\mathcal{U}} \langle\langle \mathbf{T}, \mathbf{w}\circ\varphi_{t_0}\rangle\rangle \,\mathrm{d}A. \tag{5.82}$$

Let us denote $\mathbf{W}=\mathbf{w}\circ\varphi_t$ and note that $\mathbf{W}$ is a spatial vector field with components W^a.

Lemma 5.5: *The surface integral term in* (5.82) *is transformed to a volume integral as*

$$\int_{\partial\mathcal{U}} \left\langle\left\langle \mathbf{T}, \mathbf{W}\right\rangle\right\rangle \mathrm{d}A = \int_{\mathcal{U}} \left(\left\langle\left\langle \mathrm{Div}\, \mathbf{P}, \mathbf{W}\right\rangle\right\rangle + \boldsymbol{\tau}:\boldsymbol{\omega} + \boldsymbol{\tau}:\mathbf{k}\right)\mathrm{d}V, \tag{5.83}$$

where, $\tau^{ab}=P^{aB}F^b_B$ *is the Kirchhoff stress and* $\boldsymbol{\omega}$ *and* $\mathbf{k}$ *have the coordinate representations* $k_{ab}=\frac{1}{2}(W_{a|b}+W_{b|a})$ and $\omega_{ab}=\frac{1}{2}(W_{a|b}-W_{b|a})$.

Proof: The integrand has the following component form:

$$T^a g_{ab} W^b = P^{aC} G_{CD} N^D g_{ab} W^b = (P^{aC} g_{ab} W^b) G_{CD} N^D. \tag{5.84}$$

Now using divergence theorem the surface integral is transformed to an integral on $\mathcal{U}$ with an integrand with the following component form:

$$(P^{aC} g_{ab} W^b)_{|C} = P^{aC}{}_{|C} g_{ab} W^b + P^{aC} g_{ab} W^b{}_{|C}, \tag{5.85}$$

where use was made of the fact that $g_{ab|C}=0$. Note that

$$W^b{}_{|C} = \frac{\partial W^b}{\partial X^C} + \gamma^b_{cd} W^c F^d{}_C = W^b{}_{,d} F^d{}_C + \gamma^b_{cd} W^c F^d{}_C = (W^b{}_{,d} + \gamma^b_{cd} W^c) F^d{}_C = W^b{}_{|d} F^d{}_C. \tag{5.86}$$

Therefore,

$$\begin{aligned}(P^{aC} g_{ab} W^b)_{|C} &= P^{aC}{}_{|C} g_{ab} W^b + P^{aC} W_{a|d} F^d{}_C \\ &= P^{aC}{}_{|C} g_{ab} W^b + P^{aC} F^d{}_C \left[\tfrac{1}{2}(W_{a|d} + W_{d|a}) + \tfrac{1}{2}(W_{a|d} - W_{d|a})\right],\end{aligned} \tag{5.87}$$

which proves the lemma. □

Substituting (5.83) into (5.82) yields

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(\left\langle\left\langle \mathbf{V}, \mathbf{W}\right\rangle\right\rangle + \frac{1}{2}\left\langle\left\langle \mathbf{W}, \mathbf{W}\right\rangle\right\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \left(2\rho_0 \frac{\partial E}{\partial \mathbf{g}} - \boldsymbol{\tau}\right):\mathbf{k}\,\mathrm{d}\mathbf{V} - \int_{\mathcal{U}} \boldsymbol{\tau}:\boldsymbol{\omega}\,\mathrm{d}\mathbf{V}$$
$$- \int_{\mathcal{U}} \left\langle\left\langle \mathrm{Div}\, \mathbf{P} + \rho_0 \mathbf{B} - \rho_0 \mathbf{A}, \mathbf{W}\right\rangle\right\rangle \mathrm{d}\mathbf{V} = \mathbf{0}. \tag{5.88}$$

As $\mathbf{W}$ and $\mathcal{U}\subset\mathcal{B}$ are arbitrary we conclude that,

$$\frac{\partial \rho_0}{\partial t} = 0, \tag{5.89}$$

$$\boldsymbol{\tau} = 2\rho_0 \frac{\partial E}{\partial \mathbf{g}}, \tag{5.90}$$

$$\boldsymbol{\tau}^{\mathsf{T}} = \boldsymbol{\tau}, \tag{5.91}$$

$$\mathrm{Div}\,\mathbf{P}+\rho_0\mathbf{B}=\rho_0\mathbf{A}. \tag{5.92}$$

In conclusion, these computations result in the following proposition.

Proposition 5.6: Energy balance written in material form, but still with the assumption of spatial covariance yields results that are identical to those of energy balance written in spatial form, also with covariance under spatial diffeomorphisms.

The converse can be proved similar to what was done in the previous subsection.

VI. TRANSFORMATION OF ENERGY BALANCE UNDER MATERIAL DIFFEOMORPHISMS

As was seen in the preceding section, invariance of balance of energy under an arbitrary change in spatial frame is equivalent to (1) balance of linear momentum, (2) balance of angular momentum, (3) conservation of mass, and (4) Doyle-Ericksen formula. To our best knowledge, there is no material version of this theorem in the literature. Our motivation for studying the possibility of material invariance of energy balance was to gain a better understanding of configurational forces as they are believed to be related to rearrangements of the reference configuration. It turns out that, in general, energy balance cannot be invariant under diffeomorphisms of the reference configuration and what one should be looking for instead is the way in which energy balance transforms under material diffeomorphisms. In this section we first obtain such a transformation formula under an arbitrary time-dependent material diffeomorphism [see Eq. (6.51)] and then obtain the conditions under which balance of energy is materially covariant.

A. The energy balance material transformation formula

We begin with a discussion of how energy balance transforms under material diffeomorphisms. Define

$$E(\mathbf{X},t,\mathbf{G})=\Psi(\mathbf{X},t,\mathbf{C}(\mathbf{F}(\mathbf{X}),\mathbf{g}(\varphi_t(\mathbf{X}))),\mathbf{G}), \tag{6.1}$$

where $\Psi=\Psi(\mathbf{X},t,\mathbf{G},\mathbf{C})$ is the material free energy density. Material (Lagrangian) energy balance can be written as

$$\frac{d}{\mathrm{d}t}\int_{\mathcal{U}}\rho_0\left(E+\frac{1}{2}\langle\langle\mathbf{V},\mathbf{V}\rangle\rangle\right)\mathrm{d}V=\int_{\mathcal{U}}\rho_0(\langle\langle\mathbf{B},\mathbf{V}\rangle\rangle+R)\mathrm{d}V+\int_{\partial\mathcal{U}}(\langle\langle\mathbf{T},\mathbf{V}\rangle\rangle+H)\mathrm{d}A, \tag{6.2}$$

which can be simplified to read

$$\int_{\mathcal{U}}\frac{d}{\mathrm{d}t}\left[\rho_0\left(E+\frac{1}{2}\langle\langle\mathbf{V},\mathbf{V}\rangle\rangle\right)\right]\mathrm{d}V=\int_{\mathcal{U}}\rho_0\left(\langle\langle\mathbf{B},\mathbf{V}\rangle\rangle+R\right)\mathrm{d}V+\int_{\partial\mathcal{U}}(\langle\langle\mathbf{T},\mathbf{V}\rangle\rangle+H)\mathrm{d}A, \tag{6.3}$$

where $\mathcal{U}$ is an arbitrary nice subset of the reference configuration $\mathcal{B}$, $\mathbf{B}$ is body force per unit undeformed mass, $\mathbf{V}(\mathbf{X},t)$ is the material velocity, $\rho_0(\mathbf{X},t)$ is the material density, $R(\mathbf{X},t)$ is the heat supply per unit undeformed mass, and $H(\mathbf{X},t,\hat{\mathbf{N}})$ is the heat flux across a surface with normal $\hat{\mathbf{N}}$ in the undeformed configuration (normal to $\partial\mathcal{U}$ at $\mathbf{X}\in\partial\mathcal{U}$). It is to be noted that this is balance of energy for a deformed part of the body written in terms of quantities that are defined with respect to the undeformed (reference) configuration. Here we assume that we have a material manifold which is a Riemannian manifold $(\mathfrak{B},\mathbf{G})$ and a given reference configuration $\mathcal{B}\subset\mathfrak{B}$.

Change of reference frame: In this paragraph we consider a change of frame for the reference configuration and look at the transformed quantities for the new reference configuration. A reframing of the reference configuration is a diffeomorphism

$$\Xi_t:(\mathfrak{B},\mathbf{G})\to(\mathfrak{B},\mathbf{G}'). \tag{6.4}$$

A change of frame can be thought of as a change of coordinates in the reference configuration (passive definition) or a rearrangement of microstructure (active definition). Under such a framing, a nice subset $\mathcal{U}$ is mapped to another nice subset $\mathcal{U}'=\Xi_t(\mathcal{U})$ and a material point $\mathbf{X}$ is mapped to

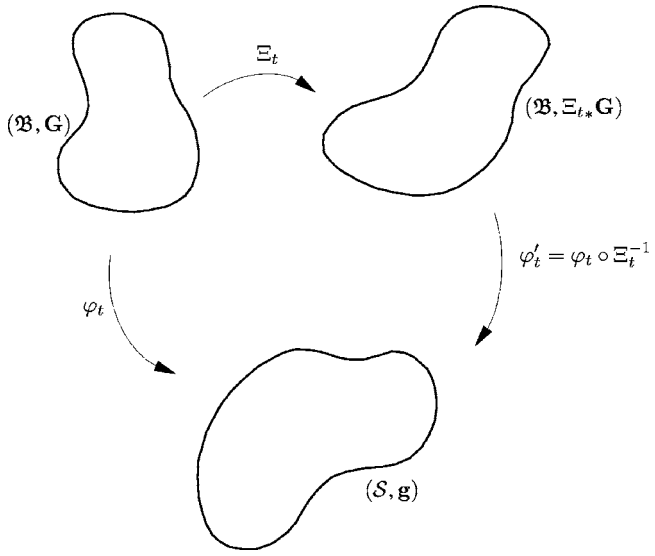


FIG. 2. A material reframing and the corresponding deformation maps.

$\mathbf{X}' = \Xi_t(\mathbf{X})$. Note that $\mathbf{X}$ is the position of a particle in the reference configuration, i.e., material points are identified with their positions in the reference configuration (which is arbitrary). The change of frame is mathematically a mapping between two manifolds and one would expect to define an object on $(\mathfrak{B}, \mathbf{G}')$ as push-forward of the corresponding object on $(\mathfrak{B}, \mathbf{G})$.

The deformation mapping for the new reference configuration is $\varphi'_t = \varphi_t \circ \Xi_t^{-1}$. This can be clearly seen in Fig. 2. The material velocity in $\mathcal{U}'$ is

$$\mathbf{V}'(\mathbf{X}', t) = \frac{\partial}{\partial t}\varphi'_t(\mathbf{X}') = \frac{\partial \varphi_t}{\partial t} \circ \Xi_t^{-1}(\mathbf{X}') + T\varphi_t \circ \frac{\partial \Xi_t^{-1}}{\partial t}(\mathbf{X}'). \tag{6.5}$$

We assume that

$$\Xi_t|_{t=t_0} = \mathrm{Id}, \quad \frac{\partial \Xi_t}{\partial t}(\mathbf{X}) = \mathbf{W}(\mathbf{X}, t). \tag{6.6}$$

Note that $\mathbf{W}$ is the infinitesimal generator of the rearrangement Ξ_t. It can be shown that at $t = t_0$,

$$\frac{\partial \Xi_t^{-1}}{\partial t}(\mathbf{X}')\bigg|_{t=t_0} = -\mathbf{W}(\mathbf{X}, t). \tag{6.7}$$

Thus, at $t = t_0$,

$$\mathbf{V}' = \mathbf{V} - \mathbf{F}\mathbf{W}. \tag{6.8}$$

To find the relation between $\mathbf{G}$ and $\mathbf{G}'$ we note that the Finger tensor $\mathbf{b} = \varphi_{t*}\mathbf{G}$ is a spatial tensor and hence independent of framing of the reference configuration. Thus,

$$\mathbf{b} = \varphi_{t*}\mathbf{G} = (\varphi'_t)_*\mathbf{G}'. \tag{6.9}$$

That is,

$$\mathbf{G}' = (\varphi_t \circ \Xi_t^{-1})^* \circ \varphi_{t*}\mathbf{G} = (\Xi_t^{-1})^* \circ \varphi_t^* \circ \varphi_{t*}\mathbf{G} = (\Xi_t^{-1})^*\mathbf{G} = \Xi_{t*}\mathbf{G} = (T\Xi_t)^{-*}\mathbf{G}(T\Xi_t)^{-1}. \tag{6.10}$$

Note that for an arbitrary $\mathbf{X}_0 \in \mathcal{B}$,

$$\mathbf{F}(\mathbf{X}_0):T_{\mathbf{X}_0}\mathcal{B}\to T_{\varphi_t(\mathbf{X}_0)}\mathcal{S} \quad \text{and} \quad \mathbf{F}'(\mathbf{X}_0'):T_{\mathbf{X}_0'}\mathcal{B}\to T_{\varphi_t'(\mathbf{X}_0')}\mathcal{S}.$$

Given $\mathrm{d}\mathbf{X}\in T_{\mathbf{X}_0}\mathcal{B}$,

$$\mathrm{d}\mathbf{x}=\mathbf{F}(\mathbf{X}_0)\cdot d\mathbf{X} \quad \text{and} \quad \mathrm{d}\mathbf{X}'=T\Xi_t\cdot\mathrm{d}\mathbf{X}.$$

Hence,

$$\mathrm{d}\mathbf{x}=\mathbf{F}'(\mathbf{X}_0')\cdot\mathrm{d}\mathbf{X}'=\mathbf{F}'(\mathbf{X}_0')\circ T\Xi_t\cdot\mathrm{d}\mathbf{X}=\mathbf{F}(\mathbf{X}_0)\cdot\mathrm{d}\mathbf{X}$$

for all $\mathrm{d}\mathbf{X}\in T_{\mathbf{X}_0}\mathcal{B}$. Thus,

$$\mathbf{F}'=\Xi_{t*}\mathbf{F}, \tag{6.11}$$

where

$$\Xi_{t*}\mathbf{F}=\mathbf{F}\circ(T\Xi_t)^{-1}. \tag{6.12}$$

The easier way of proving this is the following:

$$\mathbf{F}'=T\varphi_t'=T(\varphi_t\circ\Xi_t^{-1})=T\varphi_t\circ(\Xi_t)^{-1}=\mathbf{F}\circ(\Xi_t)^{-1}. \tag{6.13}$$

The material internal energy density is assumed to have the following tensorial property:

$$E'(\mathbf{X}',t,\mathbf{G}')=E(\mathbf{X},t,\mathbf{G}). \tag{6.14}$$

Note that this is different from assuming local covariance for internal energy density. This is simply the material analogue of (5.78); all that (6.14) says is that internal energy density at $\mathbf{X}'$ evaluated by the transformed metric $\mathbf{G}'$ is equal to the internal energy density at $\mathbf{X}$ evaluated by the metric $\mathbf{G}$. We know that $\mathbf{G}'=\Xi_{t*}\mathbf{G}$, thus

$$E'(\mathbf{X}',t,\mathbf{G})=E(\mathbf{X},t,\Xi_t^*\mathbf{G}). \tag{6.15}$$

This means that

$$\left.\frac{d}{\mathrm{d}t}\right|_{t=t_0}E'(\mathbf{X}',t,\mathbf{G})=\frac{\partial E}{\partial t}+\frac{\partial E}{\partial\mathbf{G}}:\mathfrak{L}_{\mathbf{W}}\mathbf{G}. \tag{6.16}$$

Remark: Marsden and Hughes[28] defined covariant constitutive equations by looking at isometries of $T_{\mathbf{X}_0}\mathcal{B}$ at a given point $\mathbf{X}_0\in\mathcal{B}$. This is why they did not need to consider an explicit dependence of Ψ on $\mathbf{G}$. Another more general way of defining material covariance for the strain energy function Ψ is to assume that for any local diffeomorphism $\Lambda:T_{\mathbf{X}_0}\mathcal{B}\to T_{\Lambda(\mathbf{X}_0)}\Lambda(\mathcal{B})$ that leaves $\mathbf{X}_0$ fixed,

$$\Psi(\mathbf{X}_0,\mathbf{G},\mathbf{C})=\Psi(\mathbf{X}_0,\Lambda^*\mathbf{G},\Lambda^*\mathbf{C}). \tag{6.17}$$

Note that this is different from the implication of Cartan's space-time, e.g.,

$$\Psi(\mathbf{X}',\mathbf{G}',\mathbf{C}')=\Psi(\mathbf{X},\Xi^*\mathbf{G}',\Xi^*\mathbf{C}'),$$

for an arbitrary diffeomorphism $\Xi:\mathfrak{B}\to\mathfrak{B}$. We emphasize that this relation and similarly (6.14) do not put any restrictions on material properties. Ju and Papadopoulos[26,27] proved that a consequence of (6.17) is the following infinitesimal covariance condition:

$$\mathbf{G}\frac{\partial\Psi}{\partial\mathbf{G}}+\mathbf{C}\frac{\partial\Psi}{\partial\mathbf{C}}=\mathbf{0}, \tag{6.18}$$

which is equivalent to

$$\frac{\partial \Psi}{\partial \mathbf{G}} = -\mathbf{G}^{-1}\mathbf{C}\frac{\partial \Psi}{\partial \mathbf{C}} = -\frac{1}{2}\mathbf{G}^{-1}\mathbf{C}\mathbf{S} = -\frac{1}{2}\mathbf{F}^{\mathrm{T}}\mathbf{P}. \tag{6.19}$$

We will obtain this condition in the sequel as a consequence of assuming material covariance of energy balance.

Example: Consider a (materially uniform) Neo-Hookean material with the following energy density

$$\Psi(\mathbf{X},\mathbf{G},\mathbf{C}) = \mu[\mathrm{tr}(\mathbf{C}) - 3] = \mu(C_{IJ}G^{IJ} - 3). \tag{6.20}$$

We now show that this is an example of a materially covariant material. Note that

$$\left(\mathbf{C}\frac{\partial \Psi}{\partial \mathbf{C}}\right)^{J}_{I} = \mu C_{IK}G^{KJ}. \tag{6.21}$$

Also

$$\left(\mathbf{G}\frac{\partial \Psi}{\partial \mathbf{C}}\right)^{J}_{I} = \mu G_{IK}C_{MN}\frac{\partial G^{MN}}{\partial G_{KJ}} = -\frac{\mu}{2}C_{MN}G_{IK}(G^{MK}G^{JN} + G^{MJ}G^{KN}) = -\mu C_{IK}G^{KJ}, \tag{6.22}$$

i.e.,

$$\mathbf{C}\frac{\partial \Psi}{\partial \mathbf{C}} + \mathbf{G}\frac{\partial \Psi}{\partial \mathbf{G}} = \mathbf{0}. \tag{6.23}$$

□

Spatial covariance of strain energy function (material-frame-indifference) can be defined similarly (see Ref. 41). However, one should note that this is different from Marsden and Hughes point of departure for developing a covariant theory of elasticity; in Marsden and Hughes' theory[28] balance of energy is assumed to be covariant and not the energy function. In covariant energy balance, a global diffeomorphism is considered and energy balance is assumed to be invariant under this global diffeomorphism.

Balance of energy for reframings of the reference configuration: One way to obtain the governing balance equations of a continuum is to use the homogeneity of the ambient space and postulate that if a deformed body satisfies the balance of energy, any framing of it should satisfy the balance of energy as well. This is a postulate and cannot be proved. But, one can justify it (or motivate it) by the fact that the ambient space $\mathcal{S}$ is homogeneous. Invariance of energy balance under framings of the reference configuration is less obvious and, in general, it turns out not to hold. The following is the main conclusion of this section. *Under referential diffeomorphisms, material energy balance has some extra terms in it. The extra terms correspond to some forces that contribute to the rate of change of energy when the reference configuration evolves.*

Consider a deformation mapping $\varphi_t : \mathcal{B} \to \mathcal{S}$ and a referential diffeomorphisms $\Xi_t : \mathfrak{B} \to \mathfrak{B}$. The mapping $\varphi'_t = \varphi_t \circ \Xi_t^{-1} : \mathcal{B}' \to \mathcal{S}$, where $\mathcal{B}' = \Xi_t(\mathcal{B})$, represents the deformation of the new (evolved) reference configuration. We are interested in understanding the form of material energy balance for $\Xi_t(\mathcal{U}) \subset \mathcal{B}'$ for any nice $\mathcal{U} \subset \mathcal{B}$. In addition to contributions from the mapping φ'_t, in general, one should expect to see contributions from the referential mapping Ξ_t as well, i.e., evolution of reference configuration may, in general, contribute to the energy balance. Now the balance of energy should include the following two groups of terms:

(i) Looking at φ'_t as the deformation of $\mathcal{B}'$ in $\mathcal{S}$, one has the usual material energy balance for $\Xi_t(\mathcal{U})$. Transformation of fields from $(\mathfrak{B}, \mathbf{G})$ to $(\mathfrak{B}, \mathbf{G}')$ follows Cartan's space-time theory.

(ii) Nonstandard terms may appear to represent the energy associated with the material evolution.

Here a comment is in order. The mapping that represents all the physical processes is φ_t. This mapping is the composition of φ'_t and Ξ_t and hence it is expected that, in general, both φ'_t and Ξ_t represent part of the physical processes. This means that standard deformation represented by φ'_t and evolution of microstructure (or any other material evolution) represented by Ξ_t should contribute to balance of energy. (This is similar to Gurtin's idea[20,21] of including both standard and nonstandard terms in the expression of working. However, here we consider the full balance of energy.) This rough picture should be enough to convince the reader that the lack of invariance of energy balance under Ξ_t should not be surprising. Lack of invariance implies the appearance of some new terms that are work-conjugate to $\mathbf{W}_t=(\partial/\partial t)\Xi_t$. Let us denote the volume and surface forces conjugate to $\mathbf{W}$ by $\mathbf{B}_0$ and $\mathbf{T}_0$, respectively.

Instead of looking at spatial framings, we fix the deformed configuration and look at framings of the reference configuration. We postulate that energy balance for each nice subset $\mathcal{U}'$ has the following form:

$$\frac{d}{dt}\int_{\mathcal{U}'}\left(E'+\frac{1}{2}\rho'_0\langle\langle\mathbf{V}',\mathbf{V}'\rangle\rangle\right)dV'=\int_{\mathcal{U}'}\rho'_0(\langle\langle\mathbf{B}',\mathbf{V}'\rangle\rangle+R')dV'+\int_{\partial\mathcal{U}'}(\langle\langle\mathbf{T}',\mathbf{V}'\rangle\rangle+H')dA'$$
$$+\int_{\mathcal{U}'}\langle\langle\mathbf{B}'_0,\mathbf{W}_t\rangle\rangle dV'+\int_{\partial\mathcal{U}'}\langle\langle\mathbf{T}'_0,\mathbf{W}_t\rangle\rangle dA', \tag{6.24}$$

where $\mathcal{U}'=\Xi_t(\mathcal{U})$ and $\mathbf{B}'_0$ and $\mathbf{T}'_0$ are unknown vector fields at this point. Using Cartan's space-time theory, it is assumed that the primed quantities have the following relations with the unprimed quantities

$$dV'=\Xi_t{}^*dV\ (J(\Xi_t)dV'=dV),\quad R'(\mathbf{X}',t)=R(\mathbf{X},t),$$

$$\rho'_0(\mathbf{X}',t)=\rho_0(\mathbf{X}),\quad H'(\mathbf{X}',\hat{\mathbf{N}}',t)=H(\mathbf{X},\hat{\mathbf{N}},t), \tag{6.25}$$

$$\mathbf{T}'(\mathbf{X}',\hat{\mathbf{N}}',t)=T\Xi_t(\mathbf{X})\cdot\mathbf{T}(\mathbf{X},\hat{\mathbf{N}},t).$$

We know that

$$\mathbf{B}'-\mathbf{A}'=\Xi_t{}^*(\mathbf{B}-\mathbf{A}). \tag{6.26}$$

Thus

$$(\mathbf{B}'-\mathbf{A}')\big|_{t=t_0}=\mathbf{B}-\mathbf{A}. \tag{6.27}$$

Note that if α is a 3-form on $\mathcal{U}$, then

$$\frac{d}{dt}\bigg|_{t=t_0}\int_{\mathcal{U}'}\alpha'=\int_{\mathcal{U}}\frac{d}{dt}\bigg|_{t=t_0}(\Xi_t^*\alpha'), \tag{6.28}$$

where $\mathcal{U}'=\Xi_t(\mathcal{U})$. Thus

$$\frac{d}{dt}\bigg|_{t=t_0}\int_{\mathcal{U}'}E'dV'=\int_{\mathcal{U}}\frac{d}{dt}\bigg|_{t=t_0}(\Xi_t^*E')dV=\int_{\mathcal{U}}\left(\frac{\partial E}{\partial t}+\frac{\partial E}{\partial\mathbf{G}}:\mathfrak{L}_{\mathbf{W}}\mathbf{G}\right)dV. \tag{6.29}$$

Material balance of energy for $\mathcal{U}'\subset\mathcal{B}'$ at $t=t_0$ reads

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(E+\frac{1}{2}\langle\langle \mathbf{V}-\mathbf{FW},\mathbf{V}-\mathbf{FW}\rangle\rangle\right)\mathrm{d}V+\int_{\mathcal{U}}\rho_0\left(\frac{\partial E}{\partial t}+\frac{\partial E}{\partial \mathbf{G}}:\mathfrak{L}_{\mathbf{W}}\mathbf{G}+\langle\langle \mathbf{V}-\mathbf{FW},\mathbf{A}'|_{t=t_0}\rangle\rangle\right)\mathrm{d}V$$
$$=\int_{\mathcal{U}}\rho_0(\langle\langle \mathbf{B}'|_{t=t_0},\mathbf{V}-\mathbf{FW}\rangle\rangle+R)\mathrm{d}V+\int_{\partial\mathcal{U}}(\langle\langle \mathbf{T},\mathbf{V}-\mathbf{FW}\rangle\rangle+H)\mathrm{d}A+\int_{\mathcal{U}}\langle\langle \mathbf{B}_0,\mathbf{W}\rangle\rangle\mathrm{d}V$$
$$+\int_{\partial\mathcal{U}}\langle\langle \mathbf{T}_0,\mathbf{W}\rangle\rangle\mathrm{d}A. \tag{6.30}$$

Note that $\mathbf{T}_0$ and $\mathbf{B}_0$ are defined on $\mathcal{B}$ and $\mathbf{T}_0'$ and $\mathbf{B}_0'$ are the corresponding quantities defined on $\Xi_t(\mathcal{B})$. Here we assume that $\mathbf{T}_0'=\Xi_{t^*}\mathbf{T}_0$ and $\mathbf{B}_0'=\Xi_{t^*}\mathbf{B}_0$. Subtracting balance of energy for $\mathcal{U}$ from this and noting that $(\mathbf{A}'-\mathbf{B}')_{t=t_0}=\mathbf{A}-\mathbf{B}$ we obtain

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(-\langle\langle \mathbf{V},\mathbf{FW}\rangle\rangle+\frac{1}{2}\langle\langle \mathbf{FW},\mathbf{FW}\rangle\rangle\right)\mathrm{d}V+\int_{\mathcal{U}}\rho_0\left(\frac{\partial E}{\partial \mathbf{G}}:\mathfrak{L}_{\mathbf{W}}\mathbf{G}-\langle\langle \mathbf{FW},\mathbf{A}\rangle\rangle\right)\mathrm{d}V$$
$$=-\int_{\mathcal{U}}\langle\langle \rho_0\mathbf{B},\mathbf{FW}\rangle\rangle\mathrm{d}V-\int_{\partial\mathcal{U}}\langle\langle \mathbf{T},\mathbf{FW}\rangle\rangle\mathrm{d}A+\int_{\mathcal{U}}\langle\langle \mathbf{B}_0,\mathbf{W}\rangle\rangle\mathrm{d}V+\int_{\partial\mathcal{U}}\langle\langle \mathbf{T}_0,\mathbf{W}\rangle\rangle\mathrm{d}A. \tag{6.31}$$

Cauchy's theorem implies that

$$\langle\langle \mathbf{T},\mathbf{FW}\rangle\rangle=\langle\langle \mathbf{FW},\langle\langle \mathbf{P},\hat{\mathbf{N}}\rangle\rangle\rangle\rangle, \tag{6.32}$$

where $\mathbf{P}$ is the first Piola-Kirchhoff stress tensor. Similarly

$$\mathbf{T}_0=\langle\langle \mathbf{P}_0,\hat{\mathbf{N}}\rangle\rangle. \tag{6.33}$$

Lemma 6.1: The surface integral in material energy balance has the following transformation:

$$\int_{\partial\mathcal{U}}\langle\langle \mathbf{F}^{\mathsf{T}}\mathbf{T},\mathbf{W}\rangle\rangle\mathrm{d}A=\int_{\mathcal{U}}\mathrm{Div}\langle\langle \mathbf{F}^{\mathsf{T}}\mathbf{P},\mathbf{W}\rangle\rangle\mathrm{d}V=\int_{\mathcal{U}}[\langle\langle \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}),\mathbf{W}\rangle\rangle+\mathbf{F}^{\mathsf{T}}\mathbf{P}:\mathbf{\Omega}+\mathbf{F}^{\mathsf{T}}\mathbf{P}:\mathbf{K}]\mathrm{d}V, \tag{6.34}$$

where

$$\mathbf{\Omega}_{IJ}=\tfrac{1}{2}(G_{IK}W^K{}_{|J}-G_{JK}W^K{}_{|I})=\tfrac{1}{2}(W_{I|J}-W_{J|I}), \tag{6.35}$$

$$\mathbf{K}_{IJ}=\tfrac{1}{2}(G_{IK}W^K{}_{|J}+G_{JK}W^K{}_{|I})=\tfrac{1}{2}(W_{I|J}+W_{J|I}),\quad \mathbf{K}=\tfrac{1}{2}\mathfrak{L}_{\mathbf{W}}\mathbf{G}. \tag{6.36}$$

Proof: In components the integrand can be written as

$$(\mathbf{F}^{\mathsf{T}})^A{}_a T^a G_{AB} W^B. \tag{6.37}$$

But

$$T^a=P^{aC}G_{CD}N^D. \tag{6.38}$$

Hence in components the integrand reads

$$((\mathbf{F}^{\mathsf{T}})^A{}_a P^{aC}G_{AB}W^B)G_{CD}N^D. \tag{6.39}$$

Using the divergence theorem the surface integral is transformed to an integral on $\mathcal{U}$ with the following integrand in components:

$$((\mathbf{F}^{\mathsf{T}})^{A}{}_{a}P^{aC}G_{AB}W^{B})_{|C} = ((\mathbf{F}^{\mathsf{T}}\mathbf{P})^{AC}G_{AB}W^{B})_{|C} = (\mathbf{F}^{\mathsf{T}}\mathbf{P})^{AC}{}_{|C}G_{AB}W^{B} + (\mathbf{F}^{\mathsf{T}}\mathbf{P})^{AC}G_{AB}W^{B}{}_{|C}$$
$$= (\mathbf{F}^{\mathsf{T}}\mathbf{P})^{AC}{}_{|C}G_{AB}W^{B} + (\mathbf{F}^{\mathsf{T}}\mathbf{P})^{AC}\left[\tfrac{1}{2}(G_{AB}W^{B}{}_{|C} + G_{CB}W^{B}{}_{|A}) + \tfrac{1}{2}(G_{AB}W^{B}{}_{|C} - G_{CB}W^{B}{}_{|A})\right], \tag{6.40}$$

where use was made of the fact that $G_{AB|C}=0$. □

Similarly,

$$\int_{\partial\mathcal{U}} \langle\langle \mathbf{T}_0, \mathbf{W}\rangle\rangle \mathrm{d}A = \int_{\mathcal{U}} \mathrm{Div}\langle\langle \mathbf{P}_0, \mathbf{W}\rangle\rangle \mathrm{d}V = \int_{\mathcal{U}} [\langle\langle \mathrm{Div}(\mathbf{P}_0), \mathbf{W}\rangle\rangle + \mathbf{P}_0{:}\boldsymbol{\Omega} + \mathbf{P}_0{:}\mathbf{K}]\mathrm{d}V. \tag{6.41}$$

By definition, at time $t=t_0$ the transformed balance of energy should be the same as the balance of energy for $\mathcal{U}$. Subtracting the material balance of energy for $\mathcal{U}$ from the above balance law and considering conservation of mass, we obtain

$$\int_{\mathcal{U}} \rho_0 \frac{\partial E}{\partial \mathbf{G}}{:}\mathfrak{L}_{\mathbf{W}}\mathbf{G}\mathrm{d}V + \int_{\mathcal{U}} \langle\langle \rho_0 \mathbf{F}^{\mathsf{T}}(\mathbf{B}-\mathbf{A}), \mathbf{W}\rangle\rangle \mathrm{d}V - \int_{\mathcal{U}} \langle\langle \rho_0 \mathbf{B}_0, \mathbf{W}\rangle\rangle \mathrm{d}V + \int_{\partial\mathcal{U}} \langle\langle \mathbf{F}^{\mathsf{T}}\mathbf{T} - \mathbf{T}_0, \mathbf{W}\rangle\rangle \mathrm{d}A = 0. \tag{6.42}$$

Thus

$$\int_{\mathcal{U}} \left(2\rho_0 \frac{\partial E}{\partial \mathbf{G}} + \mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0\right){:}\frac{1}{2}\mathfrak{L}_{\mathbf{W}}\mathbf{G}\mathrm{d}V + \int_{\mathcal{U}} (\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0){:}\boldsymbol{\Omega}\mathrm{d}V + \int_{\mathcal{U}} \langle\langle \rho_0 \mathbf{F}^{\mathsf{T}}(\mathbf{B}-\mathbf{A}) - \mathbf{B}_0 + \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) - \mathrm{Div}\,\mathbf{P}_0, \mathbf{W}\rangle\rangle \mathrm{d}V = 0. \tag{6.43}$$

Now using the balance of linear momentum the identity (6.43) simplifies to

$$\int_{\mathcal{U}} \left(2\rho_0 \frac{\partial E}{\partial \mathbf{G}} + \mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0\right){:}\frac{1}{2}\mathfrak{L}_{\mathbf{W}}\mathbf{G}\mathrm{d}V + \int_{\mathcal{U}} (\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0){:}\boldsymbol{\Omega}\mathrm{d}V + \int_{\mathcal{U}} \langle\langle \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0) - \mathbf{F}^{\mathsf{T}}\mathrm{Div}\,\mathbf{P} - \mathbf{B}_0, \mathbf{W}\rangle\rangle \mathrm{d}V = 0. \tag{6.44}$$

Because $\mathcal{U}$ and $\mathbf{W}$ are arbitrary

$$\mathbf{P}_0 = 2\rho_0 \frac{\partial E}{\partial \mathbf{G}} + \mathbf{F}^{\mathsf{T}}\mathbf{P}, \tag{6.45}$$

$$(\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0)^{\mathsf{T}} = \mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0, \tag{6.46}$$

$$\mathbf{B}_0 = \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0) - \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}. \tag{6.47}$$

Note that (6.46) is trivially satisfied after having (6.45). Thus we have

$$\mathbf{P}_0 = 2\rho_0 \frac{\partial E}{\partial \mathbf{G}} + \mathbf{F}^{\mathsf{T}}\mathbf{P}, \tag{6.48}$$

$$\mathbf{B}_0 = \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0) - \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}. \tag{6.49}$$

Note that $\mathbf{P}_0$ is a measure of anisotropy (deviation from material Doyle-Ericksen formula). This is an interesting result that in a natural way shows the contribution of some nonstandard terms to balance of energy when reference configuration evolves.

Thus we have proven the following theorem.

Theorem 6.2: *Under a referential diffeomorphism* $\Xi_t{:}\mathfrak{B}\to\mathfrak{B}$, *and assuming that material energy density transforms tensorially*, *i.e.*,

$$E'(\mathbf{X}',t,\mathbf{G}) = E(\mathbf{X},t,\Xi_t^*\mathbf{G}), \tag{6.50}$$

material energy balance has the following transformation:

$$\frac{d}{\mathrm{d}t}\int_{\Xi_t(\mathcal{U})}\left(E' + \frac{1}{2}\rho_0'\langle\langle\mathbf{V}',\mathbf{V}'\rangle\rangle\right)\mathrm{d}V' = \int_{\Xi_t(\mathcal{U})}\rho_0'(\langle\langle\mathbf{B}',\mathbf{V}'\rangle\rangle + R')\mathrm{d}V' + \int_{\partial\Xi_t(\mathcal{U})}(\langle\langle\mathbf{T}',\mathbf{V}'\rangle\rangle + H')\mathrm{d}A'$$
$$+ \int_{\Xi_t(\mathcal{U})}\langle\langle\mathbf{B}_0',\mathbf{W}_t\rangle\rangle\mathrm{d}V' + \int_{\partial\Xi_t(\mathcal{U})}\langle\langle\mathbf{T}_0',\mathbf{W}_t\rangle\rangle\mathrm{d}A', \tag{6.51}$$

where

$$\mathbf{T}_0' = \Xi_{t*}\left[\left\langle\left\langle 2\rho_0\frac{\partial E}{\partial\mathbf{G}} + \mathbf{F}^{\mathsf{T}}\mathbf{P},\hat{\mathbf{N}}\right\rangle\right\rangle\right], \tag{6.52}$$

$$\mathbf{B}_0' = \Xi_{t*}\left[\mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P} - \mathbf{P}_0) - \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}\right], \tag{6.53}$$

and the other quantities are already defined.

B. Consequences of assuming invariance of energy balance

This section shows the consequences of assuming material covariance of energy balance. It turns out that energy balance, in general, cannot be materially covariant.

Material energy balance is invariant under material diffeomorphisms if and only if the following relations hold between the nonstandard terms:

$$\mathbf{P}_0 = \mathbf{0} \quad \text{or} \quad 2\rho_0\frac{\partial E}{\partial\mathbf{G}} = -\mathbf{F}^{\mathsf{T}}\mathbf{P}, \tag{6.54}$$

$$\mathbf{B}_0 = \mathbf{0} \quad \text{or} \quad \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) = \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}. \tag{6.55}$$

Equation (6.54) is the material Doyle-Ericksen formula and (6.55) is the configurational inviscidity constraint, which will be defined in the sequel. Let us now start with the "naive" assumption that energy balance is materially covariant and see what its consequences are.

Material covariance of energy balance: Let us postulate that the balance of energy is invariant under a diffeomorphism $\Xi_t:\mathfrak{B}\to\mathfrak{B}$, i.e.,

$$\frac{d}{\mathrm{d}t}\int_{\mathcal{U}'}\rho_0'\left(E' + \frac{1}{2}\langle\langle\mathbf{V}',\mathbf{V}'\rangle\rangle\right)\mathrm{d}V' = \int_{\mathcal{U}'}\rho_0'(\langle\langle\mathbf{B}',\mathbf{V}'\rangle\rangle + R')\mathrm{d}V' + \int_{\partial\mathcal{U}'}(\langle\langle\mathbf{T}',\mathbf{V}'\rangle\rangle + H')\mathrm{d}A'. \tag{6.56}$$

Proposition 6.3: If material energy balance is invariant under arbitrary material diffeomorphisms $\Xi_t:\mathfrak{B}\to\mathfrak{B}$, *then*

$$\frac{\partial\rho_0}{\partial t} = 0, \tag{6.57}$$

$$2\rho_0\frac{\partial E}{\partial\mathbf{G}} = -\mathbf{F}^{\mathsf{T}}\mathbf{P}, \tag{6.58}$$

$$\mathbf{F}^{\mathsf{T}}\mathbf{P} = \mathbf{P}^{\mathsf{T}}\mathbf{F}, \tag{6.59}$$

$$\mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) = \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}. \tag{6.60}$$

Conversely, if the above four conditions hold, then material energy balance is invariant under any material diffeomorphism.

Proof: Material balance of energy for $\mathcal{U}' \subset \mathcal{B}'$ at $t=t_0$ reads

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(E + \frac{1}{2}\langle\langle \mathbf{V}-\mathbf{FW}, \mathbf{V}-\mathbf{FW}\rangle\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0\left(\frac{\partial E}{\partial t} + \frac{\partial E}{\partial \mathbf{G}}:\mathfrak{L}_{\mathbf{W}}\mathbf{G} + \langle\langle \mathbf{V}-\mathbf{FW}, \mathbf{A}'|_{t=t_0}\rangle\rangle\right)\mathrm{d}V$$

$$= \int_{\mathcal{U}} \rho_0(\langle\langle \mathbf{B}'|_{t=t_0}, \mathbf{V}-\mathbf{FW}\rangle\rangle + R)\mathrm{d}V + \int_{\partial\mathcal{U}} (\langle\langle \mathbf{T}, \mathbf{V}-\mathbf{FW}\rangle\rangle + H)\mathrm{d}A. \tag{6.61}$$

Subtracting balance of energy for $\mathcal{U}\subset\mathcal{B}$ from this and noting that $(\mathbf{A}'-\mathbf{B}')_{t=t_0}=\mathbf{A}-\mathbf{B}$ we obtain

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(-\langle\langle \mathbf{V}, \mathbf{FW}\rangle\rangle + \frac{1}{2}\langle\langle \mathbf{FW}, \mathbf{FW}\rangle\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \rho_0\left(\frac{\partial E}{\partial \mathbf{G}}:\mathfrak{L}_{\mathbf{W}}\mathbf{G} - \langle\langle \mathbf{FW}, \mathbf{A}\rangle\rangle\right)\mathrm{d}V$$

$$= -\int_{\mathcal{U}} \langle\langle \rho_0\mathbf{B}, \mathbf{FW}\rangle\rangle \mathrm{d}V - \int_{\partial\mathcal{U}} \langle\langle \mathbf{T}, \mathbf{FW}\rangle\rangle \mathrm{d}A. \tag{6.62}$$

We know that

$$\int_{\partial\mathcal{U}} \langle\langle \mathbf{F}^{\mathsf{T}}\mathbf{T}, \mathbf{W}\rangle\rangle \mathrm{d}A = \int_{\mathcal{U}} \left[\langle\langle \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}), \mathbf{W}\rangle\rangle + \mathbf{F}^{\mathsf{T}}\mathbf{P}:\boldsymbol{\Omega} + \mathbf{F}^{\mathsf{T}}\mathbf{P}:\frac{1}{2}\mathfrak{L}_{\mathbf{W}}\mathbf{G}\right]\mathrm{d}V. \tag{6.63}$$

Thus, (6.62) simplifies to

$$\int_{\mathcal{U}} \frac{\partial \rho_0}{\partial t}\left(-\langle\langle \mathbf{V}, \mathbf{FW}\rangle\rangle + \frac{1}{2}\langle\langle \mathbf{FW}, \mathbf{FW}\rangle\rangle\right)\mathrm{d}V + \int_{\mathcal{U}} \left(2\rho_0\frac{\partial E}{\partial \mathbf{G}} + \mathbf{F}^{\mathsf{T}}\mathbf{P}\right):\frac{1}{2}\mathfrak{L}_{\mathbf{W}}\mathbf{G}\,\mathrm{d}V + \int_{\mathcal{U}} \mathbf{F}^{\mathsf{T}}\mathbf{P}:\boldsymbol{\Omega}\,\mathrm{d}V$$

$$+ \int_{\partial\mathcal{U}} \langle\langle \mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) + \rho_0\mathbf{F}^{\mathsf{T}}(\mathbf{B}-\mathbf{A}), \mathbf{W}\rangle\rangle\,\mathrm{d}V = 0. \tag{6.64}$$

As $\mathcal{U}$ and $\mathbf{W}$ are arbitrary, we have

$$\frac{\partial \rho_0}{\partial t} = 0, \tag{6.65}$$

$$2\rho_0\frac{\partial E}{\partial \mathbf{G}} = -\mathbf{F}^{\mathsf{T}}\mathbf{P}, \tag{6.66}$$

$$\mathbf{F}^{\mathsf{T}}\mathbf{P} = \mathbf{P}^{\mathsf{T}}\mathbf{F}, \tag{6.67}$$

$$\mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) + \rho_0\mathbf{F}^{\mathsf{T}}\mathbf{B} = \rho_0\mathbf{F}^{\mathsf{T}}\mathbf{A}. \tag{6.68}$$

Equation (6.65) is nothing but material conservation of mass. Equation (6.66) is the material Doyle-Ericksen formula. This is what Lu and Papadopoulos[26] call infinitesimal material covariance. Equation (6.67) is balance of configurational angular momentum or isotropy of the material. [Note that if (6.66) holds then (6.67) holds trivially.] Finally, Eq. (6.68) is a condition that must be satisfied for the balance of energy to be invariant under material diffeomorphisms. This constraint is equivalent to

$$\mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) = \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}. \tag{6.69}$$

Assuming the above four conditions, it is easy to show that material energy balance is invariant under arbitrary material diffeomorphisms.

Ideal fluids do satisfy all these conditions. In fact, their transformation properties under material diffeomorphisms gives rise to Kelvin's circulation theorem and it is a key ingredient in the geometric approach to fluid mechanics; see the introduction to the Marsden and Ratiu book[29] for a discussion and references to the literature.

C. Material energy balance and defects

We now make a connection between (6.69) and Eshelby's idea of force on a defect. The idea of a driving force in continuum mechanics goes back to Eshelby[13–15] and this notion is important in developing evolution laws for the movement of defects, including dislocations, vacancies, interfaces, cavities, cracks, etc. Driving forces on these defects cause climb and glide of dislocations, diffusion of point defects, migration of interfaces, changing the shape of cavities and propagation of cracks, to mention a few examples. Eshelby defined the force on a defect as the generalized force corresponding to position of the defect (in the reference configuration), which is thought of as a generalized displacement. Eshelby studied inhomogeneities in elastostatic and elastodynamic systems by considering the explicit dependence of the elastic energy density on position in the reference configuration.

Defect forces: Suppose the elastic energy density has an explicit dependence on $\mathbf{X}$ (the position of material points in the undeformed configuration), i.e.,

$$W = W(\varphi, \mathbf{F}, \mathbf{X}), \tag{6.70}$$

where φ and $\mathbf{F}$ are the deformation mapping and the deformation gradient, respectively. Consider an open neighborhood Ω of an isolated defect. Force on the defect in the sense of Eshelby is defined as

$$\mathbf{F}^{\text{defect}} = \int_{\Omega} \left(\frac{\partial W}{\partial \mathbf{X}} \right)_{\text{explicit}} \mathrm{d}V = \int_{\Omega} \operatorname{Div} \mathbf{E} \, \mathrm{d}V = \int_{\partial\Omega} \mathbf{E}\hat{\mathbf{N}} \, \mathrm{d}A, \tag{6.71}$$

where $\mathbf{E} = W\mathbf{I} - \mathbf{F}^{\mathsf{T}}\mathbf{P}$ is Eshelby's energy-momentum tensor. It turns out that for a crack (thought of as a defect) $\mathbf{F}^{\text{defect}}$ is related to the celebrated J-integral;[37] J is the component of $\mathbf{F}^{\text{defect}}$ in the direction of crack propagation.

The following proposition makes an explicit connection between (6.69) and Eshelby's idea of force on a defect.

Proposition 6.4: Suppose an elastic material in an isothermal and quasistatic deformation satisfies the internal constraint $\operatorname{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) = \mathbf{F}^{\mathsf{T}} \operatorname{Div} \mathbf{P}$. *In the absence of body forces*, *force on a defect in the sense of Eshelby would be*

$$\mathbf{F}^{\text{defect}} = \int_{\Omega} \left(\frac{\partial W}{\partial \mathbf{X}} \right)_{\text{explicit}} \mathrm{d}V = \int_{\Omega} \operatorname{Div} \mathbf{E} \, \mathrm{d}V = \int_{\partial\Omega} W\hat{\mathbf{N}} \, \mathrm{d}A. \tag{6.72}$$

Proof: Note that

$$\mathbf{F}^{\text{defect}} = \int_{\partial\Omega} \mathbf{E}\hat{\mathbf{N}} \, \mathrm{d}A = \int_{\partial\Omega} W\hat{\mathbf{N}} \, \mathrm{d}A - \int_{\Omega} \mathbf{F}^{\mathsf{T}} \operatorname{Div} \mathbf{P} \, \mathrm{d}V = \int_{\partial\Omega} W\hat{\mathbf{N}} \, \mathrm{d}A.$$

This means that the configurational traction on $\partial\Omega$ is normal to $\partial\Omega$ at all points, i.e., the configurational stress is hydrostatic. For this reason we call the internal constraint $\operatorname{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) = \mathbf{F}^{\mathsf{T}} \operatorname{Div} \mathbf{P}$, the configurational inviscidity constraint.

If there is a stationary surface $\mathcal{S}$ across which deformation gradient and other quantities have jump discontinuities, the balance of standard forces reads

$$[\![\mathbf{P}]\!]\hat{\mathbf{N}} = \mathbf{0}. \tag{6.73}$$

Now let us look at the normal jump in Eshelby's energy-momentum tensor,

$$[\![\mathbf{E}]\!]\hat{\mathbf{N}} = [\![\Psi\mathbf{I} - \mathbf{F}^{\mathsf{T}}\mathbf{P}]\!]\hat{\mathbf{N}} = [\![\Psi]\!]\hat{\mathbf{N}} - [\![\mathbf{F}^{\mathsf{T}}]\!]\langle\mathbf{P}\rangle\hat{\mathbf{N}} - \langle\mathbf{F}^{\mathsf{T}}\rangle[\![\mathbf{P}]\!]\hat{\mathbf{N}}, \tag{6.74}$$

where $\langle\cdot\rangle$ denotes average of inner and outer traces. Using Hadamard's compatibility equations,

$$[\![\mathbf{F}]\!]\hat{\mathbf{t}} = \mathbf{0} \quad \text{for all } \hat{\mathbf{t}} \text{ such that } \hat{\mathbf{t}}\cdot\hat{\mathbf{N}} = 0, \tag{6.75}$$

it can be easily shown that

$$\hat{\mathbf{N}}\cdot[\![\mathbf{E}]\!]\hat{\mathbf{N}} = [\![\Psi]\!] - [\![\mathbf{F}]\!]\hat{\mathbf{N}}\cdot\mathbf{P}\hat{\mathbf{N}}, \quad \hat{\mathbf{t}}\cdot[\![\mathbf{E}]\!]\hat{\mathbf{N}} = -\mathbf{F}\hat{\mathbf{t}}\cdot[\![\mathbf{P}]\!]\hat{\mathbf{N}}. \tag{6.76}$$

Now if the balance of standard forces hold one concludes that

$$\hat{\mathbf{t}}\cdot[\![\mathbf{E}]\!]\hat{\mathbf{N}} = 0. \tag{6.77}$$

This means that jump in configurational traction on $\partial\Omega$ is always normal to $\partial\Omega$. However, the previous remark shows that in the absence of body forces the condition $\mathrm{Div}(\mathbf{F}^{\mathsf{T}}\mathbf{P}) = \mathbf{F}^{\mathsf{T}}\,\mathrm{Div}\,\mathbf{P}$ implies that the configurational traction itself is normal to $\partial\Omega$.

Are configurational forces newtonian?: There have been doubts and discussions concerning the nature of configurational forces in the literature already starting from Eshelby himself. Eshelby strongly believed that force on a defect is fictitious and is different from the usual forces in mechanics. He defined force on a defect to be the thermodynamic force conjugate to the generalized coordinates defining the defect, for example, the crack tip position in the case of a crack. Eshelby[16] observed that the configurational force on a disclination in a liquid crystal is a real force. A similar observation was made by Nabarro[34] for dislocations. Kröner[23] and Ericksen[11,12] have similar discussions. Batra[4] argues that force on a defect is equal to the standard force exerted on the boundary of a subbody embracing the defect. Steinmann[42] introduces the spatial signature of a material force. One should note that this viewpoint is not in agreement with Gurtin's theory in which standard and configurational forces have their own balance laws.

Batra[4] proves a theorem that states that force on a defect is equal to the resultant of tractions on the boundary of any region enclosing this single defect. This seems to be a very surprising result. First of all, if body forces are considered resultant of tractions on different regions embodying the defect cannot be independent of the region as in this case stress tensor is not divergence free. Barta suggests that problems involving the J-integral could be reinterpreted using his theorem. As a matter of fact, the J-integral can serve as a counter example for Batra's theorem. The reason is that in the case of a linear elastic material in mode I fracture, for example, the J-integral is quadratic in K_I while the stress is linear in K_I and hence the resultant of tractions acting on the boundary of a small region enclosing the crack would be linear in K_I. This means that the J-integral, which is the component of configurational force in the direction of crack growth, cannot be a real force. The incorrectness of Batra's theorem is because of the way he defines force on a defect. Force on a defect in the sense of Eshelby is the rate of change of potential energy of the elastic body with respect to changes in the position of the defect in the reference configuration. Batra defines force on a defect to be the rate of change of energy with respect to changes of position of the defect in the current configuration. This is the source of his surprising result. One should note that direct and inverse motions describe the same physical process and cannot lead to different conclusions regarding forces. Having the duality picture is useful but one should note that positions of defects in the reference and current configurations are not related by the standard deformation mapping as the evolution of defects is an independent kinematical process.

Standard forces in continuum mechanics are one forms in the deformed configuration, i.e., at each point $x \in \mathcal{S}$, force is an element of $T_x^*\mathcal{S}$. Configurational forces on the other hand are one forms in the reference configuration, i.e., at each point $X \in \mathcal{B}$, configurational force is an element of $T_X^*\mathcal{B}$. Therefore, geometrically it is meaningless to ask if a configurational force is a real force

very much like asking whether the deformation gradient (a two-point tensor) is symmetric. This is why arguments like the one proposed by Steinmann[43] where he defines a spatial signature for a material force do not make sense from the geometric standpoint.

Plasticity and embeddings: A traditional means of introducing configurational forces is based on remapping the reference configuration of the body. However, this approach tacitly assumes that the reference configuration can be embedded in Euclidean space. This approach fails when there is no natural embedding of the reference configuration. A case in point is provided by multiplicative plasticity,[24] where the total deformation gradient at a point x has the representation: $\mathbf{F}(x) = \mathbf{F}^e(x)\mathbf{F}^p(x)$, where $\mathbf{F}^e(x)$ and $\mathbf{F}^p(x)$ are the elastic and plastic deformation gradients, both of which fail to be a gradient in general. The plastic deformation mapping $\mathbf{F}^p(x)$ defines an *intermediate configuration* that defines the reference configuration for the elasticity of the material. In particular, the elastic energy density is assumed to be of the form $W(\mathbf{F}^e, x)$. Since $\mathbf{F}^p(x)$ is not the derivative of a mapping, the intermediate configuration cannot be embedded in Euclidean space. Therefore, remapping cannot be applied to deriving configurational forces directly from $W(\mathbf{F}^e, x)$. By contrast, the present approach can be applied for that purpose, for example, by equipping the intermediate configuration with a constant metric.

The derivation of certain conserved integrals, such as the L-integral that gives the configurational torque on isotropic subbodies, relies on the metric structure of the embedding Euclidean space. In addition, the conventional formulation of material symmetry also presumes the existence of an Euclidian embedding. Such an embedding may not be natural or available in certain models of materials, such as liquid crystals or smectic polymers, where the reference configuration may include a unit director field.

VII. NOETHER'S THEOREM AND BALANCE OF CONFIGURATIONAL FORCES

As is well known, there is a strong connection between conservation laws and symmetries. If the Euler-Lagrange equations are satisfied and the Lagrangian density of a system is invariant under a group of transformations, Noether's theorem gives the corresponding conserved quantity. In this sense, conservation laws are related to symmetries of a given system. Marsden and Hughes[28] consider material invariance in elasticity (in the absence of body forces) and show that invariance of Lagrangian density under rigid translations in the reference configuration results in the following conservation law

$$\frac{\partial}{\partial t}(\partial_{\dot{\phi}}\mathfrak{L}\cdot D\phi\cdot\mathbf{W}) + \mathrm{DIV}(\partial_{\mathbf{F}}\mathfrak{L}\cdot D\phi\cdot\mathbf{W} - \mathfrak{L}\mathbf{W}) = 0. \tag{7.1}$$

This has been obtained assuming that the flow of $\mathbf{W}$ is volume-preserving and that $\mathcal{L}$ does not explicitly depend on X. For a constant $\mathbf{W}$, this equation in our notation reads

$$\mathrm{Div}\left[\left(\Psi - \frac{1}{2}\rho_0|\mathbf{V}|^2\right)\mathbf{I} - \mathbf{F}^{\mathrm{T}}\mathbf{P}\right] = -\frac{\partial}{\partial t}(\rho_0\mathbf{F}^{\mathrm{T}}\mathbf{V}). \tag{7.2}$$

It is seen that this is identical to balance of configurational linear momentum if ρ_0 and Ψ are independent of $\mathbf{X}$ (note that this is stronger that homogeneity of $\mathfrak{L}$). Ignoring the inertial effects, Noether's theorem results in

$$\mathrm{Div}(\Psi\mathbf{I} - \mathbf{F}^{\mathrm{T}}\mathbf{P}) = \mathbf{0}. \tag{7.3}$$

Roughly speaking, Noether's theorem states that when the Euler-Lagrange equations are satisfied, any symmetry of the Lagrangian density corresponds to a conserved quantity. Here we revisit Noether's theorem for nonlinear elasticity assuming that undeformed and deformed configurations are Riemannian manifolds. Writing action in the reference configuration, Lagrangian density has the following explicit independent variables:

$$\mathcal{L} = \mathcal{L}(X^A, \varphi^a, \dot{\varphi}^a, F^a{}_A, G_{AB}, g_{ab}). \tag{7.4}$$

For the sake of clarity, we consider spatial and material symmetries of the Lagrangian density separately.

A. Spatial covariance of Lagrangian density

Theorem 7.1: *If the Lagrangian density is spatially covariant, then the following hold: (i) spatial homogeneity of the Lagrangian density and (ii) the Doyle-Ericksen formula.*

Proof: Suppose ψ_s is a flow on $\mathcal{S}$ generated by a vector field $\mathbf{w}$, i.e.,

$$\left.\frac{d}{\mathrm{d}s}\right|_{s=0} \psi_s \circ \varphi = \mathbf{w} \circ \varphi. \tag{7.5}$$

Invariance of $\mathcal{L}$ means that

$$\mathcal{L}\left(X^A, \psi_s^a(\varphi), \frac{\partial \psi_s^a}{\partial x^b}\dot{\varphi}^b, \frac{\partial \psi_s^a}{\partial x^b}F^b{}_A, G_{AB}, -\frac{\partial \psi_s^c}{\partial x^a}\frac{\partial \psi_s^d}{\partial x^b}g_{cd}\right) = \mathcal{L}(X^A, \varphi^a, \dot{\varphi}^a, F^a{}_A, G_{AB}, g_{ab}). \tag{7.6}$$

[This reminds us of the definition of covariance for internal energy density. So, it would be very natural to expect some connection between Noether's theorem and covariant balance laws.] Now differentiating the above relation with respect to s and then evaluating it at $s=0$ [This is somewhat similar to subtracting two balance relations and evaluating the result at $t=t_0$], one obtains

$$\frac{\partial \mathcal{L}}{\partial \varphi^a}w^a + \frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\frac{\partial w^a}{\partial x^b}\dot{\varphi}^b + \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^A \frac{\partial w^a}{\partial x^b}F^b{}_A - 2\frac{\partial \mathcal{L}}{\partial g_{ab}}\frac{\partial w^c}{\partial x^a}g_{bc} = 0. \tag{7.7}$$

Note that

$$\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\frac{\partial w^a}{\partial x^b}\dot{\varphi}^b = \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}w^a\right) - \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)w^a. \tag{7.8}$$

After some manipulations, it can be shown that

$$\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^A \frac{\partial w^a}{\partial x^b}F^b{}_A = \left[\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^A w^a\right]_{|A} - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A} w^a - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b{}^A \gamma^b_{ac}F^c{}_A w^a. \tag{7.9}$$

Also

$$-2\frac{\partial \mathcal{L}}{\partial g_{ab}}\frac{\partial w^c}{\partial x^a}g_{bc} = -\left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a{}^A w^c\right]_{|A} + \left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a{}^A\right]_{|A}^{\ w^c} + 2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bd}\gamma^d_{ac}w^c. \tag{7.10}$$

Therefore, symmetry of $\mathcal{L}$ implies that

$$\begin{aligned}&\left[\frac{\partial \mathcal{L}}{\partial \varphi^a} - \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)_a - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A} - \left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b{}^A F^c{}_A\gamma^b_{ac} + 2\frac{\partial \mathcal{L}}{\partial g_{cd}}g_{bd}\gamma^b_{ac}\right]w^a + \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}w^a\right)\\ &\quad + \left[\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a{}^A w^a\right]_{|A} - \left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a{}^A w^c\right]_{|A} + \left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a{}^A\right]_{|A} w^c = 0.\end{aligned} \tag{7.11}$$

Note that the term multiplied by w^a is zero if the Euler-Lagrange equations are satisfied. Thus, Noether's theorem states that

$$\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}w^a\right)+\left[\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a^{\ A}w^a\right]_{|A}-\left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a^{\ A}w^c\right]_{|A}+\left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a^{\ A}\right]_{|A}w^c=0. \tag{7.12}$$

Note that

$$\left[\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a^{\ A}w^a\right]_{|A}=\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A}w^a+\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a^{\ A}F^b_{\ A}w^a{}_{|b}. \tag{7.13}$$

Also

$$\left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a^{\ A}w^c\right]_{|A}=\left[2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}(\mathbf{F}^{-1})_a^{\ A}\right]_{|A}w^c+2\frac{\partial \mathcal{L}}{\partial g_{ab}}g_{bc}w^c{}_{|a}. \tag{7.14}$$

Therefore (7.12) is simplified to

$$\left[\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)+\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A}\right]w^a+\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)\frac{\partial w^a}{\partial t}+\left[\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a^{\ A}F^c_{\ A}-2\frac{\partial \mathcal{L}}{\partial g_{bc}}g_{ab}\right]w^a{}_{|c}=0. \tag{7.15}$$

Note that

$$\frac{\partial w^a}{\partial t}=\frac{\partial w^a}{\partial x^c}\dot{\varphi}^c=\dot{\varphi}^c w^a{}_{|c}-\gamma^a_{cd}w^d\dot{\varphi}^c. \tag{7.16}$$

Therefore statement of Noether's theorem, Eq. (7.12) can be rewritten as

$$\left[\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)+\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A}-\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^d}\gamma^d_{ac}\dot{\varphi}^c\right]w^a+\left[\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_a^{\ A}F^c_{\ A}+\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\dot{\varphi}^c-2\frac{\partial \mathcal{L}}{\partial g_{bc}}g_{ab}\right]w^a{}_{|c}=0. \tag{7.17}$$

Note that

$$\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\dot{\varphi}^c=\rho_0 g_{ab}\dot{\varphi}^b\dot{\varphi}^c. \tag{7.18}$$

If Lagrangian density is covariant, i.e., if $\mathbf{w}$ is arbitrary then (7.17) implies that

$$2\frac{\partial \mathcal{L}}{\partial g_{ab}}=g^{bc}\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_c^{\ A}F^a_{\ A}+g^{bc}\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^c}\dot{\varphi}^a, \tag{7.19}$$

$$\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)+\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A}-\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^d}\gamma^d_{ac}\dot{\varphi}^c=0. \tag{7.20}$$

Equation (7.19) can be rewritten as

$$2\frac{\partial W}{\partial g_{ab}}=g^{bc}\left(\frac{\partial W}{\partial \mathbf{F}}\right)_c^{\ A}F^a_{\ A}, \tag{7.21}$$

which is nothing but the Doyle-Ericksen formula. [Note that this includes balance of angular momentum.] Note that

$$\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)+\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A}-\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^d}\gamma_{ac}^d\dot{\varphi}^c=\frac{\partial \mathcal{L}}{\partial \varphi^a}-\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b^{\ A}F^c{}_A\gamma_{ac}^b+2\frac{\partial \mathcal{L}}{\partial g_{cd}}g_{bd}\gamma_{ac}^b-\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^b}\dot{\varphi}^c\gamma_{ac}^b. \tag{7.22}$$

But

$$-\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_b^{\ A}F^c{}_A+2\frac{\partial \mathcal{L}}{\partial g_{cd}}g_{bd}=\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^b}\dot{\varphi}^c. \tag{7.23}$$

Thus

$$\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}\right)+\left(\frac{\partial \mathcal{L}}{\partial \mathbf{F}}\right)_{a\ |A}^{\ A}-\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^d}\gamma_{ac}^d\dot{\varphi}^c=\frac{\partial \mathcal{L}}{\partial \varphi^a}. \tag{7.24}$$

Hence (7.20) implies that

$$\frac{\partial \mathcal{L}}{\partial \varphi^a}=0. \tag{7.25}$$

□

Note that this theorem implies that arbitrary flows and in particular rigid translations cannot be transitive (in the sense of Gotay *et al.*[17,18]) for arbitrary Lagrangian densities.

B. Material covariance of Lagrangian density

Let us first consider the case of Euclidean spaces. Consider a flow Λ_s on $\mathcal{B}$ generated by a vector field $\mathbf{W}$. Invariance of $\mathcal{L}$ with respect to this flow means that

$$\mathcal{L}\left(\Lambda_s^A(X),\varphi^a,\dot{\varphi}^a,\left[\left(\frac{\partial \Lambda_s}{\partial X}\right)^{-1}\right]_A^B F^a{}_B\right)=\mathcal{L}(X^A,\varphi^a,\dot{\varphi}^a,F^a{}_A). \tag{7.26}$$

Differentiating the above relation with respect to s and evaluating the result at $s=0$, one obtains

$$\frac{\partial \mathcal{L}}{\partial X^A}W^A-\frac{\partial \mathcal{L}}{\partial F^a{}_A}\frac{\partial W^B}{\partial X^A}F^a{}_B=0. \tag{7.27}$$

If $\mathbf{W}$ is a constant, then

$$\frac{\partial \mathcal{L}}{\partial X^A}=0, \tag{7.28}$$

i.e., the Lagrangian density must be materially homogeneous. This is also what Nelson[35,36] obtains. After some manipulation and assuming that Euler-Lagrange equations are satisfied (7.27) can be rewritten as

$$\frac{\partial}{\partial X^A}\left(\mathcal{L}W^A-\frac{\partial}{\partial F^a{}_A}F^a{}_BW^B\right)-\frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}F^a{}_AW^A\right)-\mathcal{L}\frac{\partial W^A}{\partial X^A}=0, \tag{7.29}$$

where use was made of the fact that $\mathbf{W}$ is time independent. For a volume-preserving flow this gives us

$$\frac{\partial}{\partial X^A}\left(\mathcal{L}W^A - \frac{\partial}{\partial F^a{}_A}F^a{}_B W^B\right) - \frac{\partial}{\partial t}\left(\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}F^a{}_A W^A\right) = 0, \tag{7.30}$$

which is what Marsden and Hughes[28] obtain. Now let us consider the general case of Riemannian manifolds and assume that Λ_s is a flow on the Riemannian manifold $(\mathfrak{B}, \mathbf{G})$ generated by a vector field $\mathbf{W}$, i.e.,

$$\left.\frac{d}{\mathrm{d}s}\right|_{s=0} \Lambda_s(X) = \mathbf{W}(X), \quad X \in \mathcal{B}. \tag{7.31}$$

Theorem 7.2: *If the Lagrangian density is materially covariant then the following hold*: (i) *material homogeneity of the Lagrangian density and* (ii) *material Doyle-Ericksen formula*.

Proof: Invariance of $\mathcal{L}$ with respect to Λ_s means that

$$\begin{aligned}&\mathcal{L}\left(\Lambda_s^A(X), \varphi^a, \dot{\varphi}^a, \left[\left(\frac{\partial \Lambda_s}{\partial X}\right)^{-1}\right]^B_A F^a{}_B, g_{ab}, \left[\left(\frac{\partial \Lambda_s}{\partial X}\right)^{-1}\right]^C_A \left[\left(\frac{\partial \Lambda_s}{\partial X}\right)^{-1}\right]^D_B G_{CD}\right)\\ &\quad = \mathcal{L}(X^A, \varphi^a, \dot{\varphi}^a, F^a{}_A, g_{ab}, G_{AB}).\end{aligned} \tag{7.32}$$

Differentiating the above relation with respect to s and evaluating the result at $s=0$, one obtains

$$\frac{\partial \mathcal{L}}{\partial X^A}W^A - \frac{\partial \mathcal{L}}{\partial F^a{}_A}\frac{\partial W^B}{\partial X^A}F^a{}_B - 2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}\frac{\partial W^C}{\partial X^K} = 0. \tag{7.33}$$

Note that

$$-\frac{\partial \mathcal{L}}{\partial F^a{}_A}\frac{\partial W^B}{\partial X^A}F^a{}_B = -\left(F^a{}_B\frac{\partial \mathcal{L}}{\partial F^a{}_A}W^B\right)_{|A} + \left(F^a{}_B\frac{\partial \mathcal{L}}{\partial F^a{}_A}\right)_{|A}W^B + F^a{}_C\frac{\partial \mathcal{L}}{\partial F^a{}_A}\Gamma^C_{AB}W^B \tag{7.34}$$

and

$$-2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}\frac{\partial W^C}{\partial X^K} = -\left(2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}W^C\right)_{|K} + \left(2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}\right)_{|K}W^C + 2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{BD}\Gamma^B_{CK}W^C. \tag{7.35}$$

Also

$$\left(F^a{}_B\frac{\partial \mathcal{L}}{\partial F^a{}_A}\right)_{|A}W^B = \left(\frac{\partial F^a{}_B}{\partial X^A} - F^a{}_C\Gamma^C_{BA}\right)\frac{\partial \mathcal{L}}{\partial F^a{}_A}W^B + F^a{}_A\left[\left(\frac{\partial \mathcal{L}}{\partial F^a{}_B}\right)_{|B} + \frac{\partial \mathcal{L}}{\partial F^b{}_B}F^c{}_B\gamma^b_{ac}\right]W^A. \tag{7.36}$$

Assuming that Euler-Lagrange equations are satisfied and using the above identities after a lengthy series of simplifications, one obtains

$$\left(\mathcal{L}W^A - \frac{\partial \mathcal{L}}{\partial F^a{}_B}W^B\right)_{|A} - \frac{\partial}{\partial t}\left(F^a{}_A\frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a}W^A\right) - \mathcal{L}W^A{}_{|A} - \left(2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}W^C\right)_{|K} + \left(2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}\right)_{|K}W^C = 0. \tag{7.37}$$

Note that

$$-\left(2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}W^C\right)_{|K} + \left(2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}\right)_{|K}W^C = -2\frac{\partial \mathcal{L}}{\partial G_{DK}}G_{DC}W^C_{|K}. \tag{7.38}$$

Therefore in this case Noether's theorem states that

$$\left(\mathcal{L}W^A - \frac{\partial \mathcal{L}}{\partial F^a{}_B} W^B\right)_{|A} - \frac{\partial}{\partial t}\left(F^a_A \frac{\partial \mathcal{L}}{\partial \dot{\varphi}^a} W^A\right) - \mathcal{L}W^A{}_{|A} - 2\frac{\partial \mathcal{L}}{\partial G_{DK}} G_{DC} W^C{}_{|K} = 0. \tag{7.39}$$

Note that

$$\left(F^a{}_B \frac{\partial \mathcal{L}}{\partial F^a{}_A} W^B\right)_{|A} = \frac{\partial}{\partial X^A}\left(F^a{}_B \frac{\partial \mathcal{L}}{\partial F^a{}_A}\right) W^B + F^a{}_B \frac{\partial \mathcal{L}}{\partial F^a{}_A} W^B + F^a{}_B \frac{\partial \mathcal{L}}{\partial F^a{}_A}\left(W^B \Gamma^C_{AC} - W^C \Gamma^B_{CA}\right). \tag{7.40}$$

Using the above relation and some lengthy simplifications, one can rewrite (7.39) as

$$\left[\frac{\partial \mathcal{L}}{\partial X^A} + \left(\frac{\partial \mathcal{L}}{\partial F^a{}_C} F^a{}_B + 2\frac{\partial \mathcal{L}}{\partial G_{CD}} G_{BC}\right)\Gamma^B_{AC}\right] W^A - \left(\frac{\partial \mathcal{L}}{\partial F^a{}_A} F^a{}_B + 2\frac{\partial \mathcal{L}}{\partial G_{AC}} G_{BC}\right) W^B = 0. \tag{7.41}$$

If $\mathcal{L}$ is materially covariant, i.e., if $\mathbf{W}$ is arbitrary, then

$$\frac{\partial \mathcal{L}}{\partial X^A} + \left(\frac{\partial \mathcal{L}}{\partial F^a{}_C} F^a{}_B + 2\frac{\partial \mathcal{L}}{\partial G_{CD}} G_{BC}\right)\Gamma^B_{AC} = 0, \tag{7.42}$$

$$\frac{\partial \mathcal{L}}{\partial F^a{}_A} F^a{}_B + 2\frac{\partial \mathcal{L}}{\partial G_{AC}} G_{BC} = 0. \tag{7.43}$$

Or equivalently

$$\frac{\partial \mathcal{L}}{\partial X^A} = 0, \tag{7.44}$$

$$\frac{\partial W}{\partial F^a{}_A} F^a{}_B + 2\frac{\partial W}{\partial G_{AC}} G_{BC} = 0, \tag{7.45}$$

where W is the material potential energy density. Note that (7.45) is nothing but the material Doyle-Ericksen formula (6.66). □

Remarks: There are some differences between covariant energy balance (CEB) and Lagrangian density covariance (LDC):

(i) CEB is global while LDC is local.
(ii) In CEB the arbitrary vector fields $\mathbf{w}$ and $\mathbf{W}$ are time-dependent (being velocities), in general, while in LDC they are time independent.
(iii) In writing balance of energy in CEB for a material diffeomorphism spatial quantities contribute to energy balance. But in LDC a material flow does not affect the spatial quantities.

VIII. CONCLUSIONS AND FUTURE DIRECTIONS

The results of this paper can be summarized as follows.

(i) We studied continuum mechanics of bodies with global referential evolutions by enlarging the configuration manifold to two Riemannian manifolds with their own metrics. A deformation is then a pair of referential evolution, i.e., a motion in the referential manifold, and a standard motion. We showed that in the absence of discontinuities, configurational and standard equations of motion are equivalent even if the metrics are allowed to vary.

(ii) The classical theorem of Green, Naghdi, and Rivilin[19] was revisited and a material version of it was investigated. We showed that under a referential isometry balance of energy cannot be invariant, in general, and obtained its transformation.

(iii) The idea of covariance in elasticity was reviewed. We revisited a theorem by Marsden and Hughes[28] and some of the details of its proof were clarified and a proof was given for its converse. It was also shown that spatial covariance of material energy balance leads to identical results.

(iv) We posed the question that whether energy balance can be materially covariant. It was shown that, in general, energy balance cannot be invariant under referential diffeomorphisms. We obtained the transformation of energy balance under arbitrary material diffeomorphisms. We found conditions under which energy balance is materially covariant. It was shown that in the absence of body forces the nontrivial condition for material covariance of balance of energy is equivalent to configurational stress tensor (Eshelby's stress tensor) being hydrostatic. It was shown that for ideal fluids energy balance is materially covariant.

(v) An explicit relation between covariance and Noether's theorem was found. We showed that spatial covariance of a Lagrangian density implies spatial homogeneity of the Lagrangian density and the Doyle-Ericksen formula. Similarly, material covariance of a Lagrangian density implies its material homogeneity and the material Doyle-Ericksen formula.

In summary, spatial covariance is reasonable and holds for most materials. The transformation properties of energy balance under material reframings was obtained. However, material covariance of energy balance only holds for special materials, such as ideal fluids.

The main application of the ideas presented in this paper will be in gaining a better understanding of the continuum theory of defects. In particular, if one repeats some of the developments presented in this paper in a space-time setting, one should, in principle, be able to obtain dynamic equations for evolution of defects. Another important relevant problem would be the study of covariance and its meaning in discrete systems. This may lead to a better understanding of "stress" in discrete systems.

(Received 31 January 2005; accepted 15 March 2006; published online 28 April 2006)

In this paper we prove that the two-dimensional superintegrable systems with quadratic integrals of motion on a manifold can be classified by using the Poisson algebra of the integrals of motion. There are six general fundamental classes of superintegrable systems. Analytic formulas for the involved integrals are calculated in all the cases. All the known superintegrable systems are classified as special cases of these six general classes. © *2006 American Institute of Physics.*

I. INTRODUCTION

In classical mechanics, an integrable system on a manifold of N dimensions, is a system which has N integrals of motion in evolution. Superintegrable (or maximally integrable) system is a system possessing the maximum number of constants of motion, i.e., $2N-1$ integrals of motion.

The simplest case is the two-dimensional superintegrable problems with integrals of motion, which are linear and quadratic functions of momenta. The investigation of such superintegrable systems on a two-dimensional manifold is a quite old problem, dated in the 19th century. Initially the problem was formulated as a geometry problem. The challenge was to find two-dimensional manifolds whose geodesics are curves which possess additional integrals than the free Hamiltonian. This problem was studied in the four volume treatise of Darboux *Leçons sur la Théorie Générale des Surfaces*.[1] The main result of this study is that, there are five classes of general forms of metrics, whose geodesics have three integrals of motion (the Hamiltonian and two additional functionally independent integrals). These metrics are called "formes essentielles" and they depend on four parameters. All the metrics having more than two integrals of motion can be obtained as partial cases of these "formes essentielles" by choosing appropriate values of the four parameters. The five classes of metrics are tabulated in "Tableau VII" by Koenigs (Ref. 1. Vol. IV, p. 385).

In classical mechanics language, Darboux and Koenigs results can be translated as searching manifolds, where the free Hamiltonian accepts quadratic integrals of motion. The evolution of this problem is to find superintegrable systems, whose Hamiltonian is the free Hamiltonian plus a potential and these systems possess additional quadratic integrals of motion.

The simplest integrable and superintegrable systems are the systems defined on the real plane. A comprehensive review of the real two-dimensional integrable classical systems on the plane is given in Refs. 2 and 3 The complex superintegrable systems with quadratic moments on a flat space were recently catalogued by Kalnins, Miller, Pogosyan *et al.*[4–7] The flat space is a two-dimensional manifold with curvature zero. The Drach potentials are also systems defined on a

[a)]Electronic mail: daskalo@math.auth.gr

manifold with curvature zero. The Drach systems with quadratic integrals of motion were investigated by Rañada.[8] The superintegrable systems on the hyperbolic plane were studied in Refs. 9 and 10. These systems were studied separately, while they are connected by obvious coordinate transformations. Therefore they are naturally connected, i.e., there is a common classification scheme of all these systems.[9,10]

The case of nonflat space is under current intensive investigation. The superintegrable systems on the sphere were studied in Refs. 8, 9, and 11 and they were classified in Ref. 6 The sphere is a special case of manifold with constant curvature. In Refs. 9 and 10 the superintegrable systems on the sphere and on the hyperbolic plane were studied using a unified formulation.

In the case of manifolds of nonconstant curvature, the known examples of superintegrable systems are those which are defined on manifolds which are surfaces of revolution. The corresponding problem of the geodesics with three quadratic integrals of motion on surfaces of revolution was treated by Koenigs in Ref. 1 Vol. IV, p. 377. Recently Kalnins and collaborators classified the superintegrable systems on a surface of revolution[12,13] using the manifolds which were provided by Koenigs.

In two recent papers Kalnins, Kress, and Miller[14,15] give a comprehensive study of the two-dimensional superintegrable sytems. In Ref. 15, they prove that the general Koenigs essential forms of metrics correspond to the most general forms of superintegrable systems. Also they have shown that every two-dimensional superintegrable system is Stäckel equivalent to a two-dimensional nondegenerate superintegrable system on a constant curvature space.

Kress[16] in collaboration with Kalnins and Miller studied the Stäckel equivalence classes of the superintegrable systems on the spaces of constant curvature, and they have shown that there are six equivalence classes. The general classes of Koenigs classification given by the Table VII in Ref. 1 are five. That means that there is a sixth class which should be added in the Koenigs classification scheme. In this paper we investigate this sixth class, which completes the Koenigs classification. This class is the nondegenerate superintegrable system generated by the case VI_6 of Koenigs.

An interesting question is, whether there could be a general classification scheme of superintegrable systems with quadratic integrals of motion, which contains all the equivalence classes of superintegrable systems on a manifold with constant curvature and the general classes of manifolds, which were introduced by Koenigs. The classification schemes are based on the Darboux relations derived for the invariants, which are defined on a specific manifold. In this paper we propose a classification scheme based on the properties of the Poisson algebra of the integrals of motion. Then we show that there is indeed such a classification scheme, which determines the supporting manifold metric. We must notice that the Kress[16] equivalence classes are derived by classifying the Poisson algebra of integrals of motion. The proposed classes of superintegrable systems in this paper correspond to the equivalent classes studied in Ref. 16. Analytic formulas for the metrics of the permitted manifolds, the potentials and the integrals of motion are calculated.

This paper is organized as follows: In Sec. II the general form of the integrable two-dimensional system with one quadratic integral of motion is derived. The results of this section correspond to the Darboux treatise paragraphs (Ref. 1, No. 593, Vol. III, pp. 30 and 31), but we give a brief modern derivation of the formulas including the potentials in our discussion. These formulas will be used in the following sections. The carrying manifold is a Liouville or a Lie surface. Therefore there are two classes of integrable systems. In a specific coordinate system, which is called Liouville (or Lie) system, the analytic expressions of the potential and the integrals of motion are given and the action is calculated. In Sec. III the Poisson algebra of the integrals of a superintegrable two-dimensional system is discussed. This algebra is a quadratic algebra, the coefficients of the quadratic terms are characteristic of the carrying manifold. In Sec. IV we prove that the coefficients of the Poisson algebra impose the classification of the superintegrable systems with two quadratic integrals in six fundamental classes. The method of analytic calculation of form of the permitted carrying manifolds, the potentials and the integrals of motion are discussed. In this section we prove that the general form of the superintegrable potential can be written as a fraction $V=w(x,y)/g(x,y)$ and the two functions $w(x,y)$ and the metric $g(x,y)$ are two solutions of

the same partial differential equation. The existence of the Poisson algebra was assumed as obvious by several authors.[4–7,17–29] In the Appendix we give a proof of the existence of the Poisson algebra, for two-dimensional superintegrable systems with quadratic integrals of motion. In Sec. V the analytic formulas of the manifolds and integrals are given for all the six fundamental classes of superintegrable systems. From these analytic formulas we can show that there are new superintegrable systems, because they are defined on manifolds which have not constant curvature and are not surfaces of revolution. In Sec. VI the superintegrable systems corresponding to the Koenigs essential forms of Table VII are given. In Sec. VII the superintegrable systems on a surface of revolution are studied. We find that there is a new system which was not revealed by the other classification schemes. In Sec. VIII the superintegrable systems on a manifold with curvature zero are studied and in Sec. IX the systems on a manifold with constant curvature are listed. In Sec. X the systems with a linear and a quadratic integral of motion are discussed. Finally, in Sec. XI the results of the paper are summarized.

II. INTEGRABLE SYSTEMS ON A TWO-DIMENSIONAL MANIFOLD

Let us consider an integrable system defined on a two-dimensional manifold with metric,

$$\mathrm{d}s^2 = E(u,v)\mathrm{d}u^2 + 2F(u,v)\mathrm{d}u\,\mathrm{d}v + G(u,v)\mathrm{d}v^2.$$

There is a conformal coordinate system where the metric can be written as

$$\mathrm{d}s^2 = g(x,y)\mathrm{d}x\,\mathrm{d}y. \tag{1}$$

The passage from the original coordinate system (u,v) to the conformal one (x,y) can be realized by using the Beltrami partial differential equation. We must notice that the choice of the conformal coordinate system is not unique, i.e., there are several conformal coordinate systems for a given metric, these systems are conformally equivalent.

In a conformal coordinate system the general form of the Hamiltonian is

$$H = \frac{p_x p_y}{g(x,y)} + V(x,y), \tag{2}$$

where the Hamiltonian is a quadratic form of the momenta.

Let us consider an integral of motion which is quadratic in momenta. The most general form can be written as

$$I = A(x,y)p_x^2 + B(x,y)p_y^2 - 2p_x p_y \frac{\beta(x,y)}{g(x,y)} + Q(x,y). \tag{3}$$

By definition the Poisson bracket between the Hamiltonian and the integral of motion is zero,

$$\{I,H\}_P = \frac{\partial I}{\partial x}\frac{\partial H}{\partial p_x} - \frac{\partial I}{\partial p_x}\frac{\partial H}{\partial x} + \frac{\partial I}{\partial y}\frac{\partial H}{\partial p_y} - \frac{\partial I}{\partial p_y}\frac{\partial H}{\partial y} = 0. \tag{4}$$

The above equality implies restrictions on the functions involved in Eqs. (2) and (3). The left-hand side of the above equation is an odd function of cubic order in the momenta. The coefficients of p_x^3 and p_y^3 must be zero

$$\frac{\partial A}{\partial y} = 0 \Rightarrow A = A(x),$$

$$\frac{\partial B}{\partial x} = 0 \Rightarrow B = B(y). \tag{5}$$

The coefficients of $p_x^2 p_y$ and $p_y^2 p_x$ in (4) must be indeed zero,

$$\frac{\partial \beta}{\partial y} = A(x)\frac{\partial g}{\partial x} + \frac{g}{2}A'(x), \tag{6}$$

$$\frac{\partial \beta}{\partial x} = B(y)\frac{\partial g}{\partial y} + \frac{g}{2}B'(y). \tag{7}$$

The partial x derivative of the right-hand side in (6) is equal to the y derivative of the right-hand side in Eq. (7), therefore

$$(A''(x) - B''(y))g(x,y) + 3A'(x)\frac{\partial g}{\partial x} - 3B'(y)\frac{\partial g}{\partial y} + 2A(x)\frac{\partial^2 g}{\partial x^2} - 2B(y)\frac{\partial^2 g}{\partial y^2} = 0. \tag{8}$$

The coefficients of p_x and p_y in (4) must be zero,

$$\begin{aligned} \frac{\partial Q}{\partial y} &= 2A(x)\frac{\partial V}{\partial x} + 2\beta(x,y)\frac{\partial V}{\partial y}, \\ \frac{\partial Q}{\partial x} &= 2B(y)\frac{\partial V}{\partial y} + 2\beta(x,y)\frac{\partial V}{\partial y}. \end{aligned} \tag{9}$$

The above relations imply

$$g(x,y)\left(2A(x)\frac{\partial^2 V}{\partial x^2} - 2B(y)\frac{\partial^2 V}{\partial y^2} + 3A'(x)\frac{\partial V}{\partial x} - 3B'(y)\frac{\partial V}{\partial y}\right) + 4\left(A(x)\frac{\partial g}{\partial x}\frac{\partial V}{\partial x} - B(y)\frac{\partial g}{\partial y}\frac{\partial V}{\partial y}\right) = 0. \tag{10}$$

At this point we must distinguish two cases. In the first case $A(x)$ and $B(y)$ are both different from zero, whereas in the second case $B(y)$ is assumed to be zero.

Class I: $A(x)B(y) \neq 0$.

Following the method given in Koenigs original paper, we can choose a new coordinate system

$$\xi = \int \frac{\mathrm{d}x}{\sqrt{A(x)}} \quad \text{and} \quad \eta = \int \frac{\mathrm{d}y}{\sqrt{B(y)}},$$

where the associated momenta are

$$p_\xi = \sqrt{A(x)}p_x \quad \text{and} \quad p_\eta = \sqrt{B(y)}p_y.$$

In this case the metric is written

$$\mathrm{d}s^2 = \hat{g}(\xi,\eta)\mathrm{d}\xi\,\mathrm{d}\eta, \quad \text{where } \hat{g}(\xi,\eta) = g(x,y)\sqrt{A(x)B(y)}.$$

In these new coordinate system (ξ, η) all the above equations are considerably simplified. We can easily show that the formulas are the same by replacing $x \to \xi$, $y \to \eta$ and fixing $A(x)=1$ and $B(y)=1$. For simplicity reasons we omit the hat on the metric $\hat{g}(\xi,\eta) \to g(\xi,\eta)$. Equations (2) and (3) are written

$$\begin{aligned} H &= \frac{p_\xi p_\eta}{g(\xi,\eta)} + V(\xi,\eta), \\ I &= p_\xi^2 + p_\eta^2 - 2p_\xi p_\eta \frac{\beta(\xi,\eta)}{g(\xi,\eta)} + Q(\xi,\eta). \end{aligned} \tag{11}$$

We call these specific coordinates (ξ, η) *Liouville coordinates*. In Liouville coordinates the Hamil-

tonian H *and* the integral I are written as it was given in Eq. (11). In the Liouville coordinates, Eq. (8) is considerably simplified,

$$\frac{\partial^2 g}{\partial \xi^2} - \frac{\partial^2 g}{\partial \eta^2} = 0$$

the general solution is

$$g(\xi, \eta) = F(\xi + \eta) + G(\xi - \eta),$$
