Now select some sets in $\mathrm{Max}(\mathcal{P}_{T_c}(A_b), \subset)$, and verify the main condition for them. The most simple case is $M=\{i^b_U(\varphi)\}_{\varphi\in L_b(U)}$. It is almost obvious, that $M\in\mathrm{Max}(\mathcal{P}_{T_c}(A_b), \subset)$. Choose any point in V and denote it by e, $e\in V$. Set $U=\{e\}$. Take any $B\subset M$, and write it as $B=\{i^b_{\{e\}}(\sigma)\}_{\sigma\in S}$, S is some subset of $L_b(\{e\})$. For $C:=M\backslash B$ we have $C=\{i^b_{\{e\}}(\sigma)\}_{\sigma\in S'}$, where $S'=L_b(\{e\})\backslash S$. It is necessary to show, that if $l\in B^{T_c}$ and $l_1\in C^{T_c}$, then $(l,l_1)\in T_c$. We have, $B^{T_c}=C\sqcup(B^{T_c}\backslash C)$ and $C^{T_c}=B\sqcup(C^{T_c}\backslash B)$. If $l\in C$ or $l_1\in B$, then the requirement is satisfied. The nontrivial case is $l\in B^{T_c}\backslash C$ and $l_1\in C^{T_c}\backslash B$. Assume, that such l and l_1 exist, and let $l=i^b_U(\varphi)$, $\varphi\in L_b(U)$, and $l_1=i^b_{U_1}(\varphi_1)$, $\varphi_1\in L_b(U_1)$. Note, that $U, U_1\neq\{e\}$. Invoking the explicit description (9) of the relation T_c, we conclude, that such l and l_1 exist iff

$$\exists\lambda\in\mathbb{Z}/2\ \forall\,\sigma\in S:\ \sum_{v\in\{e\}\Delta U}\sigma(v)=\lambda,$$

$$\exists\lambda'\in\mathbb{Z}/2\ \forall\,\sigma\in S':\ \sum_{v\in\{e\}\Delta U_1}\sigma(v)=\lambda'.$$

There exist two possibilities (1) $U=U_1$; (2) $U\neq U_1$. Consider the possibility $U=U_1$. In this case one must have

$$S=\left\{\sigma\in L_b(\{e\})\middle|\ \sum_{v\in\{e\}\Delta U}\sigma(v)=\lambda\right\},$$

since otherwise S' cannot satisfy the condition above. The parameter λ' corresponding to S' is, of course, $\lambda'=1+\lambda$. For $l=i^b_U(\varphi)$, using the description of T_c, we obtain, $\varphi(e)=\lambda+b(\#U)+c(\#(\{e\}\Delta U))+1$. Similarly, for l_1 we have $\varphi_1(e)=\lambda'+b(\#U_1)+c(\#(\{e\}\Delta U_1))+1=1+\varphi(e)$. Hence, $\varphi_1(\cdot)\neq\varphi(\cdot)$, and $(l,l_1)\in T_c$. Now look at the possibility $U_1\neq U$. This implies that the sets $\{e\}\Delta U$ and $\{e\}\Delta U_1$ are also different. Hence, there exists a point z, belonging to one of these sets, and not belonging to the other. Without loss of generality, let $z\in\{e\}\Delta U_1$ and $z\notin\{e\}\Delta U$. First, assume, that it is possible to choose them so that $z\neq e$. In this case, take any σ such that $\Sigma_{v\in\{e\}\Delta U_1}\sigma(v)=1+\lambda'$. Look at $\Sigma_{v\in\{e\}\Delta U}\sigma(v)$. If it is equal to λ, then modify the value of $\sigma(\cdot)$ in the point z by adding 1. This does not change the sum with U_1, and we obtain $\Sigma_{v\in\{e\}\Delta U}\sigma(v)=1+\lambda$. This σ belongs neither to S, nor to S'. But this is a contradiction, since S and S' partition the set $L_b(\{e\})$ of all possible σ. Therefore, the pair (l,l_1) cannot exist. It remains to consider the case when the only option for z is $z=e$. We have $U\not\ni e$ and $U_1=\{e\}\sqcup U$. Then the parameters λ and λ' associated to S and S' may be written as $\lambda=b(1)+\Sigma_{v\in U}\sigma(v)$, σ—any element of S, and $\lambda'=\Sigma_{v\in U}\sigma'(v)$, σ'—any element of S'. Since S and S' partition $L(\{e\})$, S' must coincide with the set of *all* σ' such that $\Sigma_{v\in U}\sigma'(v)=\lambda'$ (otherwise it is impossible to define λ for S). Therefore, for every $\sigma\in S$ we have $\Sigma_{v\in U}\sigma(v)=1+\lambda'$, and one obtains $\lambda=b(1)+1+\lambda'$. Since $l=i^b_U(\varphi)$ is in relation T_c with every $i^v_{\{e\}}(\sigma)$, invoking the definition of $L(U)$ and the description of T_c, it follows that $\varphi(e)+b(\#_4U)+\lambda=c(\#_4U+1)+1$. Similarly, for $\varphi_1\in L(\{e\}\Delta U)$, we arrive at $\varphi_1(e)+b(\#_4U+1)+[1+\lambda+b(1)]=c(\#_4U)+1$. Hence,

$$\varphi(e)+\varphi_1(e)=1+b(1)+b(\#_4U)+b(\#_4U+1)+c(\#_4U)+c(\#_4U+1).$$

On the other hand, the requirement $(i^b_U(\varphi), i^b_{U_1}(\varphi_1))$ implies, that $\varphi(e)+\varphi_1(e)=1+c(1)$. Therefore, one obtains a condition

$$b(1)+c(1)+b(\#_4U)+c(\#_4U)+b(\#_4U+1)+c(\#_4U+1)=0.$$

Since this must be valid for generic U, we obtain

$$b(0)+c(0)=0,\quad b(2)+c(2)=0,$$
$$b(1)+c(1)+b(3)+c(3)=0. \tag{23}$$

The latter is the equation we already have, and the first two imply the other equation, but are not equivalent to it. Hence, under these conditions, the main property of T_c for the set $M=\{i^b_{\{e\}}(\sigma)\}_{\sigma\in L_b(\{e\})}$ is established.

Let us consider some other subsets $M\in \mathrm{Max}(\mathcal{P}_{T_c}(A_b),\subset)$. There exists a natural map $\eta: A_b\to\mathcal{P}(V)$, $i^b_U(\varphi)\mapsto U$. For every $B\subset A_b$, call the set $\{\eta(l)\}_{l\in B}$ the *shadow* of B. Take any nonempty subset $\Omega\subset V$. Under some additional assumptions on $b(\cdot)$ and $c(\cdot)$, it will be shown that there exist sets $M\in\mathrm{Max}(\mathcal{P}_{T_c}(A_b),\subset)$ of the form

$$M=\bigsqcup_{U\in\mathcal{P}_{\mathrm{odd}}(\Omega)}\{i^b_U(\varphi)\}_{\varphi\in Q_U},$$

where Q_U are some subsets of $L_b(U)$, and

$$\mathcal{P}_{\mathrm{odd}}(\Omega):=\{U\subset\Omega\,|\,\#U \text{ is odd}\}.$$

Similarly, one may introduce the set $\mathcal{P}_{\mathrm{even}}(\Omega)$ consisting of all subsets of Ω of even cardinality. We will impose such conditions of $b(\cdot)$ and $c(\cdot)$, that the following statement will be true: if $B\subset A_b$ has a shadow which contains a subset being an element of $\mathcal{P}_{\mathrm{even}}(\Omega)$, then it does not belong to $\mathcal{P}_{T_c}(A_b)$.

More precisely, take any $\Omega\subset V$, such that $\#\Omega$ is even. Assume that $b(\cdot)$ and $c(\cdot)$ satisfy the conditions (23). Is it possible to have a set $B\in\mathcal{P}_{T_c}(A_b)$ consisting of $\#\Omega+1$ elements, such that $\#\Omega$ of them are of the form $i^b_{\{v\}}(\sigma_v)$, $\sigma_v\in L_b(\{v\})$, $v\in\Omega$, and the other element is of the form $i^b_\Omega(\varphi)$, $\varphi\in L_b(\Omega)$? Denote $\mathcal{E}(\Omega):=\{U\subset\Omega\,|\,\#U=2\}$. Assume that $i^b_{\{v\}}(\sigma_v)$, $\sigma_v\in L_b(\{v\})$, $v\in\Omega$, are pairwise in relation T_c. For $z\neq v$ we have $\sigma_z(v)+\sigma_v(z)=1+c(2)$. Choose and fix any order $\prec$ on V and associate to this collection of elements a function $\tau:\mathcal{E}(\Omega)\to\mathbb{Z}/2$, $\tau(zw):=\sigma_v(z)$, $v\prec z$. Hence, for any $vv_1\in\mathcal{E}(\Omega)$,

$$\sigma_v(v_1)=\begin{cases}\tau(vv_1) & \text{if } v\prec v_1,\\ \tau(vv_1)+1+c(2) & \text{if } v\succ v_1.\end{cases}$$

Now investigate what this means for φ. For every $v\in\Omega$, the definition of T_c yields,

$$\sum_{z\in\{v\}\Delta\Omega}(\sigma_v(z)+\varphi(z))=c(\#_4\Omega-1)+1.$$

The fact $\Sigma_{z\in\Omega}\varphi(z)=b(\#_4\Omega)$ yields

$$\varphi(v)=\sum_{z\in\Omega\setminus\{v\}}\sigma_v(z)+b(\#_4\Omega)+c(\#_4\Omega-1)+1,$$

where $v\in\Omega$. Apply summation over $v\in\Omega$ and invoke once more the mentioned fact to obtain

$$\frac{m(m-1)}{2}(c(2)+1)+m[b(m)+c(m-1)+1]=b(m),$$

where $m:=\#_4\Omega$. If this were true for generic Ω, one would have the following four equalities corresponding to $m=0,1,2,3$, respectively, $b(0)=0$, $c(0)+1=0$, $(c(2)+1)+b(2)=0$, and $(c(2)+1)+c(2)+1=0$. The latter is just an identity. The third one is not valid, since we already have a condition $b(2)+c(2)=0$. Moreover, since $b(0)+c(0)=0$, either the first or the second equality is not valid as well. Set $b(0)=c(0)=1$. Hence, m cannot be 0 or 2, i.e., $\#\Omega$ cannot be even. We have

$$b(0)=1,\quad c(0)=1,$$

$$b(2)+c(2)=0, \tag{24}$$

$$b(1)+c(1)+b(3)+c(3)=0.$$

It is impossible to have a collection consisting of elements of A_b of the form $i_v^b(\sigma_v)$, $v\in\Omega$, and $i_\Omega^b(\varphi)$, if $\#\Omega$ is even. In case $\#\Omega$ is odd, the values of $\varphi(\cdot)$ are determined by the function $\tau:\mathcal{E}(\Omega)\to\mathbb{Z}/2$, associated to $\sigma_v(\cdot)$, $v\in\Omega$. The values on the points of $V\backslash\Omega$ can be chosen arbitrary.

Now suppose one has a collection of elements $l_1,l_2,\ldots,l_n\in A_b$ which are pairwise in relation T_c. Denote $U_i:=\eta(l_i)$, $i=1,2,\ldots,m$, where $\eta:A_b\to\mathcal{P}(V)$ is the natural map mentioned above. Some of these sets may have cardinality 1, and some may contain more points. Denote by Ω the union of all U_i such that $\#U_i=1$. Note, that it is possible that Ω is empty. There exists a bijection $A_b\tilde{\to}A_b$ which respects the relation T_c, which transforms this collection into a collection with the following property: every U_i is a subset of Ω. Indeed, we have constructed the maps $\hat{\theta}_S^{(\bar{a})}$. These maps respect the relation T_c on A_b. If $l\in A_b$ satisfies $\eta(l)=U$, then $l'=\hat{\theta}_S^{(\bar{a})}(l)$ satisfies $\eta(l')=T_S(U)$. Let $l_1,l_2,\ldots,l_n\in A_b$ be as above. Denote $U_i:=\eta(l_i)$, $i=1,2,\ldots,n$, and construct the corresponding Ω. If there exists U_{i_0}, which is not a subset of Ω, then one can take a point $v_0\in U_0\backslash\Omega$. Look at the composition $T_{\bar{U}_{i_0}}\circ T_{\bar{U}_{i_0}\sqcup\{v_0\}}\circ T_{\bar{U}_{i_0}}$. This map transfers U_{i_0} into a one-point set $\{v_0\}$, and at the same time leaves all the one point-sets $\{v\}$, $v\in\Omega$, fixed. Therefore, if one applies a composition $\hat{\theta}^{(a)}_{\bar{U}_{i_0}}\circ\hat{\theta}^{(a)}_{\bar{U}_{i_0}\sqcup\{v_0\}}\circ\hat{\theta}^{(a)}_{\bar{U}_{i_0}}$ to each $l_1,l_2,\ldots,l_n$, one increases the number of points in Ω by 1. Proceeding this way we arrive at the situation where all U_i are subsets of the corresponding Ω. Of course, in this case, all U_i will have odd cardinalities. Note, that the cardinality of Ω need not be odd.

Take any $l_1,l_2,\ldots,l_n$, such that $\eta(l_i)=\{e_i\}$, $i=1,2,\ldots,n$, $e_i\in V$ some points, such that $e_i\neq e_j$ for $i\neq j$. Assume that $(l_i,l_j)\in T_c$, $i\neq j$. Hence $\Omega=\{e_1,e_2,\ldots,e_n\}$. Take any $U\subset\Omega$ and try to construct $l\in A_b$ of the form $l=i_U^b(\varphi)$, $\varphi\in L_b(U)$, such that for all i, $(l,l_i)\in T_c$. The cardinality $\#U$ needs to be odd. Let $U=\{e_i\}_{i\in I}$, where $I\subset\{1,2,\ldots,n\}$, $\#I$ is odd. The elements l_k, $k=1,2,\ldots,n$, are of the form $l_k=i^b_{\{e_k\}}(\sigma_k)$, the σ_k element of $L_b(\{e_k\})$. The requirement that $(l_i,l)\in T_c$ for every $i\in I$, yields

$$\varphi(e_i)=\sum_{i'\in I\backslash\{i\}}\sigma_i(e_{i'})+b(\#_4I)+c(\#_4I-1)+1.$$

Similarly, the requirement that for every $q\in\{1,2,\ldots,n\}\backslash I$, the pair $(l_q,l)\in T_c$, yields,

$$\varphi(e_q)=\sum_{i\in I}\sigma_q(e_i)+b(1)+b(\#_4I)+c(\#_4I+1)+1.$$

Therefore, the values of $\varphi(\cdot)$ on the points of Ω are determined, and on the points of $V\backslash\Omega$ remain arbitrary. Now take any $W\subset\Omega$, $W\neq U$, $\#W$ is odd. Let $W=\{e_j\}_{j\in J}$, $J\subset\{1,2,\ldots,n\}$. There exists $l'\in A_b$ of the form $l'=i_W^b(\psi)$, $\psi\in L_b(W)$, which is in relation T_c with every $l_1,l_2,\ldots,l_n$. The values of the function $\psi(\cdot)$ on the points of Ω are given by formulas similar to the ones above, and on $V\backslash\Omega$ can be assigned in an arbitrary way. Is it possible to have $(l',l)\in T_c$? It turns out, that l and l' are *always* in T_c. Note, that the condition for $(l,l')\in T_c$ involves only the values of $\varphi(\cdot)$ and $\psi(\cdot)$ in the points of Ω (more precisely, only in e_s, $s\in I\Delta J$). For these values one has the corresponding expressions via $\sigma_k(\cdot)$, $k=1,2,\ldots,n$. Substitute them into the mentioned condition and take into account, that $\sigma_k(e_{k'})+\sigma_{k'}(e_k)=c(2)+1$. After simplification, the expression reduces to

$$\frac{\#(I\Delta J)(\#(I\Delta J)-1)}{2}(c(2)+1)+c(\#_4(I\Delta J))+1+\#(I\cap\bar{J})\{c(\#_4 I-1)+c(\#_4 J+1)\}$$

$$+\#(J\cap\bar{I})\{c(\#_4 J-1)+c(\#_4 I+1)\}+\#(I\Delta J)[b(1)+b(\#_4 I)+b(\#_4 J)]=0.$$

In order to compute the value of the left-hand side it suffices to know $\#_4 I$, $\#_4 J$, and $\#_4(I\cap J)$. Recall, that $\#I$ and $\#J$ are odd. Hence, it remains to run through all the $2\times 2\times 4=16$ (in fact, even 8, due to the symmetry with respect to permutation of I and J) possibilities and look at what happens to the equation above. A straightforward (Maple) computation shows that each time one obtains either an identity $0\equiv 0$, or an equality $c(0)=1$. The latter is already present in the list of assumptions (24) concerning $b(\cdot)$ and $c(\cdot)$ above. Therefore, indeed $(l,l')\in T_c$.

Associate to the set $l_1,l_2,\ldots,l_n$ the function $\tau:\mathcal{E}(\Omega)\to\mathbb{Z}/2$ as explained above. One may write all formulas in terms of this function. Construct from it a function $\hat{\tau}:\Omega\times\Omega\to\mathbb{Z}/2$ of two arguments,

$$\hat{\tau}(v,v_1):=\begin{cases}\tau(vv_1) & \text{if } v\prec v_1,\\ b(1) & \text{if } v=v_1,\\ \tau(vv_1)+c(2)+1 & \text{if } v\succ v_1.\end{cases} \tag{25}$$

Note, that for $v\neq v_1$, one has $\hat{\tau}(v,v_1)=\hat{\tau}(v_1,v)+c(2)+1$. Next, construct a function $\tilde{\tau}:\mathcal{P}_{\mathrm{odd}}(\Omega)\times\Omega\to\mathbb{Z}/2$, as follows. Set $\tilde{\tau}(\{v\},v):=\hat{\tau}(v,v)=b(1)$, and for $U\neq\{v\}$ set

$$\tilde{\tau}(U,v):=\sum_{z\in U}\hat{\tau}(v,z)+b(\#_4 U)+b(1)+c(\#_4(U\Delta\{v\}))+1. \tag{26}$$

It is convenient to rewrite the formulas obtained above using this notation. For $l_i=i^b_{\{e_i\}}(\sigma_i)$, $i=1,2,\ldots,n$, we have

$$\forall z\in\Omega:\sigma_i(z)=\tilde{\tau}(\{e_i\},z).$$

For an element l of the form $l=i^b_U(\varphi)$, $\varphi\in L_b(U)$, $U\subset\Omega$, $\#U$ is odd, which is in relation T_c with every l_i, we have

$$\forall z\in\Omega:\varphi(z)=\tilde{\tau}(U,z).$$

The values of $\sigma_i(w)$ and $\varphi(w)$ in $w\in V\backslash\Omega$ remain arbitrary.

Now, take any nonempty $\Omega\subset V$, and take any function $\tau:\mathcal{E}(\Omega)\to\mathbb{Z}/2$. Define $\tilde{\tau}$ corresponding to τ by the formulas (25) and (26). For every $U\in\mathcal{P}_{\mathrm{odd}}(\Omega)$, denote

$$Q_U:=\{\varphi\in L_b(U)\,|\,\forall z\in\Omega:\varphi(z)=\tilde{\tau}(U,z)\}. \tag{27}$$

Note, that every $\varphi\in Q_U$ should satisfy $\Sigma_{z\in U}\tilde{\tau}(U,z)=b(\#_4 U)$. This yields the following condition:

$$\frac{\#U(\#U-1)}{2}(c(2)-1)+\#Uc(\#_4 U-1)-1=0.$$

The value of the left-hand side is determined by $\#_4 U$. Since $\#U$ is odd, it is necessary to consider just two cases, $\#_4 U=1$ and $\#_4 U=3$. In the first case one obtains $c(0)=1$, i.e., the condition we already have above, and the second case reduces to $0\equiv 0$.

Consider now the following set (for some Ω and τ):

$$M:=\bigsqcup_{U\in\mathcal{P}_{\mathrm{odd}}(\Omega)}\{i^b_U(\varphi)\}_{\varphi\in Q_U}. \tag{28}$$

The elements of M are pairwise in relation T_c. The cardinality of Ω is n, and the cardinality of V is N. On the points of $V\backslash\Omega$ a function $\varphi\in Q_U$ may take any value. In total there are 2^{N-n} possibilities for that. The number of all subsets of Ω is 2^n, and among them the number of those with odd cardinality is 2^{n-1}. Hence $\#M=2^{n-1}\times 2^{N-n}=2^{N-1}$. This number coincides with $\#L_b(W)$

for every nonempty $W \subset V$. It is not difficult to show that $M \in \mathrm{Max}(\mathcal{P}_{T_c}(A_b), \subset)$. Indeed, if $\Omega = V$, then it is impossible to have an element of the form $i^b_W(\psi)$ which is in relation T_c with every element of M, since if $\#W$ is odd, then such element is already in M, and the case $\#W$ being even is excluded due to conditions above. Consider a proper nonempty Ω. For the same reasons, W cannot be a subset of Ω. Hence, there exists a point $w \in W \backslash \Omega$. Consider $\theta' := \theta^{(\bar{a})}_{\bar{W}} \circ \theta^{(\bar{a})}_{\bar{W \sqcup \{w\}}} \circ \theta^{(\bar{a})}_{\bar{W}}$. Apply θ' to every element of M and to $i^b_W(\psi)$. The set M will still be of the form as above, but, perhaps, corresponding to a different τ, and the image of $i^b_W(\psi)$ after θ' is projected by the natural map $\eta: A_b \to \mathcal{P}(V)$ into the point $\{w\}$. Therefore, it suffices to consider just the case $W = \{w\}$. Take any $z \in \Omega$ and look at $\{i^b_{\{z\}}(\varphi)\}_{\varphi \in Q_{\{z\}}}$. As φ varies over $Q_{\{z\}}$, its value in w sweeps up the whole $\mathbb{Z}/2$. Therefore, it is impossible to satisfy $(i^b_{\{z\}}(\varphi), i^b_{\{w\}}(\psi)) \in T_c$ simultaneously for all φ. Hence, M is maximal.

Choose and fix any $B \subset M$. One has

$$B = \bigsqcup_{U \in \mathcal{P}_{\mathrm{odd}}(\Omega)} \{i^b_U(\varphi)\}_{\varphi \in S_U}, \tag{29}$$

where $S_U \subset Q_U$ are subsets (some of S_U, or even all, may be empty). Take any $i^b_W(\psi)$, $W \in \mathcal{P}(V)$, $\psi \in L_b(W)$, and look at what the condition $i^b_W(\psi) \in B^{T_c}$ means. It is necessary to consider different possibilities for W. Start with the case where W is a subset of Ω, and the number of elements in it is even. For any $U \in \mathcal{P}_{\mathrm{odd}}(\Omega)$ and any $\varphi \in S_U$, one must have $\Sigma_{z \in U \Delta W}(\psi(z) + \varphi(z)) = c(\#_4(U \Delta W)) + 1$. This is equivalent to

$$\sum_{z \in U} \psi(z) = \sum_{z \in W} \varphi(z) + b(\#_4 W) + b(\#_4 U) + c(\#_4(U \Delta W)) + 1.$$

Since $W \subset \Omega$, the values of $\varphi(z)$ are known, $\varphi(z) = \tilde{\tau}(U, z)$. Therefore, in the case $W \in \mathcal{P}_{\mathrm{even}}(\Omega)$, the requirement $i^b_W(\psi) \in B^{T_c}$ is rewritten as follows:

$$\begin{aligned}(i^b_W(\psi) \in B^{T_c}) = \bigwedge_{U \in \mathcal{P}_{\mathrm{odd}}(\Omega)} \Bigg(& S_U = \varnothing \ \text{ or } \sum_{z \in U} \psi(z) = \sum_{z \in W} \tilde{\tau}(U, z) + b(\#_4 W) \\ & + b(\#_4 U) + c(\#_4(U \Delta W)) + 1 \Bigg).\end{aligned} \tag{30}$$

There is a similar expression in case $W \in \mathcal{P}_{\mathrm{odd}}(\Omega)$, but special care is needed for the variant $U = W$,

$$\begin{aligned}(i^b_W(\psi) \in B^{T_c}) = (\psi \notin S_W) \quad \text{and} \quad \bigwedge_{\substack{U \in \mathcal{P}_{\mathrm{odd}}(\Omega) \\ U \neq W}} \Bigg(& S_U = \varnothing \ \text{ or } \sum_{z \in U} \psi(z) \\ & = \sum_{z \in W} \tilde{\tau}(U, z) + b(\#_4 W) + b(\#_4 U) + c(\#_4(U \Delta W)) + 1 \Bigg).\end{aligned} \tag{31}$$

Finally, there is a more complicated case, when W contains a part outside Ω, i.e., $W \cap \bar{\Omega} \neq \varnothing$. In this case we must deal with the sum $\Sigma_{z \in W} \varphi(z)$, but only part of $\varphi(z)$ are known, i.e., those that correspond to $z \in W \cap \Omega$, can be expressed as $\tilde{\tau}(U, z)$. Instead of the equality above, we obtain

$$\begin{aligned}(i^b_W(\psi) \in B^{T_c}) = \bigwedge_{U \in \mathcal{P}_{\mathrm{odd}}(\Omega)} \Bigg(& S_U = \varnothing \ \text{ or } \sum_{z \in U} \psi(z) = \sum_{z \in W \cap \Omega} \tilde{\tau}(U, z) + \sum_{z \in W \cap \bar{\Omega}} (\text{any } \varphi \in S_U)(z) \\ & + b(\#_4 W) + b(\#_4 U) + c(\#_4(U \Delta W)) + 1 \Bigg).\end{aligned} \tag{32}$$

The sum on the right-hand side containing φ should not depend on the choice of $\varphi \in S_U$, so we have a condition on S_U ensuring the existence of $i^b_W(\psi) \in B^{T_c}$ with such W.

First, consider in more detail the term $\psi \notin S_W$, $W \in \mathcal{P}_{\text{odd}}(\Omega)$ in the formula (31). Since $S_W \subset Q_W$, it splits into a disjunction $(\psi \in Q_W \setminus S_W) \vee (\psi \notin Q_W)$. The case that is described by the second term means that there exists a nontrivial $\chi: \Omega \to \mathbb{Z}/2$, such that $\psi(z) = \tilde{\pi}(W,z) + \chi(z)$, $z \in \Omega$. Since $\psi \in L_b(W)$, χ must satisfy $\Sigma_{z \in W} \chi(z) = 0$. It is convenient to view χ as an indicator function χ_Z of some nonempty subset $Z \in \mathcal{P}(\Omega)^\times := \mathcal{P}(\Omega) \setminus \{\varnothing\}$. Therefore, we have

$$(\psi \notin S_W) = (\psi \in Q_W \setminus S_W) \vee (\psi \notin Q_W),$$

while

$$(\psi \notin Q_W) = \bigvee_{\substack{Z \in \mathcal{P}(\Omega)^\times, \\ \#_2(Z \cap W) = 0}} [\psi(z \in \Omega) = \tilde{\pi}(W,z) + \chi_Z(z)].$$

Note that the cardinality of Z need not be odd.

The expression for $i^b_W(\psi) \in B^{T_c}$, $W \in \mathcal{P}_{\text{odd}}(\Omega)$, reduces to

$$(i^b_W(\psi) \in B^{T_c}) = (\psi \in Q_W \setminus S_W) \quad \text{or} \bigvee_{\substack{Z \in \mathcal{P}(\Omega)^\times, \\ \#_2(Z \cap W) = 0}} \left\{ [\psi(z \in \Omega) = \tilde{\pi}(W,z) + \chi_Z(z)] \quad \text{and} \right.$$
$$\left. \bigwedge_{\substack{U \in \mathcal{P}_{\text{odd}}(\Omega), \\ \#_2(U \cap Z) = 1}} (S_U = \varnothing) \right\}. \tag{33}$$

Note, that for the conjunction on the right-hand side of the formula one first obtains the range of possible values of U in the form $U \in \mathcal{P}_{\text{odd}}(\Omega)$, $\#_2((U \Delta W) \cap Z) = 1$, but since $\#_2(Z \cap W) = 0$, one has $\#_2((U \Delta W) \cap Z) = \#_2(U \cap Z)$.

Now one needs to consider arbitrary $i^b_W(\psi) \in B^{T_c}$ and $i^b_{W_1}(\psi_1) \in (M \setminus B)^{T_c}$, and then verify that $i^b_{W_1}(\psi_1)$ is in relation T_c with $i^b_W(\psi)$. The formulas for $i^b_{W_1}(\psi_1)$ are similar, except that it is necessary to replace all S_U with $Q_U \setminus S_U$. We must establish the following implication:

$$(i^b_W(\psi) \in B^{T_c}) \quad \text{and} \quad (i^b_{W_1}(\psi_1) \in (M \setminus B)^{T_c}) \Rightarrow (i^b_W(\psi), i^b_{W_1}(\psi_1)) \in T_c. \tag{34}$$

There are three possibilities for W and three possibilities for W_1 described above. In total, due to the symmetry of T_c, this yields $3 + 3(3-1)/2 = 6$ combinations. Each needs to be investigated separately verifying whether a strengthening of the conditions on $b(\cdot)$ and $c(\cdot)$ results. The result is the following.

Theorem 2: *Assume that the number N of points in V is divisible by 4. Let* $b, c: \mathbb{Z}/4 \to \mathbb{Z}/2$ *be two functions, such that* $b(0) = c(0) = 1$, $b(2) + c(2) = 0$, *and* $\Sigma_{i=1,3}(b(i) + c(i)) = 0$. *Define the finite set* A_b *and the relation* T_c *on* A_b *by (8) and (9) using (21). Then the relation* T_c *is saturated.*

Proof: The aim is to establish the implication (34). The proof splits naturally into six parts, corresponding to the six combinations mentioned above.

(1) The case $W, W_1 \in \mathcal{P}_{\text{odd}}(\Omega)$. We have a formula (31) for W, and there exists a similar formula for W_1 obtained after replacing S_U by $Q_U \setminus S_U$. If $W = W_1$, then one needs to show that $\psi(\cdot) \neq \psi_1(\cdot)$. In this case, for some $Z \in \mathcal{P}(\Omega)^\times$, $\psi(z \in \Omega) = \tilde{\pi}(W,z) + \chi_Z(z)$, and for all $U \in \mathcal{P}_{\text{odd}}(\Omega)$ such that $\#((U \Delta W) \cap Z)$ is odd, $S_U = \varnothing$. Similarly, for some $Z_1 \in \mathcal{P}(\Omega)^\times$, $\psi_1(z \in \Omega) = \tilde{\pi}(W,z) + \chi_{Z_1}(z)$, and for all $U_1 \in \mathcal{P}_{\text{odd}}(\Omega)$ such that $\#((U_1 \Delta W) \cap Z_1)$ is odd, $Q_{U_1} \setminus S_{U_1} = \varnothing$. If $Z \neq Z_1$, then $\psi(\cdot) \neq \psi_1(\cdot)$, since $\chi_Z(\cdot) \neq \chi_{Z_1}(\cdot)$. Hence, the implication holds. If $Z = Z_1$, then for every of the mentioned U, we have $S_U = \varnothing$ and $Q_U \setminus S_U = \varnothing$. Since Q_U is not empty, this possibility cannot occur. So the implication is established for $W = W_1$. Now assume, that $W \neq W_1$. One needs to verify that $\Sigma_{z \in W \Delta W_1}(\psi(z) + \psi_1(z)) = c(\#_4(W \Delta W_1)) + 1$. Observe that from the definition of M, and the property that relates Q_U and $\tilde{\pi}(U,z)$, for any $U, U_1 \in \mathcal{P}_{\text{odd}}(\Omega)$, we have

$$\sum_{z\in U\Delta U_1}(\tilde{\pi}(U,z)+\tilde{\pi}(U_1,z))=c(\#_4(U\Delta U_1))+1.$$

Hence, if $\psi\in Q_W\backslash S_W\subset Q_W$ and $\psi_1\in S_{W_1}\subset Q_{W_1}$, the requirement is satisfied. Now let $\psi\notin Q_W$, but $\psi_1\in S_{W_1}$. For $\psi(\cdot)$ we have a nonempty $Z\subset\Omega$, such that $\psi(z\in\Omega)=\tilde{\pi}(W,z)+\chi_Z(z)$. Moreover, whenever $U\in\mathcal{P}_{\text{odd}}(\Omega)$ and $\#((U\Delta W)\cap Z)$ is odd, one has $S_U=\emptyset$. For $\psi_1(\cdot)$ we have $\psi_1(z\in\Omega)=\tilde{\pi}(W,z)$. Therefore, the required equality holds iff $\Sigma_{z\in W\Delta W_1}\chi_Z(z)=0$, i.e., $\#((W\Delta W_1)\cap Z)$ is even. But $\#((W\Delta W_1)\cap Z)$ cannot be odd, since then (specializing U to W_1) one obtains $S_{W_1}=\emptyset$, i.e., $\psi_1(\cdot)$ does not exist. Hence, in this case the implication is established. The dual case, i.e., $\psi\in Q_W\backslash S_W$ and $\psi_1\notin Q_{W_1}$, is completely similar. It remains to investigate the possibility $\psi\notin Q_W$ and $\psi_1\notin Q_{W_1}$. For some nonempty $Z\subset\Omega$, $\#(Z\cap W)$ even, one has $\psi(z\in\Omega)=\tilde{\pi}(W,z)+\chi_Z(z)$. Similarly, for some nonempty $Z_1\subset\Omega$, $\#(Z_1\cap W_1)$ even, one has $\psi_1(z\in\Omega)=\tilde{\pi}(W_1,z)+\chi_{Z_1}(z)$. One needs an equality $\Sigma_{z\in W\Delta W_1}(\chi_Z(z)+\chi_{Z_1}(z))=0$, i.e., $\#((W\Delta W_1)\cap Z)$ and $\#((W\Delta W_1)\cap Z_1)$ are either both odd, or both even. To establish it, use the conjunctions over U and U_1 present in the corresponding formulas. Note, that $Z\cap Z_1$ needs to be empty. Indeed, otherwise one may take any $v\in Z\cap Z_1$ and set $U=U_1=\{v\}$. Since for these U and U_1, $\#_2(U\cap Z)=\#_2(U_1\cap Z_1)=1$, we have $S_{\{v\}}=\emptyset$ and $S_{\{v\}}=Q_{\{v\}}$, this contradicts $Q_{\{v\}}\neq\emptyset$. Hence, $Z\cap Z_1=\emptyset$. Moreover, Z and Z_1 should partition Ω, since otherwise one can set $U=U_1=\{v,v_1,w\}$, where $v\in Z$, $v_1\in Z_1$, and $w\in\Omega\backslash(Z\sqcup Z_1)$. For these, U and U_1 again have intersections with Z and Z_1, respectively, of odd cardinalities, and one obtains a contradiction between $S_{\{v,v_1,w\}}=\emptyset$ and $S_{\{v,v_1,w\}}=Q_{\{v,v_1,w\}}$ results. Now, we obtain $\Sigma_{z\in W\Delta W_1}(\chi_Z(z)+\chi_{Z_1}(z))=\Sigma_{z\in W\Delta W_1}\chi_\Omega(z)=\#_2(W\Delta W_1)=\#_2W+\#_2W_1$. Since $\#_2W=\#_2W_1=1$, this sum vanishes. This completes the proof of the implication (34) for $W,W_1\in\mathcal{P}_{\text{odd}}(\Omega)$.

(2) Now consider the case where both $W,W_1\in\mathcal{P}_{\text{even}}(\Omega)$. First look at the expression (30) corresponding to $i^b_W(\psi)\in B^{T_c}$. We have a conjunction over $U\in\mathcal{P}_{\text{odd}}(\Omega)$ on the right-hand side. In particular, U can be equal to $\{v\}$, where $v\in W$. Is it possible to have $\forall v\in W: S_{\{v\}}\neq\emptyset$? We claim that the answer is no. Indeed, if $S_{\{v\}}$ is not empty, then we have $\Sigma_{z\in\{v\}\Delta W}(\psi(z)+\tilde{\pi}(\{v\},z))=c(\#_4W-1)+1$. Apply summation over $v\in W$ and infer that $\tilde{\pi}(\{v\},z)=\hat{\pi}(v,z)$ and $\hat{\pi}(v,z)+\hat{\pi}(z,w)=c(2)+1$. This yields $(\#W-1)b(\#_4W)+(\#_4W(\#_4W-1)/2)(c(2)+1)=0$. If $\#_4W=0$, then one obtains $b(0)=0$, which is impossible, since we already have a condition $b(0)=1$. If $\#_4W=2$, then $b(2)+c(2)+1=0$, again contradicting the earlier assumption $b(2)+c(2)=0$. Therefore, there always exists $v\in W$, such that $S_{\{v\}}=\emptyset$. Similarly, we may analyze the expression for $i^b_{W_1}(\psi_1)\in(M\backslash B)^{T_c}$, and conclude that there exists $v_1\in W_1$, such that $S_{\{v_1\}}=W_{\{v_1\}}$. Start with the case $W_1=W$. Is it possible to have $\psi(\cdot)=\psi_1(\cdot)$? Suppose that ψ and ψ_1 coincide. For every $v\in W$, if $S_{\{v\}}\neq\emptyset$, then we have $\psi(v)=\Sigma_{z\in W}\hat{\pi}(v,z)+b(\#_4W)+b(1)+c(\#_4W-1)+1$. If $S_{\{v\}}=\emptyset$, then $S_{\{v\}}\neq Q_{\{v\}}$, and this implies $\psi_1(v)=\Sigma_{z\in W}\hat{\pi}(v,z)+b(\#_4W)+b(1)+c(\#_4W-1)+1$. But $\psi_1(v)=\psi(v)$, so we have the same expression for $\psi(v)$ in all $v\in W$. For the same reasons as mentioned above, the condition $\Sigma_{v\in W}\psi(b)=b(\#_4W)$ yields a contradiction. Therefore, $\psi(\cdot)$ and $\psi_1(\cdot)$ cannot be equal, and the implication of the form (34) for $W=W_1$ is established. Now assume, that $W_1\neq W$. It is necessary to show, that $\Sigma_{z\in W\Delta W_1}(\psi(z)+\psi_1(z))=c(\#_4(W\Delta W_1))+1$, whenever $i^b_W(\psi)\in B^{T_c}$ and $i^b_{W_1}(\psi_1)\in(M\backslash B)^{T_c}$ exist. Look at the expression (30) for $i^b_W(\psi)\in B^{T_c}$. Specialize U to a one-point set $U=\{u\}$, $u\in\Omega$. If $S_{\{u\}}\neq\emptyset$, then the value of $\psi(u)$ is known. How do we find the values of $\psi(\cdot)$ in other points of Ω? Actually, we do not need to know the value of $\psi(z)$ for each $z\in\Omega$, but just the sum $\Sigma_{z\in W\Delta W_1}\psi(z)$.

Let us establish an auxiliary fact first. We have $W\in\mathcal{P}_{\text{even}}(\Omega)$. Take any $U\in\mathcal{P}_{\text{odd}}(\Omega)$. Then $U\Delta W$ is a subset of Ω, and, moreover, $U\Delta W\in\mathcal{P}_{\text{odd}}(\Omega)$, since $\#_2U\Delta W=\#_2U+\#_2W$. Suppose, that $S_U\neq\emptyset$. Is it possible to have $S_{U\Delta W}\neq\emptyset$ as well? Suppose, that it is. For $U',U''\in\mathcal{P}(V)$, denote

$$g_{b,c}(U',U'')\coloneqq b(\#_4U')+b(\#_4U'')+c(\#_4(U'\Delta U''))+1.$$

One has

$$\sum_{z\in U}\psi(z)=\sum_{z\in W}\tilde{\pi}(W,z)+g_{b,c}(U,W),$$

$$b(\#_4 W) + \sum_{z \in U} \psi(z) = \sum_{z \in W} \tilde{\tau}(U \Delta W, z) + g_{b,c}(U \Delta W, W).$$

Sum the two equations and regroup the terms

$$\sum_{z \in W} [\tilde{\tau}(U,v) + \tilde{\tau}(U \Delta W, v)] = b(\#_4 W) + g_{b,c}(U,W) + g_{b,c}(U \Delta W, W).$$

Since $\tilde{\tau}(U,v) = \Sigma_{z \in U} \hat{\tau}(v,z) + g_{b,c}(U, \{v\})$, and, similarly, $\tilde{\tau}(U \Delta W, v) = \Sigma_{z \in U \Delta W} \hat{\tau}(v,z) + g_{b,c}(U \Delta W, \{v\})$, we obtain

$$\tilde{\tau}(U,v) + \tilde{\tau}(U \Delta W, v) = \sum_{z \in W} \hat{\tau}(v,z) + b(\#_4 U) + b(\#_4(U \Delta W)) + c(\#_4(U \Delta \{v\})) + c(\#_4(U \Delta W \Delta \{v\})).$$

It remains to sum over $v \in W$, and reduce the sum with $\hat{\tau}(v,z)$ on the right-hand side, taking into account that $\hat{\tau}(v,v) \equiv b(1)$, and $\hat{\tau}(v,z) + \hat{\tau}(z,v) = c(2) + 1$, $z \neq v$. Since $\#W$ is even, expressing $\#(U \Delta W)$ in terms of $\#U$, $\#W$, and $\#(U \cap W)$, yields

$$\frac{m(m-1)}{2}(c(2)+1) + t\{c(n-1) + c(n+m-2t+1) + c(n+1) + c(n+m-2t-1)\} + c(n) + c(n+m-2t) = b(n) + b(m) + b(n+m-2t),$$

where $m := \#_4 W$, $n := \#_4 U$, and $t := \#_4(U \cap W)$. This equation should be valid for generic W and U. The value of m can be 0 or 2, the value of n can be 1 or 3, and the value of t can be 0, 2, or 3. In total this yields $2 \times 2 \times 4 = 16$ variants. A straightforward (Maple) computation shows, that each of the variants reduces to one of the following four equations: either $b(0) = 0$, or $1 + b(2) + c(2) = 0$, or $b(0) + \Sigma_{i=1,3}(b(i) + c(i)) = 0$, or $1 + \Sigma_{i=1,2,3}(b(i) + c(i)) = 0$. Each of the four equations contradicts the already imposed assumptions on $b(\cdot)$ and $c(\cdot)$. Therefore, the following fact is established (recall, that $\#W$ is even):

$$\forall U \in \mathcal{P}_{\text{odd}}(\Omega) : (S_U \text{ or } S_{U \Delta W}) = \varnothing .$$

In a similar way (recall, that $\#W_1$ is also even), one obtains

$$\forall U \in \mathcal{P}_{\text{odd}}(\Omega) : S_U = Q_U \text{ or } S_{U \Delta W_1} = Q_{U \Delta W_1}.$$

Since $W \neq W_1$, there exists $e \in W \Delta W_1$. Take such e. Observe, that $\#(\{e\} \Delta W)$ and $\#(\{e\} \Delta W_1)$ are odd. Specializing U to $\{e\} \Delta W$, one obtains two facts: (1) $S_{\{e\} \Delta W} = \varnothing$ or $S_{\{e\}} = \varnothing$; (2) $S_{\{e\} \Delta W} = Q_{\{e\} \Delta W}$ or $S_{\{e\} \Delta W \Delta W_1} = Q_{\{e\} \Delta W \Delta W_1}$. Similarly, specializing U to $\{e\} \Delta W_1$, one obtains two more facts: (3) $S_{\{e\} \Delta W_1} = \varnothing$ or $S_{\{e\} \Delta W \Delta W_1} = \varnothing$; (4) $S_{\{e\} \Delta W_1} = Q_{\{e\} \Delta W_1}$ or $S_{\{e\}} = Q_{\{e\}}$. Look at the set $S_{\{e\}}$. It is either empty, or nonempty. If $S_{\{e\}} = \varnothing$, then, due to the fourth fact, $S_{\{e\} \Delta W_1} = Q_{\{e\} \Delta W_1}$. This, together with the third fact, implies $S_{\{e\} \Delta W \Delta W_1} = \varnothing$. From the second fact, $S_{\{e\} \Delta W} = Q_{\{e\} \Delta W}$. Now consider the second possibility, $S_{\{e\}} \neq \varnothing$. The first fact then implies $S_{\{e\} \Delta W} = \varnothing$. Hence, due to the second fact, $S_{\{e\} \Delta W \Delta W_1} = Q_{\{e\} \Delta W \Delta W_1}$. From the third fact, $S_{\{e\} \Delta W_1} = \varnothing$. Then the fourth fact yields $S_{\{e\}} = Q_{\{e\}}$. Therefore, we have an alternative, either

$$S_{\{e\}} = \varnothing , \quad S_{\{e\} \Delta W \Delta W_1} = \varnothing ,$$

$$S_{\{e\} \Delta W} = Q_{\{e\} \Delta W}, \quad S_{\{e\} \Delta W_1} = Q_{\{e\} \Delta W_1},$$

or

$$S_{\{e\}} = Q_{\{e\}}, \quad S_{\{e\} \Delta W \Delta W_1} = Q_{\{e\} \Delta W \Delta W_1},$$

$$S_{\{e\}\Delta W} = \varnothing, \quad S_{\{e\}\Delta W_1} = \varnothing.$$

In both cases there is a way to compute the sums $\Sigma_{z\in W\Delta W_1}\psi(z)$ and $\Sigma_{z\in W\Delta W_1}\psi_1(z)$. In the first case, the values of $\Sigma_{z\in\{e\}\Delta W\Delta W_1}\psi_1(z)$ and $\psi_1(e)$ are known. Their sum yields $\Sigma_{z\in W\Delta W_1}\psi_1(z)$. The sum $\Sigma_{z\in W\Delta W_1}\psi(z)$ should be computed as the sum of $\Sigma_{z\in\{e\}\Delta W}\psi(z)$ and $\Sigma_{z\in\{e\}\Delta W_1}\psi(z)$. The second case is dual to the first one (the roles of ψ and ψ_1 must be interchanged). So we always know $\Sigma_{z\in W\Delta W_1}(\psi(z)+\psi_1(z))$. It remains to compute this value, and then, using the assumptions about $b(\cdot)$ and $c(\cdot)$, verify that it reduces to $c(\#_4(W\Delta W_1))+1$. This is done by a straightforward computation. Consider, for example, the first option. One has

$$\sum_{z\in\{e\}\Delta W}\psi(z) = \sum_{v\in W}\tilde{\pi}(\{e\}\Delta W, v) + g_{b,c}(\{e\}, W),$$

$$\sum_{z\in\{e\}\Delta W_1}\psi(z) = \sum_{v\in W}\tilde{\pi}(\{e\}\Delta W_1, v) + g_{b,c}(\{e\}\Delta W_1, W).$$

This yields

$$\sum_{z\in W\Delta W_1}\psi(z) = \sum_{v\in W}[\tilde{\pi}(\{e\}\Delta W, v) + \tilde{\pi}(\{e\}\Delta W_1, v)] + c(1) + c(\#_4(W\Delta W_1) - 1) + b(\#_4(\{e\}\Delta W)) + b(\#_4(\{e\}\Delta W_1)).$$

Expanding the definitions of $\tilde{\pi}(\cdot,\cdot)$ in the square brackets, and then taking into account that $\#W$ is even, we obtain

$$\sum_{z\in W\Delta W_1}\psi(z) = \sum_{v\in W}\sum_{z\in W\Delta W_1}\hat{\pi}(v,z) + b(\#_4(\{e\}\Delta W)) + b(\#_4(\{e\}\Delta W_1)) + c(1) + c(\#_4(W\Delta W_1) - 1) + \sum_{v\in W}[c(\#_4(\{e\}\Delta W\Delta\{v\})) + c(\#_4(\{e\}\Delta W_1\Delta\{v\}))].$$

A similar computation yields

$$\sum_{z\in W\Delta W_1}\psi_1(z) = \sum_{v\in W_1}\sum_{z\in W\Delta W_1}\hat{\pi}(v,z) + c(\#_4(\{e\}\Delta W)) + c(\#_4(\{e\}\Delta W_1)) + b(1) + b(\#_4(W\Delta W_1) - 1) + \sum_{v\in W_1}[c(\#_4(\{e\}\Delta\{v\})) + c(\#_4(\{e\}\Delta W\Delta W_1\Delta\{v\}))].$$

Now, sum these equalities. On the right-hand side a sum of the form $\Sigma_{z,v\in W\Delta W_1}\hat{\pi}(v,z)$ appears; it is easily computed using $\hat{\pi}(v,v)\equiv b(1)$, and for $z\neq v$, $\hat{\pi}(v,z)+\hat{\pi}(z,v)=c(2)+1$. Hence an expression for $\Sigma_{z\in W\Delta W_1}(\psi(z)+\psi_1(z))$ in terms of $b(\cdot)$ and $c(\cdot)$ is obtained. On the other hand, we must verify that it is equal to $c(\#_4(W\Delta W_1))+1$. Denote $m := \#_4 W$, $m_1 := \#_4 W_1$, and $t := \#_4(W\cap W_1)$. Equate the two expressions mentioned and simplify the result taking into account, that $\#W$ and $\#W_1$ are even. It is necessary to consider the cases, $e\in W\setminus W_1$ and $e\in W_1\setminus W$, but in the end the result is the same,

$$\frac{m+m_1-2t}{2}[c(2)+1] + c(m) + c(m_1) + c(m+2) + c(m_1+2) + t\{c(m_1) + c(m_1+2) + c(m+m_1-2t) + c(m+m_1-2t+2)\} + b(m-1) + b(m_1+1) + b(1) + b(m+m_1-2t-1) + c(m-1) + c(m_1+1) + c(1) + c(m+m_1-2t-1) = c(m+m_1-2t) + 1.$$

It is straightforward to verify (best of all in Maple), that for all $m,m_1=0,2$ and all $t=0,1,2,3$, this equation reduces to one of the following: $1+c(0)=0$, of $\Sigma_{i=1,3}(b(i)+c(i))=0$, or $1+c(0)+\Sigma_{i=1,3}(b(i)+c(i))=0$, or $0=0$. Due to the assumptions above, this always holds. Hence, it is

established that if $W, W_1 \in \mathcal{P}_{\text{even}}(\Omega)$, then any $i^b_W(\psi) \in B^{T_c}$ is in relation T_c with any $i^b_{W_1}(\psi_1) \in (M\backslash B)^{T_c}$.

(3) Now consider the third possibility: let W and W_1 both contain points outside Ω, i.e., $W \cap \bar{\Omega} \neq \varnothing$ and $W_1 \cap \bar{\Omega} \neq \varnothing$. Take any $i^b_W(\psi) \in B^{T_c}$ and $i^b_{W_1}(\psi_1) \in (M\backslash B)^{T_c}$. Then we need to show, that $\psi_1(\cdot) \neq \psi(\cdot)$. There is an expression (32) for ψ and the expression for ψ_1 is similar. For every $U \in \mathcal{P}_{\text{odd}}(\Omega)$, such that $S_U \neq \varnothing$, the following quantity needs to be well defined: $\lambda_U := \Sigma_{z \in W \cap \bar{\Omega}} \varphi(z)$, where φ is an element of S_U. Similarly, if $S_U \neq Q_U$, then the following quantity is well defined: $\mu_U := \Sigma_{z \in W_1 \cap \bar{\Omega}} \varphi_1(z)$, where φ_1 is an element of $Q_U \backslash S_U$. Let us start with the case $W_1 = W$. Note, that the set of values of $\Sigma_{z \in U \cap \bar{\Omega}} \phi(z)$ as ϕ varies over the entire Q_U is $\mathbb{Z}/2$. Therefore, if $S_U \neq \varnothing$ and $S_U \neq Q_U$, then one has $\mu_U = 1 + \lambda_U$. Is it possible to have $S_U = \varnothing$ or $S_U = Q_U$ at all? If $S_U = \varnothing$, then, in particular, $S_U \neq Q_U$, and, μ_U needs to be well defined. At the same time, the corresponding sum $\Sigma_{z \in W_1 \cap \bar{\Omega}} \varphi_1$ ranges over $\mathbb{Z}/2$ as φ_1 varies over $Q_U \backslash S_U = Q_U$. Hence, μ_U is not defined, and therefore, S_U cannot be empty. For similar reasons, S_U cannot be equal to Q_U. So, we have $\forall U \in \mathcal{P}_{\text{odd}}(\Omega) : S_U \neq \varnothing, Q_U$. If $W_1 = W$, we must show, that $\psi(\cdot) \neq \psi_1(\cdot)$. This follows from the fact, that $\Sigma_{z \in U} \psi(z) + \Sigma_{z \in W} \tilde{\pi}(U, z) + g_{b,c}(U, W)$ should be equal to λ_U and $\mu_U = 1 + \lambda_U$ at the same time, a contradiction! Now let $W_1 \neq W$. One needs to compute the sum $\Sigma_{z \in W \Delta W_1}(\psi(z) + \psi_1(z))$. We can say nothing about the values of $\psi(z)$ and $\psi_1(z)$ in the points $z \notin \Omega$. Let us show, that these values are not needed, i.e., we show, that $W \Delta W_1 \subset \Omega$. The latter is equivalent to the statement, that the sets $K := W \cap \bar{\Omega}$ and $K_1 := W_1 \cap \bar{\Omega}$ coincide. Indeed, for every $U \in \mathcal{P}_{\text{odd}}(\Omega)$ the quantities $\lambda_U = \Sigma_{z \in K} \varphi(z)$ and $\mu_U = \Sigma_{z \in K_1} \varphi_1(z)$ are defined ($\varphi \in S_U$, $\varphi_1 \in Q_U \backslash S_U$). The definition (27) of Q_U implies, that the values of $\phi \in Q_U$ in the points outside Ω are not restricted by any condition. Hence, if $K \neq K_1$, there exists $\phi \in Q_U$, such that $\Sigma_{z \in K} \phi(z) = 1 + \lambda_U$ and $\Sigma_{z \in K_1} \phi(z) = 1 + \mu_U$. But such $\phi \notin S_U$, $Q_U \backslash S_U$, a contradiction! Hence, $K = K_1$, and $W \Delta W_1 \subset \Omega$. Since $K = K_1$, it follows that $\mu_U = 1 + \lambda_U$, $U \in \mathcal{P}_{\text{odd}}(\Omega)$. Take any $u \in \Omega$, and specialize U to $\{u\}$. This yields

$$\psi(u) = \sum_{v \in W \cap \Omega} \tilde{\pi}(\hat{u}, v) + \lambda_{\hat{u}} + g_{b,c}(\{u\}, W),$$

$$\psi_1(u) = \sum_{v \in W_1 \cap \Omega} \tilde{\pi}(\hat{u}, v) + (1 + \lambda_{\hat{u}}) + g_{b,c}(\{u\}, W_1).$$

Sum these two equalities, and then preform summation over $u \in W \Delta W_1$. The result should be $c(\#_4(W \Delta W_1)) + 1$. Note, that on the other hand, the terms with $\tilde{\pi}(\hat{u}, v)$ on the right-hand side are of the form $\Sigma_{u,v \in W \Delta W_1} \tilde{\pi}(\hat{u}, v)$, and this sum can be expressed in terms of $b(\cdot)$ and $c(\cdot)$ as above. Denote $m := \#_4 W$, $m_1 := \#_4 W_1$, and $t := \#_4(W \cap W_1)$. After simplifications, the result can be written in the form,

$$\frac{q(q-1)}{2}[c(2) + 1] + q(1 + b(1) + b(m) + b(m_1)) + (m - t)\{c(m - 1) + c(m_1 + 1)\} + (m_1 - t) \times \{c(m + 1) + c(m_1 - 1)\} + c(q) + 1 = 0,$$

where $q := m + m_1 - 2t$. The variables m, m_1, and t, vary over $\mathbb{Z}/4$. It remains to verify (easiest in Maple) that for each of the possible $4 \times 4 \times 4 = 64$ variants this equality is true. Each time the left-hand side reduces to one of the following variants: $1 + c(0)$, $1 + b(0)$, $b(2) + c(2)$, $b(1) + b(3) + c(1) + c(3)$, or a linear combination of the mentioned ones. Hence, due to the imposed conditions, the equality is always valid. This means, that $(i^b_W(\psi), i^b_{W_1}(\psi_1)) \in T_c$ in case $W \cap \bar{\Omega} \neq \varnothing$ and $W_1 \cap \bar{\Omega} \neq \varnothing$.

(4) Now it is necessary to consider three mixed cases. Start with $W \in \mathcal{P}_{\text{even}}(\Omega)$ and $W_1 \in \mathcal{P}_{\text{odd}}(\Omega)$. Assume, that $i^b_W(\psi) \in B^{T_c}$ and $i^b_{W_1}(\psi_1) \in (M\backslash B)^{T_c}$. For ψ_1 there are two possibilities. The first one is that $\psi_1 \in S_W$, and hence $\psi_1(z) = \tilde{\pi}(W_1, z)$, $z \in \Omega$. The other is that $\psi_1(\cdot)$ in the points $z \in \Omega$ is of the form $\psi_1(z) = \tilde{\pi}(W_1, z) + \chi_Z(z)$, where Z is some nonempty subset of Ω, such that

$\#(Z\cap W)$ is even. In the latter case, for all $U\in\mathcal{P}_{\mathrm{odd}}(\Omega)$ such that $\#(U\cap Z)$ is odd, $S_U=Q_U$. Concerning $\psi(\cdot)$ one can say, that for all $U\in\mathcal{P}_{\mathrm{odd}}(\Omega)$, either $S_U=\varnothing$, or $\Sigma_{z\in U}\psi(z)=\Sigma_{z\in W}\tilde{\tau}(U,z)+g_{b,c}(U,W)$. Consider the first possibility for ψ_1. In particular this implies that $S_{W_1}\neq\varnothing$. Hence the sum $\Sigma_{z\in W_1}\psi(z)$ is known. On the other hand, since $\psi_1\in S_W\subset Q_W$, one has $\psi_1(z\in\Omega)=\tilde{\tau}(W_1,z)$. From this $\Sigma_{z\in W_1}\psi(z)=\Sigma_{z\in W}\psi_1(z)+g_{b,c}(W,W_1)$, i.e., $(i^b_W(\psi),i^b_{W_1}(\psi_1))\in T_c$ follows. Now consider the second possibility for ψ_1 (the one with Z). Observe, that $\#_2(W\Delta W_1)=\#_2W+\#_2W_1=1$, i.e., $W\Delta W_1\in\mathcal{P}_{\mathrm{odd}}(\Omega)$. Look at $(W\Delta W_1)\cap Z$. We have $\#_2(W\Delta W_1)\cap Z=\#_2((W\cap Z)\Delta(W_1\cap Z))=\#_2(W\cap Z)$. Therefore, if $\#(W\cap Z)$ is odd, take $U=W\Delta W_1$ and obtain $S_{W\Delta W_1}=Q_{W\Delta W_1}$. In particular, $S_{W\Delta W_1}\neq\varnothing$, leading to the expression for $\Sigma_{z\in W\Delta W_1}\psi(z)$. The values of $\psi_1(z)$ are known at all points $z\in\Omega$, so there is no problem to compute $\Sigma_{z\in W\Delta W_1}\psi_1(z)$. Taking into account, that $\Sigma_{v\in W\Delta W_1}\chi_Z(v)=\#((W\Delta W_1)\cap Z)=1$, and then expressing $\tilde{\tau}$ via $\hat{\tau}$ and $g_{b,c}$, we obtain

$$\sum_{z\in W\Delta W_1}[\psi(z)+\psi_1(z)]=1+\sum_{v,z\in W}\hat{\tau}(v,z)+\sum_{v,z\in W_1}\hat{\tau}(v,z)+\sum_{v\in W}g_{b,c}(\{v\},W\Delta W_1)+\sum_{v\in W\Delta W_1}g_{b,c}(\{v\},W_1)+g_{b,c}(W\Delta W_1,W).$$

On the other hand, this sum should be equal to $c(\#_4(W\Delta W_1))+1$. Expressing the sums with $\hat{\tau}(v,z)$ in terms of $b(\cdot)$ and $c(\cdot)$, one obtains the following equality:

$$\begin{aligned}(m+m_1)b(1)+\left(\frac{m(m-1)}{2}+\frac{m_1(m_1-1)}{2}\right)[c(2)+1]+(m-t)c(q-1)+tc(q+1)\\+m\{b(1)+b(q)+1\}+(m-t)c(m_1+1)+(m_1-t)c(m_1-1)+q\{b(1)+b(m_1)+1\}+b(q)\\+b(m)+c(m_1)+c(q)+1=0,\end{aligned}$$

where $m:=\#_4W$, $m_1:=\#_4W_1$, $t:=\#_4(W\cap W_1)$, $q:=m+m_1-2t$. It is necessary to verify that this equality is true for every $m=0,2$, every $m_1=1,3$, and $t=0,1,2,3$. This is done by a straightforward computation (in Maple). In each variant, the left-hand side reduces to a linear combination of the expressions $1+b(0)$, $1+c(0)$, $b(2)+c(2)$, and $\Sigma_{i=1,3}(b(i)+c(i))$. Due to the conditions on $b(\cdot)$ and $c(\cdot)$ imposed above, the equality is always true, so one has $(i^b_W(\psi),i^b_{W_1}(\psi_1))\in T_c$ for $W\in\mathcal{P}_{\mathrm{even}}(\Omega)$, $W_1\in\mathcal{P}_{\mathrm{odd}}(\Omega)$.

(5) Now consider the next case. Suppose that there exist $i^b_W(\psi)\in B^{T_c}$, $i^b_{W_1}(\psi_1)\in(M\backslash B)^{T_c}$, where $W_1\cap\bar{\Omega}\neq\varnothing$ and $W\in\mathcal{P}_{\mathrm{even}}(\Omega)$. Take any $U\in\mathcal{P}_{\mathrm{odd}}(\Omega)$. For ψ we have $S_U=\varnothing$ or $\Sigma_{z\in U}\psi(z)=\Sigma_{v\in W}\tilde{\tau}(U,v)+g_{b,c}(U,W)$. For ψ_1 we have $S_U=Q_U$ or $\Sigma_{z\in U}\psi_1(z)=\Sigma_{v\in W_1\cap\Omega}\tilde{\tau}(U,v)+\mu_U+g_{b,c}(U,W_1)$, where $\mu_U=\Sigma_{z\in W_1\cap\bar{\Omega}}\varphi(z)$, φ being an element of $Q_U\backslash S_U$. Observe, that S_U cannot be empty, since either $S_U=Q_U$, or μ_U is defined. Therefore, we always know the sum $\Sigma_{z\in U}\psi(z)$. In particular, U can be of the form $\{w\}$, where $w\in W$, then $\psi(w)=\Sigma_{v\in W}\tilde{\tau}(w,v)+b(\#_4W)+b(1)+c(\#_4(W\Delta\{w\}))+1$. Sum over all $w\in W$, and use the fact that $\#W$ is even. This yields $\Sigma_{w\in W}\psi(w)=\Sigma_{v,w\in W}\tilde{\tau}(w,v)$. On the other hand, this sum should be equal to $b(\#_4W)$. Hence one derives $b(m)=(m(m-1)/2)[c(2)+1]$, $m:=\#_4W$. If $m=0$, one obtains $b(0)=0$, and if $m=2$, one obtains $b(2)=c(2)+1$. In both cases this contradicts the assumptions on $b(\cdot)$ and $c(\cdot)$. This means, that the pair $(i^b_W(\psi),i^b_{W_1}(\psi_1))$ cannot exist.

(6) It remains to investigate just the case where one of the sets W or W_1 is an odd subset of Ω, and the other contains at least one point outside Ω. Let $W\in\mathcal{P}_{\mathrm{odd}}(\Omega)$ and $W_1\cap\bar{\Omega}\neq\varnothing$. Suppose, that $i^b_W(\psi)\in B^{T_c}$ and $i^b_{W_1}(\psi_1)\in(M\backslash B)^{T_c}$. First look at the condition for ψ_1. For any $U\in\mathcal{P}_{\mathrm{odd}}(\Omega)$, the set S_U cannot be empty, since one has either $S_U=Q_U$ or the quantity $\mu_U:=\Sigma_{z\in W_1\cap\bar{\Omega}}\varphi(z)$ needs to be defined (φ is an element of $Q_U\backslash S_U$; if φ varies over the entire Q_U, the sum ranges over the entire $\mathbb{Z}/2$ and μ_U is undefined). Now look at the condition for ψ. First investigate the possibility $\psi(z)=\tilde{\tau}(W,z)+\chi_Z(z)$, $z\in\Omega$, for some nonempty $Z\subset\Omega$, with $\#(Z\cap W)$ even. If $\#Z$ is odd, then take $U=Z$. This yields $S_Z=\varnothing$, contradicting the previous fact. If $\#Z$ is even, then since $\#W$ is odd, there always exist a point $e\in W\backslash Z$. [This is implied by the facts that $\#W$ is odd and $\#(W\cap Z)$ is even,

and therefore $\#(W\backslash Z)$ is odd.] Set $U=\{e\}\sqcup Z$. This yields $S_{\{e\}\sqcup Z}=\varnothing$, again a contradiction. Hence the only possibility that remains for ψ is $\psi\in Q_W\backslash S_W$. For this case the values of $\psi(\cdot)$ are known in every point of Ω. Since such ψ is assumed to exist, $S_W\neq Q_W$. Now, set $U=W$ in the condition for ψ_1 [one can do it since $W\in\mathcal{P}_{\mathrm{odd}}(\Omega)$]. This yields $\Sigma_{z\in W}\psi_1(z)=\Sigma_{z\in W_1\cap\Omega}\tilde{\pi}(W,z)+\mu_U+g_{b,c}(W,W_1)$. But $\tilde{\pi}(W,z)$ is just the value of $\psi(z)$. Recall, that the definition of μ_U contains an arbitrary function $\varphi\in Q_U\backslash S_U$. Take $\varphi=\psi$. In the result, one obtains $\Sigma_{z\in W}\psi_1(z)=\Sigma_{z\in W_1}\psi(z)+g_{b,c}(W,W_1)$, i.e., $(i^b_W(\psi),i^b_{W_1}(\psi_1))\in T_c$. This completes the proof that T_c satisfies the main condition (6). Applying the described construction to the set A_b and relation T_c, one obtains a coherent orthoalgebra. □

VII. ABSENSE OF BIVALUATIONS

Recall, that we have made the following assumptions in order to construct an orthoalgebra: N is divisible by 4, $b(0)=1$, $c(0)=1$, $b(2)+c(2)=0$, and $\Sigma_{i=1,3}(b(i)+c(i))=0$. Let us show that such orthoalgebra cannot admit bivaluations. Take $N+1$ elements of $\mathrm{Max}(\mathcal{P}_{T_c}(A_b),\subset)$: N elements $B_v:=\{i^b_{\{v\}}(\sigma)\}_{\sigma\in L_b(\{v\})}$, $v\in V$, and an element $\hat{B}:=\{i^b_V(\pi)\}_{\pi\in L_b(V)}$. Note, that $\hat{B}$ is transformed into B_v if one applies $\hat{\theta}^{(\bar{a})}_{\{v\}}\hat{\theta}^{(\bar{a})}_V\hat{\theta}^{(\bar{a})}_{\{v\}}$ to each of its elements. Recall, that the ground set of our orthoalgebra is $\mathcal{P}^{T_c}(A_b)$. Every singleton $\{l\}$, where $l\in(\sqcup_{v\in V}B_v)\sqcup\hat{B}$ is in this ground set, $\{l\}\in\mathcal{P}^{T_c}(A_b)$. For every $v\in V$ the sum $\oplus_{l\in B_v}\{l\}$ is defined and equals A_b, i.e., the $\mathbf{1}$ of the orthoalgebra. Also, $\oplus_{l\in\hat{B}}\{l\}=\mathbf{1}$. Assume that there exists a bivaluation $f:X_{b,c}\to\mathbb{B}$, where $X_{b,c}$ denotes the constructed orthoalgebra. One has the following equalities in $\mathbb{B}$: $\oplus_{l\in B_v}f(\{l\})=\mathbf{1}$, $v\in V$, and $\oplus_{l\in\hat{B}}f(\{l\})=\mathbf{1}$. Since $\oplus$ in $\mathbb{B}$ is defined just in three cases, $\mathbf{0}\oplus\mathbf{0}$, $\mathbf{1}\oplus\mathbf{0}$, and $\mathbf{0}\oplus\mathbf{1}$, one derives two statements: (1) $\forall v\in V\exists!\,l\in B_v:f(l)=\mathbf{1}$; (2) $\exists!\,l\in\hat{B}:f(l)=\mathbf{1}$. Denote these uniquely defined elements by $l_v\in B_v$, $v\in V$, and $\hat{l}\in\hat{B}$, respectively. Any pair (l,l'), $l'\neq l$, of these elements cannot be in T_c. Indeed, then $l\oplus l'$ would have been defined. Applying to it f, $f(l)\oplus f(l')=\mathbf{1}\oplus\mathbf{1}$, follows a contradiction. Write $l_v=i^b_{\{v\}}(\sigma_v)$, $\sigma_v\in L_b(\{v\})$, and $\hat{l}=i^b_V(\hat{\pi})$, $\hat{\pi}\in L_b(V)$. The definition of T_c yields, for any $v,v_1\in V$, $v\neq v_1$, that

$$\sigma_v(v_1)+\sigma_{v_1}(v)=c(2),$$

$$\sum_{z\in V\backslash\{v\}}(\pi(z)+\sigma_v(z))=c(3).$$

Take the sum over $v\in V$ for the second equality. Using the definition of $L_b(V)$ one obtains

$$(N-1)b(0)+\sum_{\substack{z,v\in V,\\ z\prec v}}(\sigma_z(v)+\sigma_v(z))=Nc(3),$$

where $\prec$ is any order on V. Now, using the first equality, and then the fact that N is divisible by 4, one arrives at $b(0)=0$. This contradicts the assumption $b(0)=1$. Therefore, a bivaluation of $X_{b,c}$ cannot exist.

VIII. ISOMORPHIC ORTHOALGEBRAS

There are several options for the choice of $b(\cdot)$ and $c(\cdot)$ satisfying the conditions of the theorem. Let us derive a *sufficient* condition for two orthoalgebras of the form $X_{b,c}$ to be isomorphic. Select any (b,c) satisfying the conditions of the theorem, and any (b',c') satisfying the same conditions. Construct $A_b:=\sqcup_{U\in\mathcal{P}(\Omega)}L_b(U)$ and $A_{b'}:=\sqcup_{U\in\mathcal{P}(\Omega)}L_{b'}(U)$, and define the relations T_c and $T_{c'}$ on A_b and $A_{b'}$, respectively. Denote by $i^b_U:L_b(U)\rightarrowtail A_b$ and $i^{b'}_U:L_{b'}(U)\rightarrowtail A_{b'}$ the canonical injections. Suppose that there exists a bijective map $\hat{t}:A_b\xrightarrow{\sim}A_{b'}$, such that $(l,l_1)\in T_c$ implies $(\hat{t}(l),\hat{t}(l_1))\in T_{c'}$. Then this map induces a bijection $\mathcal{P}^{T_c}(A_b)\xrightarrow{\sim}\mathcal{P}^{T_{c'}}(A_{b'})$, which establishes an isomorphism of the orthoalgebras $X_{b,c}$ and $X_{b',c'}$. Let us try to construct such a map and investigate what kind of relations between b, c, b', and c', emerge.

The map $\hat{t}$ is defined by a collection of bijections $\{t_U\}_{U\in\mathcal{P}(V)}$, where $t_U: L_b(U)\tilde{\to}L_{b'}(U)$. Let us search for t_U in the form

$$t_U(\psi)(v) = \psi(v) + \alpha_U(v),$$

where $\alpha_U(v)$ are some $\mathbb{Z}/2$-valued parameters, $U\in\mathcal{P}(V)$, $v\in V$. Denote

$$\tilde{b}_U := b(\#_4 U) + b'(\#_4 U),$$

$$\tilde{c}_{U,U_1} := c(\#_4(U\Delta U_1)) + c'(\#_4(U\Delta U_1)) + \tilde{b}_U + \tilde{b}_U.$$

The requirement that $\Sigma_{v\in U}\psi(v)=b(\#_4 U)\Rightarrow\Sigma_{v\in U}t_U(\psi)(v)=b'(\#_4 U)$, yields for every $U\in\mathcal{P}(V)$ an equation on $\alpha_U(\cdot)$,

$$\sum_{v\in U}\alpha_U(v) = \tilde{b}_U.$$

Similarly, for every $U,U_1\in\mathcal{P}(V)$, $U\neq U_1$, the requirement that for any $\psi\in L_b(U)$, $\psi_1\in L_b(U_1)$, $\Sigma_{v\in U\Delta U_1}(\psi(v)+\psi_1(v))=c(\#_4(U\Delta U_1))+1\Rightarrow\Sigma_{v\in U\Delta U_1}(t_U(\psi)(v)+t_U(\psi_1)(v))=c'(\#_4(U\Delta U_1))+1$, yields an equation

$$\sum_{v_1\in U_1}\alpha_U(v_1) + \sum_{v\in U}\alpha_{U_1}(v) = \tilde{c}_{U,U_1}.$$

These equations are similar to Eqs. (17) and (18), for $a_{S,U}(v)$ derived above. It is not difficult to solve them. First consider the case, $\#U=1$ and $\#U_1=1$. From this it follows, that $\alpha_{\{v\}}(z)$ is a solution of the corresponding system iff it is of the form $\alpha_{\{v\}}(z)=\alpha^{(\nu)}_{\{v\}}(z)$, where

$$\alpha^{(\nu)}_{\{v\}}(z) := \begin{cases} \nu(zv) & \text{if } z\prec v,\\ \tilde{b}_{\{v\}} & \text{if } z=v,\\ \nu(zv)+\tilde{c}_{\{z\},\{v\}} & \text{if } z\succ v,\end{cases}$$

where $\nu:\mathcal{E}(V)\to\mathbb{Z}/2$ is an arbitrary function, and $\prec$ is some chosen and fixed order on V. The other $\alpha_Q(v)$, $\#Q\geqslant 2$, may be found from the specialization $U=\{v\}$, $U_1=Q$, in the equation with $\tilde{c}_{U,U_1}$. This yields $\alpha_Q(v)=\alpha^{(\nu)}_Q(v)$, where

$$\alpha^{(\nu)}_Q(v) = \tilde{c}_{\{v\},Q} + \sum_{z\in Q}\alpha^{(\nu)}_{\{v\}}(z).$$

Now consider the equations with $\tilde{b}_U$, corresponding to $U=Q$, $\#Q\geqslant 2$, and the equations with $\tilde{c}_{U,U_1}$, corresponding to $U=Q$, $U_1=Q_1$, with $\#Q,\#Q_1\geqslant 2$. This leads to the following solvability conditions:

$$\tilde{c}_{Q,Q_1} + \sum_{z\in Q}\tilde{c}_{\{z\},Q_1} + \sum_{z_1\in Q_1}\tilde{c}_{Q,\{z_1\}} + \sum_{\substack{z\in Q,\\ z_1\in Q_1}}\tilde{c}_{\{z\},\{z_1\}} = 0, \tag{35}$$

$$\sum_{v\in Q}\tilde{c}_{\{v\},Q} + \sum_{\substack{v,z\in Q,\\ z\succ v}}\tilde{c}_{\{v\},\{z\}} = \tilde{b}_Q + \sum_{v\in Q}\tilde{b}_{\{v\}}. \tag{36}$$

Note that if one formally takes Q or Q_1 of cardinality 1, the corresponding equality trivializes. Note also that this system of equations becomes the system of equations (19) and (20), for $c^{(S)}_{Q,Q_1}$ and $b^{(S)}_Q$ investigated above, if one formally replaces $\tilde{c}_{Q,Q_1}$ with $c^{(S)}_{Q,Q_1}$, and $\tilde{b}_Q$ with $b^{(S)}_Q$. From the

definition of $\tilde{b}_U$, it is clear that its value is determined by $\#_4 U$, i.e., $\tilde{b}_U = \beta(\#_4 U)$, where $\beta: \mathbb{Z}/4 \to \mathbb{Z}/2$ is some function. Similarly, $\tilde{c}_{U,U_1}$ can be written as $\tilde{c}_{U,U_1} = \gamma(\#_4(U \Delta U_1)) + \beta(\#_4 U) + \beta(\#_4 U_1)$, where $\gamma: \mathbb{Z}/4 \to \mathbb{Z}/2$ is some function. It is necessary to substitute these expressions into the solvability conditions (35) and (36), above. The values of the resulting expressions are determined by $m := \#_4 Q$, $m_1 := \#_4 Q_1$, and $t := \#_4(Q \cap Q_1)$. Analyzing the $4 \times 4 \times 4 = 64$ corresponding variants, we should discover which assumptions on $\beta(\cdot)$ and $\gamma(\cdot)$ emerge. The equation with four $\tilde{c}$ yields

$$\{\gamma(m + m_1 - 2t) + \beta(m) + \beta(m_1)\} + (m - t)\gamma(m_1 + 1) + t\gamma(m_1) + m[\beta(1) + \beta(m_1)] + (m_1 - t)\gamma(m + 1) + t\gamma(m) + m_1[\beta(1) + \beta(m)] + \left(\frac{t(t-1)}{2} + (m - t)t + (m_1 - t)t + (m - t)(m_1 - t)\right)\gamma(2) = 0.$$

The equation with $\tilde{b}$ yields

$$m\{\gamma(m - 1) + \beta(1) + \beta(m)\} + \frac{m(m-1)}{2}\gamma(2) = \beta(m) + m\beta(1).$$

A straightforward (Maple) computation shows, that all these equalities hold iff

$$\gamma(0) = 0, \quad \gamma(2) = 0, \quad \gamma(1) + \gamma(3) = 0,$$

$$\beta(0) = 0, \quad \beta(2) = 0, \quad \beta(1) + \beta(3) = 0.$$

Recall that $b'(i) = b(i) + \beta(i)$, $c'(i) = c(i) + \gamma(i)$, $i \in \mathbb{Z}/4$. Hence, if the additions $\beta(\cdot)$ and $\gamma(\cdot)$ satisfy these conditions, the corresponding orthoalgebras are isomorphic.

IX. THE PROJECTIVE LINES

Let $N=4$. Set $b(0) = c(0) = 1$ and the other $b(i) = c(i) = 0$, $i = 1, 2, 3$. We have the set A_b and the relation $T_c \subset A_b \times A_b$. Let us write just A and T in this case. Let us show how (only in this particular case) the main condition on T may be established in a different way (not combinatorial, but geometric).

Take a Hilbert space $\mathcal{H}$ of finite dimension $d = 2^{N-1} = 8$ over $\mathbb{C}$. Consider $\mathbb{P}(\mathcal{H})$ equipped with the orthogonality relation $\perp$. Suppose, that there exists an *injective* map $\mu: A \rightarrowtail \mathbb{P}(\mathcal{H})$, such that $\forall x, x_1 \in A: (x, x_1) \in T \Leftrightarrow \mu(x) \perp \mu(x_1)$. Then the main property for T can be easily established. Indeed, take any $M \in \mathrm{Max}(\mathcal{P}_T(A), \subset)$, and then any $B \subset M$. The map μ sends M into a set of d pairwise orthogonal projective lines. An element $x \in A$ falls into B^T iff its image $\mu(x)$ is orthogonal to every $\mu(y)$, $y \in B$. The latter is equivalent to $\mu(x) \in (\mathrm{span}\{\mu(y) \,|\, y \in B\})^{\perp} =: P_1$. Similarly, $x \in A$ falls into $(M \backslash B)^T$ iff $\mu(x) \in (\mathrm{span}\{\mu(y) \,|\, y \in M \backslash B\})^{\perp} =: P_2$. Since $\mu(y)$, $y \in M$, are pairwise orthogonal and the span over them is the whole space $\mathcal{H}$, the subspaces P_1 and P_2 have trivial intersection and are mutually orthogonal. For any $x_1 \in B$ and any $x_2 \in M \backslash B$, we have $\mu(x_1) \in P_1$ and $\mu(x_2) \in P_2$. Hence $\mu(x_2) \perp \mu(x_1)$, and this is equivalent to $(x_1, x_2) \in T$. So the main property of T is established.

In case $N=4$ the map μ mentioned can be constructed. This fact relies on the results of Ref. 10. Set $\mathcal{H} = (\mathbb{C}^2)^{\otimes 3}$. Take any orthonormal basis $\{\varphi_\alpha\}_\alpha$ in $\mathbb{C}^2$ indexed by $\alpha \in \mathbb{Z}/2$. Define a map $u: (\mathbb{Z}/2)^2 \to \mathbb{R}$ as follows: $u(1,1) := -1$ and $u(i,j) := 1$ for $(i,j) \neq (1,1)$. Construct another orthonormal basis $\{\psi_\beta\}_{\beta \in \mathbb{Z}/2}$ in $\mathbb{C}^2$ by defining $\psi_\beta := (1/\sqrt{2}) \Sigma_\alpha u(\alpha, \beta) \varphi_\alpha$. Recall that $A = \sqcup_{U \in \mathcal{P}(V)} L(U)$, where $L(U)$ consists of all functions $\phi: V \to \mathbb{Z}/2$, such that $\Sigma_{z \in U} \phi(z) = b(\#_4 U)$. Note that since we have $b(0) = 1$, the set $L(\varnothing)$ is empty. Hence the latter disjoint union can be viewed as being taken over $U \in \mathcal{P}(V)^{\times} := \mathcal{P}(V) \backslash \{\varnothing\}$. Denote by $i_U: L(U) \rightarrowtail A$ the canonical injections. The elements $\mu(i_U(\phi)) \in \mathbb{P}(\mathcal{H})$, $U \in \mathcal{P}(V)^{\times}$, $\phi \in L(U)$, are defined as follows. In Ref. 10 there were defined 120 projective lines in $\mathcal{H}$ denoted by Ψ^v_σ, $X^{vw}_\varkappa$, Φ^v_ρ, and F_π, where $v, w \in V$, $w \neq v$, and the indices σ, $\varkappa$, ρ, and π vary over the sets S_v, K_{vw}, R_v, and Λ, respectively, defined as follows:

$$S_v := \mathrm{Maps}(\{\{v,z\}|z \in V\setminus\{v\}\} \to \mathbb{Z}/2),$$

$$K_{vw} := \mathrm{Maps}(\{\{v,w\}\} \sqcup (V\setminus\{v,w\}) \to \mathbb{Z}/2),$$

$$R_v := \mathrm{Maps}(\{\{z,w\}|z,w \in V\setminus\{v\}, z \neq w\} \to \mathbb{Z}/2),$$

$$\Lambda := \left\{ \pi \in \mathrm{Maps}(V \to \mathbb{Z}/2) | \sum_{z\in V} \pi(z) = 1 \right\}.$$

The corresponding formulas for the projective lines are given in terms of φ_α, ψ_β, and $u(\alpha,\beta)$ $(\alpha,\beta \in \mathbb{Z}/2)$, and discussed in more detail in that paper. Note that the index sets S_v, K_{vw}, R_v, and Λ, all have cardinality $2^3=8$.

Let us establish bijections $\alpha_v : L(\{v\}) \tilde{\to} S_v$, $\beta_{vw} : L(\{v,w\}) \tilde{\to} K_{vw}$, $\gamma_v : L(V\setminus\{v\}) \tilde{\to} R_v$, and $\lambda : L(V) \tilde{\to} \Lambda$. For $v \in V$ and $\phi \in L(\{v\})$, set

$$\alpha_v(\phi)(vz) := \phi(z), \quad z \in V\setminus\{v\}.$$

For $v,w \in V$, $w \neq v$, and $\phi \in L(\{v,w\})$, set

$$\beta_{vw}(\phi)(vw) := \phi(v) = \phi(w),$$

$$\beta_{vw}(\phi)(z) := \phi(t), \quad \beta_{vw}(\phi)(t) := \phi(z),$$

where z and t are the two different elements of $V\setminus\{v,w\}$. [Note, that $\phi(v)=\phi(w)$, since $b(2)=0$.] For every $v \in V$ and $\phi \in L(V\setminus\{v\})$, set

$$\gamma_v(\phi)(V\setminus\{v,z\}) := 1 + \phi(v) + \phi(z), \quad z \in V\setminus\{v\}.$$

Finally, for every $\phi \in L(V)$, set

$$\lambda(\phi)(v) := 1 + \phi(v), \quad v \in V.$$

The collection of bijections α_v, β_{vw}, γ_v, and λ, define an injective map $\mu : A \rightarrowtail \mathbb{P}(\mathcal{H})$ by the formulas $i_{\{v\}}(\phi_1) \mapsto \Psi^v_{\alpha_v(\phi_1)}$, $i_{\{v,w\}}(\phi_2) \mapsto X^{vw}_{\beta_{vw}(\phi_2)}$, $i_{V\setminus\{v\}}(\phi_3) \mapsto \Phi^v_{\gamma_v(\phi_3)}$, and $i_V(\phi_0) \mapsto F_{\lambda(\phi_0)}$, where $\phi_1 \in L(\{v\})$, $\phi_2 \in L(\{v,w\})$, $\phi_3 \in L(V\setminus\{v\})$, and $\phi_0 \in L(V)$. It is straightforward to verify that it transforms a pair $(i_U(\phi), i_W(\phi')) \in T$ $(\phi \in L(U), \phi' \in L(W), U,W \in \mathcal{P}(V)^\times)$, into a pair of orthogonal projective lines. Note, that the only facts needed in order to prove this, are the following four properties of $u(\cdot,\cdot)$: (1) $u(\alpha,\beta)=u(\beta,\alpha)$; (2) $u(\alpha,\beta+\gamma)=u(\alpha,\beta)u(\alpha,\gamma)$; (3) $\Sigma_{\beta\in\mathbb{Z}/2} u(\alpha,\beta)u(\beta,\alpha)=2\delta_{\alpha,\gamma}$; (4) $u(\alpha,1+\alpha) \equiv 1$. Therefore T satisfies the main condition.

Let us mention, how to obtain in principle the formulas for the projective lines (for $N=4$). The result will be just the 120 projective lines constructed in Ref. 10. The configuration of these lines is saturated (i.e., every subset of pairwise orthogonal lines is contained in a set of eight pairwise orthogonal lines) and has a Kochen-Specker-type property.[6] More precisely, this set contains a subset of $40=5\times 8$ projective lines, which are implicitly present in the no-hidden-variables argument due to Mermin.[8] Denote the lines as l^U_ϕ, $U \in \mathcal{P}(V)^\times$, $\phi \in L(U)$. It is convenient to view the set of four points V as a disjoint union of the ground set of $\mathbb{Z}/3$ and a singleton $\{*\}$, where $*$ is a formal symbol. Write $\mathbb{Z}/3$ additively, and denote its elements as 0, 1, and 2. For $\xi \in L(\{*\})$, set

$$l^{\{*\}}_\xi := \mathbb{C} \bigotimes_{i\in\mathbb{Z}/3}^{2i} \varphi_{\xi(i)},$$

where the upper indices denote the ordering of the factors in the tensor product. Let $\{\varphi_\alpha\}_\alpha$ and $\{\psi_\beta\}_\beta$ be the orthonormal bases in $\mathbb{C}^2$ as above. For $k \in \mathbb{Z}/3$ and $\xi \in L(\{k\})$, set

$$l_{\xi}^{\{k\}} := \mathbb{C}\left\{ \varphi_{\xi(*)}^{2k} \otimes \bigotimes_{j\in(\mathbb{Z}/3)\setminus\{k\}} \psi_{\xi(j)}^{k+j} \right\}.$$

For any $U\in\mathcal{P}(V)$, $\#U\geqslant 2$, one can search for the projective line corresponding to $\eta\in L(U)$ in the form

$$l_{\eta}^{U} := \sum_{\xi\in L(\{*\})} B_{\eta}^{U}(\xi) \bigotimes_{i\in\mathbb{Z}/3} \varphi_{\xi(i)}^{2i},$$

where $B_{\eta}^{U}(\xi)\in\mathbb{C}$ are some coefficients. The conditions

$$\sum_{z\in U\Delta\{v\}} (\eta(z)+\xi(z)) = c(\#_4(U\Delta\{v\}))+1 \Rightarrow l_{\xi}^{\{v\}} \perp l_{\eta}^{U},$$

where v varies over V, and ξ varies over $L(\{v\})$, yield (for every U and η) a system of equations on $\{B_{\eta}^{U}(\xi)\}_{\xi}$. This system is homogeneous and linear, but overdetermined. Nevertheless, it turns out that it has nontrivial solutions. Moreover, for every $U\in\mathcal{P}(V)$, the obtained projective lines $\{l_{\eta}^{U}\}_{\eta\in L(U)}$ are pairwise orthogonal, and for every $U,U_1\in\mathcal{P}(V)$, if $U\neq U_1$, then $l_{\eta}^{U}\neq l_{\eta_1}^{U_1}$, where $\eta\in L(U)$, $\eta_1\in L(U_1)$. A straightforward computation shows, that the orthogonality relation between the lines corresponding to different $U,U_1\in\mathcal{P}(V)^{\times}$, $U\neq U_1$, is described by the formula

$$l_{\eta}^{U} \perp l_{\eta_1}^{U_1} \Leftrightarrow \sum_{z\in U\Delta U_1} (\eta(z)+\eta(z_1)) = c(\#_4(U\Delta U_1))+1,$$

where $\eta\in L(U)$, $\eta_1\in L(U_1)$. It remains to define the injection $\mu: A\rightarrowtail\mathbb{P}(\mathcal{H})$ by the formula $\mu(i_U(\phi)) := l_{\phi}^{U}$, $U\in\mathcal{P}(V)^{\times}$, $\phi\in L(U)$.

Upper and lower bounds for an eigenvalue associated with a positive eigenvector

published online 28 February 2006)

When an eigenvector of a semibounded operator is positive, we show that a remarkably simple argument allows to obtain upper and lower bounds for its associated eigenvalue. This theorem is a substantial generalization of Barta-type inequalities and can be applied to non-necessarily purely quadratic Hamiltonians. An application for a magnetic Hamiltonian is given and the case of a discrete Schrödinger operator is also discussed. It is shown how this approach leads to some explicit bounds on the ground-state energy of a system made of an arbitrary number of attractive Coulombian particles. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2168124]

I. INTRODUCTION

In most situations, the principal eigenvalue of a semibounded operator cannot be obtained explicitly whereas it plays a crucial role in physics: the smallest vibration frequency of an elastic system, the fundamental mode of an electromagnetic cavity, the ground-state energy of a quantum system with a finite number of degrees of freedom, the energy of the vacuum in a quantum field theory, the equilibrium state at zero temperature in statistical physics, etc. There are actually very few ways—which are usually specific to a restricted class of systems[1]—to obtain accurate approximations of an eigenvalue with a rigorous control on the errors and a reasonable amount of numerical computations. For instance, in a typical Dirichlet-Laplacian problem defined for an open connected set $\mathcal{Q}\subset\mathbb{R}^d$; $d\in\mathbb{N}$; Barta's inequalities (Barta, 1937) allow to bound to the lowest eigenvalue e_0: The determination of a lower (respectively, upper) bound requires the finding of the absolute minimum (respectively, maximum) of a smooth function defined on $\mathcal{Q}$. Compared to the general and traditional methods like the Rayleigh-Schrödinger perturbative series and the Rayleigh-Ritz or Temple variational methods, an advantage of Barta's approach is not only to naturally provide both an upper and a lower bound, but also does not involve the calculation of any integral. Therefore, generalizations of Barta's inequalities can lead to interesting spectral information. This generalization has been carried out in two directions:

(i) For Laplacian operators acting on square integrable functions defined on a Riemannian manifold (for a recent work on this subject, see Bessa and Montenegro, 2004).

(ii) For Schrödinger operators of the form $-\Delta+V$ acting on square integrable functions defined on an open set of $\mathbb{R}^d$ (Barnsley, 1978; Baumgartner, 1979; Thirring, 1979; Crandall and Reno, 1982; Schmutz, 1985) or more generally second order elliptic operators (Protter and Weinberger, 1966; Berestycki *et al.*, 1994; Harrell II, 2005).

[a)]mouchet@phys.univ-tours.fr

[1]Finding lower bounds for the smallest eigenvalue of a typical Hamiltonian is far more difficult than finding upper bounds. For successful attempts, see for instance the moment method proposed by Handy and Bessis, 1985, the Riccati-Padé method proposed in Fernández *et al.*, 1989 and the lower bounds obtained for few-body systems by Benslama *et al.*, 1998.

In both cases, the proofs of Barta's inequalities involve the use of a Kato-type inequality and therefore rely extensively on the somehow specific properties of the purely quadratic differential operator. In this paper, we propose a significant extension of Barta's inequalities that will rely on the properties of one eigenvector only. More precisely, with a remarkably simple argument, we will show that we can obtain upper and lower bounds for the eigenvalue e_0 associated with the eigenvector Φ_0 of an operator, under the only hypothesis that Φ_0 is real and non-negative. This result includes cases (i) and (ii) because the Krein-Rutman theorem guarantees the positivity of Φ_0 (Reed and Simon, 1978a, Sec. XIII.12) for the smallest eigenvalue e_0,[2] but also applies for a much wider class of operators including the following.

(iii) the Schrödinger operators involving a magnetic field, e.g., the hydrogen atom in a Zeeman configuration;

(iv) discrete Hamiltonians, e.g., the one occurring in the Harper model;[3]

(v) some integral or pseudodifferentiable operators, e.g., the Klein-Gordon or spinless Salpeter Hamiltonians.

The next section fixes the notations, proves the main general results (theorems 1 and 2). Section III shows how the original argument given in Sec. II actually embraces and generalizes the Barta-type inequalities that have been already obtained in the literature and furnishes guidelines to numerically improve the bounds on e_0. Sections IV and V provide two applications in the differentiable case (many-body problem) and in the discrete case, respectively.

II. BOUNDING THE PRINCIPAL EIGENVALUE WITH THE LOCAL ENERGY

A. General inequalities

In the following, $\mathcal{Q}$ will be a locally compact space endowed with a positive Radon measure μ. $\langle\psi|\varphi\rangle$ will denote the scalar product between two elements ψ and φ belonging to the Hilbert space of the square integrable complex functions $\mathsf{L}^2(\mathcal{Q},\mu)$,

$$\langle\psi|\varphi\rangle = \int_{\mathcal{Q}} \bar{\psi}(q)\varphi(q)\mathrm{d}\mu(q).$$

$\mathsf{D}(H)$ will denote the domain of the operator H acting on $\mathsf{L}^2(\mathcal{Q},\mathrm{d}\mu)$. The crucial hypothesis on H is the following.

Hypothesis 1: The operator H is symmetric and has one real eigenvector $\Phi_0 \in \mathsf{D}(H)$ *such that* $\Phi_0 \geqslant 0$ (*almost everywhere with respect to* μ) *on* $\mathcal{Q}$.

If e_0 stands for the eigenvalue of H associated with Φ_0, the symmetry of H implies that, for all $\varphi \in \mathsf{D}(H)$, we have $\langle\Phi_0|(H-e_0)\varphi\rangle=0$ that is

$$\forall\,\varphi \in \mathsf{D}(H), \quad \int_{\mathcal{Q}} \overline{\Phi_0}(q)(H-e_0)\varphi(q)\mathrm{d}\mu(q) = 0.$$

Taking the real part of the integral, we can see that the support of $q\mapsto \mathrm{Re}[\overline{\Phi_0}(q)(H-e_0)\varphi(q)]$ either is empty, either contains two disjoints open sets $\mathcal{Q}_\pm$ such that $\mathrm{Re}(\overline{\Phi_0}(H-e_0)\varphi) \gtrless 0$ and $\mu(\mathcal{Q}_\pm)>0$. The hypothesis of positivity of Φ_0 implies that on $\mathcal{Q}_\pm$, we have $\mathrm{Re}[(H-e_0)\varphi] \gtrless 0$. The last results motivates the following definition.

Definition 1 (*local energy*): *For any* φ *in* $\mathsf{D}(H)$, *the* local energy *is the function* $E_\varphi: \mathcal{Q}\to\bar{\mathbb{R}}$ *defined by*

---

[2]The positivity of Φ_0 is also required for the traditional proofs of Barta's inequalities; this explains why, in case (i) and (ii), they concern the lowest eigenvalue only.

[3]After the first version of this paper was written, the author became aware of the paper by Barnsley and Duffin, 1980 where a similar argument as the one presented here was proposed (Theorem 7) for the bounds on an eigenvalue of a finite matrix.

$$E_\varphi(q) = \frac{\mathrm{Re}(H\varphi(q))}{\mathrm{Re}(\varphi(q))}. \tag{1}$$

Therefore from what precedes, we have obtained the main theorem.

Theorem 1: *For any symmetric operator H on $\mathsf{L}^2(\mathcal{Q},\mu)$ having an eigenvalue e_0 whose corresponding eigenfunction is non-negative almost everywhere on $\mathcal{Q}$, we have*

$$\forall \varphi \in \mathsf{D}(H) \text{ such that } \mathrm{Re}(\varphi) \geqslant 0, \quad \inf_{\mathcal{Q}}(E_\varphi) \leqslant e_0 \leqslant \sup_{\mathcal{Q}}(E_\varphi). \tag{2}$$

Actually, for a nonsymmetric operator K, we can keep working with its adjoint K^* and easily generalize the above argument.

Theorem 2: *Let K being an operator on $\mathsf{L}^2(\mathcal{Q},\mu)$ having an eigenvalue k_0 whose corresponding eigenfunction is real and non-negative almost everywhere on $\mathcal{Q}$, we have $\forall \varphi \in \mathsf{D}(K^*)$ such that $\varphi > 0$,*

$$\inf_{\mathcal{Q}}\left[\frac{\mathrm{Re}(K^*\varphi)}{\varphi}\right] \leqslant \mathrm{Re}(k_0) \leqslant \sup_{\mathcal{Q}}\left[\frac{\mathrm{Re}(K^*\varphi)}{\varphi}\right], \tag{3a}$$

$$\inf_{\mathcal{Q}}\left[-\frac{\mathrm{Im}(K^*\varphi)}{\varphi}\right] \leqslant \mathrm{Im}(k_0) \leqslant \sup_{\mathcal{Q}}\left[-\frac{\mathrm{Im}(K^*\varphi)}{\varphi}\right]. \tag{3b}$$

This generalization may be of physical relevance. There are some models (e.g., the so-called "kicked" systems, or quantized maps) where the dynamics are described "stroboscobically", i.e., implemented by a unitary operator (the Floquet evolution operator) that cannot be constructed from a smooth Hamiltonian. However, we will not consider this possibility here, and up to the end of this paper, H will denote a symmetric operator.

B. Optimization strategy

Since generally, the eigenfunction Φ_0 is not known exactly, it will be approximated with the help of test functions that belong to a trial space $\mathsf{T}(H) \subset \mathsf{D}(H)$, very much like the variational method. Since we want a test function to mimic Φ_0 at best, we will restrict $\mathsf{T}(H)$ to functions that respect the *a priori* known properties of Φ_0: its positivity, its boundary conditions and its symmetries if there are any. For each test function the error on e_0 is controlled by inequalities (2). Therefore, the strategy for obtaining reasonable approximations is clear: First, we must choose or construct φ to eliminate all the singularities of the local energy in order to work with a bounded function and second, perturb the test function in the neighborhood of the absolute minimum (respectively, maximum) of the local energy in order to increase (respectively, decrease) its value. For practical and numerical computations, this perturbation will be implemented by constructing a diffeomorphism $\Lambda \to \mathsf{T}(H), \lambda \mapsto \varphi_\lambda$ from a finite dimensional differentiable real manifold Λ of control parameters λ and the optimized bounds for e_0 will be

$$\sup_{\Lambda}\inf_{\mathcal{Q}}(E_{\varphi_\lambda}) \leqslant e_0 \leqslant \inf_{\Lambda}\sup_{\mathcal{Q}}(E_{\varphi_\lambda}). \tag{4}$$

III. INEQUALITIES IN THE DIFFERENTIABLE CASE: OLD AND NEW

A. General considerations

When H is a local differential operator, i.e., involves a finite number of derivatives in an appropriate representation (for instance in position or in momentum representation), one can therefore construct an algorithm that does not require any integration but differential calculus only. In an analytic and in a numerical perspective, this may be a significant advantage on the pertur-

bative or variational methods even though it is immediate to see[4] that the upper bound given by (2) is always larger than $\langle\varphi|H\varphi\rangle/\langle\varphi|\varphi\rangle$. The global analysis appears only through the determination of the singularities and the *absolute* extrema of the local energy that may have bifurcated when the control parameter λ varies smoothly. For a Schrödinger operator, the possible singularities of the potential on $\bar{\mathcal{Q}}$ like a Coulombian divergence or an unbounded behavior at infinite distances may furnish a strong guideline for constructing relevant test functions (see Sec. III D below). We have given in Mouchet, 2005, some heuristic and numerical arguments to show how this strategy can be fruitful. In the present paper, the main focus will concern rigorous results and will explain how some of them can be obtained with great simplicity even for systems as complex as those involved in the many-body problem.

B. Case (i) Barta's inequalities

They immediately appear as a particular case of Theorem 1.

Theorem 3 (Barta, 1937): *Let $\mathcal{Q}$ be a connected bounded Riemannian manifold endowed with the metric g and H, the opposite of the Laplacian Δ_g acting on the functions in $\mathsf{L}^2(\mathcal{Q},\mu)$ that satisfy Dirichlet boundary conditions on the boundary $\partial\mathcal{Q}$. The lowest eigenvalue e_0 of H is such that, for all positive $\varphi\in\mathcal{C}^2(\mathcal{Q})$,*

$$\inf_{\mathcal{Q}}\left(-\frac{\Delta_g\varphi}{\varphi}\right)\leqslant e_0\leqslant\sup_{\mathcal{Q}}\left(-\frac{\Delta_g\varphi}{\varphi}\right). \tag{5}$$

Proof: It follows directly from Theorem 1, with the local energy given by $E_\varphi=-\Delta_g\varphi/\varphi$: The spectrum of H is discrete and the Krein-Rutman theorem assures that Hypothesis 1 is fulfilled for e_0 being the lowest (and simple) eigenvalue. ■

Remark 1: The Dirichlet boundary conditions are not essential and can be replaced by any other type of boundary conditions provided that Hypothesis 1 remains fulfilled. However, as explained in Sec. II B, *for obtaining interesting bounds on e_0 extending $\mathsf{T}(H)$ to test functions that do not fulfill the boundary conditions* (*as proposed by Duffin, 1947*) *seems not appropriate*.

C. Case (ii) Duffin-Barnsley-Thirring inequalities

Extensions of Barta's inequalities for Schrödinger operators have been obtained partially by Duffin (Duffin, 1947) and Barnsley (Barnsley, 1978) (for the lower bound only) and completely (lower and upper bound) by Thirring (Thirring, 1979) using Kato's inequalities (see also Schmutz, 1985).

Theorem 4 (Duffin, 1947; Barnsley, 1978; Thirring, 1979): *Let $H=-\Delta+V$ be a Schrödinger operator acting on $\mathsf{L}^2(\mathbb{R}^d)$ having an eigenvalue below the essential spectrum. Then the lowest eigenvalue e_0 of H is such that for any strictly positive $\varphi\in\mathsf{D}(H)$,*

$$\inf_{\mathbb{R}^d}\left(V-\frac{\Delta\varphi}{\varphi}\right)\leqslant e_0\leqslant\sup_{\mathbb{R}^d}\left(V-\frac{\Delta\varphi}{\varphi}\right). \tag{6}$$

The proof is similar to the one presented above with the local energy being now $E_\varphi=V-\Delta\varphi/\varphi$. This argument has the advantage on the existing ones that it does not involve the specific properties of the Laplacian and can be immediately transposed to the larger class of the differential operators (not necessarily of second order) that fulfill Hypothesis 1.

D. Case (iii) magnetic Schrödinger operators

In the presence of a magnetic field, Schrödinger operators take the form $H=(\mathrm{i}\partial_q+A(q))^2+V(q)$ with $A:\mathcal{Q}\to\mathbb{R}^d$ being a smooth magnetic potential vector and $V:\mathcal{Q}\to\mathbb{R}$ a smooth scalar

[4]For each positive φ, it follows from $\langle\varphi|H\varphi\rangle=\mathrm{Re}[\langle\varphi|H\varphi\rangle]=\int_{\mathcal{Q}}\varphi(q)\mathrm{Re}[H\varphi(q)]\mathrm{d}\mu(q)=\int_{\mathcal{Q}}\varphi^2(q)E_\varphi(q)\mathrm{d}\mu(q)\leqslant\langle\varphi|\varphi\rangle\sup_{\mathcal{Q}}(E_\varphi(q))$.

potential. The Krein-Rutman theorem may not apply whereas there still exists a non-negative real eigenfunction (e_0 may be not simple nor the lowest eigenvalue) (Helffer *et al.*, 1999).

In the particular case of the hydrogen atom in a constant and uniform magnetic field, Hypothesis 1 is fulfilled for all values of the magnetic field (Avron *et al.*, 1977; Avron *et al.*, 1978) and indeed concerns the lowest eigenvalue. Therefore Theorem 1 applies and furnishes relevant analytical bounds that can be improved numerically as shown in (Mouchet, 2005).

Proposition 1: The smallest eigenvalue e_0 of the (3d-)Zeeman Hamiltonian

$$H = \frac{1}{2}\left(-i\vec{\nabla} + \frac{1}{2}\vec{r}\times\vec{B}\right)^2 - \frac{1}{r} \tag{7}$$

is such that

$$\forall B \geqslant 0, \quad e_0 \leqslant -1/2 + B/2. \tag{8}$$

Proof: In cylindrical coordinates (ρ, θ, z) where the magnetic field is $\vec{B}=B\vec{u}_z$, the test function of the form $\varphi=\exp(-\sqrt{\rho^2+z^2}-B\rho^2/4)$ is constructed, according to the strategy explained in Sec. II B, in order to respect the rotational invariance of the ground state (Avron *et al.*, 1977) and eliminate both singularities at $r\to 0$ and at $\rho\to\infty$. Indeed such a choice leads straightforwardly to the bounded local energy

$$E_\varphi = -1/2 + B/2 - \frac{\rho^2 B}{2\sqrt{\rho^2+z^2}}. \tag{9}$$

The upper bound follows. ■

IV. APPLICATION TO THE MANY-BODY PROBLEM

A. Expression of the local energy in terms of two-body functions

We will consider in this section a N-body nonrelativistic bosonic system in d dimensions; $(d,N)\in(\mathbb{N}\backslash\{0,1\})^2$; whose Hamiltonian is given by

$$\tilde{H} = \sum_{i=0}^{N-1} -\frac{1}{2m_i}\Delta_i + V(\vec{r}_0, \ldots, \vec{r}_{N-1}) \tag{10}$$

acting on $\mathsf{L}^2(\mathbb{R}^{Nd})$, endowed with the canonical Lebesgue measure, and where $\forall i\in\{0,\ldots,N-1\}$, $\vec{r}_i\in\mathbb{R}^d$. Δ_i is the Laplacian in the $\vec{r}_i$ variables and $m_i\in\mathbb{R}^+\backslash\{0\}$ the mass of the ith particle. The spinless bosons interact only by the two-body radial potentials $v_{ij}=v_{ji}:\mathbb{R}\to\mathbb{R}$, i.e., V is given by

$$V = \sum_{\substack{i,j=0\\ i<j}}^{N-1} v_{ij}(r_{ij}), \tag{11}$$

where $r_{ij}=r_{ji}=\|\vec{r}_j-\vec{r}_i\|$. Once the center of mass is removed, the Hamiltonian $\tilde{H}$ leads to a reduced Hamiltonian H acting on $\mathsf{L}^2(\mathbb{R}^{(N-1)d})$ [see for instance Sec. XI.5 of (Reed and Simon, 1978b)] and we will suppose in the following that H has at least one eigenvector.[5] Therefore, Hypothesis 1 is fulfilled for e_0 being the lowest (and simple) eigenvalue. A natural choice for test functions is to consider factorized ones of the form

[5]Physically, this can be achieved with a confining external potential (a "trap" is currently used in experiments involving cold atoms). Formally, this can be obtained in the limit of one mass, say m_0, being much larger than the others. The external potential appears to be the $v_{0,i}$'s, created by such an infinitely massive motionless device. It will trap the remaining $N-1$ particles in some bounded states if the $v_{0,i}$'s increase sufficiently rapidly with the $r_{0,i}$'s.

$$\varphi(\vec{r}_0,\ldots,\vec{r}_{N-1}) = \prod_{\substack{i,j=0\\ i<j}}^{N-1} \phi_{ij}(r_{ij}), \tag{12}$$

where $\phi_{ij} \in \mathsf{L}^2(\mathbb{R}^+)$ and $\phi_{ji}=\phi_{ij}>0$. One can check easily that the total momentum of such a test function vanishes. The corresponding local energy (1) is given by

$$E_\varphi(q_N) = \sum_{\substack{i,j=0\\ i<j}}^{N-1} \left[\frac{-1}{2m_{ij}\phi_{ij}(r_{ij})} \left(\phi''_{ij}(r_{ij}) + \frac{d-1}{r_{ij}} \phi'_{ij}(r_{ij}) \right) + v_{ij}(r_{ij}) \right] - \sum_{(\widehat{j,i,k})} \frac{1}{m_i} S'_{ij}(r_{ij}) S'_{ik}(r_{ik}) \cos(\widehat{j,i,k}), \tag{13}$$

where $q_N \in \mathcal{Q}_N = \mathbb{R}^{(N-1)d}$ stands for the $(N-1)d$ relative coordinates $(\vec{r}_1-\vec{r}_0,\ldots,\vec{r}_{N-1}-\vec{r}_0)$, m_{ij} for the reduced masses $m_i m_j/(m_i+m_j)$, S'_{ij} is the derivative of $S_{ij}=\ln(\phi_{ij})$. The last sum involves all the $N(N-1)(N-2)/2$ angles $(\widehat{j,i,k})$ between $\vec{r}_j-\vec{r}_i$ and $\vec{r}_k-\vec{r}_i$ that can be formed with all the triangles made of three distinct particles.

Whenever each v_{ij} allows for a two-body bounded state, we can choose ϕ_{ij} to be the eigenvector of $-(2m_{ij})^{-1}\Delta+v_{ij}$ having the smallest eigenvalue $\epsilon^{(2)}_{ij}$. Moreover, if $v_{ij}(r)$ is bounded when $r\to\infty$, from an elementary semiclassical analysis [see for instance (Maslov and Fedoriuk, 1981)] it follows that S'_{ij} is also bounded since asymptotically we have $S'_{ij}(r)\sim_{r\to\infty} -\sqrt{2m_{ij}[v_{ij}(r)-\epsilon^{(2)}_{ij}]}$. It follows that the local energy is also bounded and finite lower and upper bounds on e_0 can be found. For instance, directly from expression (13), we have the following.

Proposition 2: If, for all $(i,j)\in\{0,\ldots,N-1\}^2$, $i\neq j$, $v_{ij}(r)$ *is bounded when* $r\to\infty$ *and* $-(2m_{ij})^{-1}\Delta+v_{ij}$ *has a smallest eigenvalue* $\epsilon^{(2)}_{ij}$ *obtained for* $\phi_{ij}=\exp S_{ij}$, *then the smallest eigenvalue* e_0 *of the N-body Hamiltonian in the center-of-mass frame is bounded by*

$$\sum_{\substack{i,j=0\\ i<j}}^{N-1} \epsilon^{(2)}_{ij} - \frac{s^2}{2m} N(N-1)(N-2) \leqslant e_0 \leqslant \sum_{\substack{i,j=0\\ i<j}}^{N-1} \epsilon^{(2)}_{ij} + \frac{s^2}{2m} N(N-1)(N-2), \tag{14}$$

where $m=\min_i m_i$ *and* $s=\max_{i,j} \sup_{\mathbb{R}^+} |S'_{ij}|$.

For potentials that are relevant in physics [see for instance the effective power-law potentials of the form $v_{ij}(r)=\mathrm{sign}(\beta) r^\beta$; $\beta\in\mathbb{R}$; between massive quarks as studied by Benslama *et al.*, 1998], the analytic form of the two-body eigenvector is not known in general and some numerical computations are required to obtain the absolute maximum and minimum of the local energy (13).

B. The local energy for a general Coulombian problem

When N is large, the estimation (14) is quite rough, in particular it does not take into account the constraints between the several angles. More precise results are obtained for the Coulombian problem where $v_{ij}(r)=e_{ij}/r$ with $e_{ij}\in\mathbb{R}$ and $d>1$. In that case, provided a bounded state exists and that we keep the test function (12) in $\mathsf{L}^2(\mathbb{R}^{(N-1)d})$, we choose a constant derivative $S'_{ij}=2e_{ij}m_{ij}/(d-1)$ in order to get rid of the Coulombian singularities of V. We obtain a bounded local energy given by

$$E_\varphi(q_N) = \sum_{\substack{i,j=0\\ i<j}}^{N-1} -\frac{2m_{ij}e_{ij}^2}{(d-1)^2} - \frac{4}{(d-1)^2} \sum_{(\widehat{j,i,k})} \frac{m_{ij}m_{ik}e_{ij}e_{ik}}{m_i} \cos(\widehat{j,i,k}). \tag{15}$$

C. Identical purely attractive Coulombian particles

The case where all the N particles are identical and attract each other, i.e., when $\forall(i,j)\in\{0,\ldots,N-1\}^2$, $i\neq j$, $m_i=1$ and $e_{ij}=-1$, has been extensively studied in the literature, in particular the asymptotic behavior of e_0 with large N may have some dramatic consequences on the

thermodynamical limit (Fisher and Ruelle, 1966; Lenard and Dyson, 1967; Lévy-Leblond, 1969; Lieb, 2005). The local energy method allows to obtain in a much simpler way energy bounds that are comparable to those already obtained by other methods. Actually, (15) simplifies to

$$E_\varphi(q_N) = -\frac{1}{(d-1)^2}\left[\tfrac{1}{2}N(N-1) + F_N(q_N)\right] \tag{16}$$

with $F_2 \equiv 0$ and for $N \geqslant 3$,

$$F_N(q_N) = \sum_{\widehat{(j,i,k)}} \cos(\widehat{j,i,k}). \tag{17}$$

The angular function F_N depends only on the geometrical configuration of the N vertices $(\vec{r}_0, \ldots, \vec{r}_{N-1})$, i.e., it is invariant under the group of Euclidean isometries and the scale invariance of the Coulombian interaction makes it invariant under dilations as well.

Lemma 1: $\inf_{\mathcal{Q}_3} F_3 = 1$ *is obtained when the three points are aligned.* $\sup_{\mathcal{Q}_3} F_3 = 3/2$ *is obtained when the three points make an equilateral triangle.*

Proof: The extrema of F_3 correspond to the extrema of the function defined by $(\theta_0, \theta_1, \theta_2) \mapsto \cos\theta_0 + \cos\theta_1 + \cos\theta_2$ under the constraint $\theta_0 + \theta_1 + \theta_2 = \pi$ for $(\theta_0, \theta_1, \theta_2)$ being the three angles $\widehat{(1,0,2)}$, $\widehat{(0,1,2)}$, $\widehat{(0,2,1)}$, respectively. The Lagrange multiplier method leads to the determination of the extrema of the function $[0;\pi]^3 \to \mathbb{R}$ defined by $(\theta_0, \theta_1, \theta_2) \mapsto \cos\theta_0 + \cos\theta_1 + \cos\theta_2 + l(\theta_0 + \theta_1 + \theta_2 - \pi)$; $l \in \mathbb{R}$. We immediately obtain that the extremal points are located at $(\theta_0, \theta_1, \theta_2) = (\pi/3, \pi/3, \pi/3)$ and $(\theta_0, \theta_1, \theta_2) = (0, 0, \pi)$ together with the solutions that are obtained by circular permutations. It is easy to check that the first solution provides an absolute maximum for F_3 and the second ones an absolute minimum. ■

An immediate consequence of the preceding lemma is the following.

Proposition 3: The lowest energy e_0 *of* $N \geqslant 2$ *identical attractive Coulombian spinless particles in* $d > 1$ *dimensions is such that*

$$e_0 \leqslant -\frac{1}{(d-1)^2}\frac{1}{6}N(N-1)(N+1) \tag{18}$$

when the individual masses equal to unity and the attractive potential is $-1/r$.

Proof: The sum on the angles that defines F_N in (17) can be written as a sum of $N(N-1)(N-2)/6$ F_3-terms calculated for all the triangles that belong to the N-uplet made of the N vertices. Since, from Lemma 1 the absolute minimum of F_3 is obtained for a flat configuration, when all the N points are aligned all the F_3-terms reach their absolute minimum simultaneously and the absolute minimum of F_N is obtained. We have

Lemma 2: $\inf_{\mathcal{Q}_N} F_N = \frac{1}{6}N(N-1)(N-2)$ *is obtained when all the N points are aligned.*

The upper bound (18) follows from (16). ■

More generally, for a given N-uplet (i.e., a set of exactly N points), clustering the sum (17) in M-uplets $(N \geqslant M \geqslant 3)$ allows to find bounds on F_N from bounds on F_M. Indeed, we can write

$$F_N(q_N) = \sum_{q_M} \frac{(M-3)!\,(N-M)!}{(N-3)!} F_M(q_M), \tag{19}$$

where the sum is taken on all the M-uplets, labeled by the coordinates q_M, that belong to the given N-uplet. This sum involves exactly $N!/(M!\,(N-M)!)$ terms and we have, therefore,

Lemma 3: $\forall (N,M) \in \mathbb{N}^2$ *such that* $N \geqslant M \geqslant 3$,

$$\sup_{\mathcal{Q}_N} F_N \leqslant \frac{N(N-1)(N-2)}{M(M-1)(M-2)} \sup_{\mathcal{Q}_M} F_M. \tag{20}$$

For a given N, $\sup_{\mathcal{Q}_N} F_N$ is not known exactly but the ordered sequence

$$\frac{\sup_{\mathcal{Q}_N} F_N}{N(N-1)(N-2)} \leqslant \frac{\sup_{\mathcal{Q}_{N-1}} F_{N-1}}{(N-1)(N-2)(N-3)} \leqslant \cdots \leqslant \frac{\sup_{\mathcal{Q}_M} F_M}{M(M-1)(M-2)} \leqslant \cdots \leqslant \frac{\sup_{\mathcal{Q}_3} F_3}{3.2.1} = \frac{1}{4} \tag{21}$$

shows that in order to improve the lower bounds on (16), we must try to find $\sup_{\mathcal{Q}_M} F_M$ with M being the largest as possible. However, when considering identity (19) for $N=4$ and $M=3$ together with Lemma 1 we have the following.

Lemma 4: $\sup_{\mathcal{Q}_4} F_4=6$ *is obtained when the four points make a regular tetrahedron.*

Then $\sup_{\mathcal{Q}_4} F_4/(4.3.2)=\sup_{\mathcal{Q}_3} F_3/(3.2.1)=1/4$ and no better estimate is obtained when considering $M=4$ rather than $M=3$. Numerical investigations lead to the following conjectures.

Conjecture 1: (C_5) *When* $d=3$,

$$\sup_{\mathcal{Q}_5} F_5 = \frac{9}{2} + \frac{6(h_0+1)}{\sqrt{h_0^2+\frac{1}{3}}} - \frac{1}{h_0^2+\frac{1}{3}} \simeq 14.591\,594$$

with

$$6h_0 = 1 + \sqrt{-1 + \sqrt[3]{7+4\sqrt{3}} + \frac{1}{\sqrt[3]{7+4\sqrt{3}}}} + \sqrt{-2 - \sqrt[3]{7+4\sqrt{3}} - \frac{1}{\sqrt[3]{7+4\sqrt{3}}} + 8\frac{1}{\sqrt{-1+(7+4\sqrt{3})^{1/3}+(7+4\sqrt{3})^{-1/3}}}} \tag{22}$$

is obtained when the five points make two mirror-symmetric tetrahedrons sharing one common equilateral basis, their other faces being six isosceles identical triangles.

Remark 2: The only free parameter of the specific configuration can be chosen to be the height h of one tetrahedron (the length of the edges of the common equilateral basis being fixed to one). The maximum of $h\mapsto F_5$ *is reached for* h_0 *being the greatest solution of* $9h^4-6h^3+3h^2-2h+1/3$ *that is precisely given by* (22).

Remark 3: The pyramidal configurations with a squared basis leads to a local maximum that gives $F_5=15/2+5\sqrt{2}\simeq 14.57$.

Conjecture 2: (C_6) *When* $d=3$, $\sup_{\mathcal{Q}_6} F_6=12(1+\sqrt{2})$ *is obtained when the six points make a regular octahedron.*

Conjecture 3: (C_8) *When* $d=3$,

$$\sup_{\mathcal{Q}_8} F_8 = 16\left[\frac{4}{5} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{5}} + \frac{4(1+\sqrt{2})}{\sqrt{5}\sqrt{5+4\sqrt{2}}} + \frac{3+2\sqrt{2}}{\sqrt{5+4\sqrt{2}}} - \frac{1}{5+4\sqrt{2}}\right] \simeq 79.501$$

is obtained when the eight points make two identical squares (whose edges have length one) lying in two parallel planes separated by a distance $h=\sqrt{1+2\sqrt{2}}/2$. *The axis joining the centers of the two squares is perpendicular to the squares and the two squares are twisted one from the other by a relative angle of* $\pi/4$.

Remark 4: The cube corresponds to $F_8=8(3\sqrt{2}+\sqrt{3}+3/2+\sqrt{6})\simeq 79.393$.

Conjecture 4: (C_∞) *When* $d=3$ *and* $N\to\infty$, *the configuration that maximizes* F_N *corresponds to N points uniformly distributed on a sphere and* $\sup_{\mathcal{Q}_N} F_N \sim \frac{2}{9}N^3+o(N^3)$.

Remark 5: The ambiguity of distributing N points uniformly on a sphere (Saff and Kuijlaars, 1997 and references therein) vanishes for large N as far as a uniform density is obtained. Assuming such a uniform density, the continuous limit of F_N/N^3 *is a triple integral on the sphere than can be computed exactly to* $2/9$.

The upper bound (18) for $d=3$ is slightly above the one obtained by Lévy-Leblond, 1969, Eq. (17), p. 807, namely $-(5/8)^2N(N-1)^2/8$, and the numerical estimate $-0.0542N(N-1)^2$ by Basdevant *et al.*, 1990, Eq. (16), p. 63. For the lower bounds, from Lemmas 1 or 4, we have obtained the following.

Proposition 4: The lowest energy e_0 of $N \geqslant 2$ identical attractive Coulombian spinless particles in $d > 1$ dimensions is such that

$$-\frac{1}{(d-1)^2}\frac{1}{4}N^2(N-1) \leqslant e_0 \tag{23}$$

when the individual masses equal to unity and the attractive potential is $-1/r$.

The same result has been obtained for $d=3$ by Basdevant *et al.*, 1990, Eq. (11), p. 62 and is slightly better than $-N(N-1)^2/8$ given by Lévy-Leblond, 1969 Eq. (13), p. 807. For $N \geqslant M \geqslant 4$, this lower bound can be improved to

$$-\frac{1}{(d-1)^2}N(N-1)\left(\frac{1}{2}+\alpha_M(N-2)\right) \leqslant e_0 \tag{24}$$

with

$$\alpha_M = \frac{\sup_{\mathcal{Q}_M} F_M}{M(M-1)(M-2)} \leqslant \frac{1}{4}. \tag{25}$$

If conjecture (C_5) [respectively (C_6), (C_8), and (C_∞)] is correct we get, when $d=3$, $\alpha_5 \simeq 0.2432$ (respectively, $\alpha_6 \simeq 0.2414$, $\alpha_8 \simeq 0.2366$, and $\alpha_\infty \sim 2/9$) and the lower bounds are, therefore, improved.

Some numerical investigations, in particular a systematic comparison with the lower bounds obtained with variational methods in (Benslama *et al.*, 1998) for $N=3$ and $N=4$ Coulombian particles will be given elsewhere (Mouchet, 2006).

V. APPLICATION TO DISCRETE HAMILTONIANS

Where $q \in \mathbb{Z}^d$; $d \in \mathbb{N}$; the discretized analog of a local differential operator corresponds to a Hamiltonian that couples at most a finite number of basis vectors (e.g., the nearest neighbors on the lattice $\mathbb{Z}^d$). For instance, when $d=1$, it can be seen as a Hermitian band matrix (finite or infinite) of finite half-width in an appropriate basis. Possibly with renumbering the q's, on $\ell^2(\mathbb{Z}^d)$ H has the form:

$$(H\varphi)_q = \sum_{\substack{\nu \in \mathbb{Z}^d \\ |\nu|_\infty \leqslant N_b}} H_{q,q+\nu}\varphi_{q+\nu}, \tag{26}$$

where $N_b \in \mathbb{N}$, $\forall (q,q') \in \mathbb{Z}^d \times \mathbb{Z}^d$, $H_{q',q} = \bar{H}_{q,q'} \in \mathbb{C}$ and $|\nu|_\infty$ stands for $\max(|\nu_1|,\ldots,|\nu_d|)$. φ will be taken as a discrete set of real strictly positive numbers, and the local energy $E_\varphi(q)$ is computed, for a given q, with elementary algebraic operations whose number is finite and all the smaller than N_b are small: its value at a given q depends on $(2N_b)^d+1$ components of φ at most. Under hypothesis 1,[6] if, say, for a given test vector φ, the absolute maximum of E_φ occurs only at a unique finite q_m, one can immediately improve the upper bound by a finite amount, for instance just by varying φ_{q_m} only, until $E_\varphi(q_m)$ is not an absolute maximum anymore. Only $(2N_b)^d+1$ values of the local energy will be affected by the variation of just one component of φ. One can see easily that this approach leads to a wide variety of algorithms where a sequence of optimization steps is constructed; each step involves a number of optimization parameters and functions that is usually much smaller [of order $(2N_b)^d$ or less] than the dimension of the original matrix.

Discrete Schrödinger operators are important particular cases of Hamiltonians (26) with $N_b = 1$. They are relevant models for the description of quantum (quasi-) particles evolving in periodic crystals. For $d=1$, they can be written as

[6]We have seen at the end of Sec. II A that the symmetry hypothesis can be relaxed.

$$(H\varphi)_q = -\varphi_{q+1} - \varphi_{q-1} + V(q)\varphi_q, \tag{27}$$

where the potential V is a real bounded function on $\mathbb{Z}$. By possibly subtracting a constant positive real number to V, the bounded operator $-H$ can be made positive and ergodic: First, for any positive and non-identically vanishing φ and φ' in $\ell^2(\mathbb{Z})$, $-H\varphi$ remains positive. Second, $\langle\varphi'|(-H)^{|q'-q|}\varphi\rangle = \varphi'_{q'}\varphi_q + (\text{positive terms}) \neq 0$ for any given pair of strictly positive components $\varphi'_{q'}$ and φ_q with $q' \neq q$. [In the marginal case where φ and φ' both vanish everywhere but on the same point, we have $\langle\varphi'|(-H)\varphi\rangle) \neq 0$. Therefore Theorem XIII.43 of (Reed and Simon, 1978a) applies: if H has indeed one eigenvalue, hypothesis 1 is fulfilled for e_0 being the smallest eigenvalue of H. In that case, inequalities (2) takes the following form:

Proposition 5: When the discrete Schrödinger operator (27) *admits at least one eigenvalue and when V is bounded, then the smallest eigenvalue* e_0 *is such that,* $\forall\varphi \in \ell^2(\mathbb{Z})$ *such that* $\varphi > 0$,

$$\inf_{q\in\mathbb{Z}}\left(-\frac{\varphi_{q+1}+\varphi_{q-1}}{\varphi_q} + V(q)\right) \leqslant e_0 \leqslant \sup_{q\in\mathbb{Z}}\left(-\frac{\varphi_{q+1}+\varphi_{q-1}}{\varphi_q} + V(q)\right). \tag{28}$$

When V is actually a N-periodic real function, the spectral problem (see Reed and Simon, 1978a for instance) leads to the search of complex series $(u_q)_{q\in\mathbb{Z}}$ such that

$$\forall\,\eta = (\eta_1, \eta_2) \in [0;1[^2 \quad \begin{cases} -u_{q+1} - u_{q-1} + V(q+\eta_2)u_q = e(\eta)u_q, \\ u_{q+N} = e^{i2\pi\eta_1}u_q. \end{cases} \tag{29}$$

The spectrum of H is the bounded set $\sigma(H) = \{e(\eta)\,|\,\eta \in [0;1[^2\} \subset \mathbb{R}$. It is given by the reunion for all η's of the N eigenvalues of finite $N\times N$ Hermitian matrices $H^{(\eta)}$ obtained after transforming (29) with the one-to-one mapping $u_q \mapsto u_q \exp(-\mathrm{i}2\pi q\eta_1/N)$. As far as positive solutions of (29) are concerned, we will take $\eta_1 = 0$ and will look for the smallest eigenvalue $e_0(\eta_2)$ of

$$H^{(0,\eta_2)} = \begin{pmatrix} V(\eta_2) & -1 & 0 & \cdots & 0 & -1 \\ -1 & V(1+\eta_2) & -1 & 0 & \cdots & 0 \\ 0 & -1 & V(2+\eta_2) & -1 & \cdots & \cdots \\ 0 & \cdots & \cdots & & \cdots & \cdots \\ -1 & 0 & \cdots & 0 & -1 & V(N-1+\eta_2) \end{pmatrix}. \tag{30}$$

Remark 6: The (rational) Harper model (Harper, 1955b; Harper, 1955a) [*also called the almost Mathieu equation (Bellissard and Simon, 1982)*] *corresponds to* $V(q) = -V_0\cos(2\pi qM/N)$ *where* $V_0 > 0$, (M,N) *being strictly positive coprimes integers. For a given N and M,* $\sigma(H)$ *appears to be made of N bands. The union of these bands for each rational number* M/N *between 0 and 1 produces the so-called Hofstadter butterfly (Hofstadter, 1976).*

We are therefore able to produce two nontrivial bounds on the lowest eigenvalue $e_0(\eta_2)$ without any diagonalization:

Proposition 6: When V is N-periodic, $\forall\,\eta_2 \in [0;1[$, *the smallest eigenvalue* $e_0(\eta_2)$ *of* (30) *is such that* $\forall\varphi \in (\mathbb{R}^+\backslash\{0\})^N$,

$$\min_{q\in\{0,\ldots,N-1\}}\left(-\frac{\varphi_{q+1}+\varphi_{q-1}}{\varphi_q} + V(q+\eta_2)\right) \leqslant e_0(\eta_2) \tag{31a}$$

and

$$e_0(\eta_2) \leqslant \max_{q\in\{0,\ldots,N-1\}}\left(-\frac{\varphi_{q+1}+\varphi_{q-1}}{\varphi_q} + V(q+\eta_2)\right) \tag{31b}$$

(the indices labeling the components of φ *are taken modulo N).*

Therefore, we can bound the bottom of the Hofstadter butterfly with the help of any test function.

Corollary 1: For the rational Harper Hamiltonian

$$H\varphi_q = -\varphi_{q+1} - \varphi_{q-1} - V_0 \cos\left(2\pi q \frac{M}{N}\right)\varphi_q, \tag{32}$$

we have $\forall \varphi \in (\mathbb{R}^+\backslash\{0\})^N$

$$\min_{q\in\{0,\ldots,N-1\}}\left[-\frac{\varphi_{q+1}+\varphi_{q-1}}{\varphi_q} - V_0 \cos\left(2\pi q \frac{M}{N}\right)\right] \leqslant \inf[\sigma(H)] \tag{33a}$$

and

$$\inf[\sigma(H)] \leqslant \max_{q\in\{0,\ldots,N-1\}}\left[-\frac{\varphi_{q+1}+\varphi_{q-1}}{\varphi_q} - V_0 \cos\left(2\pi q \frac{M}{N}\right)\right]. \tag{33b}$$

Proof: In the Harper model, for each rational number M/N, the lowest eigenvalue is obtained for $\eta=(0,0)$. It is a direct application of Reed and Simon, 1978a, Theorem XIII.89(e) and thus inequalities (33) follow directly from (31). ■

Choosing for φ, at first guess, semiclassical approximations (i.e., corresponding to large N) constructed from Mathieu functions are therefore expected to provide numerical reasonable bounds.

VI. CONCLUSION

It has been shown on various examples how theorem 1 can be used to obtain rigorous estimates on the principal value of any symmetric operator. Its simplicity, its low cost in computations and its wide domain of applications make the method presented in this article a powerful tool for controlling bounds. In many situations, it provides nontrivial complementary information to those obtained by traditional or more system-dependent methods. Unfortunately, this paper does not extend the method to fermionic systems (see for instance, Sigal, 1995 and references therein) where the spatial wave function of the ground state has generically nontrivial nodes (Ceperley, 1991) that cannot be known *a priori* even with some considerations on symmetries.

This paper presents some clues for further developments of optimization algorithms. However it remains an open question whether such algorithms really bear the potential of an efficient treatment and will overcome the possible difficulties one may face in realistic problems.

Covariant canonical formalism for four-dimensional BF theory

Mauricio Mondragón[a),c)] and Merced Montesinos[b),d)]
Departamento de Física, Cinvestav, Av. Instituto Politécnico Nacional 2508, San Pedro Zacatenco, 07360, Gustavo A. Madero, Ciudad de México, México

(Received 24 February 2004; accepted 16 November 2005; published online 8 February 2006)

The covariant canonical formalism for four-dimensional BF theory is performed. The aim of the paper is to understand in the context of the covariant canonical formalism both the reducibility that some first class constraints have in Dirac's canonical analysis and also the role that topological terms play. The analysis includes also the cases when both a cosmological constant and the second Chern character are added to the pure BF action. In the case of the BF theory supplemented with the second Chern character, the presymplectic 3-form is different to the one of the BF theory in spite of the fact both theories have the same equations of motion while on the space of solutions they both agree to each other. Moreover, the analysis of the degenerate directions shows some differences between diffeomorphisms and internal gauge symmetries. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2161805]

I. INTRODUCTION

In the path integral quantization of a given field theory one needs to sum the exponential of the classical action weighted with a suitable factor over all possible configurations of the fields under consideration. If the theory under study is a gauge theory one needs, in addition, to factor out the gauge transformations in such a way that the sum includes only equivalence classes of gauge transformed fields. So, intuitively, it is expected that any change in the action principle, yielding the same classical equations of motion, provides a completely different quantum theory. For instance, if the Yang-Mills Lagrangian density $\mathrm{tr}\, F\wedge\star F$ is modified adding the term $\theta\,\mathrm{tr}\, F\wedge F$ the resulting quantum theory is sensitive to this contribution even when it does not modify the classical equations of motion.[1] One way to understand, at the classical level, the cause of having a different quantum theory for the Yang-Mills field is to realize that, in the generic case, the specification of the Lagrangian density is equivalent to specify the symplectic geometry in the various phase spaces associated with the classical theory. Thus, if the Lagrangian density changes, the symplectic geometry also does generically. If one accepts that what defines a dynamical system is its equations of motion then this knowledge is not enough to specify the symplectic geometry on the various phase spaces involved. If, on the other hand, one accepts that what defines a dynamical system is its equations of motion plus an action principle (which provides its equations of motion), then one is in a different situation. The difference is that, as we have already mentioned, the specification of the Lagrangian density provides a symplectic structure. Thus, an action principle plays a double role: (1) it provides the equations of motion and also (2) provides the symplectic geometry. Before going into the analysis of the BF theory, which is the subject of

this paper, let us emphasize this point with a very simple example borrowed from dynamical systems with a finite number of degrees of freedom. The equations of motion for the two-dimensional isotropic harmonic oscillator $\ddot{x}+\omega^2 x=0$ and $\ddot{y}+\omega^2 y=0$ can be obtained from the Lagrangian $\mathcal{L}(x,y,\dot{x},\dot{y})=m(\dot{x}\dot{y}-\omega^2 xy)$ or from $\mathcal{L}_{\text{usual}}(x,y,\dot{x},\dot{y})=\frac{1}{2}m(\dot{x}^2+\dot{y}^2-\omega^2x^2-\omega^2y^2)$. Moreover, $\mathcal{L}\neq\mathcal{L}_{\text{usual}}+\mathrm{d}F(x,y,t)/\mathrm{d}t$. Note also that we are not making a change of coordinates, which are the same for both cases. The symplectic structures coming from these Lagrangians are very distinct to each other even when they both provide the same equations of motion.[2] Coming back to field theory, it has been shown, in the context of Dirac's canonical analysis, that the symplectic potential changes if one adds topological terms to the Lagrangian density of tetrad gravity.[3] On the other hand, using the covariant canonical formalism, it has been shown that the inclusion of topological terms in Lagrangians for string theory also modifies the original symplectic potential.[4,5]

In this paper, in the context of the covariant canonical formalism,[6–9] we perform the covariant canonical analysis of four-dimensional BF theory, BF theory plus a cosmological constant Λ, and BF plus the second Chern character $F^{IJ}\wedge F_{IJ}$. These theories are topological in the sense that there is no fixed background metric g on the four-dimensional manifold $\mathcal{M}$ in which they are defined. In addition, they are topological in the sense that they have no local degrees of freedom. A more detailed analysis of the covariant canonical formalism for BF theory can be found in Ref. 10. Of course, the inclusion of the second Chern character does not modify the equations of motion while the cosmological constant does. However, the aim of the paper is to study the symplectic geometry involved. It must be emphasized that Dirac's canonical analysis for BF theory has been already done[11,12] (see also the Appendix). In Ref. 12 it is shown that the first class constraints $\tilde{\Psi}^a{}_{IJ}:=\frac{1}{2}\tilde{\eta}^{abc}F_{bcIJ}(A)\approx 0$ are reducible. Dirac's canonical analysis for BF theory with a cosmological constant is reported in the Appendix, where it is shown that now the reducibility equations involve both the Gauss constraints $\tilde{\Psi}^{IJ}$ and the other set of first class constraints $\tilde{\Psi}^a{}_{IJ}:=\frac{1}{2}\tilde{\eta}^{abc}F_{bcIJ}-\Lambda\epsilon_{IJKL}\tilde{\Pi}^{aKL}\approx 0$. This is so because of the cosmological constant Λ. In both cases, the reducibility equations in Dirac's canonical analysis come from the Bianchi identities $DF_{IJ}=0$. So, the covariant canonical formalism is an opportunity to understand the role these identities play on this formalism.

II. BF THEORY

The four-dimensional BF theory with SO(3,1) as the internal relevant group is defined by the equations of motion

$$F_{IJ}=0,\quad DB^{IJ}=0, \tag{1}$$

where $F_{IJ}(A)=\mathrm{d}A_{IJ}+A_{IK}\wedge A^K{}_J$ is the curvature of the Lorentz connection 1-form A_{IJ}, $B^{IJ}=\frac{1}{2}B^{IJ}_{\alpha\beta}\,\mathrm{d}x^\alpha\wedge\mathrm{d}x^\beta$ is a set of six 2-forms, $DB^{IJ}:=\mathrm{d}B^{IJ}+A^I{}_K\wedge B^{KJ}+A^J{}_K\wedge B^{IK}$ is the covariant derivative of B^{IJ}; $I,J=0,1,2,3$ are Lorentz indexes which are raised and lowered with the Minkowski metric η_{IJ}. Even though the analysis will be restricted to a Lorentz BF theory, the results are generic in the sense that hold for any BF theory in 4-space-time dimensions. The choice of the Lorentz group is only to fix the notation that might be used for the case of BF gravity.

In the context of the covariant canonical formalism, the *kinematical* phase space $\mathcal{F}$ of the theory is defined as the space formed by all smooth Lorentz connections A_{IJ} and B^{IJ} fields. Any generic point of $\mathcal{F}$ is not required to satisfy the equations of motion of the BF theory. The space of solutions to the equations of motion $\bar{\mathcal{F}}$ is considered as submanifold of $\mathcal{F}$ and is formed by all points of $\mathcal{F}$ that satisfy the equations of motion of Eq. (1). The reduced (or physical) phase space for the theory is reached by making the quotient of $\bar{\mathcal{F}}$ by the gauge transformations of the theory.[6,7] Even though the term "phase space" has been used to name these different manifolds, it must be emphasized that, at this stage, $\mathcal{F}$, $\bar{\mathcal{F}}$, and the reduced phase space carry no intrinsic symplectic geometry. Thus, although the equations of motion of Eq. (1) are used to define $\bar{\mathcal{F}}$, they are not enough to uniquely endow the various phase spaces for the theory already mentioned with sym-

plectic geometry. Where does symplectic geometry come from then? One possibility is from action principles, specifying the Lagrangian density.[13] The equations of motion of Eq. (1) are usually obtained from the action[11]

$$S[A,B] = \int_{\mathcal{M}} B^{IJ} \wedge F_{IJ}[A] \tag{2}$$

(see also Refs. 14 and 15 for alternative choices of the action). To get the geometry, one needs to proceed along the following lines. The first order variation of the Lagrangian 4-form $\mathbf{L}[A,B] = B^{IJ} \wedge F_{IJ}[A]$ is

$$\delta\mathbf{L}[A,B] = (\delta B^{IJ}) \wedge F_{IJ} - (DB^{IJ}) \wedge \delta A_{IJ} + \mathrm{d}\boldsymbol{\Theta}(B,\delta A), \tag{3}$$

from which the *presymplectic potential* 3-form

$$\boldsymbol{\Theta}(B,\delta A) := B^{IJ} \wedge \delta A_{IJ}, \tag{4}$$

is read off. Now, by taking into account an arbitrary smooth two-parameter family of field configurations and computing the antisymmetric combination of the variations in $\mathbf{L}[A,B],[\delta_1,\delta_2]\mathbf{L}[A,B]=0$ yields[8]

$$\mathrm{d}\omega(\delta_1 A,\delta_1 B,\delta_2 A,\delta_2 B) = (\delta_1 B^{IJ}) \wedge \delta_2 F_{IJ} - (\delta_2 DB^{IJ}) \wedge \delta_1 A_{IJ} - (\delta_1 \leftrightarrow \delta_2), \tag{5}$$

where

$$\omega(\delta_1 A,\delta_1 B,\delta_2 A,\delta_2 B) = (\delta_1 B^{IJ} \wedge \delta_2 A_{IJ} - \delta_2 B^{IJ} \wedge \delta_1 A_{IJ}) \tag{6}$$

is the *presymplectic* 3-form.[16]

A. "Fundamental" set of local gauge transformations

(i) *Local Lorentz transformations*: The action is fully gauge invariant under any arbitrary finite local Lorentz transformation. The infinitesimal version of this transformation is

$$\delta_\epsilon A_{IJ} = D\epsilon_{IJ},$$

$$\delta_\epsilon B^{IJ} = -\epsilon^I{}_K B^{KJ} - \epsilon^J{}_K B^{IK}, \tag{7}$$

where ϵ_{IJ} are the infinitesimal gauge parameters. The change of the Lagrangian $\mathbf{L}[A,B]$ induced by the infinitesimal variation of the fields, given in Eq. (7), is

$$\delta_\epsilon \mathbf{L}[A,B] = \delta_\epsilon B^{IJ} \wedge F_{IJ} + B^{IJ} \wedge \delta_\epsilon F_{IJ} = 0. \tag{8}$$

Therefore, from Eqs. (3) and (8) the *Noether current* 3-form $\mathbf{J}_N[A,B,\epsilon]$ (Ref. 8) associated with the symmetry (7) is[17]

$$\mathbf{J}_N[A,B,\epsilon] = \boldsymbol{\Theta}(B,D\epsilon_{IJ}) = B^{IJ} \wedge D\epsilon_{IJ}, \tag{9}$$

which can be rewritten as

$$\mathbf{J}_N[A,B,\epsilon] = \mathrm{d}\mathbf{Q}[B,\epsilon] - \epsilon_{IJ} \wedge DB^{IJ}, \tag{10}$$

with

$$\mathbf{Q}[B,\epsilon] := \epsilon_{IJ} B^{IJ}, \tag{11}$$

the corresponding *Noether current potential* 2-form. Equation (10) has the *same* structure that appears in the Noether current associated with infinitesimal diffeomorphisms in theories with dynamical background metric in the sense that the right-hand side of Eq. (10) is the exterior derivative of the Noether current potential 2-form $\mathbf{Q}[B,\epsilon]$ plus a term proportional to (one set of)

the equations of motion.[18] There is *a priori* no reason for an internal symmetry, like (7), behaves in the same manner as diffeomorphisms.

Degenerate directions: These can be obtained from the symplectic inner product between the gauge transformation δ_ϵ and an arbitrary variation δ by taking $\delta_1 \equiv \delta$ and $\delta_2 = \delta_\epsilon$. From Eqs. (6) and (7),

$$\omega(\delta A, \delta B, \delta_\epsilon A, \delta_\epsilon B) = \mathrm{d}(\epsilon_{IJ}\delta B^{IJ}) - \epsilon_{IJ}\delta(DB^{IJ}) = \mathrm{d}(\delta \mathbf{Q}[B,\epsilon]) - \epsilon_{IJ}\delta(DB^{IJ}). \tag{12}$$

Note that on the right-hand side of Eq. (12) appears one term involving the linearized Eulerian derivative, $\delta(DB^{IJ})$, but no terms proportional to Eulerian derivatives themselves appear explicitly. As it will be seen, later on, this is a difference with respect to infinitesimal diffeomorphisms (see Sec. II B). Thus, we have

$$\Omega_\Sigma(\delta A, \delta B, \delta_\epsilon A, \delta_\epsilon B) \coloneqq \int_\Sigma \omega(\delta A, \delta B, \delta_\epsilon A, \delta_\epsilon B) = -\int_\Sigma \epsilon_{IJ}\delta DB^{IJ} + \int_{\delta\Sigma} (\epsilon_{IJ}\delta B^{IJ}). \tag{13}$$

The integral over Σ depends on the gauge parameters ϵ_{IJ}, the fields (A_{IJ}, B^{KL}) and their variations while the integral over $\delta\Sigma$ depends only on the gauge parameters ϵ_{IJ} and the variation of the B^{IJ} fields, δB^{IJ}. Both integrals, in general, do not vanish and therefore the gauge transformation of Eq. (7) does not qualify as a degenerate direction unless additional assumptions are imposed. In particular, one has the following.

Proposition: If the linearized Eulerian derivative $\delta(DB^{IJ})$ vanishes, $\delta(DB^{IJ}) = 0$, and the arbitrary variations δB^{IJ} have compact support in the interior of Σ, $\delta B^{IJ}|_{\delta\Sigma} = 0$, then

$$\Omega_\Sigma(\delta A, \delta B, \delta_\epsilon A, \delta_\epsilon B) = 0, \tag{14}$$

without imposing any additional restrictions on the gauge parameters ϵ_{IJ}. Note that (A_{IJ}, B^{KL}) need not be a point of the space of solutions to the equations of motion $\bar{\mathcal{F}}$ in order for Eq. (14) to hold (see also Ref. 19). Nevertheless, it is a common fact to restrict the analysis to $\bar{\mathcal{F}}$ and also to take $(\delta A_{IJ}, \delta B^{KL})$ as tangent vectors to $\bar{\mathcal{F}}$. Of course, the integral over $\partial\Sigma$ in Eq. (13) also vanishes if the gauge parameters ϵ_{IJ} vanish at $\partial\Sigma$, i.e., if the infinitesimal gauge transformation of Eq. (7) is the identity at $\partial\Sigma$.

Canonical transformations:

Proposition: The infinitesimal gauge transformation of Eq. (7) is a canonical transformation.

Proof: From the gauge transformation of Eq. (7),

$$A'_{IJ} = A_{IJ} + D\epsilon_{IJ},$$

$$B'^{IJ} = B^{IJ} - \epsilon^I{}_K B^{KJ} - \epsilon^J{}_K B^{IK}, \tag{15}$$

we can compute two arbitrary variations of the gauge-transformed fields of Eq. (15) (Ref. 7),

$$\delta_i A'_{IJ} = \delta_i A_{IJ} - \delta_i A^K{}_I \epsilon_{KJ} - \delta_i A^K{}_J \epsilon_{IK},$$

$$\delta_i B'^{IJ} = \delta_i B^{IJ} - \epsilon^I{}_K \delta_i B^{KJ} - \epsilon^J{}_K \delta_i B^{IK}. \tag{16}$$

So,

$$\begin{aligned}\omega' \coloneqq (\delta_1 B'^{IJ} \wedge \delta_2 A'_{IJ} - \delta_2 B'^{IJ} \wedge \delta_1 A'_{IJ}) &= (\delta_1 B^{IJ} - \epsilon^I{}_K \delta_1 B^{KJ} - \epsilon^J{}_K \delta_1 B^{IK}) \wedge (\delta_2 A_{IJ} - \delta_2 A^K{}_I \epsilon_{KJ} \\ &- \delta_2 A^K{}_J \epsilon_{IK}) - (\delta_2 B^{IJ} - \epsilon^I{}_K \delta_2 B^{KJ} - \epsilon^J{}_K \delta_2 B^{IK}) \wedge (\delta_1 A_{IJ} - \delta_1 A^K{}_I \epsilon_{KJ} - \delta_1 A^K{}_J \epsilon_{IK}) = \omega,\end{aligned} \tag{17}$$

exactly, i.e., without using any additional conditions. Therefore,

$$\Omega'_\Sigma \coloneqq \int_\Sigma \omega(\delta_1 A', \delta_1 B', \delta_2 A', \delta_2 B') = \int_\Sigma \omega(\delta_1 A, \delta_1 B, \delta_2 A, \delta_2 B) = \Omega_\Sigma. \tag{18}$$

(ii) *B's transform like connections*: The infinitesimal version of this gauge transformation is

$$\delta_\chi A_{IJ} = 0,$$

$$\delta_\chi B^{IJ} = D\chi^{IJ}, \tag{19}$$

where the gauge parameters χ^{IJ} are 1-forms. However, this symmetry is peculiar in the sense that it does not satisfy the definition of symmetry in a strict sense.[8] To see this, the variation of the Lagrangian $\mathbf{L}[A,B]$ induced by the variation of the fields is computed

$$\delta_\chi \mathbf{L}[A,B] = D\chi^{IJ} \wedge F_{IJ}, \tag{20}$$

which has not the desired form in the sense that the right-hand side of Eq. (20) is not of the form $\mathrm{d}\boldsymbol{\alpha}$. To continue, we must rewrite the right-hand side of the last equation,

$$\delta_\chi \mathbf{L}[A,B] = \mathrm{d}(\chi^{IJ} \wedge F_{IJ}) + \chi^{IJ} \wedge DF_{IJ}. \tag{21}$$

Thus, the right-hand side of Eq. (21) is not, in a strict sense, of the form $\mathrm{d}\boldsymbol{\alpha}$. It acquires this form just if the Bianchi identities $DF_{IJ}=0$ are used. However, when computing the transformation of the Lagrangian $\mathbf{L}[A,B]$ induced by the transformation of the fields it is not allowed to use the equations of motion in order to check if the transformation of the fields does (or does not) qualify as a gauge symmetry. A purist might say that the second term on the right-hand side of Eq. (21) involves no equations of motion simply because the Bianchi identities do *not* qualify as equations of motion in the sense that they do not appear when the first order variation of the Lagrangian is computed [see Eq. (3)].

Therefore, from Eqs. (3) and (21),

$$\mathrm{d}(\chi^{IJ} \wedge F_{IJ}) + \chi^{IJ} \wedge DF_{IJ} = (D\chi^{IJ}) \wedge F_{IJ}, \tag{22}$$

and so

$$\mathrm{d}\mathbf{J}_N[A,\chi] = -\chi^{IJ} \wedge DF_{IJ} + (D\chi^{IJ}) \wedge F_{IJ}, \tag{23}$$

with[17]

$$\mathbf{J}_N[A,\chi] := \chi^{IJ} \wedge F_{IJ}, \tag{24}$$

the Noether current associated with the local symmetry (19). Note that $\mathbf{J}_N[A,\chi]$ is proportional to the Eulerian derivative F_{IJ}. Note that if the equations of motion hold (i.e., if $F_{IJ}=0$ hold) and the Bianchi identities hold (i.e., if $DF_{IJ}=0$ hold) then the Noether current is identically conserved. Moreover, note that $\mathbf{J}_N[A,\chi]$ identically vanishes on-shell, i.e., $\mathbf{J}_N=0$ if $F_{IJ}=0$.

Degenerate directions: Again, from the symplectic inner product between the gauge transformation δ_χ and an arbitrary variation δ and Eqs. (6) and (19),

$$\omega(\delta A, \delta B, \delta_\chi A, \delta_\chi B) = \mathrm{d}(\delta(-\chi^{IJ} \wedge A_{IJ})) - \chi^{IJ} \wedge \delta F_{IJ}. \tag{25}$$

Note that on the right-hand side of Eq. (25) appears the linearized Eulerian derivative δF_{IJ} but not the Eulerian derivatives themselves in contrast to what happens with diffeomorphisms (see Sec. II B). Thus, we have

$$\Omega_\Sigma(\delta A, \delta B, \delta_\chi A, \delta_\chi B) := \int_\Sigma \omega(\delta A, \delta B, \delta_\chi A, \delta_\chi B) = -\int_\Sigma \chi^{IJ} \wedge \delta F_{IJ} - \int_{\partial\Sigma} (\chi^{IJ} \wedge \delta A_{IJ}). \tag{26}$$

Again, the integral over Σ depends on the gauge parameters χ^{IJ}, the field A_{IJ} and its first order variations δA_{IJ} while the integral over $\partial\Sigma$ depends only on the gauge parameters χ^{IJ} and the variations of the field A_{IJ}, δA_{IJ}. Both integrals, in general, do not vanish and therefore the gauge transformation of Eq. (19) does not qualify as a degenerate direction unless additional assumptions are imposed. In particular, one has the following.

Proposition: If the linearized Eulerian derivative δF_{IJ} vanishes, $\delta F_{IJ}=0$, and the arbitrary variations δA_{IJ} have compact support in the interior of Σ, $\delta A_{IJ}|_{\partial\Sigma}=0$, then

$$\Omega_\Sigma(\delta A, \delta B, \delta_\chi A, \delta_\chi B) = 0, \tag{27}$$

without imposing any additional conditions on the gauge parameters χ^{IJ}. Note also that in order for Eq. (27) to hold it is not necessary that the point (A_{IJ}, B^{KL}) belongs to the space of solutions to the equations of motion $\bar{\mathcal{F}}$. Nevertheless, it is a common fact to restrict the analysis to this case and also to take $(\delta A_{IJ}, \delta B^{KL})$ as tangent vectors to $\bar{\mathcal{F}}$. Of course, the integral over $\partial\Sigma$ in Eq. (26) also vanishes if the gauge parameters χ^{IJ} vanish at $\partial\Sigma$, i.e., if the infinitesimal gauge transformation of Eq. (19) is the identity at $\partial\Sigma$.

Canonical transformations:

Proposition: The transformation induced by the gauge symmetry of Eq. (19) is an infinitesimal canonical transformation.

Proof: In fact, from Eq. (19),

$$A'_{IJ} = A_{IJ},$$

$$B'^{IJ} = B^{IJ} + D\chi^{IJ}, \tag{28}$$

we can compute two arbitrary variations of the gauge-transformed fields[7]

$$\delta_i A'_{IJ} = \delta_i A_{IJ},$$

$$\delta_i B'^{IJ} = \delta_i B^{IJ} + \delta_i A^I{}_K \wedge \chi^{KJ} + \delta_i A^J{}_K \wedge \chi^{IK}, \quad i = 1,2. \tag{29}$$

So,

$$\omega' := (\delta_1 B'^{IJ} \wedge \delta_2 A'_{IJ} - \delta_2 B'^{IJ} \wedge \delta_1 A'_{IJ}) = (\delta_1 B^{IJ} + \delta_1 A^I{}_K \wedge \chi^{KJ} + \delta_1 A^J{}_K \wedge \chi^{IK}) \wedge \delta_2 A_{IJ} - (\delta_2 B^{IJ} + \delta_2 A^I{}_K \wedge \chi^{KJ} + \delta_2 A^J{}_K \wedge \chi^{IK}) \wedge \delta_1 A_{IJ} = \omega, \tag{30}$$

exactly, i.e., without using any additional conditions. Therefore,

$$\Omega'_\Sigma := \int_\Sigma \omega(\delta_1 A', \delta_1 B', \delta_2 A', \delta_2 B') = \int_\Sigma \omega(\delta_1 A, \delta_1 B, \delta_2 A, \delta_2 B) = \Omega_\Sigma, \tag{31}$$

under the infinitesimal gauge transformation of Eq. (19).

B. Diffeomorphisms

The gauge symmetries discussed in Sec. II A can also be obtained by using Dirac's canonical analysis. In addition, Dirac's canonical analysis shows that the full set of constraints are first class. There are no second class constraints in the theory. However, the first class constraints $\tilde{\Psi}^a{}_{IJ}$ (which generate the δ_χ symmetry) are *reducible* on account of the Bianchi identities $DF_{IJ}=0$ which imply the reducibility equation $D_a\tilde{\Psi}^a{}_{IJ}=0$. Once reducibility is taken into account the counting of the local degrees of freedom is zero, showing that the theory has only global degrees of freedom (see, for instance, Ref. 12 and the Appendix). Moreover, it is also known that the theory is diffeomorphism covariant. Therefore, the transformation of the fields induced by diffeomorphisms must be built from the "fundamental" set of gauge transformations (7) and (19). (The quotation marks in the word "fundamental" emphasize the fact that the gauge transformations are not independent on account of the reducibility of the constraints.) In fact, a diffeomorphism induces a change in the fields A_{IJ} given by

$$\delta_\xi A_{IJ} = \mathcal{L}_\xi A_{IJ} = \xi \cdot F_{IJ} + D\epsilon_{IJ} = \xi \cdot F_{IJ} + \delta_\epsilon A_{IJ}, \tag{32}$$

as well as in the fields B^{IJ},

$$\delta_\xi B^{IJ} = \mathcal{L}_\xi B^{IJ} = \xi \cdot DB^{IJ} - \epsilon^I{}_K B^{KJ} - \epsilon^J{}_K B^{IK} + D\chi^{IJ} = \xi \cdot DB^{IJ} + \delta_\epsilon B^{IJ} + \delta_\chi B^{IJ}, \tag{33}$$

where $\epsilon_{IJ} := \xi \cdot A_{IJ}$ is a set of 0-forms and $\chi^{IJ} := \xi \cdot B^{IJ}$ is a set of 1-forms.

Noether current: The *Noether current* 3-form associated with diffeomorphisms is[17]

$$\mathbf{J}_N[A,B,\xi] = \mathbf{\Theta}(B,\mathcal{L}_\xi A) - \xi \cdot \mathbf{L} = \mathrm{d}\mathbf{Q}[A,B,\xi] - (\xi \cdot A_{IJ})DB^{IJ} - (\xi \cdot B^{IJ}) \wedge F_{IJ}, \tag{34}$$

where

$$\mathbf{Q}[A,B,\xi] = (\xi \cdot A_{IJ})B^{IJ}, \tag{35}$$

is the *Noether current potential* 2-form. If (A_{IJ}, B^{IJ}) is a point of the space of solutions to the equations of motion $\bar{\mathcal{F}}$ then $\mathbf{J}_N[A,B,\xi]$ can be obtained from the Noether current potential $\mathbf{J}_N[A,B,\xi] = \mathrm{d}\mathbf{Q}[A,B,\xi]$. The *Noether charge* $\mathcal{Q}_\Sigma(\xi)$ associated with infinitesimal diffeomorphisms is given by the integral of $\mathbf{J}_N[A,B,\xi]$ over Σ,

$$\mathcal{Q}_\Sigma(\xi) := \int_\Sigma \mathbf{J}_N[A,B,\xi] = \int_{\partial\Sigma} \mathbf{Q}[A,B,\xi] - \int_\Sigma [(\xi \cdot A_{IJ})DB^{IJ} + (\xi \cdot B^{IJ}) \wedge F_{IJ}]. \tag{36}$$

Proposition: If (A_{IJ}, B^{IJ}) is a point in $\bar{\mathcal{F}}$ then the Noether charge just has a contribution from the boundary of Σ,

$$\mathcal{Q}_\Sigma(\xi) = \int_{\partial\Sigma} \mathbf{Q}[A,B,\xi] = \int_{\partial\Sigma} (\xi \cdot A_{IJ})B^{IJ}. \tag{37}$$

Canonical transformation induced by diffeomorphisms: The transformation of the fields induced by a diffeomorphism is

$$A'_{IJ} = A_{IJ} + \mathcal{L}_\xi A_{IJ},$$

$$B'^{IJ} = B^{IJ} + \mathcal{L}_\xi B^{IJ}, \tag{38}$$

and so[7]

$$\delta_i A'_{IJ} = \delta_i A_{IJ} + \delta_i(\mathcal{L}_\xi A_{IJ}) = \delta_i A_{IJ} + \mathcal{L}_\xi(\delta_i A_{IJ}),$$

$$\delta_i B'^{IJ} = \delta_i B^{IJ} + \delta_i(\mathcal{L}_\xi B^{IJ}) = \delta_i B^{IJ} + \mathcal{L}_\xi(\delta_i B^{IJ}). \tag{39}$$

Therefore, at first order in the gauge parameters,

$$\omega' := (\delta_1 B'^{IJ} \wedge \delta_2 A'_{IJ} - \delta_2 B'^{IJ} \wedge \delta_1 A'_{IJ}) = \omega + \mathcal{L}_\xi \omega. \tag{40}$$

Finally,

$$\Omega'_\Sigma := \int_\Sigma \omega' = \int_\Sigma \omega + \int_\Sigma (\xi \cdot \mathrm{d}\omega + \mathrm{d}(\xi \cdot \omega)) = \Omega_\Sigma + \int_\Sigma (\xi \cdot \mathrm{d}\omega + \mathrm{d}(\xi \cdot \omega)). \tag{41}$$

If the linearized Eulerian derivatives vanish, i.e., if $\delta_i(F_{IJ}) = 0$ and $\delta_i(DB^{IJ}) = 0$, $i = 1,2$ then $\mathrm{d}\omega = 0$, and so

$$\Omega'_\Sigma = \Omega_\Sigma + \int_\Sigma \mathrm{d}(\xi \cdot \omega) = \Omega_\Sigma + \int_{\partial\Sigma} \xi \cdot \omega. \tag{42}$$

Note that A_{IJ} and B^{IJ} in $\delta_i(F_{IJ})=0$ and $\delta_i(DB^{IJ})=0$ are *not* required to be solutions to the equations of motion $F_{IJ}=0$ and $DB^{IJ}=0$, i.e., $\delta_i A_{IJ}$ and $\delta_i B^{IJ}$ are tangent to $\mathcal{F}$ but not to $\bar{\mathcal{F}}$. Thus, if

$$\int_{\partial\Sigma} \xi \cdot \omega = 0, \tag{43}$$

then

$$\Omega'_\Sigma = \Omega_\Sigma. \tag{44}$$

This result can be summarized in the following:

Proposition: If the linearized Eulerian derivatives $\delta_i(F_{IJ})=0$ and $\delta_i(DB^{IJ})=0$ hold then Eq. (43) is a necessary and sufficient condition for Ω_Σ be invariant under the transformation associated with infinitesimal diffeomorphisms, i.e., if the linearized Eulerian derivatives $\delta_i(F_{IJ})=0$ and $\delta_i(DB^{IJ})=0$ hold then Eq. (43) is a necessary and sufficient condition for infinitesimal diffeomorphisms to be canonical transformations.

It is clear that in the particular case when Σ has no boundary, i.e., $\partial\Sigma=\emptyset$ then Eq. (43) holds without any additional restrictions on ξ.

Degenerate directions: The starting point is the expression for the presymplectic 3-form with $\delta_1=\delta$ an arbitrary variation and δ_2 is taken as the variation induced by the Lie derivative on the dynamical fields. From Eqs. (6) and (38),

$$\omega(\delta A, \delta B, \mathcal{L}_\xi A, \mathcal{L}_\xi B) = (\delta B^{IJ} \wedge \mathcal{L}_\xi A_{IJ} - \mathcal{L}_\xi(B^{IJ} \wedge \delta A_{IJ}) + B^{IJ} \wedge \delta(\mathcal{L}_\xi A_{IJ})). \tag{45}$$

Now, by taking $\delta=\mathcal{L}_\xi$ in the expression for the presymplectic current potential 3-form of Eq. (4) and computing its variation one has

$$\delta\mathbf{\Theta}(B, \mathcal{L}_\xi A) = \delta B^{IJ} \wedge \mathcal{L}_\xi A_{IJ} + B^{IJ} \wedge \delta(\mathcal{L}_\xi A_{IJ}). \tag{46}$$

Inserting the right-hand side of Eq. (46) into the right-hand side of Eq. (45) one gets

$$\omega(\delta A, \delta B, \mathcal{L}_\xi A, \mathcal{L}_\xi B) = \delta\mathbf{\Theta}(B, \mathcal{L}_\xi A) - \mathcal{L}_\xi(B^{IJ} \wedge \delta A_{IJ}) = \delta\mathbf{\Theta}(B, \mathcal{L}_\xi A) - \mathcal{L}_\xi\mathbf{\Theta}(B, \delta A). \tag{47}$$

On the other hand, the variation of the Noether current 3-form is

$$\begin{aligned}\delta\mathbf{J}_N[A,B,\xi] &= \delta\mathbf{\Theta}(B,\mathcal{L}_\xi A) - \xi\cdot\delta\mathbf{L} = \delta\mathbf{\Theta}(B,\mathcal{L}_\xi A) - \xi\cdot((\delta B^{IJ})\wedge F_{IJ} - (DB^{IJ})\wedge\delta A_{IJ} + \mathrm{d}\mathbf{\Theta}(B,\delta A))\\ &= \omega(\delta A,\delta B,\mathcal{L}_\xi A,\mathcal{L}_\xi B) + \mathcal{L}_\xi\mathbf{\Theta}(B,\delta A) - \xi\cdot((\delta B^{IJ})\wedge F_{IJ} - (DB^{IJ})\wedge\delta A_{IJ})\\ &\quad - \xi\cdot\mathrm{d}\mathbf{\Theta}(B,\delta A) = \omega(\delta A,\delta B,\mathcal{L}_\xi A,\mathcal{L}_\xi B) - \xi\cdot((\delta B^{IJ})\wedge F_{IJ} - (DB^{IJ})\wedge\delta A_{IJ})\\ &\quad + \mathrm{d}(\xi\cdot\mathbf{\Theta}(B,\delta A)).\end{aligned} \tag{48}$$

To get the second line on the right-hand side, Eq. (3) was used while Eq. (47) was used to get the third line. Inserting the explicit expression for $\delta\mathbf{J}_N[A,B,\xi]$ given in Eq. (34) into the left-hand side of Eq. (48) one has

$$\begin{aligned}\omega(\delta A,\delta B,\mathcal{L}_\xi A,\mathcal{L}_\xi B) &= \mathrm{d}(\delta\mathbf{Q}_N[A,B,\xi] - \xi\cdot\mathbf{\Theta}(B,\delta A)) - (\xi\cdot A_{IJ})\,\delta DB^{IJ} - (\xi\cdot B^{IJ})\wedge\delta F_{IJ}\\ &\quad + (\delta B^{IJ})\wedge(\xi\cdot F_{IJ}) - (\xi\cdot DB^{IJ})\wedge\delta A_{IJ}.\end{aligned} \tag{49}$$

Note that, in contrast to Eqs. (12) and (25), in the case of diffeomorphisms the symplectic inner product between δ_ξ and an arbitrary variation δ involves both Eulerian derivatives and the linearized Eulerian derivatives. One has the following:

Proposition: Let (A_{IJ},B^{IJ}) be a point in $\bar{\mathcal{F}}$; let $(\delta A_{IJ},\delta B^{IJ})$ be a solution to the linearized Eulerian derivatives at (A_{IJ},B^{IJ}) [i.e., $(\delta A_{IJ},\delta B^{IJ})$ are such that $\delta(DB^{IJ})=0$ and $\delta F_{IJ}=0$ and are tangent to $\bar{\mathcal{F}}$ at (A_{IJ},B^{IJ})]. Then, we have

$$\omega(\delta A, \delta B, \mathcal{L}_\xi A, \mathcal{L}_\xi B) = \mathrm{d}(\delta \mathbf{Q}_N[A,B,\xi] - \xi \cdot \mathbf{\Theta}(B, \delta A)), \tag{50}$$

and thus, integrating on Σ,

$$\Omega_\Sigma(\delta A, \delta B, \mathcal{L}_\xi A, \mathcal{L}_\xi B) \coloneqq \int_\Sigma \omega(\delta A, \delta B, \mathcal{L}_\xi A, \mathcal{L}_\xi B) = \oint_{\partial\Sigma} (\delta \mathbf{Q}_N[A,B,\xi] - \xi \cdot \mathbf{\Theta}(B, \delta A)). \tag{51}$$

Inserting the explicit expressions for $\mathbf{Q}_N[A,B,\xi]$ and $\mathbf{\Theta}(B,\delta A)$ one has

$$\Omega_\Sigma(\delta A, \delta B, \mathcal{L}_\xi A, \mathcal{L}_\xi B) = \oint_{\partial\Sigma} [\delta((\xi \cdot A_{IJ})B^{IJ}) - \xi \cdot (B^{IJ} \wedge \delta A_{IJ})] = \oint_{\partial\Sigma} [(\xi \cdot A_{IJ})\delta B^{IJ} - (\xi \cdot B^{IJ}) \wedge \delta A_{IJ}]. \tag{52}$$

Some remarks follow: (1) first of all, Eq. (52) tells us that, in the context of the covariant canonical formalism, not all diffeomorphisms are to be regarded as gauge because the right-hand side of (52) will *not* vanish for any ξ, (2) note that if $(A_{IJ}, B^{IJ}) \in \bar{\mathcal{F}}$ then $\xi \cdot A_{IJ} \neq 0$ and $\xi \cdot B^{IJ} \neq 0$ in the generic case. Moreover, note that the right-hand side of (52) vanishes for all (A_{IJ}, B^{IJ}) of $\bar{\mathcal{F}}$ and for all tangent variation $(\delta A_{IJ}, \delta B^{IJ})$ to $\bar{\mathcal{F}}$ in (A_{IJ}, B^{IJ}) if and only if ξ vanishes at the boundary $\partial\Sigma$, $\xi|_{\partial\Sigma} = 0$. Thus, just those diffeomorphisms which are the identity at $\partial\Sigma$ must be regarded as gauge. One could say that the gauge transformation is broken at $\partial\Sigma$ in the sense that $\xi|_{\partial\Sigma} = 0$. However, from that perspective one would be *a priori* assuming that all diffeomorphisms are gauge which as the previous analysis shows is not the case. Let ζ be a diffeomorphism such that it does not vanish at $\partial\Sigma$. The full set of these ζ's span the *boundary symmetry group*. Thus, the covariant canonical formalism tells us *boundary symmetry group* is *not* a gauge group (see also Ref. 9 understand the role of diffeomorphisms in the case of general relativity).

Existence of a Hamiltonian: For variations δA_{IJ} with compact support in the interior of Σ, i.e., $\delta A_{IJ}|_{\partial\Sigma} = 0$,

$$\Omega_\Sigma = \delta \oint_{\partial\Sigma} (\zeta \cdot A_{IJ}) B^{IJ} = \delta \oint_{\partial\Sigma} \mathbf{Q}[A,B,\zeta], \tag{53}$$

which means that a Hamiltonian conjugate to ζ on Σ exists and that its Hamiltonian density is precisely the Noether potential $\mathbf{Q}[A,B,\zeta]$. We have assumed that ζ does *not* vanish at $\partial\Sigma$ and thus, by definition, ζ is not a degenerate direction.

On the other hand, for variations δB_{IJ} with compact support in the interior of Σ, i.e., $\delta B^{IJ}|_{\partial\Sigma} = 0$,

$$\Omega_\Sigma = \delta \oint_{\partial\Sigma} -(\zeta \cdot B^{IJ}) \wedge A_{IJ}, \tag{54}$$

so there exists a Hamiltonian conjugate to ζ on Σ.

Relationship between the Noether currents: It is possible to compare the Noether current associated with diffeomorphisms, $\mathbf{J}_N[A,B,\xi]$, with the currents associated to the fundamental set of gauge symmetries

$$\begin{aligned}\mathbf{J}_N[A,B,\xi] &= B^{IJ} \wedge \mathcal{L}_\xi A_{IJ} - \xi \cdot (B^{IJ} \wedge F_{IJ}) = B^{IJ} \wedge [\xi \cdot F_{IJ} + D\epsilon_{IJ}] - (\xi \cdot B^{IJ}) \wedge F_{IJ} - B^{IJ} \wedge (\xi \cdot F_{IJ}) \\ &= B^{IJ} \wedge D\epsilon_{IJ} - \chi^{IJ} \wedge F_{IJ} = \mathbf{J}_N[A,B,\epsilon] - \mathbf{J}_N[A,\chi].\end{aligned} \tag{55}$$

In a more appropriate notation

$$\mathbf{J}_N[A,B,\xi] = (\mathbf{J}_N[A,B,\epsilon] - \mathbf{J}_N[A,\chi])\big|_{\epsilon_{IJ}=\xi\cdot A_{IJ}, \chi^{IJ}=\xi\cdot B^{IJ}}. \tag{56}$$

Note also that $\mathbf{J}_N[A,B,\xi] = \mathbf{J}_N[A,B,\epsilon]$ because $\mathbf{J}_N[A,\chi] = 0$ on shell (i.e., if $F_{IJ} = 0$). Moreover, note that

$$\mathbf{Q}[A,B,\xi]=(\xi\cdot A_{IJ})B^{IJ}=\epsilon_{IJ}B^{IJ}=\mathbf{Q}[B,\epsilon]. \tag{57}$$

III. BF THEORY PLUS A COSMOLOGICAL CONSTANT

The four-dimensional BF theory with SO(3,1) as the internal group and supplemented with a cosmological constant Λ is defined by the equations of motion

$$F_{IJ}=2\Lambda\ {}^*B_{IJ},\quad DB_{IJ}=0, \tag{58}$$

where ${}^*B_{IJ}=\frac{1}{2}\varepsilon_{IJKL}B^{KL}$ is the dual of B^{IJ}. If SO(4) were taken as the internal group then $\eta_{IJ}\rightarrow\delta_{IJ}$, the connection were valued in the Lie algebra of SO(4) and ${}^{*2}=+1$. Equations (58) can be obtained from the action principle[11,20]

$$S[A,B]=\int_{\mathcal{M}}B^{IJ}\wedge F_{IJ}[A]-\Lambda\int_{\mathcal{M}}B^{IJ}\wedge\ {}^*B_{IJ}. \tag{59}$$

Thus, in contrast to BF theory, the space of solutions to the equations of motion $\bar{\mathcal{F}}_{BF+\Lambda}$ is now defined by Eq. (58). To get the geometry, one needs to compute the first order variation of the Lagrangian 4-form $\mathbf{L}[A,B]=B^{IJ}\wedge F_{IJ}[A]-\Lambda B^{IJ}\wedge {}^*B_{IJ}$,

$$\delta\mathbf{L}[A,B]=(\delta B^{IJ})\wedge(F_{IJ}-2\Lambda\ {}^*B_{IJ})-(DB^{IJ})\wedge\delta A_{IJ}+\mathrm{d}\mathbf{\Theta}(B,\delta,A), \tag{60}$$

from which the *presymplectic potential* 3-form

$$\mathbf{\Theta}(B,\delta A):=B^{IJ}\wedge\delta A_{IJ}, \tag{61}$$

is read off. Therefore, the presymplectic 3-form ω is the same of the BF theory. The symplectic structure induced on $\bar{\mathcal{F}}_{BF+\Lambda}$ is simply the pullback to $\bar{\mathcal{F}}_{BF+\Lambda}$ of the curl of $\mathbf{\Theta}$ on the kinematical phase space.

Degenerate directions:

(1) The symplectic inner product between $\delta_1=\delta$ and $\delta_2=\delta_\epsilon$, $\omega(\delta A,\delta B,\delta_\epsilon A,\delta_\epsilon B)$, has the same analytical form of the BF theory.

(2) The symplectic inner product between $\delta_1=\delta$ and $\delta_2=\delta_\chi$ where $\delta_\chi A_{IJ}=\Lambda\epsilon_{IJKL}\chi^{KL}$ and $\delta_\chi B^{IJ}=D\chi^{IJ}$ (Ref. 17) is now

$$\omega(\delta A,\delta B,\delta_\chi A,\delta_\chi B)=\mathrm{d}(\delta(-\chi^{IJ}\wedge A_{IJ}))-\chi^{IJ}\wedge\delta(F_{IJ}-2\Lambda\ {}^*B_{IJ}). \tag{62}$$

(3) The Noether current associated with diffeomorphisms acquires the form[17]

$$\mathbf{J}_N[A,B,\xi]=\mathrm{d}\mathbf{Q}_N[A,B,\xi]-(\xi\cdot A_{IJ})DB^{IJ}-(\xi\cdot B^{IJ})\wedge(F_{IJ}-2\Lambda\ {}^*B_{IJ}), \tag{63}$$

with the Noether current potential 2-form $\mathbf{Q}_N[A,B,\xi]$ having the same analytical form than the one of the BF theory. Due to the fact that $\omega(\delta A,\delta B,\mathcal{L}_\xi A,\mathcal{L}_\xi B)=\mathrm{d}(\delta\mathbf{Q}_N[A,B,\xi]-\xi\cdot\mathbf{\Theta}(B,\delta A))$ if the equations of motion and the linearized Eulerian derivatives hold and because $\mathbf{Q}_N[A,B,\xi]$ and $\mathbf{\Theta}(B,\delta A)$ have the same form of the BF theory, then analysis of the degenerate directions is the same of the BF theory. Finally, note that now $\delta_\xi,\delta_\epsilon$, and δ_χ are not related by (32) but by $\delta_\xi A_{IJ}=\xi\cdot(F_{IJ}-2\Lambda\ {}^*B_{IJ})+\delta_\epsilon A_{IJ}+\delta_\chi A_{IJ}$ while $\delta_\xi B^{IJ}=\xi\cdot DB^{IJ}+\delta_\epsilon B^{IJ}+\delta_\chi B^{IJ}$ retains his form with $\epsilon_{IJ}=\xi\cdot A_{IJ},\chi^{IJ}=\xi\cdot B^{IJ}$.

IV. BF THEORY PLUS THE SECOND CHERN CHARACTER

Now, the action we consider is the action for BF theory supplemented with the second Chern character

$$S[A,B]=\int_{\mathcal{M}} B^{IJ}\wedge F_{IJ}[A]+\theta\int_{\mathcal{M}} F^{IJ}[A]\wedge F_{IJ}[A], \tag{64}$$

with θ a parameter. The first order variation of the Lagrangian 4-form $\mathbf{L}[A,B]=B^{IJ}\wedge F_{IJ}+\theta F^{IJ}\wedge F_{IJ}$ is

$$\delta\mathbf{L}[A,B]=\delta B^{IJ}\wedge F_{IJ}-(DB^{IJ}+2\theta DF^{IJ})\wedge\delta A_{IJ}+\mathrm{d}\mathbf{\Theta}, \tag{65}$$

where

$$\mathbf{\Theta}=(B^{IJ}+2\theta F^{IJ})\wedge\delta A_{IJ}, \tag{66}$$

is the presymplectic potential 3-form [cf. Eq. (4)]. From Eq. (65), it is clear that the equations of motion $F_{IJ}=0$ and $DB^{IJ}+2\theta DF^{IJ}=0$ coming from Eq. (64) reduce to those of the BF theory because the Bianchi identities $DF_{IJ}=0$ always hold. Thus, the inclusion of the second Chern character does not modify the classical dynamics of the BF theory, as expected. This means that the space of solutions to the equations of motion $\bar{\mathcal{F}}$ is the same for both theories. Nevertheless, in spite of the fact that the equations of motion are the same, the presymplectic 3-form changes. For the present case one has

$$\omega=\delta_1(B^{IJ}+2\theta F^{IJ})\wedge\delta_2 A_{IJ}-\delta_2(B^{IJ}+2\theta F^{IJ})\wedge\delta_1 A_{IJ} \tag{67}$$

[cf. Eq. (6)]. Therefore, the presymplectic 3-forms coming from Eqs. (2) and (64) are distinct. On the space of solutions $\bar{\mathcal{F}}$, the symplectic structure of Eq. (67) is the same as the symplectic structure of Eq. (6), of course (see also Ref. 15).

Degenerate directions:

(1) The symplectic inner product between $\delta_1=\delta$ and $\delta_2=\delta_\epsilon$ is now

$$\omega(\delta A,\delta B,\delta_\epsilon A,\delta_\epsilon B)=\mathrm{d}(\epsilon_{IJ}\delta B^{IJ}+2\theta\delta A^{IJ}\wedge D\epsilon_{IJ})-\epsilon_{IJ}\delta(DB^{IJ}) \tag{68}$$

and so

$$\Omega_\Sigma(\delta A,\delta B,\delta_\epsilon A,\delta_\epsilon B)=-\int_\Sigma \epsilon_{IJ}\delta DB^{IJ}+\int_{\partial\Sigma}(\epsilon_{IJ}\delta B^{IJ}+2\theta\delta A^{IJ}\wedge D\epsilon_{IJ}). \tag{69}$$

Therefore, if the linearized Eulerian derivative $\delta(DB^{IJ})$ vanishes, $\delta(DB^{IJ})=0$, and the arbitrary variations $(\delta A^{IJ},\delta B^{IJ})$ have compact support in the interior of Σ, $\delta A^{IJ}|_{\partial\Sigma}=0$ and $\delta B^{IJ}|_{\partial\Sigma}=0$, then

$$\Omega_\Sigma(\delta A,\delta B,\delta_\epsilon A,\delta_\epsilon B)=0, \tag{70}$$

without imposing any additional restrictions on the gauge parameters ϵ_{IJ}. The integral over $\partial\Sigma$ in Eq. (69) also vanishes if both the gauge parameters ϵ_{IJ} vanish and satisfy $D\epsilon_{IJ}=0$ at $\partial\Sigma$.

(2) The symplectic inner product between $\delta_1=\delta$ and $\delta_2=\delta_\chi$ is the same as the one of the BF theory.

(3) Now, we consider diffeomorphisms. The Noether current associated with diffeomorphisms acquires the form

$$\mathbf{J}_N[A,B,\xi]=\mathrm{d}\mathbf{Q}_N[A,B,\xi]-(\xi\cdot A_{IJ})(DB^{IJ}+2\theta DF^{IJ})-(\xi\cdot B^{IJ})\wedge F_{IJ}, \tag{71}$$

where

$$\mathbf{Q}_N[A,B,\xi]=(\xi\cdot A_{IJ})(B^{IJ}+2\theta F^{IJ}), \tag{72}$$

is the *Noether current potential* 2-form. Therefore, the Noether charge is the same as in the BF theory if the equations of motion are satisfied. Moreover, if both the equations of

motion and the linearized equations of motion hold, then symplectic inner product between $\delta_1=\delta$ and $\delta_2=\delta_\xi$ becomes

$$\Omega_\Sigma(\delta A,\delta B,\mathcal{L}_\xi A,\mathcal{L}_\xi B)=\oint_{\partial\Sigma}(\delta\mathbf{Q}_N[A,B,\xi]-\xi\cdot\mathbf{\Theta}(B,\delta A)). \tag{73}$$

Inserting the explicit expressions for $\mathbf{Q}_N[A,B,\xi]$ and $\mathbf{\Theta}(B,\delta A)$ one has

$$\begin{aligned}\Omega_\Sigma(\delta A,\delta B,\mathcal{L}_\xi A,\mathcal{L}_\xi B)&=\oint_{\partial\Sigma}[\delta(\xi\cdot A_{IJ}(B^{IJ}+2\theta F^{IJ}))-\xi\cdot((B^{IJ}+2\theta F^{IJ})\wedge\delta A_{IJ})]\\&=\oint_{\partial\Sigma}[(\xi\cdot A_{IJ})\delta B^{IJ}-(\xi\cdot B^{IJ})\wedge\delta A_{IJ}],\end{aligned} \tag{74}$$

because $F^{IJ}=0$ and $\delta F^{IJ}=0$, by hypothesis. Last equation has the same analytical form as the one of the BF theory. Therefore, the inclusion of the second Chern character does not modify the degenerate directions in the case of diffeomorphisms.

V. CONCLUSIONS AND PERSPECTIVES

To conclude, we emphasize the role that the Bianchi identities $DF_{IJ}=0$ play in four-dimensional BF theories. On the one hand, they are the cause of having the symmetry δ_χ in the various four-dimensional BF theories already discussed. On the other hand, in the case of the BF theory with a nonvanishing cosmological constant Λ the combination of the Bianchi identities together with the equation of motion $F_{IJ}=2\Lambda*B_{IJ}$ "generates" dynamics for the B^{IJ} fields in the sense that they imply $DB_{IJ}=0$. This fact is the origin of the reducibility of the corresponding first class constraints of the theory in Dirac's canonical analysis. This same phenomenon appears, in essence, in the action[17]

$$S[A,B,\phi]=\int_{\mathcal{M}}B^{IJ}\wedge F_{IJ}-\frac{1}{2}\phi_{IJKL}B^{IJ}\wedge B^{KL}, \tag{75}$$

with $\phi_{IJKL}=-\phi_{JIKL}=-\phi_{IJLK}=\phi_{KLIJ}$ where the combination of the Bianchi identities and the equations of motion $F_{IJ}=\phi_{IJKL}B^{KL}$ and $DB^{IJ}=0$ generates dynamics for the ϕ_{IJKL} fields in the sense that these equations imply $(D\phi_{IJKL})\wedge B^{KL}=0$. From the lesson learned from the case of the BF theory plus a cosmological constant Λ, we would expect that the theory defined by Eq. (75) has also reducibility in the constraints in the context of Dirac's analysis. We consider the present analysis as a first step towards the covariant canonical analysis of BF gravity.[21]

ACKNOWLEDGMENTS

APPENDIX: REVIEW OF DIRAC'S CANONICAL ANALYSIS FOR FOUR-DIMENSIONAL BF THEORY

To compare some results of this Appendix with some results of the covariant canonical formalism one must make the changes $\epsilon_{IJ}\to-\epsilon_{IJ}$ and $\epsilon_a^{IJ}\to-\chi_a^{IJ}$ in this Appendix.

(1) *BF theory*: By making the $3+1$ decomposition, a straightforward computation shows that the action (2) acquires the form

$$S[A_{aIJ},\tilde{\Pi}^{aIJ},\lambda_{IJ},\lambda_a{}^{IJ}]=\int_{\mathcal{M}} d^4x\left[\dot{A}_{aIJ}\tilde{\Pi}^{aIJ}-\lambda_{IJ}D_a\tilde{\Pi}^{aIJ}-\lambda_a{}^{IJ}\left(\frac{1}{2}\tilde{\eta}^{abc}F_{bcIJ}\right)\right]+\int_{\mathcal{M}} d^4x\partial_a(\lambda_{IJ}\tilde{\Pi}^{aIJ}), \tag{A1}$$

where the phase space variables $(A_{aIJ},\tilde{\Pi}^{bKL})$ and Lagrange multipliers λ_{IJ} and $\lambda_a{}^{IJ}$ are defined in terms of the initial configuration variables as $\tilde{\Pi}^{aIJ}:=\frac{1}{2}\tilde{\eta}^{abc}B_{bc}{}^{IJ}$, $\lambda_{IJ}:=-A_{0IJ}$, $\lambda_a{}^{IJ}:=-B_{0a}{}^{IJ}$, $D_a\tilde{\Pi}^{aIJ}:=\partial_a\tilde{\Pi}^{aIJ}+A_a{}^I{}_K\tilde{\Pi}^{aKJ}+A_a{}^J{}_K\tilde{\Pi}^{aIK}$. If the space-time $\mathcal{M}$ has the topology $\mathcal{M}=\Sigma\times R$ and Σ has no boundary the second integral on the right-hand side of (A1) can be neglected. The lowercase letters a,b are space ones and run from 1 to 3. Notice that the Lorentz indices I,J are not split holding in this way the full Lorentz group. The variation of Eq. (A1) with respect to the phase space variables yields the equations of motion

$$\dot{A}_{aIJ}=-D_a\lambda_{IJ},$$

$$\dot{\tilde{\Pi}}^{aIJ}=2\lambda^{[I}{}_K\tilde{\Pi}^{aKJ]}-\tilde{\eta}^{abc}D_b\lambda_c{}^{IJ}, \tag{A2}$$

with $D_a\lambda_{IJ}=\partial_a\lambda_{IJ}-A_a{}^K{}_I\lambda_{KJ}-A_a{}^K{}_J\lambda_{IK}$. The variation with respect to the Lagrange multipliers gives the constraints

$$\tilde{\Psi}^{IJ}:=D_a\tilde{\Pi}^{aIJ}\approx 0,\quad \tilde{\Psi}^a{}_{IJ}:=\frac{1}{2}\tilde{\eta}^{abc}F_{bcIJ}(A)\approx 0, \tag{A3}$$

which are first class. The infinitesimal gauge transformation generated by the Gauss constraint $\tilde{\Psi}^{IJ}$ is

$$A'_{aIJ}=A_{aIJ}-D_a\epsilon_{IJ},\quad \widetilde{\Pi'}^{aIJ}=\tilde{\Pi}^{aIJ}+\epsilon^{IM}\tilde{\Pi}^a{}_M{}^J-\epsilon^{JM}-\tilde{\Pi}^a{}_M{}^I, \tag{A4}$$

and

$$A'_{aIJ}=A_{aIJ},\quad \widetilde{\Pi'}^{aIJ}=\tilde{\Pi}^{aIJ}-\tilde{\eta}^{abc}D_b\epsilon^{IJ}{}_c, \tag{A5}$$

is the gauge transformation generated by the constraint $\tilde{\Psi}^a{}_{IJ}$. However, even though the constraints $\tilde{\Psi}^{IJ}$ are irreducible the constraints $\tilde{\Psi}^a{}_{IJ}$ are not, i.e., they are *reducible*. This is so because the Bianchi identities $DF_{IJ}=0$ imply the relationship among the $\tilde{\Psi}^a{}_{IJ}$'s,

$$\tilde{\Phi}_{IJ}:=D_a\tilde{\Psi}^a{}_{IJ}=0. \tag{A6}$$

The counting of physical degrees of freedom is as follows. There are $3\times 6=18$ configuration variables A_{aIJ} and $6+[(3\times 6)-6]=18$ *independent* first class constraints. Therefore, the system has no local degrees of freedom.[12] Alternatively, the independent number of gauge parameters is $18=6$ (the ϵ_{IJ}'s) $+12$ $(=18-6$ independent gauge parameters from $\epsilon_a^{IJ})$.

(2) *BF theory plus a cosmological constant*: By performing the $3+1$ decomposition the action (59) can be written as

$$S[A_{aIJ},\tilde{\Pi}^{aIJ},\lambda_{IJ},\lambda_a{}^{IJ}]=\int d^4x\left[\dot{A}_{aIJ}\tilde{\Pi}^{aIJ}-\lambda_{IJ}D_a\tilde{\Pi}^{aIJ}-\lambda_a{}^{IJ}\left(\tfrac{1}{2}\tilde{\eta}^{abc}F_{bcIJ}-\Lambda\epsilon_{IJKL}\tilde{\Pi}^{aKL}\right)\right]. \tag{A7}$$

The equations of motion are

$$\dot{A}_{aIJ}=-D_a\lambda_{IJ}-\Lambda\epsilon_{IJKL}\lambda_a{}^{KL},$$

$$\dot{\tilde{\Pi}}^{aIJ} = 2\lambda^{[I}{}_K\tilde{\Pi}^{aKJ]} - \tilde{\eta}^{abc}D_b\lambda_c{}^{IJ}. \tag{A8}$$

The constraints are

$$\tilde{\Psi}^{IJ} := D_a\tilde{\Pi}^{aIJ}, \quad \tilde{\Psi}^a{}_{IJ} := \tfrac{1}{2}\tilde{\eta}^{abc}F_{bcIJ} - \Lambda\epsilon_{IJKL}\tilde{\Pi}^{aKL}. \tag{A9}$$

The evolution of the constraints provides no more constraints. To compute the algebra of constraints it is convenient to smear them

$$\Psi[u] := \int d^3x u_{IJ}\tilde{\Psi}^{IJ}, \quad \Psi[N] := \int d^3x N^{IJ}{}_a\tilde{\Psi}^a_{IJ}. \tag{A10}$$

The constraint algebra is

$$\{\Psi[u],\Psi[v]\} = \Psi[[u,v]], \quad \{\Psi[u],\Psi[N]\} = \Psi[[u,N]], \quad \{\Psi[N],\Psi[M]\} = 0, \tag{A11}$$

with $[u,v]_{IJ} := u_I{}^M v_{MJ} - u_J{}^M v_{MI}$, $[u,N]^{IJ}{}_a = u^I{}_K N^{KJ}{}_a - u^J{}_K N^{KI}{}_a$. The infinitesimal gauge transformation generated by the Gauss constraint $\tilde{\Psi}^{IJ}$ is

$$A'_{aIJ} = A_{aIJ} - D_a\epsilon_{IJ}, \quad \tilde{\Pi}'^{aIJ} = \tilde{\Pi}^{aIJ} + \epsilon^{IM}\tilde{\Pi}^a{}_M{}^J - \epsilon^{JM}\tilde{\Pi}^a{}_M{}^I, \tag{A12}$$

and

$$A'_{aIJ} = A_{aIJ} - \Lambda\epsilon_{IJKL}\epsilon^{KL}{}_a, \quad \tilde{\Pi}'^{aIJ} = \tilde{\Pi}'^{aIJ} = \tilde{\Pi}^{aIJ} - \tilde{\eta}^{abc}D_b\epsilon^{IJ}{}_c, \tag{A13}$$

is the infinitesimal gauge transformation generated by the constraint $\tilde{\Psi}^a{}_{IJ}$. Again, the Bianchi identities imply that the constraints are reducible

$$D_a\tilde{\Psi}^a{}_{IJ} + \Lambda\epsilon_{IJKL}\tilde{\Psi}^{KL} = 0. \tag{A14}$$

Like in pure BF gravity the system has $3\times 6=18$ configuration variables and $6+[(3\times 6)-6]=18$ independent first class constraints. Therefore, the system has no local degrees of freedom, as expected because the addition of a cosmological constant does not add local degrees of freedom. However, a key difference with respect to the case without cosmological constant Λ is that there the constraints $\tilde{\Psi}^a{}_{IJ}$ and $\tilde{\Psi}^{IJ}$ are independent while in the present case they are related through the reducibility equation given in Eq. (A14). Moreover, due to the fact the reducibility equation involves now the Gauss constraints too, there are 18 independent gauge parameters among the 6 of ϵ_{IJ}'s and the 18 of ϵ_a^{IJ}'s. One can take these independent number of gauge parameters as the 18 of the ϵ_a^{IJ}'s. By doing this, one might say that the local Lorentz transformation is redundant if a cosmological constant is present.

(Received 19 October 2005; accepted 24 December 2005; published online 16 February 2006)

We investigate stability of both localized time-periodic coherent states (pulsons) and uniformly distributed coherent states (oscillating condensate) of a real scalar field satisfying the Klein-Gordon equation with a logarithmic nonlinearity. The linear analysis of time-dependent parts of perturbations leads to the Hill equation with a singular coefficient. To evaluate the characteristic exponent we extend the Lindemann-Stieltjes method, usually applied to the Mathieu and Lamé equations, to the case that the periodic coefficient in the general Hill equation is an unbounded function of time. As a result, we derive the formula for the characteristic exponent and calculate the stability-instability chart. Then we analyze the spatial structure of the perturbations. Using these results we show that the pulsons of any amplitudes, remaining well-localized objects, lose their coherence with time. This means that, strictly speaking, all pulsons of the model considered are unstable. Nevertheless, for the nodeless pulsons the rate of the coherence breaking in narrow ranges of amplitudes is found to be very small, so that such pulsons can be long-lived. Further, we use the obtained stability-instability chart to examine the Affleck-Dine-type condensate. We conclude the oscillating condensate can decay into an ensemble of the nodeless pulsons. © *2006 American Institute of Physics.*

I. INTRODUCTION

Nonlinear localized field configurations, nontopological solitons, are currently considered as models of various physical objects, from elementary particles to giant lumps of dark matter in the form of soliton stars and galactic halos.[1–3] Stability properties of solitons were investigated by many authors, and a number of important results has been obtained (see, e.g., Ref. 4 and references therein). In particular, Hobart[5] and Derrick[6] have proved that static multidimensional scalar solitons are energetically unstable, and, hence, these objects cannot last in a real world for a long time. One way to avoid this theorem is to invoke time dependence. Along this line main efforts were focused on the stability analysis of the stationary states, i.e., coherent states of a complex scalar field oscillating harmonically in time. It turned out, however, that for a wide class of relativistic models these states can be only conditionally stable, i.e., stable with respect to a certain type of perturbations (e.g., conserving the scalar charge).[4] As to the time-periodic states of a more general form, both complex and real, there are presently no strong analytical results on their stability.

In this paper we examine stability of time-periodic configurations of the form

$$\phi = \phi_0(t,\mathbf{r}) = a(t)u(\mathbf{r}) \tag{1}$$

satisfying the nonlinear Klein-Gordon equation

$$\phi_{tt} - \Delta\phi + U'(\phi) = 0. \tag{2}$$

These are coherent states in the sense the field oscillates synchronously at all spatial points. It is necessary to stress that we consider real solutions, so that the energy density oscillates as well [in

contrast to the stationary states for which $a(t) \propto e^{i\omega t}$]. Solitons with oscillating energy density are usually called pulsons.

It turns out that for real ϕ the ansatz (1) determines uniquely the potential $U(\phi)$ in Eq. (2). Namely, if neither $a(t)$ nor $u(\mathbf{r})$ are constants, the only potential admitting such solutions will have the form[7]

$$U(\phi) = \tfrac{1}{2}\phi^2[m^2 + \lambda(1 - \ln \phi^2)], \tag{3}$$

where m^2 and λ are arbitrary constants.

Originally, the Klein-Gordon equation with a logarithmic potential of this type has been introduced in the quantum field theory by Rosen.[8] Later on Bialynicki-Birula and Mycielski[9] have rediscovered this equation and also considered its nonrelativistic version, the nonlinear Schrödinger equation.[10]

In inflationary cosmology and in modern supersymmetric field theories the logarithmic nonlinearities appear naturally when quantum corrections to effective potentials are allowed for.[11–14] In this context the expression in the square brackets of Eq. (3) can be treated as a dynamic inflaton mass term m_S^2 that is the bare inflaton mass term m^2 plus the logarithmic correction. It can be represented in the commonly considered form[14–21] by the substitution $\ln \phi^2 = 1 + \ln(\Phi/M)^2$, $\lambda/m^2 = -K$, where Φ is an inflaton scalar field, M is a large mass scale, K is a constant (usually negative and small). Thus our consideration is also relevant to dynamics of the pulson exitations of a real inflaton field oscillating around a vacuum value.

Note that the multidimensional pulsons probably exist in other scalar models as well. Thus the long-living oscillating spherically symmetric localized states were numerically found in the sine-Gordon, ϕ^4, and $\phi^3 - \phi^4$ models[22–26] (see Ref. 27 for a review). Unfortunately, the analytic form of these solutions is so far unknown.

The model (2) and (3) is unique in the sense it has a whole family of exact pulson solutions of the form (1), all existing in any number of spatial dimensions.[7] This is also true for complex version of the model.[28,29] The real pulsons we are dealing with are the limiting states of the complex ones, when the scalar charge tends to zero. Other limiting states are Q-balls[15,16] for which $a(t) \propto e^{i\omega t}$. It is believed that Q-balls can arise due to fragmentation of the Affleck-Dine condensate.[18–21] We will see below that the parametric instability of the oscillating condensate leads to the resonant fragmentation that can give rise to the pulson formation at the nonlinear stage. Like Q-balls,[17] pulsons interact elastically or inelastically in collisions depending on their relative velocities, phases, and rest masses.[30,31] Thus, in model (2) and (3) the light pulsons with given relative velocities interact always elastically, independently of their phases. In contrast, the collisions of heavy pulsons can result in formation of the so-called explosons, localized states with exponentially growing amplitude.[30] For the intermediate masses the picture depends essentially on the phases of the colliding pulsons and impact velocity determining the duration of the interaction.[31]

The above results suggest that there is a domain of parameters where pulsons are stable, at least in short time interactions. But in what sense? How long a pulson conserves its characteristic features once interaction ends? If pulsons are long-lived objects they will be interesting candidates for the dark matter constituents having time-dependent density. What is known about stability of an isolated pulson at the long time scale? Surprisingly, but very few. In Ref. 29 it was argued in favor of its perfect stability. No deviations from the exact solution (1) were found after about 1000 oscillations. However, our preliminary numerical experiments[32,33] have shown that the pulsons of certain amplitudes, even perturbed by computer round-off errors only, gradually lose their coherency, remaining well-localized oscillating objects. This has motivated the closer examination.

In the present paper we clarify how long the pulsons can conserve the coherency depending on their parameters. For this purpose we investigate stability of the spherically symmetric pulson solutions (1) with respect to small initial perturbations of an arbitrary form.

The paper is organized as follows. In Sec. II the main properties of the real pulsons of the model considered are reviewed. Section III is wholly devoted to the linear stability analysis. We arrive at the singular Hill equation and generalize the Lindemann-Stieltjes method to evaluate the

characteristic exponent. On this basis we examine stability of the pulsons and discuss fragmentation of the oscillating Affleck-Dine-type condensate. In Sec. IV we make some remarks concerning the complex pulsons and summarize the main results.

II. PULSONS AS COHERENT STATES

Assuming λ positive, let us first eliminate the constants m^2 and λ from consideration by the scaling $t \to \lambda^{-1/2} t$, $\mathbf{r} \to \lambda^{-1/2}\mathbf{r}$, $\phi \to \phi \exp(m^2/2\lambda)$. In the new variables the field ϕ may be thought of as satisfying Eq. (2) with the potential

$$U(\phi) = \tfrac{1}{2}\phi^2(1 - \ln \phi^2). \tag{4}$$

It is the potential we will deal with. It has local minimum at $\phi=0$ and two maxima at $\phi=\pm 1$, at the minimum the potential having the singularity: its second derivative tends to infinity as $\phi \to 0$.

The substitution of the ansatz (1) into Eq. (2) leads then to two independent equations,

$$a_{tt} = -\frac{d}{da}\left[\frac{1}{2}a^2(1 - \ln a^2)\right], \tag{5}$$

$$\Delta u = -\frac{d}{du}\left[\frac{1}{2}u^2(\ln u^2 - 1)\right]. \tag{6}$$

Note that the potentials in the square brackets of Eqs. (5) and (6) have the same form as the potential (4) taken with plus and minus signs, respectively. The existence of the oscillating localized solutions (1) is thus apparent from consideration of motion of a mechanical particle in these potentials.

Let us consider in more detail the oscillatory solutions of Eq. (5). Using the Hamiltonian and denoting $\xi = a/a_{\max}$ ($0 < a_{\max} < 1$, $-1 \leqslant \xi \leqslant 1$), we obtain

$$\xi_t^2 = \omega_0^2(1 - \xi^2) + \xi^2 \ln \xi^2, \tag{7}$$

where

$$\omega_0^2 = 1 - \ln a_{\max}^2 > 1. \tag{8}$$

In the case of small amplitudes, $a_{\max}^2 \ll 1$, $\omega_0^2 \gg 1$, Eq. (7) gives

$$\xi(t) \approx \cos \omega_0 t. \tag{9}$$

Thus, we have quasiharmonic high-frequency oscillations which are however nonlinear since their period,

$$T \approx \frac{2\pi}{|\ln a_{\max}^2|^{1/2}}, \tag{10}$$

depends on the amplitude.[33] In the next approximation from Eq. (7) we find

$$T = \frac{2\pi}{\omega_0}\left[1 + \frac{0.307}{\omega_0^2} + O\left(\frac{1}{\omega_0^4}\right)\right]. \tag{11}$$

In the case of near-critical amplitudes, when $a_{\max}^2 \to 1$, the oscillations become almost rectangular and have the period

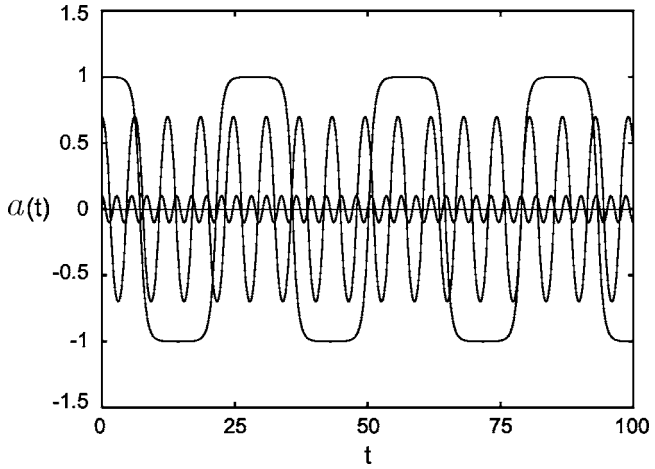

FIG. 1. Oscillatory solutions of Eq. (5) for $a_{\max}=0.1$, $a_{\max}=0.7$, and $a_{\max}=0.9999$.

$$T \approx 2\sqrt{2} \ln \frac{1}{1-a_{\max}^2}. \tag{12}$$

Examples of solutions of Eq. (5) are shown in Fig. 1.

The spatial structure of a pulson is determined by Eq. (6). In the spherically symmetric case this equation has a discrete spectrum of localized N-nodal solutions $u_N(r)$ with the first derivatives vanishing at the origin[34] (see Fig. 2). The simplest of them, the nodeless solution, has a Gaussian-type shape,

$$u_0(r) = e^{(3-r^2)/2}, \tag{13}$$

and is usually called gausson.[8–10] It is agreed that its effective radius equals $\sqrt{2}$. In the multinodal solutions, as r increases, the field undergoes spatial oscillations of the half-wavelength $L \lesssim 2\sqrt{2}$ and then decays as

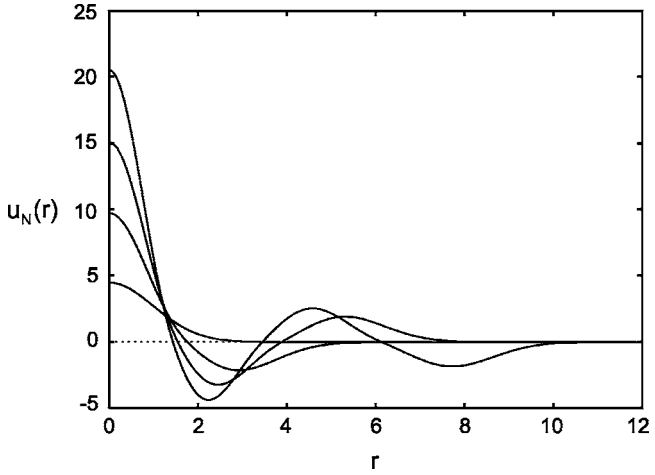

FIG. 2. Spectrum of the spherically symmetric N-nodal solutions $u_N(r)$ of Eq. (6): $u_0(0)=e^{3/2}$, $u_1(0)=9.726$, $u_2(0)=15.084$, $u_3(0)=20.526,\ldots$.

$$u_N(r) \approx C_N e^{-(r-\rho_N)^2/2} \quad (r \gg r-\rho_N,\ N \gg 1), \tag{14}$$

where C_N is the value of the last extremum of $u_N(r)$ attained at $r=\rho_N$, $C_N \to (-1)^N e^{1/2} (N \to \infty)$, $\rho_N \sim NL$. Thus, the pulsons of the model (2) and (4) are well-localized states of the inhomogeneity length L, at all points the field oscillating coherently with the period T. (To return to the physical units these scales should be multiplied by $\lambda^{-1/2}$.) In our dimensionless variables the pulsons are characterized by two parameters only: the amplitude $a_{\max}$ and the number of the nodes N [or T and $u_N(0)$, respectively].

It should be stressed that, due to nonanalyticity of $U(\phi)$ at $\phi=0$, the right-hand sides of Eqs. (5) and (6) are nonanalytic when a and u become zero. Hence, the solutions $a(t)$ and $u(r)$ themselves become nonanalytic at those points t and r where they pass through zero. Thus in the solution (9) we have dropped the terms which are small (of the order of ω_0^{-2}) but nonanalytic when $\xi(t)=0$. In the general case from Eq. (7) it follows that $\xi(t)$ passes through zero at $t=t_m$ as

$$\underset{t \to t_m}{\xi(t)} = \pm\, \omega_0 (t-t_m)\left[1 + \tfrac{1}{6}(t-t_m)^2 \ln(t-t_m)^2 + O((t-t_m)^2)\right], \tag{15}$$

where $\pm$ sign is taken for $\xi_t(t_m) \gtrless 0$. It is seen that ξ_{ttt} becomes infinite as $t \to t_m$. Similarly, one can show that in the vicinity of the nth node $(n=1,\ldots,N)$,

$$\underset{r \to r_n}{u(r)} = u_r(r_n)(r-r_n)\left[1 - \frac{r-r_n}{r_n} - \frac{1}{6}(r-r_n)^2 \ln(r-r_n)^2 + O((r-r_n)^2)\right]. \tag{16}$$

As we will see below, the nonanalyticity of $U(\phi)$ gives rise to some specific features of the stability analysis.

III. THE LINEAR STABILITY ANALYSIS

Consider a small fluctuation $\eta(t,\mathbf{r})$ around the spherically symmetric pulson (1), $\phi=\phi_0(t,r) + \eta(t,\mathbf{r})$. In the linear approximation the equation for η reads

$$\eta_{tt} - \Delta\eta - (2 + \ln \phi_0^2)\eta = 0. \tag{17}$$

Seeking a solution in the form $\eta(t,\mathbf{r}) \propto X(t)\Psi(\mathbf{r})$ we arrive at the equations

$$X_{tt} + (E - 2 - \ln a^2)X = 0, \tag{18}$$

$$\Delta\Psi + (E + \ln u^2)\Psi = 0, \tag{19}$$

where E is some constant.

The expression in the parentheses of Eq. (17) is $-U''(\phi_0)$. It becomes infinite, as well as the expressions in the parentheses of Eqs. (18) and (19), at the points t_m and r_n where $a(t)$ and $u(r)$ become zero. Thus we need to analyze the second order differential equations with singular coefficients. We begin with Eq. (18) which has the periodic singular coefficient $\ln a^2(t)$ and hence belongs to the class of Hill equations.

A. Singular Hill equation and generalized Lindemann-Stieltjes method

It turns out to be very useful to look at the problem as a whole, considering first the Hill equation of a general form

$$X_{tt} + h(z(t))X = 0. \tag{20}$$

We will assume that $h(z)$ is an integral function of z, while $z(t)$ is a real-valued periodic (of a period τ) even function of t, having, in general, singularities, but such, that $h(z(t))$ remains still integrable.

It is well known that the Hill equation describes the physical systems in which the parametric resonance can occur. In the context of our stability analysis we will be interested in real resonant solutions of Eq. (20). In accordance with the Floquet theory (see, e.g., Ref. 35), any one of these solutions can be represented as a linear combination of the fundamental solutions

$$X_+(t) = \varphi(t)e^{\mu t}, \quad X_-(t) = \varphi(-t)e^{-\mu t}, \tag{21}$$

where $\varphi(t)$ is a τ-periodic or τ-antiperiodic real function, $\mu > 0$ is the characteristic exponent. In the case that $z(t)$ is unbounded it is impossible to obtain the solutions and evaluate μ by expansions in Fourier series, following the standard Hill approach. Another way is to apply the Lindemann-Stieltjes method.[36] In some cases it allows one to obtain the results in a closed analytical form.[37–40] We first outline this method in the context of the general Hill equation (20) with an extension to the case that the periodic function $z(t)$ is unbounded. In doing so we follow Ref. 39 where the method was used to construct the resonant solutions of the Lamé equation.

The main idea is as follows. Let us treate z as a new "time" variable instead of t. In each interval of monotonicity of $z(t)$ we define

$$y(z) = X(t). \tag{22}$$

Assume that the periodic function $z(t)$ satisfies the equation

$$z_t^2 = g(z), \tag{23}$$

where $g(z)$ is an integral function of z. Equation (20) then becomes

$$g(z)y'' + \tfrac{1}{2}g'(z)y' + h(z)y = 0 \tag{24}$$

(hereinafter the prime denotes $d/\mathrm{d}z$).

Let us first suppose $z(t)$ is bounded. Equation (23) then shows that it is differentiable. Zeros of the function $g(z)$ on the complex z plane, taken to be isolated, are singular points of Eq. (24). Since $z(t)$ is periodic and real-valued, among singular points there are two, ζ_1 and ζ_2, lying on the real axis and being minimal and maximal values which $z(t)$ acquires at the endpoints of the intervals of monotonicity. Also, it follows that $g'(\zeta_{1,2}) \neq 0$. Physically, this is well understood, since ζ_1 and ζ_2 can be treated as turning points in periodic motion of a mechanical particle, e.g., of a nonlinear oscillator, under the action of the force $g'/2$. From Eq. (23) it is clear that the interval $[\zeta_1, \zeta_2]$ does not contain other singular points of Eq. (24).

For example, in the case of the Mathieu equation we have $z(t) = \cos^2 t$, $g(z) = 4z(1-z)$, so that Eq. (24) has the regular singular points $z = \zeta_1 = 0$, $z = \zeta_2 = 1$, both being the turning points. In addition, the equation has an irregular singularity at infinity. For the Lamé equation $z(t) = \mathrm{sn}^2(t, \varkappa)$, $g(z) = 4z(1-z)(1-\varkappa^2 z)$. Equation (24) then has the regular singular points $z = \zeta_1 = 0$, $z = \zeta_2 = 1$, $z = \varkappa^{-2} > 1$, first two of them being the turning points, and a regular singularity at infinity.

In general, it is easy to verify that the turning points $\zeta_{1,2}$ are regular singular points of Eq. (24), the exponents at each being 0 and 1/2. This implies that in the vicinity of each turning point ζ there exist two independent solutions of Eq. (24), $y^{(0)}(z;\zeta)$ and $y^{(1/2)}(z;\zeta)$, having asymptotics $1 + O(z-\zeta)$ and $(z-\zeta)^{1/2}[1 + O(z-\zeta)]$, correspondingly.

Now let us consider any one interval of monotonicity of the τ-periodic even function $z(t)$. Denote as $y_1(z)$ and $y_2(z)$ those two linearly independent solutions of Eq. (24) one of which coinsides, by Eq. (22), with the increasing solution (21), $X_+(t)$, and another with the decreasing one, $X_-(t)$, on the interval chosen. Since $\varphi(t)$ is either τ-periodic or τ-antiperiodic, the product $\varphi(t)\varphi(-t) = X_+X_- = y_1y_2 = w(z)$ is always τ-periodic even function defined on the whole t axis. Hence, at the endpoints of the intervals of monotonicity of $z(t)$, i.e., at $t_m = m\tau/2 (m = 0, \pm 1, \ldots)$, the derivative $[(X_+X_-)_t]_{t=t_m} = 0$ or, what is the same,

$$(w'\sqrt{g})_{z=\zeta_{1,2}} = 0. \tag{25}$$

In the vicinity of a turning point ζ the solutions y_1 and y_2 can be represented as linear combinations of the solutions $y^{(0)}$ and $y^{(1/2)}$. Consequently, the singularity $(z-\zeta)^{1/2}$ is the only one which the function $w(z)=y_1y_2$ might have. But its existence is in contradiction with Eq. (25), because $g'(\zeta)\neq 0$ and, hence, $g(z)_{z\to\zeta}\sim g'(\zeta)(z-\zeta)$. Therefore, the product y_1y_2 is analytic at $z=\zeta_{1,2}$. Recall now that the interval $[\zeta_1,\zeta_2]$ does not contain other singular points of Eq. (24) and the singular points are assumed to be isolated. We thus conclude that on the complex z plane there exists a vicinity of the interval $[\zeta_1,\zeta_2]$, i.e., an open domain $D\supset[\zeta_1,\zeta_2]$, in which y_1y_2 is an analytic function of z. In addition, it follows that y_1^2 and y_2^2 of necessity have singularities of the type $(z-\zeta)^{1/2}$ and, thus, cannot satisfy Eq. (25).

Now consider the case that one of the turning points or both are at infinity. This implies that at the corresponding instants t_m the functions $z(t)$ and $z_t(t)$ become unbounded, the latter changing the sign. Nevertheless, we assume that in the vicinities of t_m the function $h(z(t))$ in Eq. (20) is integrable and X is continuous, whence it follows that X_t and, therefore, w_t are also continuous. Hence, as before, $(w_t)_{t=t_m}=0$ due to evenness and periodicity, so that we arrive at Eq. (25) again, where $\zeta_1=-\infty$ and/or $\zeta_2=+\infty$.

It is easy to verify that the bilinear combinations y_1^2, y_1y_2, and y_2^2 constitute the fundamental system of solutions of the third-order differential equation

$$g(z)w''' + \tfrac{3}{2}g'(z)w'' + \left(\tfrac{1}{2}g''(z) + 4h(z)\right)w' + 2h'(z)w = 0. \tag{26}$$

Equation (25) is thus a common criterion for selection of the solution

$$w = y_1y_2 \tag{27}$$

from the set of solutions of Eq. (26). In the case that $z(t)$ is bounded, Eq. (25) is the equivalent to the requirement that a solution of Eq. (26) be analytic in D. If $z(t)$ is unbounded, Eq. (25) will give the boundary conditions at infinity which must be satisfied in solving Eq. (26). In this case $w(z)$ will be analytic in a vicinity D of one of the intervals $(-\infty,\zeta_2]$, $[\zeta_1,\infty)$, $(-\infty,\infty)$.

Thus, in a neighborhood of any one point $\zeta\in D$ we can write the expansions

$$\begin{pmatrix} w(z) \\ g(z) \\ h(z) \end{pmatrix} = \sum_{n=0}^{\infty} \begin{pmatrix} w_n \\ g_n \\ h_n \end{pmatrix} (z-\zeta)^n. \tag{28}$$

Substitution of (28) into Eq. (26) leads to the following set of equations for the coefficients:

$$m\sum_{n=1}^{m+2} n(m+n)g_{m-n+2}w_n + 4\sum_{n=0}^{m}(m+n)h_{m-n}w_n = 0 \tag{29}$$

$(m=1,2,\ldots)$. Thus for $m=1$ we have

$$6g_0w_3 + 3g_1w_2 + (g_2+4h_0)w_1 + 2h_1w_0 = 0. \tag{30}$$

Assuming $w(\zeta)\neq 0$, we normalize $w(z)$ by $w_0=1$. Then, at given w_1 and w_2 the remaining coefficients w_n are determined from Eqs. (29). The choice of w_1 and w_2 is not arbitrary but determined by Eq. (25). Thus, setting $\zeta=\zeta_1$ and, hence, $g_0=0$, we must choose w_1 in such a way that the series (28) for w (or its continuation) converges at the second turning point ζ_2, or satisfies the boundary condition at infinity (25) if $\zeta_2=+\infty$. For the Mathieu and Lamé equations this leads to the function $w(z)$ which is an integral one, for the latter it is a polynomial.[36] In these cases the domain D is evidently the z plane with $|z|<\infty$.

Let us suppose the function $w(z)$ (27) is found. Return now to Eqs. (20)–(24). Denote as W the Wronskian of the solutions (21),

$$X_+X_{-t} - X_{+t}X_- = W = \text{const}. \tag{31}$$

Setting

$$\begin{aligned} y_1 &= X_+, \quad y_2 = X_- \quad (z_t \geqslant 0), \\ y_1 &= X_-, \quad y_2 = X_+ \quad (z_t \leqslant 0), \end{aligned} \tag{32}$$

we then obtain

$$y_1 y_2' - y_1' y_2 = W/\sqrt{g}, \tag{33}$$

where $\sqrt{g} \geqslant 0$ is assumed. The system of equations (27) and (33) can be easily solved, which gives

$$y_{1,2}^2 = \exp \int \frac{f_\mp}{w\sqrt{g}} \mathrm{d}z, \tag{34}$$

where

$$f_\pm = w'\sqrt{g} \pm W. \tag{35}$$

Now let us insert $y_{1,2}$ (34) back into Eq. (24). We obtain

$$2gww'' + g'ww' - gw'^2 + 4hw^2 + W^2 = 0. \tag{36}$$

By this formula one can find the constant W^2 from a knowledge of $w(z)$ in a vicinity of any point z. Thus, calculating (36) at any one finite turning point ζ we obtain [in terms of expansions (28) with normalization $w_0 = 1$]

$$W^2 = -4h_0 - g_1 w_1. \tag{37}$$

Alternatively, one can take zeros z_i of $w(z)$. [The functions $g(z)$ and $w(z)$ do not have common zeros because otherwise the Wronskian (31) would be zero.] Then we find

$$W^2 = g(z_i)w'^2(z_i). \tag{38}$$

The requirement for positivity of W^2 determines the values of parameters of Eq. (20) (resonance zones) for which the resonant solutions exist.

Let us construct these solutions. Consider the intervals of monotonicity $t_1 \leqslant t \leqslant t_2 (z_t \geqslant 0)$, $t_2 \leqslant t \leqslant t_3 (z_t \leqslant 0)$, etc. According to (32) and (34) we can write

$$\begin{aligned} X_\pm^2(t)_{t_1 \leqslant t \leqslant t_2} &= X_\pm^2(t_1) \exp \int_{\zeta_1}^{z} \frac{f_\mp}{w\sqrt{g}} \mathrm{d}z, \\ X_\pm^2(t)_{t_2 \leqslant t \leqslant t_3} &= X_\pm^2(t_2) \exp \int_{\zeta_2}^{z} \frac{f_\pm}{w\sqrt{g}} \mathrm{d}z, \text{etc}. \end{aligned} \tag{39}$$

To find the characteristic exponent μ consider, e.g., the growing solution $X_+(t)$. Setting $t = t_2$, $z(t_2) = \zeta_2$ in the first equation of (39) and $t = t_3$, $z(t_3) = \zeta_1$ in the second one, we can express $X_+^2(t_3)$ through $X_+^2(t_1)$. Using Eq. (21) and taking into account that $t_3 = t_1 + \tau$, $\varphi(t+\tau) = \pm\varphi(t)$, we thus obtain

$$\mu = -\frac{W}{\tau} \int_{\zeta_1}^{\zeta_2} \frac{\mathrm{d}z}{w\sqrt{g}}. \tag{40}$$

Recall that τ is the period of $z(t)$, the constant W is determined from Eq. (37) or Eq. (38), its sign being taken opposite to that of the integral in (40) to provide for positivity of μ. Since $w(z)$ has

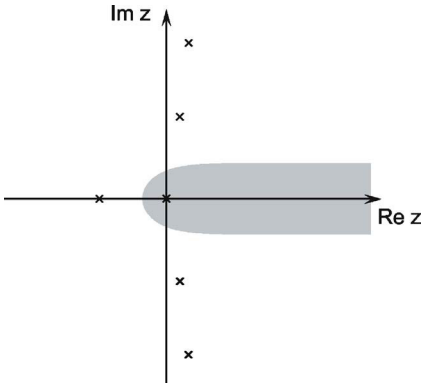

FIG. 3. The layout of zeros of $g(z)$ (43) on the complex z plane. The vicinity D (shaded) of the interval $[0,\infty)$ belongs to the domain of analyticity of $w(z)$.

zeros, the integrals in Eqs. (39) and (40) are understood as their principal values. Formula (40) is a simple generalization of the ones used previously in Refs. 37–40.

B. Evaluation of the characteristic exponent

Let us return to Eq. (18). It can be written in the form of Eq. (20) if we set

$$z(t) = -\ln(a/a_{\max})^2, \quad z(0) = 0, \tag{41}$$

$$h(z) = E - 3 + \omega_0^2 + z. \tag{42}$$

Equation (7) then immediately gives

$$g(z) = 4[\omega_0^2(e^z - 1) - z]. \tag{43}$$

Zeros of this function are shown in Fig. 3. Since $\xi(t)=a/a_{\max}$ oscillates with the period T in the interval $-1\leqslant\xi\leqslant 1$ [see Eqs. (7)–(12)], the function $z(t)$ (41) oscillates with the period $\tau=T/2$ between the turning points $\zeta_1=0$ and $\zeta_2=+\infty$. To calculate the characteristic exponent by the formula (40) we need to know the function $w(z)$ which is the solution of Eq. (26) with boundary conditions (25). Unfortunately, for given $h(z)$ (42) and $g(z)$ (43), Eq. (26) cannot be solved analytically. We solve it numerically[33] for various values of the parameters E and $\omega_0^2=1-\ln a_{\max}^2$. Doing so, we use the conditions (25) in the following way. As discussed above, the fulfillment of (25) at a finite turning point means analyticity of $w(z)$ in some vicinity of this point. Therefore, we can use the expansions (28) setting there $\zeta=\zeta_1=0$, $g_0=0$, $g_1=4(\omega_0^2-1)$, $g_n=4\omega_0^2/n!(n=2,3,\ldots)$, $h_0=E+\omega_0^2-3$, $h_1=1$. Equation (30) then gives

$$w_2 = -\frac{1 + (2E + 3\omega_0^2 - 6)w_1}{6(\omega_0^2 - 1)}. \tag{44}$$

We thus solve Eq. (26) with the following conditions at $z=0$: $w(0)=1$, $w'(0)=w_1$, $w''(0)=2w_2$. Given values of E and ω_0^2, we choose w_1 so as to satisfy the condition (25) at infinity,

$$(w'\sqrt{g})_{z\to+\infty} \to 0. \tag{45}$$

At the same time, since μ is assumed to be real, the values of E, ω_0^2, and w_1 must provide for positivity of W^2,

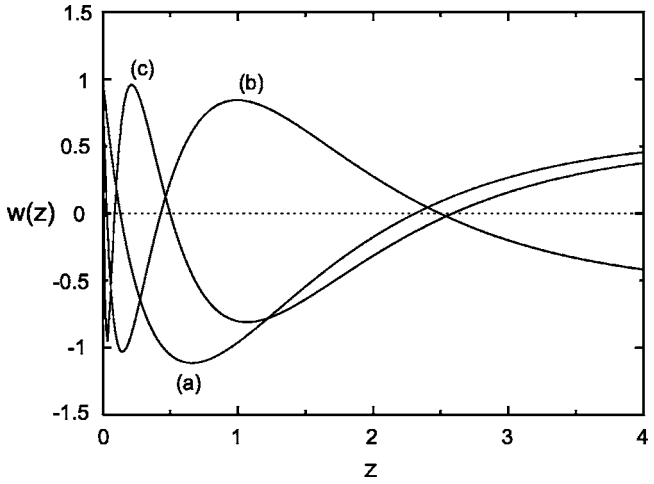

FIG. 4. Behavior of $w(z)$ for $E=4$ in the different resonance zones: (a) zone Z_1, $a^2_{\max}=0.5625$, (b) zone Z_2, $a^2_{\max}=0.9025$, (c) zone Z_3, $a^2_{\max}=0.9598$. The values of $a^2_{\max}$ chosen correspond to the centers of zones where μ achieves its maxima. One can see that the number of zeros of $w(z)$ is unit above the number of a zone.

$$W^2 = 4[3 - E - \omega_0^2 - (\omega_0^2 - 1)w_1] > 0 \tag{46}$$

[see Eqs. (37) and (40)]. Conditions (45) and (46) determine the resonance zones in the space of parameters E and ω_0^2 (or $a^2_{\max}$). Hereinafter the zones will be referred to as Z_j and numbered sequentially as E grows (with $a^2_{\max}$ fixed) starting with $j=-1$ in the region $E<0$. Figure 4 shows the solutions $w(z)$ for zones Z_1, Z_2, and Z_3 lying in the region $E>2$. Now, knowing $w(z)$, we can calculate the integral in (40). Because $w(z)$ has zeros, we first transform the integrand with the help of Eq. (36) extracting the total derivative. Owing to the condition (45), the latter does not contribute to the principal value of the integral, while the remaining terms give

$$\int_0^\infty \frac{dz}{w\sqrt{g}} = -\frac{1}{2W^2}\int_0^\infty [\sqrt{g}(w'\sqrt{g})' \ln w^2 + 8hw]\frac{dz}{\sqrt{g}}. \tag{47}$$

The integrand on the right-hand side of Eq. (47) is more convenient for numerical integration because its singularities are all integrable. We perform the integration in (47), calculate W^2 by the formula (46), and find the period $T=2\tau$ by integration of Eq. (7). These procedures are carried out numerically for a set of grid points in every resonance zone. In this way from (40) we obtain the characteristic exponent μ as a function of E and $a^2_{\max}$.

To check this result we derive $\mu(E, a^2_{\max})$ directly from analysis of numerical solutions of Eq. (18). Examples of these solutions for resonance zones Z_1, Z_2, and Z_3 are shown in Fig. 5. The growth of the amplitude with time is clearly seen. The function $\mu(E, a^2_{\max})$ so derived is found to be fully coincident with the one obtained by the formula (40).

The resulting stability-instability chart is presented in Fig. 6. Figure 6(a) shows the region $E>2$. There is an infinite series of narrow resonance zones $Z_1, Z_2, Z_3, \ldots$, the first one having the highest magnitude (≈ 0.08 at the maximum). All these zones originate from the point $E=2$, $a^2_{\max}=1$ at which $\mu=0$ [see Eqs. (40) and (46)]. In the region $E\leqslant 2$ we have two zones, Z_0 and Z_{-1}, lying in the ranges $0<E<2$ and $E<0$, correspondingly. Since in these zones the values of μ proved to be much greater than in $Z_1, Z_2, \ldots$, we depict the surface $\mu(E, a^2_{\max})$ for this region separately, in Fig. 6(b).

C. Spatial structure of the perturbation

Consider now Eq. (19). It has the form of the Schrödinger equation for a quantum particle of the energy E moving in the potential $-\ln u^2$. Since the potential tends to $+\infty$ with growing r [as r^2,

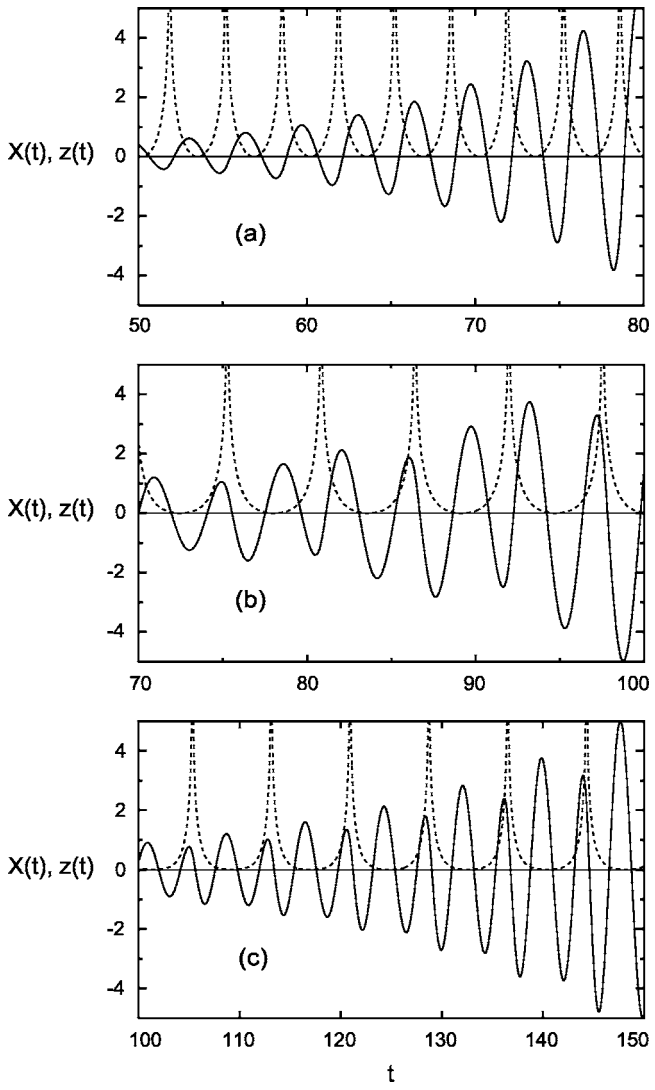

FIG. 5. Resonant solutions of Eq. (18), $X(t)\sim X_+(t)=\varphi(t)e^{\mu t}$, (solid lines) and the function $z(t)=-\ln(a/a_{\max})^2$ (dashed lines): (a) zone Z_1, (b) zone Z_2, (c) zone Z_3. The initial conditions are: $a(0)=a_{\max}$, $a_t(0)=0$, $X_t(0)=0$, $X(t)$ is normalized in a proper way. The values of E and $a_{\max}^2$ in each zone are the same as in Fig. 4. It is seen that $\varphi(t)$ is τ-periodic in Z_1, τ-antiperiodic in Z_2, τ-periodic in Z_3, and so on, in accordance with the solutions (39) [see Eqs. (35) and (38) and Fig. 4].

see Eqs. (13) and (14)], the energy spectrum is discrete, $E=E_n$, and the corresponding eigenfunctions $\Psi_n(\mathbf{r})$ are all localized. In the case of the nodeless pulson (13) we have the isotropic harmonic oscillator. Its eigenfunctions are well known (see, e.g., Ref. 41). We write them as follows:

$$\Psi_n(\mathbf{r})=\sum_{l=0}^{n}[1+(-1)^{n-l}]R_{nl}(r)Y_l(\theta,\varphi), \tag{48}$$

$$R_{nl}(r)=r^l e^{-r^2/2}\Phi\left(-\frac{n-l}{2},l+\frac{3}{2},r^2\right), \tag{49}$$

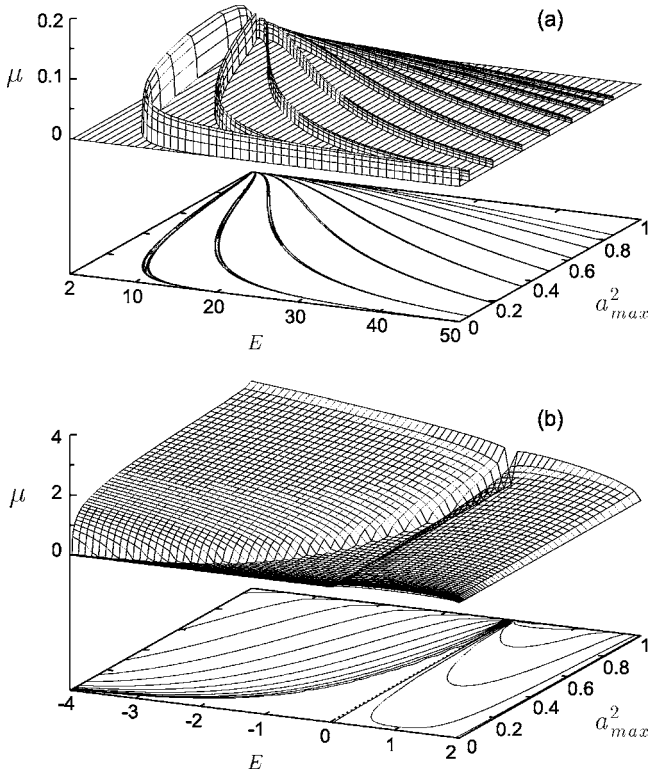

FIG. 6. The stability-instability chart: (a) $E>2$, first 10 zones are shown, (b) $E\leqslant 2$.

$$Y_l(\theta,\varphi)=\sum_{m=-l}^{l} c_{l,m}P_l^{|m|}(\cos\theta)e^{im\varphi}. \tag{50}$$

Here $\Phi(\alpha,\gamma,x)$ is the Kummer function, $P_\nu^\mu(x)$ are the associated Legendre functions, $c_{l,m}$ are constants, $c_{l,-m}=c_{l,m}^*$. The energy spectrum is given by

$$E=E_n=2n \quad (n=0,1,2,\dots). \tag{51}$$

(Our energy levels are shifted with respect to the conventional ones since the minimum of the potential $-\ln u_0^2$ is -3.)

In the case of the nodal pulsons the picture becomes more complicated due to the loss of the orbital degeneracy. The corresponding eigenfunctions and eigenvalues can be calculated only numerically. As an example, in Fig. 7 is shown the energy spectrum for perturbations of the one-nodal pulson.

Note that there always exist the eigenvalues $E=0$, $l=0$ and the corresponding eigenfunction $\Psi_0(r)\propto u(r)$. This fact immediately follows from the comparison of Eqs. (6) and (19). The corresponding $X_0(t)$ in $\eta(t,\mathbf{r})$ is an oscillating function with the amplitude growing linearly with time. It is easy to see, however, that this mode is physically meaningless. Indeed, it will formally appear if we perturb the pulson by a small variation of its amplitude $a_{\max}$ but not the form $u(r)$. Due to nonlinearity, this results in a pulson with slightly shifted frequency. Then the difference of the perturbed and unperturbed pulsons, i.e., $\eta(t,r)$, will have the form of beats generated by two oscillations with close frequencies and the same profile $u(r)$. The function $X_0(t)$ approximates the initial, linearly growing part of a beat. We exclude this mode from the subsequent consideration, since it belongs to the class of perturbations that conserve a pulson as a whole. Next, for the nodal pulsons only, there is a mode with $E=0$, $l=1$ (see Fig. 7). Since this mode cannot grow faster than linearly in time, we also do not take it into account. Further, we should exclude the mode resulting

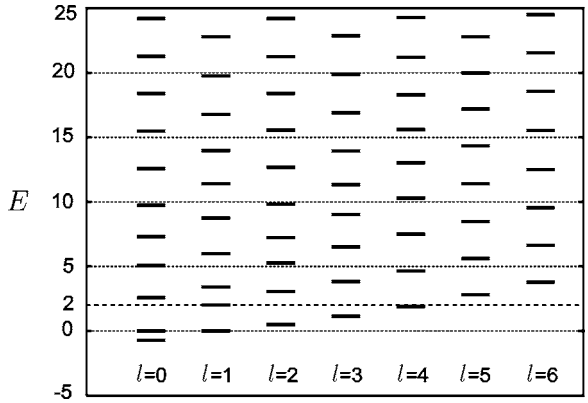

FIG. 7. The energy levels for the perturbations with different orbital numbers l. The case of the one-nodal pulson.

from a small translation of the pulson. The corresponding eigenfunction is proportional to $\mathbf{n}\nabla u$, where $\mathbf{n}$ is a displacement vector. Using Eqs. (6) and (19) one can easily show that this mode corresponds to $E=2$, $l=1$. Thus the resulting perturbation is written as

$$\eta(t,\mathbf{r}) = \sum_n X_n(t)\Psi_n(\mathbf{r}), \tag{52}$$

where X_n is a solution of Eq. (18) with $E=E_n$, $E_n \neq 0,2$. If E_n and $a^2_{\max}$ are in a resonance zone, $X_n(t)$ will be represented as a linear combination of the solutions (21) and, hence, will grow with time as $e^{\mu(E_n,a^2_{\max})t}$.

D. Instability of the pulsons

The arrangement of the resonance zones on the $(E,a^2_{\max})$ plane indicates that for any spectrum E_n there always exist the ranges of $a^2_{\max}$ where pulsons are unstable. But do the values of $a^2_{\max}$ exist for which the pulsons are stable? To answer this question let us return to the surface $\mu(E,a^2_{\max})$ depicted in Fig. 6. Take, at first, the spectrum for the nodeless pulson. We choose the sections $\mu_n(a^2_{\max})$ of the surface $\mu(E,a^2_{\max})$ by $E=2n$ and project them on the $(\mu,a^2_{\max})$ plane. As a result, the pattern shown in Fig. 8(a) emerges. It is clearly seen the tendency to the total filling of the interval $0<a^2_{\max}<1$ by the resonant peaks as the successively higher energy levels are accounted for. This implies that for any given $a^2_{\max}$ there always exists an unstable mode with $\mu=\mu_n(a^2_{\max})$, i.e., strictly speaking, all nodeless pulsons are unstable. On the other hand, the figure shows that there are domains of $a^2_{\max}$ where the peaks are very small. These domains are the gaps between the main peaks originated from the low-energy cross sections of the surface $\mu(E,a^2_{\max})$ over a few first zones. In the gaps the exponent μ is small, so that the corresponding pulsons are long-lived. For example, in Ref. 33 we observed numerically the nodeless pulson with $a^2_{\max}=0.49$ that conserved its coherency against the radially symmetric perturbations over the course of several hundreds of periods.

Further, the above projective procedure is performed using the spectrum of the one-nodal pulson (Fig. 7). The main contribution here is made by the sections with the energies $E_n=-0.7142$ ($l=0$), 0.4833 ($l=2$), 1.1222 ($l=3$), and 1.8996 ($l=4$) falling into zones Z_{-1} and Z_0, the projections of the first and the third sections overlapping the other ones. The result is presented in Fig. 8(b). We see that $a^2_{\max}$ axis is totally full. Thus, the one-nodal pulson has neither stability nor even quasistability domains. It seems likely that things will get worse, not better, if one goes to the multinodal pulsons. We thus conclude that, strictly speaking, all pulsons of the model considered are unstable. But nodeless pulsons can be quasistable in narrow ranges of amplitudes. It is the

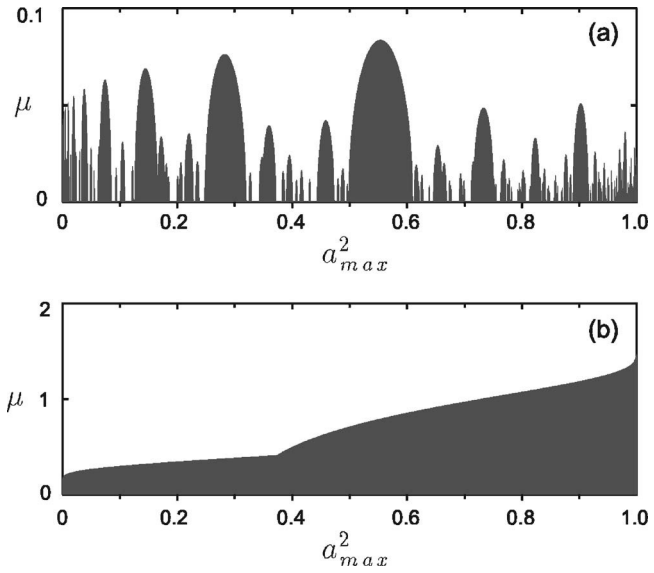

FIG. 8. Superposition of the sections $\mu_n(a^2_{\max})$ of the surface $\mu(E,a^2_{\max})$: (a) the nodeless pulson, $E_n=4,6,8,\ldots,50$, ($n=2,3,4,\ldots,25$), (b) the one-nodal pulson, $E_n=-0.7142,0.4833,1.1222,1.8996,\ldots$.

long-lived pulsons that can be of astrophysical and cosmological interest. If the dark matter consists of scalar particles, such pulsons will be realistic candidates for the dark matter objects having oscillating density.[42]

E. On the instability of the Affleck-Dine-type condensate

The obtained stability-instability chart turns out to be appropriate for the stability analysis of the nonlocalized coherent states as well. As an example, we consider a uniformly distributed background $\phi_0(t)$, a scalar condensate, oscillating around the minimum of the potential (4) at $\phi=0$. This state can be formally obtained from Eq. (1) if we set there $u(\mathbf{r})\equiv 1$. We thus assume that $\phi_0(t)$ obeys Eq. (5). Taking the perturbed state $\phi=\phi_0(t)+\eta(t,\mathbf{r})$, in the linear approximation from Eqs. (2) and (4) we readily obtain

$$A_{tt}+(k^2-2-\ln\phi_0^2)A=0, \tag{53}$$

where $A(t,\mathbf{k})$ is the Fourier amplitude of the perturbation, and $k=|\mathbf{k}|$. It is seen that the real and imaginary parts of this equation have the form of Eq. (20) with $h(z)$ given by Eq. (42), $z=-\ln(\phi_0/\phi_{0\,\max})^2$, $\omega_0^2=1-\ln\phi_{0\max}^2$, and $E=k^2$. Returning to the stability-instability chart (Fig. 6) we note that in the region $E\geqslant 0$ maximal values of μ are attained in the zone Z_0 for which $0<E<2$. Interestingly, this band exactly coincides with the one obtained in Ref. 20 for the power-law potential approximating (3) when $\lambda\ll 1$. In the interior of Z_0 the exponent μ depends almost not at all on the amplitude of the condensate oscillations and is a sufficiently smooth function of k^2 with a maximum at $k^2=k_0^2\approx 1$ where $\mu\approx 0.5$. Therefore, if the initial power spectrum $|A(0,\mathbf{k})|^2$ lies in the region $0\lesssim|\mathbf{k}|\lesssim\sqrt{2}$ and, in addition, its characteristic width along $\mathbf{k}$ is small, $\Delta k\ll\sqrt{2}$, then the growth of the perturbation amplitude will not be accompanied by significant changes in the structure of the perturbation. The limiting case of such perturbations is a harmonic wave. Otherwise, if $\Delta k\gtrsim\sqrt{2}$, the shape of the power spectrum will vary with time so that a maximum will appear at $k_0\approx 1$. As a result, the effective width of the spectrum will become smaller, $\Delta k\lesssim 1$. In this case, if the initial spectrum is sufficiently isotropic in $\mathbf{k}$ space, the parametric amplification of the perturbations will result in the emergence of the localized field configurations of the characteristic size $\Delta r\sim 1/\Delta k\gtrsim 1$ that agrees with the radius of the gausson (see Sec. II). At this scale the field practically does not undergo spatial oscillations since the corresponding wavelength

$2\pi/k_0 \gtrsim 1$. We thus expect that at the nonlinear stage these configurations will turn into the nodeless pulsons. Their period will be equal to the period of the condensate oscillations since in the zone Z_0 the parametric amplification proceeds at the basic frequency. Gradually, the energy of the oscillating condensate will go to ensemble of the arising pulsons, this process resulting in the damping of the background oscillations. As to the pulsons themselves, they can be long-lived or short-lived depending on their amplitudes, in accordance with the results of the preceding subsection.

Note, that numerical simulations performed for the complex version of the model (2) and (3) have shown the fragmentation of both the rotating[18,19] and oscillating[20] Affleck-Dine condensate. The localized configurations arising in the condensate have been identified with Q-balls. We belive, however, that the configurations observed in the oscillating condensate are in fact the complex pulsons (see Sec. IV), rather than the usual Q-balls. This possibility was early discussed in Ref. 15 where an attempt to simulate the complex pulson has been made.

The resonant exitation of the pulsons was also observed in the two-vacuum $\phi^4-\phi^6$ model within a regularly oscillating background[39] and in the ϕ^4 model within an initially thermalized background.[43] Note that in two-vacuum models the pulsons can play the role of nuclei of a new phase. In Ref. 39 the general suggestion has been made that the parametric resonance can underlie the mechanism responsible for the first-order phase transitions in nonlinear nondissipative systems. This conjecture turns out to be in agreement with recent results of Ref. 44 where the resonant nucleation within the thermalized background have been numerically observed in the $\phi^3-\phi^4$ model. Note, in addition, that the dynamical nucleation can also take place in the nonlinear Schrödinger equation.[45]

IV. CONCLUDING REMARKS

In this paper we have examined only the linear stage of instability at which small deformations of the pulson's shape result in loss of the coherence. There is numerical evidence that in time the growth of the perturbations becomes saturated due to nonlinear effects.[33] We thus suggest that in the model considered the pulsons, while unstable, remain well localized objects with no tendency for spreading or collapsing.

Further, we dealt with a real scalar field. It would be interesting to perform the similar analysis for a complex scalar field too. It is believed that the existence of the scalar charge can stabilize a field lump. For Q-balls this fact is well established (so-called Q-theorem[2,4,27]). In contrast, for the complex pulsons this is an open question. As it was shown in Refs. 28 and 29, the field equation (2) with $U'=-\phi\ln(\phi\phi^*)$ admits the exact pulson solutions of the form $\phi_0(t,r)=a(t)u(r)e^{i\theta(t)}$, where $a(t)$, $u(r)$, and $\theta(t)$ are real. The function $u(r)$ satisfies Eq. (6) as before, while $a(t)$ oscillates with a period T in accordance with the equation

$$a_{tt}=-\frac{d}{da}\left[\frac{1}{2}a^2(1-\ln a^2)+\frac{q^2}{2a^2}\right], \tag{54}$$

where q is a real constant, $q^2<(2e)^{-1}$, and $\theta_t=qa^{-2}$. The constant q is proportional to the charge of the scalar field. In contrast to Eq. (5), the potential in the square brackets of Eq. (54) prevents $a(t)$ from being zero. Without loss of generality one may assume $a(t)$ positive, so that the oscillations occur arround the minimum of the potential at $a=a_0$, where a_0 is the least positive root of the equation $a^4\ln a^2=-q^2$. If a is at rest in this minimum, then $\theta(t)=qa_0^{-2}t+\theta(0)$, and we have the standard Q-ball. Physically, Eq. (54) describes the motion of a mechanical particle with an angular momentum q in the potential $(a^2/2)(1-\ln a^2)$. The condition for its trajectory to be closed is $\theta(T)-\theta(0)=2\pi m/n$, where m and n are arbitrary integers (see, e.g., Ref. 46). In fact, it relates the energy of the particle and its angular momentum whereby such trajectories exist. In our case this means periodicity of the solution $\phi_0(t,r)$ with the period nT. Obviously, there is an infinity of such solutions. Taking $\phi_0(t,r)$ and considering the partial perturbation $\eta\propto X(t)\Psi(\mathbf{r})$ one can find that the function $\Psi(\mathbf{r})$, assumed to be real, satisfies Eq. (19) as before, while $X(t)$ obeys the equation

$$X_{tt} + (E - 1 - \ln a^2)X = e^{2i\theta}X^*, \tag{55}$$

where E is a real constant. This equation can be represented as a system of four real first-order equations with periodic coefficients of the periods T and nT. It is significant that, since $a(t) \neq 0$, these coefficients are bounded in time, so that one can attempt to estimate the characteristic exponent of the system using the standard methods.[47]

Also, it would be interesting to examine stability of a self-gravitating pulson. Hopefully, gravitation can expand the domains of (quasi)stability, as it is the case for Q-balls.[4] These are possible subjects of our future work.

In the present paper we have investigated stability of both the coherent localized states (pulsons) and nonlocalized states (uniformly oscillating scalar condensate) of the real scalar field. Our main analytical result is the generalization of the Lindemann-Stieltjes method to the case that the periodic coefficient in the Hill equation is unbounded in time. Our main numerical result is the stability-instability chart with the values of characteristic exponent calculated in the resonance zones. Using this chart we have found the gaps in the set of the pulson amplitude values in which the real nodeless pulsons conserve the coherency for an extremely long time. Also, considering the oscillating scalar condensate, we have detemined the wavelength of the most unstable mode. This wavelength turned out to be equal to the characteristic size of the nodeless pulson. We thus suggest the pulsons can be formed due to resonant fragmentation of the scalar condensate. These are our main physical results.

(Received 2 December 2005; accepted 21 December 2005; published online 27 February 2006)

It has been known for some time that for a large class of nonlinear field theories in Minkowski space with two-dimensional target space the complex eikonal equation defines integrable submodels with infinitely many conservation laws. These conservation laws are related to the area-preserving diffeomorphisms on target space. Here we demonstrate that for all these theories there exists, in fact, a weaker integrability condition which again defines submodels with infinitely many conservation laws. These conservation laws will be related to an Abelian subgroup of the group of area-preserving diffeomorphisms. As this weaker integrability condition is much easier to fulfill, it should be useful in the study of those nonlinear field theories. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2168400]

I. INTRODUCTION

Recently there has been rising interest in nonlinear field theories which allow for the existence of knotlike solitons. The probably best known of these models, the Faddeev-Niemi model,[1,2] for example, finds some applications in condensed matter physics.[3,4] Further, some versions of it are discussed as possible candidates for a low-energy effective theory of Yang-Mills theory.[5,6] In addition, there is some intrinsical mathematical interest in theories with knot solitons. Generally, these models are described by a complex field $u:\mathbb{R}^3\times\mathbb{R}\to\mathcal{M}:(\vec{x},t)\to u(\vec{x},t)$ where $\mathcal{M}$ is a two-dimensional target space manifold and u plays the role of a complex coordinate on this manifold.

The Faddeev-Niemi model has the two-sphere as target space and is given by the Lagrangian density

$$\mathcal{L}_{\mathrm{FN}}=\mathcal{L}_2-\lambda\mathcal{L}_4, \tag{1}$$

where λ is a dimensionful coupling constant, $\mathcal{L}_2$ is

$$\mathcal{L}_2=4\frac{\partial_\mu u\partial^\mu\overline{u}}{(1+u\overline{u})^2}, \tag{2}$$

and $\mathcal{L}_4$ is

[a]Electronic mail: adam@fpaxp1.usc.es
[b]Electronic mail: joaquin@fpaxp1.usc.es
[c]Electronic mail: wereszczynski@th.if.uj.edu.pl

$$\mathcal{L}_4 = 4\frac{(\partial^\mu u \partial_\mu \overline{u})^2 - (\partial^\mu u \partial_\mu u)(\partial^\nu \overline{u} \partial_\nu \overline{u})}{(1+u\overline{u})^4}. \tag{3}$$

Two more models which support solitons and can be constructed from the two Lagrangian densities $\mathcal{L}_2$ and $\mathcal{L}_4$ separately, are the AFZ (Aratyn, Ferreira, and Zimerman) model[7,8]

$$\mathcal{L}_{\mathrm{AFZ}} = -(\mathcal{L}_4)^{\frac{3}{4}} \tag{4}$$

and the Nicole model[9]

$$\mathcal{L}_{\mathrm{Ni}} = (\mathcal{L}_2)^{\frac{3}{2}}. \tag{5}$$

Here the noninteger powers for the Lagrangian densities have been chosen appropriately to avoid Derrick's theorem. More models together with some explicit soliton solutions have been constructed, e.g., in Refs. 10 and 11.

Among these models the AFZ model is special, because it has infinitely many symmetries and, as a consequence, infinitely many conservation laws.[12,13] Further, infinitely many soliton solutions can be found by an explicit integration for a special ansatz (separation of variables in toroidal coordinates), which realizes the concept of integrability in a rather explicit way. The other models do not have infinitely many symmetries, but, nevertheless, "integrable" subsectors with infinitely many conserved currents can be defined.[14,15] The condition which defines these integrable subsectors is the complex eikonal equation

$$u^\mu u_\mu = 0, \tag{6}$$

where $u_\mu \equiv \partial_\mu u$. The infinitely many conserved currents J^G_μ (defined in Sec. III) for these submodels are parametrized by an arbitrary, real function $G(u,\overline{u})$ and are, in fact, just the Noether currents for the area-preserving diffeomorphisms on target space.[12,16] [Some more ("generalized") integrability conditions, which, however, depend on the Lagrangian, have been introduced in Refs. 17 and 16.]

Here we want to demonstrate that there exists, instead of the complex eikonal equation, a weaker condition which again defines submodels with infinitely many conservation laws. Further, these integrable submodels can be defined for all Lagrangians for which the complex eikonal equation defines integrable submodels. Explicitly this condition reads

$$\overline{u}^2 u_\mu^2 - u^2 \overline{u}_\mu^2 = 0. \tag{7}$$

The infinitely many conserved currents J^G_μ for these submodels are as above, but with the additional restriction that now $G = G(u\overline{u})$. They are the Noether currents for an Abelian subgroup of the group of area-preserving diffeomorphisms on target space.

The meaning of condition (7) becomes especially transparent when we reexpress u in terms of its modulus and phase like

$$u = \exp(\Sigma + i\phi). \tag{8}$$

Then the complex eikonal equation is equivalent to the two real equations

$$\Sigma_\mu^2 = \phi_\mu^2 \tag{9}$$

and

$$\Sigma^\mu \phi_\mu = 0, \tag{10}$$

whereas the weaker condition (7) becomes Eq. (10) alone or, for time-independent u,

$$(\nabla\Sigma)\cdot(\nabla\phi) = 0. \tag{11}$$

The integrability condition (7) might be quite useful, for instance, in the case of the Faddeev-Niemi model. For the Faddeev-Niemi model soliton solutions are only known numerically up to now.[2,18–21] No solutions which solve the complex eikonal equation, as well, are known and there are even arguments against the existence of such solutions. On the other hand, it is perfectly possible that there exist solutions which solve the weaker integrability condition (7) and that this condition helps in the search for analytic solutions.

The condition (7) is in fact quite weak, i.e., quite easy to fulfill. For instance, many commonly used separation-of-variable ansätze, like the ansatz $u=\rho(r,\theta)e^{im\varphi}$ in spherical polar coordinates, or the ansatz $u=\rho(\eta)e^{i(m\varphi+n\xi)}$ in toroidal coordinates (both ρ are real), identically obey condition (7) due to the orthogonality of the corresponding basis vectors. On the other hand, for the eikonal equation these ansätze lead to a differential equation for the profile function ρ which only allows for very specific solutions, therefore providing a much stronger restriction, see, e.g., Refs. 22 and 23. In short, condition (7) applies to a rather large class of field configurations and, therefore, we believe that it will be useful for the study of nonlinear field theories with a two-dimensional target space, like the Faddeev-Niemi or the Nicole model, or the other models mentioned above.

In Sec. II we discuss the algebra of generators of area-preserving diffeomorphisms and their Abelian subalgebra on a two-dimensional manifold. Further we define the Noether charges corresponding to these generators. In Sec. III we show that condition (7) defines subsectors with infinitely many conservation laws for a very general class of Lagrangians (which cover all Lagrangians given above). Further we demonstrate that the corresponding conserved currents are indeed the Noether currents of the Abelian area-preserving diffeomorphisms.

II. ABELIAN AREA-PRESERVING DIFFEOMORPHISMS

Here we describe area-preserving diffeomorphisms and an Abelian subgroup contained within them for a two-dimensional manifold $\mathcal{M}$ which later on will be identified with the target space of the nonlinear field theories which we want to study. Concretely, we choose real coordinates (ξ^1,ξ^2) or the complex coordinate $u=\xi^1+i\xi^2$ and allow for the class of metrics

$$ds^2 = g(a)[(d\xi^1)^2+(d\xi^2)^2] = g(a)du\,d\overline{u}, \tag{12}$$

where

$$a = (\xi^1)^2+(\xi^2)^2 = u\overline{u} \tag{13}$$

and

$$du\,d\overline{u} \equiv \tfrac{1}{2}(du\otimes d\overline{u}+d\overline{u}\otimes du), \tag{14}$$

$$du\wedge d\overline{u} \equiv \tfrac{1}{2}(du\otimes d\overline{u}-d\overline{u}\otimes du). \tag{15}$$

The corresponding area two-form is

$$\Omega \equiv g(a)d\xi^1\wedge d\xi^2 = \frac{g(a)}{2i}d\overline{u}\wedge du. \tag{16}$$

The choice of conformally flat metrics does not mean a restriction in two dimensions, because any metric on a two-dimensional manifold may be chosen conformally flat by an appropriate choice of coordinates. On the other hand, the functional dependence for the metric function $g=g(a)$ is a restriction, which is however sufficiently general for our purposes. In principle, one could skip this restriction, which would just complicate the subsequent discussion without adding substantial new structures (see the remark at the end of Sec. III).

An area-preserving diffeomorphism is a transformation $u\to v(u,\overline{u})$ such that the area form (16) remains invariant (see also Refs. 12, 13, and 15),

$$\Omega \equiv \frac{1}{2i} g(u\overline{u}) \mathrm{d}\overline{u} \wedge \mathrm{d}u = \frac{1}{2i} g(v\overline{v}) \mathrm{d}\overline{v} \wedge \mathrm{d}v. \tag{17}$$

For infinitesimal transformations $v = u + \epsilon$ it is easy to see that the condition of invariance of the area form leads to

$$\epsilon_u + \overline{\epsilon_{\overline{u}}} = -\frac{g'}{g}(\overline{u}\overline{\epsilon} + u\overline{\epsilon}), \tag{18}$$

where $\epsilon_u \equiv \partial_u \epsilon$ and $g' \equiv \partial_a g(a)$. Defining

$$\epsilon = g^{-1}\delta, \quad \delta = F_{\overline{u}} \tag{19}$$

the above equation for ϵ simplifies to

$$\partial_u \partial_{\overline{u}} (F + \overline{F}) = 0. \tag{20}$$

The general solution to this equation is

$$F + \overline{F} = \zeta(u) + \overline{\zeta(\overline{u})} \tag{21}$$

but for our purposes an imaginary F,

$$F + \overline{F} = 0, \tag{22}$$

serves as a general solution, because for any F which solves (21) there exists a $\widetilde{F} = F - \zeta(u)$ which is imaginary and leads to the same $\delta = F_{\overline{u}} = \widetilde{F}_{\overline{u}}$, i.e., to the same area-preserving diffeomorphism.

Introducing the real function G via $F = iG$, the area-preserving diffeomorphisms are therefore generated by the vector fields

$$v^G = ig^{-1}(G_{\overline{u}}\partial_u - G_u \partial_{\overline{u}}) \tag{23}$$

which obey the Lie algebra

$$[v^{G_1}, v^{G_2}] = v^{G_3}, \quad G_3 = ig^{-1}(G_{1,\overline{u}} G_{2,u} - G_{1,u} G_{2,\overline{u}}). \tag{24}$$

Now we want to find an Abelian subalgebra of this Lie algebra of vector fields. It is easy to see that the commutator (24) vanishes if both $G_i, i = 1, 2$ are of the form

$$G = G(u\overline{u}). \tag{25}$$

In addition, this gives a maximal Abelian subalgebra in the sense that if $G_1 = G_1(u\overline{u})$ then $G_3 = 0 \Leftrightarrow G_2 = G_2(u\overline{u})$. These issues may be seen especially easily by introducing the modulus and phase of u, $u = \sqrt{a}e^{i\phi}$. Then the vector field v^G for $G = G(a)$ is

$$v^G = H(a)\partial_\phi, \quad H(a) \equiv g^{-1}G' \tag{26}$$

and the above statements follow immediately. In short, the G of the form $G = G(u\overline{u})$ generate a maximal Abelian subgroup of the group of area-preserving diffeomorphisms.

Due to the Abelian nature of this subgroup it is trivial to integrate the infinitesimal transformations to reach finite ones. The result is that the transformations

$$u \to e^{i\Lambda(u\overline{u})} u \tag{27}$$

form a subgroup of Abelian area-preserving diffeomorphisms, where $\Lambda = \Lambda(a)$ is an arbitrary function of its argument. In fact, these transformations leave invariant the two terms $g(a)$ and $\mathrm{d}\overline{u} \wedge \mathrm{d}u$ separately.

Finally, let us describe how these transformations are implemented for field theories. For fields $u:\mathbb{R}^d\times\mathbb{R}\to\mathcal{M}:(\vec{x},t)\to u(\vec{x},t)$ the generators of area-preserving diffeomorphisms are given by Noether charges which are constructed with the help of the canonical momenta π, $\overline{\pi}$ of the fields u and $\overline{u}$. Concretely, they read

$$Q^G = i\int d^d\mathbf{x} g^{-1}(\overline{\pi}G_u - \pi G_{\overline{u}}) \tag{28}$$

and act on functions of $u,\overline{u},\pi,\overline{\pi}$ via the Poisson bracket, where the fundamental Poisson bracket is (with $x^0=y^0$)

$$\{u(\mathbf{x}),\pi(\mathbf{y})\} = \{\overline{u}(\mathbf{x}),\overline{\pi}(\mathbf{y})\} = \delta^d(\mathbf{x}-\mathbf{y}) \tag{29}$$

as usual. The generators Q^{G_i} close under the Poisson bracket, $\{Q^{G_1},Q^{G_2}\}=Q^{G_3}$ where G_3 is as in (24). Specifically, for $G=G(a)$ they generate the Abelian area-preserving diffeomorphisms, as above.

III. INTEGRABLE SUBSECTORS

In this section we want to show that for a wide class of Lagrangian densities integrable subsectors can be defined which have infinitely many conserved Noether currents which may be related to the Abelian diffeomorphisms of the above section. The discussion in this section in some respect resembles the discussion in Ref. 16. However, the integrability condition which we shall derive here has not been discussed in that reference. We introduce the class of Lagrangian densities

$$\mathcal{L}(u,\overline{u},u_\mu,\overline{u}_\mu) = \mathcal{F}(a,b,c), \tag{30}$$

where

$$a = u\overline{u}, \quad b = u_\mu\overline{u}^\mu, \quad c = (u_\mu\overline{u}^\mu)^2 - u_\mu^2\overline{u}_\nu^2 \tag{31}$$

and $\mathcal{F}$ is at this moment an arbitrary real function of its arguments. That is to say, we allow for Lagrangian densities which depend on the fields and on their first derivatives, are Lorentz invariant, real, and obey the phase symmetry $u\to e^{i\lambda}u$ for a constant $\lambda\in\mathbb{R}$. We could relax the last condition and allow for real Lagrangian densities which depend on u and $\overline{u}$ independently, but this would just complicate the subsequent discussion without adding anything substantial. Further, all models we want to cover fit into the general framework provided by the class of Lagrangian densities (30), therefore we restrict our discussion to this class.

The canonical four-momentum for this class of models is

$$\pi_\mu \equiv \mathcal{L}_{u^\mu} = \overline{u}^\mu\mathcal{F}_b + 2(u^\lambda\overline{u}_\lambda\overline{u}_\mu - \overline{u}_\lambda^2 u_\mu)\mathcal{F}_c \tag{32}$$

and the equation of motion reads

$$\partial^\mu\pi_\mu = \mathcal{L}_u = \overline{u}\mathcal{F}_a \tag{33}$$

together with its complex conjugate.

We introduce the infinitely many currents

$$J_\mu^G = if(a)(G_u\overline{\pi}_\mu - G_{\overline{u}}\pi_\mu), \tag{34}$$

where $f(a)$ is an arbitrary but fixed real function of its argument. Further, G is an arbitrary real function of u and $\overline{u}$, and $G_u\equiv\partial_u G$. Comparing with the Noether charge (28) it is tempting to identify $f=g^{-1}$ and J_μ^G with the Noether currents of area-preserving diffeomorphisms, and we will see in a moment that for a large subclass of Lagrangian densities this identification can be made, indeed.

In a first step, let us investigate which conditions make the divergence of the above current vanish, $\partial^\mu J^G_\mu = 0$. We find after a simple calculation

$$\partial^\mu J^G_\mu = if([(M'\overline{u}G_u + G_{uu})u_\mu^2 - (M'uG_{\overline{u}} + G_{\overline{uu}})\overline{u}_\mu^2]\mathcal{F}_b + (uG_u - \overline{u}G_{\overline{u}})[M'(b\mathcal{F}_b + 2c\mathcal{F}_c) + \mathcal{F}_a]), \tag{35}$$

where

$$M \equiv \ln f \tag{36}$$

and the prime denotes the derivative with respect to a.

The condition that the second term on the right-hand side (rhs) of Eq. (35) vanishes requires that either

$$uG_u - \overline{u}G_{\overline{u}} = 0 \tag{37}$$

or

$$M'(b\mathcal{F}_b + 2c\mathcal{F}_c) + \mathcal{F}_a = 0. \tag{38}$$

Assuming condition (37) we find the general solution

$$G(u,\overline{u}) = G(u\overline{u}) \equiv G(a) \tag{39}$$

which is exactly equal to the condition (25) which restricts the generators of area-preserving diffeomorphisms to the Abelian subalgebra.

The condition that the first term on the rhs of Eq. (35) vanishes requires that either

$$\mathcal{F}_b = 0 \tag{40}$$

or that

$$[(M'\overline{u}G_u + G_{uu})u_\mu^2 - (M'uG_{\overline{u}} + G_{\overline{uu}})\overline{u}_\mu^2] = 0. \tag{41}$$

Condition (40) may, e.g., be satisfied by assuming $\mathcal{F}_b \equiv 0 \Rightarrow \mathcal{F} = \mathcal{F}(a,c)$. It follows that theories with Lagrangians $\mathcal{L} = \mathcal{F}(a,c)$ have infinitely many conserved currents (34), where G is restricted to (39). Of the models mentioned in the Introduction, only the AFZ model falls into this class. However, the AFZ model also obeys condition (38), therefore the restriction (39) is unnecessary and the J^G_μ are conserved for all G.

Alternatively we may make the first term on the rhs of Eq. (35) vanish by imposing Eq. (41). For an unrestricted G this leads to a condition on the field u,

$$u_\mu^2 = 0, \tag{42}$$

i.e., the complex eikonal equation, which, therefore, defines a submodel for which there exist infinitely many conserved currents provided that one of the two conditions (37) or (38) is imposed, in addition.

However, by invoking condition (39) we may reexpress condition (41) like

$$(M'G' + G'')F_b[\overline{u}^2 u_\mu^2 - u^2\overline{u}_\mu^2] \tag{43}$$

and, therefore, we find, instead of the complex eikonal equation, the weaker integrability condition

$$\overline{u}^2 u_\mu^2 - u^2\overline{u}_\mu^2 = 0, \tag{44}$$

i.e., Eq. (7). Therefore, for *all* Lagrangians $\mathcal{L} = \mathcal{F}(a,b,c)$ condition (44) defines submodels which have infinitely many conserved currents (34), where G is restricted to (39), again. All models mentioned in the Introduction belong to this class.

Finally, we want to investigate what happens if we impose condition (38), either alternatively or in addition to condition (39) [we want to remark that condition (38) is fulfilled by all models mentioned in the Introduction]. Equation (38) can be solved easily by the method of characteristics and has the general solution

$$\mathcal{F}(a,b,c) = \mathcal{F}\left(\frac{b}{f}, \frac{c}{f^2}\right). \tag{45}$$

This solution allows us to interpret the Lagrangian in terms of the target space geometry and to identify the currents (34) with the Noether currents of the area-preserving diffeomorphisms of Sec. II, as we want to demonstrate briefly. Indeed, trading the complex u field for two real target space coordinates ξ^α, $u \to (\xi^1, \xi^2)$, the expressions on which $\mathcal{F}$ may depend can be expressed as follows. The first term is

$$\frac{b}{f} = \frac{u_\mu \overline{u^\mu}}{f} = g_{\alpha\beta}(\xi)\partial^\mu \xi^\alpha \partial_\mu \xi^\beta, \tag{46}$$

where $\alpha = 1, 2$, etc., and the target space metric $g_{\alpha\beta}$ is diagonal and conformally flat for the coordinate choice $\xi^1 = \mathrm{Re}\, u$, $\xi^2 = \mathrm{Im}\, u$, i.e.,

$$g_{\alpha\beta} = g(a)\,\delta_{\alpha\beta} \equiv f^{-1}\delta_{\alpha\beta}. \tag{47}$$

For the second term we get

$$\frac{c}{f^2} = \tilde{\epsilon}_{\alpha\beta}\tilde{\epsilon}_{\gamma\delta}\partial^\mu \xi^\alpha \partial_\mu \xi^\gamma \partial^\nu \xi^\beta \partial_\nu \xi^\delta, \tag{48}$$

where

$$\tilde{\epsilon}_{\alpha\beta} = g\epsilon_{\alpha\beta}, \quad g = f^{-1} = \det{}^{1/2}(g_{\gamma\delta}) \tag{49}$$

and $\epsilon_{\alpha\beta}$ is the usual antisymmetric symbol in two dimensions. We remark that the two terms are different in that the first one, b/f, depends on the target space metric, whereas the second one only depends on the determinant of the target space metric. For this class of Lagrangians the currents (34) are the Noether currents of area-preserving diffeomorphisms on target space, and the condition $G = G(a)$ defines these Noether currents for the subgroup of Abelian area-preserving diffeomorphisms defined in Sec. II, as announced.

Remark: The Abelian subalgebra spanned by generators of the form $G = G(u\overline{u})$ is by no way the only Abelian subalgebra that exists for the algebra of vector fields v^G of Eq. (24). In fact, any subset of G of the form $G(u,\overline{u}) = \tilde{G}_i[h(u,\overline{u})]$ where h is an arbitrary but fixed function forms an Abelian subalgebra, i.e., $[v^{\tilde{G}_1}, v^{\tilde{G}_2}] = 0$. This follows from the fact that for an area-preserving diffeomorphism the vector field $v^{\tilde{G}}$ must be perpendicular to the (target space) gradient of h, i.e., it must point into the direction $h = \mathrm{const}$. Indeed,

$$v^{\tilde{G}}h = i\tilde{G}'(h_{\overline{u}}\partial_u - h_u\partial_{\overline{u}})h = i\tilde{G}'(h_{\overline{u}}h_u - h_u h_{\overline{u}}) = 0. \tag{50}$$

However, these Abelian subalgebras for $h \neq u\overline{u}$ do not play a special role in our discussion, i.e., they do not produce new integrability conditions. The reason why $h = u\overline{u}$ plays a special role lies in the fact that our metric function (Weyl factor) g depends on it, $g = g(u\overline{u})$. Had we chosen a different functional dependence $g = g[h(u,\overline{u})]$ for the metric function, then the corresponding generators $\tilde{G}_i[h(u,\overline{u})]$ of an Abelian subalgebra would define a nontrivial new integrability condition. For example, in the case $g = g(\xi^1) \equiv g[(u+\overline{u})/2]$ we find the integrability condition

$$u_\mu^2 - \vec{u}_\mu^2 = 0 \quad \text{or } (\xi^1)_\mu (\xi^2)^\mu = 0. \tag{51}$$

A target space with a metric of the form $g=g(\xi^1)$, however, does not have the topology of the two-sphere (but rather the topology of $\mathbb{R}^2$ or of a cylinder). Therefore, the corresponding field theory does not have a nontrivial Hopf index and, consequently, does not give rise to knot solitons. In this sense it is, therefore, less interesting.

Global visibility of naked singularities

Roberto Giambò[a)]
Dipartimento di Matematica e Informatica, Università di Camerino, Italy

(Received 20 October 2005; accepted 19 December 2005;
published online 17 February 2006)

Global visibility of naked singularities is analyzed here for a class of spherically symmetric spacetimes, extending previous studies—limited to inhomogeneous dust cloud collapse—to more physical valid situations in which pressures are non-vanishing. Existence of nonradial geodesics escaping from the singularity is shown, and the observability of the singularity from far-away observers is discussed.
 [DOI: 10.1063/1.2167919]

I. INTRODUCTION

The study of gravitational collapse of spherically symmetric solutions in general relativity led to many examples of locally naked singularities, starting from pioneering works in the early 1980's—a quite exhaustive and updated list of references can be found in Refs. 1 and 2. Most of these papers concentrate on the aim to find photons emanated from the singularity and escaping the Schwarzschildian trapped region at least locally. Moreover, the analysis has been always limited to the study of *radial* null geodesics, quite simplifying then the system to study, which remains not defined at the singular point, but fully decouples.

However, in order to study the effects of these photons for a distant observer, global behavior of null geodesics must be studied in full generality, since *nonradial* geodesics, with nonzero angular momentum, determine the angular diameter of the central naked singularity as seen by the observers, giving the measure of the "size" of the singularity. In this direction there are in literature quite detailed studies of Tolman-Bondi self-similar dust cloud collapse. In Refs. 3 and 4 necessary conditions—which actually turn out to be sufficient—for nonradial geodesics existence are derived, and behavior at infinity of these photons is numerically studied for some particular case. Further, a complete result of nonradial geodesic existence but under the assumption of self-similarity of the dust solution is fully proved in Ref. 5, and considerations about topology of the singularity are derived.

Of course, the dust model cannot be considered as a good physical model of singularity formation, because pressures are expected to occur during the collapse. In this paper we extend the results on dust models to a wide class of solutions, found in Ref. 6, for which local nakedness results from a suitable choice of initial data. This class represents the wider set found so far of locally naked singularities in the gravitational collapse of elastic materials. Since these models are not pressureless, and in particular radial pressure does not generally vanish along a timelike hypersurface, a junction between a solution from this class and a anisotropic generalization of de Sitter space-time discussed in Ref. 7 is performed to construct a global model. It is found that properties satisfied by dust solution and showed in previously cited works remains qualitatively valid for this wider class of collapsing space-times.

The paper is organized as follows. Interior and exterior solutions are described in Sec. II, and local existence of nonradial geodesic—which are continued in the exterior space-time using junc-

[a)]Electronic mail: roberto.giambo@unicam.it (URL:http://dmi.unicam.it/~giambo)

tion conditions—is derived in Sec. III. The resulting behavior for a distant observer is analyzed in Sec. IV, together with some remarks about photons with infinite redshift. Last, Sec. V is devoted to overall conclusions.

II. COLLAPSE OF SPHERICAL ANISOTROPIC MATTER

In this part we briefly review the model we will deal with for the rest of the paper. The space-time will be made by two different solutions to Einstein field equations: an interior part, that collapses until singularity forms, and an exterior part, that is matched with the former at a timelike hypersurface in order to satisfy Israel-Darmois conditions;[8] it amounts to say that both first and second fundamental forms induced by the two solutions on this hypersurface, respectively, coincide. The interior part is described by the collapsing anisotropic solutions found in Ref. 6, which will be matched with the de Sitter generalizations discussed in Ref. 7 (see also references therein).

A. Interior region

The interior region is provided by a class of anisotropic collapsing matter. To describe it, the use of area-radius coordinates, first introduced by Ori,[9] turns out to be more useful than the usual comoving reference frame

$$\mathrm{d}s^2 = -e^{2\nu}\mathrm{d}t^2 + \frac{1}{\eta}\mathrm{d}r^2 + R^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2). \tag{2.1}$$

Indeed, as well known,[10] the general spherical matter distribution can be given assigning energy density ϵ and pressures p_r and p_t as suitable functions of the triple (r,R,η). Under the assumption $\partial p_r/\partial\eta=0$, in Ref. 6 it is shown that the metric takes the form

$$\mathrm{d}s^2 = -A(r,R)\mathrm{d}r^2 - 2B(r,R)\mathrm{d}R\,\mathrm{d}r - C(r,R)\mathrm{d}R^2 + R^2(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2), \tag{2.2a}$$

where

$$A = \left(1 - \frac{2\Psi}{R}\right)G^2, \quad B = -G\frac{Y}{u}, \quad C = \frac{1}{u^2}. \tag{2.2b}$$

In (2.2b), the two functions $\Psi(r,R)$ and $Y(r,R)$ are arbitrary (positive) functions while

$$u^2 = Y^2 + \frac{2\Psi}{R} - 1, \tag{2.2c}$$

and the function G is given in terms of a quadrature,

$$G(r,R) = \int_R^r \frac{1}{Y(r,\sigma)}\frac{\partial(1/u)}{\partial r}(r,\sigma)\,\mathrm{d}\sigma + \frac{1}{Y(r,r)u(r,r)}. \tag{2.2d}$$

In particular, the function Ψ represents Misner–Sharp mass. Conditions on Taylor developments of the above quantities may be given to characterize complete collapse and naked singularity formation, that we summarize in the following theorem.

Theorem 2.1 (Ref. 6):

(1) *In the space-time described by the metric* (2.2a), (2.2b), (2.2c), and (2.2d), *the singularity forms at the center* $r=0$ *in a finite amount of comoving time if Taylor development of the function* Ru^2 *is as follows*:

$$Ru^2 = \alpha r^3 + \beta r^2 R + \gamma r R^2 + \delta R^3 + o(r^2+R^2)^{3/2} \quad (\alpha > 0). \tag{2.3}$$

(2) *Under the above condition, and introduced the Taylor development of the* (*regular*) *function* $G(r,0)$

$$G(r,0) = \xi r^{n-1} + o(r^{n-1}), \tag{2.4}$$

then the central singularity is (*locally*) *naked if*, $n=1$, $n=2$, *or* $n=3$ *and* $\xi > \alpha\omega_{\text{crit}}$ *where* $\omega_{\text{crit}} = (26+15\sqrt{3})/2$.

We also remark that this model possesses nonvanishing anisotropic pressures, which are given by[6]

$$p_r = -\frac{1}{4\pi R^2}\frac{\partial \Psi}{\partial R}, \tag{2.5}$$

$$p_t = -\frac{1}{8\pi u R G}\left(\frac{1}{Y}\frac{\partial^2 \Psi}{\partial r\, \partial R} - \frac{1}{Y^2}\frac{\partial \Psi}{\partial r}\frac{\partial Y}{\partial R} + u\, G\frac{\partial^2 \Psi}{\partial R^2}\right), \tag{2.6}$$

and in this sense the model can be considered physically more reasonable than Tolman-Bondi dust collapsing sphere, where the space-time is ruled by the pressureless equation of state $p_r = p_t = 0$.

B. Exterior region

In our model, since the internal source is given by (2.2a), one cannot hope, in general, that radial pressure vanishes at some timelike hypersurface $\Sigma = \{(t, r, \theta, \phi) : r = r_b\}$. This is a quite restrictive feature of dust cloud collapsing model[11] or also nonvanishing radial pressure models,[10] that here arise only as very special cases, that happen when $\Psi = \Psi(r)$. Therefore, it cannot be possible to consider Schwarzschild vacuum solution as external region, if we want Israel–Darmois condition to be satisfied.

Hence, we perform a junction between the internal source satisfying conditions stated in Theorem 2.1, and the anisotropic generalization of de Sitter space-time, which are a class of spherically symmetric solutions of Einstein equation satisfying the condition $\epsilon + p_r = 0$ and admitting a particular G_4 group of motions (see Ref. 7). A coordinate transformation exists, that brings the line element in the form

$$\mathrm{d}s^2 = -\chi(R)\mathrm{d}T^2 + \chi(R)^{-1}\,\mathrm{d}R^2 + R^2\,\mathrm{d}\Omega^2, \quad \chi(R) = 1 - \frac{2M(R)}{R}, \tag{2.7}$$

thereby obtaining a family of solutions as Misner-Sharp mass $M(R)$ varies. In Ref. 12 it is shown that, actually, *any* spherically symmetric line element (2.1) can be matched with a metric of this family at a timelike hypersurface Σ as before, under the condition of continuity of mass only. Therefore, it suffices to choose

$$M(R) = \Psi(r_b, R), \quad \forall\, R \in [0, r_b]$$

and junction conditions will be certainly satisfied for all (comoving) times $t \geqslant 0$. The value of the external mass for bigger values of R depends on the internal space-time at comoving times prior to observation starting, and we will suppose that it is chosen such that

$$\limsup_{R \to +\infty} M(R) < +\infty\,. \tag{2.8}$$

C. Energy condition

In order to deal with a physically reasonable class of solutions, we impose the weak energy condition (WEC) on the energy-momentum tensor T of the space-time. Basically, this means $T(v, v) \geqslant 0$ for all timelike vectors v, and it is easily seen[6] that it holds in the internal region if, for each $r \in [0, r_b]$, the two functions of the variable R only

$$R \mapsto \frac{1}{Y(r,R)} \frac{\partial \Psi}{\partial r}(r,R), \quad R \mapsto \frac{\partial \Psi}{\partial R}(r,R) \tag{2.9}$$

are non-negative subsolutions of the *same* ODE,

$$\frac{\mathrm{d}F}{\mathrm{d}R} \leqslant \frac{2}{R} F(R) \tag{2.10}$$

for $R>0$. In particular, for $r=r_b$, the above condition ensures WEC in the external region also [see Ref. 12, Eq. (4.6)].

Models of internal solutions satisfying (2.3), (2.8) and WEC can be easily found: for instance, the choice

$$\Psi(r,R) = \int_0^r \gamma(s) s^2 \, \mathrm{d}s + \int_0^R \chi(\sigma) \sigma^2 \, \mathrm{d}\sigma, \quad Y = Y(r), \tag{2.11}$$

with $\gamma(s)$ and $\chi(\sigma)$ positive and not increasing in $[0,+\infty)$, allows for (2.3) and the weak energy condition to be satisfied. As an example, one may take

$$\chi(\sigma) = \frac{1}{(1+R^3)^4}$$

in order to satisfy also (2.8). Note that, with the choice of χ=constant, the space-time coincides with the so-called Tolman-Bondi-de Sitter (TBdS), and that is the reason why, in Ref. 6, the models arising from the above choice (2.11) are termed *anisotropysations of TBdS space-time*.

III. NULL GEODESICS FROM THE SINGULARITY

A. Geodesic equations

As stated in Theorem 2.1, conditions on the metric functions allow to determine when the central singularity is locally naked. This is made by showing the existence of a future pointing radial null geodesic which lies in the region $R>2\Psi$ and may be traced back to the central singularity. In Ref. 6 it is shown that, to obtain violations of cosmic censorship in spherical symmetry, one may restrict oneself in looking for null geodesic which are radial only. In other words, if a singularity is radially censored, it is censored all the way. Nevertheless, if one wants to study visibility under a more general point of view, also nonradial light rays should be taken into account.

Let κ be the affine parameter of the null geodesic. Without loss of generality, we will suppose that the geodesic lies in the hypersurface $\theta=\pi/2$, and then the angular components of tangent vector along the geodesic read

$$\kappa^\theta := \frac{\mathrm{d}\theta}{\mathrm{d}\kappa} = 0, \quad \kappa^\phi := \frac{\mathrm{d}\phi}{\mathrm{d}\kappa} = \frac{\ell}{R^2}, \tag{3.1}$$

where ℓ is the (conserved) angular momentum. Let us also introduce a function q such that

$$\kappa^r := \frac{\mathrm{d}r}{\mathrm{d}\kappa} = \frac{1}{qRG}. \tag{3.2}$$

Then, expressing R, θ, and ϕ as functions of r instead of κ, the equations for null geodesics can be given in the following form:

$$\frac{\mathrm{d}R}{\mathrm{d}r} = uG\left[Y - u\sqrt{1+\left(\frac{\ell q}{u}\right)^2} \right], \tag{3.3a}$$

$$\frac{\mathrm{d}\theta}{\mathrm{d}r}=0, \quad \frac{\mathrm{d}\phi}{\mathrm{d}r}=\frac{\ell qG}{R}, \tag{3.3b}$$

and

$$-\frac{1}{q}\frac{\mathrm{d}q}{\mathrm{d}r}-\frac{1}{G}\frac{\mathrm{d}G}{\mathrm{d}r}-\frac{1}{R}\frac{\mathrm{d}R}{\mathrm{d}r}-\frac{CA_{,r}+B(A_{,R}-2B_{,r})}{2G^2}-\frac{CA_{,R}-BC_{,r}}{G^2}\frac{\mathrm{d}R}{\mathrm{d}r}+\frac{BC_{,R}+C(C_{,r}-2B_{,R})}{2G^2}\left(\frac{\mathrm{d}R}{\mathrm{d}r}\right)^2$$
$$+\ell^2\frac{q^2B}{R}=0, \tag{3.3c}$$

and A,B,C are given in (2.2b). Dealing with radial geodesics results in vanishing of ℓ, and so (3.3a), which is found imposing that the geodesic is null, becomes an ODE in the R function only, which is enough to study at least the existence of corresponding pregeodesics. On the other side, when $\ell\neq 0$, also (3.3c) must be studied.

Before to state and show results, we restrict the analysis hereafter to the case when n in (2.4) is equal to 3. As it will be cleared in Remark 3.4, this particular situation—that, as seen in the statement of Theorem 2.1, has a sort of "endstate transition"—corresponds to a so–called *strong curvature* singularity, unlike $n=1,2$ cases—at least along null radial geodesics. We refer the reader to Remark 3.4 below and, for instance, to Refs. 13–15 for a general insight about strong curvature conditions.

B. Null geodesics existence

Existence of null radial geodesics has already been proved in Ref. 6, using comparison arguments in ODE. We here complete the analysis about the asymptotic behavior of the geodesics finding also an existence result for nonradial geodesics.

Remark 3.1: In the forthcoming Proposition it will be shown that the null geodesic equation can be put in the form

$$\frac{\mathrm{d}y}{\mathrm{d}r}=\frac{1}{r}f(y)+g(r,y), \tag{3.4}$$

where $y(r)\in\mathbb{R}^n$ and $f:\mathbb{R}^n\to\mathbb{R}$, $g:\mathbb{R}^{n+1}\to\mathbb{R}$ are $\mathcal{C}^1$ functions; introducing a new independent variable s such that $\mathrm{d}r/\mathrm{d}s=-r(s)$ then, from (3.4), we obtain the system

$$\frac{\mathrm{d}y}{\mathrm{d}s}=-f(y(s))-r(s)g(r(s),y(s)),$$
$$\frac{\mathrm{d}r}{\mathrm{d}s}=-r(s), \tag{3.5}$$

whose solutions describe parametrizations of solutions of (3.4) by the parameter s. Equilibria of the above system (as $s\to+\infty$) are given by points $(y_0,0)$ where y_0 is a root of $f(y)=0$, and searching for these equilibria amounts to search for admissible solutions of the so-called *root equation*, first introduced in Ref. 16 for the study of radial light rays.

The key point is that these equilibria for the null geodesic equation will be shown to be hyperbolic—see, e.g., Ref. 17 for basic concepts about hyperbolic dynamical systems—and that is the reason why the root equation solution's existence is a necessary but also sufficient condition for light rays existence.

Proposition 3.2: *Under the hypotheses of Theorem 2.1, when, with reference to equation* (2.4), $n=3$ *and* $\xi>\alpha\omega_{\mathrm{crit}}$, *there exists infinite null geodesics emanating from the central singularity and escaping from the trapped region* $\{R>2\Psi\}$. *In particular, there exists three numbers* x_1, x_2, x_c, *depending on* α *and* ξ, *with* $x_c>x_2>x_1>\alpha$, *such that these geodesics can be divided in the following classes*:

(1) *infinite radial and nonradial geodesics such that* $R(r)=x_1r^3+o(r^3)$,
(2) *infinite nonradial null geodesic such that* $R(r)=x_2r^3+o(r^3)$, *and*
(3) *a radial geodesic (Cauchy horizon) such that* $R_c(r)=x_cr^3+o(r^3)$, *which bounds from above any geodesic in classes* (1) *and* (2), *in the sense that* $R_c(r)>R_g(r)$, $\forall\, r>0$, *for any other geodesic* $R_g(r)$.

Moreover, the nonradial geodesic of case (1) *have finite* $\lim_{r\to 0^+}\phi(r)$, *whereas nonradial geodesics of case* (2) *are such that* $\lim_{r\to 0^+}\phi(r)=-\infty$.

Proof: Let us consider system (3.3a), (3.3b), and (3.3c). We are interested in determining existence of solutions such that $R(r)$ lies above the apparent horizon $R_h(r)$, which is known (see Ref. 6 for details) to have the behavior $R_h(r)=\alpha r^3+o(r^3)$. Then, we first introduce a new unknown function $z(r)$ in place of R, which is defined as

$$z(r)=\sqrt{\frac{R(r)}{\alpha r^3}}, \tag{3.6}$$

and we will study the system made by the first and the last equation above, in the unknown functions $(z(r),q(r))$—with $q(r)$ given by (3.2)—since the equation for ϕ can be decoupled from these. Moreover, note that since ℓ appears in (3.3a), (3.3b), and (3.3c) as a factor of the quantity ℓq only, we will consider $\ell q(r)$ instead of $q(r)$ as variable.

We first observe that $z(r)$ and $q(r)$ must be bounded from below by 1 and 0, respectively, in order for the solution to be physically acceptable. Then, estimates of terms involved in (3.3a) will be performed, under the additional hypothesis that $z(r)$ is also bounded from below, and Eqs. (3.3a) and (3.3c) become, with the further position

$$\omega=\frac{\xi}{\alpha},$$

$$\frac{\mathrm{d}z}{\mathrm{d}r}=\frac{1}{r}w(z,\ell\, q)+g_1(r,z,\ell\, q), \tag{3.7a}$$

$$\ell\frac{\mathrm{d}q}{\mathrm{d}r}=\frac{1}{r}[\ell\, q(k(z)-(\ell q)^2h(z)+w(z,\ell\, q)\tilde{k}(z))]+\ \ell\, qg_2(r,z,\ell\, q), \tag{3.7b}$$

where

$$w(z,\ell\, q)=-\frac{2z^4+\sqrt{1+(\ell q)^2z^2}z^3-\omega z+\sqrt{1+(\ell q)^2z^2}\omega}{2z^3}, \tag{3.7c}$$

$$k(z)=\frac{\omega^2-10z^3\omega-2z^6}{2z^3(\omega+z^3)}, \tag{3.7d}$$

$$h(z)=\frac{\omega+z^3}{z}, \tag{3.7e}$$

$$\tilde{k}(z)=-\frac{z^3+4\omega}{z(\omega+z^3)}, \tag{3.7f}$$

and $g_i(r,z,\ell q)$, $i=1,2$ are continuous functions.

Let us check equilibria of (3.7a) and (3.7b), using the idea from Remark 3.1. The following cases happen:

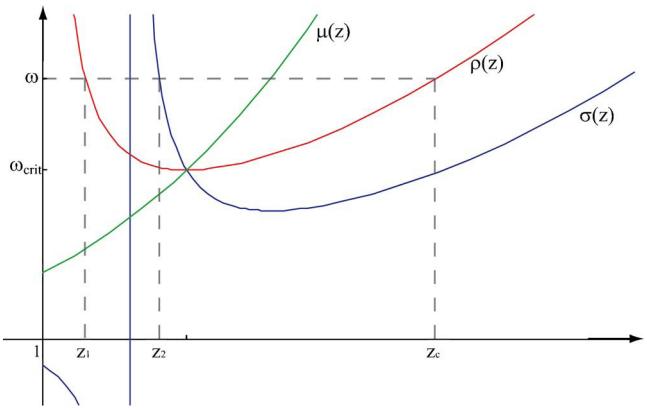

FIG. 1. (Color online) The curves $\rho(z)$ (3.9), $\sigma(z)$ (3.12), and $\mu(z)$ intersect each other at the local minimum of $\rho(z)$, attained for $z=(1+\sqrt{3})/2$, $\rho(z)=\omega_{\text{crit}}$ (see Theorem 2.1).

(a) $\ell q=0, z$ such that $w(z,0)=0$;

(b) $\ell q=\sqrt{k(z)/h(z)}, z$ such that $w(z,\sqrt{k(z)/h(z)})=0$.

First, in both cases it can be seen that $(g_1(r,z,\ell q),\ell q g_2(r,z,\ell q))$ is regular in a neighborhood of $(0,z,\ell q)$ where $(z,\ell q)$ is an equilibrium as above. Let us now discuss the character of these equilibria.

In case (a), the situation goes as follows. With reference to the notation of Remark 3.1, the Jacobian computed in the equilibrium $(z,0)$ is given by

$$J_{(z,0)}f=\begin{pmatrix}\dfrac{\partial w}{\partial z}(z,0) & \dfrac{\partial w}{\partial q}(z,0)\\ 0 & k(z),\end{pmatrix}, \tag{3.8}$$

and one finds that there exists a *root function*

$$\rho(z)=\frac{2z^4+z^3}{z-1}, \tag{3.9}$$

such that

$$w(z,0)=0 \;\Leftrightarrow\; \rho(z)=\omega, \tag{3.10a}$$

$$\frac{\partial w}{\partial z}(z,0)=-\frac{1}{2z^2}\rho'(z). \tag{3.10b}$$

Moreover, $k(z)>0$ if and only if $\omega>\mu(z):=(5+\sqrt{27})z^3$. The curves $\rho(z)$ and $\mu(z)$ are depicted in Fig. 1. For the acceptable range of ω, that is $\omega>\omega_{\text{crit}}$ (see Theorem 2.1), there exists a unique value z_1 that satisfies (3.10a) and such that $k(z_0)>0$. From (3.10b), we have that also $(\partial w/\partial z)\times(z_1,0)>0$. This means that the Jacobian (3.8) has two positive eigenvalues and therefore we have part (1) of the claim, with an infinite number of radial geodesics tending to this equilibrium point, for every $\ell\geqslant 0$. Note that this situation (1) covers also radial geodesic existence, that is when $\ell=0$. Using (3.6), the curves $R(r)$ behaves like $R(r)=\alpha z_1^2 r^3+o(r^3)$.

If $\omega>\omega_{\text{crit}}$, from Fig. 1 we see that there exists another value of $z=z_c$ satisfying $\rho(z_c)=\omega$. In this case we have two negative eigenvalues of (3.8). With reference to the system put in the form (3.5), the equilibrium is again hyperbolic, but the stable manifold has dimension 1, and therefore a single null geodesic tending to the equilibrium exists. Actually, it can be shown that this geodesic is radial, since it can be seen that at least a radial null geodesic tending to the equilibrium exists.

Indeed, radial geodesics are solutions of the ODE (3.7a) under the assumption $\ell=0$. We can easily see that $z=z_c$ is an equilibrium of (3.7a), such that there exist a unique solution tending to this equilibrium. Since radial geodesics are solutions of (3.7a) and (3.7b) with $\ell q\equiv 0$, we conclude that the (unique) solution of (3.7a) and (3.7b) must be radial. The corresponding $x=\alpha z_c^2$ represents *Cauchy horizon* direction.

We also note that the corresponding function $R_c(r)$ must bound from above any other geodesic $R_g(r)$. Of course, this must be true for any other radial geodesic near $r=0$, and therefore for any other value of r by uniqueness of Cauchy problem solution. Let us show that this also holds true for nonradial geodesic. By contradiction, let $R_g(r)$ be a nonradial geodesic, such that its projection on the (r,R) plane bounds from above $R_c(r)$ for some r_*, that is $R_g(r_*)>R_c(r_*)$. Since $R_g(r)$ is a subsolution of radial null geodesic equation, and $R_c(r)$ is a solution of the same ODE, therefore we can find a radial null geodesic $R_n(r)$ with initial data $R_n(r_*)\in]R_c(r_*),R_g(r_*)[$, and trace it back until $R_n(0)=0$, obtaining a radial geodesic $R_n(r)>R_c(r)$ in a right neighborhood of $r=0$, which as said before is absurd, and claim (3) is complete.

Let us now discuss case (b) to get claim (2) of the Proposition.

We first observe that this time it must be $k(z)>0$ otherwise we have no equilibria. Arguing as in the previous case, we find that the determinant of the Jacobian in the equilibrium—say $(z_2,\sqrt{k(z_2)/h(z_2)})$—is given by

$$-2k(z_2)\frac{\mathrm{d}w(z,\sqrt{k(z)/h(z)})}{\mathrm{d}z}\Big|_{z=z_2}. \tag{3.11}$$

The root function in this case is given by

$$\sigma(z)=\frac{4z^5}{2z^2-3}, \tag{3.12}$$

which has the properties

$$w\left(z_2,\sqrt{\frac{k(z_2)}{h(z_2)}}\right)=0 \;\Leftrightarrow\; \sigma(z_2)=\omega, \tag{3.13a}$$

$$\frac{\partial w}{\partial z}\left(z_2,\sqrt{\frac{k(z_2)}{h(z_2)}}\right)=-\gamma^2\sigma'(z_2), \tag{3.13b}$$

where γ is some nonvanishing constant. The situation is depicted in Fig. 1. For any $\omega>\omega_{\mathrm{crit}}$ there exists a unique value of z_2 satisfying (3.13a) with $k(z_2)>0$. Using (3.13b), we get that the quantity (3.11) is negative and then there exists one and only one positive eigenvalue of the Jacobian, which results in the existence of infinite nonradial null geodesic such that the corresponding $R(r)$ behaves like $R(r)=\alpha z_2^2 r^3+o(r^3)$. Indeed, the stable manifold of the system put in the form (3.5) has dimension 2.

Notice that, in this case, there are no other choices available since the other root of the equation $\sigma(z)=\omega$ lies in the $\{k<0\}$ region.

To complete the proof, let us now analyze the behavior of the angular function $\phi(r)$. Using (3.3b), and the above estimates,

$$\frac{\mathrm{d}\phi}{\mathrm{d}r}\cong \ell\left(\frac{h(z)}{z}\right)\frac{q}{r}. \tag{3.14}$$

For a nonradial geodesic from case (1), $q\to 0$ as $r\to 0^+$, and then, from (3.7b), $\mathrm{d}q/\mathrm{d}r\cong k(z_1)\times(q/r)$, from which $q(r)\cong r^{k(z_1)}$, and then, using (3.14), $\phi(r)$ has a finite limit as $r\to 0^+$.

For a nonradial geodesic from case (2) conversely, q tends to a finite positive value and then the function $\phi(r)$ goes like kr^{-1}, which determines a negative diverging behavior of the function $\phi(r)$. □

Remark 3.3: These results are completely consistent with the analysis carried out in Refs. 4 and 5, which have established a double topological nature of the naked singularity in the particular case of dust solution under self-similarity assumption. In particular, case (1) corresponds to a region of the singularity foliated by a 2-sphere, whereas case (2) corresponds to a topologically pointwise singular region.

Remark 3.4: If we look at the behavior of the quantity $k^2R_{\alpha\beta}K^\alpha K^\beta$ along null radial geodesics, where $R_{\alpha\beta}$ is Ricci tensor, $K^\alpha=\mathrm{d}x^\alpha/\mathrm{d}k$ is the tangent vector of the geodesic with parameter k, we get

$$k^2R_{\alpha\beta}K^\alpha K^\beta=\frac{k^2\Psi_{,r}}{4\pi R^2u^3GY}(K^R)^2. \tag{3.15}$$

In view of the above theorem, Eqs. (3.2) and (3.3a) ensure that there exists $\lim_{k\to 0^+}K^R$, then $(k/R)K^R$ tends to a finite nonzero limit value. Since both G and $\Psi_{,r}$ goes like r^2, and Y,u tends to a finite nonzero limit along the geodesics, the quantity in (3.15) goes to a finite nonzero value. It follows that these null geodesics terminate in a strong curvature singularity in the sense of Tipler[14].

IV. FARAWAY VISIBILITY OF THE SINGULARITY

A. Size of the singularity

In the following, we will study the behavior at infinity of null geodesics emanating from the singularity. We have already seen that there exists an infinite number of light rays escaping from the trapped region; these geodesics arrives at the boundary of the collapsing sphere of anisotropic matter with some value $R(r_b)$, and they must be continued by studying the behavior of null geodesics in the external region (2.7) escaping from the boundary and such that $R=R(r_b)$.

The equation for null geodesics—that, without loss of generality, we will suppose to lie in the subspace $\{\theta=\pi/2\}$—is given by

$$\frac{\mathrm{d}T}{\mathrm{d}\kappa}=\frac{\omega}{\chi(R)},\quad \frac{\mathrm{d}R}{\mathrm{d}\kappa}=\omega\sqrt{1-\frac{\chi(R)}{R^2}\left(\frac{\ell}{\omega}\right)^2},\quad \frac{\mathrm{d}\theta}{\mathrm{d}\kappa}=0,\quad \frac{\mathrm{d}\phi}{\mathrm{d}\kappa}=\frac{\ell}{R^2}, \tag{4.1}$$

where κ denotes as usual the affine parameter and ℓ and ω are constant of motion.

As explained in Ref. 4, since the metric (2.7) does not depend on T we can uniquely associate to an observer $R=R_0$ an orthonormal basis of the tangent space to a point (T,R_0,θ,ϕ) of the outer region [i.e., such that $R_0>2M(R_0)$], which will be denoted by

$$\{e_{(T)}=\chi(R_0)^{-1/2}\partial_T, e_{(R)}=\chi(R_0)^{1/2}\partial_R, e_{(\theta)}=R_0^{-1}\partial_\theta, e_{(\phi)}=(R_0\sin\theta)^{-1}\partial_\phi\}.$$

Then, if we consider a null geodesic with affine parameter κ emanating from the singularity passing for $R=R_0$, and denote by $\kappa^\alpha=\mathrm{d}X^\alpha/\mathrm{d}\kappa$ its tangent vector, this observer measures an angle δ between the light ray and the radial direction equal to

$$\delta=\arctan\left(\frac{g_{\mu\alpha}e^\mu_{(\phi)}\kappa^\alpha}{g_{\mu\alpha}e^\mu_{(R)}\kappa^\alpha}\right)=\frac{\ell}{\omega}\sqrt{\frac{\chi(R_0)}{R_0^2-(\ell/\omega)^2\chi(R_0)}}. \tag{4.2}$$

The above quantity depends on the geodesic, and therefore the supremum made among the set $\mathfrak{S}$ of all singular geodesics detected at $R=R_0$ gives a measure of the singularity detected by the observer. One can conceive the right-hand side above, fixing R_0, as a function in (ℓ/ω) which results to be increasing. Therefore, the "size" of the singularity detected by the faraway observer is related to the quantity

$$b:=\sup_{\mathfrak{S}}\frac{\ell}{\omega},$$

which can be regarded[4] as a sort of *impact parameter*.

Using this definition, it is not hard to prove an extension of the result already proved for the particular case studied in Ref. 4.

Proposition 4.1: If the boundary of the interior region $r=r_b$ is sufficiently small, then the nonradial geodesics of largest impact parameters emanating from the singularity are such that the angular function $\phi\to-\infty$ in the approach to the singularity [*case* (2) *of Proposition 3.2, see also Remark 3.3*].

Proof: Of course, we will consider only nonradial geodesics, when $\ell\neq 0$.

Using continuity of the metric along the junction hypersurface, one gets

$$\frac{\mathrm{d}T}{\mathrm{d}\kappa}=\frac{\mathrm{d}T}{\mathrm{d}R}\frac{\mathrm{d}R}{\mathrm{d}\kappa}+\frac{\mathrm{d}T}{\mathrm{d}r}\frac{\mathrm{d}r}{\mathrm{d}\kappa}=\left[-\frac{Y}{\chi u}\frac{\mathrm{d}R}{\mathrm{d}r}+G\right]\frac{\mathrm{d}r}{\mathrm{d}\kappa}, \tag{4.3}$$

and using (4.1), together with (3.2), (3.3a), and (3.3b) one finds the angular frequency ω and therefore the impact parameter b, which is given by

$$b=\sup_{\mathfrak{S}}\left(\frac{R(r)\,\ell\,q(r)}{Y(r,R(r))\sqrt{u^2(r,R(r))+(\ell\,q(r))^2}-u^2(r,R(r))}\right)\Big|_{r=r_b}. \tag{4.4}$$

With reference to the cases listed in Proposition 3.2, let $R_1(r)$ be a nonradial geodesic from case (1), and let $R_2(r)$ a (necessarily nonradial) geodesic from case (2). It is easy to verify that, as $r\to 0^+$, the quantity in round brackets in (4.4) tends to 0 along $R_1(r)$ and tends to a finite nonzero value along $R_2(r)$. Then, if r_b is sufficiently small, we can suppose that this quantity, along R_2, bounds from above the same quantity computed along R_1 until $r=r_b$. □

B. Redshift

Following Ref. 18, the frequency shift z between a source and an observer, respectively, located at events P_1 and P_2, connected by a null geodesic with tangent vector $\vec{\kappa}$ with respect to the affine parameter, is defined as

$$1+z=\frac{g_{P_1}(\vec{\kappa},u_{(s)})}{g_{P_2}(\vec{\kappa},u_{(o)})}. \tag{4.5}$$

where $u_{(s)}$ and $u_{(o)}$ are the 4-velocities of the source and the observer, respectively.

To determine the redshift associated to the singular geodesics, the numerator above will be replaced by a limit expression as P_1 approaches the central singularity. Let us therefore consider a singular geodesic passing at event P_2 in the exterior space such that $R(P_2)=R_0$. Using the basis (4.3), together with (4.1), it is easy to see that the denominator in (4.5) is given by $-\chi(R_0)^{1/2}\omega$, which under the hypothesis (2.8) is always finite also if R_0 tends to infinity. On the other side, the velocity field in the interior space-time is given by $-u(r,R)\partial_R$, and using (3.2) and (3.3a) one finds that the absolute value of the numerator in (4.5) is given by

$$\lim_{r\to 0^+}\frac{1}{R(r)}\left[\left(\frac{u(r,R(r))}{q(r)}\right)^2+\ell^2\right]^{1/2}=+\infty, \tag{4.6}$$

which results in an infinite frequency shift. Actually we can observe that calculation of (4.6) above seems a feature of all singular spherically symmetric models, at least for nonradial geodesics, when $\ell\neq 0$. In the case under our study, moreover, (4.6) holds also for *radial* geodesic since, using Proposition 3.2 and Eq. (2.2c), $u(r,R(r))\cong u_0\neq 0$, and both $R(r)$ and $q(r)$ are infinitesimal. It appears also to be possible the study of the limit in (4.6) in a even more general framework, and work in this direction is in progress.

All in all, these models show the same feature described in Ref. 18 for dust solutions: in the case corresponding to a strong naked singularity (along radial geodesic), null geodesics are infinitely redshifted. (As pointed out in Ref. 18, it can be possible that the strength of the singularity

may have a directional behavior, that is the singularity is weak—in the sense explained in Remark 3.4—along some geodesics, and strong among others.) Therefore, it can be said that there exists a form of weak censorship for such class of solutions, at least at the classical level. Of course however, quantum phenomena might change this scenario, as suggested by some authors (see Refs. 4 and 11).

V. DISCUSSION AND CONCLUSIONS

In this paper we have studied visibility of the naked singularity for a faraway observer, investigating global behavior of null (radial and nonradial) geodesics in a class of spherically symmetric singular space-times. The interior part belongs to a wide class of anisotropic solutions; as known from the analysis carried out in Ref. 6, the end state of the central singularity is determined by the lower order term n of Taylor development of a quantity determined by the metric. In this paper we considered the case $n=3$, which has a special interest since (i) the end state is determined by the value of a certain parameter ξ/α, that causes a sort of "phase transition" between naked singularity and black hole situations, and (ii) radial geodesics terminates into a strong curvature singularity, as observed in Remark 3.4.

The exterior part belongs to the class of anisotropic generalization of de Sitter solution discussed in Ref. 7. The form of the metric closely resembles the Schwarzschild line element, but the mass here depends on the areal coordinate R since a constant mass would not properly match an interior solution with nonvanishing radial pressures. Indeed, if Misner-Sharp masses for both solutions (interior and exterior) coincide at a hypersurface $r=\text{const}$, this ensures Darmois junction conditions to hold along this hypersurface.

Existence of nonradial geodesics is crucial to investigate global visibility. The system of ODE satisfied by the nonradial geodesics does not decouple and the most suitable way seems to study equilibrium points of this system. It turns out that there are two values $x_1<x_2$, depending on the data of the space-time, such that there is an infinite number of nonradial geodesic $R(r)$ emanating with "direction" x_1 [i.e., such that $\lim_{r\to 0} R(r)/r^3=x_1$] and infinite nonradial geodesics with direction x_2. This result is not in contrast with previous results regarding self-similar collapse[5] where one has infinite geodesic with direction x_1 vs only one geodesic with direction x_2. Indeed, as the proof of Proposition 3.2 points out, the stable manifold of the equilibrium has dimension 3 in the first case and 2 in the second one. Self-similarity assumption simplifies the geometry of these stable manifolds, shrinking them by one dimension.

It must be remarked that a crucial fact is that ODE system can be brought in the form (3.4), where the equilibria are all hyperbolic. This is a feature of all collapsing matter models known in literature, which excluded pathological situations such as the ones outlined in Ref. 11, and explains why the so-called *root equation* method repeatedly exploited in previous works—based on the existence of a certain limit which in principle cannot be taken for granted (see for instance Refs. 3, 16, and 4)—leads all the same to the conclusions one would expect.

The analysis of the ODE system allowed us to determine a sort of "impact parameter" that characterizes the "size" of the singularity as it is seen by a faraway observer. It turns out that photons emanated by the naked singularity are infinitely redshifted also when pressures are present, as has been already shown (see Ref. 18) for the pressureless Tolman-Bondi collapse.

We show that the borderline cases in the proof of the positive energy theorem for initial data sets, on spin manifolds, in dimensions $n \geqslant 3$, are only possible for initial data arising from embeddings in Minkowski space-time. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2167809]

I. INTRODUCTION

Witten's proof of the positive energy theorem[10] shows that, under appropriate conditions, the time-component of the energy-momentum vector p is non-negative. For various reasons it is of interest to understand precisely the borderline cases, with a vanishing, or perhaps lightlike, p. In the context of initial data sets this has been done in detail in an accompanying paper[5] in space-dimension three. It is the purpose of this work to generalize the results proved there to all spin initial data manifolds of dimension $n \geqslant 3$.

The argument presented in Ref. 5 proceeds as follows: in the borderline cases, Witten's proof provides one or more covariantly constant "KIDs" (by definition, those are the initial data counterparts of space-time Killing vectors).[4] A careful study of such KIDs shows that their existence implies the vanishing of mass, and then flatness of space-time along the initial data. One then concludes by showing that the Killing development of the initial data set is flat.

Not unexpectedly, all those arguments can be extended to higher dimensions, after adjustment of the rates of decay of the fields. The only part of the proof where essential work is needed is the algebra proving existence of KIDs. This is based on Ref. 8, and presented in Sec. III. On the other hand, the analysis of the KIDs is essentially identical to that in Ref. 5, so we will (mainly) only present the statements of the results needed for the positive energy theorem here.

The notation and conventions of Ref. 5 are used throughout. We assume that the space-dimension n is larger than or equal to three.

Our main results can be summarized as follows.

Theorem 1.1: *Let* $(\mathcal{M}, g_{\mu\nu})$ *be an* $(n+1)$*-dimensional space-time,* $n \geqslant 3$*, with a Killing vector field which is asymptotically null along an (appropriately regular, see Sec. II below) asymptotically flat spacelike hypersurface* $\mathcal{J}$*. Then the ADM energy-momentum vector of* $\mathcal{J}$ *vanishes.*

The precise hypotheses needed for Theorem 1.1 are the conditions on the asymptotic behavior of (g, K) in (2.18) and (2.19) below, together with the matter decay conditions (2.20) and (2.22). Theorem 1.1 is a special case of Theorem 2.5 below.

Theorem 1.2 (Timelike "future-pointing" energy-momentum theorem): *Under natural regu-*

larity and matter-energy conditions (see the conditions of Theorem 3.2 below), the ADM energy-momentum vector p^μ of a spin initial-data manifold $\mathcal{J}$ satisfies

$$p^0 > \sqrt{\sum_{i=1}^{n} (p^i)^2},$$

unless $(\mathcal{J}, g_{ij}, K_{ij})$ are initial data for Minkowski space-time.

Theorem 1.1 is a loose rephrasing of Theorem 3.2 below.

There are well-known counterparts of this with trapped boundaries, which are of no concern to us here because they always lead to a strict inequality.

It would be natural to extend the result to cover the Bondi mass, both in three and higher dimensions. The starting point of the calculations of the proof of Theorem 3.2 is the existence of a parallel spinor, which follows from the analysis in Ref. 7 when the Bondi mass is null in space-dimension three. The calculations that follow apply without modifications, yielding a parallel isotropic KID. One expects that this is incompatible with a nonvanishing Trautman-Bondi mass, but a complete analysis of this has not been carried out so far.

II. KIDs IN *n*-DIMENSIONAL ASYMPTOTICALLY FLAT INITIAL DATA SETS, $n \geqslant 3$

We have the following string of propositions, which are the building stones of the proof of Theorem 2.5 below.

Proposition 2.1: Let $R>0$ and let (g_{ij}, K_{ij}) be initial data on $\mathcal{J}_R \equiv \mathbb{R}^n \backslash B(R)$ satisfying

$$g_{ij} - \delta_{ij} = O_k(r^{-\alpha}), \quad K_{ij} = O_{k-1}(r^{-1-\alpha}), \tag{2.1}$$

with some $k>1$ and some $\alpha>0$. Let N be a C^2 scalar field and Y^i a C^2 vector field on $\mathcal{J}_R$ such that

$$2NK_{ij} + \mathcal{L}_Y g_{ij} = 0. \tag{2.2}$$

Define ρ, J^i, and τ_{ij} by the equations

$$2\rho = {}^nR + (K^i_{\ i})^2 - K^{ij}K_{ij}, \tag{2.3}$$

$$J^i = D_j(K^{ij} - K^k_{\ k} g^{ij}), \tag{2.4}$$

$$\tau_{ij} - \tfrac{1}{2} g^{k\ell}\tau_{k\ell} g_{ij} = {}^nR_{ik} + K^k_{\ k}K_{ij} - 2K_{ik}K^k_{\ j} - N^{-1}(\mathcal{L}_Y K_{ij} + D_i D_j N) - \tfrac{\rho}{2} g_{ij}, \tag{2.5}$$

and assume that ρ and τ_{ij} satisfy

$$\rho = O_{k-2}(r^{-2-\alpha}), \quad \tau_{ij} = O_{k-2}(r^{-2-\alpha}). \tag{2.6}$$

Then there exists numbers $\Lambda_{\mu\nu} = \Lambda_{[\mu\nu]}$ such that we have, for r large,

$$D_i Y_j - \Lambda_{ij} = O_{k-1}(r^{-\alpha}), \quad Y^i - \Lambda_{ij}x^j = \begin{cases} O(r^{1-\alpha}), & \alpha \neq 1, \\ O(\ln r), & \alpha = 1, \end{cases} \tag{2.7}$$

$$D_i N - \Lambda_{i0} = O_{k-1}(r^{-\alpha}), \quad N - \Lambda_{i0}x^i = \begin{cases} O(r^{1-\alpha}), & \alpha \neq 1, \\ O(\ln r), & \alpha = 1. \end{cases} \tag{2.8}$$

If $\Lambda_{\mu\nu}=0$, then there exist numbers A^μ such that we have

$$Y^i - A^i = O_k(r^{-\alpha}), \quad N - A^0 = O_k(r^{-\alpha}). \tag{2.9}$$

If $\Lambda_{\mu\nu}=A^\mu=0$, then $Y^i \equiv N \equiv 0$.

Proof: See Sec. II and Appendix C of Ref. 5.

Proposition 2.2: Let $R>0$ and let (g_{ij},K_{ij}) be initial data on $\mathcal{J}_R$ satisfying

$$g_{ij}-\delta_{ij}=O_2(r^{-\alpha}),\quad K_{ij}=O_1(r^{-1-\alpha}),\quad \alpha>(n-2)/2, \tag{2.10}$$

$$J^i=O(r^{-n-\epsilon}),\quad \rho=O(r^{-n-\epsilon}),\quad \epsilon>0. \tag{2.11}$$

Let N be a C^1 scalar field and Y^i a C^1 vector field on $\mathcal{J}_R$ such that

$$N-A^0=O_1(r^{-\alpha}),\quad Y^i\to_{r\to\infty}A^i, \tag{2.12}$$

for some set of constants $(A^\mu)\not\equiv 0$, satisfying

$$2NK_{ij}+\mathcal{L}_Y g_{ij}=O_1(r^{-(n-1)-\epsilon}). \tag{2.13}$$

Let p^μ be the ADM energy-momentum of $\mathcal{J}_R$. Then

(1) *If $A^0=0$, then $p^0=0$.*
(2) *If $A^0\neq 0$, then p^μ is proportional to A^μ.*

Proof: See the proof of Proposition 3.1 in Ref. 5. □

Proposition 2.3: Under the hypotheses of Proposition 2.2, suppose further that N is C^2 and that

$$\tau_{ij}=O(r^{-n-\epsilon}). \tag{2.14}$$

If

$$(A^0)^2<\sum_i A^iA^i, \tag{2.15}$$

then p^μ vanishes.

Proof: See the proof of Proposition 3.2 in Ref. 5. □

Proposition 2.4: Under the hypotheses of Proposition 2.2, assume moreover that N is C^2, that (2.14) holds and that

$$NK_{ij}+D_iY_j=O_1(r^{-(n-1)-\epsilon}), \tag{2.16}$$

$$K_{ij}Y^j+D_iN=O_1(r^{-(n-1)-\epsilon}), \tag{2.17}$$

$$A^\mu A_\mu\neq 0.$$

Then the ADM energy-momentum p^μ vanishes.

Proof: See the proof of Proposition 3.3 in Ref. 5. Note that the proof in Ref. 5 uses the equality of the Komar and the ADM masses for translational, asymptotically timelike Killing vectors, while Proposition 2.3 shows that one only needs to consider timelike A^μ's to complete the proof. The equality of those masses, which is well known in space-dimension three,[3] can also be established in higher dimensions by an asymptotic analysis of the stationary Einstein equations when the sources decay sufficiently fast. □

The notation used in the next theorem is explained in the Appendix.

Theorem 2.5: *Let $R>0$ and let (g_{ij},K_{ij}) be initial data on $\mathcal{J}_R=\mathbb{R}^n\backslash B(R)$ satisfying*

$$g_{ij}-\delta_{ij}=O_{3+\lambda}(r^{-\alpha}),\quad K_{ij}=O_{2+\lambda}(r^{-1-\alpha}), \tag{2.18}$$

$$\alpha>\begin{cases}1/2, & n=3,\\ n-3, & n\geqslant 4,\end{cases}\qquad \epsilon>0,\quad 0<\lambda<1. \tag{2.19}$$

$$J^i = O_{1+\lambda}(r^{-n-\epsilon}), \quad \rho = O_{1+\lambda}(r^{-n-\epsilon}). \tag{2.20}$$

Let N be a scalar field and Y^i a vector field on $\mathcal{J}_R$ such that

$$N \to_{r\to\infty} A^0, \quad Y^i \to_{r\to\infty} A^i, \quad A^\mu A_\mu = 0,$$

for some constants $A^\mu \not\equiv 0$. Suppose further that

$$2NK_{ij} + \mathcal{L}_Y g_{ij} = O_{3+\lambda}(r^{-(n-1)-\epsilon}), \tag{2.21}$$

$$\tau_{ij} = O_{1+\lambda}(r^{-n-\epsilon}), \tag{2.22}$$

Then the ADM energy-momentum of $\mathcal{J}_R$ vanishes.

Proof: See the proof of Theorem 3.4 in Ref. 5. We note that in our context, Ref. 5, Eq. (3.40) reads as follows:

$$g_{nA} = \begin{cases} C_{AB}(x^n)\partial_B \ln \rho + O_{(1)}(\rho^{-1-\epsilon} \ln \rho), & n = 3, \\ C_{AB}(x^n)\partial_B \dfrac{1}{\rho^{n-3}} + O_{(1)}(\rho^{-(n-2)-\epsilon}), & n \geqslant 4. \end{cases} \tag{2.23}$$

Similarly instead of Ref. 5, Eq. (3.47) we have

$$\frac{\partial g_{AB}}{\partial x^n} = \begin{cases} D_{ABCD}\partial_C\partial_D \ln \rho + O_{(1)}(\rho^{-2-\epsilon} \ln \rho), & n = 3, \\ D_{ABCD}\partial_C\partial_D \dfrac{1}{\rho^{n-3}} + O_{(1)}(\rho^{-(n-1)-\epsilon}), & n \geqslant 4. \end{cases} \tag{2.24}$$

Finally, there are misprints in the definitions of the quantities Ω and Ω' in the proof there; the correct definitions, in all dimensions, are

$$\Omega = \lim_{\rho\to\infty} \sum_C \int_{S^{n-2}(\rho,x^n)} (x^A \partial_C g_{nA} - g_{nC}) \mathrm{d}S_C,$$

$$\Omega' = \lim_{\rho\to\infty} \int_{S^{n-2}(\rho,x^n)} ((n-1)(x^A x^B \partial_C \partial_n g_{AB} - 2x^B \partial_n g_{CB}) - x^A x^A \partial_C \partial_n g_{BB} + 2x_C \partial_n g_{AB}) \mathrm{d}S_C,$$

where summation over every repeated occurrence of indices is implicitly understood, regardless of their positions. [We take this opportunity to point out that Eq. (2.20) of Ref. 5 should be replaced by $\rho = O_{k-2}(r^{-2-\alpha})$, $\tau_{ij} = O_{k-2}(r^{-2-\alpha})$. Furthermore, Eqs. (2.15) and (3.34) of Ref. 5 are mutually incompatible; the correct one is (2.15).] Here $\rho^2 = (x^1)^2 + \cdots + (x^{n-1})^2$, while $S^{n-2}(\rho,a)$ is a sphere (or circle, when $n=3$) of radius ρ centered at $x^1 = \cdots = x^{n-1} = 0$ lying in the plane $x^n = a$. Finally the $\mathrm{d}S_C$'s are the usual surface forms $\mathrm{d}S_C = \partial_C \rfloor (\mathrm{d}x^1 \wedge \cdots \wedge \mathrm{d}x^{n-1})$, and $\rfloor$ denotes contraction. □

III. THE RIGID POSITIVE ENERGY THEOREM

The following strengthens somewhat Theorem 4.1 of Ref. 5 in the case $n=3$, and generalizes that theorem to higher dimensions; the calculations here are closely related to those in Ref. 8.

Theorem 3.1 [(rigid) positive energy theorem]: *Consider a data set $(\mathcal{J}, g_{ij}, K_{ij})$, with $(\mathcal{J}, g_{ij})$ a complete Riemannian spin manifold of dimension $n \geqslant 3$, and with $g_{ij} \in C^2$, $K_{ij} \in C^1$. Suppose that $\mathcal{J}$ contains an asymptotically flat end $\mathcal{J}_R$ diffeomorphic to $\mathbb{R}^n \backslash B(R)$ for some $R > 0$, with $B(R)$—a coordinate ball of radius R, where the fields (g, K) satisfy*

$$|g_{ij} - \delta_{ij}| + |r\partial_k g_{ij}| + |rK_{ij}| \leqslant Cr^{-\alpha}, \tag{3.1}$$

for some constants $C > 0$ and $\alpha > \max(1/2, n-3)$, with $r = \sqrt{\sum_{i=1}^n (x^i)^2}$. Suppose moreover that the quantities ρ and J,

$$2\rho := {}^3R + (K^k{}_k)^2 - K^{ij}K_{ij}, \tag{3.2}$$

$$J^k := D_l(K^{kl} - K^k{}_k g^{kl}), \tag{3.3}$$

satisfy

$$\sqrt{g_{ij}J^iJ^j} \leqslant \rho \leqslant C(1+r)^{-n-\epsilon}, \quad \epsilon > 0. \tag{3.4}$$

Then the ADM energy-momentum (m, p^i) *of any of the asymptotic ends of* $\mathcal{J}$ *satisfies*

$$m \geqslant \sqrt{p_i p^i}. \tag{3.5}$$

If $m=0$, *then* $\rho \equiv J^i \equiv 0$, *and there exists an isometric embedding* i *of* $\mathcal{J}$ *into Minkowski space-time* $(\mathbb{R}^{n+1}, \eta_{\mu\nu})$ *such that* K_{ij} *represents the extrinsic curvature tensor of* $i(\mathcal{J})$ *in* $(M, \eta_{\mu\nu})$. *Moreover* $i(\mathcal{J})$ *is an asymptotically flat Cauchy surface in* $(\mathbb{R}^{n+1}, \eta_{\mu\nu})$.

Theorem 3.1 has been formulated under differentiability requirements which are stronger than necessary, compare Refs. 2 and 9. Unfortunately our proof that ADM energy-momentum cannot be null requires even more differentiability and asymptotic decay conditions.

Theorem 3.2: *Under the hypotheses of Theorem 3.1, suppose moreover that*

$$g_{ij} - \delta_{ij} = O_{3+\lambda}(r^{-\alpha}), \quad K_{ij} = O_{2+\lambda}(r^{-1-\alpha}), \tag{3.6}$$

$$\rho = O_{1+\lambda}(r^{-n-\epsilon}), \tag{3.7}$$

with some $0 < \lambda < 1$. *Then the ADM energy-momentum cannot be null.*

Proofs of Theorems 3.1 and 3.2: We use a Witten-type argument, as follows. Let $(\mathfrak{S}, \langle\cdot,\cdot\rangle)$ be any Riemannian bundle of real spinors over (M, g) with scalar product $\langle\cdot,\cdot\rangle$, such that Clifford multiplication (which we denote by $X\cdot$) is antisymmetric. We suppose that there exists a bundle isomorphism $\gamma_0 : \mathfrak{S} \to \mathfrak{S}$ with the following properties:

$$\gamma_0^2 = 1, \tag{3.8a}$$

$$\forall X \in TM, \quad \gamma_0 X\cdot = -X\cdot\gamma_0, \tag{3.8b}$$

$${}^t\gamma_0 = \gamma_0, \tag{3.8c}$$

$$D\gamma_0 = \gamma_0 D, \tag{3.8d}$$

where ${}^t\gamma_0$ denotes the transpose of γ_0 with respect to $\langle\cdot,\cdot\rangle$, and D is the usual Riemannian spinorial connection associated with the metric g.

[Such a map always exists if $\mathfrak{S}$ is obtained by pulling-back a space-time spinor bundle, using an externally oriented isometric embedding of (M, g) in a Lorentzian space-time. Then the Clifford product $n\cdot$, where n is the field of Lorentzian unit normals to the image of M, has the required properties. If, however, such a map does not exist, we proceed as follows: let $\mathfrak{S}' = \mathfrak{S} \oplus \mathfrak{S}$ be the direct sum of two copies of $\mathfrak{S}$, equipped with the direct sum metric $\langle\cdot,\cdot\rangle_\oplus$:

$$\langle(\psi_1,\psi_2),(\varphi_1,\varphi_2)\rangle_\oplus := \langle\psi_1,\varphi_1\rangle + \langle\psi_2,\varphi_2\rangle. \tag{3.9}$$

We set, for $X \in TM$,

$$\gamma_0(\psi_1,\psi_2) := (\psi_2,\psi_1), \tag{3.10a}$$

$$X\cdot(\psi_1,\psi_2) := (X\cdot\psi_1, -X\cdot\psi_2), \tag{3.10b}$$

$$D_X(\psi_1,\psi_2) := (D_X\psi_1, D_X\psi_2). \tag{3.10c}$$

One readily verifies that (3.10b) defines a representation of the Clifford algebra on $\mathfrak{S}'$, and that (3.8) holds.]

Given an initial data set (M, g, K), a vector field X, and a spinor field ξ we set

$$K(X) := K_i{}^j X^i e_j \cdot , \tag{3.11}$$

$$\nabla_X \xi := D_X \xi + \tfrac{1}{2} K(X) \gamma_0 \xi. \tag{3.12}$$

Here e_i is a local orthonormal basis of TM; it is straightforward to check that (3.11) does not depend upon the choice of this basis. (To make things clear, (3.12) defines ∇ in terms of the Riemannian spin connection D and of the extrinsic curvature tensor K_{ij}. If the spin bundle arises from a space-time bundle, then ∇ coincides with the canonical space-time spinorial derivative, when restricted to space directions.)

We will need an explicit expression for the curvature of ∇.

Proposition 3.3: For every $X, Y \in \Gamma(T\mathcal{J})$ we have

$$R_{X,Y} = {}^n R_{X,Y} + \tfrac{1}{2} \mathrm{d}^D K(X,Y) \gamma_0 - \tfrac{1}{4} (K(X)K(Y) - K(Y)K(X)), \tag{3.13}$$

where R is the curvature of ∇, ${}^n R$ is that of D, and

$$\mathrm{d}^D K(e_i, e_j) = (K^k{}_{j;i} - K^k{}_{i;j}) e_k.$$

Proof: We have

$$\begin{aligned}
\nabla_X \nabla_Y \psi &= \left(D_X + \tfrac{1}{2} K(X) \gamma_0\right)\left(D_Y \psi + \tfrac{1}{2} K(Y) \gamma_0 \psi\right) \\
&= D_X D_Y \psi + \tfrac{1}{2} K(X) \gamma_0 D_Y \psi + \tfrac{1}{2} ((D_X K)(Y) \gamma_0 \psi + K(D_X Y) \gamma_0 \psi + K(Y) \gamma_0 D_X \psi) \\
&\quad + \tfrac{1}{4} K(X) \gamma_0 K(Y) \gamma_0 \psi \\
&= D_X D_Y \psi + \tfrac{1}{2} (K(X) \gamma_0 D_Y \psi + K(Y) \gamma_0 D_X \psi) + \tfrac{1}{2} ((D_X K)(Y) \gamma_0 \psi + K(D_X Y) \gamma_0 \psi) \\
&\quad - \tfrac{1}{4} K(X) K(Y) \psi,
\end{aligned}$$

so that

$$\begin{aligned}
R_{X,Y} \psi &= \nabla_X \nabla_Y \psi - \nabla_Y \nabla_X \psi - \nabla_{[X,Y]} \psi \\
&= D_X D_Y \psi - D_Y D_X \psi - D_{[X,Y]} \psi - \tfrac{1}{2} K([X,Y]) \gamma_0 \psi \\
&\quad + \tfrac{1}{2} (((D_X K)(Y) - (D_Y K)(X)) \gamma_0 \psi + K(D_X Y - D_Y X) \gamma_0 \psi) \\
&\quad - \tfrac{1}{4} (K(X)K(Y) - K(Y)K(X)) \psi,
\end{aligned}$$

and the vanishing of the torsion of the Levi-Civita connection gives the result. □

We now run the usual Witten argument (see, e.g., Ref. 2) using the connection ∇ and the associated Dirac operator $\mathcal{D} = e^i \cdot \nabla_i$. Under the current conditions the ADM energy-momentum of $\mathcal{J}$ is finite and well defined,[1,6] and the Witten boundary integral reproduces the ADM energy-momentum. The arguments in Ref. 2 shows that, again under the current conditions, for every spinor field $\mathring{\psi}$, with constant entries in the natural spin frame in the asymptotic region, one can find a solution ψ to the Witten equation which asymptotes to $\mathring{\psi}$. Witten's identity subsequently implies that

$$\langle \mathring{\psi}, p \cdot \mathring{\psi} \rangle \geqslant 0, \tag{3.14}$$

where

$$p\cdot := m\gamma_0 + p^i e_i\cdot ,$$

and $p=(m,p^i)$ is the ADM momentum. This gives (3.5).

The equality case, which is the main interest here, is only possible if p is lightlike or vanishes. In either case one obtains a spinor field $\psi\in\Gamma(\mathfrak{S})$ which is asymptotic to $\mathring{\psi}$, and satisfies

$$\nabla\psi = 0, \tag{3.15}$$

$$\langle\psi,\mathcal{R}\psi\rangle = 0. \tag{3.16}$$

Here

$$\mathcal{R} := \tfrac{1}{2}(\rho + J^i e_i\cdot\gamma_0)$$

is the (non-negative) spinorial endomorphism which appears in the identity

$$\mathcal{D}^*\mathcal{D} = \nabla^*\nabla + \mathcal{R}.$$

The idea of the calculations that follow is to show, roughly speaking, that the space-time is a *pp*-wave space-time, perhaps with matter decaying at infinity, with a null Killing vector, which by the results in the preceding section is only possible if we are in Minkowski space-time. We start with an analysis of the curvature tensor.

As ψ is ∇-parallel we have $R_{XY}\psi=0$, and from Proposition 3.3 one finds, for all $X,Y\in T\mathcal{J}$,

$$\langle {}^nR_{X,Y}\psi,\psi\rangle - \tfrac{1}{2}\langle \mathrm{d}^D K(X,Y)\cdot\gamma_0\psi,\psi\rangle - \tfrac{1}{4}\langle (K(X)K(Y)-K(Y)K(X))\psi,\psi\rangle = 0.$$

Both the first and third term vanish since the spinorial curvature can be written as

$${}^nR_{XY}\psi = -\frac{1}{2}\sum_{i<j} {}^nR(X,Y,e_i,e_j)e_i\cdot e_j\cdot\psi,$$

and since the Clifford product of two distinct elements of an ON basis is antisymmetric. [We use the conventions

$${}^nR(e_i,e_j)e_k = D_{e_i}D_{e_j}e_k - D_{e_j}D_{e_i}e_k - D_{[e_i,e_j]}e_k = {}^nR^s{}_{kij}e_s = {}^nR(e_m,e_k,e_i,e_j)g^{sm}e_s,$$

$${}^nR_{ij} = {}^nR^k{}_{ikj},$$

where ${}^nR_{ij}$ is the Ricci tensor of g.] Thus we obtain

$$\langle \mathrm{d}^D K(X,Y)\gamma_0\psi,\psi\rangle = 0. \tag{3.17}$$

Let us denote by N the function

$$N = \langle\psi,\psi\rangle, \tag{3.18}$$

and by Y the real 1-form defined as

$$Y(X) = -\langle\gamma_0 X\cdot\psi,\psi\rangle. \tag{3.19}$$

Using this notation, (3.17) can be rewritten as

$$K_{ki;j}Y^k = K_{kj;i}Y^k. \tag{3.20}$$

We continue with the following calculation:

$$\sum_{k=1}^{n} e_k \cdot R_{e_s,e_k} = \sum_{k=1}^{n} e_k \cdot \left({}^n R_{e_s,e_k} - \frac{1}{4}(K(e_s)K(e_k) - K(e_k)K(e_s)) + \frac{1}{2}\mathrm{d}^D K(e_s,e_k)\gamma_0 \right)$$

$$= -\frac{1}{4}({}^n R_s{}^{kij} + K_s{}^i K^{kj} - K^{ki}K_s{}^j)e_k \cdot e_i \cdot e_j \cdot + \frac{1}{2}(K^{mk}{}_{;k} - K^m{}_s{}^{;k})e_k \cdot e_m \cdot \gamma_0. \tag{3.21}$$

In order to analyze the curvature terms in the before-last line of (3.21), recall the convenient identity [to prove (3.22), note first that the result is clearly true if all indices are distinct or equal; the final formula follows by inspection of the remaining possibilities].

$$e_k \cdot e_i \cdot e_j \cdot = e_{[k} \cdot e_i \cdot e_{j]} \cdot - g_{ki} e_j \cdot + g_{ij} e_k \cdot - g_{kj} e_i \cdot \ . \tag{3.22}$$

(Square brackets around indices denote antisymmetrization, and parentheses denote symmetrization.) The Bianchi identity ${}^n R_s{}^{[kij]} = 0$ immediately implies

$${}^n R_s{}^{kij} e_k \cdot e_i \cdot e_j \cdot = 2 {}^n R_s{}^i e_i \cdot .$$

Next, the undifferentiated extrinsic curvature terms in next-to-last line of (3.21) can be manipulated as

$$K_s{}^i K^{kj} \underbrace{e_k \cdot e_i \cdot}_{-2g_{ki} - e_i \cdot e_k \cdot} e_j \cdot - K_s{}^j \underbrace{K^{ki} e_k \cdot e_i \cdot}_{-K^{ki} g_{ki}} e_j \cdot = -2K_s{}^i K^{kj} g_{ki} e_j \cdot - K_s{}^i e_i \cdot \underbrace{K^{kj} e_k \cdot e_j \cdot}_{-K^{ki} g_{kj}} + K_s{}^j K^{ki} g_{ki} e_j \cdot$$

$$= 2(-K^{kj}K_{sk} + K^k{}_k K_s{}^j) e_j \cdot ,$$

which results in

$$({}^n R_s{}^{kij} + K_s{}^i K^{kj} - K^{ki} K_s{}^j) e_k \cdot e_i \cdot e_j \cdot = 2({}^n R_s{}^i + K^k{}_k K_s{}^i - K^{ki} K_{sk}) e_i \cdot =: 2E_s{}^i e_i \cdot =: 2E(e_s). \tag{3.23}$$

Using again that ψ is ∇-parallel we have $\Sigma_{k=1}^n e_k \cdot R_{e_s,e_k}\psi = 0$. Equations (3.21) and (3.23) show that

$$(E(e_s) - (K^{mk}{}_{;s} - K^m{}_s{}^{;k}) e_k \cdot e_m \cdot \gamma_0)\psi = 0.$$

Multiplying by $e_r \cdot$ and taking a scalar product with ψ we obtain

$$-NE_{rs} = (K^{mk}{}_{;s} - K^m{}_s{}^{;k}) \langle \psi, \underbrace{e_r \cdot e_k \cdot e_m \cdot}_{= e_{[r} \cdot e_k \cdot e_{m]} \cdot - g_{rk} e_m \cdot + g_{rm} e_k \cdot - g_{km} e_r \cdot} \gamma_0 \psi \rangle$$

$$= (K^{mk}{}_{;s} - K^m{}_s{}^{;k}) \langle \psi, (-g_{rk} e_m \cdot + g_{rm} e_k \cdot - g_{km} e_r \cdot) \gamma_0 \psi \rangle$$

$$= (K^{mk}{}_{;s} - K^m{}_s{}^{;k})(-g_{rk} Y_m + g_{rm} Y_k - g_{km} Y_r) = -(K_{rs;k} - K_{ks;r}) Y^k + J_s Y_r, \tag{3.24}$$

where we have used the fact that the products $e_r \cdot e_m \cdot$ and $e_r \cdot e_k \cdot e_m \cdot \gamma_0$ are antisymmetric when all indices are distinct, and therefore give no contribution in (3.24). Hence

$$N({}^n R_{ij} + K^k{}_k K_{ij} - K_{ik} K^k{}_j) = (K_{ij;k} - K_{kj;i}) Y^k - J_j Y_i. \tag{3.25}$$

Taking a trace implies

$$N\rho = -J^i Y_i. \tag{3.26}$$

Antisymmetrizing (3.25) in i and j and using (3.20) one finds

$$J_i = \sigma Y_i \tag{3.27}$$

for some function σ.

We wish, now, to show that the pair (N, Y^i) defined by (3.18) and (3.19) satisfies (2.2). It is convenient to choose an ON basis $\{e_i\}_{i=1}^n$ which satisfies $e_i=\partial_i$ and $D_{e_i}e_j=0$ at the point under consideration, then

$$\begin{aligned}
-D_iY_j &= \partial_i\langle\gamma_0 e_j\cdot\psi,\psi\rangle = \langle\gamma_0 e_j\cdot D_i\psi,\psi\rangle + \langle\gamma_0 e_j\cdot\psi, D_i\psi\rangle \\
&= 2\langle\gamma_0 e_j\cdot \underbrace{D_i\psi}_{-\frac{1}{2}K_i^k e_k\cdot\gamma_0\psi},\psi\rangle \\
&= -K_i^k\langle e_j\cdot e_k\cdot\psi,\psi\rangle = -K_i^k\underbrace{\langle e_{[j}\cdot e_{k]}\cdot\psi,\psi\rangle}_{0} - K_i^k\underbrace{\langle e_{(j}\cdot e_{k)}}_{-g_{jk}}\cdot\psi,\psi\rangle \\
&= NK_{ij},
\end{aligned}$$

as desired.

Next,

$$D_iN = \partial_i\langle\psi,\psi\rangle = 2\langle\psi, D_i\psi\rangle = -\langle\psi, K_i^k e_k\gamma_0\psi\rangle = -K_{ik}Y^k$$

[compare (2.17)]. For further use we note that $d(N^2-|Y|^2)=0$, and as $N^2-|Y|^2\to_{r\to\infty}0$ [since equality is attained in (3.14)] we conclude that

$$N^2 = |Y|^2.$$

Further differentiation yields

$$D_iD_jN = N(K\circ K)_{ij} - D_iK_{jk}Y^k.$$

Inserting this into (2.5) and using the relations above leads to our key formula

$$N^2\tau_{ij} = \rho Y_iY_j. \tag{3.28}$$

Note that $N\to_{r\to\infty}0$ implies $Y\to_{r\to\infty}0$. The last part of Proposition 2.1 gives then $N\equiv 0$, hence $\psi=0$, contradicting the fact that we have a nontrivial solution of the Witten equation. Thus N approaches a nonzero constant at infinity by (2.9), and our hypothesis on the decay of ρ provides decay of τ_{ij}. We can therefore apply Proposition 2.4 and Theorem 2.5 to conclude that the ADM momentum vanishes. But then for any $\mathring{\psi}$ there exists an associated ∇-parallel ψ. Let $\mathring{\psi}_a$, $a=1,\ldots,m$, form a basis and let ψ_a be the parallel spinor that asymptotes to $\mathring{\psi}_a$. Now,

$$\nabla\langle\psi_a,\psi_b\rangle = 0,$$

which implies that the ψ_a's form a basis of $\mathfrak{S}_p$ at every $p\in\mathcal{J}$. It follows that $R_{XY}\psi_a=0$ for a collection of spinors forming a basis at each point, hence

$$R_{XY} = 0. \tag{3.29}$$

Choose $\mathring{\psi}$ so that $N\to 1$ and $Y\to 0$. [If no such $\mathring{\psi}$ exists, we pass to $\mathfrak{S}'$ with the structures defined by (3.9) and (3.10), choose any $\mathring{\chi}$ with norm one-half, then $\mathring{\psi}=(\mathring{\chi},\mathring{\chi})$ will have the desired property.] Let $\widetilde{\mathcal{J}}$ be the universal covering space of $\mathcal{J}$ with corresponding data $(\widetilde{\mathcal{J}},\widetilde{g}_{ij},\widetilde{K}_{ij},\widetilde{N},\widetilde{Y}^j)$, and consider the *Killing development* thereof: by definition, this is $\widetilde{\mathcal{M}}=\mathbb{R}\times\widetilde{\mathcal{J}}$ endowed with the metric

$$\tilde{g}_{\mu\nu} = -\tilde{N}^2\,\mathrm{d}u^2 + \tilde{g}_{ij}(\mathrm{d}x_i + \tilde{Y}^i\,\mathrm{d}u)(\mathrm{d}x_j + \tilde{Y}^j\,\mathrm{d}u),$$

where $\tilde{N}(u,x)=\tilde{N}(x)$, $\tilde{g}_{ij}(u,x)=\tilde{g}_{ij}(x)$, $\tilde{Y}^j(u,x)=\tilde{Y}^j(x)$. Similarly let $(\mathcal{M},g_{\mu\nu})$ be the Killing development of $(\mathcal{J},g_{ij},K_{ij},N,Y^j)$. It should be clear that $(\tilde{\mathcal{M}},\tilde{g}_{\mu\nu})$ is the universal pseudo-Riemannian covering of $(\mathcal{M},g_{\mu\nu})$.

Equations (3.26)–(3.29) and the Codazzi-Mainardi embedding equations [compare (3.13)] show then that both $(\tilde{\mathcal{M}},\tilde{g}_{\mu\nu})$ and $(\mathcal{M},g_{\mu\nu})$ are flat. The remaining arguments of the proof of Ref. 5 Theorem 4.1 apply to show that $(\tilde{\mathcal{M}},\tilde{g}_{\mu\nu})=(\mathcal{M},g_{\mu\nu})=(\mathbb{R}^{n+1},\eta_{\mu\nu})$, as desired. □

APPENDIX: WEIGHTED HÖLDER SPACES

Consider a function f defined on $\mathcal{J}_R\equiv\mathbb{R}^n\backslash B(R)$, where $B(R)$ is a closed ball of radius $R>0$. We shall write $f=O_k(r^\beta)$ if there exists a constant C such that we have

$$0\leqslant i\leqslant k,\quad |\partial^i f|\leqslant Cr^{\beta-i}.$$

For $\sigma\in(0,1)$ we shall write $f=O_{k+\sigma}(r^\beta)$ if $f=O_k(r^\beta)$ and if there exists a constant C such that we have

$$|y-x|\leqslant r(x)/2 \Rightarrow |\partial^k f(x)-\partial^k f(y)|\leqslant C|x-y|^\sigma r^{\beta-k-\sigma}.$$

Let us note that $f=O_{k+1}(r^\beta)$ implies $f=O_{k+\sigma}(r^\beta)$ for all $\sigma\in(0,1)$, so that the reader unfamiliar with Hölder type spaces might wish to simply replace, in the hypotheses of our theorems, the $k+\sigma$ by $k+1$ wherever convenient.

A systematic derivation of the Riemannian Barrett-Crane intertwiner

Suresh K. Maran
Department of Physics and Astronomy, University of Pittsburgh, Pittsburgh, Pennsylvania 15260

(Received 9 November 2005; accepted 3 January 2006; published online 23 February 2006)

The Barrett-Crane intertwiner for the Riemannian general relativity is systematically derived by solving the quantum Barrett-Crane constraints corresponding to a tetrahedron (except for the nondegeneracy condition). It was shown by Reisenberger that the Barrett-Crane intertwiner is the unique solution. The systematic derivation can be considered as an alternative proof of the uniqueness. The new element in the derivation is the rigorous imposition of the cross-simplicity constraint. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2168397]

I. INTRODUCTION

A quantization of a four-simplex for the Riemannian general relativity was proposed by Barrett and Crane.[1] It was built on the idea of the Barrett-Crane intertwiner. It was shown by Reisenberger[2] that the Barrett-Crane intertwiner is the unique solution to the Barrett-Crane constraints corresponding a tetrahedron (except for the nondegeneracy condition). Here we present an alternative proof of uniqueness by systematically deriving the Barrett-Crane intertwiner by imposing the Barrett-Crane constraints.

II. REVIEW

The bivectors B_i associated with the 10 triangles of a four-simplex in a flat Riemannian space satisfy the following properties called the Barrett-Crane constraints:[1]

(1) The bivector changes sign if the orientation of the triangle is changed.
(2) Each bivector is simple.
(3) If two triangles share a common edge, then the sum of the bivectors is also simple.
(4) The sum of the bivectors corresponding to the edges of any tetrahedron is zero. This sum is calculated taking into account the orientations of the bivectors with respect to the tetrahedron.
(5) The six bivectors of a four-simplex sharing the same vertex are linearly independent.
(6) The volume of a tetrahedron calculated from the bivectors is real and non-zero.

The items two and three can be summarized as follows:

$$B_i \wedge B_j = 0 \quad \forall\, i,j,$$

where $A \wedge B = \varepsilon_{IJKL} A^{IJ} B^{KL}$ and the i,j represents the triangles of a tetrahedron. If $i=j$, it is referred to as the simplicity constraint. If $i \neq j$ it is referred as the cross-simplicity constraints.

Barrett and Crane have shown[1] that these constraints are sufficient to restrict a general set of 10 bivectors E_b so that they correspond to the triangles of a geometric four-simplex up to translations and rotations in a four dimensional flat Riemannian space.

A quantum four-simplex for Riemannian general relativity is defined by quantizing the Barrett-Crane constraints.[1] The bivectors B_i are promoted to the Lie operators $\hat{B}_i$ on the representation space of the relevant group and the Barrett-Crane constraints are imposed at the quantum level. The last two constraints are inequalities and they are difficult to impose. For these reasons

here after we refer to a state sum model that satisfies only the first four constraints as an *essential Barrett-Crane model*, while a state sum model that satisfies all the six constraints as a *rigorous Barrett-Crane model*. The Barrett-Crane intertwiner corresponds to essential Barrett-Crane model only. We will do a systematic derivation of the essential Barrett-Crane model here.

A. The simplicity constraint

Our treatment of the simplicity constraints is basically a review of work done before.[1,3] The group $SO(4,R)$ is isomorphic to $SU(2)\times SU(2)/Z_2$. An element B of the Lie algebra of $SO(4)$ can be split into the left-handed and the right-handed $SU(2)$ components,

$$B = B_L + B_R. \tag{1}$$

There are two Casimir operators for $SO(4)$ which are

$$\varepsilon_{IJKL}B^{IJ}B^{KL}$$

and

$$\delta_{IK}\delta_{JL}B^{IJ}B^{KL},$$

where η_{IK} is the flat Euclidean metric. In terms of the left- and right-handed split we can expand the Casimir operators as

$$\varepsilon_{IJKL}B^{IJ}B^{KL} = B_L \cdot B_L - B_R \cdot B_R$$

and

$$\delta_{IK}\delta_{JL}B^{IJ}B^{KL} = B_L \cdot B_L + B_R \cdot B_R,$$

where the dot products are the trace in the $SU(2)$ Lie algebra coordinates.

The bivectors are to be quantized by promoting the Lie algebra vectors to Lie operators on the unitary representation space of $SO(4)\cong SU(2)\times SU(2)/Z_2$. The relevant unitary representations of $SO(4)$ are labeled by a pair (J_L,J_R) of unitary representations of $SU(2)$. The elements of the representation space $D_{J_L}\otimes D_{J_R}$ are the eigenstates of the Casimirs and on them the operators reduce to the following:

$$\varepsilon_{IJKL}\hat{B}^{IJ}\hat{B}^{KL} = \frac{J_L(J_L+1) - J_R(J_R+1)}{2}\hat{I} \tag{2}$$

and

$$\delta_{IK}\delta_{JL}\hat{B}^{IJ}\hat{B}^{KL} = \frac{J_L(J_L+1) + J_R(J_R+1)}{2}\hat{I}. \tag{3}$$

The equation (2) implies that on $D_{J_L}\otimes D_{J_R}$ the simplicity constraint $B\wedge B=0$ is equivalent to the condition $J_L=J_R$. We would like to find a representation space on which the representations of $SO(4)$ are restricted precisely by $J_L = J_R$.

In Ref. 3 it has been shown for $SO(N,R)$ that the simplicity constraint reduces the Hilbert space associated to a triangle to that of the L^2 functions on S^{N-1}. Consider a square integrable function $f(x)$ on the sphere S^3 defined by

$$x \cdot x = 1, \quad \forall\, x \in \mathbf{R}^4.$$

It can be Fourier expanded in the representation matrices of $SU(2)$ using the isomorphism $S^3 \cong SU(2)$,

$$f(x) = \sum_J d_J \,\mathrm{Tr}(F_J T_J(\mathfrak{g}(x)^{-1})), \tag{4}$$

where $\mathfrak{g}: S^3 \to \mathrm{SU}(2)$ is an isomorphism from S^3 to $\mathrm{SU}(2)$, $F^{m_1}_{m_2 J}$ the Fourier coefficients, $T^{m_1}_{m_2 J}(g)$ are the matrix elements of spin J representation of an element $g \in \mathrm{SU}(2)$ and d_J the dimension of the J representation. The group action of $g=(g_L, g_R) \in \mathrm{SO}(4)$ on $x \in S^3$ is given by

$$\mathfrak{g}(gx) = g_L^{-1}\mathfrak{g}(x)g_R. \tag{5}$$

Using Eq. (4) we can consider the $T_J(\mathfrak{g}(x))(m_1, m_2)$ as the basis functions of L^2 functions on S^3. The matrix elements of the action of g on S^3 is given by

$$\int \overline{T^{m_1}_{m_2' J'}}(\mathfrak{g}(x)) T^{m_1}_{m_2 J}(\mathfrak{g}(gx))\mathrm{d}x = \frac{1}{d_J}\overline{T^{m_1}_{m_1' J'}}(g_L) T^{m_2'}_{m_2 J}(g_R)\delta(J' - J).$$

The representation matrices are precisely those of SO(4) only restricted by the constraint $J_L = J_R$. Since we have all the simple representations included in the representation, the simplicity constraint effectively reduces the Hilbert space H to the space of L^2 functions on S^3.

B. The cross-simplicity constraints

Next we quantize the cross-simplicity constraint part of the Barrett-Crane constraint. Consider the quantum state space associated with a pair of triangles 1 and 2 of a tetrahedron. A general quantum state that just satisfies the simplicity constraints $B_1 \wedge B_1 = 0$ and $B_2 \wedge B_2 = 0$ is of the form $f(x_1, x_2) \in L^2(S^3 \times S^3)$, $x_1, x_2 \in S^3$.

On the elements of $L^2(S^3 \times S^3)$ the action $B_1 \wedge B_2$ is equivalent to the action of $(B_1 + B_2) \wedge (B_1 + B_2)$. [Please notice that $(\hat{B}_1 + \hat{B}_2) \wedge (\hat{B}_1 + \hat{B}_2) = \hat{B}_1 \wedge \hat{B}_1 + \hat{B}_2 \wedge \hat{B}_2 + 2B_1 \wedge \hat{B}_2$. But since $\hat{B}_1 \wedge \hat{B}_1 = \hat{B}_2 \wedge \hat{B}_2 = 0$ on $f(x_1, x_2)$ we have $(\hat{B}_1 + \hat{B}_2) \wedge (\hat{B}_1 + \hat{B}_2) f(x_1, x_2) = \hat{B}_1 \wedge \hat{B}_2 f(x_1, x_2)$.] This implies that the cross-simplicity constraint $B_1 \wedge B_2 = 0$ requires the simultaneous rotation of x_1, x_2 involve only the $J_L = J_R$ representations. The simultaneous action of $g=(g_L, g_R)$ on the arguments of $f(x_1, x_2)$ is

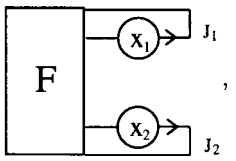
$$gf(x_1, x_2) = f(g_L^{-1} x_1 g_R, g_L^{-1} x_2 g_R). \tag{6}$$

The harmonic expansion of $f(x_1, x_2)$ in terms of the basis function $T_J(\mathfrak{g}(x))(m_1, m_2)$ is

$$f(x_1, x_2) = \sum_J F^{m_1' m_2'}_{m_1 m_2 J_1 J_2} T^{m_1}_{m_1' J_1}(\mathfrak{g}(x_1)) T^{m_2}_{m_2' J_2}(\mathfrak{g}(x_2)).$$

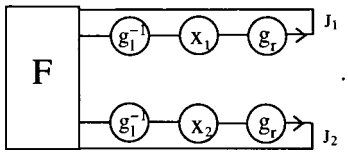
The rest of the calculations can be understood graphically. The last equation can be graphically written as follows:

$$f(x_1, x_2) = \sum_{J_1 J_2}$$



where the box F represents the Fourier coefficient $F^{m_1' m_2'}_{m_1 m_2 J_1 J_2}$. The action of $g \in \mathrm{SO}(4)$ on f is

$$gf(x_1,x_2)=\sum_{J_1J_2}$$



(7)

Now for any $h\in \mathrm{SU}(2)$,

$$T^{b_1}_{a_1J_1}(h)T^{b_2}_{a_2J_1}(h)=\sum_{J_3} C^{b_1b_2J_3}_{J_1J_2b_3}\overline{C}^{J_1J_2a_3}_{a_1a_2J_3}T^{b_3}_{a_3J_3}(h),$$

where C's are the Clebsch-Gordan coefficients of SU(2).[4] We have assumed all the repeated indices are either integrated or summed over for the previous and the next two equations. Using this we can rewrite the g_L and g_R parts of the result (7) as follows:

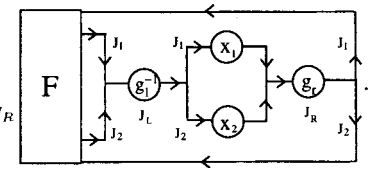
$$T^{m_1}_{a_1J_1}(g_L^{-1})T^{m_2}_{a_2J_2}(g_L^{-1})=\sum_{J_L} C^{m_1m_2J_L}_{J_1J_2m_3}\overline{C}^{J_1J_2a_3}_{a_1a_2J_L}T^{m_3}_{a_3J_L}(g_L^{-1}) \tag{8}$$

and

$$T^{b_1}_{\acute{m}_1J_1}(g_R)T^{b_2}_{\acute{m}_2J_2}(g_R)=\sum_{J_L} C^{b_1b_2J_R}_{J_1J_2b_3}\overline{C}^{J_1J_2\acute{m}_3}_{\acute{m}_1\acute{m}_2J_R}T^{b_3}_{\acute{m}_3J_R}(g_R). \tag{9}$$

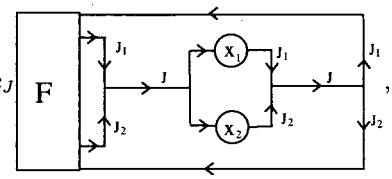
Now we have

$$gf(x_1,x_2)=\sum_{J_1J_2J_LJ_R}$$



To satisfy the cross-simplicity constraint the expansion of $gf(x_1,x_2)$ must have contribution only from the terms with $J_L=J_R$. Let me remove all the terms which do not satisfy $J_L=J_R$. Also let me set $g=I$. Now we can deduce that the functions denoted by $\tilde{f}(x_1,x_2)$ obtained by reducing $f(x_1,x_2)$ using the cross-simplicity constraints must have the expansion,

$$\tilde{f}(x_1,x_2)=\sum_{J_1J_2J} c_J$$



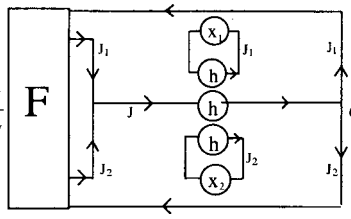
(10)

where the coefficients c_J introduced depends on the precise definition of the cross-simplicity projector. But as we will see, the final answer does not depend on the c_J's. Now the Clebsch-Gordan coefficient terms in the expansion can be reexpressed using the following equation:

$$C^{m_1m_2J}_{J_1J_2m_3}\overline{C}^{J_1J_2\acute{m}_3}_{\acute{m}_1\acute{m}_2J}=\frac{1}{d_J}\int_{\mathrm{SU}(2)} T^{m_1}_{\acute{m}_1J_1}(h)T^{m_2}_{\acute{m}_2J_2}(h)\overline{T}^{m_3}_{m_3J}(h)\mathrm{d}h, \tag{11}$$

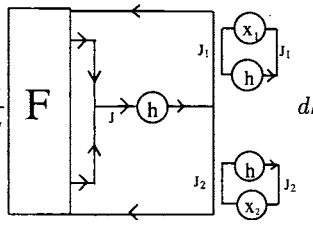
where h, $\tilde{h}\in \mathrm{SU}(2)$ and dh the bi-invariant measure on SU(2). Using this in the two middle Clebsch-Gordan coefficients of $\tilde{f}(x_1,x_2)$ we get

$$\tilde{f}(x_1,x_2)=\sum_{J_1J_2J}\int_{SU(2)}\frac{c_J}{d_J}$$



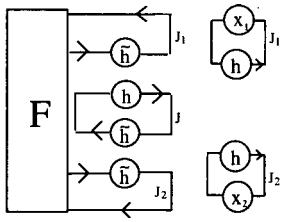
This result can be rewritten for clarity as

$$\tilde{f}(x_1,x_2)=\sum_{J_1J_2J}\int_{SU(2)}\frac{c_J}{d_J}$$



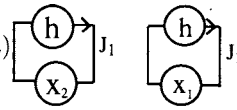
Once again applying Eq. (11) to the remaining two Clebsch-Gordan coefficients we get

$$\tilde{f}(x_1,x_2)=\sum_{J_1J_2J}c_J\iint_{SU(2)\times SU(2)}\left(\frac{1}{d_J}\right)^2$$



By rewriting the above expression, we deduce that a general function $\tilde{f}(x_1,x_2)$ that satisfies the cross-simplicity constraint must be of the form

$$\tilde{f}(x_1,x_2)=\sum_{J_1J_2}\int_{SU(2)}F_{J_1J_2}(h)$$



$$dh,$$

$$=\sum_{J_1J_2}\int_{SU(2)}F_{J_1J_2}(h)tr(T_{J_1}(\mathfrak{g}(x_1)h)tr(T_{J_2}(\mathfrak{g}(x_2)h)dh,$$

where $F_{J_1J_2}(h)$ is arbitrary.

If $\Psi(x_1,x_2,x_3,x_4)$ is the quantum state of a tetrahedron that satisfies all of the simplicity constraints and the cross-simplicity constraints, it must be of the form

$$\Psi(x_1,x_2,x_3,x_4) \tag{12}$$

$$=\sum_{J_1J_2J_3J_4}F_{J_1J_2J_3J_4}(h)\mathrm{tr}(T_{J_1}(\mathfrak{g}(x_1)h)\mathrm{tr}(T_{J_2}(\mathfrak{g}(x_2)h)$$

$$\mathrm{tr}(T_{J_3}(\mathfrak{g}(x_3)h)\mathrm{tr}(T_{J_4}(\mathfrak{g}(x_4)h)\mathrm{d}h.$$

This general form is deduced by requiring that for every pair of variables with the other two fixed, the function must be the form of the right-hand side of Eq. (12)

C. The SO(4) Barrett-Crane intertwiner

Now the quantization of the fourth Barrett-Crane constraint demands that Ψ is invariant under the simultaneous rotation of its variables. This is achieved if $F_{J_1J_2J_3J_4}(h)$ is a constant function of h. Therefore the quantum state of a tetrahedron is spanned by

$$\Psi_{J_1J_2J_3J_4}(x_1,x_2,x_3,x_4) = \int_{n\in S^3} \prod_i T_{J_i}(\mathfrak{g}(x_i)\mathfrak{g}(n))\mathrm{d}n, \tag{13}$$

where the measure dn on S^3 is derived from the bi-invariant measure on SU(2).

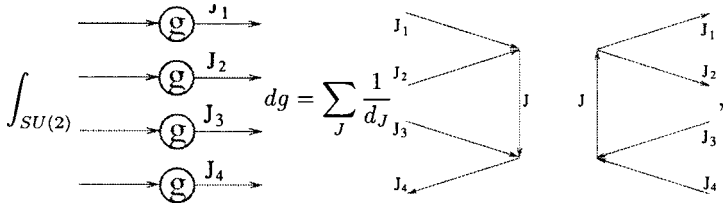
The quantum state can be diagrammatically represented as follows:

$\Psi_{J_1J_2J_3J_4}(x_1,x_2,x_3,x_4) =$  $dn.$

A unitary representation T_J of $SU(2)$ can be considered as an element of $D_J \otimes D_J^*$ where D_J^* is the dual representation of D_J. So using this the Barrett-Crane intertwiner can be written as an element $|\Psi_{J_1J_2J_3J_4}\rangle \in \otimes_i D_{J_i} \otimes D_{J_i}^*$ as follows:

$\Psi_{J_1J_2J_3J_4}\rangle =$  $dn.$

Since $SU(2) \approx S^3$, using the following graphical identity:



the Barrett-Crane solution can be rewritten as

$|\Psi_{J_1J_2J_3J_4}\rangle =$ 
which emerges as an intertwiner in the familiar form in which Barrett and Crane proposed it for the Riemannian general relativity.

(Received 25 December 2003; accepted 22 November 2005;
published online 10 February 2006)

We present a derivation of a formula that gives dynamics of an integrable cellular automation associated with crystal bases. This automaton is related to type D affine Lie algebra and contains usual box-ball systems as a special case. The dynamics is described by means of such objects as carriers, particles, and antiparticles. We derive it from an analysis of a recently obtained formula of the combinatorial R (an intertwiner between tensor products of crystals) that was found in a study of geometric crystals. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2161390]

I. INTRODUCTION

The crystal basis theory[10,11] has played an important role in studies of solvable lattice models and integrable systems since more than a decade. In this context Ref. 9 by Kang, Kashiwara, and Misra has provided useful families of crystal bases associated with affine Lie algebras $A_n^{(1)}$, $B_n^{(1)}$, $C_n^{(1)}$, $D_n^{(1)}$, $A_{2n-1}^{(2)}$, $A_{2n}^{(2)}$, and $D_{n+1}^{(2)}$. We call the first algebra *type A* and the fourth one *type D*. In Ref. 3 we have obtained a formula of the *combinatorial R* (an intertwiner of the crystals) associated with the type A algebra. From the viewpoint of integrable systems an intriguing fact in Ref. 3 is that this formula has been derived from a discrete soliton equation (the nonautonomous discrete KP equation) by a procedure known as the ultradiscretization. Since then there has been progress which goes beyond the type A case. In a study of geometric crystals associated with the type D algebra we have obtained an explicit formula of a *tropical R*, an intertwiner of geometric crystals.[13] The tropical R is a birational map between totally positive rational functions, while the combinatorial R is a bijective map between finite sets. Further analysis of this tropical R and the combinatorial R derived from it should be an important task in studies of integrable systems, since they are connected with discrete and ultradiscrete soliton equations of type D Lie algebra symmetry.[14]

The purpose of this paper is to investigate a *piecewise linear formula* of the above-mentioned combinatorial R for the type D crystals in Ref. 13. Our main result is the derivation of the limit of the formula that leads to the *particle antiparticle description* of an integrable cellular automaton (Theorem 13). This description was recently obtained[15] by using a *factorization of the combinatorial R into Weyl group operators*, a property that had been found and proved in Ref. 7. We emphasize that the result proves a nontrivial fact that the factorization of the combinatorial R can be conducted in two different ways, via the Weyl operator description and via the piecewise linear formula. This point is new even in the type A case (Theorem 3).

We briefly explain the background to our problem. There were studies on one dimensional cellular automata known as the box-ball systems.[17–21] It was found that dynamics in these automata was controlled by the combinatorial R of the type A crystals.[2,3] Based on the families of crystals in Ref. 9 integrable cellular automata associated with crystals of the other types were also constructed.[5,6] A question about such generalized automata arose as to whether we could give a description of their dynamics as box-ball-like systems. To answer this question the particle antiparticle description was found.[8,15]

In Ref. 15 it was found that the automata associated with crystal bases of any types of affine

Lie algebra in Ref. 9 can be embedded into the type D case. Thus one can obtain the particle antiparticle description of these automata from that of the type D case. This is the reason why we devote ourselves into this particular case.

The plan of this paper is as follows. In Sec. II the automaton associated with the type A crystals is reviewed. The piecewise linear formula of the combinatorial R is presented. The particle description of the automaton is proved in terms of the piecewise linear formula. In Sec. III we discuss the piecewise linear formula of the combinatorial R of the type D crystals. Its reduction to the type A case is also shown. The automaton associated with the type D crystals is explained in Sec. IV. The formula of a factorized dynamics of an inhomogeneous automaton (Theorem 13) is reviewed. This formula is proved in Sec. V using the piecewise linear formula of the combinatorial R. Proofs of several lemmas are given in the Appendix.

II. $A^{(1)}_{n-1}$ CASE

A. Combinatorial R

We begin with type A case. Instead of $A^{(1)}_n$ we adopt $A^{(1)}_{n-1}$ crystals because it enables us to compare the results with those in the $D^{(1)}_n$ crystals. For the notation we use overlines to distinguish the symbols from those in the type D case, writing $\bar{B}$ for a crystal, $\bar{R}$ for the combinatorial R and so on.

As a set the $A^{(1)}_{n-1}$ crystal $\bar{B}_l$ (l is any positive integer) is given by

$$\bar{B}_l = \left\{ (x_1, \ldots, x_n) \in \mathbb{Z}^n_{\geqslant 0} \,\middle|\, \sum_{i=1}^{n} x_i = l \right\}. \tag{1}$$

The other properties of this crystal are available in Ref. 9. In this paper we use no other property of $\bar{B}_l$. We will write simply $\bar{B}$ or $\bar{B}'$ for $\bar{B}_l$ with arbitrary l.

Definition 1: Given a pair of variables $x=(x_1,\ldots,x_n)\in\bar{B}$, $y=(y_1,\ldots,y_n)\in\bar{B}'$, let $\bar{R}:(x,y)\mapsto(x',y')$ be the piecewise linear map defined by $x'=(x'_1,\ldots,x'_n)$, $y'=(y'_1,\ldots,y'_n)$ where

$$x'_i = y_i + P_{i+1} - P_i,$$

$$y'_i = x_i + P_i - P_{i+1}.$$

Here P_i is given by

$$P_i = \max_{1\leqslant j\leqslant n}\left(\sum_{k=1}^{j-1}(y_{k+i-1}-x_{k+i-1}) + y_{j+i-1}\right). \tag{2}$$

The indices herein involved are interpreted in modulo n.

Except for the notation this formula is the same one as defined in Proposition 4.1 of Ref. 3. The normalization of (2) is so chosen as the P_1 to take the same expression as the formula in Theorem 5.1 of Ref. 9. The property of $\bar{R}$ to intertwine the actions of Kashiwara operators in the crystal basis theory was essentially proved in Sec. I of Ref. 13. It ensures that the (x',y') falls into $\bar{B}'\times\bar{B}$.

We note that there exist other ways to present the combinatorial R (e.g., Refs. 4 and 16) but which are not used in this paper.

B. Automaton

Now we consider the automaton. In Ref. 3 the space of automaton extends infinitely towards both ends

$$\cdots \times \bar{B}_{l_{i-1}} \times \bar{B}_{l_i} \times \bar{B}_{l_{i+1}} \times \cdots .$$

For our purposes it is sufficient to consider a finite size system like

$$\bar{B}_{l_1} \times \cdots \times \bar{B}_{l_N}. \tag{3}$$

Let $L(\gg \Sigma_{i=1}^{N} l_i)$ be an integer. We call a particular letter for the ground state of the automaton a *vacuum*. We can use any letter in $\{1, \ldots, n\}$ as a vacuum of the automaton.[15] Throughout this paper we adopt n as the letter for the vacuum. As in Ref. 7 we define

$$\bar{B}_L[n] = \{(x_1, \ldots, x_n) \in \bar{B}_L | x_n \gg x_a \text{ for any } a \neq n\}.$$

We write $\bar{B} \times \bar{B}' \simeq \bar{B}' \times \bar{B}$ for correspondence by $\bar{R}$. Take any $x \in \bar{B}_L[n]$. Applying $\bar{R}$ successively we have

$$\bar{B}_L[n] \times (\bar{B}_{l_1} \times \cdots \times \bar{B}_{l_N}) \simeq (\bar{B}_{l_1} \times \cdots \times \bar{B}_{l_N}) \times \bar{B}_L[n],$$

$$x \times Y \mapsto X' \times y', \tag{4}$$

that gives the following.

Definition 2: The time evolution operator $\bar{T}$ of the automaton is given by

$$\bar{T}: Y \mapsto X'.$$

It means that we regard Y and X' in (4) as two automaton states before and after the time evolution. We note that the operator $\bar{T}$ actually depends on x.

C. Particle description

There is an interpretation of the automaton that we call a particle description. It is the description of the box-ball systems in Refs. 17–20. Suppose we have balls with index $a(1 \leqslant a \leqslant n-1)$ that we call *a-balls*. For $x=(x_1, \ldots, x_n) \in \bar{B}_{l_i}$ we associate a box of capacity l_i that has x_a a-balls $(1 \leqslant a \leqslant n-1)$ in it. Then an element of $\bar{B}_{l_1} \times \cdots \times \bar{B}_{l_N}$ is regarded as a one dimensional array of boxes of capacities $l_1, \ldots, l_N$ with these balls. For any $a(1 \leqslant a \leqslant n-1)$ we consider a carrier of a-balls that we call an *a-carrier*. We assume that the a-carrier has a sufficiently large capacity, so that it can carry arbitrary number of a-balls at a time.

First we suppose $l_i=1$ for all i. We call the associated automaton *basic*.[15] In this case the x represents a box with an a-ball if $x_a=1$ for $a \neq n$. It represents an empty box if $x_n=1$. For any a we write $\boxed{a}$ for x with $x_a=1$. The carrier goes along the array of boxes. Then there are four actions in the loading-unloading process by the a-carrier:

(1) If the carrier has at least one ball and meets an empty box, we unload a ball from the carrier and put it into the box.
(2) If the carrier meets a box with an a-ball, we pick up the ball and load it into the carrier.
(3) If the carrier meets a box with a b-ball $(b \neq a)$, we do nothing.
(4) If the carrier has no ball and meets an empty box, we do nothing.

These actions are depicted by the left four pictures in Fig. 1. For any $a(1 \leqslant a \leqslant n-1)$ let $\mathcal{K}_a$ be a *particle motion operator* that acts on the space of automaton (array of boxes) and does the actions in the loading-unloading process explained above. We assume that the $\mathcal{K}_a$ depends on x in (4) in such a way that the a-carrier has x_a balls in it at the beginning where x_a is the ath element of the x. Then for the basic automaton we have[2,3]

$$\bar{T} = \mathcal{K}_1 \mathcal{K}_2 \cdots \mathcal{K}_{n-1}.$$

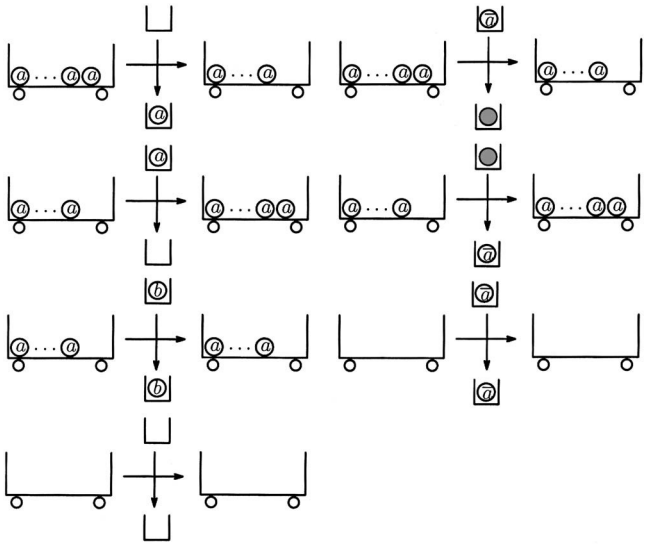

FIG. 1. The loading and unloading process by the carrier of balls with index a. A gray ball represents the bound state of a particle and an antiparticle. It is assumed that $b \neq a, \bar{a}$.

Now we consider a not necessarily basic case which we call *inhomogeneous*.[15] We denote by $\mathcal{P}$ the operator that reduces the automaton into a basic one, and by $\mathcal{Q}$ the operator that makes a rearrangement of balls.[15] To explain them we first let $N=1$ in (4),

$$\bar{B}_L[n] \times \bar{B}_l \simeq \bar{B}_l \times \bar{B}_L[n].$$

Then let

$$\mathcal{P}:\bar{B}_l \to \underbrace{\bar{B}_1 \times \cdots \times \bar{B}_1}_{l}$$

be the operator which sends $y=(y_1, \ldots, y_n) \in \bar{B}_l$ into

$$\underbrace{\boxed{n} \times \cdots \times \boxed{n}}_{y_n} \times \cdots \times \underbrace{\boxed{1} \times \cdots \times \boxed{1}}_{y_1}.$$

Its inverse $\mathcal{P}^{-1}$ can be defined only on such arrays in which the letters are arranged in decreasing order. Let

$$\mathcal{Q}:\underbrace{\bar{B}_1 \times \cdots \times \bar{B}_1}_{l} \to \underbrace{\bar{B}_1 \times \cdots \times \bar{B}_1}_{l}$$

be the operator which packs $\boxed{n}$'s into the left end. Next we consider the case $N>1$. We insert walls between the $\bar{B}_{l_i}$'s in (3) to mark their positions. Then by $\mathcal{P}$ we denote the operator that applies the above $\mathcal{P}$ on each $\bar{B}_{l_i}$, and by $\mathcal{Q}$ or $\mathcal{P}^{-1}$ those that applies the above $\mathcal{Q}$ or $\mathcal{P}^{-1}$ on each $\bar{B}_1 \times \cdots \times \bar{B}_1$ between the walls. Now we have[1,15] the following.

Theorem 3: *The time evolution operator of the inhomogeneous automaton is given by*

$$\bar{T} = \mathcal{P}^{-1}\mathcal{Q}\mathcal{K}_1\mathcal{K}_2 \cdots \mathcal{K}_{n-1}\mathcal{P}. \tag{5}$$

This theorem means that the time evolution of the inhomogeneous automaton can be reduced into that of the basic one only by inserting a simple rearrangement.

D. Proof of the particle description

The reduction of an inhomogeneous automaton to a basic one (Theorem 3) was first presented by Fukuda.[1] We gave another proof of this theorem (and its generalization to type D case) in Ref. 15. Here we show still another proof of this theorem that uses the piecewise linear formula in Definition 1. This is the proof that was inferred in Sec. II D of Ref. 3 but was not explicitly given there. Let $p_i=\lim_{x_n\to\infty} P_i$. Then by (2) we have

$$p_i = \max_{1\leqslant j\leqslant n+1-i}\left(\sum_{k=1}^{j-1}(y_{k+i-1}-x_{k+i-1})+y_{j+i-1}\right). \tag{6}$$

From Definition 1 and (6) we obtain $p_n=y_n$ and

$$p_i = \max\{y_i, y_i - x_i + p_{i+1}\}, \tag{7}$$

$$x_i' = \min\{p_{i+1}, x_i\}. \tag{8}$$

Note that the relation (7) is a descending recursion formula for p_i's on i. Let $x\in \bar{B}_L[n]$ and $y \in \bar{B}_l$ be a pair of variables. Let $\mathcal{K}_a$ be the particle motion operator introduced in Section II C. Then it is easy to see that the p_i's (respectively, x_i''s) for $1\leqslant i\leqslant n-1$ obtained by (7) [respectively by (8)] denote the number of *empty boxes* (respectively, the number of *boxes with balls with index i*) in the automaton state $\mathcal{K}_i\cdots\mathcal{K}_{n-1}\mathcal{P}y$. We also see that the a-carrier finally has $y_a'=x_a+y_a-x_a'$ balls in it. This proves the factorization of $\bar{T}$ in (5) for the case $N=1$ in (4). The assertion of the theorem for the case $N>1$ follows immediately by repeated use of this case, where we adopt the final states of the carriers for $\bar{B}_{l_i}$ in (3) as their initial states for $\bar{B}_{l_{i+1}}$.

III. $D_n^{(1)}$ COMBINATORIAL R

A. Piecewise linear formula

As a set the $D_n^{(1)}$ crystal B_l (l is any positive integer) is given by

$$B_l = \left\{(x_1,\ldots,x_n,\bar{x}_n,\ldots,\bar{x}_1)\in \mathbb{Z}_{\geqslant 0}^{2n} \mid x_n\bar{x}_n=0, \sum_{i=1}^{n}(x_i+\bar{x}_i)=l\right\}. \tag{9}$$

The other properties of this crystal are available in a preprint version of Ref. 11 (Kyoto Univ., RIMS-887, 1992) or in, e.g., Ref. 12. In this paper we use no other property of B_l. We will write simply B or B' for B_l with arbitrary l.

Definition 4: Let $x=(x_1,\ldots,\bar{x}_1)\in B$, $y=(y_1,\ldots,\bar{y}_1)\in B'$ be a pair of variables. The involutive automorphisms $*$, σ_1, σ_n, on x,y are defined by

$$*: x_i \leftrightarrow \bar{y}_i, \bar{x}_i \leftrightarrow y_i \quad (1\leqslant i\leqslant n),$$

$$\sigma_1: x_1 \leftrightarrow \bar{x}_1, y_1 \leftrightarrow \bar{y}_1,$$

$$\sigma_n: x_n \leftrightarrow \bar{x}_n, y_n \leftrightarrow \bar{y}_n.$$

For any function $F=F(x,y)$ we denote by F^a the function obtained from F by applying $a=(*,\sigma_1,\sigma_a)$ to it. For $x\in B_l$ we write $\ell(x)$ for l.

Definition 5: Given a pair of variables $x=(x_1,\ldots,\bar{x}_1)\in B$, $y=(y_1,\ldots,\bar{y}_1)\in B'$, let $R:(x,y)\mapsto(x',y')$ be the piecewise linear map defined by $x'=(x_1',\ldots,\bar{x}_1')$, $y'=(y_1',\ldots,\bar{y}_1')$ where

$$x_1' = y_1 + V_0^{\sigma_1} - V_1,$$

$$x_i' = y_i + V_{i-1} - V_i + W_i - W_{i-1} \quad (2 \leqslant i \leqslant n-1),$$

$$x_n' = y_n + V_{n-1} - V_n^{\sigma_n},$$

$$\bar{x}_i' = \bar{y}_i + V_{i-1} - V_i \quad (1 \leqslant i \leqslant n),$$

$$y_i' = x_i + V_{i-1}^* - V_i^* \quad (1 \leqslant i \leqslant n),$$

$$\bar{y}_1' = \bar{x}_1 + V_0^{\sigma_1} - V_1^*,$$

$$\bar{y}_i' = \bar{x}_i + V_{i-1}^* - V_i^* + W_i - W_{i-1} \quad (2 \leqslant i \leqslant n-1),$$

$$\bar{y}_n' = \bar{x}_n + V_{n-1}^* - V_n^{\sigma_n}. \tag{10}$$

Here V_i and W_i are given by

$$V_i = \max_{1 \leqslant j \leqslant n-1} \{\alpha_{i,j}, \alpha_{i,j}'\}, \tag{11}$$

$$W_i = \max(V_i + V_{i-1}^* - y_i, V_{i-1} + V_i^* - \bar{x}_i) + \min(x_i, \bar{y}_i) \quad (1 \leqslant i \leqslant n-2), \tag{12}$$

$$W_{n-1} = V_n + V_n^{\sigma_n}. \tag{13}$$

The functions $\alpha_{i,j} = \alpha_{i,j}(x,y)$ and $\alpha_{i,j}' = \alpha_{i,j}'(x,y)$ in (11) are given by

$$\alpha_{i,j}(x,y) = \max(\delta_{j,n-1}\beta_i, \bar{y}_j - x_j) + \begin{cases} \ell(x) + \sum_{k=j+1}^{i} (\bar{y}_k - \bar{x}_k) & \text{for } j \leqslant i, \\ \ell(y) + \sum_{k=i+1}^{j} (\bar{x}_k - \bar{y}_k) & \text{for } j > i, \end{cases} \tag{14}$$

$$\alpha_{i,j}'(x,y) = \max(\delta_{j,n-1}\beta_i', x_j - \bar{y}_j) + \ell(x) + \sum_{k=1}^{i} (\bar{y}_k - \bar{x}_k) + \sum_{k=1}^{j} (y_k - x_k), \tag{15}$$

where

$$\beta_i = \begin{cases} x_n - \bar{y}_n & \text{for } i \neq n-1, n, \\ 0 & \text{for } i = n-1, \\ \bar{x}_n - y_n & \text{for } i = n, \end{cases}$$

$$\beta_i' = \begin{cases} \bar{y}_n - x_n & \text{for } i \neq n-1, n, \\ \max(y_n - 2\bar{x}_n, \bar{y}_n - 2x_n) & \text{for } i = n-1, \\ y_n - \bar{x}_n & \text{for } i = n. \end{cases}$$

The map R is the combinatorial R for the $D_n^{(1)}$ crystals. The property of R to intertwine the actions of Kashiwara operators in the crystal basis theory was proved in Theorem 4.28 of Ref. 13. It ensures that the (x', y') falls into $B' \times B$.

Remark 6: We have changed the notation from Ref. 13 since our present formalism uses both x_n and $\bar{x}_n$. The changes are listed in Table I.

TABLE I. The correspondence of the notation between this paper and in Ref. 13 for the piecewise linear formula of the $D_n^{(1)}$ combinatorial R. The z in the first column denotes x, y, x', or y'. It is assumed that $i \neq n-1$, n in the last two columns.

This paper	Reference 13	This paper	Reference 13	This paper	Reference 13
z_n	$\max(z_n,0)$	V_n	V_{n-1}	$\alpha_{i,j(\neq n-1)}$	$\max(\theta_{i,j},\eta_{i,j})$
$\bar{z}_n$	$\max(-z_n,0)$	$V_n^{\sigma_n}$	V_{n-1}^*	$\alpha'_{i,j(\neq n-1)}$	$\max(\theta'_{i,j},\eta'_{i,j})$
z_{n-1}	$z_{n-1}+\min(z_n,0)$	V_{n-1}, V_{n-1}^*		$\alpha_{i,n-1}$	$\max(\eta_{i,n-1},\eta_{i,n})$
$\bar{z}_{n-1}$	$\bar{z}_{n-1}+\min(z_n,0)$	$*$	$*\circ\sigma_n$	$\alpha'_{i,n-1}$	$\max(\eta'_{i,n-1},\eta'_{i,n})$

According to the correspondence in Table I one of the formulas in Eq. (4.66) of Ref. 13 is now translated into

$$x'_n = y_n + \max(V_n - \bar{y}_n, V_n^{\sigma_n} - y_n) - V_n^{\sigma_n},$$

$$\bar{x}'_n = \bar{y}_n + \max(V_n - \bar{y}_n, V_n^{\sigma_n} - y_n) - V_n.$$

In order to make them coincide with the relations in (10) we should define the V_{n-1} as $\max(V_n - \bar{y}_n, V_n^{\sigma_n} - y_n)$. Actually the above definition of V_{n-1} is equivalent to this. In other words we have the following.

Lemma 7: The following relation holds:

$$V_{n-1} = \max(V_n - \bar{y}_n, V_n^{\sigma_n} - y_n). \tag{16}$$

Proof: We have

$$\alpha_{n-1,j} = \max(\alpha_{n,j} - \bar{y}_n, \alpha_{n,j}^{\sigma_n} - y_n),$$

$$\alpha'_{n-1,j} = \max(\alpha'_{n,j} - \bar{y}_n, (\alpha'_{n,j})^{\sigma_n} - y_n),$$

for $1 \leqslant j \leqslant n-1$. In order to check these relations we can use $\max(-x_n,-\bar{x}_n)=\max(-y_n,-\bar{y}_n)=0$. The claim of the lemma follows immediately from these relations. □

Remark 8: The transformation properties of the piecewise linear functions V_i and W_i under the automorphisms σ_1, $*$, and σ_n will be used afterwards, so we list them in Table II. It was quoted from Ref. 13 and adjusted by the correspondence in Table I.

Some more relations on the piecewise linear functions will be used later. We give them at the beginning of the Appendix.

B. Reduction of the $A_{n-1}^{(1)}$ case

We realize that the piecewise linear formula in type D case has a rather bulky expression in contrast with its type A counterpart: See Definitions 1 and 5. In order to understand its structure it

TABLE II. The transformation of the piecewise linear functions V_i and W_i in Definition 5 by the automorphisms σ_1, $*$, and σ_n in Definition 4.

	V_0	$V_i(1 \leqslant i \leqslant n-1)$	V_n	$W_i(1 \leqslant i \leqslant n-1)$
σ_1	$V_0^{\sigma_1}$	v_i	V_n	W_i
$*$	V_0	V_i^*	V_n	W_i
σ_n	V_0	V_i	$V_n^{\sigma_n}$	W_i

is worth trying to study some special limits of the formula. Here we consider a reduction to the type A case. We observe that the piecewise linear map R in Definition 5 for the $D_n^{(1)}$ crystals becomes the intertwiner of the $A_{n-1}^{(1)}$ crystals under the reduction.

Theorem 9: *Set*

$$\bar{x}_i = y_i = 0 \quad \text{for } 1 \leqslant i \leqslant n. \tag{17}$$

Then the map $R:(x,y)\mapsto(x',y')$ *in Definition 5 reduces to*

$$x_i' = y_i + P_{i+1} - P_i,$$

$$y_i' = x_i + P_i - P_{i+1},$$

$$\bar{x}_i' = 0,$$

$$\bar{y}_i' = 0,$$

where P_i *was defined by (2).*

This theorem follows from Lemma 10 below.

Lemma 10: Under the specialization (17) the following relations hold:

$$V_i = \ell(x) + P_1, \quad V_i^* = \ell(x) + P_{i+1} \quad (0 \leqslant i \leqslant n),$$

$$V_0^{\sigma_1} = \ell(x) + P_2, \quad V_n^{\sigma_n} = \ell(x) + P_n,$$

$$W_i = 2\ell(x) + P_1 + P_{i+1} \quad (1 \leqslant i \leqslant n-1).$$

We shall give a proof of this lemma in the Appendix.

We note that the reduction from type D to type A (Theorem 9) itself can also be obtained from the description of the combinatorial R in Ref. 4 since the insertion algorithms for types A and D in Ref. 4 coincide under the condition (17).

IV. $D_n^{(1)}$ AUTOMATON

A. Definition

We now present a brief definition of the $D_n^{(1)}$ automaton using the crystals and the combinatorial R. For a more complete definition, see Refs. 5 and 6. We consider a finite size system like

$$B_{l_1} \times \cdots \times B_{l_N}.$$

Let $L(\geqslant \Sigma_{i=1}^N l_i)$ be an integer. We define

$$B_L[n] = \{(x_1, \ldots, x_n, \bar{x}_n, \ldots, \bar{x}_1) \in B_L | x_n \gg x_a \text{ for any } a \neq n\}. \tag{18}$$

Take any $x \in B_L[n]$. Applying the combinatorial R successively we have

$$B_L[n] \times (B_{l_1} \times \cdots \times B_{l_N}) \simeq (B_{l_1} \times \cdots \times B_{l_N}) \times B_L[n],$$

$$x \times Y \mapsto X' \times y', \tag{19}$$

that gives the following.

Definition 11: The time evolution operator T of the automaton is given by

$$T: Y \mapsto X'.$$

Remarks similar to those after Definition 2 also apply here.

B. Particle antiparticle description

We consider a particle antiparticle description of this automation.[8,15] This is a generalization of the particle description in Sec. III C. Suppose we have balls with index a and $\bar{a}$, $(1 \leqslant a \leqslant n-1)$ that we call an a-ball and an $\bar{a}$-ball respectively. The a-ball and the $\bar{a}$-ball are regarded as a particle and an antiparticle one another. We introduce a pair annihilation process in which a pair of particle and antiparticle makes a bound state, and a pair creation process where the bound state breaks up into a pair of particle and antiparticle of another kind. To each $x = (x_1, \ldots, x_n, \bar{x}_n, \ldots, \bar{x}_1) \in B_{l_i}$ we associate a box of capacity l_i that has x_a a-balls, $\bar{x}_a$ $\bar{a}$-balls $(1 \leqslant a \leqslant n-1)$, and $\bar{x}_n$ bound states in it. Then any element of $B_{l_1} \times \cdots \times B_{l_N}$ can be regarded as a one dimensional array of boxes of capacities $l_1, \ldots, l_N$ with the balls and the bound states. For any $a(1 \leqslant a \leqslant n-1)$ we introduce the notion of an a-carrier as in Sec. III C, and that of a carrier for $\bar{a}$-balls that we call an *$\bar{a}$-carrier*. Assume that their capacities are sufficiently large.

First we consider a basic case, i.e., we suppose $l_i = 1$ for all i. In this case the x represents a box with an a-ball if $x_a = 1$ and a box with an $\bar{a}$-ball if $\bar{x}_a = 1$ for $a \neq n$. It represents an empty box if $x_n = 1$ and a box with a bound state if $\bar{x}_n = 1$. We write $\boxed{a}$ for x with $x_a = 1$ and write $\boxed{\overline{a}}$ for x with $\bar{x}_a = 1$.

Remark 12: In what follows we write a also for a number with an overline as well as that without an overline. We interpret $\bar{\bar{a}} = a$ and $x_{\bar{a}} = \bar{x}_a$. We call $\bar{x}_a$ the $\bar{a}$th element of x.

Besides the four actions in the loading-unloading process in Sec. III C we have three additional actions by the a-carrier:

(5) If the carrier has at least one ball and meets a box with an $\bar{a}$-ball, we unload a ball from the carrier and make a bound state in the box.
(6) If the carrier meets a box with a bound state, we extract an a-ball from the bound state, load it into the carrier, and leave an $\bar{a}$-ball in the box.
(7) If the carrier has no ball and meets a box with an $\bar{a}$-ball, we do nothing.

These actions are depicted by the right three pictures in Fig. 1.

For any $a \in \{1, \ldots, n-1\} \cup \{\overline{n-1}, \ldots, \overline{1}\}$ (see Remark 12) let $\mathcal{K}_a$ be a particle motion operator[8,15] that acts on the space of automaton and does the actions in the loading-unloading process explained above. We assume that the $\mathcal{K}_a$ depends on x in (19) in such a way that the a-carrier has x_a balls in it at the beginning, where x_a is the ath element of x. Then for the basic automaton we have[8]

$$T = \mathcal{K}_{\overline{n-1}} \cdots \mathcal{K}_{\bar{2}} \mathcal{K}_{\bar{1}} \mathcal{K}_1 \mathcal{K}_2 \cdots \mathcal{K}_{n-1}.$$

Now we consider an inhomogeneous case. We define the operators $\mathcal{P}$ and $\mathcal{Q}$ as in Sec. III C but modify them to be suitable for the type D case.[15] To define them we first set $N = 1$ in (19),

$$B_L[n] \times B_l \simeq B_l \times B_L[n]. \tag{20}$$

Then let

$$\mathcal{P}: B_l \to \underbrace{B_1 \times \cdots \times B_1}_{l}$$

be the operator which sends $y = (y_1, \ldots, y_n, \bar{y}_n, \ldots, \bar{y}_1) \in B_l$ into

$$\underbrace{\boxed{\bar{1}}\times\cdots\times\boxed{\bar{1}}}_{\bar{y}_1}\times\cdots\times\underbrace{\boxed{\bar{n}}\times\cdots\times\boxed{\bar{n}}}_{\bar{y}_n}\times\underbrace{\boxed{n}\times\cdots\times\boxed{n}}_{y_n}\times\cdots\times\underbrace{\boxed{1}\times\cdots\times\boxed{1}}_{y_1}. \tag{21}$$

Its inverse $\mathcal{P}^{-1}$ can be defined only on such arrays in which the letters are arranged as in (21). Let

$$\mathcal{Q}:\underbrace{B_1\times\cdots\times B_1}_{l}\to\underbrace{B_1\times\cdots\times B_1}_{l}$$

be the operator which packs $\boxed{n}$'s into the left end and $\boxed{\bar{n}}$'s into the right end. For the case $N>1$ we generalize the definitions of these operators in the same way as in Sec. III C. Now we have the following.

Theorem 13: *The time evolution operator of the inhomogeneous automaton is given by*

$$T=\mathcal{P}^{-1}\mathcal{K}_{\overline{n-1}}\cdots\mathcal{K}_{\bar{2}}\mathcal{K}_{\bar{1}}\mathcal{Q}\mathcal{K}_1\mathcal{K}_2\cdots\mathcal{K}_{n-1}\mathcal{P}. \tag{22}$$

In Ref. 15 a proof of this theorem was given by means of the factorization of the combinatorial R in Ref. 7. In the remaining part of this paper we give another proof of this theorem that uses the piecewise linear formula of the combinatorial R in Definition 5.

V. PROOF OF THE PARTICLE ANTIPARTICLE DESCRIPTION

A. Limit of the piecewise linear formula

We study a limit of the piecewise linear formula of the map R in Definition 5. Let $F=F(x,y)$ be any function of $(x,y)\in B\times B'$. The limit we consider here is to adopt the $B_L[n]$ in (18) as the B. We introduce the following normalized limits:

$$\lim_{\star}F=\lim_{x_n\to\infty,\bar{x}_n\to 0}(F(x,y)-\ell(x)), \tag{23}$$

$$\lim_{\star\star}F=\lim_{x_n\to\infty,\bar{x}_n\to 0}(F(x,y)-2\ell(x)). \tag{24}$$

First we consider the limit (23) of V_i. For the sake of notational simplicity we denote $\lim_{\star}V_i$ by v_i. For $a=\sigma_1$, σ_n or $*$ we denote $\lim_{\star}V_i^a$ by v_i^a. Note that if $a=\sigma_n$ or $*$ the v_i^a is not necessarily equal to the function that is obtained from v_i by applying a to it, whereas if $a=\sigma_1$ it is. Next we consider the limit (24) of W_i. We shall denote $\lim_{\star\star}W_i$ by w_i.

The relations in Lemma 23 in the Appendix become recursion relations in the limit (23). We let $(x)_+$ denote $\max(x,0)$.

Lemma 14: *For $F=V_i$, V_i^*, $V_0^{\sigma_1}$ or $V_n^{\sigma_n}$ the limit $\lim_{\star}F$ exists. Moreover the following relations hold:*

$$v_n^{\sigma_n}=v_{n-1}^*=y_n-\bar{y}_n, \tag{25}$$

$$v_{n-1}^*=y_i-x_i+\max\{v_i^*,(x_i-\bar{y}_i)_+\}\quad(1\leqslant i\leqslant n-1), \tag{26}$$

$$v_i=\max\{\bar{y}_i-\bar{x}_i+v_{i-1},(\bar{y}_i-x_i)_+\}\quad(1\leqslant i\leqslant n-1), \tag{27}$$

$$v_n=\bar{y}_n-y_n+\max\{y_n+\bar{y}_{n-1}-\bar{x}_{n-1}+v_{n-2},(y_n+\bar{y}_{n-1}-x_{n-1})_+\}. \tag{28}$$

We consider the limit (24) of the defining relations of W_i [(12) and (13)].

Lemma 15: *The following relation holds:*

$$w_i=v_i+v_i^*-\min\{v_i^*-v_{i-1}^*+y_i,v_i-v_{i-1}+\bar{x}_i\}+\min\{x_i,\bar{y}_i\}\quad(1\leqslant i\leqslant n-1). \tag{29}$$

These lemmas will be used in proofs of Lemmas 20 and 21. We shall give their proofs in the Appendix.

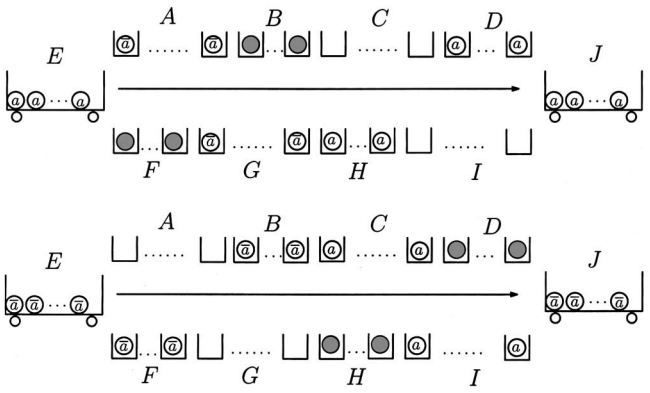

FIG. 2. The meaning of the map γ in Definition 16 by the particle antiparticle description of the automaton.

B. Analysis of the particle antiparticle description

We now consider a recursion formula satisfied by the numbers of items in the particle antiparticle description. For this purpose we introduce the following.

Definition 16: For any non-negative integers A,B,C,D,E, define the piecewise linear map

$$\gamma:(A,B,C,D,E) \mapsto (F,G,H,I,J)$$

by

$$F = \min(A,E),$$

$$G = B + (A-E)_+,$$

$$H = \min(C,B + (E-A)_+),$$

$$I = D + (C - B - (E-A)_+)_+,$$

$$J = D + (B - C + (E-A)_+)_+.$$

The identities $F+G=A+B$, $H+I=C+D$, and $F+H+J=B+D+E$ can be checked easily and will be used afterwards. We give an interpretation of the map γ in the particle antiparticle description that is illustrated in Fig. 2. Recall the seven actions in the loading-unloading process by the a-carrier (Fig. 1) that were explained in Secs. II C and IV B. We write *act-i* for the action with number i in the lists. Note that the a can represent an overlined number in Fig. 1. In Fig. 2 the boxes with b-balls ($b \neq a, \bar{a}$) have been omitted because of act-3. In the upper picture of Fig. 2 we are applying act-5 (or act-7 if $E=0$), act-6, act-1 [or act-4 if $B+(E-A)_+=0$], and act-2 from left to right. In the lower picture we are applying act-1 (or act-4 if $E=0$), act-2, act-5 [or act-7 if $B+(E-A)_+=0$], and act-6.

In what follows we always assume

$$x_n \gg 0 \quad \text{and } \bar{x}_n = 0. \tag{30}$$

Let B and B' be the $D_n^{(1)}$ crystals.

Definition 17: For each pair of variables $x=(x_1,\ldots,\bar{x}_1) \in B$, $y=(y_1,\ldots,\bar{y}_1) \in B'$, define the set of variables $z^{(i)}, \bar{z}^{(i)} (0 \leqslant i \leqslant 2n-2)$, $y_i^{\circ}, \bar{y}_i^{\circ} (1 \leqslant i \leqslant n-1)$, $x_i', \bar{x}_i', y_i', \bar{y}_i' (1 \leqslant i \leqslant n)$ as follows.

(1) Set

$$\bar{z}^{(0)} = \bar{y}_n, \quad z^{(0)} = y_n. \tag{31}$$

TABLE III. The correspondence between the variables in Definition 17 and the items in the particle antiparticle description.

Variables	Items at time t_i	Variables	Items at time $\bar{t}_i$
$z^{(n-i)}$	Empty boxes	$z^{(n-1+i)}$	Empty boxes
$\bar{z}^{(n-i)}$	Boxes with bound states	$\bar{z}^{(n-1+i)}$	Boxes with bound states
$y_i^{\bigcirc}$	Boxes with i-balls	x_i'	Boxes with i-balls
$\bar{y}_i^{\bigcirc}$	Boxes with $\bar{i}$-balls	$\bar{x}_i'$	Boxes with $\bar{i}$-balls
y_i'	Balls in the i-carrier	$\bar{y}_i'$	Balls in the $\bar{i}$-carrier

(2) Define $z^{(n-i)}, \bar{z}^{(n-i)}, y_i^{\bigcirc}, \bar{y}_i^{\bigcirc} y_i' (1 \leqslant i \leqslant n-1)$ as

$$\gamma(\bar{y}_i,\ \bar{z}^{(n-1-i)},\ z^{(n-1-i)},\ y_i,\ x_i) = (\bar{z}^{(n-i)},\ \bar{y}_i^{\bigcirc},\ y_i^{\bigcirc},\ z^{(n-i)},\ y_i'), \tag{32}$$

by descending recursion on i. Here the function γ is given by Definition 16.

(3) Define $z^{(n-1+i)}, \bar{z}^{(n-1+i)}, x_i', \bar{x}_i', \bar{y}_i' (1 \leqslant i \leqslant n-1)$ as

$$\gamma(z^{(n-2+i)},\ \bar{y}_i^{\bigcirc},\ y_i^{\bigcirc},\ \bar{z}^{(n-2+i)},\ \bar{x}_i) = (\bar{x}_i',\ z^{(n-1+i)},\ \bar{z}^{(n-1+i)},\ x_i',\ \bar{y}_i'), \tag{33}$$

by recursion on i.

(4) Set

$$x_n' = z^{(2n-2)}, \quad \bar{x}_n' = \bar{z}^{(2n-2)}, \quad y_n' = \ell(x) - \sum_{i=1}^{n-1} (y_i' + \bar{y}_i'), \quad \bar{y}_i' = 0. \tag{34}$$

Remark 18: Let us consider the case when $x \in B_L[n]$ and $y \in B_l$. Then the numbers represented by the variables $z^{(i)}$, etc., in Definition 17 are equal to the numbers of items in the particle antiparticle description in Sec. IV B. More precisely these items appear within the time evolution process by T in Theorem 13 for the case $N=1$. See Table III. In the table t_i and $\bar{t}_i$ are defined as follows: For $1 \leqslant i \leqslant n-1$ we let t_i (respectively, $\bar{t}_i$) denote the time just after the i-carrier (respectively, $\bar{i}$-carrier) has passed, where the automaton state is given by $\mathcal{K}_i \cdots \mathcal{K}_{n-1} \mathcal{P} y$ (respectively, $\mathcal{K}_{\bar{i}} \cdots \mathcal{K}_{\bar{1}} \mathcal{Q} \mathcal{K}_1 \cdots \mathcal{K}_{n-1} \mathcal{P} y$).

C. Proof

We now give the proof of Theorem 13 that we have promised at the end of Sec. IV. It is obtained from the following.

Theorem 19: *Let $x=(x_1, \ldots, \bar{x}_1) \in B$, $y=(y_1, \ldots, \bar{y}_1) \in B'$ be a pair of variables, and suppose the condition* (30) *on x. Let $v_i, w_i, v_i^*, v_0^{\sigma_1}, v_n^{\sigma_n}$ be the functions defined in Sec. V A, and let $x_i', \bar{x}_i', y_i', \bar{y}_i' (1 \leqslant i \leqslant n)$ be the variables given by Definition 17. Then the following relations hold:*

$$x_1' = y_1 + v_0^{\sigma_1} - v_1,$$

$$x_i' = y_i + v_{i-1} - v_i + w_i - w_{i-1} \quad (2 \leqslant i \leqslant n-1),$$

$$x_n' = y_n + v_{n-1} - v_n^{\sigma_n},$$

$$\bar{x}_i' = \bar{y}_i + v_{i-1} - v_i \quad (1 \leqslant i \leqslant n),$$

$$y_i' = x_i + v_{i-1}^* - v_i^* \quad (1 \leqslant i \leqslant n),$$

$$\bar{y}_i' = \bar{x}_1 + v_0^{\sigma_1} - v_1^*,$$

$$\bar{y}_i' = \bar{x}_i + v_{i-1}^* - v_i^* + w_i - w_{i-1}, \quad (2 \leqslant i \leqslant n-1),$$

$$\bar{y}_n' = \bar{x}_n + v_{n-1}^* - v_n^{\sigma_n}. \tag{35}$$

A proof of Theorem 19 will be given after the following two lemmas.

Lemma 20: Let $A=\bar{y}_i$, $B=\min(x_{i+1},\bar{y}_{i+1})$, $C=v_i^*+\min(x_{i+1},\bar{y}_{i+1})$, $D=y_i$ *and* $E=x_i$ *in* $\gamma:(A,B,C,D,E)\mapsto(F,G,H,I,J)$. *Then*

$$F = \min(x_i,\bar{y}_i),$$

$$G = \bar{y}_i - \min(x_i,\bar{y}_i) + \min(x_{i+1},\bar{y}_{i+1}),$$

$$H = -\min(x_i,\bar{y}_i) + \min(x_{i+1},\bar{y}_{i+1}) + y_i + v_i^* - v_{i-1}^*,$$

$$I = v_{i-1}^* + \min(x_i,\bar{y}_i),$$

$$J = x_i + v_{i-1}^* - v_i^*,$$

for $1 \leqslant i \leqslant n-1$.

In what follows we set $w_0=2v_0$. Note that we have $v_0^*=v_0$ from Table II and $w_1=v_0+v_0^{\sigma_1}$ from Lemma 22 in the Appendix.

Lemma 21: Let $A=v_{i-1}+\min(x_i,\bar{y}_i)$, $B=\bar{y}_i-\min(x_i,\bar{y}_i)+\min(x_{i+1},\bar{y}_{i+1})$, $C=-\min(x_i,\bar{y}_i)+\min(x_{i+1},\bar{y}_{i+1})+y_i+v_i^*-v_{i-1}^*$, $D=\min(x_i,\bar{y}_i)+v_{i-1}+v_{i-1}^*-w_{i-1}$, *and* $E=\bar{x}_i$ *in* $\gamma:(A,B,C,D,E)\mapsto(F,G,H,I,J)$. *Then*

$$F = \bar{y}_i + v_{i-1} - v_i,$$

$$G = v_i + \min(x_{i+1},\bar{y}_{i+1}),$$

$$H = \min(x_{i+1},\bar{y}_{i+1}) + v_i + v_i^* - w_i,$$

$$I = y_i + w_i - w_{i-1} - v_i + v_{i-1},$$

$$J = \bar{x}_i + w_i - w_{i-1} - v_i^* + v_{i-1}^*,$$

for $1 \leqslant i \leqslant n-1$.

We shall give proofs of these lemmas in the Appendix.

Proof of Theorem 19: Suppose $i=n-1$ in Lemma 20. Then we have $B=\bar{y}_n=\bar{z}^{(0)}$ and $C=y_n=z^{(0)}$ because of (25), (30), and (31). Then by comparing (32) with Lemma 20 we see that $\bar{z}^{(1)}$, $\bar{y}_{n-1}^{\bigcirc}$, $y_{n-1}^{\bigcirc}$, $z^{(1)}$, and y_{n-1}' in (32) should be equal to F, G, H, I, and J. Thus the expression for y_{n-1}' was obtained. The expressions for $y_i'(1 \leqslant i \leqslant n-2)$, as well as those for $\bar{z}^{(n-i)}$, $\bar{y}_i^{\bigcirc}$, $y_i^{\bigcirc}$, $z^{(n-i)}$ will be obtained by descending recursion on i, where one uses F and I as B and C in the next step.

Since B and C in Lemma 21 are equal to G and H in Lemma 20, we have $B=\bar{y}_i^{\bigcirc}$ and $C=y_i^{\bigcirc}$ in Lemma 21. We also see that when $i=1$ we have $A=z^{(n-1)}$ and $D=\min(x_1,\bar{y}_1)=\bar{z}^{(n-1)}$ in Lemma 21, from the result obtained in the preceding paragraph. Then by comparing (33) with Lemma 21 we see that $\bar{x}_1'$, $z^{(n)}$, $\bar{z}^{(n)}$, x_1', and $\bar{y}_1'$ in (33) are equal to F, G, H, I, and J in Lemma 21 if $i=1$. Thus the expressions for $x_1', \bar{x}_1', y_1'$ were obtained. The expressions for $x_i', \bar{x}_i', y_i'(2 \leqslant i \leqslant n-2)$ will be obtained by recursion on i, where one uses G and H as A and D in the next step.

Then from (34) we can obtain the expressions for x'_n and $\bar{x}'_n$ in (35) since we have (30) and (25). It is clear that the relation $\bar{y}'_n=0=\bar{x}_n+v^*_{n-1}-v^{\sigma_n}_n$ holds. Then the expression for y'_n in (35) is obtained from the condition $\ell(y')=\ell(x)$. The proof is completed. □

Finally we give the proof of Theorem 13.

Proof of Theorem 13: If we impose the condition (30) on the defining relations (10) in Definition 5 then their right-hand sides become those of (35) because of the existence of the limiting functions defined in the Appendix. Then Theorem 19 tells that the numbers represented by $x'_i, \bar{x}'_i, y'_i, \bar{y}'_i$ in Definition 5 are equal to those by the same symbols in Definition 17 under this condition. Then according to Remark 18 we see that the time evolution T by Definition 11 is identical to the T in Theorem 13 for the case $N=1$. The assertion for the case $N>1$ follows immediately by repeated use of this case, where we adopt the final states of the carriers for B_{l_i} in (19) as their initial states for $B_{l_{i+1}}$. □

APPENDIX: PROOFS OF THE LEMMAS

Before giving the proofs we present some relations between piecewise linear functions. They are used in the main text and in this Appendix. These relations have been essentially obtained in Ref. 13.

Ultradiscretization[18,20,21] is a procedure to derive an equation of piecewise linear functions from an equation of totally positive (i.e., having no minus sign) rational functions. It is realized as a transformation that replaces $+$, $\times$, and / by max(min), $+$ and $-$, respectively. As the ultradiscretization of Lemma 4.12 of Ref. 13 we have the following.

Lemma 22: The following relation holds:

$$W_1 = V_0 + V_0^{\sigma_1}. \tag{A1}$$

This lemma is used just above Lemma 21. The next lemma is obtained from the formulas $(4.23)^*$, (4.23), and (4.24) of Ref. 13 by the ultradiscretization.

Lemma 23: The following relations hold:

$$\max\{V^*_i, \ell(x), \ell(x)+x_i-\bar{y}_i\} = \max\{x_i-y_i+V^*_{i-1}, \ell(y), \ell(y)+x_i-\bar{y}_i\}, \tag{A2}$$

$$\max\{V_i, \ell(y), \ell(y)+\bar{y}_i-x_i\} = \max\{\bar{y}_i-\bar{x}_i+V_{i-1}, \ell(x), \ell(x)+\bar{y}_i-x_i\}, \tag{A3}$$

$$\max\{V_n, \ell(y)+X\} = \max\{\bar{y}_{n-1}+\bar{y}_n-\bar{x}_{n-1}-\bar{x}_n+V_{n-2}, \ell(x)+X\}, \tag{A4}$$

where $1\leqslant i\leqslant n-2$ *and* $X=\bar{y}_n-y_n+(\bar{y}_{n-1}+y_n-x_{n-1}-\bar{x}_n)_+$.

Here we write $(x)_+$ for $\max(x,0)$. This lemma will be used in the proof of Lemma 14.

Proof of Lemma 10

Proof: We derive the expression for V_i. First we suppose $i\neq n-1,n$. Then under the specialization (17) we have $V_i=\max_{1\leqslant j\leqslant n-1}\{\alpha_{i,j}, \alpha'_{i,j}\}$ with

$$\alpha_{i,j} = x_n\delta_{j,n-1} + \begin{cases} \ell(x) & \text{for } j\leqslant i, \\ \ell(y) & \text{for } j>i, \end{cases}$$

$$\alpha'_{i,j} = \ell(x) + \sum_{k=1}^{j-1} (y_k - x_k) + y_j.$$

Since $\alpha_{i,j(\leqslant i)} \leqslant \alpha'_{i,1}$ and $\alpha_{i,j(>i)} \leqslant \alpha_{i,n-1}$, we can drop off $\alpha_{i,j(\neq n-1)}$ in the max. Thus we obtain the desired result from (2) with $i=1$. Now we suppose $i=n-1$ or n. Then we have

$$\alpha_{i,j} = \ell(x) + \begin{cases} 0 & \text{for } i = n-1, \\ \max(-y_n, -x_{n-1}) & \text{for } i = n, \end{cases}$$

$$\alpha'_{i,j} = \ell(x) + \sum_{k=1}^{j-1} (y_k - x_k) + y_j + \delta_{j,n-1} \max(y_n - x_{n-1}, 0).$$

Since $\alpha_{i,j} \leqslant \alpha'_{i,1}$, we can drop off $\alpha_{i,j}$ in the max and obtain the desired result.

We derive the expression for V_i^*. Note that if $i=0,n$ it has already been proved since $V_i^* = V_i$ for $i=0,n$. Suppose $i \neq 0,n$. Then under the specialization (17) we have $V_i^* = \max_{1 \leqslant j \leqslant n-1}\{\alpha_{i,j}^*, (\alpha'_{i,j})^*\}$ with

$$\alpha_{i,j}^* = x_j + \begin{cases} \ell(y) + \sum_{k=j+1}^{i} (x_k - y_k) & \text{for } j \leqslant i, \\ \ell(x) + \sum_{k=i+1}^{j} (y_k - x_k) & \text{for } j > i, \end{cases}$$

$$(\alpha'_{ij})^* = \delta_{j,n-1} x_n + \ell(y) + \sum_{k=1}^{i} (x_k - y_k).$$

Since $(\alpha'_{i,j(\neq n-1)})^* \leqslant \alpha'_{i,1}$, we can drop off $(\alpha_{i,j(\neq n-1)})^*$ in the max. The remaining candidates are

$$\alpha_{i,i+1}^* = \ell(x) + y_{i+1},$$

$$\alpha_{i,i+2}^* = \alpha_{i,i+1}^* - x_{i+1} + y_{i+2},$$

$$\cdots,$$

$$\alpha_{i,n-1}^* = \alpha_{i,n-2}^* - x_{n-2} + y_{n-1},$$

$$(\alpha'_{i,n-1})^* = \alpha_{i,n-1}^* - x_{n-1} + y_n,$$

$$\alpha_{i,1}^* = (\alpha'_{i,n-1})^* - x_n + y_1,$$

$$\alpha_{i,2}^* = \alpha_{i,1}^* - x_1 + y_2,$$

$$\cdots,$$

$$\alpha_{i,i}^* = \alpha_{i,i-1}^* - x_{i-1} + y_i.$$

Thus we obtain the desired result.

We derive the expression for $V_0^{\sigma_1}$. Under the specialization (17) we have $V_0^{\sigma_1} = \max_{1 \leqslant j \leqslant n-1}\{\alpha_{0,j}^{\sigma_1}, (\alpha'_{0,j})^{\sigma_1}\}$ with

$$\alpha_{0,j}^{\sigma_1} = \ell(y) + x_1 - (1 - \delta_{j,1})y_1 + \delta_{j,n-1}x_n,$$

$$(\alpha'_{0,j})^{\sigma_1} = \ell(x) + \sum_{k=2}^{j} (y_k - x_k) + (1 - \delta_{j,1})x_j.$$

Since $\alpha_{0,j(\neq n-1)}^{\sigma_1} \leqslant \alpha_{0,1}^{\sigma_1}$ and $(\alpha'_{0,1})^{\sigma_1} \leqslant (\alpha'_{0,2})^{\sigma_1}$, we can drop off $\alpha_{0,j(\neq 1,n-1)}^{\sigma_1}$ and $(\alpha'_{0,1})^{\sigma_1}$ in the max and obtain the desired result.

We derive the expression for $V_n^{\sigma_n}$. Under the specialization (17) we have $V_n^{\sigma_n} = \max_{1 \leqslant j \leqslant n-1}\{\alpha_{n,j}^{\sigma_n}, (\alpha'_{n,j})^{\sigma_n}\}$ with

$$\alpha_{n,j}^{\sigma_n} = \ell(x) + y_n - (1 - \delta_{j,n-1})x_n,$$

$$(\alpha'_{n,j})^{\sigma_n} = \ell(x) + y_n - x_n + \sum_{k=1}^{j-1} (y_k - x_k) + y_j.$$

Since $\alpha_{n,j(\neq n-1)}^{\sigma_n} \leqslant (\alpha'_{n,1})^{\sigma_n}$, we can drop off $\alpha_{n,j(\neq n-1)}^{\sigma_n}$ in the max and obtain the desired result.

The expression for W_{n-1} is derived from (13), and that for $W_{i(\neq n-1)}$ is from (12) and the following lemma. □

Lemma 24: Let P_i be the function that was defined by (2). Then

$$P_{i+1} \geqslant P_i - y_i.$$

Proof: It is easy to see that

$$P_i - y_i = \max_{1 \leqslant j \leqslant n} \{A_j\}, \quad P_{i+1} = \max_{2 \leqslant j \leqslant n+1} \{x_i + A_j\},$$

where

$$A_j = \sum_{k=1}^{j-1} (y_{i+k} - x_{i+k-1}).$$

The claim of the lemma holds since we have $x_i \geqslant 0$ and $x_i + A_2 = y_{i+1} \geqslant 0 = A_1$. □

Proof of Lemma 14

Proof: By definition we have $V_n^{\sigma_n} = \max_{1 \leqslant j \leqslant n-1}\{\alpha_{n,j}^{\sigma_n}, (\alpha'_{n,j})^{\sigma_n}\}$, where

$$(\alpha_{n,j})^{\sigma_n} = \max(\delta_{j,n-1}(x_n - \bar{y}_n), \bar{y}_j - x_j) + \ell(x) + \sum_{k=j+1}^{n-1} (\bar{y}_k - \bar{x}_k) + y_n - x_n,$$

$$(\alpha'_{n,j})^{\sigma_n} = \max(\delta_{j,n-1}(\bar{y}_n - x_n), x_j - \bar{y}_j) + \ell(x) + \sum_{k=1}^{n-1} (\bar{y}_k - \bar{x}_k) + \sum_{k=1}^{j} (y_k - x_k) + y_n - x_n.$$

In the limit $\lim_\star$ the only element that survives in the max is $(\alpha_{n,n-1})^{\sigma_n}$, which yields $v_n^{\sigma_n} = y_n - \bar{y}_n$. In the same way the relation

$$v_{n-2}^* = y_{n-1} + y_n - x_{n-1} + (x_{n-1} - \bar{y}_{n-1} + y_n)_+, \tag{A5}$$

can be obtained by a direct calculation. Then from (A2) we see that the v_i^*'s exist and the relation (26) holds for $1 \leqslant i \leqslant n-2$ by descending induction on i. Since $V_0 = V_0^*$ (Table II) we have $v_0 = v_0^*$. Then from (A3) and (A4) we see that v_i's exist for $i \neq n-1$, and that the relations (27) for $1 \leqslant i \leqslant n-2$ and (28) hold, by induction on i. Since v_n and $v_n^{\sigma_n}$ exist, we see by (16) that the function v_{n-1} also exists and equals to $\max\{v_n - \bar{y}_n, -\bar{y}_n\}$. Substituting (28) into $v_{n-1} = \max\{v_n$

$-\bar{y}_n,-\bar{y}_n\}$ we obtain (27) for $i=n-1$. From $*$ of (16) we obtain $v^*_{n-1}=y_n-\bar{y}_n$. Then from (A5) and $\max\{-y_n,-\bar{y}_n\}=0$ we obtain (26) for $i=n-1$. From σ_1 of (A2) the existence of $v_0^{\sigma_1}$ can be verified. The proof is completed. □

Proof of Lemma 15

Proof: For $1\leqslant i\leqslant n-2$ the relations follow immediately from (12). We consider the case $i=n-1$. We obtain $w_{n-1}=v_n+v_n^{\sigma_n}$ from (13). First we suppose $x_{n-1}\leqslant\bar{y}_{n-1}$. Then from Lemma 14 we obtain $v_{n-1}=\bar{y}_{n-1}+\max\{-\bar{x}_{n-1}+v_{n-2},-x_{n-1}\}$. It yields the relations $v_n+v_n^{\sigma_n}=v_{n-1}+y_n$ and

$$\text{RHS of (29)} = v_{n-1}+y_n-\bar{y}_n+x_{n-1}-\min\{x_{n-1}-\bar{y}_n,\bar{x}_{n-1}-v_{n-2}-v_{n-1}\}=v_{n-1}+y_n-\min\{0,\bar{y}_n+(\bar{y}_{n-1}-x_{n-1})+(\bar{x}_{n-1}-x_{n-1}-v_{n-2})_+\}=v_{n-1}+y_n.$$

Thus the assertion of the lemma was proved in this case. Now we suppose $x_{n-1}>\bar{y}_{n-1}$. Then

$$\text{RHS of (29)} = v_{n-1}+y_n-\bar{y}_n+\bar{y}_{n-1}-\min\{x_{n-1}-(x_{n-1}-\bar{y}_{n-1}-y_n)_+-\bar{y}_n,\bar{x}_{n-1}-v_{n-2}-v_{n-1}\}=\max\{(y_n+\bar{y}_{n-1}-x_{n-1})_+ +v_{n-1},v_{n-2}+\bar{y}_{n-1}-\bar{x}_{n-1}+y_n-\bar{y}_n\}.$$

From Lemma 14 we have $v_{n-1}=(\bar{y}_{n-1}-\bar{x}_{n-1}+v_{n-2})_+$. Therefore

$$\text{RHS of (29)} = \max\{(y_n+\bar{y}_{n-1}-x_{n-1})_+,\bar{y}_{n-1}-\bar{x}_{n-1}+y_n+v_{n-2}+\max\{-y_n,-\bar{y}_n,\bar{y}_{n-1}-x_{n-1}\}\}.$$

The last expression gives $v_n+v_n^{\sigma_n}$ since the inner max vanishes. The proof is completed. □

Proof of Lemma 20

Proof: The expressions for F and G are given by definition. The expression for I is given by $I=C+D-H$, and that for J is by $J=I+B-C+E-F$. Thus it suffices to prove H. We have

$$H=\min(C,B+E-F)=\min(x_{i+1},\bar{y}_{i+1})+\min\{v_i^*,-\min(x_i,\bar{y}_i)+x_i\}=\min(x_{i+1},\bar{y}_{i+1})+v_i^*-\min(x_i,\bar{y}_i)+x_i-\max\{v_i^*,-\min(x_i,\bar{y}_i)+x_i\}.$$

Then by (26) we obtain the desired result. □

Proof of Lemma 21

Proof: The expression for G is given by $G=A+B-F$, that for I is by $I=C+D-H$, and that for J is by $J=I+B-C+E-F$. Thus it suffices to prove F and H. For F we have

$$F=\min(A,E)=\bar{y}_i+v_{i-1}+\min\{\min(x_i,\bar{y}_i)-\bar{y}_i,\bar{x}_i-\bar{y}_i-v_{i-1}\}=\bar{y}_i+v_{i-1}-\max\{-\min(x_i,\bar{y}_i)+\bar{y}_i,-\bar{x}_i+\bar{y}_i+v_{i-1}\}.$$

Then by (27) we obtain the desired result. For H we have

$$H=\min(C,B+E-F)=\min(x_{i+1},\bar{y}_{i+1})-\min(x_i,\bar{y}_i)+\min\{v_i^*-v_{i-1}^*+y_i,v_i-v_{i-1}+\bar{x}_i\}.$$

Then by (29) we obtain the desired result. □

We prove that the continuous one-dimensional Schrödinger equation with an analytic quasi-periodic potential has positive Lyapunov exponents in the bottom of the spectrum for large couplings. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2167808]

I. INTRODUCTION

In this short paper we study the one-dimensional Schrödinger equation with a quasi-periodic potential:

$$(H_\theta u)(t) \equiv -u''(t) + \lambda V(t, \theta + \omega t)u(t) = Eu(t). \tag{1.1}$$

Here $V: \mathbb{T} \times \mathbb{T}^d \to \mathbb{R}$ $(\mathbb{T} = \mathbb{R}/\mathbb{Z}, d \geqslant 1)$ is assumed to be a real-analytic function which attains its minimum value at most finitely many points in $\mathbb{T}^{d+1}$. Moreover, the frequency vector $\omega \in \mathbb{R}^d$ satisfies the Diophantine condition $(\mathrm{DC})_{\kappa,\tau}$,

$$\|\omega \cdot n\| \geqslant \frac{\kappa}{|n|^\tau} \quad \forall\, n \in \mathbb{Z}^d \setminus \{0\}$$

for some constants $\kappa > 0, \tau > d$. The coupling constant λ is positive and the phase θ is in $\mathbb{T}^d$. We shall study the behavior of the solutions to (1.1) for energies E in the bottom of the spectrum of the operator H_θ in the regime of large coupling constants λ. Recall that the spectrum of H_θ, which we denote by $\sigma(H_\theta)$, as a set, is independent of the phase θ.

Writing (1.1) as the system

$$X'(t) = \begin{pmatrix} 0 & 1 \\ \lambda V(t, \theta + \omega t) - E & 0 \end{pmatrix} X(t), \quad X(t) = \begin{pmatrix} u(t) \\ u'(t) \end{pmatrix}, \tag{1.2}$$

we denote by $M_t(\theta, E)$ its fundamental solution. Since the above matrix lies in $sl(2, \mathbb{R})$ for all t, it is clear that $M_t(\theta, E) \in SL(2, \mathbb{R})$ for all t. The Lyapunov exponent is defined as

$$L(E) = \lim_{t \to \infty} \frac{1}{t} \int_{\mathbb{T}^d} \ln \|M_t(\theta, E)\| \mathrm{d}\theta \geqslant 0.$$

We leave the dependence on λ implicit.

By adding a constant to V if needed, we can without loss of generality assume that $\min V = 0$.

Our main result is the following.

Theorem 1: *There is a constant $c_0 = c_0(V) > 0$ and a $\lambda_0 = \lambda_0(V, \kappa, \tau) > 0$ such that for all $\lambda > \lambda_0$,*

$$L(E) \geqslant c_0 \sqrt{\lambda},$$

for all $E \in [0, \lambda^{2/3}]$.

[a)]Electronic mail: bjerklov@math.utoronto.ca

This theorem generalizes the Sorets-Spencer result.[4] It is likely that the spectrum of H_θ in $[0,\lambda^{2/3}]$ is pure-point (for a.e. θ) with exponentially decaying eigenfunctions, i.e., there is a situation of Anderson localization. See Ref. 2 for an example when this is the case.

It is well known that $\min\{E:E\in\sigma(H_\theta)\}\leqslant \text{const}\ \sqrt{\lambda}$, where the constant depends on the shape of the minimum of V and the modulus of the frequency vector ω (recall that we have assumed that $\min V=0$). Hence our result indeed covers energies in the spectrum, provided that λ is sufficiently large.

From Eliasson's result[1] we know that there is an $E_0>0$ such that the spectrum in $\sigma(H_\theta)\cap[E_0,\infty)$ is purely absolutely continuous, and $L(E)=0$ on the spectrum. Hence, as the energy increases, the dynamics undergo a dramatic change. It is still unknown what is happening in the transition region, i.e., for energies $\lambda^{2/3}<E<E_0$.

For a more detailed introduction to the subject, we refer to Refs. 1–4, and the references therein.

II. PROOF OF THEOREM 1

The proof of Theorem 1 is based on a method developed by Goldstein and Schlag in Ref. 3, where they, among many other things, prove an analog of Theorem 1 for the discrete Schrödinger equation. This method relies on two tools: a large deviation estimate and the so-called avalanche principle. Below we will apply this method to the present problem.

We assume that the frequency vector $\omega\in\mathbb{R}^d$ satisfies the Diophantine condition $(\text{DC})_{\kappa,\tau}$ for some $\kappa,\tau>0$. Moreover, the energy E is always assumed to be in the interval $[0,\lambda^{2/3}]$, and λ should be sufficiently large, depending on V and the Diophantine condition.

As above, we let $M_t(\theta,E)$ denote the fundamental solution to (1.2). We introduce the matrix

$$A(\theta,E)=M_1(\theta,E)\in \mathrm{SL}(2,\mathbb{R}),\quad \theta\in\mathbb{T}^d,$$

i.e., we integrate time-one. In view of system (1.2), we have the relation

$$M_n(\theta,E)=A(\theta+(n-1)\omega,E)\cdots A(\theta+\omega,E)A(\theta,E)$$

for $n=1,2,3,\ldots$.

Let

$$L_n(E)=\frac{1}{n}\int_{\mathbb{T}^d}\ln\|M_n(\theta,E)\|\mathrm{d}\theta$$

be the approximated Lyapunov exponents. By definition

$$L(E)=\lim_{n\to\infty}L_n(E).$$

Since V is analytic, it is clear that $A(\cdot,E)$ is analytic in some complex neighborhood of $\mathbb{T}^d$. Consequently,

$$f_n(\theta)=\frac{1}{n}\ln\|M_n(\theta,E)\|$$

is a bounded plurisubharmonic function in some neighborhood of $\mathbb{T}^d$.

We note that we have the following upper bound:

$$\sup_{\theta\in\mathbb{T}^d}\|A(\theta,E)\|\leqslant\exp(c_2\sqrt{\lambda}),$$

where the constant $c_2>0$ only depends on V. This follows easily from (1.1): if $\|(u(0),u'(0))\|=1$, then $\|(u(1),u'(1))\|$ cannot be larger than $\exp(c_2\sqrt{\lambda})$. In particular, this implies that we have the upper bounds

$$|f_n(\theta)| \leqslant c_2\sqrt{\lambda} \quad \text{and } L_n(E) \leqslant c_2\sqrt{\lambda} \quad \text{for } n = 1,2,3,\ldots . \tag{2.1}$$

From the fact that $M_n(\theta+\omega)=A(\theta+n\omega)M_n(\theta)A(\theta)^{-1}$ we deduce that

$$\sup_{\theta\in\mathbb{T}^d}|f_n(\theta+\omega)-f_n(\theta)| \leqslant \frac{\text{const}}{n},$$

where the constant only depends on the norm of $A(\theta)$. By applying Proposition 9.1 in Ref. 3, Sec. 9 we obtain the large deviation estimate

$$\int_{\mathbb{T}^d}\left|\frac{1}{n}\ln\|M_n(\theta,E)\|-L_n(E)\right| \leqslant c_0\sqrt{\lambda}n^{-\sigma},$$

where the constants $c_0>0$ and $\sigma>0$ only depend on V, κ, and τ. Combining this estimate with the avalanche principle (Ref. 3, Proposition 2.2) one gets the following (see Lemma 11.1 in Ref. 3): There is an integer $l_0=l_0(c_0,\sigma)>0$ such that if

$$L_l(E) > \sqrt{\lambda}l^{-\sigma/4} \quad \text{and } L_l(E)-L_{2l}(E) < \frac{L_l(E)}{8} \tag{2.2}$$

for some $l\geqslant l_0$, then $L(E)\geqslant L_l(E)/2$.

Thus, to prove the statement of Theorem 1, i.e., that $L(E)>c_0\sqrt{\lambda}$, we only have to establish $L_l(E)>2c_0\sqrt{\lambda}$ and (2.2) for some $l>l_0$. The main tool is the following lemma.

Lemma 2.1: There exists a constant $c_1=c_1(V)>0$ such that for any integer $n>0$ there is a $\lambda_1=\lambda_1(V,d,n)>0$ such that

$$L_n(E) > c_1\sqrt{\lambda}$$

for all $E\in[0,\lambda^{2/3}]$ and for all $\lambda\geqslant\lambda_1$.

Proof: For simplicity we assume that V has a unique minimum. The case with finitely many minimum points is treated similarly. Below we always assume that $\lambda>0$ is sufficiently large, depending only on n, d, and V. Since $V:\mathbb{T}\times\mathbb{T}^d\to\mathbb{R}$ has the unique minimum 0, at $(x_0,y_0)\in\mathbb{T}\times\mathbb{T}^d$ say, there exists a $\delta>0$ such that $V(x,y)>3\delta$ for all $|x-x_0|>1/100$ and all $y\in\mathbb{T}^d$.

Define

$$G_n=\left\{\theta\in\mathbb{T}^d:\inf_{0\leqslant t\leqslant n}\lambda V(t,\theta+t\omega)-\lambda^{2/3}>0\right\}.$$

Clearly $\text{mes}(G_n)\to 1$ as $\lambda\to\infty$, so for large λ we have

$$\text{mes}(G_n) > 1/2. \tag{2.3}$$

For any $\theta\in G_n$ and any $E\in[0,\lambda^{2/3}]$ it now follows from the above definitions that for $0\leqslant t\leqslant n$,

$$\lambda V(t,\theta+t\omega)-E > \begin{cases} 2\lambda\delta & \text{if } \inf_{p\in\mathbb{Z}}|t-x_0-p|>1/100,\\ 0 & \text{otherwise.}\end{cases}.$$

Thus one verifies easily that the solution $u(t)$ to the equation

$$-u''(t)+(\lambda V(t,\theta+t\omega)-E)u(t)=0, \quad u(0)=1, \quad u'(0)=0$$

satisfies $u(n)\geqslant\exp(n\sqrt{\delta\lambda})$. Since $u(n)$ is one of the entries of the matrix $M_n(\theta,E)$, this implies that

$$\|M_n(\theta,E)\| \geqslant \exp(n\sqrt{\delta\lambda}), \quad \theta\in G_n, E\in[0,\lambda^{2/3}].$$

From this, (2.3) and the fact that M_n is in $\text{SL}(2,\mathbb{R})$, so $\|M_n(\theta,E)\|\geqslant 1$, we get

$$L_n(E) = \frac{1}{n}\int_{\mathbb{T}^d} \ln\|M_n(\theta,E)\|\mathrm{d}\theta \geqslant \frac{1}{n}\int_{G_n} \ln\|M_n(\theta,E)\|\mathrm{d}\theta \geqslant \sqrt{\delta\lambda}/2.$$

This ends the proof of the lemma. □

We now have all the pieces to complete the proof of Theorem 1. As above we assume that $\lambda > 0$ is sufficiently large, depending on V, κ, and τ. Take $\tilde{l} > l_0$, where $l_0 = l_0(c_0, \sigma) > 0$ is as above, so large that $c_1 > l^{-\sigma/4}$. Let

$$k = \left[\frac{\ln(c_2/c_1)}{\ln(8/7)}\right] + 1.$$

An application of Lemma 2.1 with $n = 2^k\tilde{l}$ yields

$$L_{2^k\tilde{l}} > c_1\sqrt{\lambda}.$$

Then there is an integer $j \in [0,2,\ldots,k]$ such that $L_{2^{j+1}\tilde{l}} > \frac{7}{8}L_{2^j\tilde{l}}$, i.e., such that

$$L_{2^{j+1}\tilde{l}} - L_{2^j\tilde{l}} < \frac{L_{2^j\tilde{l}}}{8}. \tag{2.4}$$

Indeed, since if $L_{2^{j+1}\tilde{l}} \leqslant \frac{7}{8}L_{2^j\tilde{l}}$ for all $j = 0,1,\ldots,k$, then we would have, making use of the trivial upper bound (2.1),

$$c_1\sqrt{\lambda} < L_{2^k\tilde{l}} \leqslant \left(\frac{7}{8}\right)^k L_{\tilde{l}} < \left(\frac{7}{8}\right)^k c_2\sqrt{\lambda},$$

contradicting the definition of k.

Finally, since the sequence $\{nL_n\}$ is subadditive, we also have the following estimate (since $k \geqslant j$):

$$L_{2^j\tilde{l}} \geqslant L_{2^{j+1}\tilde{l}} \geqslant \cdots \geqslant L_{2^k\tilde{l}} > c_1\sqrt{\lambda} > \tilde{l}^{-\sigma/4}\sqrt{\lambda} > (2^j\tilde{l})^{-\sigma/4}\sqrt{\lambda}. \tag{2.5}$$

Thus, (2.4) and (2.5) show that condition (2.2) holds with $l = 2^j\tilde{l} \geqslant l_0$.

Consequently,

$$L \geqslant \frac{L_l}{2} = \frac{L_{2^j\tilde{l}}}{2} \geqslant \frac{L_{2^k\tilde{l}}}{2} > \frac{c_1}{2}\sqrt{\lambda}.$$

Letting $c_0 = c_1/2$ finishes the proof of Theorem 1.

Novel solvable variants of the goldfish many-body model

M. Bruschi[a] and F. Calogero[b]

(Received 21 October 2005; accepted 21 December 2005; published online 15 February 2006)

A recent technique to identify *solvable* many-body problems in two-dimensional space yields, via a new twist, new many-body problems of "goldfish" type. Some of these models are *isochronous*, namely their *generic* solutions are *completely periodic* with a fixed period (independent of the initial data). The investigation of the behavior of some of these isochronous systems in the vicinity of their equilibrium configurations yields some amusing diophantine relations. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2167917]

I. INTRODUCTION AND MAIN RESULTS

Recently a novel technique to manufacture *solvable* many-body problems has been introduced, and some many-body problems obtained in this manner have been investigated.[5–8,10] The *solvable* character of these N-body models is manifested by the possibility to reduce the solution of their initial-value problem to algebraic operations, indeed generally just to finding the N eigenvalues of an $N \otimes N$ matrix whose time evolution is explicitly known. Some of these models are extensions of the so-called "goldfish" many-body problem, a particularly neat (hence its name)[3] Hamiltonian model interpretable as a (rotation- and translation-invariant) many-body problem in the horizontal plane. In this paper we take advantage of a new twist of this technique to manufacture a novel *solvable* model, that provides a one-parameter extension of that treated in Ref. 10, itself a one-parameter extension of the goldfish model. A further extension is also outlined, but it is also noted that it is relatively trivial, inasmuch as it is reducible to just a simple variant of the preceding treatment.

The main idea of this approach is to take as starting point a *solvable* $N \otimes N$ *matrix* evolution equation, and to then focus on the time evolution of the N *eigenvalues* of the matrix whose *explicit* time dependence is obtained by solving the initial-value problem for this matrix evolution equation. One often finds that this time evolution of the N eigenvalues is naturally interpretable as a Newtonian N-body problem: indeed this evolution is generally determined by a system of N second-order ODEs in which the "accelerations" of these N moving points (thereby interpreted as the coordinates of N "point particles") are proportional to "one- and two-body forces." However, the two-body forces generally feature time-dependent "coupling constants," whose time evolution is determined by an additional system of first-order ODEs. One can interpret these "coupling constants" as additional degrees of freedom of the problem: indeed in some cases it is possible to attribute also to them a "physical" interpretation as internal degrees of freedom of the moving particles, possibly associated with "spin" variables. Another possibility, which however emerges only exceptionally, is to find some appropriate *ansatz* for the "coupling constants," whereby a subclass of solutions of the equations of motion can be identified for which the time dependence of these quantities can be gotten rid of, obtaining thereby a more standard N-body problem involving only the coordinates of the N moving particles. All the models previously treated by this

[a]Electronic mail: mario.bruschi@roma1.infn.it
[b]Electronic mail: francesco.calogero@roma1.infn.it

approach[5–8,10] were characterized by the occurrence of such a "miracle," which is as well featured by the models introduced and discussed in this paper.

But before describing our new findings let us review tersely previous results, thereby also introducing our notation. We do not however elaborate here on the previous history of this approach, nor report the relevant references, since this has already been done in preceding papers of this series.[5–8,10]

The "goldfish" N-body problem is characterized by the Newtonian equations of motion

$$\ddot{z}_n = 2 \sum_{m=1, m\neq n}^{N} \frac{\dot{z}_n \dot{z}_m}{z_n - z_m}. \tag{1}$$

Notation: here and throughout this paper N is an arbitrary positive integer (generally $N \geqslant 2$), and indices such as n, m, ℓ are understood to run from 1 to N unless otherwise indicated; t is the *independent* variable, and superimposed dots denote differentiations with respect to this, generally *real*, variable ("time"); the *dependent* variables $z_n \equiv z_n(t)$ are instead generally *complex* numbers. In the case of this model, (1), the dependent variables $z_n(t)$ could be *real*, namely the motion could take place along the *real* axis in the *complex* z-plane; in some of the models considered below this is not possible; but in any case the motions in the *complex* z-plane are much more interesting than those restricted to the *real* axis, not only because for motions in the *complex* z-plane particle collisions are *not* generic (they only occur for a lower-dimensional set of initial data), but also because it is often possible to identify the *complex* z-plane with a *real* (say, horizontal) plane and to thereby reformulate the models under consideration as "physical" many-body problems characterized by *real* (and *rotation-invariant*) Newtonian equations determining the motion of N "physical" point particles moving in the *real* horizontal plane.[2,4] Such a reformulation is indeed possible in all the models reported and introduced in this paper and it contributes nontrivially to their interest; but we forsake to exhibit the relevant "physical" equations of motion, since obtaining them is a simple task well explained in the literature[2,4] that can therefore be left as an exercise for the diligent reader.

An interesting *solvable* variant[4] of the goldfish N-body problem (1) is characterized by the following Newtonian equations of motion:

$$\ddot{z}_n - (2\lambda + 1) i\omega \dot{z}_n - \lambda(\lambda + 1)\omega^2 z_n = 2 \sum_{m=1, m\neq n}^{N} \frac{(\dot{z}_n - i\lambda\omega z_n)(\dot{z}_m - i\lambda\omega z_m)}{z_n - z_m}. \tag{2}$$

Notation: here and hereafter i denotes the *imaginary* unit ($i^2 = -1$), ω is a *positive* constant which could be rescaled away but that we prefer to keep in evidence and to which we associate the basic period

$$T = \frac{2\pi}{\omega}, \tag{3}$$

and λ is a arbitrary dimensionless number. However we hereafter generally assume λ to be *real* and *rational*, these restrictions being sufficient to guarantee that *all the nonsingular* solutions of this N-body problem, (2), are *isochronous*, namely *completely periodic* with a period that is a *rational* multiple of the basic period (3). Note that the motions take now necessarily place in the *complex* z-plane and that the *singular* solutions are *not* generic, being characterized by the occurrence of a collision of two or more of the point particles $z_n(t)$ [they correspond to sets of initial data having lower dimensionality than the full $(4N)$-dimensional real phase space]. The Hamiltonian character of this model, and of other many-body *isochronous* problems, will be discussed in a separate paper by one of us (F.C.) and François Leyvraz.[11]

This *isochronous* model, (2), is related to the standard goldfish model (1), via the following simple change of dependent and independent variables[1] (generally referred to as "the trick"):[4–10]

$$z_n(t) = \exp(i\lambda\omega t)\zeta_n(\tau), \quad \tau = \frac{\exp(i\omega t) - 1}{i\omega}. \tag{4}$$

Indeed, this change of variables clearly implies that if the N (*complex*) coordinates $z_n(t)$ satisfy the system of N ODEs (2), then the N (*complex*) coordinates $\zeta_n(\tau)$ satisfy the system of N ODEs,

$$\zeta_n'' = 2\sum_{m=1,m\neq n}^{N} \frac{\zeta_n'\zeta_m'}{\zeta_n - \zeta_m}, \tag{5}$$

and vice versa. And it is plain that this system of N ODEs, (5), coincides with the standard goldfish model (1), up to a trivial, now merely notational, change of variables (here and hereafter appended primes denote of course derivation with respect to the argument of the functions they are appended to).

Note that, as the *real* time variable t evolves, the corresponding *complex* variable τ, see (4), travels round and round on the circle whose diameter, of length $2/\omega$, lies on the upper *imaginary* axis in the *complex* τ-plane, with its lower end at the origin ($\tau=0$) and its upper end at $\tau=2i/\omega$; clearly this fact is at the origin of the *isochronous* character of the many-body (2) (for more details see for instance Ref. 4).

The Newtonian equations of motion of the main *solvable* many-body problem introduced and discussed in Ref. 10 read as follows:

$$\ddot{z}_n = 2a\dot{z}_n z_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n - az_n^2)(\dot{z}_m - az_m^2)}{z_n - z_m}, \tag{6}$$

and their *isochronous* variant, obtained by first rewriting these equations of motion via the merely notational change of variables consisting in the replacement of the independent variable t with τ and of the dependent variables $z_n(t)$ with $\zeta_n(\tau)$ and by then applying the trick (4) with $\lambda=1$, read[10]

$$\ddot{z}_n - 3i\omega\dot{z}_n - 2\omega^2 z_n = 2a(\dot{z}_n - i\omega z_n)z_n + 2\sum_{m=1,m\neq n}^{N} \frac{(\dot{z}_n - i\omega z_n - az_n^2)(\dot{z}_m - i\omega z_m - az_m^2)}{z_n - z_m}. \tag{7}$$

Notation: here and hereafter a denotes an *arbitrary* constant, that could generally be rescaled away but that we prefer to keep in evidence. Of course for $a=0$ these two models, (6), respectively, (7), reduce to the standard goldfish model and to its *isochronous* variant, (1), respectively, (2) (with $\lambda=1$).

The (*autonomous*) Newtonian equations of motion of the first one of the *solvable* many-body problems introduced and discussed in this paper read as follows:

$$\ddot{z}_n = 2a\dot{z}_n z_n + b[\dot{z}_n - az_n^2] + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{z}_n - az_n^2][\dot{z}_m - az_m^2]}{z_n - z_m}. \tag{8}$$

Here b is an *arbitrary* constant; clearly for $b=0$ this model reduces to (6). The solution of this model is given in Sec. III (see in particular Proposition 1 and Sec. III A).

Another *solvable* N-body problem, the solution of which is provided in Sec. IV (see in particular Proposition 2 in Sec. IV A), is characterized by the following equations of motion:

$$\ddot{z}_n - (3+k)i\omega\dot{z}_n - (2+k)\omega^2 z_n = a[2\dot{z}_n - (2+k)i\omega z_n]z_n + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{z}_n - i\omega z_n - az_n^2][\dot{z}_m - i\omega z_m - az_m^2]}{z_n - z_m}. \tag{9}$$

Here k is also an *arbitrary* constant, but our main interest is in the case when k is a (*positive* or *negative*) *integer*, since this model is then *isochronous*, with the single exception of the case $k=$

-2, when the solutions are instead *multiply periodic* [and note that this model reduces to (7) for $k=0$].

Alternative formulations of these *solvable* models, (8) and (9), are provided and discussed in Sec. V. The corresponding *solvable* systems of ODEs read as follows:

$$\ddot{c}_m - 2am\dot{c}_{m+1} + (2ac_1 - b)\dot{c}_m + a^2(m+2)(m-1)c_{m+2} + a[b - m(2ac_1 - b)]c_{m+1} + a[2ac_2 - bc_1]c_m = 0, \tag{10}$$

$$\ddot{c}_m - 2ma\dot{c}_{m+1} + [2ac_1 - (2m+k+1)i\omega]\dot{c}_m + (m+2)(m-1)a^2c_{m+2} + [-2ma^2c_1 + (m+1)(2m+k)i\omega a]c_{m+1} + [2a^2c_2 - (2m+k)i\omega ac_1 - m(m+k+1)\omega^2]c_m = 0. \tag{11}$$

Notation: in each of these two dynamical systems the N dependent variables are denoted as $c_m \equiv c_m(t)$, and the rest of the notation is, we trust, self-explanatory. The index m ranges as usual from 1 to N, while the quantities c_{N+1} and c_{N+2} by definition vanish,

$$c_{N+1} = c_{N+2} = 0. \tag{12}$$

It can be moreover noted that, for each of these systems, the equation with $m=0$ is identically satisfied, provided one sets $c_0=1$. These systems look superficially linear; but they are in fact *nonlinear*, due to the presence of the dependent variables $c_1(t)$ and $c_2(t)$ in the equations of motion for the dependent variable $c_m(t)$. The second of these models, (11), is *isochronous*, namely its *generic* solutions are completely periodic with period T [see (3)],

$$c_m(t+T) = c_m(t), \tag{13}$$

provided k is an integer different from -2.

In Sec. VI we discuss the behavior of some of these systems in the neighborhood of their equilibrium configurations, focusing of course on those that do possess such (nontrivial) configurations and which are moreover *isochronous:* then the requirement that these behaviors be consistent with the *isochronous* character of these models entails some amusing *diophantine* relations, for instance determinantal formulas such as

$$\begin{vmatrix} \tilde{\mu}^2+3\tilde{\mu}-4 & 2\tilde{\mu}+8 & 0 & 0 & 0 \\ 40\beta & \tilde{\mu}^2+\tilde{\mu}-6 & 4\tilde{\mu}+6 & 4 & 0 \\ -90\beta & -20\beta & \tilde{\mu}^2-\tilde{\mu}-6 & 6\tilde{\mu} & 10 \\ 78\beta & 30\beta & 0 & \tilde{\mu}^2-3\tilde{\mu}-4 & 8\tilde{\mu}-10 \\ -24\beta & -12\beta & 0 & 0 & \tilde{\mu}^2-5\tilde{\mu} \end{vmatrix} = \prod_{j=-4}^{5} (\tilde{\mu}-j). \tag{14}$$

Here β is an arbitrary number, and there are such formulas for determinants of arbitrary order, see Sec. V (see in particular Theorem 2 and Conjecture 2).

In Sec. VII we tersely outline a generalization of the models treated in the preceding sections, but we also point out that in fact it does not represent a really substantial extension of them.

The paper is completed by two Appendixes that contain some developments, and report some formulas, whose inclusion in the main text of the paper would have disrupted the flow of the presentation.

II. A MATRIX ODE AND ITS SOLUTION

The starting point of our treatment is the following simple system of two coupled *matrix* ODEs:

$$\dot{U}(t) = a[U(t)]^2 + V(t), \quad \dot{V}(t) = b(t)V(t). \tag{15}$$

Notation: the dependent variables $U(t)$ and $V(t)$ are $N\otimes N$ matrices, the independent variable is the scalar t ("time," but occasionally we will replace below t with the *complex* variable τ), superimposed dots indicate time-differentiations, a is an arbitrary *scalar* constant (that could be rescaled away, but we prefer to keep it; note that throughout this paper we assume that a does not vanish, $a\neq 0$, because the results for the $a=0$ case are not new), and $b(t)$ is a *scalar* function of time which we reserve to assign later.

The second of these two matrix ODEs can of course be easily solved,

$$V(t)=\varphi(t)C, \tag{16a}$$

$$\varphi(t)=\exp\left[\int_0^t \mathrm{d}t'\; b(t')\right], \tag{16b}$$

$$C=V(0), \tag{16c}$$

and the system of two matrix ODEs (15) can thereby be rewritten as the single $N\otimes N$ matrix ODE,

$$\dot{U}(t)=a[U(t)]^2+\varphi(t)C. \tag{17}$$

The reason for writing the system first in the form (15) will become clear later. Note that for $b(t)=0$, $\varphi(\tau)=1$, this matrix evolution equation, (17), reduces to the matrix evolution equation that provided the starting point for the treatment given in Ref. 10.

To solve the matrix ODE (17) we set

$$U(t)=-a^{-1}\dot{W}(t)[W(t)]^{-1}, \tag{18}$$

and we thereby obtain for the $N\otimes N$ matrix $W(t)$ the following *linear* second-order ODE:

$$\ddot{W}(t)+a\varphi(t)CW(t)=0. \tag{19}$$

We now introduce the *scalar* second-order ODE,

$$\ddot{w}(\alpha;t)+\alpha\varphi(t)w(\alpha;t)=0, \tag{20}$$

where α is a *scalar* constant, and we denote with $w_{\pm}(\alpha;t)$ the two independent solutions of this ODE characterized by the initial conditions

$$w_+(\alpha;0)=1,\quad \dot{w}_+(\alpha;0)=0, \tag{21a}$$

$$w_-(\alpha;0)=0,\quad \dot{w}_-(\alpha;0)=1. \tag{21b}$$

Let us note for future reference that as a consequence of (20) and (21) there holds the Wronskian relation

$$w_+(\alpha;t)\dot{w}_-(\alpha;t)-\dot{w}_+(\alpha;t)w_-(\alpha;t)=1. \tag{22}$$

It is now clear that the solution of the initial-value problem for the *matrix* ODE (19) is provided by the formula

$$W(t)=w_+(aC;t)W(0)+w_-(aC;t)\dot{W}(0). \tag{23}$$

Note that there is no ordering ambiguity in the definition of the two $N\otimes N$ matrices $w_{\pm}(aC;t)$, since each of them only depends on the single matrix C, that of course commutes with itself [while it need not commute with $W(0)$ or $\dot{W}(0)$].

The insertion of this expression of the $N\otimes N$ matrix $W(t)$ in (18) yields, after a bit of elementary matrix algebra, the following solution of the original ODE (15):

$$U(t) = [\dot{w}_-(aC;t)U(0) - a^{-1}\dot{w}_+(aC;t)][w_+(aC;t) - aw_-(aC;t)U(0)]^{-1}, \tag{24a}$$

with the constant matrix C defined as follows [see (15) and (16c)]:

$$C = \dot{U}(0) - a[U(0)]^2. \tag{24b}$$

The matrix system (15) is considered *solvable* inasmuch as the explicit solution of the initial-value problem for it is given by these formulas, (24), that require of course knowledge of the two *scalar* solutions $w_\pm(\alpha;t)$ of the *scalar* second-order ODE (20). In the following we will consider specific cases in which this *scalar* ODE (20) can be explicitly solved in terms of standard special functions (such as, say, Bessel functions, see below).

But before ending this section let us also report the more explicit form that the solution (24) takes in the special case (that will be of interest to us, see below) in which the $N \otimes N$ matrix C is *dyadic* indeed proportional to an $N \otimes N$ projection matrix P,

$$C = cP, \quad P_{nm} = p_n p_m, \quad \sum_{n=1}^{N} p_n^2 = 1, \quad P^2 = P. \tag{25}$$

Then, after a considerable amount of tedious if trivial algebra, the solution formula (24a) with (25) can be rewritten as follows:

$$\begin{aligned} U(t) = \{U(0) + [v(t)]^{-1}\{f(t)P + g(t)PU(0) + U(0)[1 - atU(0)]^{-1}P[1 - w_+(ac;t) \\ + a[w_-(ac;t) - t]U(0)]\}\}[1 - atU(0)]^{-1}, \end{aligned} \tag{26a}$$

$$f(t) = -a^{-1}\dot{w}_+(ac;t)v(t) + [w_+(ac;t) - 1]u(t), \tag{26b}$$

$$g(t) = [\dot{w}_-(ac;t) - 1]v(t) - a[w_-(ac;t) - t]u(t), \tag{26c}$$

$$v(t) = \sum_{n,m=1}^{N} p_n\{[w_+(ac;t) - aw_-(ac;t)U(0)][1 - atU(0)]^{-1}\}_{nm}p_m, \tag{26d}$$

$$u(t) = \sum_{n,m=1}^{N} p_n\{[a^{-1}\dot{w}_+(ac;t) + [1 - \dot{w}_-(ac;t)]U(0)][1 - atU(0)]^{-1}\}_{nm}p_m. \tag{26e}$$

Note that the only matrices appearing on the right-hand sides of these formulas, (26), are $U(0)$ and P: the functions $w_\pm(ac;t)$ are now *scalars*, in contrast to the $N \otimes N$ *matrices* $w_\pm(aC;t)$ appearing on the right-hand side of (24a). Moreover, an additional simplification will be entailed below by the fact that, in the cases of interest to us, the matrix $U(0)$ will be *diagonal*, entailing that the matrix inversions involving only this matrix can be performed trivially [in contrast to what is the case for the matrix inversion on the right-hand side of (24a)]. To obtain this simplified version of the solution we took advantage of the following standard identity valid for any projection matrix P, see (25):

$$h(XPY) = h(0) + \frac{h(z) - h(0)}{z}XPY, \tag{27a}$$

with

$$PYXP = zP, \quad z = \sum_{n,m,\ell=1}^{N} p_n Y_{nm} X_{m\ell} p_\ell. \tag{27b}$$

This identity holds for any two matrices X and Y and for any *scalar* function $h(z)$ for which these formulas make good sense.

Remark: The expression (26) of the solution of the matrix evolution equation (17) is valid provided the formulas (25) hold with a finite (nonvanishing) value of the constant c. This is not the case if the $N\otimes N$ matrix C is *nilpotent*, $C^p=0$ for some positive integer value of p. The treatment of this special case is left as an instructive exercise for the diligent reader.

■

III. A NEW GOLDFISH MANY-BODY PROBLEM

To derive new solvable many-body problems of goldfish type from the solvable system of two $N\otimes N$ matrix ODEs (15) we use a (minor modification of a) by now standard technique.[5–8,10] Hence we set

$$U(t) = R(t)Z(t)[R(t)]^{-1}, \quad Z(t) = \mathrm{diag}[z_n(t)], \tag{28a}$$

$$V(t) = R(t)G(t)[R(t)]^{-1}, \quad [G(t)]_{nm} = \delta_{nm}g_n(t) + (1-\delta_{nm})g_{nm}(t), \tag{28b}$$

so that

$$\dot{U}(t) = R(t)\{\dot{Z}(t) + [M(t),Z(t)]\}[R(t)]^{-1}, \tag{29a}$$

$$\dot{V}(t) = R(t)\{\dot{G}(t) + [M(t),G(t)]\}[R(t)]^{-1}, \tag{29b}$$

where

$$M(t) = [R(t)]^{-1}\dot{R}(t), \tag{29c}$$

$$[M(t)]_{nm} = (1-\delta_{nm})\mu_{nm}(t). \tag{29d}$$

Note that the formulas (28a) imply that the N (generally *complex*) numbers $z_n(t)$ are the N eigenvalues of the $N\otimes N$ matrix $U(t)$, and that the $N\otimes N$ matrix $R(t)$ is the matrix that diagonalizes the $N\otimes N$ matrix $U(t)$. Moreover, for simplicity, we are assuming here [see (29d)] that the diagonal elements of the $N\otimes N$ matrix $M(t)$, defined in terms of $R(t)$ by (29c), *all* vanish: the legitimacy of such a choice is a well-known fact.[5–8,10]

Insertion of these formulas in (15) yields the following two $N\otimes N$ matrix ODEs:

$$\dot{Z}(t) + [M(t),Z(t)] = a[Z(t)]^2 + G(t), \tag{30a}$$

$$\dot{G}(t) + [M(t),G(t)] = b(t)G(t). \tag{30b}$$

By writing out separately the *diagonal* and *off-diagonal* parts of these matrix equations we get the following equations:

$$\dot{z}_n(t) = az_n^2(t) + g_n(t), \tag{31a}$$

$$\dot{g}_n(t) + \sum_{m=1,m\neq n}^{N} [\mu_{nm}(t)g_{mn}(t) - g_{nm}(t)\mu_{mn}(t)] = b(t)g_n(t), \tag{31b}$$

$$\mu_{nm}(t)[z_n(t) - z_m(t)] = -g_{nm}(t), \quad n \neq m, \tag{31c}$$

$$\dot{g}_{nm}(t) = \mu_{nm}(t)[g_n(t) - g_m(t)] + b(t)g_{nm}(t) - \sum_{\ell=1;\ell\neq n,m}^{N} [\mu_{n\ell}(t)g_{\ell m}(t) - g_{n\ell}(t)\mu_{\ell m}(t)], \quad n \neq m. \tag{31d}$$

By solving the first of these equations for $g_n(t)$ and the third for $\mu_{nm}(t)$ and by then inserting the results in the second and the fourth we get

$$\ddot{z}_n(t) = 2a\dot{z}_n(t)z_n(t) + b(t)[\dot{z}_n(t) - az_n^2(t)] + 2\sum_{m=1,m\neq n}^{N} \frac{g_{nm}(t)g_{mn}(t)}{z_n(t) - z_m(t)}, \tag{32a}$$

$$\frac{\dot{g}_{nm}(t)}{g_{nm}(t)} = -\frac{[\dot{z}_n(t) - az_n^2(t)] - [\dot{z}_m(t) - az_m^2(t)]}{z_n(t) - z_m(t)} + b(t) + \sum_{\ell=1;\ell\neq n,m}^{N} \left\{ \frac{g_{n\ell}(t)g_{\ell m}(t)}{g_{nm}(t)} \left[\frac{1}{z_n(t) - z_\ell(t)} + \frac{1}{z_m(t) - z_\ell(t)} \right] \right\}, \quad n \neq m. \tag{32b}$$

We now take advantage of the following *miraculous* fact: as the diligent reader will easily verify,

$$g_{nm}(t) = [\dot{z}_n(t) - az_n^2(t)]^{1/2}[\dot{z}_m(t) - az_m^2(t)]^{1/2} \tag{33}$$

provides a solution to (32b) [which has been written above in a format appropriate to facilitate checking that this is indeed true: differentiate logarithmically this formula, (33) and use (32a)]. Hence the insertion of this expression of $g_{nm}(t)$ in (32a) entails that the N-body problem characterized by the following system of N coupled Newtonian equations of motion:

$$\ddot{z}_n(t) = 2a\dot{z}_n(t)z_n(t) + b(t)[\dot{z}_n(t) - az_n^2(t)] + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{z}_n(t) - az_n^2(t)][\dot{z}_m(t) - az_m^2(t)]}{z_n(t) - z_m(t)}, \tag{34}$$

is *solvable*, to the extent the $N\otimes N$ matrix ODE (15) is itself *solvable* (as discussed in the preceding Sec. II). It is moreover clear that the substantial simplification, see above, associated with the *dyadic* nature of the constant matrix C is applicable in this case, since this $N\otimes N$ matrix is now given by the simple *dyadic* expression

$$C_{nm} = [\dot{z}_n(0) - az_n^2(0)]^{1/2}[\dot{z}_m(0) - az_m^2(0)]^{1/2}. \tag{35}$$

This formula, (35), follows from (16), (33), and (31a) via (28b) with $R(0)=\mathbf{1}$, this last assignment being a permissible one; a different assignment would cause a unitary transformation of the matrices $U(t)$ and $V(t)$, with no effect on the eigenvalues $z_n(t)$ of $U(t)$. Note that this assignment, $R(0)=\mathbf{1}$, also implies via (28a) that the $N\otimes N$ matrix $U(0)$ is *diagonal*,

$$U(0) = \mathrm{diag}[z_n(0)]. \tag{36}$$

The fact that the matrix C is *dyadic*, see (35), entails the validity of (25) with the quantities p_n and c given now in terms of the initial data $z_n(0)$, $\dot{z}_n(0)$ as follows:

$$p_n = \left[\frac{\dot{z}_n(0) - az_n^2(0)}{c} \right]^{1/2}, \quad c = \sum_{n=1}^{N} [\dot{z}_n(0) - az_n^2(0)]; \tag{37}$$

and moreover (36) entails that the scalars $v(t)$ and $u(t)$, see (26d) and (26e), are now given in terms of the initial data as follows:

$$v(t) = \sum_{n=1}^{N} p_n^2 \frac{w_+(ac;t) - a w_-(ac;t) z_n(0)}{1 - a t z_n(0)}, \tag{38a}$$

$$u(t) = \sum_{n=1}^{N} p_n^2 \frac{a^{-1}\dot{w}_+(ac;t) + [1 - \dot{w}_-(ac;t)] z_n(0)}{1 - a t z_n(0)}. \tag{38b}$$

It is also easily seen, using (22), that some additional simplifications occur in the expressions of $f(t)$ and $g(t)$, see (26b) and (26c), that may now be rewritten as follows:

$$f(t) = \sum_{n=1}^{N} p_n^2 \frac{-a^{-1}\dot{w}_+(ac;t) + [w_+(ac;t) + \dot{w}_-(ac;t) - 2] z_n(0)}{1 - a t z_n(0)}, \tag{38c}$$

$$g(t) = \sum_{n=1}^{N} p_n^2 \frac{1 - w_+(ac;t) + t\dot{w}_+(ac;t) + [1 - \dot{w}_-(ac;t)] a t z_n(0)}{1 - a t z_n(0)}. \tag{38d}$$

In conclusion there holds the following

Proposition 1: The solution $z_n(t)$ of the initial-value problem for the system of N ODEs (34) is given by the following prescription:

$$z_n(t) = \text{eigenvalues of } U(t), \tag{39}$$

[see (28a)], where the $N \otimes N$ matrix $U(t)$ is given by the formula (26a) with the constant $N \otimes N$ matrix $U(0)$, the projection matrix $P_{nm} = p_n p_m$, as well as the scalar constant c, respectively, the scalar functions $f(t)$, $g(t)$, and $v(t)$ defined in terms of the initial data by (36) and (37), respectively, (38), and with the *scalar* functions $w_\pm(\alpha;t)$ defined as the solutions characterized by the initial conditions (21) of the second-order ODE (20) with (16b). ■

This proposition demonstrates the *solvability* of the system of N ODEs (34) for the N dependent variables $z_n(t)$ by reducing its initial-value problem to the purely algebraic task of finding the N eigenvalues $z_n(t)$ of an $N \otimes N$ matrix $U(t)$ given in terms of the initial data by a quite explicit formula, see (26) with (38) and (37), the time dependence of which is encoded in the solutions of the *scalar* ODE (20) with (16b). This is a *linear* second-order ODE, generally simple enough to be explicitly solvable in terms of well-known special functions, see below.

The system of N ODEs (34) for the N dependent variables $z_n(t)$ is generally *nonautonomous* due to the explicit time dependence of the function $b(t)$, which we are still free to assign. In the following section we focus on the *autonomous* case that obtains by assuming this function $b(t)$ to be just a constant. In the sequent Sec. IV, by assigning a specific time dependence to the function $b(t)$, we obtain, via an appropriate change of *dependent* and *independent* variables, another *autonomous* version of the goldfish system which, for appropriate values of the arbitrary constants it features, has the property to be *isochronous*.

A. Autonomous case

The many-body model (34) contains the *scalar* function $b(t)$, which we are still free to assign. Of course if one sets $b(t) = 0$ one gets back to the model treated in Ref. 10. In this section we treat the case in which

$$b(t) = b \tag{40}$$

is an *arbitrary* (of course *scalar*) *constant*, entailing that the equations of motion (34) become *autonomous* [see (8)],

$$\ddot{z}_n(t) = 2a\dot{z}_n(t)z_n(t) + b[\dot{z}_n(t) - az_n^2(t)] + 2\sum_{m=1,m\neq n}^{N} \frac{[\dot{z}_n(t) - az_n^2(t)][\dot{z}_m(t) - az_m^2(t)]}{z_n(t) - z_m(t)}. \tag{41}$$

The treatment given above entails that the solution $z_n(t)$ of the initial-value problem for this problem is given by Proposition 1, with the following specific assignment of the two scalar functions $w_\pm(\alpha;t)$:

$$w_+(\alpha;t) = \frac{Y_0'[x(0)]J_0[x(t)] - J_0'[x(0)]Y_0[x(t)]}{Y_0'[x(0)]J_0[x(0)] - J_0'[x(0)]Y_0[x(0)]}, \tag{42a}$$

$$w_-(\alpha;t) = \frac{4\{-Y_0[x(0)]J_0[x(t)] + J_0[x(t)]Y_0[x(t)]\}}{\alpha^{1/2}\{Y_0'[x(0)]J_0[x(0)] - J_0'[x(0)]Y_0[x(0)]\}}, \tag{42b}$$

where

$$x(t) = \frac{\alpha^{1/2}}{2b}\exp\left[\frac{bt}{2}\right] \tag{42c}$$

and $J_0(x)$ and $Y_0(x)$ are the standard Bessel functions of order zero (see for instance Ref. 12). Indeed these two functions, see (42), are the solutions characterized by the initial conditions (21) of the second-order ODE,

$$\ddot{w}(\alpha;t) + \alpha\exp(bt)w(\alpha;t) = 0, \tag{43}$$

that clearly corresponds to (20) with (16b) and (40). An explicit expression of the time dependence of these two functions is provided by the following two formulas:

$$J_0[x(t)] = \sum_{k=0}^{\infty} \frac{1}{(k!)^2}\left[\frac{-\alpha\exp(bt)}{16}\right]^k, \tag{44a}$$

$$Y_0[x(t)] = \left(\frac{2}{\pi}\right)\sum_{k=0}^{\infty} \frac{1}{(k!)^2}\left[\frac{-\alpha\exp(bt)}{16}\right]^k\left[bt + \frac{1}{2}\ln\left(\frac{\alpha}{4b^2}\right) + \gamma_k\right], \tag{44b}$$

$$\gamma_k = -\sum_{\ell=1}^{k}\ln\left(\frac{1+\ell}{\ell}\right) + \sum_{\ell=k+1}^{k}\left[\frac{1}{\ell} - \ln\left(\frac{1+\ell}{\ell}\right)\right]. \tag{44c}$$

These expressions clearly entail that, if $\mathrm{Re}(b) < 0$, in the remote future $(t \to +\infty)$

$$J_0[x(t)] = 1 + O[\exp(bt)], \tag{45a}$$

$$Y_0[x(t)] = \left(\frac{2}{\pi}\right)\left[bt + \frac{1}{2}\ln\left(\frac{\alpha}{4b^2}\right) + \gamma\right] + O[t\exp(bt)], \tag{45b}$$

$$\gamma = \gamma_0 = \sum_{\ell=1}^{\infty}\left[\frac{1}{\ell} - \ln\left(\frac{1+\ell}{\ell}\right)\right]. \tag{45c}$$

Using these formulas it is easily shown that, if $\mathrm{Re}(b) < 0$, in the remote future *all* the particles tend to the origin,

$$z_n(t) \to 0 \quad \text{as } t \to +\infty. \tag{46}$$

This outcome obtains for *generic* initial data: note that the asymptotic configuration with all

particles sitting at the origin is an equilibrium configuration, albeit not a *genuine* one (see below). The exceptional (i.e., *nongeneric*) case is when the particles are in equilibrium, which can only happen for $N=2$ and $N=3$ and entails that the constant c, see (37), vanishes, see the next section.

If $\mathrm{Re}(b)\geqslant 0$ the asymptotic behavior as $t\to\infty$ is somewhat less trivial, and we just mention qualitatively the *generic* outcome here, which obtains because asymptotically the matrix $U(t)$ equals—up to a time-dependent factor—the projection operator P (the diligent reader will verify). Then all particles but one converge to the origin, while if $\mathrm{Re}(b)=0$ that one approaches a limit cycle trajectory which circles around the origin with period $T=4\pi/|b|$ (we are of course assuming $b\neq 0$, the $b=0$ having being treated in Ref. 10), while if $\mathrm{Re}(b)>0$ it spirals exponentially towards infinity.

B. Equilibrium configuration

It is easy to show (see Appendix A) that this N-body problem, (41), has no *genuine* equilibrium configuration for $N>3$ (here and hereafter we denote as *genuine* the equilibrium configurations in which no two particles sit at the same position, namely such that $z_n\neq z_m$ for $n\neq m$). For $N=2$ the equilibrium configuration is unique (up to permutations; this obvious *caveat* applies of course to *all* equilibrium configurations, and will not be repeated below):

$$z_1=-\frac{(1+i)b}{2a},\quad z_2=-\frac{(1-i)b}{2a}. \tag{47}$$

For $N=3$ the configuration, again unique, is the same, see (47), complemented by $z_3=0$.

Note that in both these cases the constant c, see (37), vanishes (see the *Remark* at the end of Sec. II).

IV. NEW ISOCHRONOUS GOLDFISH MODEL

To manufacture another *solvable* and *autonomous* variant of the goldfish many-body problem we take as starting point the model (34) with

$$b(t)=\frac{ik\omega}{1+i\omega t} \tag{48a}$$

entailing [see (28b)]

$$\varphi(t)=(1+i\omega t)^k. \tag{48b}$$

Here and throughout ω is a *positive* constant that sets the time scale via the associated period (3); and k is an *arbitrary* dimensionless constant, but we shall see below that it is convenient, in order to obtain *isochronous* models, to assume that k is an *integer* [but different from -2; and note that, as already mentioned above, for $k=0$, i.e., $b(\tau)=0$, one obtains again the model treated in Ref. 10]. A hint of the reason why such values have a special significance is provided by (20) with (48); but we will return to this question below, so for the moment k can be considered just an arbitrary number.

With this assignment (48) the equations of motion (34) become

$$\zeta_n''(\tau)=2a\zeta_n'(\tau)\zeta_n(\tau)+\frac{ik\omega}{1+i\omega\tau}[\zeta_n'(\tau)-a\zeta_n^2(\tau)]+2\sum_{m=1,m\neq n}^{N}\frac{[\zeta_n'(\tau)-a\zeta_n^2(\tau)][\zeta_m'(\tau)-a\zeta_m^2(\tau)]}{\zeta_n(\tau)-\zeta_m(\tau)}. \tag{49}$$

Note that we made (for reasons that will be immediately clear) a trivial, *merely notational*, change [we wrote the independent variable as τ rather than t, and the dependent variables as $\zeta_n(\tau)$ rather than $z_n(t)$]: accordingly appended primes indicate here differentiations of the dependent variables $\zeta_n(\tau)$ with respect to the independent variable τ.

A. An isochronous model

We now make the following change of *dependent* and *independent* variables:

$$z_n(t) = \exp(i\omega t)\zeta_n(\tau), \tag{50a}$$

$$\tau = \frac{\exp(i\omega t) - 1}{i\omega}, \quad \exp(i\omega t) = 1 + i\omega\tau, \tag{50b}$$

entailing the relation

$$\dot{z}_n(t) - i\omega z_n(t) = \exp(i\omega t)\zeta_n'(\tau), \tag{50c}$$

hence as well

$$\dot{z}_n(0) = -i\omega z_n(0) = \zeta_n'(0). \tag{50d}$$

Note that this coincides with the trick (4), with the specific assignment $\lambda = 1$.

It is thereby easily seen that the (*nonautonomous*) system (49) becomes via (50) the following *autonomous* system, that we hereafter interpret as a many-body problem describing the motion in the *complex* z-plane of the N points $z_n(t)$ evolving as functions of the (*real*) variable t ("time"):

$$\ddot{z}_n(t) - (3+k)i\omega\dot{z}_n(t) - (2+k)\omega^2 z_n(t) = a[2\dot{z}_n(t) - (2+k)i\omega z_n(t)]z_n(t) + 2\sum_{m=1, m\neq n}^{N} \frac{[\dot{z}_n(t) - i\omega z_n(t) - az_n^2(t)][\dot{z}_m(t) - i\omega z_m(t) - az_m^2(t)]}{z_n(t) - z_m(t)}. \tag{51}$$

For $k=0$ this system reduces of course to (7), while for $k \neq 0$ it coincides with (9).

The solution of the initial-value problem for this system is then given, via (50) and (48b), by the following

Proposition 2: The solution $z_n(t)$ of the initial-value problem for this N-body problem, (51), is given by the following prescription:

$$z_n(t) = \text{eigenvalues of } \widetilde{U}(t), \tag{52a}$$

$$\widetilde{U}(t) = \exp(i\omega t)\{\widetilde{U}(0) + [\widetilde{v}(\tau)]^{-1}\{\widetilde{f}(\tau)\widetilde{P} + \widetilde{g}(\tau)\widetilde{P}\widetilde{U}(0) + \widetilde{U}(0)[1 - a\tau\widetilde{U}(0)]^{-1}\widetilde{P}[1 - \widetilde{w}_+(ac;k;\tau) + a[\widetilde{w}_-(ac;k;\tau) - \tau]\widetilde{U}(0)]\}\}[1 - a\tau\widetilde{U}(0)]^{-1}, \tag{52b}$$

$$\widetilde{U}(0) = \text{diag}[z_n(0)]. \tag{52c}$$

$$\widetilde{v}(\tau) = \sum_{n,m=1}^{N} \widetilde{p}_n^2 \frac{\widetilde{w}_+(ac;k;\tau) - a\widetilde{w}_-(ac;k;\tau)z_n(0)}{1 - a\tau z_n(0)}, \tag{52d}$$

$$\widetilde{f}(t) = \sum_{n,m=1}^{N} \widetilde{p}_n^2 \frac{-a^{-1}\widetilde{w}_+'(ac;k;\tau) + [\widetilde{w}_+(ac;k;\tau) + \widetilde{w}_-'(ac;k;\tau) - 2]z_n(0)}{1 - a\tau z_n(0)}, \tag{52e}$$

$$\widetilde{g}(t) = \sum_{n,m=1}^{N} \widetilde{p}_n^2 \frac{1 - \widetilde{w}_+(ac;k;\tau) + \tau\widetilde{w}_+'(ac;k;\tau) + [1 - \widetilde{w}_-'(ac;k;\tau)]a\tau z_n(0)}{1 - a\tau z_n(0)}, \tag{52f}$$

$$\tilde{p}_n = \left[\frac{\dot{z}_n(0) - i\omega z_n(0) - a z_n^2(0)}{\tilde{c}} \right]^{1/2}, \tag{52g}$$

$$\tilde{c} = \sum_{n=1}^{N} [\dot{z}_n(0) - i\omega z_n(0) - a z_n^2(0)]. \tag{52h}$$

The two *scalar* functions $\tilde{w}_{\pm}(\alpha;k;\tau)$ that characterize the time dependence of the $N \otimes N$ matrix $\tilde{U}(t)$ are the two solutions of the second-order ODE,

$$\tilde{w}''(\alpha;k;\tau) + \alpha(1 + i\omega\tau)^k \tilde{w}(\alpha;k;\tau) = 0, \tag{53a}$$

[see (20) with (48b)] characterized by the initial conditions

$$\tilde{w}_+(\alpha;k;0) = 1, \quad \tilde{w}'_+(\alpha;k;0) = 0, \tag{53b}$$

$$\tilde{w}_-(\alpha;k;0) = 0, \quad \tilde{w}'_-(\alpha;k;0) = 1 \tag{53c}$$

[see (21)]; and the variable τ appearing in these equations, see (52) and (53), is related to the independent variable t ("time") by (50b). ■

The *solvability* of this model is underscored by the possibility to write in explicit form the functions $\tilde{w}_{\pm}(\alpha;k;\tau)$,

$$\tilde{w}_+(\alpha;k;\tau) = \left[\frac{\xi(\tau)}{\xi(0)} \right]^{\nu} \frac{I_{1-\nu}[\xi(0)] I_{\nu}[\xi(\tau)] - I_{\nu-1}[\xi(0)] I_{-\nu}[\xi(\tau)]}{I_{1-\nu}[\xi(0)] I_{\nu}[\xi(0)] - I_{\nu-1}[\xi(0)] I_{-\nu}[\xi(0)]}, \tag{54a}$$

$$\tilde{w}_-(\alpha;k;\tau) = (-\alpha)^{-1/2} \left[\frac{\xi(\tau)}{\xi(0)} \right]^{\nu} \frac{-I_{-\nu}[\xi(0)] I_{\nu}[\xi(\tau)] + I_{\nu}[\xi(0)] I_{-\nu}[\xi(\tau)]}{I_{1-\nu}[\xi(0)] I_{\nu}[\xi(0)] - I_{\nu-1}[\xi(0)] I_{-\nu}[\xi(0)]}, \tag{54b}$$

$$\xi(t) = 2\nu \left(\frac{\alpha}{\omega^2} \right)^{1/2} (1 + i\omega\tau)^{1/(2\nu)} = \frac{2\alpha^{1/2}(1 + i\omega\tau)^{1+(k/2)}}{\omega(2+k)}, \tag{54c}$$

$$\nu = \frac{1}{2+k}, \tag{54d}$$

where $I_{\nu}(\xi)$ is the Bessel functions of the second kind (see, for instance, Ref. 12). Note that these formulas, which are valid for any value of the parameter k except $k=-2$, imply

$$\left[\frac{\xi(\tau)}{\xi(0)} \right]^{\nu} = (1 + i\omega\tau)^{1/2}, \tag{55}$$

and, more importantly for the following, that the functions $\tilde{w}_{\pm}(\alpha;k;\tau)$ are *entire* functions of the (*complex*) variable τ if k is an integer larger than -2, and that they are as well singularity free in the entire *complex* τ-plane if k is a negative integer smaller than -2 except for an essential singularity at $\tau = i/\omega$. The more direct way to verify the validity of these assertions is to note that the formulas (54c) with (54d), as well as the definition of the Bessel functions $I_{\pm\nu}(\xi)$,[12] entail

$$[\xi(\tau)]^{\nu} I_{\nu}[\xi(\tau)] = \left[\frac{2\alpha}{(2+k)^2\omega^2} \right]^{\nu} \sum_{j=0}^{\infty} \frac{1 + i\omega\tau}{j!\Gamma(j+1+\nu)} \left[\frac{\alpha(1 + i\omega\tau)^{2+k}}{(2+k)^2\omega^2} \right]^j, \tag{56a}$$

$$[\xi(\tau)]^{\nu} I_{-\nu}[\xi(\tau)] = \left[\frac{\alpha}{2(2+k)^2\omega^2} \right]^{\nu} \sum_{j=0}^{\infty} \frac{1}{j!\Gamma(j+1-\nu)} \left[\frac{\alpha(1 + i\omega\tau)^{2+k}}{(2+k)^2\omega^2} \right]^j. \tag{56b}$$

It is therefore clear that if k is a *arbitrary integer* (different from -2), the $N\otimes N$ matrix $\widetilde{U}(t)$ is *periodic* in t with period T, see (50b) and (3),

$$\widetilde{U}(t+T)=\widetilde{U}(t), \tag{57}$$

and therefore its eigenvalues $z_n(t)$ are as well periodic functions of t with a period which is a finite integer multiple J of T [due to the possibility that the eigenvalues of $\widetilde{U}(t)$ exchange their roles through the motion; but of course J cannot exceed $N!$, indeed it is generally much smaller].[13] The conclusions reported above about the *isochronicity* of the N-body problem (51) are therefore confirmed for *all integer* values of the parameter k, be they *positive* or *negative*, with the single exception of the value $k=-2$.

In the exceptional case $k=-2$ clearly [see (53)]

$$\widetilde{w}_+(\alpha;-2;\tau)=\tfrac{1}{2}(1+i\omega\tau)^{1/2}[(1+i\omega\tau)^{\Delta}+(1+i\omega\tau)^{-\Delta}], \tag{58a}$$

$$\widetilde{w}_-(\alpha;-2;\tau)=\frac{1}{2i\omega\Delta}(1+i\omega\tau)^{1/2}[(1+i\omega\tau)^{\Delta}-(1+i\omega\tau)^{-\Delta}], \tag{58b}$$

$$\Delta=\frac{1}{2}\left(1+\frac{4\alpha}{\omega^2}\right)^{1/2}, \tag{58c}$$

entailing that the functions $\widetilde{w}_{\pm}(\alpha;-2;\tau)$ have a branch point at $\tau=i/\omega$. Hence in this case the *generic* solution of the many-body model (51) is *not* completely periodic: it is *multiply periodic*, its time evolution being a nonlinear superposition of two periodic time evolutions with two periods which are integer multiples, respectively, of $T/2$ and of

$$\widetilde{T}=\frac{T}{\Delta}=2T\left(1+\frac{4a\widetilde{c}}{w^2}\right)^{-1/2}=4\pi(\omega^2+4a\widetilde{c})^{-1/2}. \tag{59}$$

Note that, in contrast to the period T, see (3), this second period $\widetilde{T}$ does depend on the initial data, see (59) with (52h); of course the solution is *completely periodic* whenever $\widetilde{T}$ and T are *congruent*.

The formulas written above remain valid for *arbitrary* (even *complex*) values of the parameter k, but in this paper we do not discuss such cases.

B. Equilibrium configurations

In this section we report tersely some simple results for the equilibrium configurations of the solvable *isochronous* system defined above. An outline of the derivation of these simple findings is provided in Appendix A. More information on the equilibrium configurations (when they exist for the N-body problem with *arbitrary* N) are provided in Sec. VI.

For $N=2$ the only *genuine* equilibrium configuration of the model (51) is $z_1=0$ and $z_2=\omega/ia$; this equilibrium configuration exists for all values of the parameter k. For $N>2$ there exist *genuine* equilibrium configurations in which none of the coordinates z_n takes one of these two values (namely such that $z_n\neq 0$ and $z_n\neq\omega/ia$) only if $k=-(N+1)$ or $k=N-3$. The first case is characterized by the relations

$$\sum_{n=1}^{N} z_n=0, \tag{60a}$$

$$\sum_{n=1}^{N} z_n^2 = 0; \tag{60b}$$

the second is instead characterized by the relations

$$\sum_{n=1}^{N} z_n = \frac{N\omega}{ia}, \quad \sum_{n=1}^{N} z_n^2 = -N\left(\frac{\omega}{a}\right)^2. \tag{61}$$

Moreover there are two corresponding *genuine* equilibrium configurations of the $(N+1)$-body problem with the same values of the N coordinates z_n and with $z_{N+1}=0$ (provided $z_n \neq 0$), respectively, $z_{N+1}=\omega/ia$ (provided $z_n \neq \omega/ia$); and there is a corresponding *genuine* equilibrium configuration of the $(N+2)$-body problem with the same values of the coordinates z_n and with $z_{N+1}=0$, $z_{N+2}=\omega/ia$ (provided $z_n \neq 0$ and $z_n \neq \omega/ia$).

V. ALTERNATIVE FORMULATIONS

Alternative formulations of the *solvable* many-body problems reported above can be obtained by introducing the time-dependent monic polynomial $\psi(z,t)$, of degree N in z, whose N zeros $z_n(t)$ evolve according to the *solvable* models described above,

$$\psi(z,t) = \prod_{n=1}^{N} [z - z_n(t)] = z^N + \sum_{m=1}^{N} c_m(t) z^{N-m} \tag{62a}$$

$$= \sum_{m=0}^{N} c_m(t) z^{N-m}, \quad c_0 = 1, \tag{62b}$$

and by then considering the systems of ODEs characterizing the time evolution of the N coefficients $c_m(t)$ of this polynomial. These systems of N ODEs for the N coefficients $c_m(t)$ constitute then new, and clearly no less *solvable*, dynamical systems. To obtain these results the formulas collected in Appendix B are quite useful, and they allow us to report without further ado the relevant results.

Remark: Clearly whenever the N numbers $z_n(t)$ are identified as the N eigenvalues of an $N \otimes N$ matrix $U(t)$, the polynomial $\psi(z,t)$ is given by the formula

$$\psi(z,t) = \det[z - U(t)]. \tag{63}$$

■

It is now easily seen that, if the N zeros $z_n(t)$ evolve according to the Newtonian equations of motion (8), the polynomial $\psi(z,t)$ satisfies the PDE,

$$\psi_{tt} + 2az^2\psi_{zt} + a^2z^4\psi_{zz} + [2ac_1(t) - b - 2(N-1)az]\psi_t + az^2[2ac_1(t) - b - 2(N-2)az]\psi_z + a\{2ac_2(t) - bc_1(t) + [bN - 2(N-1)ac_1(t)]z + N(N-3)az^2\}\psi = 0, \tag{64}$$

and this clearly entails that the coefficients $c_m(t)$ evolve according to the following system of N ODEs:

$$\ddot{c}_m - 2ma\dot{c}_{m+1} + (2ac_1 - b)\dot{c}_m + (m+2)(m-1)a^2c_{m+2} + [b - m(2ac_1 - b)]ac_{m+1} + [2ac_2 - bc_1]ac_m = 0. \tag{65}$$

The special case of this system with $b=0$ (as well as its *isochronous* version) have been already discussed in Ref. 10.

Likewise, if the N zeros $z_n(t)$ evolve according to the Newtonian equations of motion (9), the polynomial $\psi(z,t)$ satisfies the PDE,

$$\psi_{tt} + 2(i\omega + az)z\psi_{zt} + (i\omega + az)^2 z^2 \psi_{zz} + [2ac_1(t) - (2N + k + 1)i\omega - 2(N-1)az]\psi_t + \{(2N+k)\omega^2 + 2i\omega a c_1(t) + [2a^2 c_1(t) - (4N + k - 4)i\omega a]z - 2(N-2)a^2 z^2\} z\psi_z + \{2a^2 c_2(t) - (2N+k)i\omega a c_1(t) - N(N+k+1)\omega^2[-2(N-1)a^2 c_1(t) + N(2N+k-2)i\omega a]z + N(N-3)a^2 z^2\}\psi = 0, \tag{66}$$

and this clearly entails that the coefficients $c_m(t)$ evolve according to the following system of N ODEs:

$$\ddot{c}_m - 2ma\dot{c}_{m+1} + [2ac_1 - (2m + k + 1)i\omega]\dot{c}_m + (m+2)(m-1)a^2 c_{m+2} + [-2ma^2 c_1 + (m+1)(2m+k)i\omega a]c_{m+1} + [2a^2 c_2 - (2m+k)i\omega a c_1 - m(m+k+1)\omega^2]c_m = 0. \tag{67}$$

Note that, in writing these two systems of ODEs (65) and (67) satisfied by the dependent variables $c_m(t)$, we always assume, consistently with our notational prescriptions, that the index m ranges from 1 to N, with the "boundary conditions"

$$c_{N+1} = c_{N+2} = 0; \tag{68}$$

but in fact in both these two cases the equations of motion are also identically satisfied for $m = 0$ with $c_0 = 1$, consistently with (62b).

Consistently with the rescaled notation of Appendix A we now set

$$c_m(t) = \left(\frac{\omega}{ia}\right)^m \gamma_m(t), \tag{69}$$

and we thereby rewrite the system of ODEs (67) as follows:

$$\ddot{\gamma}_m + 2mi\omega\dot{\gamma}_{m+1} - [2\gamma_1 + 2m + k + 1]i\omega\dot{\gamma}_m - (m+2)(m-1)\omega^2\gamma_{m+2} + [2m\gamma_1 + (m+1)(2m+k)]\omega^2\gamma_{m+1} - [2\gamma_2 + (2m+k)\gamma_1 + m(m+k+1)]\omega^2\gamma_m = 0, \tag{70a}$$

$$\gamma_{N+1} = \gamma_{N+2} = 0. \tag{70b}$$

VI. EQUILIBRIUM CONFIGURATIONS, BEHAVIOR IN THEIR VICINITY, DIOPHANTINE RELATIONS

The results of Appendix A entail that, via the rescaled definition

$$z_n = \frac{\omega u_n}{ia}, \tag{71}$$

the N equilibrium positions of the model characterized by the Newtonian equations of motion (9) (which is *isochronous* for all integer values of k except $k = -2$) are characterized as the solutions of the two sets of N algebraic equations

$$s(N-1) = 2\sum_{m=1, m\neq n}^{N} \frac{u_m^{(s)}(1 - u_m^{(s)})}{u_n^{(s)} - u_m^{(s)}}, \quad s = \pm \tag{72}$$

[see (A7b) and (A10)]. We moreover know that these two sets of equilibrium configurations, corresponding to the two signs of the parameter s, are characterized by the values of the parameters k respectively σ_1 and σ_2 [see (9), respectively, (A8)] related to N by the simple expressions (A10). [Other equilibrium configurations of the N-body problem can be obtained from the solutions of (72) with N replaced by $N-1$ and either $u_N^{(s)} = 0$ or $u_N^{(s)} = 1$, or from (72) with N replaced by $N-2$ and $u_{N-1}^{(s)} = 0$, $u_N^{(s)} = 1$; as explained in Sec. IV C.]

Remark 6.1: The solutions of these two systems of algebraic equations, (72), are clearly related by the simple formula

$$u_n^{(s)} = 1 - u_n^{(-s)}. \tag{73}$$

■

Hence we can hereafter restrict consideration to the simpler case with $s=-1$, setting for notational convenience $u_n^{(-)}=u_n$. This entails $\sigma_1=\sigma_2=0$, see (A8) and (A10), as well as

$$k = -(N+1) \tag{74}$$

and

$$1 - N = 2 \sum_{m=1, m\neq n}^{N} \frac{u_m(1-u_m)}{u_n - u_m}. \tag{75a}$$

■

By replacing the numbers u_m with $(u_m-u_n)+u_n$ in the numerator on the right-hand side of this system we rewrite, after some elementary algebra, this system of N algebraic equations as follows:

$$N - 1 - 2(N-2)u_n = 2 \sum_{m=1, m\neq n}^{N} \frac{u_n(1-u_n)}{u_n - u_m}. \tag{75b}$$

It is now convenient to introduce the polynomial $\varphi(u)$, of degree N in the variable u, that has the N numbers u_n, solutions of this system of N algebraic equations, (75), as its N zeros,

$$\varphi(u) = \prod_{n=1}^{N} (u - u_n) = \sum_{m=0}^{N} \alpha_m u^{N-m}, \quad \alpha_0 = 1. \tag{76}$$

It is then easy, using the formulas of Appendix B [see in particular (B2a), (B2b), (B2f), and (B2h)], to conclude from (75b) that the polynomial $\varphi(u)$ is characterized by the second-order linear differential ODE,

$$u^2\varphi'' - 2(N-2)u\varphi' + N(N-3)\varphi = u\varphi'' - (N-1)\varphi'. \tag{77}$$

Remark 6.2: This ODE coincides with that characterizing the Jacobi polynomial $P_N^{(\alpha,\beta)}(2u-1)$ via the identification $\alpha=-N+2$, $\beta=-N$. But this observation is somewhat misleading because the Jacobi polynomial $P_N^{(\alpha,\beta)}$ (see Ref. 12) is not properly defined when its parameters α and β are *negative integers*, as it is indeed the case here. ■

Remarkably (as the diligent reader will verify), the *general* solution of the ODE (77) is the following polynomial:

$$\varphi(u) = (1-\beta)u^N + \beta\left[(u-1)^N + N(u-1)^{N-1} + \tfrac{1}{2}N(N-1)(u-1)^{N-2}\right], \tag{78}$$

where β is an *arbitrary* constants [and we adjusted the second *arbitrary* constant featured by the *general* solution of the second-order ODE (77) by imposing that the polynomial $\varphi(u)$ be *monic*, see (76)]. Note that, with this choice, the coefficients α_m, see (76), are defined by the following formula:

$$\alpha_0 = 1, \quad \alpha_m = (-)^m \frac{\beta(m-1)(m-2)N!}{2[m!(N-m)!]}, \quad m = 1, \ldots, N. \tag{79}$$

Note that these formulas entail

$$\alpha_1 = \alpha_2 = 0. \tag{80}$$

Correspondingly the numbers u_n are the N zeros of this polynomial (78),

$$\varphi(u_n) = 0, \tag{81}$$

see (76).

A. Behavior near equilibrium

Let us now consider the behavior of the *isochronous* system (51), respectively, (11) in the neighborhood of their equilibrium configurations, see Appendix A, respectively, just above.

We treat first the system (51). Consistently with the notation of Appendix A [see (A6)] we now set

$$z_n(t) = \left(\frac{\omega}{ia}\right) u_n + \varepsilon w_N(t), \tag{82}$$

and by treating ε as a small parameter we obtain for the N-vector $\underline{w} \equiv (w_1, \ldots, w_N)$ the system of N linear ODEs,

$$\ddot{\underline{w}} + i\omega \underline{A}\, \dot{\underline{w}} + \omega^2 \underline{B}\, \underline{w} = 0, \tag{83}$$

with the two $N \otimes N$ matrices $\underline{A}$ and $\underline{B}$ defined as follows:

$$A_{nm} = \delta_{nm}(2u_n - 1) + 2(1 - \delta_{nm}) \frac{u_n(1 - u_n)}{u_n - u_m}, \tag{84a}$$

$$B_{nm} = -2\delta_{nm} \sum_{m=1, m\neq n}^{N} \frac{u_n u_m (1 - u_n)(1 - u_m)}{(u_n - u_m)^2} + 2(1 - \delta_{nm}) \frac{u_n(1 - u_n)(u_m^2 - 2u_n u_m + u_n)}{(u_n - u_m)^2}. \tag{84b}$$

Note that in this section we denote N-vectors, respectively, $N \otimes N$ matrices by underlined lower-case, respectively, upper-case (italic) letters. To obtain these expressions of the matrices $\underline{A}$ and $\underline{B}$ we also used the formula (A7b). Remarkably, the number N does not appear explicitly in the definitions of these two matrices, except to the extent of defining their rank and the upper limit of the sum in (84b); but its value does of course influence the values of the N numbers u_n, see above.

Clearly the *general* solution of the N-vector second-order ODE (83) reads

$$\underline{w}(t) = \sum_{j=1}^{2N} [\, \eta_j \exp(i\mu_j \omega t) \underline{w}^{(j)}], \tag{85a}$$

where the $2N$ constants η_j are *arbitrary*, while the $2N$ numbers μ_j, respectively, the $2N$ (time-independent) N-vectors $\underline{w}^{(j)}$ are the eigenvalues, respectively, the eigenvectors of the (generalized) eigenvalue equation

$$(\mu_j^2 + \mu_j \underline{A} - \underline{B}) \underline{w}^{(j)} = 0, \quad j = 1, 2, \ldots, 2N. \tag{85b}$$

But we know that the system (51) is *isochronous*, namely its *generic* solution is *completely periodic* with period T, see (3). Hence the solution (85) must also possess this property, and this clearly entails the following *diophantine*

Theorem 1: Let the N numbers $u_n \equiv u_n(\beta)$ be the N zeros of the polynomial $\varphi(u)$ [see (78), and note the arbitrariness of the constant β], and let the two $N \otimes N$ matrices $\underline{A}$ and $\underline{B}$ be defined in terms of these N numbers by the formulas (84); then the $2N$ eigenvalues μ_j of the generalized eigenvalue equation (85b) are *all integers*. ■

We have verified this finding by performing some numerical computations, and we are thereby led to proffer the following (more specific) *diophantine*

Conjecture 1: Let the N numbers $u_n \equiv u_n(\beta)$ be the N zeros of the polynomial $\varphi(u)$ [see (78),

and note the arbitrariness of the constant β], and let the two $N\otimes N$ matrices $\underline{A}$ and $\underline{B}$ be defined in terms of these N numbers by the formulas (84); then

$$\det[\mu^2+\mu\underline{A}-\underline{B}]=\prod_{j=1-N}^{N}(\mu-j). \tag{86}$$

■

Let us now proceed and treat analogously the *isochronous* system (11), or rather its rescaled version (70a). Hence we set

$$\gamma_m=\alpha_m+\varepsilon\rho_m(t), \tag{87}$$

where the numbers α_m characterize the equilibrium configuration and we will treat again ε as a small parameter. Clearly the numbers α_m satisfy the linear recursion relations

$$-(m+2)(m-1)\alpha_{m+2}-(m+1)(N+1-2m)\alpha_{m+1}+m(N-m)\alpha_m=0, \tag{88a}$$

with the additional conditions

$$\alpha_{N+1}=\alpha_{N+2}=0, \tag{88b}$$

which obtain, to the lowest order in ε, by inserting (87) in the system of ODEs (70) satisfied by the dependent variables $\gamma_m(t)$. Note that, to simplify these equations, (88a), we also used the fact that α_1 and α_2 vanish, see (80), as well of course as the fact that we are restricting attention to the value $k=-(N+1)$, see (74). As implied by their definition and by the treatment given above these numbers α_m are given by the explicit formulas (79), as the diligent reader will verify

To the next order in ε we get the linearized system of ODEs,

$$\begin{aligned}&\ddot{\rho}_m+2mi\omega\dot{\rho}_{m+1}+(N-2m)i\omega\dot{\rho}_m-(m+2)(m-1)\omega^2\rho_{m+2}-(m+1)(N+1-2m)\omega^2\rho_{m+1}\\&\quad+2m\alpha_{m+1}\omega^2\rho_1+m(N-m)\omega^2\rho_m-2\alpha_m\omega^2\rho_2+(N+1-2m)\alpha_m\omega^2\rho_1=0,\end{aligned} \tag{89a}$$

which has again been simplified by taking advantage of (80) and (74). We now rewrite this system in more compact form as follows:

$$\ddot{\underline{\rho}}+i\omega\underline{\tilde{A}}\dot{\underline{\rho}}-\omega^2\underline{\tilde{B}}\underline{\rho}=0, \tag{89b}$$

where the N-vector $\underline{\rho}\equiv\underline{\rho}(t)$ has of course the components $\rho_m\equiv\rho_m(t)$ and the two $N\otimes N$ matrices $\underline{\tilde{A}}$ and $\underline{\tilde{B}}$ are defined (componentwise) as follows:

$$\tilde{A}_{m,n}=(N-2m)\delta_{m,n}+2m\delta_{m+1,n}, \tag{90}$$

$$\begin{aligned}\tilde{B}_{m,n}&=m(N-m)\delta_{m,n}-(m+1)(N+1-2m)\delta_{m+1,n}-(m+2)(m-1)\delta_{m+2,n}\\&\quad+[2m\alpha_{m+1}+(N+1-2m)\alpha_m]\delta_{1,n}-2\alpha_m\delta_{2,n},\end{aligned} \tag{91a}$$

where the numbers α_m are of course defined by (79) with (88b). Hence, proceeding in close analogy with the treatment given above we arrive at the following findings.

Theorem 2: Let the two $N\otimes N$ matrices $\underline{\tilde{A}}$ and $\underline{\tilde{B}}$ be defined by (90) and (91a) with (79) and (88b). Then the $2N$ eigenvalues $\tilde{\mu}_j$ of the generalized eigenvalue equation

$$(\tilde{\mu}_j^2+\tilde{\mu}_j\underline{A}-\underline{B})\underline{\tilde{w}}^{(j)}=0,\quad j=1,2,\ldots,2N \tag{91b}$$

are all integer numbers. ■

Conjecture 2: Let the two $N\otimes N$ matrices $\underline{\tilde{A}}$ and $\underline{\tilde{B}}$ be defined by (90) and (91a) with (79) and (88b). Then

$$\det[\tilde{\mu}^2 + \tilde{\mu}\underline{\tilde{A}} - \underline{\tilde{B}}] = \prod_{j=1-N}^{N} (\tilde{\mu} - j). \tag{92}$$

■

For small values of N this conjecture can of course be easily verified by explicit computation. For instance for $N=5$ it yields the result (14).

VII. A FURTHER EXTENSION

A further extension of our results obtains if we take as starting point of our treatment, instead of the *solvable* matrix evolution equation (15), the following (more general, but still *solvable*) matrix evolution equation:

$$\dot{U}(t) = a[U(t)]^2 + V(t), \quad \dot{V}(t) = b(t)V(t) + f(t)[V(t)]^2. \tag{93}$$

Here $f(t)$ is an *arbitrary* (*scalar*) function. Of course this equation reduces back to (15) for $f(t) = 0$.

The developments of Secs. II and III can then be repeated and they lead to the following, apparently more general, variant of (34):

$$\begin{aligned}\ddot{z}_n(t) = {} & 2a\dot{z}_n(t)z_n(t) + b(t)[\dot{z}_n(t) - az_n^2(t)] + f(t)[\dot{z}_n(t) - az_n^2(t)]^2 \\ & + \sum_{m=1, m\neq n}^{N} ([\dot{z}_n(t) - az_n^2(t)][\dot{z}_m(t) - az_m^2(t)]\{f(t) + 2[z_n(t) - z_m(t)]^{-1}\}),\end{aligned} \tag{94}$$

which can however clearly be rewritten in the following equivalent form:

$$\ddot{z}_n(t) = 2a\dot{z}_n(t)z_n(t) + \tilde{b}(t)[\dot{z}_n(t) - az_n^2(t)] + 2\sum_{m=1, m\neq n}^{N} \frac{[\dot{z}_n(t) - az_n^2(t)][\dot{z}_m(t) - az_m^2(t)]}{z_n(t) - z_m(t)}, \tag{95a}$$

with

$$\tilde{b}(t) = b(t) + f(t)\sum_{n=1}^{N} [\dot{z}_n(t) - az_n^2(t)]. \tag{95b}$$

It is thereby clear that the system of N Newtonian equations of motion (94) is identical to the system (34), up to the replacement of the *arbitrary* (*scalar*) function $b(t)$ with the function $\tilde{b}(t)$, see (95b). Moreover, by summing (95a) over n from 1 to N one notes that

$$\frac{d}{dt}\sum_{n=1}^{N} [\dot{z}_n(t) - az_n^2(t)] = \tilde{b}(t)\sum_{n=1}^{N} [\dot{z}_n(t) - az_n^2(t)] \tag{96}$$

entailing

$$\sum_{n=1}^{N} [\dot{z}_n(t) - az_n^2(t)] = c\exp\left[\int_0^t dt'\ \tilde{b}(t')\right] \tag{97a}$$

with

$$c = \sum_{n=1}^{N} [\dot{z}_n(0) - az_n^2(0)] \tag{97b}$$

[see, incidentally, (37)], so that the function $\tilde{b}(t)$ turns out, see (95b), to be related to the (*a priori arbitrary*) function $b(t)$ by the formula

$$\tilde{b}(t) = b(t) + cf(t)\exp\left[\int_0^t \mathrm{d}t'\ \tilde{b}(t')\right], \tag{98a}$$

which is easily inverted to read

$$\tilde{b}(t) = b(t) + [\tilde{b}(0) - b(0)]\frac{f(t)}{f(0)}\exp\left[\int_0^t \mathrm{d}t'\ b(t')\right]. \tag{98b}$$

One therefore concludes that, in spite of the additional generality of the matrix evolution equation (93) with respect to the matrix evolution (15), the *solvable* Newtonian system one finally arrives at starting from (93) is not really more general than that, see (34), obtained in Secs. II and III starting from (15). Hence we do not pursue this generalization in this paper.

APPENDIX A: EQUILIBRIUM CONFIGURATIONS

In this appendix we outline the calculations that yield the results about the equilibrium configurations of the many-body problems (41) and (51), as reported above.

To treat the first case, (41), we set, for notational convenience,

$$Z \equiv \sum_{n=1}^{N} z_n, \quad S \equiv \sum_{n=1}^{N} z_n^2. \tag{A1}$$

The equilibrium configuration of this system (41) is clearly characterized by the following set of N algebraic equations:

$$baz_n^2 = 2a^2 \sum_{m=1, m\neq n}^{N} \frac{z_n^2 z_m^2}{z_n - z_m}. \tag{A2a}$$

Here we assume $a \neq 0$, and as well $z_n \neq 0$, hence we replace the above system with the following one:

$$b = 2a \sum_{m=1, m\neq n}^{N} \frac{z_m^2}{z_n - z_m}. \tag{A2b}$$

Note that the structure of the above equations, see (A2), entails that, to every *genuine* equilibrium configuration of N points z_n satisfying (A2b) and such that $z_n \neq 0$, there also corresponds a *genuine* equilibrium configuration of $N+1$ points with the same N values z_n and with $z_{N+1}=0$.

Summing (A2a) over n from 1 to N we clearly get

$$S = 0, \tag{A3}$$

since the sum on the right-hand side vanishes due to the antisymmetry of the summand under the exchange of the two dummy indices n and m. Likewise, summing (A2b) over n from 1 to N and taking advantage of the possibility to exchange in the double sum on the right-hand side the two dummy indices n and m we easily get

$$Z = -\frac{Nb}{2(N-1)a}. \tag{A4}$$

Finally, multiplying (A2b) by z_n and then summing over n from 1 to N, taking again advantage of the possibility to exchange in the double sum on the right-hand side the two dummy indices n and m and using (A3) we easily get

$$bZ = -aZ^2, \tag{A5}$$

and it is then immediately seen, via (A4), that this yield $N=2$ (in addition to the unacceptable result $N=0$).

To analyze the equilibrium configuration of the second system, (51), it is convenient to rescale the dependent variables by setting

$$z_n = \frac{\omega u_n}{ia}, \tag{A6}$$

assuming hereafter that neither one of the two constants a, ω vanish. The equilibrium configuration is then clearly characterized by the following set of N algebraic equations:

$$(2+k)u_n(u_n-1) = -2u_n(u_n-1)\sum_{m=1,m\neq n}^{N}\frac{u_m(u_m-1)}{u_n-u_m}. \tag{A7a}$$

We now restrict consideration to equilibrium configurations of N points z_n such that $u_n \neq 0$ and $u_n \neq 1$: note that the structure of these algebraic equations implies then the possibility to extend our findings for the N-body system (51) to analogous $(N+1)$-body and $(N+2)$-body systems, as reported in Sec. IV C. We therefore rewrite these algebraic equations as follows:

$$2+k = 2\sum_{m=1,m\neq n}^{N}\frac{u_m(1-u_m)}{u_n-u_m}. \tag{A7b}$$

It is now convenient, proceeding in close analogy to what we did just above, to introduce the two quantities

$$\sigma_1 = \sum_{n=1}^{N} u_n, \quad \sigma_2 = \sum_{n=1}^{N} u_n^2, \tag{A8}$$

and to thereby obtain [by summing (A7b) over n from 1 to N after multiplying it, respectively, by $u_n\,(1-u_n)$, by 1, and by u_n] the three relations

$$\sigma_1 = \sigma_2, \tag{A9a}$$

$$2(N-1)\sigma_1 = N(N+k+1), \tag{A9b}$$

$$(2+k)\sigma_1 = \sigma_1^2 - \sigma_2. \tag{A9c}$$

It is then a matter of trivial algebra to obtain the formulas

$$k = s(N-1)-2, \quad \sigma_1 = \sigma_2 = \frac{N(1+s)}{2}, \quad s = \pm 1, \tag{A10}$$

which entail the results reported in Sec. IV C, and are the basis for the further developments reported in Sec. VI.

APPENDIX B: SOME USEFUL POLYNOMIAL IDENTITIES

We report here some useful identities: several of them are copied from Sec. 2.3.2 of Ref. 4, a few are analogous to those explicitly given there (and their proofs are sufficiently standard to be forsaken).

Let $\psi(z,t)$ be a monic polynomial of degree N in z, and let us denote with $c_m(t)$ its N coefficients and with $z_n(t)$ its N zeros,

$$\psi(z,t) = z^N + \sum_{m=1}^{N} c_m(t) z^{N-m} = \prod_{n=1}^{N} [z - z_m(t)], \tag{B1a}$$

so that clearly

$$\sum_{n=1}^{N} z_n(t) = -c_1(t), \quad \sum_{n=1}^{N} [z_n(t)]^2 = [c_1(t)]^2 - 2c_2(t), \tag{B1b}$$

and so on. Then clearly

$$z\psi_z(z,t) = Nz^N + \sum_{m=1}^{N} (N-m) c_m(t) z^{N-m}, \tag{B1c}$$

$$z^2\psi_{zz}(z,t) = N(N-1)z^N + \sum_{m=1}^{N} (N-m)(N-m-1) c_m(t) z^{N-m}, \tag{B1d}$$

and so on;

$$\psi_t(z,t) = \sum_{m=1}^{N} \dot{c}_m(t) z^{N-m}, \tag{B1e}$$

$$\psi_{tt}(z,t) = \sum_{m=1}^{N} \ddot{c}_m(t) z^{N-m}, \tag{B1f}$$

and so on.

Likewise,

(Received 25 October 2005; accepted 21 December 2005;
published online 21 February 2006)

In this paper we provide a complete description of the first integrals of the classical Bianchi IX system that can be described by a general class of formal power series. As a corollary we also obtain a complete description of some of its analytic first integrals in a neighborhood of the origin. In particular, we prove that the system is not completely integrable by analytic first integrals. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2168123]

I. INTRODUCTION TO THE PROBLEM

The Bianchi IX model can be written as the Hamiltonian system (see Ref. 4):

$$\begin{aligned}
\dot{q}_1 &= F_1(q,p) = 12q_1(p_1q_1 - p_2q_2 - p_3q_3),\\
\dot{q}_2 &= F_2(q,p) = 12q_2(-p_1q_1 + p_2q_2 - p_3q_3),\\
\dot{q}_3 &= F_3(q,p) = 12q_3(-p_1q_1 - p_2q_2 + p_3q_3),\\
\dot{p}_1 &= F_4(q,p) = -12p_1(p_1q_1 - p_2q_2 - p_3q_3) - \tfrac{1}{3}(q_1 - q_2 - q_3),\\
\dot{p}_2 &= F_5(q,p) = -12p_2(-p_1q_1 + p_2q_2 - p_3q_3) - \tfrac{1}{3}(-q_1 + q_2 - q_3),\\
\dot{p}_3 &= F_6(q,p) = -12p_3(-p_1q_1 - p_2q_2 + p_3q_3) - \tfrac{1}{3}(-q_1 - q_2 + q_3),
\end{aligned} \tag{1}$$

with the Hamiltonian

$$\begin{aligned}
H = {} & 6(p_1^2q_1^2 + p_2^2q_2^2 + p_3^2q_3^2 - 2p_1q_1p_2q_2 - 2p_1q_1p_3q_3 - 2p_2q_2p_3q_3)\\
& + \tfrac{1}{6}(q_1^2 + q_2^2 + q_3^2 - 2q_1q_2 - 2q_1q_3 - 2q_2q_3).
\end{aligned}$$

Of course, here (q,p) denotes $(q_1,q_2,q_3,p_1,p_2,p_3)$.

The solutions which lie in the zero level set of the Hamiltonian H, provide a model for describing the evolution of the universe, see for instance, Ref. 6. Furthermore, the set defined as

[a)]Electronic mail: jllibre@mat.uab.es
[b)]Electronic mail: cvalls@math.ist.utl.pt

$$C = \{(q,p) \in \mathbb{R}^6 | q_i \geqslant 0, i = 1,2,3,\ q_1 q_2 q_3 = 0\},$$

is the phase space gravitational collapse set. It should noted that since $q_i=0$ are invariant under the flow of (1), the phase space gravitational collapse set C is invariant under the flow given by (1). We note that in our study of the first integrals of system (1), the invariant sets $q_i=0$, will play a main role.

Recently, this system has been intensively investigated from the point of view of integrability by using different methods. One of these methods is the Painlevé test (see, for instance, Refs. 7 and 3) where the authors prove that the solutions of the equation of motion do not have movable critical points and conjecture that system (1) is not integrable. Another method is the numerical computation of the Lyapunov exponents (see Ref. 2), where the authors also conjecture the nonintegrability of system (1). In Ref. 4 the authors, by means of symplectic geometrical techniques, study the local integrability of system (1). In Ref. 11 it is shown that system (1) is not completely integrable in the Birkhoff sense. In Ref. 12 the author proves that the Hamiltonian system (1) is not completely integrable with rational first integrals using techniques from the differential Galois theory. Moreover, in Ref. 10, the authors, applying the Darboux theory of integrability, provide a complete description of the Darboux polynomials, exponential factors, rational first integrals and Darbouxian first integrals for this model.

The aim of this paper is to study the existence of first integrals of system (1) that can be described by formal series. We use these tools for proving similar results to the ones of this paper for the Lorenz system and for the Einstein-Yang-Mills system, see Refs. 8 and 9. But the use of formal series in the study of differential equations and, in particular, in the existence of their first integrals is a classical tool. Indeed, for instance, solutions described by formal series around singularities have been studied by Seidenberg,[15] the existence of first integrals given by formal series have been studied by Nemytskii and Stepanov,[14] Moussu.[13] etc. However, the greatest success in using formal series to study differential equations has been achieved by Écalle[5] who used them to prove the Dulac's conjecture.

In this paper we say that a *formal first integral* $f=f(q,p)$ of system (1) is a formal power series in the variables q and p such that

$$\sum_{k=1}^{3} \left(\frac{\partial f}{\partial q_i} F_i(q,p) + \frac{\partial f}{\partial p_i} F_{i+3}(q,p) \right) = 0,$$

is different from a polynomial. In Ref. 10 the authors have proved that all polynomial first integrals of system (1) are polynomial functions in the variable H. The first main result of this paper is the following.

Theorem 1: *All formal first integrals of the Bianchi IX model* (1) *are formal series in the variable H.*

Here an *analytic first integral* of system (1) is an analytic function in the variables q and p which is constant over the trajectories of system (1) and it is different from a polynomial. The second main result of this paper is the following.

Theorem 2: *All analytic first integrals of the Bianchi IX model* (1) *in a neighborhood of the origin are analytic functions in the variable H.*

Theorems 1 and 2 are an immediate consequence of Theorems 3 and 4 stated below. We first observe that since $\dot{H}=0$, we can rewrite system (1) as the following system in the seven variables $(q_1,q_2,q_3,p_1,p_2,p_3,H)$:

$$\dot{q}_1 = F_1(q,p) = 12q_1(p_1q_1 - p_2q_2 - p_3q_3),$$

$$\dot{q}_2 = F_2(q,p) = 12q_2(-p_1q_1 + p_2q_2 - p_3q_3),$$

$$\dot{q}_3 = F_3(q,p) = 12q_3(-p_1q_1 - p_2q_2 + p_3q_3),$$

$$\dot{p}_1 = F_4(q,p) = -12p_1(p_1q_1 - p_2q_2 - p_3q_3) - \tfrac{1}{3}(q_1 - q_2 - q_3),$$

$$\dot{p}_2 = F_5(q,p) = -12p_2(-p_1q_1 + p_2q_2 - p_3q_3) - \tfrac{1}{3}(-q_1 + q_2 - q_3),$$

$$\dot{p}_3 = F_6(q,p) = -12p_3(-p_1q_1 - p_2q_2 + p_3q_3) - \tfrac{1}{3}(-q_1 - q_2 + q_3),$$

$$\dot{H} = F_7(q,p) = 0. \tag{2}$$

We say that a formal first integral $f=f(q_1,q_2,q_3,p_1,p_2,p_3,H)$ of system (2) is a formal power series in the variables q, p, and H such that

$$\sum_{k=1}^{3}\left(\frac{\partial f}{\partial q_i}F_i(q,p) + \frac{\partial f}{\partial p_i}F_{i+3}(q,p)\right) + \frac{\partial f}{\partial H}F_7(q,p) = 0.$$

Theorem 3: *All formal first integrals of system* (2) *are formal series in the variable H.*

Here an *analytic first integral* of system (2) is an analytic function in the variables q, p, and H which is constant over the trajectories of system (2).

Theorem 4: *All analytic first integrals of system* (2) *in a neighborhood of the origin are analytic functions in the variable H.*

The proofs of Theorems 3 and 4 are given in Sec. III.

We say that the functions $F_1,\ldots,F_n$ are in *involution* if $\{F_i,F_j\}=0$ for all $i\neq j$, where $\{\cdot,\cdot\}$ denotes the Poisson bracket. Moreover, they are *independent* if the one-forms $dF_1,\ldots,dF_n$ are linearly independent over a full Lebesgue measure subset of the common definition domain of F_j for $j=1,\ldots,n$. By definition, a Hamiltonian system with n degrees of freedom having n independent first integrals in involution is *completely integrable*, see for more details Ref. 1.

As a direct consequence of Theorem 2, we have the next result.

Corollary 5: The Bianchi IX model (1) *is not completely integrable by analytic first integrals.*

The paper is organized as follows. In Sec. II we provide some auxiliary results that will be used all through the paper and will be crucial to prove Theorem 3. Finally, in Sec. III we provide the proofs of Theorems 3 and 4.

II. AUXILIARY RESULTS

In this section we provide some auxiliary results that will be used along the paper.

Lemma 6: Let x and y be one-dimensional variables. Given a formal power series $f(x)$, there exists a formal power series $g(x,y)$ such that

$$f(x) + f(y) = f(x+y) + f(0) - xyg(x,y).$$

Proof: We write $f(z)=f(0)+\Sigma_{j=1}^{\infty}f_jz^j$. Then, using Newton's binomial formula,

$$f(x+y) + f(0) = 2f(0) + \sum_{j=1}^{\infty} f_j(x+y)^j = 2f(0) + \sum_{j=1}^{\infty} f_j \sum_{k=0}^{j}\binom{j}{k}x^k y^{j-k} = f(x) + f(y)$$

$$+ xy\sum_{j=2}^{\infty} f_j \sum_{k=0}^{j-2}\binom{j}{k+1}x^k y^{j-2-k} = f(x) + f(y) + xyg(x,y).$$

■

Lemma 7: Let x_k be one-dimensional variables for $k=1,\ldots,n$ with $n>1$. Let $f=f(x_1,\ldots,x_n)$ be a formal power series such that in $x_l=c_0$, $f(x_1,\ldots,x_n)|_{x_l=c_0}=\bar{f}$, where c_0 is a constant, f is a formal power series in the variables $x_1,\ldots,x_{l-1}$, $x_{l+1},\ldots,x_n$ and $l\in\{1,\ldots,n\}$. Then, there exists a formal series $g=g(x_1,\ldots,x_n)$ such that $f=\bar{f}+(x_l-c_0)g$.

Proof: We denote by $\mathbb{Z}^+$ the set of all non-negative integers. We write

$$f=\sum_{(k_1,\ldots,k_n)\in(\mathbb{Z}^+)^n} f_{k_1,\ldots,k_n}x_1^{k_1}\cdots x_n^{k_n}.$$

Without loss of generality we can assume $l=1$. Then, writing $x_1=c_0+(x_1-c_0)$, we have

$$f=\sum_{(k_1,\ldots,k_n)\in(\mathbb{Z}^+)^n} f_{k_1,\ldots,k_n}(c_0+(x_1-c_0))^{k_1}x_2^{k_2}\cdots x_n^{k_n}.$$

Now, by the Newton's binomial formula we have

$$\begin{aligned}f&=\sum_{(k_1,\ldots,k_n)\in(\mathbb{Z}^+)^n} f_{k_1,\ldots,k_n}\sum_{j=0}^{k_1}\binom{k_1}{j}c_0^j(x_1-c_0)^{k_1-j}x_2^{k_2}\cdots x_n^{k_n}\\&=\sum_{(k_1,\ldots,k_n)\in(\mathbb{Z}^+)^n} f_{k_1,\ldots,k_n}c_0^{k_1}x_2^{k_2}\ldots x_n^{k_n}\\&\quad+(x_1-c_0)\sum_{(k_1,\ldots,k_n)\in(\mathbb{Z}^+)^n} f_{k_1,\ldots,k_n}\sum_{j=0}^{k_1-1}\binom{k_1}{j}c_0^j(x_1-c_0)^{k_1-j-1}x_2^{k_2}\cdots x_n^{k_n}\\&=f(c_0,x_2,\ldots,x_n)+(x_1-c_0)g(x_1,\ldots x_n)=\bar{f}+(x_1-c_0)g,\end{aligned}$$

which finishes the proof of the lemma. ■

The following lemmas are auxiliary results, that will be used in the proof of Proposition 13, Proposition 15, and Theorem 1.

Proposition 8: Any analytic first integral f of the differential system

$$\dot{x}=12xu,\quad \dot{y}=12yu+\tfrac{1}{3},\quad \dot{z}=12zu+\tfrac{1}{3},\quad \dot{u}=-12u^2-\tfrac{1}{3},\tag{3}$$

in $\mathbb{R}^4$ *is an analytic function* $f=f(F_1(x,u),F_2(y,u),F_3(z,u))$ *in the variables* $(F_1(x,u),F_2(u,y),F_3(u,z))$, *where*

$$F_1(x,u)=x^2(1+36u^2),\quad F_2(y,u)=6\sqrt{1+36u^2}y+\arcsin(6u)\tag{4}$$

and

$$F_3(z,u)=6\sqrt{1+36u^2}z+\operatorname{arcsinh}(6u).\tag{5}$$

Proof: Since $F_1(x,u)$, $F_2(y,u)$, and $F_3(z,u)$ are three functionally independent analytical first integrals of the four-dimensional system (3), any other analytical first integral must be an analytic function of them. ■

From Proposition 8 it follows the next result.

Corollary 9: Any formal first integral f of system (3) *is a formal power series in the variables* $F_1(x,u)$, $f_2(y,u)$, *and* $f_3(u,z)$, *where* $f_2(y,u)$ *and* $f_3(u,z)$ *are, respectively, the power series of* $F_2(y,u)$ *and* $F_3(u,z)$ *in a neighborhood of the origin.*

We observe that since

$$\sqrt{1+36u^2}=1+18u^2+O(u^4),\quad \operatorname{arcsinh}(u)=u\left[1-\frac{u^2}{6}+O(u^4)\right]$$

we get

$$\begin{aligned}f_2(y,u)&=6y(1+18u^2+O(u^4))+6u(1-6u^2+O(u^4)),\\f_3(z,u)&=6z(1+18u^2+O(u^4))+6u(1-6u^2+O(u^4)).\end{aligned}\tag{6}$$

Proposition 10: Any analytic first integral f of the differential system

$$\dot{x} = 12xu, \quad \dot{y} = 12yu, \quad \dot{z} = 12zu + \tfrac{1}{3}, \quad \dot{u} = -12u^2 - \tfrac{1}{3}, \tag{7}$$

in $\mathbb{R}^4$ *is an analytic function* $f=f(F_1(x,u),F_3(y,u),F_4(z,u))$ *in the variables* $(F_1(x,u),F_3(y,u),F_4(z,u))$, *where* $F_1(x,u)$ *was introduced in* (4), $F_3(z,u)$ *was introduced in* (5) *and* $F_4(y,u)=y^2(1+36u^2)$.

Proof: Since $F_1(x,u)$, $F_3(y,u)$, and $F_4(z,u)$ are three functionally independent analytical first integrals of the four-dimensional system (7), any other analytical first integral must be an analytic function of them. ■

From Proposition 10 it follows the next result.

Lemma 11: Any analytic first integral f *of system* (7) *in* $x\neq 0$ *of the form* $f=g/x^{2m}$, *where* m *is a positive integer and* g *is a formal power series, can be written in the form*

$$f = \frac{y^{2m}}{x^{2m}} \sum_{k,l,n\geqslant 0} f_{k,m+l,n} F_1(x,u)^k F_4(y,u)^l f_3(z,u)^n.$$

Proof: Since f is an analytic first integral of system (7) in $x\neq 0$, we have from Proposition 10 that in $x\neq 0$, $f=f(F_1(x,u),F_3(z,u),F_4(y,u))$. Since f is of the form $f=g/x^{2m}$ with g being a formal series, and only $F_1(x,u)$ depends on x (in the form x^2), we obtain

$$f = \frac{1}{F_1(x,u)^m} \sum_{k,l,n\geqslant 0} f_{k,l,n} F_1(x,u)^k F_4(y,u)^l f_3(z,u)^n.$$

Using that $F_1=x^2F_4/y^2$ we get

$$f = \frac{y^{2m}}{x^{2m}F_4(y,u)^m} \sum_{k,l,n\geqslant 0} f_{k,l,n} F_1(x,u)^k F_4(y,u)^l f_3(z,u)^n, \tag{8}$$

and since f must be analytic in $x\neq 0$, we have that the sum in (8) with $l=0,1,\ldots,m-1$ must be zero, i.e.,

$$\sum_{k,n\geqslant 0} \sum_{l=0}^{m-1} f_{k,l,n} F_1(x,u)^k F_4(y,u)^l f_3(z,u)^n = 0,$$

and thus, (8) becomes

$$f = \frac{y^{2m}}{x^{2m}} \sum_{k,l,n\geqslant 0} f_{k,m+l,n} F_1(x,u)^k F_4(y,u)^l f_3(z,u)^n,$$

which finishes the proof of the lemma. ■

Let $\tau,\sigma:\mathbb{C}[q_1,q_2,q_3,p_1,p_2,p_3,H]\to\mathbb{C}[q_1,q_2,q_3,p_1,p_2,p_3,H]$ be the automorphism

$$\tau(q_i) = -q_i, \quad \tau(p_i) = -p_i, \quad i=1,2,3, \quad \tau(H) = H;$$

$$\sigma(q_1) = q_2, \sigma(q_2) = q_3, \sigma(\sigma_3) = q_1, \sigma(p_1) = p_2, \sigma(p_2) = p_3, \sigma(p_3) = p_1, \sigma(H) = H.$$

Then, the following proposition holds.

Proposition 12: Let g *be a formal first integral of system* (2).

(a) *Then* $f=(g\cdot\sigma g\cdot\sigma^2 g)\cdot\tau(g\cdot\sigma g\cdot\sigma^2 g)$ *is another formal first integral of system* (2) *invariant by* τ *and* σ. *Here* $\cdot$ *denotes multiplication*.

(b) *Moreover, the monomials of* f *are of the form* $q_1^{j_1}q_2^{j_2}q_3^{j_3}p_1^{l_1}p_2^{l_2}p_3^{l_3}H^m$ *with* $j_1+j_2+j_3+l_1+l_2+l_3$ *even*.

Proof: Statement (a) of the proposition follows taking into account that system (2) is invariant under τ, σ, and σ^2. To prove statement (b) we write f in formal power series of its variables as

$$f=\sum_{(j_1,j_2,j_3,l_1,l_2,l_3,m)\in(\mathbb{Z}^+)^7} f_{j_1,j_2,j_3,l_1,l_2,l_3,m}q_1^{j_1}q_2^{j_2}q_3^{j_3}p_1^{l_1}p_2^{l_2}p_3^{l_3}H^m.$$

Then, since f is invariant by τ, it must hold that $f-\tau(f)=0$. That is, the formal power series

$$\sum_{(j_1,j_2,j_3,l_1,l_2,l_3,m)\in(\mathbb{Z}^+)^7}(1-(-1)^{j_1+j_2+j_3+l_1+l_2+l_3})f_{j_1,j_2,j_3,l_1,l_2,l_3,m}q_1^{j_1}q_2^{j_2}q_3^{j_3}p_1^{l_1}p_2^{l_2}p_3^{l_3}H^m$$

must be zero. This implies that $j_1+j_2+j_3+l_1+l_2+l_3$ must be even. ■

Proposition 13: Let $n\in\{1,2,3\}$. System (2) *restricted to $q_n=0$ has the two first integrals*

$$H_{2n-1}=6(p_mq_m-p_rq_r)^2+\tfrac{1}{6}(q_m-q_r)^2,\quad H_{2n}=q_mq_r,$$

where $\{m,n,r\}=\{1,2,3\}$. If g is a formal first integral of system (2) *invariant by τ and σ, then $f=g_{|q_n=0}$ is a formal power series in the variables H_{2n-1} and H_{2n}.*

Proof: We shall prove only the case $n=1$ since the other two cases can be proved in the same way. In this case, we can consider $m=2$ and $r=3$. It is easy to check that H_1 and H_2 are first integrals of system (2) restricted to $q_1=0$.

Let $f=f(q_2,q_3,p_1,p_2,p_3,H_1)$ be the restriction of g to $q_1=0$. Then, f is a formal first integral of system (2) restricted to $q_1=0$. We write f as

$$f=\sum_{k\geqslant 0}f_kH_1^k,\quad f_k=f_k(q_2,q_3,p_1,p_2,p_3),\tag{9}$$

where f_k are formal series in their variables. From the fact that f is a formal first integral of system (2) restricted to $q_1=0$, it satisfies

$$12q_2(p_2q_2-p_3q_3)\frac{\partial f}{\partial q_2}-12q_3(p_2q_2-p_3q_3)\frac{\partial f}{\partial q_3}+\left(12p_1(p_2q_2+p_3q_3)+\frac{1}{3}(q_2+q_3)\right)\frac{\partial f}{\partial p_1}$$
$$-\left(12p_2(p_2q_2-p_3q_3)+\frac{1}{3}(q_2-q_3)\right)\frac{\partial f}{\partial p_2}+\left(12p_3(p_2q_2-p_3q_3)+\frac{1}{3}(q_2-q_3)\right)\frac{\partial f}{\partial p_3}=0.$$

We denote by $\bar{f}$ the restriction of f to the set

$$F=\{q_2=0,\ H_1=0\}=\{q_2=0,q_3^2(p_3^2+1/36)=0\}.$$

We note that on $q_2=q_3=0$ all the points $(0,0,p_1,p_2,p_3)$ are singular points of system (2) restricted to $q_1=0$, and thus we do not obtain any information on $\bar{f}$ by restricting f to the subset $q_2=q_3=0$ of F. We shall compute the restriction $\hat{f}$ of f to $q_2=0$ $q_3\neq 0$. In this case, $\hat{f}$ is a formal power series that satisfy, after dividing by q_3,

$$12q_3p_3\frac{\partial\hat{f}}{\partial q_3}+\left(12p_1p_3+\frac{1}{3}\right)\frac{\partial\hat{f}}{\partial p_1}+\left(12p_2p_3+\frac{1}{3}\right)\frac{\partial\hat{f}}{\partial p_2}-\left(12p_3^2+\frac{1}{3}\right)\frac{\partial\hat{f}}{\partial p_3}=0.$$

Then, $\hat{f}$ is a formal first integral of system (3) (setting $x=q_3$, $u=p_3$, $y=p_1$ and $z=p_2$) and from Corollary 9 we get

$$\hat{f}=\sum_{k,l,n\leqslant 0}\hat{f}_{k,l,n}F_1(q_3,p_3)^kf_2(p_1,p_3)^lf_3(p_2,p_3)^n\tag{10}$$

with $F_1(q_3,p_3)$ introduced in (4) and $f_2(p_1,p_3)$, $f_3(p_2,p_3)$ were introduced in Corollary 9. Now, by definition $\bar{f}$ is the restriction of $\hat{f}$ to $F_1(q_3,p_3)=0$. Thus, from (10), we have

$$\bar{f} = \sum_{l,n\geqslant 0} \hat{f}_{0,l,n} f_2(p_1,p_3)^l f_3(p_2,p_3)^n = \sum_{l,n\geqslant 0} \bar{f}_{l,n} f_2(p_1,p_3)^l f_3(p_2,p_3)^n.$$

Now, let f^* be the restriction of g to $H=0$. Then, f^* is a formal power series and since g and H are invariant by σ, $\sigma(f^*)=f^*$. Furthermore, if we denote by f_1^* the restriction of f^* to $q_1=q_2=q_3=0$, we have that f_1^* is equal to the restriction of $\bar{f}$ to $q_3=0$, and since $\bar{f}$ does not depend on q_3, $\bar{f}$ is invariant by σ. So, $\sigma(\bar{f})=\bar{f}$ and $\sigma^2(\bar{f})=\bar{f}$. This implies that

$$\bar{f} = \sum_{l,n\geqslant 0} \bar{f}_{l,n} f_2(p_1,p_3)^l f_3(p_2,p_3)^n = \sum_{l,n\geqslant 0} \bar{f}_{l,n} f_2(p_2,p_1)^l f_3(p_3,p_1)^n = \sum_{l,n\geqslant 0} \bar{f}_{l,n} f_2(p_3,p_2)^l f_3(p_1,p_2)^n. \tag{11}$$

Now, we will prove by induction that

$$\bar{f}_{l,n} = 0 \quad \text{for } l,n \geqslant 0, \quad (l,n) \neq (0,0). \tag{12}$$

Setting $p_3=0$ in the three equalities of (11) and using the form of f_2 and f_3 in (6) we get

$$\begin{aligned} \sum_{l,n\geqslant 0} \bar{f}_{l,n}(6p_1)^l(6p_2)^n &= \sum_{l,n\geqslant 0} \bar{f}_{l,n}(6p_1 + 6p_2 + O(p_2p_1^2) + O(p_1^3))^l(6p_1 + O(p_1^3))^n \\ &= \sum_{l,n\geqslant 0} \bar{f}_{l,n}(6p_2 + O(p_2^3))^l(6p_1 + 6p_2 + O(p_1p_2^2) + O(p_2^3))^n. \end{aligned} \tag{13}$$

We first compute in (13) the terms of degree 1 and we get, after dividing by 6,

$$\bar{f}_{1,0}p_1 + \bar{f}_{0,1}p_2 = \bar{f}_{1,0}(p_1+p_2) + \bar{f}_{0,1}p_1 = \bar{f}_{1,0}p_2 + \bar{f}_{0,1}(p_1+p_2),$$

which clearly implies $\bar{f}_{1,0}=\bar{f}_{0,1}=0$. This proves (12) for $l,n\geqslant 0$ with $l+n=1$.

Now we proceed by induction over the degree $l+n=k$. We assume (12) is true for $k=1,\ldots,N-1$ and we will prove it for $k=N$. By induction hypothesis, the terms of degree N in (13) are, after dividing by 6^N,

$$\sum_{l=0}^{N} \bar{f}_{l,N-l} p_1^l p_2^{N-l} = \sum_{l=0}^{N} \bar{f}_{l,N-l}(p_1+p_2)^l p_1^{N-l} = \sum_{l=0}^{N} \bar{f}_{l,N-l} p_2^l (p_1+p_2)^{N-l}. \tag{14}$$

Using the Newton's Binomial formula we can rewrite (14) as

$$\sum_{l=0}^{N} \bar{f}_{l,N-l} p_1^l p_2^{N-l} = \sum_{l=0}^{N} \bar{f}_{l,N-l} \sum_{j=0}^{l} \binom{l}{j} p_2^j p_1^{N-j} = \sum_{l=0}^{N} \bar{f}_{l,N-l} \sum_{j=0}^{N-l} \binom{N-l}{j} p_1^j p_2^{N-j}. \tag{15}$$

We will prove by induction that

$$\begin{aligned} \bar{f}_{l,N-1} = f_{N-l,l} = 0 \quad &\text{for } l = 0,\ldots,[N/2], \\ \bar{f}_{l+1,N-1} = f_{N-l-1,l+1} \quad &\text{for } l = 0,\ldots,[(N-2)/2], \end{aligned} \tag{16}$$

where $[\cdot]$ denotes the integer part function. To prove (16) for $l=0$ we first observe that if we set $p_1=0$ in the first equality of (15) we obtain $\bar{f}_{0,N}p_2^N=\bar{f}_{N,0}p_2^N$, i.e., $\bar{f}_{0,N}=\bar{f}_{N,0}$. Furthermore, if we compute in the first equality of (15) the coefficient of $p_1p_2^{N-1}$ we get

$$\bar{f}_{1,N-1} = \bar{f}_{N-1,1} + N\bar{f}_{N,0}, \tag{17}$$

and if we compute in the first and third terms of identity (15) the coefficient of $p_1^{N-1}p_2$ we get

$$\bar{f}_{N-1,1} = \bar{f}_{1,N-1} + N\bar{f}_{0,N}. \tag{18}$$

Equations (17) and (18) together with the fact that $\bar{f}_{0,N}=\bar{f}_{N,0}$ imply that $\bar{f}_{0,N}=\bar{f}_{N,0}=0$ and $\bar{f}_{1,N-1}=\bar{f}_{N-1,1}$. This finishes the proof of (16) for $l=0$.

Now, we assume that (16) is true for $l=0,\ldots,m-1$ ($m<[(N-2)/2]$) and we will prove it for $l=m$. By induction hypothesis we can write (15) as

$$\sum_{l=m}^{N} \bar{f}_{l,N-l} p_1^l p_2^{N-l} = \sum_{l=m}^{N} \bar{f}_{l,N-l} \sum_{j=0}^{l} \binom{l}{j} p_2^j p_1^{N-j} = \sum_{l=m}^{N} \bar{f}_{l,N-l} \sum_{j=0}^{N-l} \binom{N-l}{j} p_1^j p_2^{N-j}, \tag{19}$$

and we also have that $\bar{f}_{m,N-m}=\bar{f}_{N-m,m}$. Now, computing in the first equality of (19) the coefficients of $p_1^{m+1}p_2^{N-m-1}$ we get

$$\bar{f}_{m+1,N-m-1} = \bar{f}_{N-m,m+1} + (N-m)\bar{f}_{N-m,m},$$

and computing in the first and third terms of equality (19) the coefficients of $p_1^{N-m-1}p_2^{m+1}$ we get

$$\bar{f}_{N-m-1,m+1} = \bar{f}_{m+1,N-m-1} + (N-m)\bar{f}_{m,N-m}.$$

These two equalities imply, taking into account that $\bar{f}_{m,N-m}=\bar{f}_{N-m,m}$, that $\bar{f}_{N-m,m}=f_{m,N-m}=0$ and $\bar{f}_{m+1,N-m-1}=\bar{f}_{N-m-1,m+1}$. Thus, (16) is proved for $l=0,\ldots,[(N-2)/2]$.

Now, by induction hypothesis, for $l=[N/2]$ we have the following.

Case 1: if N is even then, from (14) we get

$$\bar{f}_{N/2,N/2} p_1^{N/2} p_2^{N/2} = \bar{f}_{N/2,N/2}(p_1+p_2)^{N/2} p_1^{N/2} = \bar{f}_{N/2,N/2} p_2^{N/2}(p_1+p_2)^{N/2},$$

which clearly implies $\bar{f}_{N/2,N/2}=0$. Thus, (16) is true in this case.

Case 2: if N is odd then, again from (14) we obtain

$$\begin{aligned}
&\bar{f}_{(N-1)/2,(N+1)/2}[p_1^{(N-1)/2}p_2^{(N+1)/2} + p_1^{(N+1)/2}p_2^{(N-1)/2}] \\
&\quad = \bar{f}_{(N-1)/2,(N+1)/2}[(p_1+p_2)^{(N-1)/2}p_1^{(N+1)/2} + (p_1+p_2)^{(N+1)/2}p_1^{(N-1)/2}] \\
&\quad = \bar{f}_{(N-1)/2,(N+1)/2}[p_2^{(N+1)/2}(p_1+p_2)^{(N-1)/2} + p_2^{(N-1)/2}(p_1+p_2)^{(N+1)/2}],
\end{aligned}$$

which clearly implies $\bar{f}_{(N-1)/2,(N+1)/2}=0$. Thus, (16) is true. Consequently, (12) holds. Therefore, from (11) we get that $\bar{f}=\bar{f}_{0,0}:=d_0$, being d_0 is a constant.

Therefore, if we denote by g_1 the restriction of f to $H_1=0$, then g_1 is a formal power series and since $\bar{f}$ is the restriction of g_1 to $q_2=0$, from Lemma 7, we get that $g_1=d_0+q_2h_3$ where $h_3=h_3(q_2,q_3,p_1,p_2,p_3)$ is a formal power series in its variables.

Now, making the restriction of f to $H_1=0$, $q_3=0$, and proceeding as for the restriction of f to $H_1=0$, $q_2=0$, we get that g_1 can also be written as $g_1=c_0+q_3h_4$, where c_0 is a constant and $h_4=h_4(q_2,q_3,p_1,p_2,p_3)$ is a formal power series in its variables.

Equating the two expressions for g_1, we get that $d_0=c_0$ and there exists a formal power series h_5 such that $h_3=q_3h_5$ and $h_4=q_2h_5$. Thus, g_1 can be written as $g_1=c_0+q_2q_3h_5$. Since g_1 and q_2q_3 are formal first integrals of system (2) restricted to $q_1=0$ and $H_1=0$, we get that h_5 is also a formal first integral of system (2) restricted to $q_1=0$ and $H_1=0$. Then, proceeding as we did for g_1 we get that $h_5=c_1+q_2q_3h_6$, for some formal power series h_6. Since this argument can be repeated infinitely many times, we get that g_1 is a formal power series in $H_2=q_2q_3$ and thus $g_1=g_1(H_2)$. Then, from (9) we have that $f_0=g_1(H_2)$ and thus, $f=g_1(H_2)+H_1g_2$, with $g_2=\Sigma_{k\geqslant 1}f_kH_1^{k-1}$. Thus, since f, H_2, and H_1 are formal first integrals of system (2) restricted to $q_1=0$, g_2 is also a formal first integral of system (2) restricted to $q_1=0$. Repeating the argument that we did for f_0 infinitely many times, the proposition follows. ■

Proposition 14: Any formal first integral $f=f(q_1,q_2,q_3,p_1,p_2,p_3)$ of system (2) *invariant by τ and σ can be written as*

$$f = f^1(H) + H_2 f^2(H,H_2) + H_4 f^2(H,H_4) + H_6 f^2(H,H_6) + q_1 q_2 q_3 f^3(q_1,q_2,q_3,p_1,p_2,p_3), \quad (20)$$

where f^1, f^2, and f^3 are formal power series in their variables, $H_2=q_2q_3$, $H_4=q_1q_3$, and $H_6=q_1q_2$. Furthermore, $f^3=\sigma(f^3)$ and $f^3=-\tau(f^3)$.

Proof: From Proposition 13 and Lemma 7, there exists nine formal power series $g_1,\ldots,g_9$ such that f can be written in the following three forms:

$$f = g_1(H_1) + H_2 g_2(H_1,H_2) + q_1 q_3,$$

$$f = g_4(H_3) + H_4 g_5(H_3,H_4) + q_2 g_6,$$

$$f = g_7(H_5) + H_6 g_8(H_5,H_6) + q_3 g_9.$$

Since

$$H = H_1 + 6(p_1^2 q_1^2 - 2p_1q_1p_2q_2 - 2p_1q_1p_3q_3) + \tfrac{1}{6}(q_1^2 - 2q_1q_2 - 2q_1q_3) = H_1 + q_1 h_1,$$

by Lemma 6, there exist formal power series T, T_0, and T_1 such that

$$g_1(H_1) = g_1(H) - g_1(q_1h_1) + g_1(0) - H_1q_1h_1T(H_1,q_1h_1) = g_1(H) + q_1h_1T_0(H_1,q_1,h_1) = g_1(H) + q_1T_1.$$

Using the same arguments for $g_4(H_3)$ and $g_7(H_5)$, we get that f can be written as

$$f = g_1(H) + H_2 g_2(H_1,H_2) + q_1\bar{T}_1,$$

$$f = g_4(H) + H_4 g_5(H_3,H_4) + q_2\bar{T}_2, \quad (21)$$

$$f = g_7(H) + H_6 g_8(H_5,H_6) + q_3\bar{T}_3.$$

The three equations of (21) must be equal. Thus, restricting the first and second equations of (21) to $q_1=q_2=0$ and equating them, we have that $g_1(\hat{H})=g_4(\hat{H})$, where $\hat{H}$ is the restriction of H to $q_1=q_2=0$. Thus, $g_4=g_1$. In the same way, restricting the first and third equations of (21) to $q_1=q_3=0$, we obtain that $g_7=g_1$. Since f is invariant by σ, $f=\sigma(f)$, and then the first expression of f in (21) can be written as

$$f = g_1(H) + H_4 g_2(H_3,H_4) + q_2\sigma(T_1).$$

This relation for f must coincide with the second expression of f in (21) and thus,

$$0 = H_4(g_2(H_3,H_4) - g_5(H_3,H_4)) + q_2(\sigma(\bar{T}_1) - \bar{T}_2).$$

Taking $q_2=0$ in the above equation we obtain that $g_5=g_2$. In a similar way, since $f=\sigma^2(f)$, proceeding as above for σ, we get that $g_8=g_2$.

Restricting the first and second equations of (21) to $q_2=0$, and decomposing $\bar{T}_1$ as $\bar{T}_1=T_{1,0}+q_2T_{1,1}$, with $T_{1,0}$, $T_{1,1}$ formal power series and $T_{1,0}$ not depending on q_2 (see Lemma 7), we get that $q_1T_{1,0}=H_4g_2(H_3,H_4)$ and thus, the first relation of (21) can be written as

$$f = g_1(H) + H_2 g_2(H_1,H_2) + H_4 g_2(H_3,H_4) + q_1q_2T_{1,1}. \quad (22)$$

Now, writing $T_{1,1}=T_{1,1,0}+q_3T_{1,1,1}$ with $T_{1,1,0}$, $T_{1,1,1}$ formal series and $T_{1,1,0}$ not depending on q_3, we get that restricting the third relation of (21) to $q_3=0$ and restricting (22) to $q_3=0$, we obtain that $q_1q_2T_{1,1,0}=H_6g_2(H_5,H_6)$. Thus, f can be written as

$$f = g_1(H) + H_2 g_2(H_1,H_2) + H_4 g_2(H_3,H_4) + H_6 g_2(H_5,H_6) + q_1 q_2 q_3 T_{1,1,1}. \tag{23}$$

Now, using Lemma 7, we decompose $g_2 = g_2(H_1,H_2)$ as

$$g_2(H_1,H_2) = \sum_{k\geqslant 0} c_k(H_1) H_2^k, \tag{24}$$

where c_k are formal power series in the variable H_1. Then, since $H_1 = H - q_1 h_1$, from (24) and Lemma 6, we have

$$\begin{aligned} g_2(H_1,H_2) &= \sum_{k\geqslant 0} c_k(H - q_1 h_1) H_2^k = \sum_{k\geqslant 0} c_k(H) H_2^k + q_1 \sum_{k\geqslant 0} \tilde{c}_k(q_1,q_2,q_3,p_1,p_2,p_3) H_2^k \\ &= g_2(H,H_2) + q_1 \tilde{g}_2(q_1,q_2,q_3,p_1,p_2,p_3), \end{aligned}$$

where $\tilde{g}_2$ is a formal power series in its variables. Doing the same with $g_2(H_3,H_4)$ and $g_2(H_5,H_6)$, we get that

$$g_2(H_3,H_4) = g_2(H,H_4) + q_2 \tilde{g}_5(q_1,q_2,q_3,p_1,p_2,p_3),$$

$$g_2(H_5,H_6) = g_2(H,H_6) + q_3 \tilde{g}_8(q_1,q_2,q_3,p_1,p_2,p_3),$$

being $\tilde{g}_5$ and $\tilde{g}_8$ formal series in their variables. Therefore, those relations together with (23) imply that f can be written as in (20) if one takes $f^1 = g_1$, $f^2 = g_2$, and $f^3 = T_{1,1,1} + \tilde{g}_2 + \tilde{g}_5 + \tilde{g}_8$.

From (20) and using that f is invariant by σ, we get that

$$\sigma(f) = f^1(H) + H_2 f^2(H,H_2) + H_4 f^2(H,H_4) + H_6 f^2(H,H_6) + q_1 q_2 q_3 \sigma(f^3).$$

Since this equation must coincide with (20) we get that $f^3 = \sigma(f^3)$. Furthermore, using that f is invariant by τ, we get that

$$\tau(f) = f^1(H) + H_2 f^2(H,H_2) + H_4 f^2(H,H_4) + H_6 f^2(H,H_6) - q_1 q_2 q_3 \tau(f^3).$$

Since this equation must coincide with (20) we get that $f^3 = -\tau(f^3)$. ■

Proposition 15: Let f be a formal power series restricted to $H=0$ satisfying $f=\sigma(f)$, $f=(-1)^m \tau(f)$ for a positive integer m such that

$$\frac{\mathrm{d}f}{\mathrm{d}t} = 12m(p_1 q_1 + p_2 q_2 + p_3 q_3) f, \tag{25}$$

where the derivatives are evaluated along a solution of system (2) *restricted to $H=0$. Then, $f = q_1 q_2 q_3 f_1$, for some formal power series f_1 restricted to $H=0$.*

Proof: Note that from hypothesis, f only contains monomials $q_1^{j_1} q_2^{j_2} q_3^{j_3} p_1^{l_1} p_2^{l_2} p_3^{l_3}$ such that the parity of $l_1+l_2+l_3+j_1+j_2+j_3$ is equal to the parity of m. Note that since $f=\sigma(f)$, if q_1 divides f, then, q_2 and q_3 must divide f and thus, it is enough to prove that the restriction of f to $q_1=0$ is equal to zero. We will prove it by contradiction. We denote by g_1 the restriction of f to $q_1=0$. Then, g_1 is a formal power series satisfying

$$\frac{\mathrm{d}g_1}{\mathrm{d}t} = 12m(p_2 q_2 + p_3 q_3) g_1, \tag{26}$$

where the derivatives are evaluated along a solution of system (2) restricted to $q_1 = H_1 = 0$. We assume that $g_1 \neq 0$ and we consider two different cases.

Case 1: g_1 is not divisible by $q_2 q_3$. We introduce the formal power series $g_2 = g_1 q_2^m$. Then, g_2 is a formal power series satisfying

$$\frac{dg_2}{dt} = 24mp_2q_2g_2, \tag{27}$$

where the derivatives are evaluated along a solution of system (2) restricted to $q_1=H=0$.

Now, we restrict (27) to $q_3=0$ and denote by g_2^* the restriction of g_2 to $q_3=0$. We consider $g_2^*\neq 0$ and we will reach a contradiction. If $g_2^*\neq 0$, then g_2^* satisfies (27) restricted to $q_3=0$ and since for system (2) restricted to $q_1=q_3=H=0$ and $q_2\neq 0$ we have $12p_2q_2=(dq_2/dt)/q_2$, then, on $q_2\neq 0$, we have that (27) restricted to $q_3=0$ is equivalent to $dg_2^*/g_2^*=2m\,dq_2/q_2$. That is, $g_2^*=q_2^{2m}g_3^*$ where g_3^* is a first integral of system (2) restricted to $q_1=q_3=H=0$, $q_2\neq 0$, i.e., of system

$$\dot{q}_2 = 12p_2q_2, \quad \dot{p}_1 = 12p_1p_2 + \tfrac{1}{3}, \quad \dot{p}_2 = -12p_2^2 - \tfrac{1}{3}, \quad \dot{p}_3 = 12p_3p_2 + \tfrac{1}{3},$$

after dividing by q_2. Furthermore, $g_3^*=g_2^*/q_2^{2m}$ where g_2^* is a formal power series. Introducing the change of variables

$$x = q_2, \quad y = p_1 - p_3, \quad z = p_3, \quad u = p_2, \tag{28}$$

we have that $g_3^*(q_2,p_1,p_2,p_3)=h(x,y,z,u)$, where h is a first integral of system (7). Furthermore with this change of variables $g_2^*(q_2,p_1,p_2,p_3)=h^*(x,y,z,u)$. Then, $h^*(x,y,z,u)$ is a formal power series and $h=h^*/x^{2m}$. Therefore, h satisfies the hypothesis of Lemma 11 and thus, from Lemma 11 and the change of variables (28) we have

$$g_3^* = \frac{(p_1-p_3)^{2m}}{q_2^{2m}} \sum_{k,l,n\geq 0} g^*_{3,k,m+l,n}(q_2^2(36p_2^2+1))^k((p_1-p_3)^2(36p_2^2+1))^l f_3(p_3,p_2)^n$$

which yields

$$g_2^* = (p_1-p_3)^{2m} \sum_{k,l,n\geq 0} g^*_{3,k,m+l,n}(q_2^2(36p_2^2+1)^k((p_1-p_3)^2(36p_2^2+1))^l f_3(p_3,p_2)^n \ . \tag{29}$$

However, we already know that g_2^* is also restricted to $q_2^2(36p_2^2+1)=0$ and then, from (29) we get

$$\begin{aligned} g_2^* &= (p_1-p_3)^{2m} \sum_{l,n\geq 0} g^*_{3,0,m+l,n}((p_1-p_3)^2(36p_2^2+1))^l f_3(p_3,p_2)^n \\ &= (p_1-p_3)^{2m} \sum_{l,n\geq 0} g^*_{2,l,n}((p_1-p_3)^2(36p_2^2+1))^l f_3(p_3,p_2)^n, \end{aligned} \tag{30}$$

which clearly is a formal power series.

By (30) we have that the restriction of g_2^* to $q_2=0$ is equal to g_2^*. Furthermore, the restriction of g_2^* to $q_2=0$ is also equal to the restriction of g_2 to $q_3=q_2=0$ and by definition it is equal to zero. Using (30) this implies that $g^*_{2,l,n}=0$ for $l,n\geq 0$ and thus $g_2^*=0$, a contradiction.

Then, $g_2^*=0$ and since g_2^* is the restriction of g_2 to $q_3=0$, by Lemma 7, we get that $g_2=q_3h_2$ for some formal power series $h_2=h_2(q_2,q_3,p_1,p_2,p_3)$. Furthermore, since g_2 has q_2^m as a factor, it holds that $h_2=q_2^mh_3$ for some formal power series $h_3=h_3(q_2,q_3,p_1,p_2,p_3)$. Then, using that $g_1=g_2/q_2^m$, we obtain

$$g_1 = q_3h_3. \tag{31}$$

Now, if we introduce the formal power series $g_3=g_1q_3^m$, we get that g_3 satisfies

$$\frac{dg_3}{dt} = 24mp_3q_3g_3,$$

where the derivative is evaluated along a solution of system (2) restricted to $q_1=H=0$. Then, repeating the same arguments for g_3 as we did for g_2, we obtain that g_1 can be written as

$$g_1 = q_2 h_4, \tag{32}$$

for some formal power series $h_4 = h_4(q_2, q_3, p_1, p_2, p_3)$.

Finally, equating the expressions (31) and (32) for g_1 we obtain that there exists a formal power series $h_5 = h_5(q_2, q_3, p_1, p_2, p_3)$ such that $h_3 = q_2 h_5$ and $h_4 = q_3 h_5$. Then, g_1 can be written as $g_1 = q_2 q_3 h_5$, a contradiction with the fact that g_1 was not divisible by $q_2 q_3$.

Case 2: g_1 is divisible by $q_2 q_3$. In this case, we write $g_1 = (q_2 q_3)^j h_1$, where $j \geqslant 1$ and h_1 is a formal power series which is not divisible by $q_2 q_3$. Furthermore, since $q_2 q_3$ is a first integral of system (2) restricted to $q_1 = 0$, we get that h_1 also satisfies (26). Then, the same arguments used in Case 1 for g_1 can be applied to h_1 and we shall obtain a contradiction. Hence, the proposition is proved. ■

III. PROOF OF THE THEOREMS

Now we prove Theorems 3 and 4.

Proof of Theorem 3: Let g be a formal first integral of system (2). If g is a formal first integral in the variable H the theorem is proved. So, we can assume that g is not a formal power series in the variable H. Moreover, without loss of generality the formal power series g has no independent term. We also can assume that g is not divisible by any formal power series $T(H)$ depending on H; otherwise if $T(H)$ divides g, then we can take $g/T(H)$ instead of g as a new formal first integral. By Proposition 12, we have that

$$f = (g \cdot \sigma g \cdot \sigma^2 g) \cdot \tau(g \cdot \sigma g \cdot \sigma^2 g) \tag{33}$$

is invariant by τ and σ and thus, f has all its monomials $q_1^{j_1} q_2^{j_2} q_3^{j_3} p_1^{l_1} p_2^{l_2} p_3^{l_3} H^m$ satisfying that $j_1 + j_2 + j_3 + l_1 + l_2 + l_3$ is even. Moreover, from Proposition 14, we have that f can be written as in (20). We write

$$\begin{aligned} f &= \sum_{l \geqslant 0} f_l(q_1, q_2, q_3, p_1, p_2, p_3) H^l, \\ f^1(H) &= \sum_{l \geqslant 0} f_l^1 H^l, \\ f^2(H, H_j) &= \sum_{k,l \geqslant 0} f_{k,l}^2 H_j^k H^l, \quad j = 2,4,6, \\ f^3 &= \sum_{l \geqslant 0} g_l(q_1, q_2, q_3, p_1, p_2, p_3) H^l, \end{aligned} \tag{34}$$

where f_l and g_l are formal power series in their variables not divisible by H, for $l \geqslant 0$, $k \geqslant 0$, f_l^1, $f_{k,l}^2$ are constants. Then, from (20), we have

$$f_0 = f_{|H=0} = f_0^1 + \sum_{k \geqslant 0} f_{k,0}^2 (H_2^{k+1} + H_4^{k+1} + H_6^{k+1}) + q_1 q_2 q_3 g_0. \tag{35}$$

Note that since f^3 satisfies $f^3 = \sigma(f^3)$ and we get that g_0 satisfies $g_0 = \sigma(g_0)$. Furthermore, $f^3 = -\tau(f^3)$ and thus $g_0 = -\tau(g_0)$.

Taking into account that the derivatives of H_2, H_4, and H_6 evaluated along a solution of system (2) satisfy

$$\frac{dH_2}{dt} = -24 p_1 q_1 H_2, \quad \frac{dH_4}{dt} = -24 p_2 q_2 H_4, \quad \frac{dH_6}{dt} = -24 p_3 q_3 H_6,$$

then, after dividing by $q_1 q_2 q_3$, the derivative of f_0 along a solution of system (2) is given by

$$24\sum_{k\geqslant 0}(1+k)f_{k,0}^2(p_1H_2^k+p_2H_4^k+p_3H_6^k)+12(p_1q_1+p_2q_2+p_3q_3)g_0=\frac{\mathrm{d}g_0}{\mathrm{d}t}, \tag{36}$$

where the derivatives are taken along a solution of system (2) and relation (36) is taken restricted to $H=0$.

Now, restricting (36) to $q_1=q_2=q_3=0$ (note that then $H=0$), and taking into account that this is a singular point of system (2), we obtain that $f_{0,0}^2(p_1+p_2+p_3)=0$ and thus, $f_{0,0}^2=0$. Then, (36) can be written as

$$24\sum_{k\geqslant 1}(1+k)f_{k,0}^2(p_1H_2^k+p_2H_4^k+p_3H_6^k)+12(p_1q_1+p_2q_2+p_3q_3)g_0=\frac{\mathrm{d}g_0}{\mathrm{d}t}, \tag{37}$$

where the derivatives are evaluated along a solution of system (2) and this relation is restricted to $H=0$.

Now, we denote by $\bar{g}_1$ the restriction of g_0 to $q_1=0$. Then, $\bar{g}_1$ satisfies

$$24p_1\sum_{k\geqslant 1}(1+k)f_{k,0}^2H_2^k+12(p_2q_2+p_3q_3)\bar{g}_1=\frac{\mathrm{d}\bar{g}_1}{\mathrm{d}t}, \tag{38}$$

where the derivatives are evaluated along a solution of system (2) and this relation is restricted to $q_1=H=0$.

Now, taking into account that on $q_1=q_2=0$ or $q_1=q_3=0$ we have $H_2=0$, we can proceed exactly in the same way as in the proof of Case 1 in Proposition 15 and we get that $\bar{g}_1$ must be divisible by q_2q_3, i.e., $\bar{g}_1=q_2q_3h$ for some formal series h. Furthermore, from (38) and since $H_2=q_2q_3$ is a first integral of system (2) restricted to $q_1=0$ and $H=0$, we get that, after dividing by q_2q_3, h satisfies

$$24p_1\sum_{k\geqslant 1}(1+k)f_{k,0}^2H_2^{k-1}+12(p_2q_2+p_3q_3)h=\frac{\mathrm{d}h}{\mathrm{d}t}, \tag{39}$$

with this equation restricted to $H=0$. Evaluating (39) on $q_2=q_3=0$, taking into account that those are singular points of the system (2) restricted to $q_1=0$, we obtain that $-48p_1f_{1,0}^2=0$, which clearly implies $f_{1,0}^2=0$. Hence, (39) becomes

$$24p_1H_2\sum_{k\geqslant 2}(1+k)f_{k,0}^2H_2^{k-2}+12(p_2q_2+p_3q_3)h=\frac{\mathrm{d}h}{\mathrm{d}t}$$

which is of the same kind as (38). Now, repeating the reasoning we did for $\bar{g}_1$ infinitely many times, we have that $f_{k,0}^2=0$ for all $k\geqslant 0$. Therefore, (37) becomes

$$\frac{\mathrm{d}g_0}{\mathrm{d}t}=12(p_1q_1+p_2q_2+p_3q_3)g_0,$$

where the derivative is evaluated along a solution of system (2) restricted to $H=0$. We want to prove that $g_0=0$. We will proceed by contradiction. We assume $g_0\neq 0$ and consider two different cases.

Case 1: g_0 is not divisible by $q_1q_2q_3$. It is clear that g_0 satisfies $g_0=\sigma(g_0)=\sigma^2(g_0)$ and $\tau(g_0)=-g_0$, then from Proposition 15 with $m=1$, we get that $g_0=q_1q_2q_3h_5$ for some formal series h_5, a contradiction with the fact that g_0 was not divisible by $q_1q_2q_3$.

Case 2: g_0 is divisible by $q_1q_2q_3$. In this case we write $g_0=(q_1q_2q_3)^jh_j$ with $j\geqslant 1$, $h_j\neq 0$ is not divisible by $q_1q_2q_3$. Furthermore, h_j satisfies

$$\frac{dh_j}{dt} = 12(j+1)(p_1q_1 + p_2q_2 + p_3q_3)h_j,$$

where the derivative is evaluated along a solution of system (2) restricted to $H=0$. Furthermore, $h_j=\sigma(h_j)$ and since $\tau(g_0)=-g_0$ we get that $\tau(h_j)=(-1)^{j+1}h_j$. Then, applying Proposition 15 with $m=j+1$, we get that $h_j=q_1q_2q_3h_{j+1}$ with h_{j+1} a formal series, a contradiction with the fact that h_j is not divisible by $q_1q_2q_3$.

Hence, $g_0=0$ and from (35), we have obtained that $f_0=f_0^1$, a constant and thus, from the first relation in (34) we have that

$$f = f_0^1 + H\sum_{l\geqslant 1} f_l(q_1,q_2,q_3,p_1,p_2,p_3)H^{l-1}.$$

Since H is a first integral of system (2), we get that $\Sigma_{l\geqslant 1}f_l(q_1,q_2,q_3,p_1,p_2,p_3)H^{l-1}$ is also a first integral of system (2). Then, the same arguments used for f_0 imply that $f_1=f_1^1$, a constant since this argument can be repeated infinitely many times, we get that for all $k\geqslant 0$, $f_k=f_k^1$, constants, and thus, the first equation in (34) implies that $f=f(H)=\Sigma_{l\geqslant 0}f_l^1H^l=f(H)$.

Hence, from (33) we get that f must be reducible, that is, there exist formal series $T=T(H)$ and $T_1=T_1(H)$ such that $f=T(H)T_1(H)$. Furthermore, we can assume that T is irreducible. Then, from (33) we get that $T(H)$ divides $g\cdot\sigma g\cdot\sigma^2 g$ or $\tau(g\cdot\sigma g\cdot\sigma^2 g)$. In the first case, we also can assume that divides σg or $\sigma^2 g$; otherwise we reach a contradiction with the assumptions on g. Thus, if $T(H)$ divides σg then $\sigma g=T(H)T_2$ for some formal series $T_2=T_2(q_1,q_2,q_3,p_1,p_2,p_3)$ and thus

$$g = \sigma^3 g = \sigma^2 T(H)\cdot\sigma^2 T_2$$

a contradiction with the assumptions on g. Now, we can assume that $T(H)$ divides $\sigma^2 g$. With similar arguments to those used for the case in which $T(H)$ divides σg we reach a contradiction with the assumptions on g.

Now, we assume that $T(H)$ divides $\tau(g\cdot\sigma g\cdot\sigma^2 g)$. With similar arguments to those used for the case in which $T(H)$ divides $g\cdot\sigma g\cdot\sigma^2 g$ we reach a contradiction with the assumptions on g. Thus, Theorem 3 is proved. ■

Proof of Theorem 4: Since H is an analytic first integral of system (2), it is clear that any analytic function in a neighborhood of zero in the variable H is an analytic first integral of system (2) in a neighborhood of zero. To prove that these are the only ones, we proceed by contradiction. Assume that g is an analytic first integral of system (2) which is not a function of H. Then, there exists a neighborhood $U\subset\mathbb{R}^6$ of the origin such that $g_{|U}$ is an analytic first integral of system (2) which is not a series in H. Clearly, $g_{|U}$ can be written as a formal power series which turns out to be convergent. Hence, in U, g is a formal first integral which is not a series in H, a contradiction with Theorem 3. Thus, Theorem 4 is proved. ■

(Received 3 June 2005; accepted 10 January 2006; published online 28 February 2006)

While the notion of chaos is well established for dynamical systems on manifolds, it is not so for dynamical systems over discrete spaces with N variables, as binary neural networks and cellular automata. The main difficulty is the choice of a suitable topology to study the limit $N \to \infty$. By embedding the discrete phase space into a Cantor set we provided a natural setting to define topological entropy and Lyapunov exponents through the concept of error profile. We made explicit calculations both numerical and analytic for well-known discrete dynamical models.
 [DOI: 10.1063/1.2171518]

I. INTRODUCTION

For motions on differentiable manifolds, the commonly accepted notion of chaos identifies it with the so-called *sensitive dependence* on *initial conditions* and the latter with the existence of positive Lyapunov exponents signaling exponential separation of initially close trajectories.[1] In this sense, chaotic motion means unstable behavior; there is, however, an equivalent interpretation of chaos in terms of information production.[2] This is due to a celebrated theorem by Pesin which says that, for sufficiently regular ergodic systems, the sum of the positive Lyapunov exponents coincides with the *Kolmogorov-Sinai dynamical (KS-)entropy* associated with the dynamics. The KS-entropy measures the long run unpredictability of the motion with respect to an invariant state. Further, a variational principle states that the maximal KS-entropy with respect to all possible invariant states of a homeomorphism on a compact metric space is Bowen's *topological entropy* which gives a state-independent description of the degree of chaos based on how open sets change during the motion.

Roughly speaking, in standard dynamical system contexts, chaos reveals itself through the exponential increase of errors or, equivalently, via not-less-than linear information production.

On the contrary, there is no definite agreement about what chaos should mean in discrete dynamical systems, such as binary neural networks or cellular automata, where one cannot directly appeal to differentiability and thus to the standard definition of Lyapunov exponents.

However, inspired by the equivalent manifestations of chaos, briefly sketched above, one may try to overcome the lack of differentiable structures by looking at entropylike quantities.

In the following, we shall investigate how far chaos in discrete system can be identified with the exponential increase of initial errors or with (topological) information production.

Discrete, deterministic dynamical systems, consisting of N binary variables, have finite, even though very large (2^N), number of states.[3–9] This means that their dynamics is eventually going to end up in a periodic cycle. Due to this fact, there is no room for chaotic behavior as it is usually intended, unless the number of states $N \to \infty$.

[a)]Electronic mail: fabio.benatti@ts.infn.it
[b)]Electronic mail: alberto@matcuer.unam.mx
[c)]Electronic mail: zertuche@matcuer.unam.mx

In numerical studies of continuous systems one needs to discretize the manifold in order to solve physical models based on differential equations.[10] Once the space has been discretized, the number of available states is finite and one has no longer a chaotic system since the motion eventually becomes periodic. However the discretized systems inherit the natural distance of their continuous limit, so that, if the number of states goes to infinity, one expects to smoothly retrieve the continuous structure with all its dynamical properties. The problem with discrete dynamical systems is that the "natural" distance, the so-called Hamming distance is ill-defined in the limit $N \to \infty$.[9]

To overcome these difficulties in this work we try to resort to topological techniques. On compact sets, one may define the concept of sensitive dependence on initial conditions (together with topological transitivity) by only topological means and no differentiable structure. So, we define the topology of a Cantor set and endow it with compatible metrics that remain well defined in the limit of infinitely many states.[9] Then we look at the various dynamical patterns that appear and try to characterize them by adapting standard tools from ergodic theory as, Lyapunov exponents and topological entropy.[1,11–14]

In Sec. II, we review the concept of sensitive dependence on initial conditions formulated in a topological way. We endow the space with the topology of a Cantor set and introduce metrics compatible with it. In Sec. III, Lyapunov exponents in discrete systems are defined by means of metrics and also in terms of the derivative of suitable embedding homeomorphisms into the reals. In Sec. IV, the topological entropy is formulated in terms of spanning sets; while in Sec. V, Lyapunov exponents and topological entropy are related to an appropriate indicator of error propagation, that we call *error profile*. In Sec. VI, some concrete calculations are presented and in Sec. VII conclusions are drawn and future directions of investigation briefly mentioned.

II. DEFINING CHAOS ON DISCRETE SYSTEMS

We shall study discrete systems described in the following way:[3–9] a phase space is defined by a set Ω of states $\mathbf{S}$ consisting of N bits $S_i = \{0,1\}$; $i = 1, \ldots, N$, which evolve according to binary functions $f: \Omega \to \Omega$,

$$S_i(n+1) = f_i(\mathbf{S}(n)), \tag{1}$$

that update each bit $S_i(n)$ at each stroke of time n.

In neural networks and cellular automata, in general, all bits have an equally important role in the development of the system with time. When the number N of bits is finite, the metric most suited to this state of affairs is the Hamming distance[4,5,9] given by

$$d_H(\mathbf{S},\mathbf{S}') = \sum_{i=1}^{N} |S_i - S_i'|, \tag{2}$$

for any two states $\mathbf{S}, \mathbf{S}' \in \Omega$. Note that Hamming distance counts the number of different bits between $\mathbf{S}$ and $\mathbf{S}'$, but it is not sensitive to where the differences occur.

The usual way of identifying chaos in the evolution law (1) is to study the so-called *damage spreading*.[5–7,15] One follows the dynamical development of two states with initial Hamming distance equal to one and studies how it increases with time n. The speed of damage spreading is then defined by[15]

$$v(S,S') = \lim_{n \to \infty} \frac{d_H(\mathbf{S}(n),\mathbf{S}'(n))}{n}. \tag{3}$$

Two observations are necessary at this point. The first is that the above definition does not correspond to the identification of an exponential increase of an initial small error, but only discriminates between sublinear, linear, and superlinear increase of the Hamming distance.

The second is that, in the definition, it is implicit that the number N of binary variables is infinite, otherwise there will be recurrences and the limit in (3) would automatically vanish.

However, when $N\to\infty$, the Hamming distance makes no sense since there are infinitely many states with infinite d_H, and then it fails to be a properly defined distance function.

Remark 2.1: We stress that if one wants to think of binary systems as discretizations of continuous ones, so that asymptotic quantities like (3) make sense, then the metric of the space should be well defined when $N\to\infty$. There are two alternatives: either binary systems are taken as intrinsically discrete, in such a case formula (3) is to be investigated as a possible behavior over finite time scales.[16] Or the number of states is allowed to go to infinity, in such a case, appropriate metrics that are well defined for $N\to\infty$ must be chosen in order to look at the dynamics from a topological point of view.

In this paper we are going to explore the topological point of view. Let us take $N\to\infty$ and introduce the base of open sets[17]

$$\mathcal{N}(\mathbf{S},q)=\{\mathbf{S}'\in\Omega|S_k=S'_k,1\leqslant k<q\}. \tag{4}$$

It is well known that they generate the topology of a Cantor set on Ω.[9,11,12]

Definition 2.1: A Cantor set is a topological space such that[11]

(i) it is *totally disconnected*;
(ii) *perfect*, that is, it is closed and all its points are accumulation points;
(iii) *compact*.

The main issue in what follows is the identification of chaotic behaviors in discrete systems with a Cantor structure. As observed in the introduction, the lack of differentiability excludes that one may recognize any exponential separation of trajectories from the analysis of the tangent map.

Before trying to explore the possible existence of an exponential increase of initial small errors, one may start from a weaker form of instability than the usual one and identify a minimal degree of chaoticity with the following topological definition.[9]

Definition 2.2: Let $f:\Omega\to\Omega$ be a continuous map; we say that it shows *weak sensitive dependence on initial conditions* (WSDIC) if there exists a $p\in\mathbb{N}$ such that for any $\mathbf{S}$ and any $\mathcal{N}(\mathbf{S},q)$, there exists a $\mathbf{S}'\in\mathcal{N}(\mathbf{S},q)$ and a $k\in\mathbb{N}$ such that $f^k(\mathbf{S}')\notin\mathcal{N}(f^k(\mathbf{S}),p)$.

Remark 2.2: Note that the only requisite to define WSDIC is to have a topology on Ω. Which one? It depends not on mathematical arguments, but on physical considerations. That is, which properties do we want to measure and with how much accuracy? As extreme examples, in the *trivial topology* (given by $\{\emptyset,\Omega\}$) the dynamics is going to be trivial; while, in the *discrete topology* (where any subset of Ω is an open set) all systems show WSDIC.

There are several metrics compatible with the topology generated by the base (4), the more popular is[11,12]

$$\tilde{d}(\mathbf{S},\mathbf{S}')=\sum_{i=1}^{\infty}\frac{1}{2^{i-1}}|S_i-S'_i|.$$

However, for the purpose of this work we are going to use, for any $0<\beta<1$, the following ones:

$$d_\beta(\mathbf{S},\mathbf{S}')=\beta^m \quad \text{if } S_k=S'_k \quad \forall\, 1\leqslant k<m \quad \text{and } S_m\neq S'_m, \tag{5}$$

in terms of which the base (4) can be expressed as

$$\mathcal{N}(\mathbf{S},q)=\{\mathbf{S}'\in\Omega|d_\beta(\mathbf{S},\mathbf{S}')\leqslant\beta^q\}. \tag{6}$$

Remarks 2.3:

(i) We can view the embedding process of a finite discrete system into the Cantor set as follows: Let $\mathcal{F}$ be the set of all the continuous functions $f:\Omega\to\Omega$ on the Cantor set. Then any finite discrete dynamical system with N bits described by equations (1) is an element of the set

$$\mathcal{F}_N=\{f\in\mathcal{F}|\ \forall\ \mathbf{S}\in\Omega f(\mathcal{N}(\mathbf{S},N))=\mathcal{N}(f(\mathbf{S}),N)\}.$$

(ii) There is a price to pay for working with the base (4) and their associated metrics (5). Indeed, some of the binary variables contribute more than others. At first sight, this looks as a major problem since typical binary systems such as the ones constructed with random couplings[8,18,19] evolve through functions f_i's where all the variables contribute on an equal footing to the dynamics and so, apparently, there is no reason to "dismiss" some and "privilege" others as the distances (5) do. However, if we make a permutation $\pi:\mathbb{N}\to\mathbb{N}$ of the automata's indexes, and thus reenumerate them, the induced mapping $\hat{\pi}:\Omega\to\Omega$, such that

$$\hat{\pi}(S_1,S_2,\dots)=(S_{\pi^{-1}(1)},S_{\pi^{-1}(2)},\dots), \tag{7}$$

is, as we show below, an homeomorphism and so the Cantor topology is preserved despite the fact that the new metrics are not going to be Lipschitz equivalent.[13] From this it follows that, since WSDIC is a topological property, it does not depend in which way we have numerated the automata.

Let us now show that $\hat{\pi}$ is an homeomorphism: By construction the function is a bijection so we only need to show that it is continuous. Given $\varepsilon>0$ choose $M\in\mathbb{N}$ such that $\beta^M<\varepsilon$. Now take $m\in\mathbb{N}$ such that $\pi^{-1}(i)<m$ for any $1\leqslant i<M$. Then,

$$d_\beta(\mathbf{S},\mathbf{S}')<\beta^m\Rightarrow d_\beta(\hat{\pi}(\mathbf{S}),\hat{\pi}(\mathbf{S}'))\leqslant\beta^M<\varepsilon,$$

hence continuity.

Remarks 2.4:

(i) The metrics (5) seem to establish a preferred direction along the network. However, one can always reverse it by means of the permutation

$$\hat{\pi}(S_1,S_2,\dots,S_N)=(S_N,S_{N-1},\dots,S_2,S_1)$$

and, then, take the limit $N\to\infty$ in the metrics (5).

(ii) The metrics (5) are suited to semi-infinite networks. However, when expanding to infinity finite networks with periodic boundary conditions, as we will see in the examples, more symmetric metrics are preferable. These are achieved by means of two-sided sequences $\mathbf{S}=(\dots,S_{-2},S_{-1},S_0,S_1,S_2,\dots)$ and using the metrics

$$\hat{d}_\beta(\mathbf{S},\mathbf{S}')=\beta^m\quad\text{if } S_k=S'_k\quad\forall\ |k|<m$$

$$\text{with}\quad S_m\neq S'_m\quad\text{or } S_{-m}\neq S'_{-m}$$

which also define a Cantor topology.

III. LYAPUNOV EXPONENTS

Since Definition 2.2 is a topological one, and the metrics (5) all define the same topology, we can use any of them (by fixing a β) to check if there is WSDIC or not.

However, in continuous dynamics there is a definition of *sensitive dependence on initial conditions*, which we shall refer to as *strong* (SSDIC) in comparison with the previous one (WSDIC), which is based on the concept of positive Lyapunov exponents; that is, on the expo-

nential separation of initially close trajectories.[1,11,13] Such a behavior is usually associated with exponential increase of initial small errors. We propose two different natural definitions of Lyapunov exponents. The first one is based on the metrics (5), the second one is via an embedding of Ω into the continuum, where the notion of derivative can be used.

The metrics (5) offer a natural means to measure the increase of errors in Cantor sets. In fact, given d_β, one can define Lyapunov exponents as follows:

$$\lambda_M(\mathbf{S}) = \limsup_{n\to\infty} \lim_{d_\beta(\mathbf{S},\mathbf{S}')\to 0} \frac{1}{n} \log_{\beta^{-1}} \frac{d_\beta(f^n(\mathbf{S}),f^n(\mathbf{S}'))}{d_\beta(\mathbf{S},\mathbf{S}')}. \tag{8}$$

The quantity $\lambda_M(\mathbf{S})$ depends in general on $\mathbf{S}$, it amounts to identify separation of trajectories with the following behavior:

$$d_\beta(f^n(\mathbf{S}),f^n(\mathbf{S}')) \simeq \beta^{-n\lambda_M(\mathbf{S})} d_\beta(\mathbf{S},\mathbf{S}').$$

Remarks 3.1:

(i) In (8), we have used lim sup as we do not know whether the limit for $n\to\infty$ exist as it is the case for smooth dynamical systems by Oseledec's multiplicative theorem.[2] Also, the limit when $d_\beta(\mathbf{S},\mathbf{S}')\to 0$ may very well diverge as is the case when discrete dynamical systems exhibit nearly stochastic behavior such as random Boolean networks or binary neural networks with long range connections among the variables.[8,9,15,18]

(ii) Since the distances depend on β, we use a logarithm base β^{-1} to make $\lambda_M(\mathbf{S})$ β independent.

(iii) Due to the presence of a positive λ_M because of the exponential separation of trajectories, however close to each other initially, it turns out that the SSDIC property implies the weaker WSDIC property.

One may also try a kind of differential approach to the notion of exponential instability which is based on an appropriate embedding of the Cantor set Ω into the reals (compare, the abstract mathematical approach in Ref. 20). Let us consider the following commutative diagram:

$$\begin{array}{ccc} \Omega & \overset{f}{\to} & \Omega \\ \phi\downarrow & & \downarrow\phi \\ \Xi & \overset{\tilde{f}}{\to} & \Xi \end{array} \tag{9}$$

which defines the function $\tilde{f}$, by means of a homeomorphism ϕ, with Ξ being a Cantor set embedded in the reals ($\Xi\subset\mathbb{R}$). It is important to observe that due to the commutativity of the diagram (9), the dynamics generated by f and $\tilde{f}$ are intrinsically the same because of *topological conjugacy*.[11,12] Since Ω is an uncountable compact Abelian topological group, there are uncountably many ways of constructing a homeomorphism $\phi:\Omega\to\Xi$ (for instance, by suitable translations).[21] We will consider a ϕ that is suited to the metrics (5). Explicitly, let

$$\phi(\mathbf{S}) = \sum_{k=1}^{\infty} \gamma_k S_k, \tag{10a}$$

where

$$\gamma_k = h^k(h^{-1}-1) = \left(\frac{1-\alpha}{2}\right)^k \frac{1+\alpha}{1-\alpha}, \tag{10b}$$

with

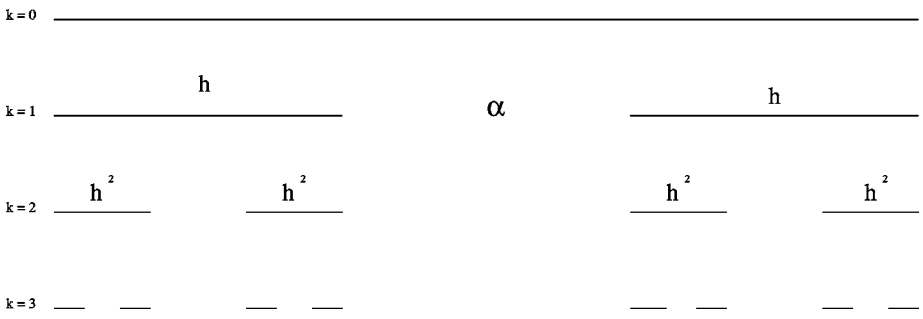

FIG. 1. Some steps in the construction of the Cantor set, with $h=(1-\alpha)/2$.

$$h = \frac{1-\alpha}{2} \quad \text{and } 0 < \alpha < 1,$$

sets the scale of the Cantor set by suppressing intervals in the proportion α (the standard choice being $\alpha = 1/3$). Figure 1 explains the idea of the construction of the Cantor set in a graphical way. Note that the self-similar nature of the Cantor set is reflected by the fact that the coefficients γ_k satisfy the following recursion relation:

$$\gamma_{k+m} = h^m \gamma_k. \tag{11}$$

Now, given any continuous function $f:\Omega \to \Omega$, we define the function $\delta_h f:\Omega \to \mathbb{R}$ by

$$\delta_h f(\mathbf{S}) = \lim_{\mathbf{S}' \to \mathbf{S}} \frac{\phi \circ f(\mathbf{S}') - \phi \circ f(\mathbf{S})}{\phi(\mathbf{S}') - \phi(\mathbf{S})}, \tag{12}$$

which has the typical properties of a derivative. In particular it maps to the vector space $\mathbb{R}$. Indeed, (12) is nothing but the derivative of the conjugate map $\tilde{f}$. Of course the actual value of $\delta_h f(\mathbf{S})$ is α-dependent, for if one wants to give the instantaneous rate of change of a function, one needs a scale. Similarly, if one wants to speak about the Hausdorff dimension of a Cantor set, one needs to embed it into $\mathbb{R}$ and the result is going to be scale dependent.

From (12), there naturally comes the following proposal of Lyapunov exponent associated with the derivative

$$\lambda_D(\mathbf{S}) = \limsup_{n \to \infty} \frac{1}{n} \log_{h^{-1}} |\delta_h f^n(\mathbf{S})|. \tag{13}$$

IV. ENTROPY

In ergodic theory, one approaches the notion of entropy from two different perspectives: the first one is statistical and based on the presence of an invariant measure, the other is topological. We shall consider the latter point of view which leads to the notion of topological entropy.[1,13,14]

Topological entropy: In the topological case, the fundamental objects are the open sets (4). We shall calculate $h_{\text{top}}(f)$ following standard techniques,[1,13] namely the so-called (n,ε)-*spanning set*. For this we need the dynamics-dependent distances

$$d_{\beta,n}(\mathbf{S},\mathbf{S}') = \max_{0 \leqslant k \leqslant n} d_\beta(f^k(\mathbf{S}), f^k(\mathbf{S}')),$$

and the corresponding open balls

$$\mathcal{B}_\beta(\mathbf{S},\varepsilon,n) = \{\mathbf{S}' \in \Omega | d_{\beta,n}(\mathbf{S},\mathbf{S}') < \varepsilon\}. \tag{14}$$

A subset $E(n,\varepsilon) \subseteq \Omega$ is called (n,ε)-spanning if

$$\Omega = \bigcup_{\mathbf{S} \in E(n,\varepsilon)} \mathcal{B}_\beta(\mathbf{S},\varepsilon,n). \tag{15}$$

That is, any (n,ε)-spanning set corresponds to an open cover of Ω. Because of the compactness of Ω, there will always be an (n,ε)-spanning set containing finitely many states $\mathbf{S}$; therefore, the minimal cardinality

$$\mathcal{S}(\varepsilon,n) = \min_{E(n,\varepsilon)} \quad \#E(n,\varepsilon)$$

of (n,ε)-spanning sets is finite.

The topological entropy $h_{\text{top}}(f)$ is defined by

$$h_{\text{top}}(f) = \lim_{\varepsilon \to 0} \limsup_{n \to \infty} \frac{1}{n} \ln \mathcal{S}(\varepsilon,n), \tag{16}$$

where the logarithm is in base 2.

Since the topological entropy $h_{\text{top}}(f)$ reflects the way open sets change in time under $f:\Omega \to \Omega$ given by (1), $h_{\text{top}}(f)$ will not depend on β. This is Bowen's definition and is based on using metrics.[13] The intrinsically topological nature of the notion rests on the fact that Bowen's formulation is equivalent to the one of Adler, Konheim, and McAndrew based on open covers.[1,13,14]

Remark 4.1: The topological entropy $h_{\text{top}}(f)$ is related by a variational principle to the metric or dynamical entropy of Kolmogorov, $h_\mu(f)$,

$$h_{\text{top}}(f) = \sup_{\mu \in \mathcal{M}(\Omega,f)} h_\mu(f), \tag{17}$$

where $\mathcal{M}(\Omega,f)$ is the space of invariant measures in Ω under the dynamics f. To establish (17) one needs a measurable structure to be defined on Ω, which is easily achieved by considering the σ-algebra generated by the open sets (4). What is more difficult to obtain is a measure μ on the σ-algebra being invariant under the dynamics: $\mu(f^{-1}(C))=\mu(C)$ for all measurable subsets $C \subseteq \Omega$. This is the meaning of the request $\mu \in \mathcal{M}(\Omega,f)$. Such a problem will be a matter of further investigation and will not be of concern in this work.

V. ERROR PROFILE AND CHAOTIC BEHAVIOR

Now we are going to study how Lyapunov exponents (8) and (13) and the topological entropy (16) are related to error propagation along the ordering defined by the metrics (5) over the network.

Let us take two near states $\mathbf{S}$ and $\mathbf{S}'$ with initial distance

$$d_\beta(\mathbf{S},\mathbf{S}') = \beta^q. \tag{18a}$$

Their evolution in time can always be written as

$$d_\beta(f^n(\mathbf{S}),f^n(\mathbf{S}')) = \beta^{q-L_n(\mathbf{S},\mathbf{S}')}, \tag{18b}$$

where $L_n(\mathbf{S},\mathbf{S}') \in \mathbb{Z}$ measures the length traveled to the left ($L_n>0$), or to the right ($L_n<0$), by the errors at the nth time step. The behavior of $L_n(\mathbf{S},\mathbf{S}')$, numerically measurable, reflects the properties of the network dynamics and is not necessarily monotonically increasing with time.

Remark 5.1: It is to be emphasized that $L_n(\mathbf{S},\mathbf{S}')$ does not correspond to the Hamming distance, since $q-L_n(\mathbf{S},\mathbf{S}')$ locates the first error that appears in the automaton ordering associated with the metrics (5). Such an error may very well be the only one, in such a case, $d_H(f^n(\mathbf{S}),f^n(\mathbf{S}'))=1$.

Thus, the picture we have in mind is as follows. Let us assume $L_n>0$, at time $n=0$, take two states $\mathbf{S}$, $\mathbf{S}'$ which agree upon the first $q-1$ bits, at time $n=1$ they agree upon the first

$q-L_1(\mathbf{S},\mathbf{S}')-1$ bits, at time $n=2$ upon the first $q-L_2(\mathbf{S},\mathbf{S}')-1$ bits, and so on. In this way, after n iterations of the dynamics (1), the first error will have propagated from position q to position $q-1-L_n(\mathbf{S},\mathbf{S}')$.

Remark 5.2: If $L_n<0$, then the initial error moves further and further away to the right with two consequences: first, it need not be the first error and thus need not appear at the exponent in (18b); second, it may become smaller and smaller contrary to the expectation that instability should amplify initial small errors. However, this is due to a preferred direction inherent in the choice of the metrics (5) as discussed in Remark 2.4(i). This also means that we can always consider $L_n>0$ in (18b) up to a reflection: this argument particularly applies to the behavior of the rule 30 in Wolfram's classification (see the examples) which seems otherwise to contradict instability.

Definition 5.1: We define the $\mathbf{S}$ *error profile* by the following limit:

$$\Lambda_n(\mathbf{S}) = \limsup_{d_\beta(\mathbf{S},\mathbf{S}')\to 0} L_n(\mathbf{S},\mathbf{S}'), \tag{19}$$

measures the length traveled by the errors at the nth time step due to two infinitesimally closed initial states.

Remark 5.3: The idea behind the previous definition is that, in physical instances, $L_n(\mathbf{S},\mathbf{S}') \approx \Lambda_n(\mathbf{S})$ once spurious boundary effects are eliminated by $\mathbf{S}'\to\mathbf{S}$ in the Cantor topology defined by the metrics (5). Numerically, the limit in (19), will be later handled by considering $\mathbf{S}$ and $\mathbf{S}'$ with $d_\beta(\mathbf{S},\mathbf{S}')$ sufficiently small.

We are now going to see how the error profile is related with the concepts introduced in the preceding sections. First, we deal with the Lyapunov exponents introduced in Sec. III.

A. Lyapunov exponents

Concerning metric-based Lyapunov exponents λ_M defined in (8), Eqs. (18) and (19) yield

$$\lambda_M(\mathbf{S}) = \limsup_{n\to\infty} \frac{\Lambda_n(\mathbf{S})}{n}. \tag{20}$$

Concerning derivative-based Lyapunov exponents λ_D defined in (13), we first calculate the derivative of a generic continuous function $f:\Omega\to\Omega$.

Consider two closed points $\mathbf{S},\mathbf{S}'\in\Omega$ with distance β^m, they are of the form [see Eq. (5)]

$$\mathbf{S} = (S_1S_2S_3\cdots S_{m-1}S_mS_{m+1}\cdots) \tag{21a}$$

and

$$\mathbf{S}' = (S_1S_2S_3\cdots S_{m-1}S'_mS'_{m+1}\cdots), \tag{21b}$$

where $S_m\neq S'_m$. Applying the homeomorphism (10a), we get

$$\Delta\mathbf{S} \equiv \phi(\mathbf{S}') - \phi(\mathbf{S}) = \sum_{k=m}^{\infty} \gamma_k(S'_k - S_k). \tag{21c}$$

The images of $\mathbf{S}$ and $\mathbf{S}'$ after the nth time-step $f^n:\Omega\mapsto\Omega$ are, in a short-hand notation,

$$f^n(\mathbf{S}) = (\zeta_1\zeta_2\zeta_3\cdots\zeta_{p_n-1}\zeta_{p_n}\zeta_{p_n+1}\cdots)$$

and

$$f^n(\mathbf{S}') = (\zeta_1\zeta_2\zeta_3\cdots\zeta_{p_n-1}\zeta'_{p_n}\zeta'_{p_n+1}\cdots),$$

where $\zeta_{p_n}\neq\zeta'_{p_n}$, with $p_n=p_n(m)$ being a function, of the initial error position m in (21). From (21c), we have that

$$\Delta \mathbf{S} = \gamma_m \mu_m + R_m,$$

where $\mu_m \equiv S'_m - S_m = \pm 1$ and $R_m \equiv \Sigma_{k=m+1}^{\infty} \gamma_k \mu_k$. Now, by means of (10b) and (11) follows that $|R_m| \leqslant \Sigma_{k=m+1}^{\infty} \gamma_k = h^m$. So that $R_m \sim \mathcal{O}(h^m)$ which gives

$$\Delta \mathbf{S} = h^m (h^{-1} - 1) \mu_m (1 + \mathcal{O}(h)).$$

An analogous expression is obtained for $\Delta f^n \equiv f^n(\mathbf{S}) - f^n(\mathbf{S}')$ giving

$$\Delta f^n = h^{p_n(m)} (h^{-1} - 1) \mu_{p_n(m)} (1 + \mathcal{O}(h)).$$

Therefore,

$$\delta_h f^n(\mathbf{S}) = \lim_{m \to \infty} \frac{\Delta f^n}{\Delta \mathbf{S}} = \lim_{m \to \infty} \mu_m \mu_{p_n(m)} h^{p_n(m) - m} (1 + \mathcal{O}(h)).$$

If the limit exists; we obtain

$$\delta_h f^n(\mathbf{S}) = \pm h^{-\Lambda_n(\mathbf{S})} (1 + \mathcal{O}(h)),$$

where

$$\Lambda_n(\mathbf{S}) \equiv \lim_{m \to \infty} (m - p_n(m)),$$

which, if exists, it is the error propagation at time n as seen through the embedding (9).

Inserting the above result into (13) yields

$$\lambda_D(\mathbf{S}) = \lim_{n \to \infty} \frac{\Lambda_n(\mathbf{S})}{n}, \tag{22}$$

which, if it exists, equals (20).

Remark 5.4: As observed in Remark 3.1(ii), the metric and derivative definitions of Lyapunov exponents do not depend on the specific scale used. The velocity of leftward propagation of errors should be a dynamical effect independent of the scale, which is exactly what turns out from above, whence the coincidence of (20) and (22).

B. Topological entropy

Consider Eqs. (18) and let us define

$$L_n^*(\mathbf{S}, \mathbf{S}') \equiv \max_{0 \leqslant k \leqslant n} L_k(\mathbf{S}, \mathbf{S}'). \tag{23}$$

From (14) it follows that

$$\mathcal{B}_\beta(\mathbf{S}, \varepsilon, n) = \{\mathbf{S}' \in \Omega | \beta^{q - L_n^*(\mathbf{S}, \mathbf{S}')} < \varepsilon\}.$$

In the particular case where the dynamics (1) is such that L_n^* is independent of $\mathbf{S}$ and $\mathbf{S}'$ let us define

$$\theta_n \equiv L_n^*(\mathbf{S}, \mathbf{S}') \tag{24}$$

and take $\varepsilon = \beta^p$. From (6) and (14) it follows that

$$\mathcal{B}_\beta(\mathbf{S}, \beta^p, n) = \{\mathbf{S}' \in \Omega | \beta^q < \beta^{p + \theta_n}\} = \{\mathbf{S}' \in \Omega | d_\beta(\mathbf{S}, \mathbf{S}') \leqslant \beta^{p + \theta_n + 1}\} = \mathcal{N}(\mathbf{S}, r_{n,p}),$$

where

$$r_{n,p} = p + \theta_n + 1.$$

Since $\mathcal{N}(\mathbf{S}, r_{n,p})$ are elements of the base (4), it follows that

$$E(n,\beta^p) = \{\mathbf{S} \in \Omega | S_k = 0 \ \forall \ k > r_{n,p}\}$$

is an (n,β^p)-spanning set with cardinality $2^{r_{n,p}}$; which, by construction, is minimal. From (16) we obtain

$$h_{\text{top}}(f) = \lim_{p\to\infty} \limsup_{n\to\infty} \frac{r_{n,p}}{n}.$$

So that,

$$h_{\text{top}}(f) = \limsup_{n\to\infty} \frac{\theta_n}{n}. \tag{25}$$

In the general case (24) is not valid and the behavior of $L_n^*(\mathbf{S},\mathbf{S}')$ depends on the fine details of the dynamics (1). In such cases, it is still possible to set an upper bound to the value of the topological entropy. Let us define

$$\eta(n) \equiv \max_{\mathbf{s},\mathbf{s}'} L_n^*(\mathbf{S},\mathbf{S}'),$$

with $\mathbf{S}$ and $\mathbf{S}'$ subject to the constraint (18a). Then [using (6) and (14)],

$$\mathcal{B}_\beta(\mathbf{S},\beta^p,n) = \{\mathbf{S}' \in \Omega | \beta^{q-L_n^*(\mathbf{S},\mathbf{S}')} < \beta^p\} \supseteq \{\mathbf{S}' \in \Omega | \beta^{q-\eta(n)} < \beta^p\} \supseteq \{\mathbf{S}' \in \Omega | d_\beta(\mathbf{S},\mathbf{S}') \leqslant \beta^{p+\eta(n)+1}\} \supseteq \mathcal{N}(\mathbf{S}, t_{n,p}),$$

where

$$t_{n,p} = p + \eta(n) + 1.$$

Now

$$E(n,\beta^p) = \{\mathbf{S} \in \Omega | S_k = 0 \ \forall \ k > t_{n,p}\},$$

is again an (n,β^p)-spanning set with cardinality $2^{t_{n,p}}$, but we cannot assure that it is minimal. So, from (16) we obtain

$$h_{\text{top}}(f) \leqslant \limsup_{n\to\infty} \frac{\eta(n)}{n},$$

which assures that, if $\eta(n)$ does not increase as n or faster, the topological entropy vanishes.

VI. EXAMPLES

A. The shift map

We begin applying the ideas developed so far to the v-shift map σ_v defined by

$$\sigma_v(S_1 S_2 S_3 \cdots) = (S_{1+v} S_{2+v} S_{3+v} \cdots).$$

Consider two points $\mathbf{S},\mathbf{S}' \in \Omega$ with distance $d_\beta(\mathbf{S},\mathbf{S}') = \beta^q$. Applying σ_v^n we obtain

$$d_\beta(\mathbf{S}(n),\mathbf{S}'(n)) = \beta^{q-vn}.$$

According to (18), (23) and (24), we see that $\theta_n = vn$; thus, from (25) we have

TABLE I. Boolean rules.

S_{i-1}	S_i	S_{i+1}	30	73	90	167
0	0	0	0	1	0	1
0	0	1	1	0	1	1
0	1	0	1	0	0	1
0	1	1	1	1	1	0
1	0	0	1	0	1	0
1	0	1	0	0	0	1
1	1	0	0	1	1	0
1	1	1	0	0	0	1

$$h_{\mathrm{top}}(f) = \upsilon > 0.$$

It is also evident that the topological entropy coincides with the Lyapunov exponents $\lambda_M = \lambda_D$ [see Eqs. (20) and (22)].

B. Networks with three inputs

We study now the evolution rule (1) in the case of interactions involving three nearest neighbors and impose periodic boundary conditions; specifically

$$S_i(n+1) = f(S_{i-1}(n), S_i(n), S_{i+1}(n)) \quad \text{for } i = 2,3,\ldots,N-1, \tag{26a}$$

$$S_1(n+1) = f(S_N(n), S_1(n), S_2(n)), \tag{26b}$$

and

$$S_N(n+1) = f(S_{N-1}(n), S_N(n), S_1(n)), \tag{26c}$$

where the transfer function f is the same for all the bits.

Due to the periodic boundary conditions, the infinite limit of these networks requires the symmetric metrics discussed in Remark 2.4(ii): this context accommodates errors propagating both to the left and to the right.

We are going to study the Boolean rules numbered 30, 73, 90, and 167 according to Wolfram's which[5–7] which we explicitly list in Table I. The first three columns give the values of three adjacent bits and the remaining columns show the corresponding bits for the two rules. We stress that the rule 90 is the XOR rule in the two adjacent bits and it is well known as "chaotic" in Wolfram's terminology.

We have considered an automaton consisting of $N = 1000$ bits and start with a random initial state. After a transient of length N^2 we let the dynamics reach a state $\mathbf{S}$. Then we choose a state $\mathbf{S}'$ which differs from $\mathbf{S}$ in the 499, 500, and 501 bits, and start to measure the speed of error profile Λ_n/n and the speed of damage spreading $d_H(\mathbf{S}(\mathbf{n}), \mathbf{S}'(\mathbf{n}))/n$. The main results are plotted in Figs. 2–4.

Figure 2 shows the spread of errors as the states $\mathbf{S}$, $\mathbf{S}'$ evolve in time, each cross corresponding to a different bit in the two configurations.

Figure 3 shows the speed of error profile as a function of time. According to (20) and (22), they exhibit, for $n \gg 1$ a Lyapunov exponent $\lambda = 1$ for all the rules but the rule 73 which shows $\lambda = 0$. The same conclusions can be extracted from the topological entropy.

Figure 4 shows the evolution in time of the speed of damage spreading. One can see that no clear behavior emerges for $n \gg 1$ that may help evaluate the damage spreading according to (3); moreover, even when, according to the Lyapunov and entropic analysis, the behavior is complex as is the case with rule 90, there is instead a clear tendency of the damage spreading to go to zero.

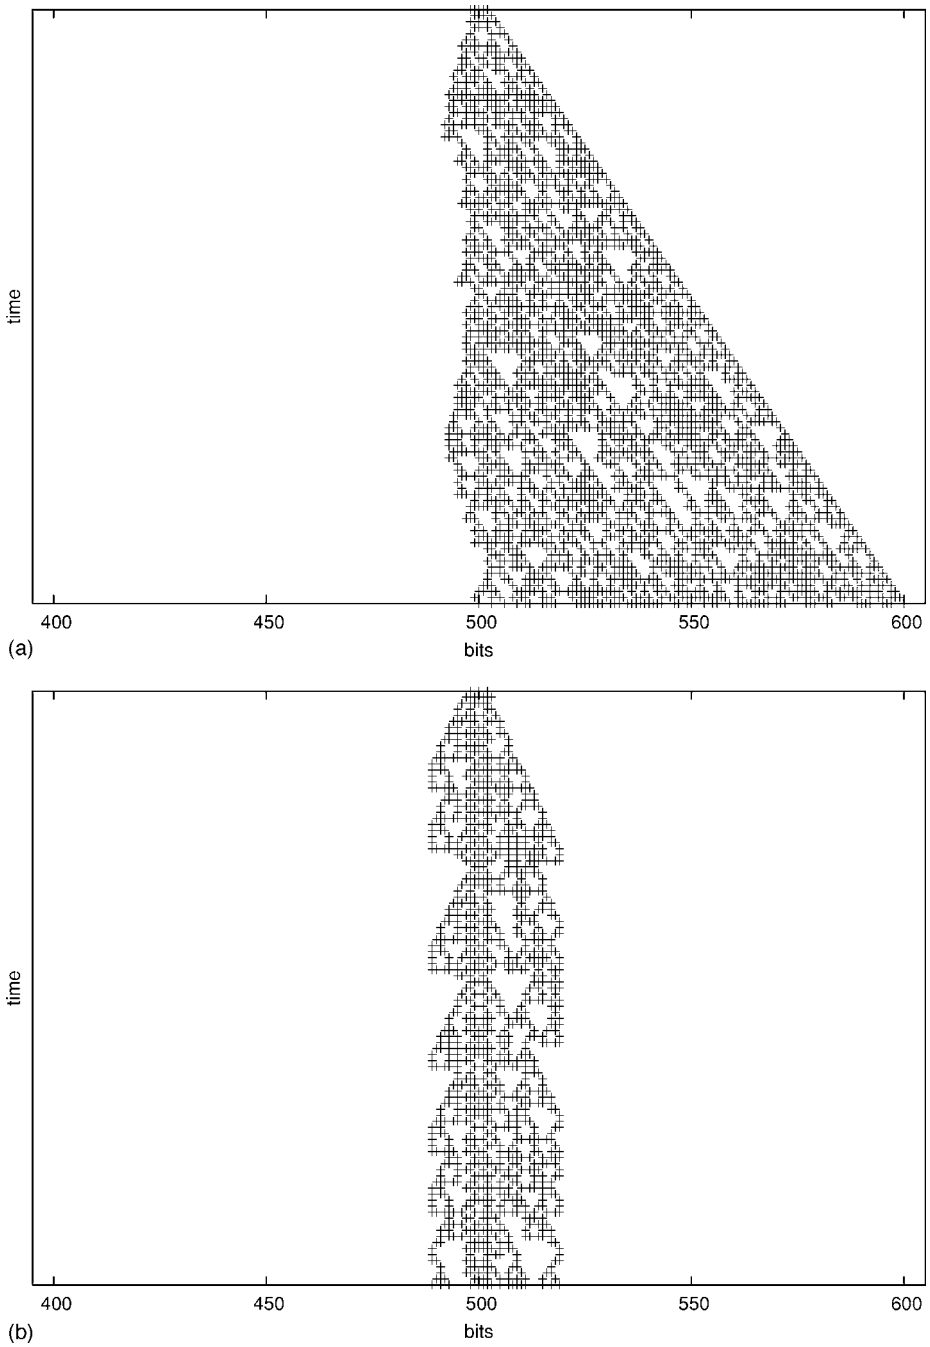

FIG. 2. (a) Spread of errors for rule 30. Starting from two states **S**, **S**′ which differ in the 499, 500, and 501 bits. A cross is plotted when the bits are different. Time goes from top to bottom for 100 iterations. (b) Spread of errors for rule 73. Starting from two states **S**, **S**′ which differ in the 499, 500, and 501 bits. A cross is plotted when the bits are different. Time goes from top to bottom for 100 iterations. (c) Spread of errors for rule 90. Starting from two states **S**, **S**′ which differ in the 499, 500, and 501 bits. A cross is plotted when the bits are different. Time goes from top to bottom for 100 iterations. (d) Spread of errors for rule 167. Starting from two states **S**, **S**′ which differ in the 499, 500, and 501 bits. A cross is plotted when the bits are different. Time goes from top to bottom for 100 iterations.

It is important to observe from Fig. 2(b) that rule 73 shows a complex behavior. However it is localized in the sense that it does not grow with N, so for $N\to\infty$, **S** and **S**′ are on a periodic attractor and so the dynamics is not chaotic. In contrast the other rules, which are chaotic, spread the errors along all the bits.

VII. CONCLUSIONS

We have endowed the phase space of binary variables with the topology of the Cantor set in the limit when the number of variables N goes to infinity. This embedding of the phase space permits us to understand the dynamical behavior of binary dynamical systems, much on the same footing as the ones over differentiable manifolds providing a mathematically solid framework for discrete systems. One of the advantages of this approach is the fact that the distance function (5)

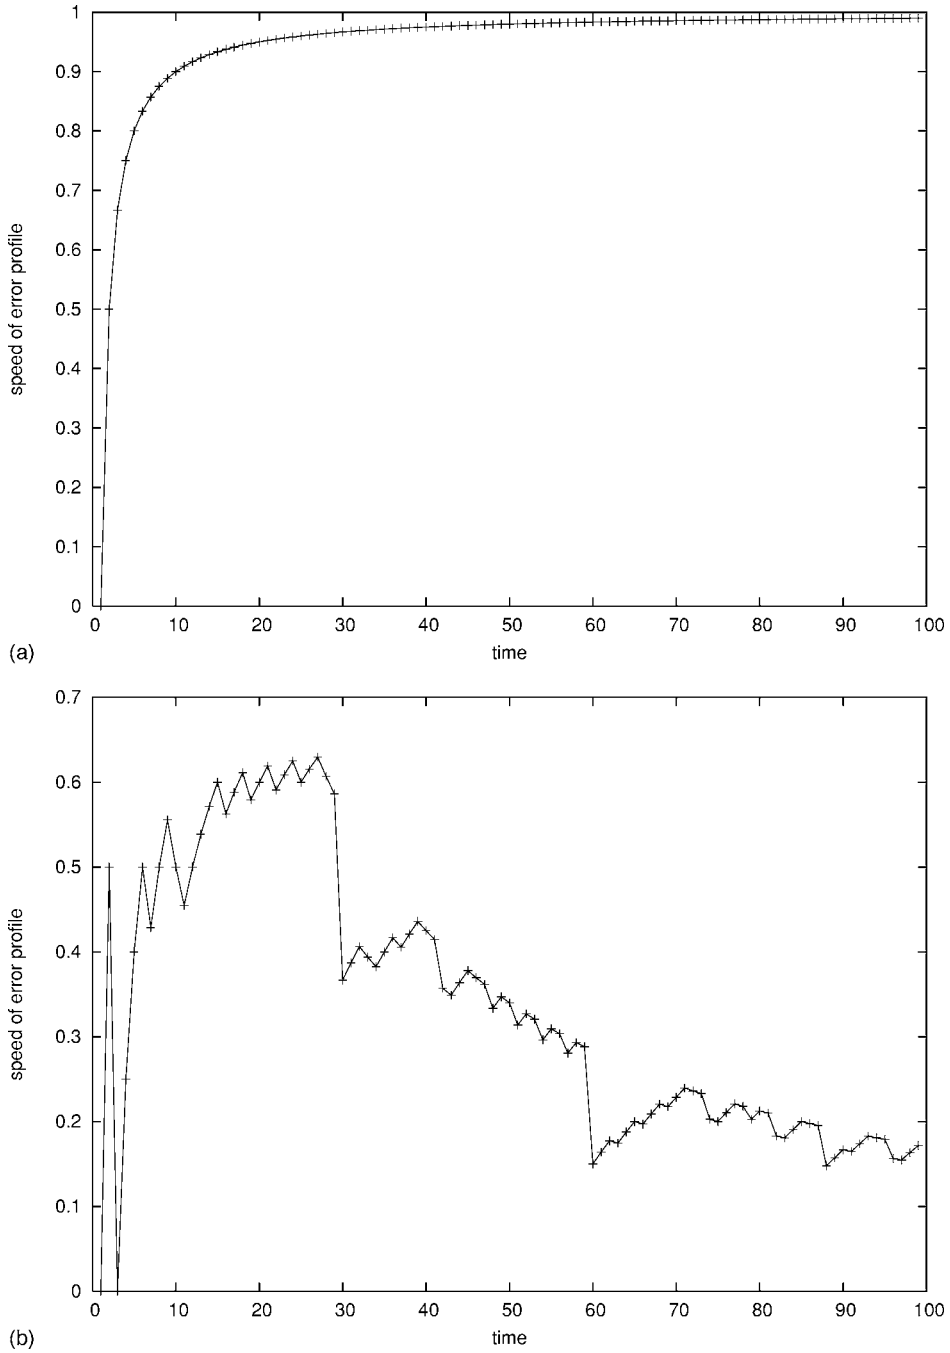

FIG. 3. (a) Evolution of the speed of error profile Λ_n/n in function of time for rule 30 showing for $n \gg 1$ a Lyapunov exponent $\lambda=1$. (b) Evolution of the speed of error profile Λ_n/n in function of time for rule 73 showing for $n \gg 1$ a Lyapunov exponent $\lambda=0$. (c) Evolution of the speed of error profile Λ_n/n in function of time for rule 90 showing for $n \gg 1$ a Lyapunov exponent $\lambda=1$. FIG. 3. (*Continued*).

We have formalized the notion of Lyapunov exponents for discrete systems in two related ways: by resorting to metrics compatible with the Cantor topology and by suitably embedding the Cantor structure into a differentiable one.

Guided by the connections between Lyapunov exponents and topological entropy in continuous system, we have also computed the topological entropy and compared it with the Lyapunov exponents calculated according to the given prescriptions. This has been done in Sec. V where we

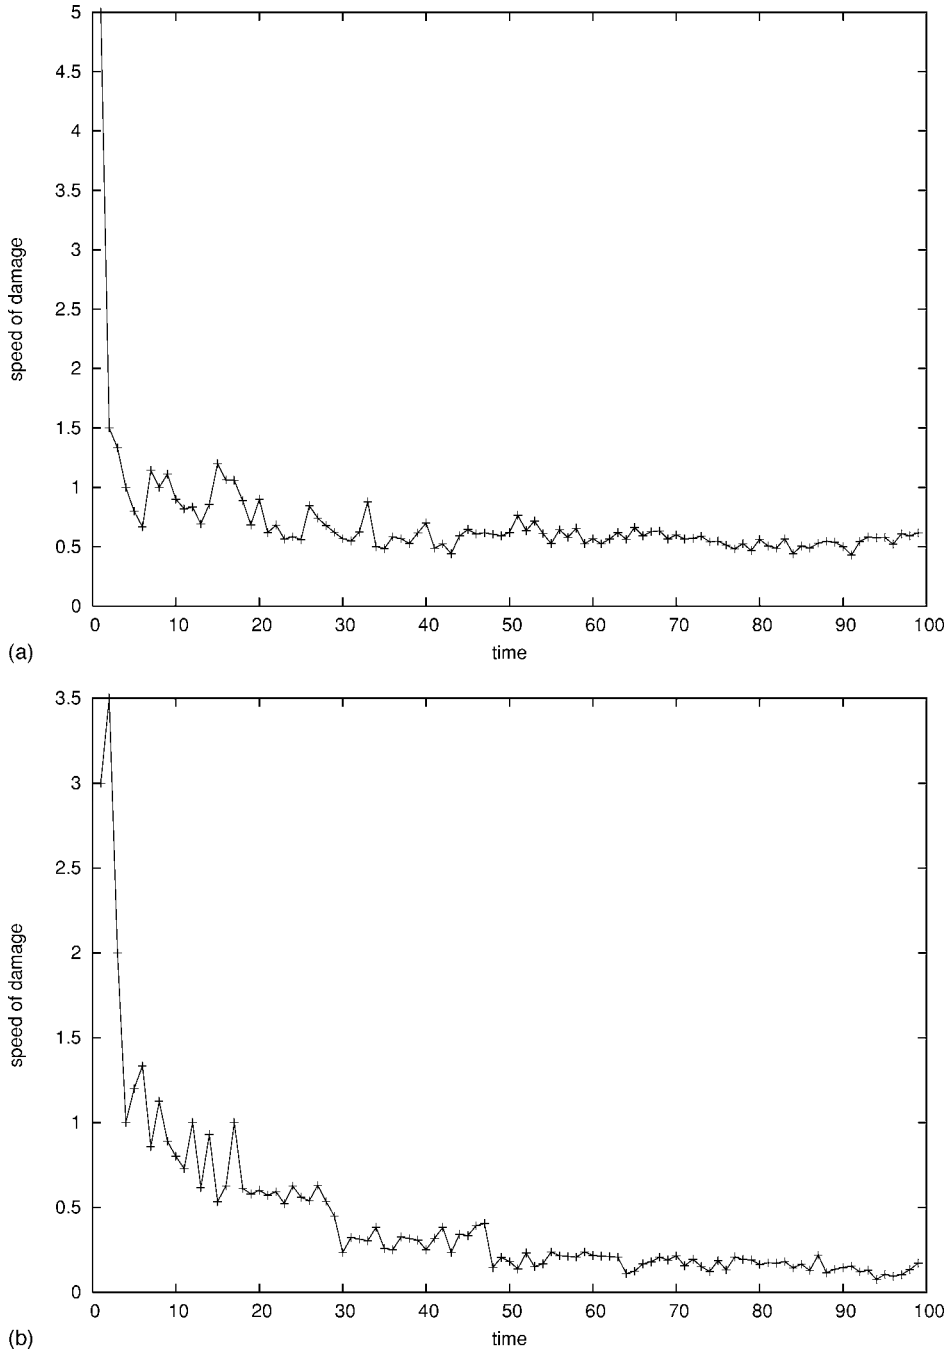

FIG. 4. (a) Evolution of the speed of damage spreading $d_H(\mathbf{S}(\mathbf{n}),\mathbf{S}'(\mathbf{n}))/n$ in function of time for rule 30. There is not a clear behavior for $n \gg 1$ which help to make an evaluation of the damage spreading. (b) Evolution of the speed of damage spreading $d_H(\mathbf{S}(\mathbf{n}),\mathbf{S}'(\mathbf{n}))/n$ in function of time for rule 73. There is not a clear behavior for $n \gg 1$ which help to make an evaluation of the damage spreading. (c) Evolution of the speed of damage spreading $d_H(\mathbf{S}(\mathbf{n}),\mathbf{S}'(\mathbf{n}))/n$ in function of time for rule 90. There is not a clear behavior for $n \gg 1$ which help to make an evaluation of the damage spreading and is tending to zero for a complex rule. (d) Evolution of the speed of damage spreading $d_H(\mathbf{S}(\mathbf{n}),\mathbf{S}'(\mathbf{n}))/n$ in function of time for rule 167. There is not a clear behavior for $n \gg 1$ which help to make an evaluation of the damage spreading and is tending to zero for a rule which has a positive Lyapunov exponent in our scheme.

related both notions to the concept of error profile which is a phenomenological quantity that can be accessed numerically and has a self-evident physical interpretation. We have illustrated all these concepts by examples in Sec. VI.

(d)

FIG. 4. (*Continued*).

Further points that deserve to be studied are

(i) The problem of the concept of a derivative. Here we have introduced it with the aid of the homeomorphism (10) which is compatible with the metrics (5). However, from the mathematical point of view it would be better if one could construct a meaningful "discrete derivative" which is homeomorphism free.

(ii) The construction of an invariant measure for the definition of the metric entropy (17), as sketched in Remark 4.1.

(iii) The application of the methods presented above to the treatment of Kauffman's models of cellular automata with connectivity K and random couplings which show a transition from an ordered phase for $K \leqslant 2$ where the length of the attractors grows as $\sqrt{N}$, to a disordered one, termed chaotic, for $K > 2$ with lengths growing as e^N.[3,5,18]

(Received 4 September 2004; accepted 6 December 2005; published online 13 February 2006)

A four-dimensional family of skew-symmetric solutions of the Jacobi equations for Poisson structures is characterized. As a consequence, previously known types of Poisson structures found in a diversity of physical situations appear to be obtainable as particular cases of new family of solutions. Additionally, it is possible to apply constructive methods for the explicit determination of fundamental properties of those solutions, such as their Casimir invariants, symplectic structure and the algorithm for the reduction to the Darboux canonical form, which have been reported only for a limited sample of known finite-dimensional Poisson structures. Moreover, the results developed are valid globally in phase space, thus ameliorating the usual scope of Darboux theorem which is of local nature. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2161804]

I. INTRODUCTION

Poisson structures[1,2] are present in many different domains of mathematical physics, such as fluid dynamics,[3] plasma physics,[4] field theory,[5] continuous media,[6] etc. In particular, finite-dimensional Poisson structures (to which this work is devoted) are relevant in the study of very different kinds of nonlinear systems, including population dynamics,[7–12] mechanics,[13–16] electromagnetism,[17] optics,[18] or plasma physics,[19] to cite a sample. The association of a finite-dimensional Poisson structure to a differential system (which is still an open problem[16,20–22]) is not only mathematically appealing, but also very useful through the use of a plethora of specialized techniques which include the development of perturbative solutions,[17] numerical algorithms,[23] stability analysis by means of the energy-Casimir[24] and energy-momentum[25] methods, characterization of invariants,[26] reductions,[2,27] analysis of integrability properties,[28] establishment of variational principles,[29] study of bifurcation properties and chaotic behavior,[18,30] etc.

When expressed in terms of a system of local coordinates on an n-dimensional manifold, finite-dimensional Poisson structures take the form

$$\dot{x}_i = \sum_{j=1}^{n} J_{ij}\partial_j H, \quad i = 1, \ldots, n. \tag{1}$$

Here and in what follows $\partial_j \equiv \partial/\partial x_j$. The C^1 real-valued function $H(x)$ in (1) is a constant of motion of the system playing the role of Hamiltonian. The $J_{ij}(x)$, called structure functions, are also C^1 and real valued and constitute the entries of an $n \times n$ structure matrix $\mathcal{J}$. The $J_{ij}(x)$ are characterized by two properties. The first one is that they are skew-symmetric,

[a)]Electronic mail: benito.hernandez@urjc.es

$$J_{ij} = -J_{ji} \quad \text{for all } i,j. \tag{2}$$

And second, they are solutions of the Jacobi equations,

$$\sum_{l=1}^{n} (J_{il}\partial_l J_{jk} + J_{kl}\partial_l J_{ij} + J_{jl}\partial_l J_{ki}) = 0, \tag{3}$$

where indices i,j,k run from 1 to n in Eqs. (2) and (3).

One of the reasons justifying the importance of the Poisson representation is the local equivalence between Poisson systems and classical Hamiltonian systems, as stated by Darboux theorem[1,2] which demonstrates that if an n-dimensional Poisson manifold has constant rank of value $2r$ everywhere, then at each point of the manifold there exist local coordinates $(p_1,\ldots,p_r,q_1,\ldots,q_r,z_1,\ldots,z_{n-2r})$ in terms of which the equations of motion become

$$\dot{q}_i = \frac{\partial H}{\partial p_i}, \quad \dot{p}_i = -\frac{\partial H}{\partial q_i}, \quad i = 1,\ldots,r,$$

$$\dot{z}_j = 0, \quad j = 1,\ldots,n-2r.$$

As mentioned above, the problem of recasting a given vector field not explicitly written in the form (1) in terms of a finite-dimensional Poisson system is an open issue of fundamental importance in this context to which important efforts have been devoted in past years in a variety of approaches and situations.[7–22] This explains, together with the intrinsic mathematical interest of the problem, the permanent attention deserved in the literature by the obtainment and classification of skew-symmetric solutions of the Jacobi equations.[7–22,31–38] Given that Eqs. (3) constitute a set of coupled nonlinear partial differential equations, the characterization of solutions of (2) and (3) has proceeded by means of either suitable *ansatzs*[7–11,32,37] or through a diversity of other approaches.[12–16,20–22,31,38] These efforts have led to the determination of certain families of solutions of increasing nonlinearity such as the constant ones (of which the symplectic matrices are just a particular case), as well as linear[2,33] (i.e., Lie-Poisson), affine-linear,[34] quadratic,[7–11,15,35,36] and cubic[37] structures, together with solutions which comprise arbitrary functions.[12–14,16,20–22,31,32,38] Simultaneously, the growing complexity of the Jacobi equations (3) as the dimension n increases has determined that the analysis is often focused on three-dimensional solutions,[9,10,12,20,21,32,37,38] while the characterization of families of dimensions four,[13] five,[14] six,[17] etc., is less frequent. In addition, some wide families of n-dimensional solutions have also been analyzed in the literature.[8,11,31,33–36]

In this work a four-dimensional family of solutions of the Jacobi equations (3) is characterized. This contribution presents several interesting features. First, it is worth noting that previously known types of Poisson structures appearing in a diversity of physical situations and systems can be seen to be obtainable as particular cases of the family of solutions, as it will be seen in the examples section. Second, in spite of their generality the solutions to be considered in what follows are amenable to explicit and detailed analysis, since it is possible to characterize globally their Casimir invariants and symplectic structure, as well as to globally provide the reduction to the Darboux canonical form. This constitutes a significant amelioration of the usual scope of Darboux theorem, which does only guarantee in principle a local reduction.[1,2] In addition, the achievement of such reduction is relevant as far as the explicit determination of the Darboux coordinates is often a complicated task, only known for a limited sample of finite-dimensional Poisson structures.[2,8,27,31,38]

The structure of the paper is as follows. In Sec. II the solutions are characterized. The symplectic structure and the constructive reduction to the Darboux canonical form are investigated in Sec. III. Examples and comments on the relationship with some previously known results are provided in Sec. IV. The work concludes in Sec. V with some final remarks.

II. CHARACTERIZATION OF THE FAMILY OF SOLUTIONS

We begin with one of the main results.

Theorem 2.1: Consider the family of functions of the form

$$J_{ij}(x) = \sigma_{ij}\eta(x)\psi_i(x_i)\psi_j(x_j)\sum_{k,l=1}^{4}\epsilon_{ijkl}\phi_l(x_l), \quad i,j=1,\ldots,4 \tag{4}$$

defined in an open domain $\Omega \subset \mathbb{R}^4$, where ϵ_{ijkl} denotes the Levi-Civita symbol and such that

(a) Constants $\sigma_{ij} \in \mathbb{R}$ are defined for every pair (i,j), $i \neq j$.
(b) $\sigma_{ij} = \sigma_{ji}$ for every pair (i,j), $i \neq j$.
(c) $\sigma_{ij} \neq 0$ for at least one pair (i,j), $i \neq j$.
(d) $\eta(x)$, $\psi_i(x_i)$, and $\phi_i(x_i)$ are $C^1(\Omega)$ functions of their respective arguments for every i.
(e) $\eta(x)$ and $\psi_i(x_i)$ are nonvanishing in Ω for every i.
(f) The differences $[\phi_i(x_i) - \phi_j(x_j)]$ are nonvanishing in Ω for every pair (i,j), $i \neq j$.

Then the set of functions $J_{ij}(x)$ defined in (4) constitutes a skew-symmetric solution of the four-dimensional Jacobi identities

$$\sum_{l=1}^{4}(J_{il}\partial_l J_{jk} + J_{kl}\partial_l J_{ij} + J_{jl}\partial_l J_{ki}) = 0, \quad i,j,k=1,\ldots,4 \tag{5}$$

and therefore $\mathcal{J}=(J_{ij})$ is a four-dimensional structure matrix, if and only if

$$\sigma_{12}\sigma_{34} = \sigma_{13}\sigma_{24} = \sigma_{14}\sigma_{23}. \tag{6}$$

Proof: Consider first functions (4) in the case $\eta=1$. Substitution of (4) in Eq. (5) of indexes (i,j,k) leads after some algebra to

$$\begin{aligned}
\sum_{l=1}^{4}(J_{il}\partial_l J_{jk} + J_{kl}\partial_l J_{ij} + J_{jl}\partial_l J_{ki}) &= \psi_i\psi_j\psi_k \sum_{r_1,r_2,s_1,s_2=1}^{4}\{(\sigma_{ij}\sigma_{jk}\epsilon_{ijr_1r_2}\epsilon_{jks_1s_2} + \sigma_{kj}\sigma_{ij}\epsilon_{kjr_1r_2}\epsilon_{ijs_1s_2}) \\
&\quad \times(\partial_j\psi_j)\phi_{r_2}\phi_{s_2} + (\sigma_{ki}\sigma_{ij}\epsilon_{kir_1r_2}\epsilon_{ijs_1s_2} + \sigma_{ji}\sigma_{ki}\epsilon_{jir_1r_2}\epsilon_{kis_1s_2})(\partial_i\psi_i)\phi_{r_2}\phi_{s_2} \\
&\quad + (\sigma_{ik}\sigma_{jk}\epsilon_{ikr_1r_2}\epsilon_{jks_1s_2} + \sigma_{jk}\sigma_{ki}\epsilon_{jkr_1r_2}\epsilon_{kis_1s_2})(\partial_k\psi_k)\phi_{r_2}\phi_{s_2} \\
&\quad + (\sigma_{is_2}\sigma_{jk}\epsilon_{is_2r_1r_2}\epsilon_{jks_1s_2} + \sigma_{ks_2}\sigma_{ij}\epsilon_{ks_2r_1r_2}\epsilon_{ijs_1s_2} \\
&\quad + \sigma_{js_2}\sigma_{ki}\epsilon_{js_2r_1r_2}\epsilon_{kis_1s_2})\psi_{s_2}\phi_{r_2}(\partial_{s_2}\phi_{s_2})\} \\
&= \psi_i\psi_j\psi_k \sum_{r_1,r_2,s_1,s_2=1}^{4}\{(\sigma_{is_2}\sigma_{jk}\delta_{jks_1s_2}^{is_2r_1r_2} + \sigma_{ks_2}\sigma_{ij}\delta_{ijs_1s_2}^{ks_2r_1r_2} \\
&\quad + \sigma_{js_2}\sigma_{ki}\delta_{kis_1s_2}^{is_2r_1r_2})\psi_{s_2}\phi_{r_2}(\partial_{s_2}\phi_{s_2})\}
\end{aligned} \tag{7}$$

where the δ symbol denotes the generalized Kronecker delta according to its standard definition, namely, given q superindexes $(i_1,\ldots,i_q)$ and q subindexes $(j_1,\ldots,j_q)$ all of them taking values in the range $(1,\ldots,n)$, then $\delta_{j_1\cdots j_q}^{i_1\cdots i_q}$ is defined by the properties: (a) it is totally antisymmetric in the superindexes; (b) it is totally antisymmetric in the subindexes; (c) if the superindexes are all different (this is, $i_{a_1} \neq i_{a_2}$ if $a_1 \neq a_2$) and the subindexes are a permutation of the superindexes, then $\delta_{j_1\cdots j_q}^{i_1\cdots i_q}$ takes the value $+1$ (respectively, -1) if $(i_1,\ldots,i_q)$ and $(j_1,\ldots,j_q)$ are permutations of the same (of different) sign; (d) the value of $\delta_{j_1\cdots j_q}^{i_1\cdots i_q}$ is zero otherwise. Consequently, it can be verified that the expression in (7) vanishes if two of the three indexes (i,j,k) are equal. Consider then the case in which i, j, and k are different. If m is the integer, $1 \leqslant m \leqslant 4$, such that (i,j,k,m) is a permutation of $(1,2,3,4)$, we arrive at

$$\sum_{l=1}^{4} (J_{il}\partial_l J_{jk} + J_{kl}\partial_l J_{ij} + J_{jl}\partial_l J_{ki})$$
$$= \psi_i\psi_j\psi_k\psi_m(\partial_m\phi_m)\{\sigma_{im}\sigma_{jk}(\phi_k - \phi_j) + \sigma_{km}\sigma_{ij}(\phi_j - \phi_i) + \sigma_{jm}\sigma_{ki}(\phi_i - \phi_k)\}$$
$$= \psi_i\psi_j\psi_k\psi_m(\partial_m\phi_m)\{(\sigma_{jm}\sigma_{ki} - \sigma_{km}\sigma_{ij})\phi_i + (\sigma_{km}\sigma_{ij} - \sigma_{im}\sigma_{jk})\phi_j + (\sigma_{im}\sigma_{jk} - \sigma_{jm}\sigma_{ki})\phi_k\}. \tag{8}$$

Now let p, where $0 \leqslant p \leqslant 4$, be the number of functions ϕ_i which have constant value everywhere in Ω. Taking into account hypothesis (f) of the theorem, there are five different possibilities to be examined for Eq. (8).

$p=0$, in this case it is straightforward that (8) vanishes if and only if (6) holds.

$p=1$, the analysis and the result are similar to those of the case $p=0$.

$p=2$, assume without loss of generality that ϕ_k and ϕ_m are constant in Ω while ϕ_i and ϕ_j are not. Then expression (8) vanishes if and only if

$$\sigma_{im}\sigma_{jk} - \sigma_{jm}\sigma_{ik} = (\sigma_{im}\sigma_{jk} - \sigma_{ij}\sigma_{km})\phi_k + (\sigma_{ij}\sigma_{km} - \sigma_{im}\sigma_{jk})\phi_m = 0.$$

Given that $\phi_k \neq \phi_m$, these equations are equivalent to (6).

$p=3$, suppose without loss of generality that ϕ_i, ϕ_j, and ϕ_k are constant in Ω, while ϕ_m is not. Then expression (8) is equal to zero if and only if

$$\{(\sigma_{jm}\sigma_{ki} - \sigma_{km}\sigma_{ij})\phi_i + (\sigma_{km}\sigma_{ij} - \sigma_{im}\sigma_{jk})\phi_j + (\sigma_{im}\sigma_{jk} - \sigma_{jm}\sigma_{ki})\phi_k\}\partial_m\phi_m = 0.$$

Taking into account that $\partial_m\phi_m$ does not vanish everywhere in Ω, and that ϕ_i, ϕ_j, and ϕ_k are arbitrary [as far as hypothesis (f) of the theorem is respected] the outcome is again that (6) is necessary and sufficient for the vanishing of (8).

$p=4$, Eqs. (8) vanish because $\partial_m\phi_m=0$ for all possible values of m. This is to be expected because in this case we are dealing with a separable structure.[31]

Then conditions (6) are necessary and sufficient for the vanishing of (8) when $0 \leqslant p \leqslant 3$. For $p=4$ expression (8) is always zero. This concludes the analysis of the case $\eta=1$. Let us now turn to the general form (4) of the solution, namely to general η. To analyze this case, consider an arbitrary four-dimensional skew-symmetric solution $J_{ij}(x)$ of the Jacobi equations. If such solution is multiplied by a $C^1(\Omega)$ function $\eta(x)$ the resulting set of functions $J^*_{ij}(x) = \eta(x)J_{ij}(x)$ will be a skew-symmetric solution of (5) if and only if η verifies

$$(J_{im}J_{jk} + J_{km}J_{ij} + J_{jm}J_{ki})\partial_m\eta = 0, \tag{9}$$

where again (i,j,k,m) denotes every permutation of $(1,2,3,4)$. We now apply condition (9) to the functions J_{ij} in (4) for which $\eta=1$, just considered in the first part of this proof. It can thus be seen that

$$J_{im}J_{jk} + J_{km}J_{ij} + J_{jm}J_{ki} = \psi_i\psi_j\psi_k\psi_m \sum_{p,q,r,s=1}^{4} \phi_q\phi_s\{\sigma_{im}\sigma_{jk}\delta^{jkrs}_{impq} + \sigma_{ij}\sigma_{km}\delta^{ijrs}_{kmpq} + \sigma_{jm}\sigma_{ki}\delta^{kirs}_{jmpq}\}. \tag{10}$$

To evaluate this expression, consider first the cases $0 \leqslant p \leqslant 3$, which are verified if and only if (6) is valid. In such situations Eq. (10) becomes

$$J_{im}J_{jk} + J_{km}J_{ij} + J_{jm}J_{ki} = \psi_i\psi_j\psi_k\psi_m\sigma_{im}\sigma_{jk} \sum_{p,q,r,s=1}^{4} \phi_q\phi_s\{\delta^{jkrs}_{impq} + \delta^{ijrs}_{kmpq} + \delta^{kirs}_{jmpq}\} = 0$$

and the result is demonstrated. For the remaining case $p=4$ it can be seen after some algebra that (10) amounts to

$$J_{im}J_{jk}+J_{km}J_{ij}+J_{jm}J_{ki}=\psi_i\psi_j\psi_k\psi_m\{(\sigma_{im}\sigma_{jk}-\sigma_{jm}\sigma_{ki})(\phi_i\phi_j+\phi_k\phi_m)$$
$$+(\sigma_{ij}\sigma_{km}-\sigma_{im}\sigma_{jk})(\phi_i\phi_k+\phi_j\phi_m)+(\sigma_{jm}\sigma_{ki}-\sigma_{ij}\sigma_{km})(\phi_i\phi_m+\phi_j\phi_k)\}. \tag{11}$$

This expression must vanish everywhere in Ω if (4) is to be a solution for arbitrary η in this case. Since $p=4$ (namely all ϕ_i are constant in Ω) then hypothesis (f) implies that there are two possibilities: either $\phi_i\neq 0$ for every $i=1,\ldots,4$; or $\phi_i=0$ for just one value of i. It can be shown in both situations that (11) vanishes if and only if (6) is verified. Consequently, the inclusion of function η implies that conditions (6) are also necessary and sufficient in the case $p=4$. This completes the proof of Theorem 2.1. Q.E.D.

Therefore the family of Poisson structures just characterized has the matrix form

$$\mathcal{J}=\eta\cdot\begin{pmatrix} 0 & \sigma_{12}\psi_1\psi_2(\phi_4-\phi_3) & \sigma_{13}\psi_1\psi_3(\phi_2-\phi_4) & \sigma_{14}\psi_1\psi_4(\phi_3-\phi_2)\\ \sigma_{12}\psi_1\psi_2(\phi_3-\phi_4) & 0 & \sigma_{23}\psi_2\psi_3(\phi_4-\phi_1) & \sigma_{24}\psi_2\psi_4(\phi_1-\phi_3)\\ \sigma_{13}\psi_1\psi_3(\phi_4-\phi_2) & \sigma_{23}\psi_2\psi_3(\phi_1-\phi_4) & 0 & \sigma_{34}\psi_3\psi_4(\phi_2-\phi_1)\\ \sigma_{14}\psi_1\psi_4(\phi_2-\phi_3) & \sigma_{24}\psi_2\psi_4(\phi_3-\phi_1) & \sigma_{34}\psi_3\psi_4(\phi_1-\phi_2) & 0 \end{pmatrix} \tag{12}$$

where additionally $\sigma_{12}\sigma_{34}=\sigma_{13}\sigma_{24}=\sigma_{14}\sigma_{23}$. For what is to follow, the next definition will be necessary.

Definition 2.2: For every open domain $\Omega\subset\mathbb{R}^4$, the set of Poisson structures defined in Ω and of the kind (4) characterized in Theorem 2.1 will be denoted $\Theta(\Omega)$.

To provide the basis for the analysis of the symplectic structure and Darboux reduction in Sec. III and also in order to complete the description of these structures, the following result is important.

Proposition 2.3: Let $\Omega\subset\mathbb{R}^4$ be an open set, then every Poisson structure $\mathcal{J}\in\Theta(\Omega)$ has constant rank of value 2 everywhere in Ω.

Proof: The determinant of $\mathcal{J}$ in (12) is

$$|\mathcal{J}|=\eta(\psi_1\psi_2\psi_3\psi_4)^2[(\sigma_{14}\sigma_{23}-\sigma_{13}\sigma_{24})(\phi_1\phi_2+\phi_3\phi_4)+(\sigma_{12}\sigma_{34}-\sigma_{14}\sigma_{23})(\phi_1\phi_3+\phi_2\phi_4)$$
$$+(\sigma_{13}\sigma_{24}-\sigma_{12}\sigma_{34})(\phi_1\phi_4+\phi_2\phi_3)]^2.$$

Due to identities (6) the result is that $|\mathcal{J}|=0$. Therefore the rank cannot be 4, but only 2 or 0. The fact that the rank is 2 everywhere in Ω is implied by conditions (c), (e), and (f) of Theorem 2.1. Q.E.D.

Proposition 2.3 provides the basis for the explicit determination of the symplectic structure and Darboux reduction of these structures. This is the purpose of the next section.

III. SYMPLECTIC STRUCTURE AND DARBOUX CANONICAL FORM

Before developing the main issues of this section it is necessary to recall a known definition[38] that will be needed for their establishment.

Definition 3.1: Let $\Omega\subset\mathbb{R}^4$ be an open set. A reparametrization of time is defined as a transformation of the form

$$d\tau=\frac{1}{\mu(x)}dt, \tag{13}$$

where t is the initial time variable, τ is the new time and $\mu(x):\Omega\to\mathbb{R}$ is a $C^1(\Omega)$ function which does not vanish in Ω.

The sense of this definition is the following: let

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \mathcal{J} \cdot \nabla H \tag{14}$$

be an arbitrary four-dimensional Poisson structure defined in an open domain $\Omega \subset \mathbb{R}^4$. Then, every reparametrization of time of the form (13) leads from (14) to the differential system,

$$\frac{\mathrm{d}x}{\mathrm{d}\tau} = \mu \mathcal{J} \cdot \nabla H. \tag{15}$$

Note however that such transformation often destroys the Poisson structure for systems of dimension higher than three,[38] because for a given $\mathcal{J}$ which is a structure matrix, $\mu\mathcal{J}$ is not necessarily a solution of (2) and (3) as it has been discussed in the proof of Theorem 2.1 in connection with the four-dimensional case.

The main purpose of this section is the investigation of the symplectic structure of family $\Theta(\Omega)$. The central result in this sense corresponds to the next theorem, for which the proof is constructive and completely classifies the different cases arising in the explicit determination of the Casimir invariants and the global reduction to the Darboux canonical form for the members of $\Theta(\Omega)$.

Theorem 3.2: For every four-dimensional Poisson system

$$\frac{\mathrm{d}x}{\mathrm{d}t} = \mathcal{J} \cdot \nabla H$$

defined in an open domain $\Omega \subset \mathbb{R}^4$ and such that $\mathcal{J} \in \Theta(\Omega)$, both a complete set of $C^2(\Omega)$ independent Casimir invariants as well as the reduction to the Darboux canonical form, can be globally constructed in Ω.

Proof: The proof begins with an auxiliary result.

Lemma 3.3: Let $\Omega \subset \mathbb{R}^4$ be an open set, then every $\mathcal{J} \in \Theta(\Omega)$ is equivalent to a Poisson structure $\mathcal{J}'$ defined in a domain Ω', of rank constant and equal to 2 in Ω' and components of the form

$$J'_{ij}(y) = \sigma_{ij} \eta'(y) \sum_{k,l=1}^{4} \epsilon_{ijkl} \phi'_l(y_l), \quad i,j = 1, \ldots, 4. \tag{16}$$

Moreover, $\mathcal{J}'$ is obtained through the change of variables globally diffeomorphic in Ω,

$$y_i(x_i) = \int \frac{\mathrm{d}x_i}{\psi_i(x_i)}, \quad i = 1, \ldots, 4 \tag{17}$$

and $\Omega' = y(\Omega)$ is the diffeomorphic image of Ω through transformation (17).

Proof of Lemma 3.3: Recall that after a general diffeomorphism $y = y(x)$, a given structure matrix $\mathcal{J}(x)$ is transformed into another one $\mathcal{J}'(y)$ according to the rule

$$J'_{ij}(y) = \sum_{k,l=1}^{n} \frac{\partial y_i}{\partial x_k} J_{kl}(x) \frac{\partial y_j}{\partial x_l}. \tag{18}$$

The use of (18) with transformation (17) on $\mathcal{J}$ leads to (16) with $\eta'(y) = \eta(x(y))$ and $\phi'_i(y) = \phi_i(x(y))$ for $i = 1, \ldots, 4$. The fact that the rank of (16) is constant and of value 2 everywhere in Ω' is a direct consequence of Proposition 2.3 and identity (18). Q.E.D.

The Poisson structure (16) will be the starting point for the rest of the proof. Now two complementary cases are to be distinguished.

Case I: $\sigma_{ij} \neq 0$ for all pairs (i,j), $i \neq j$. The analysis of this case must begin with a definition and some preliminary results.

Definition 3.4: Given an open set $\Omega \subset \mathbb{R}^4$, a Poisson structure belonging to $\Theta(\Omega)$ is said to be σ-positive if all its constants σ_{ij} can be chosen to be positive, where $i,j = 1, \ldots, 4$ and $i \neq j$.

Lemma 3.5: Let $\Omega \subset \mathbb{R}^4$ be an open set, and let $\mathcal{J} \in \Theta(\Omega)$ be a Poisson structure for which $\sigma_{ij} \neq 0$ for every pair $i \neq j$, where $i,j=1,\ldots,4$. Then $\mathcal{J}$ is σ-positive and can be expressed in terms of the set of constants $\tilde{\sigma}_{ij}=|\sigma_{ij}|$.

Proof of Lemma 3.5: From now on, we define $\sigma \equiv \sigma_{12}\sigma_{34}=\sigma_{13}\sigma_{24}=\sigma_{14}\sigma_{23}$ [recall Eq. (6)]. Four main cases can be distinguished.

Case 1: $\sigma_{ij}>0$ for all $i \neq j$. The matrix is already in σ-positive form.

Case 2: $\sigma_{ij}<0$ for all $i \neq j$. This is reduced to Case 1 by redefining $\phi_i(x_i)$ as $\tilde{\phi}_i(x_i)=-\phi_i(x_i)$ for every i.

Case 3: $\sigma>0$ with constants σ_{ij} both positive and negative. There are two subcases.

Case 3.1: There are two negative and four positive constants σ_{ij} with $i<j$.

Case 3.1.1: $\sigma_{12}<0$ and $\sigma_{34}<0$.

Case 3.1.2: $\sigma_{13}<0$ and $\sigma_{24}<0$.

Case 3.1.3: $\sigma_{14}<0$ and $\sigma_{23}<0$.

The three subcases 3.1.x are reduced in two steps.

Step 1: redefine $\phi_i(x_i)$ as $\tilde{\phi}_i(x_i)=-\phi_i(x_i)$ for every i.

Step 2: redefine $\psi_i(x_i)$ as $\tilde{\psi}_i(x_i)=-\psi_i(x_i)$ for $i=3,4$ in subcase 3.1.1, for $i=1,3$ in subcase 3.1.2 and for $i=1,4$ in subcase 3.1.3.

Case 3.2: There are two positive and four negative constants σ_{ij} with $i<j$. These are three possible cases that coincide with the ones appearing after step 1 of items 3.1.1, 3.1.2, and 3.1.3 and therefore their reduction corresponds to the transformations indicated in step 2 of those three subcases.

Case 4: $\sigma<0$. Clearly it can be assumed without loss of generality that $\sigma_{12}<0$. Then there are four possibilities.

Case 4.1: $\sigma_{13}<0$ and $\sigma_{14}<0$. Redefining $\tilde{\psi}_1(x_1)=-\psi_1(x_1)$ it is reduced to Case 1.

Case 4.2: $\sigma_{13}>0$ and $\sigma_{14}>0$. Redefining $\tilde{\psi}_2(x_2)=-\psi_2(x_2)$ it is reduced to Case 1.

Case 4.3: $\sigma_{13}>0$ and $\sigma_{14}<0$. Redefining $\tilde{\psi}_3(x_3)=-\psi_3(x_3)$ it is reduced to Case 2.

Case 4.4: $\sigma_{13}<0$ and $\sigma_{14}>0$. Redefining $\tilde{\psi}_4(x_4)=-\psi_4(x_4)$ it is reduced to Case 2.

This completes the proof of Lemma 3.5. Q.E.D.

A result that complements the last lemma is the next one.

Lemma 3.6: For every set of positive real constants $\{\sigma_{12},\sigma_{13},\sigma_{14},\sigma_{23},\sigma_{24},\sigma_{34}\}$ verifying conditions (6) there exists a unique set of positive real constants $\{\sigma_1,\sigma_2,\sigma_3,\sigma_4\}$ such that the equalities $\sigma_{ij}=\sigma_i\sigma_j$ are satisfied for every pair (i,j), with $i<j$, $1 \leqslant i \leqslant 3$, $2 \leqslant j \leqslant 4$.

Proof of Lemma 3.6: The existence of the constants σ_i can be seen on their explicit expressions

$$\sigma_1=\left(\frac{\sigma_{12}\sigma_{13}\sigma_{14}}{\sigma}\right)^{1/2}, \quad \sigma_2=\left(\frac{\sigma\sigma_{12}}{\sigma_{13}\sigma_{14}}\right)^{1/2}, \quad \sigma_3=\left(\frac{\sigma\sigma_{13}}{\sigma_{12}\sigma_{14}}\right)^{1/2}, \quad \sigma_4=\left(\frac{\sigma\sigma_{14}}{\sigma_{12}\sigma_{13}}\right)^{1/2},$$

where now $\sigma>0$. To prove uniqueness, taking logarithms of equalities $\sigma_{ij}=\sigma_i\sigma_j$ allows reducing the problem to the investigation of the following linear system:

$$\begin{pmatrix} 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 \\ 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \end{pmatrix} \cdot \begin{pmatrix} \ln \sigma_1 \\ \ln \sigma_2 \\ \ln \sigma_3 \\ \ln \sigma_4 \end{pmatrix} = \begin{pmatrix} \ln \sigma_{12} \\ \ln \sigma_{13} \\ \ln \sigma_{14} \\ \ln \sigma - \ln \sigma_{14} \\ \ln \sigma - \ln \sigma_{13} \\ \ln \sigma - \ln \sigma_{12} \end{pmatrix}. \tag{19}$$

Then the application of the Rouché-Fröbenius theorem shows that system (19) has a unique solution for $\{\sigma_1,\sigma_2,\sigma_3,\sigma_4\}$ and the result is demonstrated. Q.E.D.

Therefore notice that in Case I, Lemma 3.5 can be used to assume that all the $\sigma_{ij}>0$. Moreover, Lemma 3.6 can also be employed to write $\sigma_{ij}=\sigma_i\sigma_j$ in every case. Then from (16) we have the following type of Poisson matrix:

$$J'_{ij}(y)=\sigma_i\sigma_j\eta'(y)\sum_{k,l=1}^{4}\epsilon_{ijkl}\phi'_l(y_l),\quad i,j=1,\ldots,4 \tag{20}$$

with $\sigma_i>0$ for $i=1,\ldots,4$. We can now state.

Lemma 3.7: For an open set $\Omega\subset\mathbb{R}^4$, assume that $\mathcal{J}\in\Theta(\Omega)$ is equivalent after transformation (17) to a Poisson structure $\mathcal{J}'$ of the form (20) defined in $y(\Omega)=\Omega'\subset\mathbb{R}^4$ and such that $\sigma_i>0$ for $i=1,\ldots,4$. Then a complete set of independent Casimir invariants of such Poisson structure $\mathcal{J}'$ which are globally defined in Ω' and $C^2(\Omega')$ is given by

$$C_1(y)=\sigma_2\sigma_3\sigma_4y_1+\sigma_1\sigma_3\sigma_4y_2+\sigma_1\sigma_2\sigma_4y_3+\sigma_1\sigma_2\sigma_3y_4, \tag{21}$$

$$C_2(y)=\sigma_1\sigma_2\sigma_3\sigma_4\sum_{i=1}^{4}\int\frac{\phi_i(y_i)}{\sigma_i}\mathrm{d}y_i. \tag{22}$$

Proof of Lemma 3.7: It is an application of the Pfaffian method.[26] Q.E.D.

We can then proceed to the reduction to the Darboux canonical form in Case I. For this, consider the following change of variables globally diffeomorphic in Ω':

$$\{z_1=y_1,\ z_2=y_2,\ z_3=C_1(y),\ z_4=C_2(y)\}, \tag{23}$$

where $C_1(y)$ and $C_2(y)$ are those in (21) and (22). When the transformation rule (18) is applied for (23) to matrix (20) the result is

$$\mathcal{J}'(z)=\eta''(z)\cdot\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix} \tag{24}$$

which is defined in $\Omega''=z(\Omega')$, and where $\eta''(z)=\sigma_1\sigma_2\eta'(y(z))(\phi'_4(y(z))-\phi'_3(y(z)))$. To conclude, the reduction to the Darboux canonical form is achieved making use of Definition 3.1 to perform a time reparametrization of the form (13), namely $\mathrm{d}\tau=\eta''(z)\mathrm{d}t$, where τ is the new time and $\eta''(z)$ is clearly nonvanishing in Ω'' and $C^1(\Omega'')$. According to (14) and (15) the result is a new Poisson system with Darboux-type structure matrix,

$$\mathcal{J}_D=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix}. \tag{25}$$

The reduction is thus globally completed in Case I.

Case II: $\sigma_{ij}=0$ for some pair (i,j), $i\neq j$. Again matrix (16) is our starting point. Now notice that $\sigma=0$ and as a consequence of conditions (6) we actually have $\sigma_{ij}=0$ for at least three of the six pairs (i,j), with $i<j$, $1\leqslant i\leqslant 3$, $2\leqslant j\leqslant 4$. This leads to eight possible subcases,

$$\{(\text{II.A.1:}\quad \sigma_{14}=\sigma_{24}=\sigma_{34}=0),\quad (\text{II.A.2:}\quad \sigma_{12}=\sigma_{13}=\sigma_{14}=0),$$

$$(\text{II.A.3:}\quad \sigma_{12}=\sigma_{23}=\sigma_{24}=0),\quad (\text{II.A.4:}\quad \sigma_{13}=\sigma_{23}=\sigma_{34}=0),$$

$$(\text{II.B.1:}\quad \sigma_{13}=\sigma_{14}=\sigma_{34}=0),\quad (\text{II.B.2:}\quad \sigma_{12}=\sigma_{13}=\sigma_{23}=0),$$

$$(\text{II.B.3:}\quad \sigma_{12}=\sigma_{14}=\sigma_{24}=0),\quad (\text{II.B.4:}\quad \sigma_{23}=\sigma_{24}=\sigma_{34}=0). \tag{26}$$

As it can be seen, these subcases are grouped in two different four-member sets (II.A and II.B). The four members of each set present analogous symplectic structures and similar reduction procedures to Darboux form. Let us start with the II.A possibilities:

Lemma 3.8: For an open set $\Omega\subset\mathbb{R}^4$, assume that $\mathcal{J}\in\Theta(\Omega)$ is equivalent after transformation (17) to a Poisson structure $\mathcal{J}'$ of the form (16) defined in $y(\Omega)=\Omega'\subset\mathbb{R}^4$ and corresponding to one of the subcases II.A.1 to II.A.4 in (26). Then a complete set of independent Casimir invariants of such Poisson structure $\mathcal{J}'$ which are globally defined in Ω' and $C^2(\Omega')$ is, respectively,

$$\text{II.A.1:}\quad C_1(y)=y_4$$

$$C_2(y)=\sigma_{23}\int\phi_1(y_1)\mathrm{d}y_1+\sigma_{13}\int\phi_2(y_2)\mathrm{d}y_2+\sigma_{12}\int\phi_3(y_3)\mathrm{d}y_3$$

$$-(\sigma_{23}y_1+\sigma_{13}y_2+\sigma_{12}y_3)\phi_4(y_4);$$

$$\text{II.A.2:}\quad C_1(y)=y_1,$$

$$C_2(y)=\sigma_{34}\int\phi_2(y_2)\mathrm{d}y_2+\sigma_{24}\int\phi_3(y_3)\mathrm{d}y_3+\sigma_{23}\int\phi_4(y_4)\mathrm{d}y_4$$

$$-(\sigma_{34}y_2+\sigma_{24}y_3+\sigma_{23}y_4)\phi_1(y_1);$$

$$\text{II.A.3:}\quad C_1(y)=y_2,$$

$$C_2(y)=\sigma_{34}\int\phi_1(y_1)\mathrm{d}y_1+\sigma_{14}\int\phi_3(y_3)\mathrm{d}y_3+\sigma_{13}\int\phi_4(y_4)\mathrm{d}y_4$$

$$-(\sigma_{34}y_1+\sigma_{14}y_3+\sigma_{13}y_4)\phi_2(y_2);$$

$$\text{II.A.4:}\quad C_1(y)=y_3,$$

$$C_2(y)=\sigma_{24}\int\phi_1(y_1)\mathrm{d}y_1+\sigma_{14}\int\phi_2(y_2)\mathrm{d}y_2+\sigma_{12}\int\phi_4(y_4)\mathrm{d}y_4$$

$$-(\sigma_{24}y_1+\sigma_{14}y_2+\sigma_{12}y_4)\phi_3(y_3).$$

Proof of Lemma 3.8: It is similar to the one of Lemma 3.7. Q.E.D.

We carry out now the reduction to the Darboux canonical form for subcase II.A. For the sake of conciseness this will be done for the first possibility II.A.1, since the procedure is entirely analogous for the remaining situations II.A.2 to II.A.4. Thus for II.A.1 the following change of variables globally diffeomorphic in Ω' is defined

$$\{v_1=y_1,\ v_2=y_2,\ v_3=C_2(y),\ v_4=C_1(y)\}, \tag{27}$$

where $C_1(y)$ and $C_2(y)$ are those in Lemma 3.8 for subcase II.A.l and according to hypothesis (c) of Theorem 2.1 it is assumed $\sigma_{12}\neq 0$ without loss of generality. Applying (18) and (27) to such structure matrix it is again obtained a Poisson structure of the form $\mathcal{J}''(v)=\eta''(v)$. $\mathcal{J}_D$ defined in $v(\Omega')$, where now $\eta''(v)=\sigma_{12}\eta'(y(v))(\phi_4'(y(v))-\phi_3'(y(v)))$ and $\mathcal{J}_D$ is given in (25). The reduction

is concluded by means of a time reparametrization (13) of the form $\mathrm{d}\tau = \eta''(v)\mathrm{d}t$, where $\eta''(v)$ is nonvanishing in $v(\Omega')$ and $C^1(v(\Omega'))$. The result is thus a Poisson system with structure matrix (25) and the reduction is globally completed.

Consider the next subcases II.B in (26). For each of them both generic and nongeneric possibilities must be distinguished, according to the following definition.

Definition 3.9: Given a Poisson structure of the kind (16) characterized in Lemma 3.3 and corresponding to one of the subcases II.B.l to II.B.4 in (26), such structure will be called generic if only three of the six constants σ_{ij} vanish, for $i<j$, $1\leqslant i\leqslant 3$, $2\leqslant j\leqslant 4$, while if four or five of such constants are zero the same type of structures will be termed nongeneric.

Obviously the case in which all constants σ_{ij} vanish is excluded due to condition (c) of Theorem 2.1. Now the generic II.B subcases will be treated first. For them we have the following result.

Lemma 3.10: For an open set $\Omega\subset\mathbb{R}^4$, assume that $\mathcal{J}\in\Theta(\Omega)$ is equivalent after transformation (17) to a Poisson structure $\mathcal{J}'$ of the form (16) defined in $y(\Omega)=\Omega'\subset\mathbb{R}^4$ and corresponding to one of the generic subcases II.B.l to II.B.4 in (26). Then a complete set of independent Casimir invariants of such Poisson structure $\mathcal{J}'$ which are globally defined in Ω' and $C^2(\Omega')$ is, respectively,

$$\text{II.B.1:}\quad C_1(y)=\sigma_{23}\sigma_{24}y_1+\sigma_{12}\sigma_{24}y_3+\sigma_{12}\sigma_{23}y_4,$$

$$C_2(y)=\sigma_{23}\sigma_{24}\int\phi_1(y_1)\mathrm{d}y_1+\sigma_{12}\sigma_{24}\int\phi_3(y_3)\mathrm{d}y_3+\sigma_{12}\sigma_{23}\int\phi_4(y_4)\mathrm{d}y_4;$$

$$\text{II.B.2:}\quad C_1(y)=\sigma_{24}\sigma_{34}y_1+\sigma_{14}\sigma_{34}y_2+\sigma_{14}\sigma_{24}y_3,$$

$$C_2(y)=\sigma_{24}\sigma_{34}\int\phi_1(y_1)\mathrm{d}y_1+\sigma_{14}\sigma_{34}\int\phi_2(y_2)\mathrm{d}y_2+\sigma_{14}\sigma_{24}\int\phi_3(y_3)\mathrm{d}y_3;$$

$$\text{II.B.3:}\quad C_1(y)=\sigma_{23}\sigma_{34}y_1+\sigma_{13}\sigma_{34}y_2+\sigma_{13}\sigma_{23}y_4,$$

$$C_2(y)=\sigma_{23}\sigma_{34}\int\phi_1(y_1)\mathrm{d}y_1+\sigma_{13}\sigma_{34}\int\phi_2(y_2)\mathrm{d}y_2+\sigma_{13}\sigma_{23}\int\phi_4(y_4)\mathrm{d}y_4;$$

$$\text{II.B.4:}\quad C_1(y)=\sigma_{13}\sigma_{14}y_2+\sigma_{12}\sigma_{14}y_3+\sigma_{12}\sigma_{13}y_4,$$

$$C_2(y)=\sigma_{13}\sigma_{14}\int\phi_2(y_2)\mathrm{d}y_2+\sigma_{12}\sigma_{14}\int\phi_3(y_3)\mathrm{d}y_3+\sigma_{12}\sigma_{13}\int\phi_4(y_4)\mathrm{d}y_4.$$

Proof of Lemma 3.10: It is similar to the one of Lemma 3.7. Q.E.D.

Regarding the reduction to the Darboux canonical form for the generic II.B subcases, possibility II.B.1 will be the only one explicitly considered, since again the procedure is completely analogous for the other cases II.B.2 to II.B.4. Then for II.B.1 (generic) the transformation globally diffeomorphic in Ω' to be performed is

$$\{w_1=y_1,\ w_2=y_2,\ w_3=C_1(y),\ w_4=C_2(y)\},\tag{28}$$

where $C_1(y)$ and $C_2(y)$ are those in Lemma 3.10 for II.B.1. Once (28) is defined, the rest of the reduction for the generic II.B.1 case is entirely similar to that of subcase II.A.1.

The only remaining situations are the nongeneric II.B subcases. The results to be presented are completely analogous for the four possibilities II.B.1 to II.B.4, and consequently we shall only deal explicitly with II.B.1 for the sake of brevity. For this, notice that there are two possible nongeneric situations for II.B.1.

II.B.1.a: One of $\{\sigma_{12},\sigma_{23},\sigma_{24}\}$ vanishes. These three subcases are retrieved as particular instances of the II.A cases already analyzed, in such a way that the complete set of independent Casimir invariants and the reduction to the Darboux canonical form are also obtained as particular results of the ones given for II.A. Specifically, we may have

(i) $\sigma_{12}=0$: Such matrix is a particular case of II.A.2 in which $\sigma_{34}=0$.
(ii) $\sigma_{23}=0$: This is a particular case of II.A.4 with $\sigma_{14}=0$.
(iii) $\sigma_{24}=0$: It is a particular case of II.A.1 with $\sigma_{13}=0$.

II.B.1.b: Two of $\{\sigma_{12},\sigma_{23},\sigma_{24}\}$ vanish. Then the Casimir invariants are apparent and only a time reparametrization remains in order to reduce the Poisson system to Darboux form.

The classification is similar for the nongeneric II.B.2 to II.B.4 possibilities. Case II is thus concluded.

The demonstration of Theorem 3.2 is therefore complete. Q.E.D.

Thus not only the Poisson structures considered but also their possible kinds of Casimir invariants and global reductions to the Darboux canonical form are completely characterized after the previous results. Once the main properties have been considered in detail, it is interesting to put in perspective the family just analyzed, as far as it is closely related to other Poisson structures reported in the literature. This is the aim of the next part of the work.

IV. EXAMPLES AND RELATIONSHIP WITH OTHER SOLUTIONS

In this section the relationship of the family of solutions investigated with some other well-known Poisson structures is briefly explored. This is useful not only because the family of form (4) characterized in Theorem 2.1 provides a generalization of other structures or families of structures to be mentioned, but also because pointing up the intersections among different families should be helpful for future investigations regarding the Jacobi equations. Additionally, such illustrations provide interesting examples of the solutions analyzed throughout the paper.

Consider first the particular case of members of $\Theta(\Omega)$ for which functions $\eta(x)$ and $\phi_i(x_i)$ $(i=1,\ldots,4)$ have constant values. The result is always a separable Poisson structure,[31] namely a structure matrix of the form $J_{ij}=a_{ij}\psi_i(x_i)\psi_j(x_j)$, where the a_{ij} are real constants that constitute the entries of a skew-symmetric matrix $A=(a_{ij})$, and the $\psi_i(x_i)$ are nonvanishing $C^1(\Omega)$ functions. Recall that separable matrices are always solutions of the Jacobi equations (2) and (3) independently of the dimension of the Poisson manifold.[31] There are several interesting kinds of Poisson systems for which separable structures are natural in general dimension n, and consequently in the specific case of dimension $n=4$. This is the case of Poisson models arising in the domain of population dynamics (for either Lotka-Volterra[11] or generalized Lotka-Volterra[8] systems), plasma models[19] and systems such as the Toda and relativistic Toda lattices.[15] The interested reader is referred to the primary reference for further examples and the full details regarding issues such as the determination of the Casimir invariants and the reduction to the Darboux canonical form for separable Poisson structures.[31] Note in addition that according to Proposition 2.3 the structures belonging to $\Theta(\Omega)$ have constant rank of value 2 everywhere in Ω, while the rank of a separable matrix is the rank of A. Then it is interesting to remark that the particular case in which η and ϕ_i $(i=1,\ldots,4)$ are constant does not comprise all possible four-dimensional separable matrices but only separable structures of rank two, thus illustrating an intersection between two known families of Poisson structures.

As a second example, consider the limit case in which the functions $\psi_4(x_4)=\phi_4(x_4)=0$ are considered in (12). In the resulting Poisson structure, it is clear that x_4 is a Casimir function. Then if a reduction is carried out to the symplectic leaf $x_4=c$, the outcome is the $3d$ Poisson structure of matrix:

$$\mathcal{J}_{[3d]} = \tilde{\eta} \cdot \begin{pmatrix} 0 & \psi_1\psi_2\tilde{\phi}_3 & -\psi_1\psi_3\tilde{\phi}_2 \\ -\psi_1\psi_2\tilde{\phi}_3 & 0 & \psi_2\psi_3\tilde{\phi}_1 \\ \psi_1\psi_3\tilde{\phi}_2 & -\psi_2\psi_3\tilde{\phi}_1 & 0 \end{pmatrix}, \tag{29}$$

where $\tilde{\eta}(x_1,x_2,x_3)=\eta(x_1,x_2,x_3,c)$ and $\tilde{\phi}_i=\sigma_{jk}\phi_i$ for $i=1,2,3$, where (i,j,k) denotes an arbitrary permutation of $(1,2,3)$. Dropping the tildes for the sake of clarity, the resulting structures can also be expressed as

$$(\mathcal{J}_{[3d]})_{ij}(x_1,x_2,x_3) = \eta(x_1,x_2,x_3)\psi_i(x_i)\psi_j(x_j)\sum_{k=1}^{3}\epsilon_{ijk}\phi_k(x_k), \quad i,j=1,2,3. \tag{30}$$

Poisson structures of the form (29) and (30) have been studied in detail in the literature,[38] and actually they comprise as particular cases very different Poisson matrices employed before in several domains, including the Euler top,[2] the Kermack-McKendrick model,[10,37] certain integrable cases of the Lorenz system,[20] population models such as those of Lotka-Volterra[9,11,37] and generalized Lotka-Volterra[8] types, the Maxwell-Bloch equations,[27] the Rabinovich system,[20] or the RTW interaction equations.[20] A discussion of these particular instances as well as an analysis of structures (29) and (30) including their symplectic structure, Casimir invariants and construction of the Darboux coordinates are present in the aforementioned reference.[38] Such family is also interesting from the point of view of the separable structures considered in the first part of this section, since it is evident that all three-dimensional separable structures are particular cases of (30).

It can be thus appreciated how the identification of the solutions characterized in Theorem 2.1 leads to the establishment of some new links among different families of Poisson structures.

V. FINAL REMARKS

Every new contribution to the study of skew-symmetric solutions of the Jacobi equations tends to provide a more general perspective of the field of finite-dimensional Poisson structures. Typical features of this fact can be appreciated in the previous analysis. Not only the identification of finite-dimensional Poisson structures constitutes in itself a relevant problem from the point of view of mathematical physics, but in addition this knowledge provides a richer framework for the fundamental problem of recasting a given differential flow into a Poisson system, whenever possible. Additionally, it is worth noting that the characterization of a sufficiently general solution family often allows the conceptual and operational unification of diverse Poisson structures and systems previously well-known but unrelated, which can hereafter be regarded from a more general and economic standpoint. Examples of this have been given in Sec. IV. In particular, in such sense it is physically interesting to identify the Casimir invariants and to develop the reduction procedure to the Darboux canonical form for the solution families. These are features of special relevance when they can be globally achieved, thus providing an additional instance of a result that goes beyond the *a priori* scope of Darboux theorem and has been reported only in a limited number of cases. This kind of results suggests that the direct investigation of the Jacobi equations constitutes a fruitful line of research not only for classification purposes but also for the detailed analysis of Poisson structures, not to mention its mathematical interest as an example of nonlinear system of PDEs. Additionally to these considerations, it is worth recalling that dimension three is the simplest nontrivial case for the analysis of the Jacobi equations and has consequently been studied in much more detail than higher dimensions, as discussed in the Introduction. On the other hand, Jacobi equations (3) become increasingly complicated as dimension grows. This explains the relative scarcity of results for dimensions four and higher. Certainly, a complete knowledge of the skew-symmetric solutions of the Jacobi equations is still far, but nevertheless the investigation of the problem seems to be a unavoidable issue for a better understanding of finite-dimensional Poisson structures, and therefore of the scope of Hamiltonian dynamics.

(Received 10 November 2005; accepted 12 December 2005; published online 14 February 2006)

It is well known that nonholonomic systems obeying D'Alembert's principle are described on the Hamiltonian side, after using the Legendre transformation, by the so-called almost-Poisson brackets. In this paper we define the Lagrangian and Hamiltonian sides of a class of generalized nonholonomic systems (GNHS), obeying a generalized version of D'Alembert's principle, such as rubber wheels (like some simplified models of pneumatic tires) and certain servomechanisms (like the controlled inverted pendulum), and show that corresponding equations of motion can also be described in terms of a bracket. We present *essentially all* possible brackets in terms of which the mentioned equations can be written down, which include the brackets that appear in the literature, and point out those (if any) that are *naturally* related to each system. In particular, we show there always exists a Leibniz bracket related to a GNHS, and conversely, that every Leibniz system is a GNHS. The control of the inverted pendulum on a cart is studied as an illustrative example. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2165797]

I. INTRODUCTION

In the framework of constrained mechanical systems, recent works[1–3] have pointed out (in a more or less independent way) that, in order to find the trajectories of the system, *kinematic constraints* itself do not provide (in general) all the needed information, but, in addition, the space of possible values of the *constraint forces* (or some equivalent information) must also be specified. The problem has been analyzed from a Hamiltonian point of view in Refs. 1 and 2, and from a Lagrangian one in Ref. 3. The last reference has adopted a variational-like formulation, where such an additional information is given in terms of the space of possible values of variations. The latter is defined, essentially, by a distribution on the configuration space of the system: the so-called *variational constraints*. Possible values of constraint forces correspond to the annihilator of such a distribution, given rise in this way to a generalized version of the *Principle of Virtual Works*.

For systems with linear nonholonomic (and even with affine) constraints in the velocities, the above-mentioned additional data is usually supplied by the *D'Alembert's principle*, which has been the purpose of an extensive research for more than a century.[4–19] In such cases, kinematic constraints are determined by a distribution on the configuration space Q, and D'Alembert's principle says that variational constraints are given precisely by the same distribution. In other words, we can derive variational constrains from the kinematic ones by using this principle. Accordingly, in some sense, no additional information is needed in that situation. For general nonlinear constraints in the velocities,[20] given by submanifolds of TQ, and also for higher order constraints,[21,22] defined by submanifolds of higher order tangent bundles $T^{(k)}Q$,[23,24] the "natural" generalization of D'Alembert's principle is the so-called *Chetaev's rule* or *principle*.[25–27]

Unfortunately, as it has been shown in Marle's work[2] for servomechanisms, and in the work of Cendra *et al.*[3] for some simplified models of pneumatic tires[28–30] (which include, in some cases, higher order constraints), these principles do not always lead us to the correct equations of motion. That is to say, variational constraints derived from kinematic ones by using D'Alembert's or Chetaev's principle (depending on the form of involved kinematic constraints) give rise, in general, to wrong equations. In these cases we say the system does not satisfy D'Alembert's or Chetaev's principle. As a conclusion, kinematic and variational constraints must be taken as independent notions, and one should not attempt to derive, for instance, variational from kinematic constraints by a universal procedure.

It is worth mentioning that applicability of the above principles does not depend on the form of kinematic constraints alone, but on the way they are implemented by the constraint forces in each case: different procedures to realize the same kinematic constraints give rise to different dynamical systems.

One of the aims of the present work is to define and study a subclass of the systems presented in Ref. 3, which we shall call *generalized nonholonomic systems* (GNHS), and propose, by using the Legendre transformation, a Hamiltonian description of them. Such systems are essentially nonholonomic systems that do not necessarily satisfy D'Alembert's or Chetaev's principle. In this way, we compare the Lagrangian approach of Ref. 3 and the Hamiltonian one developed in Ref. 2. All that is contained in Sec. II.

We also start on the Hamiltonian side and define a generalized notion of a constrained Hamiltonian system (which we also call GNHS), following Marle's work, going beyond the case of Hamiltonian systems obtained by a Legendre transformation. We study existence and uniqueness conditions for related equations of motion. We define in this scenario the D'Alembert's and Chetaev's distributions, in order to introduce there the notions of D'Alembert's and Chetaev's principles, respectively. This is done in Sec. III.

In Sec. IV we develop the main aim of the paper: to obtain a bracket description of GNHS. More precisely, we write the equations of motion for such systems in terms of a bracket defined on the constraints submanifold. We present, in essence, *all* possible brackets that can be used to describe dynamic of each GNHS, which includes the brackets that appear in the literature, and point out those that are *naturally* related to such systems. In some cases these brackets turn out to be *Leibniz brackets*[31,32] and even *almost-Poisson brackets*.[2,8,9,33] However, we also consider cases in which the resulting brackets are nonlinear in one of its arguments. We give a local procedure to build up such brackets in the linear and affine cases.

On the other hand, we show that there always exists a Leibniz bracket in terms of which equations of motion can be written down. Conversely, we show that every Leibniz system can be described as the Hamiltonian formulation of a GNHS.

An interesting example from control theory, that we study all along the paper, is the inverted pendulum on a cart. We give the Lagrangian and Hamiltonian formulations, and built up the related bracket, for the control strategies developed in Refs. 2 and 34. In particular, we show how the idea of *virtual constraints*, presented in Ref. 34, can be naturally described in terms of GNHS.

II. GENERALIZED NONHOLONOMIC SYSTEMS

Let Q be an n-dimensional manifold, the *configuration space*. As usual, let us indicate by q^i a local coordinate system of Q, and by $(q^i,\dot{q}^i)$ [or $(q^i,\delta q^i)$] the induced one on TQ. We shall often omit indices.

Let us consider a triple (L,C_K,C_V) with

(i) $L:TQ\to\mathbb{R}$ a function: the *Lagrangian function*.
(ii) $C_K\subset TQ$ a submanifold: the kinematic constraints. We shall often assume that the equality $\tau(C_K)=Q$ holds, being $\tau:TQ\twoheadrightarrow Q$ the canonical projection of the tangent bundle.
(iii) C_V another submanifold: the variational constraints. Its elements will be called variations or virtual displacements. We consider two kinds of C_V:

$$C_V\subset TQ \quad \text{or} \quad C_V\subset C_K\times_Q TQ.$$

In the first case we ask C_V to be a distribution. For the second case we ask, for each $q \in \tau(C_K)$,

(i) the subsets

$$C_V[v] = C_V \cap (\{v\} \times T_qQ)$$

should be nonvoid for all $v \in C_K$ such that $\tau(v)=q$,

(ii) identifying in a natural way $C_V[v]$ with a subset of T_qQ, as we will do from now on, we also ask $C_V[v]$ to be a linear subspace with the same dimension for all $v \in C_K$.

We can think of C_K and C_V, at least locally, as being subsets

$$C_K = \{(q,\dot{q}) : R_K(q,\dot{q}) = 0\}$$

and (sum over repeated indices convention is assumed from now on)

$$C_V = \{(q,\delta q) : R_{V,i}(q)\,\delta q^i = 0\}, \tag{1}$$

or

$$C_V = \{(q,\dot{q},\delta q) : R_K(q,\dot{q}) = 0 \text{ and } R_{V,i}(q,\dot{q})\,\delta q^i = 0\}, \tag{2}$$

being R_K and each $R_{V,i}$ vector valued differentiable functions. If C_K is given by a family R_K^a of real valued functions, the condition $\tau(C_K)=Q$ is equivalent to the condition that the matrix $\partial R_K^a / \partial \dot{q}^j$ has maximal rank.

Definition 1: *We call a triple* (L, C_K, C_V) *a generalized nonholonomic system* (*GNHS*), *and we say that a curve* $q:[t_1,t_2] \to Q$ *is a trajectory of the system if its velocity belongs to* C_K *and if, in addition, it is a critical point of the action, i.e.*,

$$\delta \int_{t_1}^{t_2} L \, \mathrm{d}t = 0,$$

for variations restricted to C_V.

In other words, $q(t)$ is a trajectory of (L, C_K, C_V) if $(q(t), \dot{q}(t)) \in C_K$, and for all variations $\delta q(t)$ such that, depending on the case,

$$(q(t), \delta q(t)) \quad \text{or} \quad (q(t), \dot{q}(t), \delta q(t))$$

belongs to C_V, we have

$$\left(\frac{d}{\mathrm{d}t}\left(\frac{\partial L(q(t),\dot{q}(t))}{\partial \dot{q}^i} \right) - \frac{\partial L(q(t),\dot{q}(t))}{\partial q^i} \right) \delta q^i(t) = 0. \tag{3}$$

In abbreviated form, equations of motions can be written

$$\left(\frac{d}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{q}^i} \right) - \frac{\partial L}{\partial q^i} \right) \delta q^i = 0, \quad (q,\dot{q}) \in C_K, \quad \begin{cases} (q,\delta q) \in C_V, \\ (q,\dot{q},\delta q) \in C_V. \end{cases} \tag{4}$$

Now it is clear why C_K and C_V are called kinematic and variational constraints, respectively.

Remark 2: *It is easy to prove that, a GNHS* (L, C_K, C_V) *with* $C_V \subset TQ$ *and the related system with triple* $(L, C_K, C_K \times_Q C_V)$ (*corresponding to the second kind*) *are equivalent, in the sense that they have the same set of trajectories. This would enable us to describe all GNHS as belonging to the second kind. However, we prefer to deal with these two kinds of variational constraints separately, in order to appreciate the particular formulas that appears in each situation.*

Remark 3: *We may consider a given* C_V *of the second kind as being a submanifold of the Whitney sum* $TQ \oplus TQ$ *instead of* $C_K \times_Q TQ$. *But, as it can be easily shown, only the part included in* $C_K \times_Q TQ$ *would be relevant to describe the dynamic of the system.*

Constraint forces: Related to C_V we have a submanifold F_V, the *constraint forces space*:

(1) For a constraint $C_V \subset TQ$ of the first kind we define $F_V \subset T^*Q$ as being the codistribution given by the annihilator of C_V, i.e., $F_V = C_V^o$.
(2) For a constraint of the second kind $C_V \subset C_K \times_Q TQ$ we define

$$F_V \subset C_K \times_Q T^*Q$$

such that subsets

$$F_V[v] = F_V \cap (\{v\} \times T_q^*Q)$$

are given by the annihilator of $C_V[v]$ for all $v \in C_K$.

For short, we shall say that F_V is the annihilator of C_V, and write $F_V = C_V^o$ and $F_V^o = C_V$. In local terms [see Eqs. (1) and (2)]

$$F_V = \{(q,f): f_i = \lambda_a R_{V,i}^a(q); \lambda \in \mathbb{R}\}$$

or

$$F_V = \{(q,\dot{q},f): R_K(q,\dot{q}) = 0 \quad and \quad f_i = \lambda_a R_{V,i}^a(q,\dot{q}); \lambda \in \mathbb{R}\}.$$

In order to clarify the meaning of F_V, let us rewrite Eq. (3) as

$$\langle f, \delta q \rangle = f_i \delta q^i = 0 \tag{5}$$

for quantities

$$f_i = \frac{d}{dt}\left(\frac{\partial L}{\partial \dot{q}^i}\right) - \frac{\partial L}{\partial q^i}.$$

Then, f_i must define a covector f that belongs to the annihilator of C_V, i.e.,

$$(q(t), \dot{q}(t), f(t)) \in C_V^o = F_V.$$

Since in the Lagrangian formalism f represents constraint forces, the meaning of the submanifold F_V is now clear. Going back to Eq. (5), we have a generalized version of the *Principle of Virtual Work: constraint forces f do not realize work along virtual displacements* δq. The generalization here corresponds to the fact that the mentioned virtual displacements have nothing to do, in principle, with kinematic constraints. According to what has been said above, every GNHS can be described in terms of data (L, C_K, C_V) or, alternatively, in terms of its related triple (L, C_K, F_V).

Linear and affine constraints: When C_K is a distribution on Q (respectively, an affine subbundle of TQ) we say the system has *linear* (respectively, *affine*) *kinematic constraints*. In these cases we can write $C_K = C_K^{\text{vec}} + \nu$, being $C_K^{\text{vec}} \subset TQ$ a distribution and $\nu \subset TQ$ a section. Such submanifolds can be locally described by a set of equations for $\dot{q}$,

$$\omega_i^a(q)\dot{q}^i = \gamma^a(q), \quad 1 \leqslant a \leqslant k,$$

for each $q \in Q$. Of course, linear constraints correspond to the $\gamma^a = 0$, or equivalently, to the $\nu = 0$ case. D'Alembert's principle holds when $C_V = C_K^{\text{vec}}$, i.e., when virtual displacements δq satisfy

$$\omega_i^a(q)\delta q^i = 0, \quad 1 \leqslant a \leqslant k,$$

or equivalently, when $F_V = (C_K^{\text{vec}})^o$, which means that constraint forces do not realize work along *standard* virtual displacements: the *standard* Principle of Virtual Works.

Systems with higher order constraints: Systems defined above are a subclass of those presented in Ref. 3. There, a class of dynamical systems with higher order constraints were defined, on a manifold Q, as triples (L, C_K, C_V) with $L \in C^\infty(TQ)$,

$$C_K \subset T^{(k)}Q \quad \textit{and} \quad C_V \subset T^{(l)}Q \times_Q TQ,$$

for some $k,l \geqslant 0$. Symbol $T^{(n)}Q$ denotes the nth order tangent bundle of the manifold Q.[23,24] In particular, $T^{(0)}Q=Q$ and $T^{(1)}Q=TQ$. By definition, a curve $q:[t_1,t_2]\to Q$ is a trajectory of the system if its k-lift

$$[q]^{(k)}(t) \in C_K,$$

and Eq. (3) is fulfilled for all $\delta q(t)$ such that

$$([q]^{(l)}(t), \delta q(t)) \in C_V.$$

It is clear that GNHS correspond to the $k=1$ and $l=0,1$ cases. Note that cases with $k=0$ can be easily included in the class of GNHS. In fact, if we have constraints $C_K \subset Q$, then we can replace them by TC_K, obtaining in this way a system which is equivalent to the original one.

From now on, we shall refer to the cases $C_V \subset TQ$ and $C_V \subset C_K \times_Q TQ$ as the $l=0$ and $l=1$ cases, respectively.

We shall show in a forthcoming paper that any triple (L, C_K, C_V) with higher order constraints is equivalent to a GNHS. This is one of the reasons why we focus on such a subclass.

A. Application to servomechanisms

The inverted pendulum on a cart: In the scenario of automatic control, a widely studied mechanical system is the so-called *inverted pendulum on a cart*. It consists in a straight rod which remains in a vertical plane, such that one of its tips, say O, can move only along a straight horizontal line contained in that plane. The configuration space for this system is $Q=\mathbb{R}\times S^1$. Given $(x,\theta)\in \mathbb{R}\times S^1$, x represents the position of the point O and θ represents the angle of rotation of the rod with respect to the horizontal line, measured in the counter-clockwise sense.

The Lagrangian of the system is (neglecting friction)

$$L(x,\theta,\dot{x},\dot{\theta}) = \tfrac{1}{2}m\dot{x}^2 - ml\dot{\theta}\dot{x}\sin\theta + \tfrac{1}{2}I\dot{\theta}^2 - mgl\sin\theta, \tag{6}$$

where m is the mass of the rod, l is the distance from O to its center of mass, I is its moment of inertia with respect to O, and g is the acceleration of gravity. It is worth remarking that the system has an unstable fixed point at $\theta=\pi/2$.

A classical control problem is to take the rod from any position to the upright position, which should be converted into a stable fixed point. In order to do that, Marle suggest,[2] as a control strategy, to impose a value of $\dot{x}$ as a function of $x,\theta,\dot{\theta}$. In other words, to impose a kinematic constraint $C_K \subset TQ$ of the form

$$C_K = \{(x,\theta,\dot{x},\dot{\theta}) : \dot{x} - f(x,\theta,\dot{\theta}) = 0\}. \tag{7}$$

For instance, one can choose C_K to be an affine subbundle given by

$$\dot{x} - \rho(\theta)\dot{\theta} = \gamma(\theta), \tag{8}$$

with $\rho(\theta)=-b$ and $\gamma(\theta)=a\cos\theta$, taking $a<0$ and $b>I/ml$. This constraint is different from that appearing in Ref. 2, but it has the same effect, i.e., the upright position is effectively converted into a stable point.

Another control problem is the *orbital stabilization*, i.e., to make some periodic orbit of the system asymptotically stable. To this end, in Ref. 34 the method of *virtual constraints* were proposed and applied to the inverted pendulum on a cart. There, in order to make the pendulum oscillate around the upright position on an asymptotically stable orbit, they impose a kinematic constraint as in Eq. (8), with $\rho(\theta)=-L\cos\theta$ and $\gamma(\theta)=0$.

Note this constraint can be integrated to $x+L\sin\theta=c$, for some constant c depending on the initial conditions. This is actually the form in which appears in Ref. 34.

In both cases, constraints are realized by means of a servomechanism, which apply a horizontal force at the point O. (This force is precisely the *control law* that the constraints gives rise.) This means that constraint forces define a codistribution $F_V \subset T^*Q$ with elements of the form $\lambda\, \mathrm{d}x$. Accordingly, variational constraints define a one-dimensional distribution $C_V = F_V^o$ generated by ∂_θ, that is, $\delta x = 0$ and $\delta\theta$ arbitrary. Explicitly,

$$C_V = \{(x, \theta, \delta x, \delta\theta) : \delta x = 0\}. \tag{9}$$

Clearly, D'Alembert's principle is not valid, that is to say $C_V \neq C_K^{\mathrm{vec}}$, unless $\rho(\theta) = \gamma(\theta) = 0$.

Equations of motion of (L, C_K, C_V), given by (6), (7), and (9) are

$$\left(\frac{d}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{x}}\right) - \frac{\partial L}{\partial x}\right)\delta x + \left(\frac{d}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{\theta}}\right) - \frac{\partial L}{\partial \theta}\right)\delta\theta = 0,$$

$$\dot{x} = f(x, \theta, \dot{\theta}), \quad \delta x = 0;$$

which, using the explicit form of the Lagrangian, reduce to

$$I\ddot{\theta} - ml\ddot{x}\sin\theta + mgl\cos\theta = 0, \quad \dot{x} = f(x, \theta, \dot{\theta}).$$

Geometric formulation of the method of virtual constraints: We have just seen how the idea of virtual constraints, in the case of the inverted pendulum, fits into the scenario of GNHS. Let us briefly comment how it fits in general (as developed in Ref. 34). Given a Lagrangian system with n degrees of freedom, such a method consists in using $n-1$ independent actuators to implement $n-1$ independent constraints, the virtual constraints themselves, chosen in such a way that the resulting underactuated mechanical system (the so-called *zero dynamics*) has some periodic orbit which is asymptotically stable. The name "virtual" for the involved constraints corresponds to the fact that the actuators, i.e., constraint forces, do not satisfy D'Alembert's principle in general.

Suppose we have a mechanical system defined on an n-dimensional manifold Q and with Lagrangian function L. Following Ref. 34, it can be shown (as we have done for the inverted pendulum) that, by applying the method of virtual constraints, the resulting dynamical system can be described as a GNHS (L, C_K, C_V) with $C_K, C_V \subset TQ$ given by one-dimensional distributions. Note that $F_V \subset T^*Q$ has dimension $n-1$, corresponding to the $n-1$ independent actuators. Thus, C_K represents virtual constraints and C_V the space annihilated by the actuators.

B. Legendre transformation and the Hamiltonian side

As usual, let us denote by (q^i, p_i) the local coordinate system of T^*Q, and by $(q^i, p_i, \dot{q}^i, \dot{p}_i)$ [or $(q^i, p_i, \delta q^i, \delta p_i)$] the one induced by (q^i, p_i) on TT^*Q.

In local terms, the Legendre transformation $\mathbb{F}L : TQ \to T^*Q$ reads

$$\mathbb{F}L(q, \dot{q}) = (q, p), \quad \textit{with } p_i = \frac{\partial L}{\partial \dot{q}^i}(q, \dot{q}).$$

In what follows, we are going to assume that L is hyperregular. The energy function $E : T^*Q \oplus TQ \to \mathbb{R}$ is given by

$$E(\alpha_q, v_q) = \langle \alpha_q, v_q \rangle - L(v_q), \tag{10}$$

or in coordinates,

$$E(q, p, \dot{q}) = \sum_{i=1}^{n} p_i \dot{q}^i - L(q, \dot{q}),$$

and the Hamiltonian $H : T^*Q \to \mathbb{R}$ is given by

$$H(\alpha_q) = E(\alpha_q, \mathbb{F}L^{-1}(\alpha_q)). \tag{11}$$

We will need the function $F: T^*Q \oplus TQ \to \mathbb{R}$, such that

$$F(\alpha_q, v_q) = \langle \alpha_q, v_q \rangle - H(\alpha_q). \tag{12}$$

Now define a submanifold $D \subset T^*Q$ by

$$D = \mathbb{F}L(C_K). \tag{13}$$

The latter represents the phase space constraints associated to the kinematic constraints C_K. Note that, whenever the equality $\tau(C_K) = Q$ holds, we have $\pi(D) = Q$, being $\pi: T^*Q \twoheadrightarrow Q$ the canonical projection of the cotangent bundle.

Associated to C_V we shall define a distribution $\mathcal{V} \subset T_D T^*Q$ along D. In order to do that, denote by $\pi_*: TT^*Q \twoheadrightarrow TQ$ the differential of π, and consider the natural surjection

$$\mathfrak{s}: TT^*Q \twoheadrightarrow T^*Q \oplus TQ: V_{\alpha_q} \mapsto \alpha_q \oplus \pi_*(V_{\alpha_q}).$$

In coordinates, $\mathfrak{s}(q, p, \delta q, \delta p) = (q, p, \delta q)$. Now, we define

$$\begin{aligned} \mathcal{V} &= \mathfrak{s}^{-1}(D \times_Q C_V), \quad l = 0, \\ \mathcal{V} &= \mathfrak{s}^{-1}([\mathbb{F}L \times_Q id_{TQ}](C_V)), \quad l = 1. \end{aligned} \tag{14}$$

Note that for $l = 0$ the distribution $\mathcal{V}$ can be described alternatively as

$$\mathcal{V} = \pi_*^{-1}(C_V)|_D. \tag{15}$$

In fact,

$$\mathcal{V} = \mathfrak{s}^{-1}(D \times_Q C_V) = \pi_*^{-1}(C_V) \cap T_D T^*Q = \pi_*^{-1}(C_V)|_D.$$

Thus, for $l = 0$,

$$\mathcal{V} = \{V_{\alpha_q} \in TT^*Q : \alpha_q \in D, \pi_*(V_{\alpha_q}) \in C_V\},$$

and in coordinates,

$$\mathcal{V} = \{(q, p, \delta q, \delta p) : (q, p) \in D, (q, \delta q) \in C_V\}.$$

For $l = 1$, we can write $\mathcal{V} = \mathfrak{s}^{-1}(\mathcal{V}_1)$, with $\mathcal{V}_1 \subset T^*Q \oplus TQ$ given by

$$\mathcal{V}_1 = \{\alpha_q \oplus v_q \in T^*Q \oplus TQ : \alpha_q \in D, (\mathbb{F}L^{-1}(\alpha_q), v_q) \in C_V\}.$$

In local coordinates, using that the inverse Legendre transformation $\mathbb{F}H = \mathbb{F}L^{-1}$ is given by

$$\mathbb{F}H(q, p) = (q, \dot{q}), \quad \text{with } \dot{q}^i = \frac{\partial H}{\partial p_i}(q, p),$$

we have

$$\mathcal{V}_1 = \left\{ (q, p, \delta q) : (q, p) \in D, \left(q, \frac{\partial H}{\partial p}(q, p), \delta q \right) \in C_V \right\}. \tag{16}$$

Accordingly, for $l = 1$,

$$\mathcal{V} = \{V_{\alpha_q} \in TT^*Q : \alpha_q \in D, \mathfrak{s}(V_{\alpha_q}) = \alpha_q \oplus \pi_*(V_{\alpha_q}) \in \mathcal{V}_1\}$$

or [see (16)]

$$\mathcal{V}=\{(q,p,\delta q,\delta p):(q,p,\delta q)\in\mathcal{V}_1\}.$$

It is worth mentioning that the distributions $\mathcal{V}\subset T_DT^*Q$ above satisfy

$$\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V})=\mathcal{V}, \tag{17}$$

what implies that variations δp's are arbitrary. A direct consequence of (17) is that such distributions are coisotropic, i.e., $\mathcal{V}^\perp\subset\mathcal{V}$, where $\perp$ denotes the symplectic orthogonal with respect to the canonical 2-form ω of T^*Q.

Now, in terms of a triple $(H,D,\mathcal{V})$ as given above, we shall derive a set of equations equivalent to those coming from related Lagrangian system. This will enable us to identify the Hamiltonian side of a GNHS.

Proposition 4: *Equations of motion* (4), *defined by* (L,C_K,C_V) *with L hyperregular*, *are equivalent to*

$$\left(\dot{q}^i-\frac{\partial H}{\partial p_i}\right)\delta p_i+\left(\dot{p}_i+\frac{\partial H}{\partial q^i}\right)\delta q^i=0,\quad (q,p,\delta q,\delta p)\in\mathcal{V}, \tag{18}$$

defined by the data $(H,D,\mathcal{V})$ [*see Eqs.* (11), (13), and (14)]. *They can be derived from a variational principle*

$$\delta\int_{t_1}^{t_2}F\,\mathrm{d}t=0,\quad \textit{with variations restricted to } \mathcal{V}.$$

In turn, *Eqs.* (18) *can be intrinsically described by each one of the following equivalent equations for a vector field* $X\in TD$:

$$\omega_D(X,Y)-\mathrm{d}H|_D(Y)=0\quad \textit{for all } Y\in\mathcal{V},$$

$$\omega_D^\flat(X)-\mathrm{d}H|_D\in\mathcal{V}^o,$$

$$X-\omega_D^\sharp(\mathrm{d}H|_D)\in\mathcal{V}^\perp,$$

where ω_D *and* $\mathrm{d}H|_D$ *are the canonical 2-form of* T^*Q *and the differential* $\mathrm{d}H$ *restricted to* $T_DT^*Q\times T_DT^*Q$ *and* T_DT^*Q, *respectively*.

Proof: Equations (4) for $l=0$ are

$$\left(\frac{d}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}^i}\right)-\frac{\partial L}{\partial q^i}\right)\delta q^i=0,\quad (q,\dot{q})\in C_K,\quad (q,\delta q)\in C_V. \tag{19}$$

Having in mind that $p_i=\partial L/\partial\dot{q}^i$ and $\dot{q}^i=\partial H/\partial p_i$, and the fact that

$$\frac{\partial H}{\partial q^j}=-\frac{\partial L}{\partial q^j},$$

Eqs. (19) are equivalent to

$$\dot{q}^i-\partial H/\partial p_i=0,\quad \left(\dot{p}_i+\frac{\partial H}{\partial q^j}\right)\delta q^i=0,\quad (q,p)\in D,\quad (q,\delta q)\in C_V.$$

From definition of $\mathcal{V}$, since δp's are arbitrary, equivalence of the last equations and Eq. (18) follows immediately. For $l=1$ we must proceed similarly. We leave to the reader to show the equivalence with the phase space variational principle.

In order to show that Eq. (18) is equivalent to

$$\omega_D(X,Y) - \mathrm{d}H|_D(Y) = 0 \quad for\ all \quad Y \in \mathcal{V},$$

let us write $X \in TD$ and $Y \in \mathcal{V}$ as $X_{q,p}=(\dot{q},\dot{p})$ and $Y_{q,p}=(\delta q,\delta p)$. Then

$$[\omega_D(X,Y)]_{q,p} = \dot{q}^i \delta p_i - \dot{p}_i \delta q^i, \quad \left[\mathrm{d}H|_D(Y)\right]_{q,p} = \frac{\partial H}{\partial q^i}\delta q^i + \frac{\partial H}{\partial p_i}\delta p_i,$$

and as a consequence

$$\left[\omega_D(X,Y) - \mathrm{d}H|_D(Y)\right]_{q,p} = \left(\dot{q}^i - \frac{\partial H}{\partial p_i}\right)\delta p_i + \left(\dot{p}_i + \frac{\partial H}{\partial q^i}\right)\delta q^i,$$

as we wanted to show. ■

Summing up, related to a triple (L,C_K,C_V) we have defined another one $(H,D,\mathcal{V})$, given by Eqs. (11), (13), and (14), which gives rise to a dynamical system equivalent to the original one. Then, we can talk about (L,C_K,C_V) and $(H,D,\mathcal{V})$ as the *Lagrangian* and *Hamiltonian data*, or *Lagrangian* and *Hamiltonian side*, of a GNHS.

The inverted pendulum revisited: Let us continue with the inverted pendulum on a cart. Consider the case of affine kinematic constraints implemented by constraint forces as described above. Then,

$$C_K = \{(x,\theta,\dot{x},\dot{\theta}) : \dot{x} = \rho(\theta)\dot{\theta} + \gamma(\theta)\}$$

and

$$C_V = \{(x,\theta,\delta x,\delta\theta) : \delta x = 0\}.$$

Applying Legendre transformation, we have

$$p_x = m\dot{x} - v\dot{\theta}, \quad p_\theta = -v\dot{x} + I\dot{\theta},$$

being $v=ml\sin\theta$, and the Hamiltonian function is

$$H(x,\theta,p_x,p_\theta) = \frac{Ip_x^2 + mp_\theta^2 + 2vp_xp_\theta}{2(mI - v^2)} + vg. \tag{20}$$

The submanifold $D=\mathbb{F}L(C_K)$ is given by points of T^*Q with p_x,p_θ obeying

$$\frac{\partial H}{\partial p_x}(x,\theta,p_x,p_\theta) - \rho(\theta)\frac{\partial H}{\partial p_\theta}(x,\theta,p_x,p_\theta) = \gamma(\theta) \tag{21}$$

for all x,θ, or equivalently,

$$p_x - \chi(\theta)p_\theta = \phi(\theta) \tag{22}$$

with

$$\chi(\theta) = \frac{m\rho(\theta) - v}{I - v\rho(\theta)} \quad and \quad \phi(\theta) = \frac{\gamma(\theta)(mI - v^2)}{I - v\rho(\theta)}. \tag{23}$$

On the other hand, the distribution $\mathcal{V}$ can be described as

$$\mathcal{V} = \{(x,\theta,p_x,p_\theta,\delta x,\delta\theta,\delta p_x,\delta p_\theta) : p_x = \chi(\theta)p_\theta + \phi(\theta);\ \delta x = 0\}.$$

Then, using (18) for $\mathcal{V}$ given above, equations of motions are

$$\dot{x} = \frac{Ip_x + vp_\theta}{mI - v^2}, \quad \dot{\theta} = \frac{mp_\theta + vp_x}{mI - v^2},$$

$$\dot{p}_\theta = \frac{wp_x p_\theta}{mI - v^2} + vw\frac{Ip_x^2 + mp_\theta^2 + 2vp_x p_\theta}{(mI - v^2)^2} + wg,$$

$$p_x = \chi(\theta)p_\theta + \phi(\theta),$$

being $w = ml\cos\theta$.

III. CONSTRAINED HAMILTONIAN SYSTEMS

The inverse Legendre transformation: Consider $(H, D, \mathcal{V})$ with

(1) $H \in C^\infty(T^*Q)$,
(2) $D \subset T^*Q$ an embedded submanifold,
(3) and $\mathcal{V} \subset T_D T^*Q$ a distribution such that $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V}) = \mathcal{V}$ [recall Eq. (17)].

Suppose H is hyperregular, i.e., $\mathbb{F}H: T^*Q \to TQ$ is a diffeomorphism. Then,

(i) $L \in C^\infty(TQ)$ such that [see Eq. (12)]

$$L(v_q) = F(\mathbb{F}H^{-1}(v_q), v_q), \tag{24}$$

(ii) $C_K \subset TQ$ the submanifold of TQ defined by

$$C_K = \mathbb{F}H(D), \tag{25}$$

(iii) and C_V given by the distribution

$$C_V = \pi_*(\mathcal{V}) \subset TQ, \tag{26}$$

if for each q we have $(\pi_*)_{\alpha_q}(\mathcal{V}) = (\pi_*)_{\beta_q}(\mathcal{V})$ for all $\alpha_q, \beta_q \in D$, or by

$$C_V = [\mathbb{F}H \times_Q id_{TQ}](\mathfrak{s}(\mathcal{V})) \subset C_K \times_Q TQ, \quad otherwise, \tag{27}$$

defines a GNHS (L, C_K, C_V). Note that (26) and (27) correspond to the $l=0$ and $l=1$ cases, respectively. It can be shown that Eqs. (18) defined by the given triple $(H, D, \mathcal{V})$ (as well as their equivalent forms appearing in the last proposition) are equivalent to Eqs. (4) related to the associated Lagrangian system (L, C_K, C_V). With all that, we conclude that the Hamiltonian side of a GNHS is given by triples $(H, D, \mathcal{V})$ detailed in points (1), (2), (3) above. Nevertheless, we shall consider the following definition, inspired in Marle's work.[2]

Hamiltonian formulation of GNHS:

Definition 5: *We shall also call GNHS a triple* $(H, D, \mathcal{V})$ *with* H *an element of* $C^\infty(T^*Q)$, $D \subset T^*Q$ *a submanifold, and* $\mathcal{V} \subset T_D T^*Q$ *a distribution along* D, *whose equations of motion are*

$$X \in TD, \quad X - \omega_D^\sharp(\mathrm{d}H|_D) \in \mathcal{V}^\perp. \tag{28}$$

Last equations mean that a curve $\gamma: [t_1, t_2] \to T^*Q$ *is a trajectory of the system if its velocity* $\dot{\gamma}$ *satisfies*

$$\dot{\gamma}(t) \in TD, \quad \dot{\gamma}(t) - \omega^\sharp(\mathrm{d}H|_{\gamma(t)}) \in \mathcal{V}^\perp,$$

for all $t \in [t_1, t_2]$.

Remark 6: *We will be mainly interested in the cases in which* D *is a closed embedded submanifold of* T^*Q.

Remark 7: *Note that systems defined above give a generalization of the Hamiltonian side of a triple* (L, C_K, C_V), *since we are not asking for condition*

$$\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V}) = \mathcal{V}.$$

Up to now, regarding the relation between Lagrangian and Hamiltonian formulation of GNHS, we have proved the following results.

Theorem 8: *Every GNHS given by* (L,C_K,C_V), *with L a hyperregular Lagrangian*, *defines*, *through Eqs.* (11), (13), and (14), *a GNHS* $(H,D,\mathcal{V})$.

A GNHS given by $(H,D,\mathcal{V})$, *with H hyperregular Hamiltonian*, *defines*, *through Eqs.* (24) *to* (27), *a GNHS* (L,C_K,C_V) *iff* $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V})=\mathcal{V}$.

In both cases, (L,C_K,C_V) *and* $(H,D,\mathcal{V})$ *give rise to equivalent dynamical systems*.

Marle[2] has defined a class of constrained Hamiltonian systems given by multiplets $(P,\Lambda,H,D,\mathcal{W})$, being P a Poisson manifold with Poisson bivector Λ, H a function on P, D a submanifold of P and $\mathcal{W}\subset T_DT^*Q$ a distribution along D that represents the space where constraint forces *live* in Hamiltonian formalism. Of course, we can extend Definition 5 to arbitrary Poisson manifolds, but we shall restrict ourselves only to cotangent bundles, i.e., $P=T^*Q$ and Λ given by the canonical 2-form ω. In these cases the above multiplets can be described simply as triples $(H,D,\mathcal{W})$. Then, it is easy to see that the distribution $\mathcal{W}$ corresponds exactly to $\mathcal{V}^\perp$, in the sense that the dynamical system$(H,D,\mathcal{W})$ defined by Marle and the GNHS $(H,D,\mathcal{V})$ with $\mathcal{V}=\mathcal{W}^\perp$ are equivalent. This enables us to describe a GNHS indistinctly in terms of $\mathcal{V}$ or $\mathcal{W}$. This situation is similar to what we have on the Lagrangian side, where systems can be described by triple (L,C_K,C_V) as well as (L,C_K,F_V).

It is worth mentioning that a particular subclass of equations of the form (28) appears, following Dirac's procedure, in the Hamiltonian description of singular Lagrangian systems.[14] Then, GNHS include singular systems as a special case.

A. Existence and uniqueness conditions

Now, let us study intrinsic conditions for existence and uniqueness of solutions of Eq. (28). In order to do that, let us consider a complement $\mathcal{U}^\perp$ of TD inside T_DT^*Q, i.e., let us write $T_DT^*Q=TD\oplus\mathcal{U}^\perp$ for some appropriate $\mathcal{U}^\perp$ (we take the orthogonal instead of the direct space for later convenience). In other words,

$$\dim TD=\dim\mathcal{U} \quad \textit{and} \quad TD\cap\mathcal{U}^\perp=0.$$

Here 0 means the null section of T_DT^*Q. Let us call $\mathfrak{p}_{\mathcal{U}^\perp}$ the projection with range TD related to the decomposition above. Note the same can be done on an open set of D. The following result is immediate.

Proposition 9: *Equation* (28) *related to data* $(H,D,\mathcal{V})$ *has one and only one solution passing through a point* $x\in D$ *if decomposition* $T_DT^*Q=TD\oplus\mathcal{V}^\perp$ *holds in an open neighborhood U of x. In this case the equation in that neighborhood reduces to the form*

$$X=\mathfrak{p}_{\mathcal{V}^\perp}\omega_D^\sharp(\mathrm{d}H|_D), \tag{29}$$

being $\mathfrak{p}_{\mathcal{V}^\perp}$ *the projection with range* T_UD *related to mentioned decomposition.*

The hypothesis of the preceding proposition has been previously studied in Ref. 2, replacing $\mathcal{V}^\perp$ by $\mathcal{W}$, under the name of *regular systems*; and also in Ref. 14 within the context of singular Lagrangian systems.

Let us translate the above conditions to the Lagrangian side. Observe first that for triples $(H,D,\mathcal{V})$ such that $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V})=\mathcal{V}$, in order to have equality $T_DT^*Q=TD\oplus\mathcal{V}^\perp$, which is equivalent to conditions

$$\dim TD=\dim\mathcal{V} \quad \textit{and} \quad TD^\perp\cap\mathcal{V}=0,$$

we can ask that $\pi(D)=Q$. For instance, if $\pi(D)$ is a closed submanifold of Q, it can be shown that $TD^\perp\cap\ker\pi_*\neq 0$, and accordingly, since $\ker\pi_*\subset\mathcal{V}$ for every $\mathcal{V}$ such that $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V})=\mathcal{V}$, we have $TD^\perp\cap\mathcal{V}\neq 0$. Thus, on the Lagrangian side, in order to use the result above we shall impose the condition $\tau(C_K)=Q$ [which corresponds to $\pi(D)=Q$ under Legendre transformation].

Proposition 10: *For a GNHS given by* (L, C_K, C_V) *such that* $\tau(C_K)=Q$, *existence and uniqueness of solutions passing through a point* $v \in TQ$ *is ensured by regularity of the Lagrangian at* v *and conditions*

$$\text{for } l=0\text{: } \dim C_K = \dim C_V, \quad C_K^{(0)} \cap C_V = 0,$$

$$\text{for } l=1\text{: } \dim C_K = \tfrac{1}{2}\dim C_V, \quad C_K^{(1)} \cap C_V = 0, \tag{30}$$

in a neighborhood of v, *being*

$$C_K^{(0)} = \pi_*((\mathbb{F}L_* TC_K)^\perp), \quad C_K^{(1)} = [\mathbb{F}L^{-1} \times_Q \mathrm{id}_{TQ}] \circ \mathfrak{s}[(\mathbb{F}L_* TC_K)^\perp].$$

Proof: Consider the $l=0$ case. Everything must be understood locally. For

$$D = \mathbb{F}L(C_K) \quad \textit{and} \quad \mathcal{V} = \pi_*^{-1}(C_V)|_D$$

we have $\dim TD = 2\dim D = 2\dim C_K$ on a neighborhood of v (since L is regular there), and $\dim \mathcal{V} = \dim D + \dim C_V$. Assuming that $\dim C_K = \dim C_V$, the last equations ensure $\dim TD = \dim \mathcal{V}$. Now suppose

$$\pi_*[(\mathbb{F}L_* TC_K)^\perp] \cap C_V = 0.$$

Since

$$\pi_*((\mathbb{F}L_* TC_K)^\perp) = \pi_*(T[\mathbb{F}L(C_K)]^\perp) = \pi_*(TD^\perp)$$

and $C_V = \pi_*(\pi_*^{-1}(C_V))$, then

$$0 = \pi_*(TD^\perp) \cap \pi_*(\pi_*^{-1}(C_V)) \supseteq \pi_*(TD^\perp \cap \pi_*^{-1}(C_V))$$

$$= \pi_*(TD^\perp \cap \pi_*^{-1}(C_V) \cap T_D T^*Q) = \pi_*(TD^\perp \cap \mathcal{V}),$$

and therefore $\pi_*(TD^\perp \cap \mathcal{V}) = 0$. On the other hand, since $\tau(C_K) = Q$, and accordingly $\pi(D) = Q$, we have that $TD^\perp \cap \ker \pi_* = 0$ (see the comments before the proposition). As a direct consequence $TD^\perp \cap \mathcal{V} = 0$, and using equality $\dim TD = \dim \mathcal{V}$ we finally have $T_D T^*Q = TD \oplus \mathcal{V}^\perp$. Thus, our statement follows from previous proposition and Proposition 4. We leave to the reader the $l=1$ case. ■

For completeness, we briefly study what conditions (30) mean in local terms. We focus on the case in which C_K and C_V are distributions on Q, i.e., they are given by points $(q, \dot{q})$ and $(q, \delta q)$ such that

$$\omega_i^a(q)\dot{q}^i = 0 \quad \textit{and} \quad v_i^b(q)\delta q^i = 0, \quad 1 \leqslant a \leqslant k, \quad 1 \leqslant b \leqslant l,$$

respectively. We assume each set of equations is linearly independent. Then, condition $\dim C_K = \dim C_V$ is equivalent to equality $k=l$. Let us build up the distribution $C_K^{(0)}$. First note that $\mathbb{F}L(C_K) = D$ is given by $(q,p) \in T^*Q$ satisfying

$$\omega_i^a(q)\frac{\partial H}{\partial p_i}(q,p) = 0, \quad a = 1, \ldots, k.$$

Accordingly, $\mathbb{F}L_* TC_K = T[\mathbb{F}L(C_K)] = TD$ is defined by points $(q,p,\dot{q},\dot{p})$ obeying for all (q,p) in D,

$$\varpi_{ij}^a(q,p)\dot{q}^j + \omega_i^a(q)\frac{\partial H}{\partial p_i \partial p_j}(q,p)\dot{p}_j = 0, \quad a = 1, \ldots, k,$$

being

$$\varpi_{ij}^{a}(q,p)=\frac{\partial}{\partial q^{j}}\left(\omega_{i}^{a}(q)\frac{\partial H}{\partial p_{i}}\right)(q,p).$$

Its symplectic orthogonal is generated, for each $(q,p)\in D$, by vectors

$$V^{a}=\omega_{i}^{a}(q)\frac{\partial H}{\partial p_{i}\,\partial\, p_{j}}(q,p)\frac{\partial}{\partial q^{j}}-\varpi_{ij}^{a}(q,p)\frac{\partial}{\partial p_{j}}.$$

Applying π_{*}, we see that $C_{K}^{(0)}$ is given by elements $(q,\dot{q})\in TQ$ such that

$$\dot{q}^{j}=c_{a}\omega_{i}^{a}(q)\frac{\partial H}{\partial p_{i}\,\partial\, p_{j}}(q,p),$$

with c_{a} arbitrary and $(q,p)\in D$. Therefore, the condition $C_{K}^{(0)}\cap C_{V}=0$ means that

$$\varphi^{ab}=\omega_{i}^{a}(q)\frac{\partial H}{\partial p_{i}\,\partial\, p_{j}}(q,p)v_{j}^{b}(q) \tag{31}$$

defines a nonsingular matrix for all $(q,p)\in D$. It is easy to see that, on the Hamiltonian side, the last statement about φ^{ab} is equivalent to validity of the decomposition $T_{D}T^{*}Q=TD\oplus\mathcal{V}^{\perp}$.

B. D'Alembert's and Chetaev's distributions

Let us study two particular situations where variational constraints are related to kinematic ones. Consider an arbitrary triple (L,C_{K},C_{V}). Let us define the submanifold

$$\mathcal{K}=\mathfrak{s}^{-1}[\mathbb{F}L\times_{Q}\mathrm{id}_{TQ}](C_{K}\times_{Q}C_{K}), \tag{32}$$

and its *diagonal* part

$$\mathrm{diag}(\mathcal{K})=\mathfrak{s}^{-1}[\mathbb{F}L\times_{Q}\mathrm{id}_{TQ}](\mathrm{diag}(C_{K}\times_{Q}C_{K})). \tag{33}$$

The elements of $\mathrm{diag}(C_{K}\times_{Q}C_{K})$ are of the form (q,v,w) with $v=w\in C_{K}$. Note that $\mathcal{K}$ is a submanifold of $T_{D}T^{*}Q$, with $D=\mathbb{F}L(C_{K})$, and it can also be described as

$$\mathcal{K}=\mathfrak{s}^{-1}(D\times_{Q}C_{K})=\pi_{*}^{-1}(C_{K})|_{D}. \tag{34}$$

If C_{K} is a distribution on Q, then $\mathcal{K}$ is a distribution along D. It is the analogue of $\mathcal{V}$ for $l=0$ [see Eqs. (14) and (15)]. If $C_{K}=C_{K}^{\mathrm{vec}}+v$, i.e., it is an affine subbundle of TQ, we define the distribution

$$\mathcal{K}_{\mathrm{vec}}=\mathfrak{s}^{-1}(D\times_{Q}C_{K}^{\mathrm{vec}})=\pi_{*}^{-1}(C_{K}^{\mathrm{vec}})|_{D}.$$

For C_{K} described by equations

$$\omega_{i}^{a}(q)\dot{q}^{i}=\gamma^{a}(q),\quad 1\leqslant a\leqslant k,\quad q\in Q,$$

the related distribution $\mathcal{K}_{\mathrm{vec}}$ is given by $(q,p,\delta q,\delta p)\in T_{D}T^{*}Q$ such that

$$\omega_{i}^{a}(q)\,\delta q^{i}=0,\quad 1\leqslant a\leqslant k,\quad q\in Q.$$

In these terms, for linear (respectively, affine) constraints, D'Alembert's principle holds if and only if $\mathcal{V}=\mathcal{K}_{\mathrm{vec}}$.

Now, consider a GNHS $(H,D,\mathcal{V})$, and define

$$\mathcal{K}=\mathfrak{s}^{-1}[\mathrm{id}_{T^{*}Q}\times_{Q}\mathbb{F}H](D\times_{Q}D)=\pi_{*}^{-1}(\mathbb{F}H(D))|_{D} \tag{35}$$

and

$$\mathrm{diag}(\mathcal{K}) = \mathfrak{s}^{-1}[\mathrm{id}_{T^*Q} \times_Q \mathbb{F}H](\mathrm{diag}(D \times_Q D)); \tag{36}$$

and for D such that $\mathbb{F}H(D)$ is an affine subbundle, i.e., $\mathbb{F}H(D) = \mathbb{F}H(D)_{\mathrm{vec}} + v$, define

$$\mathcal{K}_{\mathrm{vec}} = \pi_*^{-1}(\mathbb{F}H(D)_{\mathrm{vec}})|_D.$$

Note that the above definitions are given in purely Hamiltonian terms.

Definition 11: *We shall say that D'Alembert's principle holds for* $(H, D, \mathcal{V})$ *if* $\mathbb{F}H(D)$ *is a distribution* (*respectively*, *an affine subbundle*) *and* $\mathcal{V} = \mathcal{K}$ (*respectively*, $\mathcal{K}_{\mathrm{vec}}$). *This is why*, *for linear* (*respectively*, *affine*) *constraints*, *we shall call* $\mathcal{K}$ (*respectively*, $\mathcal{K}_{\mathrm{vec}}$) *the D'Alembert's distribution*.

Let us come back to an arbitrary triple (L, C_K, C_V). When constraints are not linear or affine, the natural generalization of D'Alembert's principle is Chetaev's one, which involves the fiber bundle

$$\widetilde{C}_K = \mathfrak{s}[S^{-1}(TC_K)] \subset C_K \times_Q TQ.$$

Here, S denotes the *canonical endomorphism* $S: TTQ \to TTQ$, which in coordinates reads

$$S(q, \dot{q}, \delta q, \delta \dot{q}) = (q, \dot{q}, 0, \delta q).$$

Chetaev's principle says $C_V = \widetilde{C}_K$. In local coordinates, if C_K is given by

$$\omega^a(q, \dot{q}) = 0, \quad 1 \leqslant a \leqslant k, \quad q \in Q,$$

for certain functions ω^a on TQ, then $\widetilde{C}_K$ is given by points $(q, \dot{q}, \delta q) \in C_K \times_Q TQ$ such that,

$$\frac{\partial \omega^a}{\partial \dot{q}^i}(q, \dot{q})\, \delta q^i = 0, \quad 1 \leqslant a \leqslant k, \quad (q, \dot{q}) \in C_K. \tag{37}$$

When $\omega^a(q, \dot{q}) = \omega_i^a(q)\dot{q}^i - \gamma^a(q)$, i.e., when C_K is an affine subbundle of TQ, we have

$$\widetilde{C}_K = C_K \times_Q C_K^{\mathrm{vec}}.$$

There is a particularly interesting subclass of constraints C_K containing the linear ones, called *homogeneous*, given by functions $\omega^a(q, \dot{q})$ such that

$$\frac{\partial \omega^a}{\partial \dot{q}^i}(q, \dot{q})\, \dot{q}^i = 0, \quad 1 \leqslant a \leqslant k, \quad (q, \dot{q}) \in C_K.$$

They can be characterized by the fact that

$$\mathrm{diag}(C_K \times_Q C_K) \subseteq \widetilde{C}_K.$$

Now, for later convenience, let us define with $\widetilde{C}_K$ a distribution

$$\mathcal{L} = \mathfrak{s}^{-1}[\mathbb{F}L \times_Q \mathrm{id}_{TQ}]\widetilde{C}_K$$

along $D = \mathbb{F}L(C_K)$. Elements of $\mathcal{L}$ are points $(q, p, \delta q, \delta p) \in T_D T^*Q$ such that [see Eq. (37)]

$$\widetilde{\omega}_i^a\left(q, \frac{\partial H}{\partial p}(q,p)\right)\delta q^i = 0, \quad 1 \leqslant a \leqslant k, \quad (q,p) \in D,$$

with $\widetilde{\omega}_i^a = \partial \omega^a / \partial \dot{q}^i$. Note if $\widetilde{C}_K = C_K \times_Q C_K^{\mathrm{vec}}$, then $\mathcal{L} = \mathcal{K}_{\mathrm{vec}}$. Accordingly, for the linear and affine constraints, $\mathcal{L}$ coincide with the related D'Alembert's distribution. On the other hand, homogeneous constraints can be characterized as those such that $\mathrm{diag}(\mathcal{K}) \subseteq \mathcal{L}$.

In Hamiltonian language, for a hyperregular Hamiltonian function H and a submanifold $D \subset T^*Q$, we define

$$\mathcal{L} = \mathfrak{s}^{-1}[\mathbb{F}H^{-1} \times_Q \mathrm{id}_{TQ}]\widetilde{\mathbb{F}H(D)}, \tag{38}$$

with (in the regular situation $\mathcal{L}$ can only be locally defined)

$$\widetilde{\mathbb{F}H(D)} = \mathfrak{s}[S^{-1}(\mathbb{F}H_*(TD))].$$

Definition 12: *We shall say that* $(H, D, \mathcal{V})$ *satisfies Chetaev's principle if* $\mathcal{V} = \mathcal{L}$, *and call* $\mathcal{L}$ *the Chetaev's distribution. Also, we will say that* $(H, D, \mathcal{V})$ *has homogeneous constraints if* $\mathrm{diag}(\mathcal{K}) \subseteq \mathcal{L}$, *where* $\mathrm{diag}(\mathcal{K})$ *and* $\mathcal{L}$ *are given by* (36) and (38), *respectively.*

Note that $\mathcal{K}_{\mathrm{vec}}$ and $\mathcal{L}$ (since δp's are arbitrary) satisfy Eq. (17) and in consequence they are coisotropic.

The following result, which has been previously demonstrated,[35] ensures existence and uniqueness for equations of motion associated to constrained Hamiltonian systems satisfying D'Alembert's or Chetaev's principle. We include a proof here only for completeness.

Proposition 13: *Equation* (28) *related to the data* $(H, D, \mathcal{V})$ *has one and only one solution passing through a point* $x \in D$ *provided* H *is normal at* x (*i.e.*, $\partial^2 H / \partial p_i \partial p_j$ *is a positive or negative defined matrix at* x), $\pi(D) = Q$ *and D'Alembert's or Chetaev's principle is fulfilled in a neighborhood of* x. *In this case, Eq.* (28) *reduces near* x *to the form*

$$X = \mathfrak{p}_{\mathcal{V}^\perp} \omega_D^\sharp(\mathrm{d}H|_D), \quad \textit{with } \mathcal{V} = \mathcal{K}, \quad \mathcal{K}_{\mathrm{vec}} \textit{ or } \mathcal{L}.$$

To prove the last result it is enough to use Proposition 9 and the lemma below.

Remark 14: *Normality of* H *is ensured for Hamiltonian functions of the type* $H = T + V \circ \pi$, *being* $V : Q \to \mathbb{R}$ *the potential energy, and* $T : T^*Q \to \mathbb{R}$ *the kinetic energy, given by one-half of the quadratic form of a Riemannian metric on* Q.

Lemma 15: *Given a submanifold* $D \subset T^*Q$ *such that* $\pi(D) = Q$, *and a normal* (*ipso facto regular*) *Hamiltonian function* $H \in C^\infty(T^*Q)$ *in* $x \in D$, *then* $\mathcal{L}$ *can be defined in a neighborhood of* x *and there we have*

$$T_D T^*Q = TD \oplus \mathcal{L}^\perp = TD^\perp \oplus \mathcal{L}.$$

If $\mathbb{F}H(D)$ *is a linear* (*respectively, affine*) *subbundle of* TQ, *the same decomposition holds for* $\mathcal{K}$ (*respectively,* $\mathcal{K}_{\mathrm{vec}}$).

Proof: Since H is regular in x and $\pi(D) = Q$, submanifold D can be locally described in terms of k equations (being $k \leqslant n$)

$$\omega^a\left(q, \frac{\partial H}{\partial p}(q,p)\right) = 0, \quad 1 \leqslant a \leqslant k,$$

where functions $\omega^a(q, \dot{q})$ are such that matrix

$$\tilde{\omega}_i^a = \partial \omega^a / \partial \dot{q}^i$$

has rank k. It easily follows that TD is given by elements $(q, p, \dot{q}, \dot{p}) \in T_D T^*Q$ obeying, for each $(q, p) \in D$,

$$\varpi_i^a(q,p)\dot{q}^i + \tilde{\omega}_i^a\left(q, \frac{\partial H}{\partial p}(q,p)\right)\frac{\partial^2 H}{\partial p_l \partial p_i}(q,p)\dot{p}_l = 0,$$

with

$$\varpi_i^a(q,p) = \frac{\partial}{\partial q^i}\left(\omega^a\left(q, \frac{\partial H}{\partial p}(q,p)\right)\right).$$

In particular (using regularity of H and the fact that $\tilde{\omega}_i^a$ has rank k), TD has dimension $2n-k$. On the other hand, Chetaev's distribution $\mathcal{L}$ is locally defined and given by $(q,p,\delta q,\delta p) \in T_D T^*Q$ such that

$$\tilde{\omega}_i^a\left(q, \frac{\partial H}{\partial p}(q,p)\right)\delta q^i = 0, \quad 1 \leqslant a \leqslant k.$$

As a consequence, the elements of $\mathcal{L}^\perp$ are generated by vectors with coordinates $\tilde{\omega}_i^a$ (omitting arguments) with respect to $\partial/\partial p_i$, and null coordinates with respect to $\partial/\partial q^i$. This implies $\mathcal{L}^\perp$ has dimension k. To show decomposition in question holds, we must see that $TD \cap \mathcal{L}^\perp = 0$. But, if an element of $\mathcal{L}^\perp$ also belongs to TD, then (omitting arguments of all involved functions)

$$\tilde{\omega}_i^a \frac{\partial^2 H}{\partial p_l \partial p_i}\tilde{\omega}_l^b = 0, \quad \textit{for all } a,b.$$

This is not possible, because H is normal. ■

IV. BRACKETS FOR GNHS

We want to describe the equations of motion for a system $(H,D,\mathcal{V})$ in terms of a bracket on D. In order to do that, it would be desirable to have an expression of X as a function of $H_D := H|_D$, or more precisely, *as a function* of the differential $\mathrm{d}H_D \in T^*D$. In fact, if we could write $X = \Pi^\sharp(\mathrm{d}H_D)$, with $\Pi^\sharp : T^*D \to TD$, then the related map $\Pi : T^*D \times T^*D \to \mathbb{R}$ given by $\Pi(\sigma,\rho) = \langle \sigma, \Pi^\sharp(\rho)\rangle$, would define a bracket

$$\{\cdot,\cdot\} : C^\infty(D) \times C^\infty(D) \to C^\infty(D) : (f,g) \mapsto \{f,g\} = \Pi(\mathrm{d}f, \mathrm{d}g)$$

such that

$$\dot{f} = \{f, H_D\}, \quad \textit{for all } f \in C^\infty(D).$$

The last statement follows from the chain of equalities

$$\dot{f} = X \cdot f = \langle \mathrm{d}f, X\rangle = \langle \mathrm{d}f, \Pi^\sharp(\mathrm{d}H_D)\rangle = \Pi(\mathrm{d}f, \mathrm{d}H_D) = \{f, H_D\}.$$

Note that $\{\cdot,\cdot\}$ is always a derivation, in particular linear, with respect to the first argument. We shall see that nonlinearity with respect to the second argument can naturally appear in the presence of nonlinear kinematic constraints.

A. Intrinsic formulation

Looking at Eq. (29), it is clear that we just need to write $\mathrm{d}H|_D$ as a function of $\mathrm{d}H_D$. Using the embedding $i : D \hookrightarrow T^*Q$, since $H_D = H \circ i$, we have

$$\mathrm{d}H_D = d(H \circ i) = i^*(\mathrm{d}H|_D),$$

being $i^* : T_D^* T^*Q \twoheadrightarrow T^*D$ the pull-back of i. Thus, we essentially need to invert map i^*, in a certain way.

1. Linear and homogeneous constraints

We shall first study the case of linear kinematic constraints. Let us begin with the following general result.

Lemma 16: *Let H be a Hamiltonian function for a manifold Q, and D a submanifold of T^*Q. Then* $\mathrm{d}H|_D \in \mathrm{diag}(\mathcal{K})^\flat$ [*see Eq.* (36)]. *In particular*, $\mathrm{d}H|_D \in \mathcal{K}^\flat$.

Proof: The submanifold $\mathrm{diag}(\mathcal{K}) \subset T_D T^*Q$ is given locally by

$$\mathrm{diag}(\mathcal{K}) = \left\{ \left(q,p,\frac{\partial H}{\partial p}(q,p),\dot{p} \right) : (q,p) \in D \right\}$$

with $\dot{p}$ arbitrary. Accordingly $\mathrm{diag}(\mathcal{K})^\flat$ is given by covectors with arbitrary coordinates with respect to $\mathrm{d}q^i$'s and coordinates $\partial H/\partial p_i$ with respect to $\mathrm{d}p_i$'s. From this we obtain

$$\mathrm{d}H|_x = \left.\frac{\partial H}{\partial q^i}\right|_x \mathrm{d}q^i + \left.\frac{\partial H}{\partial p_i}\right|_x \mathrm{d}p_i \in \mathrm{diag}(\mathcal{K})^\flat, \quad \forall\, x \in D.$$

Finally, since $\mathrm{diag}(\mathcal{K}) \subset \mathcal{K}$, the last statement follows. ■

Recall from the preceding section that when $\mathbb{F}H(D)$ is a distribution on Q, then $\mathcal{K}$ is a distribution too. As we have seen in Lemma 15, the distribution $\mathcal{K}^\perp$ often gives a complement of TD in $T_D T^*Q$. Having this in mind, let us make some observations.

Consider again a complement $\mathcal{U}^\perp$ of TD inside $T_D T^*Q$, and the related projection $\mathfrak{p}_{\mathcal{U}^\perp}$. Associated to $\mathcal{U}^\perp$ we also have a decomposition

$$T^*_D T^*Q = TD^o \oplus \mathcal{U}^\flat.$$

It is clear that $i^*: T^*_D T^*Q \twoheadrightarrow T^*D$, or more precisely the restriction $i^*|_{\mathcal{U}^\flat}$, defines a bijection from $\mathcal{U}^\flat$ to T^*D [note that $\ker(i^*) = TD^o$]. From the latter we have an injective vector bundle morphism

$$\mathfrak{j}_{\mathcal{U}^\flat}: T^*D \hookrightarrow T^*_D T^*Q,$$

with range equal to $\mathcal{U}^\flat$, such that $\mathfrak{j}_{\mathcal{U}^\flat}(x) = (i^*|_{\mathcal{U}^\flat})^{-1}(x)$, for all $x \in T^*D$. Accordingly,

$$i^* \mathfrak{j}_{\mathcal{U}^\flat} = \mathrm{id}_{T^*D} \quad \textit{and} \quad \mathfrak{j}_{\mathcal{U}^\flat} i^*\big|_{\mathcal{U}^\flat} = \mathrm{id}_{\mathcal{U}^\flat}. \tag{39}$$

In addition, we can write $\mathfrak{p}_{\mathcal{U}^\perp} = i_* \mathfrak{j}^*_{\mathcal{U}^\flat}$, being $\mathfrak{j}^*_{\mathcal{U}^\flat}$ the transpose of $\mathfrak{j}_{\mathcal{U}^\flat}$.

Let us assume, from now on, the validity of the decomposition $T_D T^*Q = TD \oplus \mathcal{V}^\perp$. Then, we can set $\mathcal{U} = \mathcal{V}$ in formulas above.

Theorem 17: *Let $(H,D,\mathcal{V})$ be a GNHS such that $\mathbb{F}H(D)$ is a distribution on Q, and $T_D T^*Q = TD \oplus \mathcal{K}^\perp$ is fulfilled. Then, its equations of motion can be written $X = \Pi^\sharp(\mathrm{d}H_D)$, with*

$$\Pi^\sharp: T^*D \to TD \quad \textit{given by } \Pi^\sharp = \mathfrak{j}^*_{\mathcal{V}^\flat} \omega_D^\sharp \mathfrak{j}_{\mathcal{K}^\flat}.$$

As a consequence, related to $(H,D,\mathcal{V})$ we have a bracket on D,

$$\{f,g\} = \Pi(\mathrm{d}f,\mathrm{d}g) = \Lambda_D(\mathfrak{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathfrak{j}_{\mathcal{K}^\flat}(\mathrm{d}g)), \tag{40}$$

where $\Lambda: T^*T^*Q \times T^*T^*Q \to \mathbb{R}$ is the Poisson bivector associated to ω, and Λ_D its restriction to D.

Proof: Consider the decomposition $T_D T^*Q = TD \oplus \mathcal{K}^\perp$ and related injection $\mathfrak{j}_{\mathcal{K}^\flat}: T^*D \hookrightarrow T^*_D T^*Q$. Since $\mathrm{d}H|_D \in \mathcal{K}^\flat$ (by previous lemma), and recalling that $\mathrm{d}H_D = i^*(\mathrm{d}H|_D)$, we have [using Eq. (39) for $\mathcal{U} = \mathcal{K}$], that

$$\mathrm{d}H\big|_D = \left(\mathfrak{j}_{\mathcal{K}^\flat} i^*\big|_{\mathcal{K}^\flat}\right) \mathrm{d}H|_D = \mathfrak{j}_{\mathcal{K}^\flat}[i^*(\mathrm{d}H|_D)] = \mathfrak{j}_{\mathcal{K}^\flat}(\mathrm{d}H_D).$$

Then, from Eq. (29),

$$X = \mathfrak{p}_{\mathcal{V}^\perp} \omega_D^\sharp(\mathrm{d}H|_D) = \mathfrak{p}_{\mathcal{V}^\perp} \omega_D^\sharp(\mathfrak{j}_{\mathcal{K}^\flat}(\mathrm{d}H_D)) = \mathfrak{p}_{\mathcal{V}^\perp} \omega_D^\sharp \mathfrak{j}_{\mathcal{K}^\flat}(\mathrm{d}H_D).$$

Using now that $\mathfrak{p}_{\mathcal{V}^\perp} = i_* \mathfrak{j}^*_{\mathcal{V}^\flat}$, and identifying X and $i_* X$, the first statement of theorem follows. For the second one, we just must define for all $f,g \in C^\infty(D)$ the bilinear $\{f,g\} = \langle \mathrm{d}f, \Pi^\sharp(\mathrm{d}g) \rangle$. Then,

$$\{f,g\} = \langle \mathrm{d}f, \mathrm{j}_{\mathcal{V}^\flat}^* \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\mathrm{d}g)\rangle = \langle \mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\mathrm{d}g)\rangle$$

$$= \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathrm{j}_{\mathcal{K}^\flat}(\mathrm{d}g)),$$

and the theorem is proved. ■

Remark 18: *Note that the bracket given in theorem above is bilinear, and moreover a derivation with respect to both arguments. But it fails to be antisymmetric and Jacobi, in general. The antisymmetry property is explicitly broken by the presence of two different distributions* $\mathcal{V}$ *and* $\mathcal{K}$. *This makes the bracket to have a symmetric part, which implies*

$$\dot{H}_D = \{H_D, H_D\} \neq 0,$$

in general. In other words, the described constrained systems are generically nonconservative, unless $\mathcal{V}=\mathcal{K}$, *which holds in the D'Alembert's case.*

When $\mathcal{V}=\mathcal{K}$, the bracket we have obtained is an almost-Poisson bracket, and coincides exactly with that constructed by van der Schaft and Maschke[9] (as it will become clear later, when the local formulation is analyzed). Also, it gives rise on $\mathcal{H}=\mathcal{K}\cap TD$ to the symplectic fibration defined by Bates and Sniatycki,[8] and to a Poisson bracket on D if and only if $\mathcal{H}$ is involutive, as we show below.

Proposition 19: *Under conditions of the theorem above, suppose* $\mathcal{V}=\mathcal{K}$. *Then* Π *is antisymmetric, and we can write*

$$\Pi(\alpha,\beta) = \tilde{\omega}(\Pi^\sharp(\alpha), \Pi^\sharp(\beta)), \quad \text{for } \alpha,\beta \in T^*D,$$

being $\tilde{\omega}: TD\times TD \to \mathbb{R}$ *the closed 2-form* $\tilde{\omega}=i^*\omega_D$. *Defining* $X_f=\Pi^\sharp(\mathrm{d}f)$, *for every function* $f \in C^\infty(D)$, *the related bracket adopts the form*

$$\{f,g\} = \Pi(\mathrm{d}f, \mathrm{d}g) = \tilde{\omega}(X_f, X_g).$$

In addition, $\{,\}$ *is Jacobi if and only if* $\mathcal{K}\cap TD$ *is involutive.*

Proof: First note that $\Pi^\sharp = \mathrm{j}_{\mathcal{K}^\flat}^* \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}$, and accordingly

$$\Pi(\alpha,\beta) = \langle \alpha, \mathrm{j}_{\mathcal{K}^\flat}^* \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\beta)\rangle = \langle \mathrm{j}_{\mathcal{K}^\flat}(\alpha), \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\beta)\rangle$$

$$= \langle \omega_D^\flat \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\alpha), \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\beta)\rangle = \omega_D(\omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\alpha), \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\beta)). \tag{41}$$

On the other hand, since $\mathcal{K}$ is coisotropic (i.e., $\mathcal{K}^\perp \subset \mathcal{K}$), we have

$$\mathcal{K} = \mathcal{K} \cap (TD \oplus \mathcal{K}^\perp) = (\mathcal{K}\cap TD) \oplus \mathcal{K}^\perp,$$

or equivalently, identifying TD and $i_*(TD)$,

$$\mathrm{j}_{\mathcal{K}^\flat}^*(\mathcal{K}) = \mathfrak{p}_{\mathcal{K}^\perp}(\mathcal{K}) = \mathcal{K}\cap TD.$$

Then, given X and Y in $\mathcal{K}$,

$$\omega_D(X,Y) = \omega_D(\mathfrak{p}_{\mathcal{K}^\perp}(X), \mathfrak{p}_{\mathcal{K}^\perp}(Y)) = \omega_D(\mathrm{j}_{\mathcal{K}^\flat}^*(X), \mathrm{j}_{\mathcal{K}^\flat}^*(Y)).$$

Since range of $\omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}$ is $\mathcal{K}$, we can use the last result in Eq. (41), obtaining

$$\Pi(\alpha,\beta) = \omega_D(\mathrm{j}_{\mathcal{K}^\flat}^* \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\alpha), \mathrm{j}_{\mathcal{K}^\flat}^* \omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(\beta)),$$

from which the first part of the proposition easily follows.

For the second part, suppose $\{,\}$ is Jacobi. Then, the related Hamiltonian vector fields $X_f = \Pi^\sharp(\mathrm{d}f)$ define an involutive distribution. Since

$$\Pi^\sharp(T^*D) = \mathrm{j}^*_{\mathcal{K}^\flat}\omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat}(T^*D) = \mathrm{j}^*_{\mathcal{K}^\flat}(\mathcal{K}) = \mathcal{K} \cap TD = \mathcal{H}, \tag{42}$$

then $\mathcal{H}$ is involutive. On the other hand, if $\mathcal{H}$ is involutive, it can be easily shown that (through usual calculations of symplectic geometry)

$$\tilde{\omega}([X_f, X_g], X_h) = -\tilde{\omega}(X_{\{f,g\}}, X_h)$$

for all functions $f, g, h \in C^\infty(D)$. Using the last equation,

$$\mathrm{d}\tilde{\omega}(X_f, X_g, X_h) = 2[\{f,\{g,h\}\} + \{h,\{f,g\}\} + \{g,\{h,f\}\}],$$

and since $\mathrm{d}\tilde{\omega}=0$, the bracket $\{,\}$ is Jacobi. ■

Remark 20: *If* $(H, D, \mathcal{V})$ *is the Hamiltonian side of a triple* (L, C_K, C_K), *the related bracket* $\{,\}$ *is Jacobi if and only if* C_K *is involutive*, *as it is well known.*

Let us consider general homogeneous constraints. Recall that, given a GNHS $(H, D, \mathcal{V})$ with H hyperregular, we say that D is defined by homogeneous constraints if $\mathrm{diag}(\mathcal{K})$ is contained in $\mathcal{L}$ (the Chetaev's distribution related to the system). From Lemma 16, these systems satisfy $\mathrm{d}H|_D \in \mathcal{L}^\flat$. As a consequence we have the following result, similar to the theorem and proposition above, but changing $\mathcal{K}$ by $\mathcal{L}$.

Theorem 21: *Let* $(H, D, \mathcal{V})$ *be a GNHS with homogeneous constraints*, *i.e.*, $\mathrm{diag}(\mathcal{K}) \subseteq \mathcal{L}$, *and such that* $T_D T^*Q = TD \oplus \mathcal{L}^\perp$. *Then*, *its equations of motion can be written* $X = \Pi^\sharp(\mathrm{d}H_D)$, *with*

$$\Pi^\sharp : T^*D \to TD \quad \textit{given by } \Pi^\sharp = \mathrm{j}^*_{\mathcal{V}^\flat}\omega_D^\sharp \mathrm{j}_{\mathcal{L}^\flat}. \tag{43}$$

Its related bracket reads $\{f, g\} = \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathrm{j}_{\mathcal{L}^\flat}(\mathrm{d}g))$. *If in addition* $\mathcal{V} = \mathcal{L}$, *that is to say Chetaev's principle holds*, *then* Π *is antisymmetric and the system is conservative. In such a case* $\{,\}$ *is Jacobi if and only if* $\mathcal{L} \cap TD$ *is involutive.*

Brackets above are examples of the so-called *Leibniz brackets*.[31,32] Given a manifold D, a Leibniz bracket on D is a bilinear map

$$\{,\} : C^\infty(D) \times C^\infty(D) \to C^\infty(D)$$

such that

$$\{f \cdot g, h\} = f \cdot \{g, h\} + \{f, h\} \cdot g \quad \textit{and} \quad \{f, h \cdot g\} = h \cdot \{f, g\} + \{f, h\} \cdot g,$$

i.e., $\{,\}$ is a derivation with respect to both arguments. In such a case we say the pair $(D, \{,\})$ is a Leibniz manifold. Note that giving $\{,\}$ is the same as giving a bilinear $\Pi : T^*D \times T^*D \to \mathbb{R}$, being $\{f, g\} = \Pi(\mathrm{d}f, \mathrm{d}g)$. So, we can see a Leibniz manifold as a couple (D, Π). Given a function $h : D \to \mathbb{R}$, a dynamical system can be defined on D with equation of motion given by a vector field $X = \Pi^\sharp(\mathrm{d}h)$. The triple (h, D, Π) is called a Leibniz system. The following result is immediate.

Proposition 22: *Given a Hamiltonian system* $(H, D, \mathcal{V})$ *as in theorem above* (*in particular*, *with homogeneous constraints*), *the triple* (H_D, D, Π), *with* Π *given by* (43), *is a Leibniz system.*

2. The general case: linear and nonlinear brackets

In the preceding section, in order to build maps Π giving rise to the dynamic of the involved systems, the only properties we needed from D'Alembert's and Chetaev's distributions were that they are submanifolds $\mathcal{N} \subset T_D T^*Q$ such that

(a) $i^*|_{\mathcal{N}^\flat} : \mathcal{N}^\flat \to T^*D$ is a bijection
(b) and $\mathrm{d}H|_D \in \mathcal{N}^\flat$.

In fact, given a triple $(H, D, \mathcal{V})$, and a submanifold $\mathcal{N} \subset T_D T^*Q$ satisfying (a) and (b), that we will call an admissible submanifold, we can define the map $\mathrm{j}_{\mathcal{N}^\flat} = (i^*|_{\mathcal{N}^\flat})^{-1}$ and a bracket

$$\{f,g\} = \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathrm{j}_{\mathcal{N}^\flat}(\mathrm{d}g))$$

which reproduces on D equations of motion of the system, i.e., $\dot{f}=\{f,H_D\}$. To prove this we can simply repeat the proof of Theorem 17. Note that if $\mathcal{N}^\flat$ is not a distribution, then the bracket above is not linear, in general, with respect to the second argument. In other words,

$$\Pi^\sharp = \mathrm{j}^*_{\mathcal{V}^\flat}\omega_D^\sharp \mathrm{j}_{\mathcal{N}^\flat} : T^*D \to TD$$

is no longer a vector bundle morphism, and consequently it does not define a Leibniz bracket. Let us investigate how admissible submanifolds can be characterized.

Admissible submanifolds and pairs: Given again a decomposition $T^*_DT^*Q=TD^o\oplus\mathcal{U}^\flat$, the elements of any submanifold $\mathcal{N}^\flat \subset T^*_DT^*Q$ can be written as a sum $x+u$, with $x\in TD^o$ and $u\in\mathcal{U}^\flat$. If $i^*|_{\mathcal{N}^\flat}$ is a surjection, since $i^*(x+u)=i^*(u)$, then given $u\in\mathcal{U}^\flat$ there must exists $x\in TD^o$ such that $u+x\in\mathcal{N}^\flat$. If $i^*|_{\mathcal{N}^\flat}$ is an injection, equality $i^*(x+u)=i^*(x'+u)$ implies $x'=d$. Thus, for each $u\in\mathcal{U}^\flat$ there is only one $x\in TD^o$ such that $x+u\in\mathcal{N}^\flat$. Accordingly, bijectivity of $i^*|_{\mathcal{N}^\flat}$ ensures existence of a function $\Phi:\mathcal{U}^\flat\to T^*_DT^*Q$, with range inside TD^o, given by

$$\Phi(u) = x \quad \text{if } u+x\in\mathcal{N}^\flat.$$

In these terms $\mathcal{N}^\flat$ can be written as $\mathcal{N}^\flat=(\Phi+\mathrm{inc}_{\mathcal{U}^\flat})(\mathcal{U}^\flat)$, being $\mathrm{inc}_{\mathcal{U}^\flat}$ the inclusion of $\mathcal{U}^\flat$ inside $T^*_DT^*Q$, or alternatively,

$$\mathcal{N}^\flat = (\Psi + \mathrm{j}_{\mathcal{U}^\flat})(T^*D), \quad \text{with } \Psi = \Phi \mathrm{j}_{\mathcal{U}^\flat} : T^*D \to T^*_DT^*Q.$$

It is clear that $\mathrm{j}_{\mathcal{N}^\flat}=\Psi+\mathrm{j}_{\mathcal{U}^\flat}$. The other property that $\mathcal{N}^\flat$ must satisfy is $\mathrm{d}H|_D\in\mathcal{N}^\flat$. This is equivalent to the condition

$$\Psi(\mathrm{d}H_D) = \mathrm{d}H|_D - \mathrm{j}_{\mathcal{U}^\flat}(\mathrm{d}H_D). \tag{44}$$

Summing up, related to an admissible submanifold $\mathcal{N}^\flat$ we have

(c) a distribution $\mathcal{U}$, such that $\mathcal{U}^\flat$ is a complement of TD^o,
(d) and a map $\Psi: T^*D\to T^*_DT^*Q$ with range inside TD^o and satisfying (44).

Conversely, let us fix a pair $(\mathcal{U},\Psi)$ satisfying (c) and (d). Then, following the same steps as above, $(\mathcal{U},\Psi)$ gives rise to a submanifold $\mathcal{N}^\flat=(\Psi+\mathrm{j}_{\mathcal{U}^\flat})(T^*D)$ satisfying conditions (a) and (b). We can call such pairs $(\mathcal{U},\Psi)$ admissible pairs related to $(H,D,\mathcal{V})$.

Theorem 23: *The set of admissible pairs associated to an arbitrary system $(H,D,\mathcal{V})$ is never empty, and for each element $(\mathcal{U},\Psi)$ of this set the related bracket*

$$\{f,g\}_\Psi = \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathrm{j}_{\mathcal{U}^\flat}(\mathrm{d}g)) + \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \Psi(\mathrm{d}g)) \tag{45}$$

describes the dynamic of the system.

Proof: Given an arbitrary distribution $\mathcal{U}$ as above, we can define Ψ, for each $x\in D$, equal to $\mathrm{d}H|_D-\mathrm{j}_{\mathcal{U}^\flat}(\mathrm{d}H_D)$ for all elements of T^*_xD. ■

If Ψ is a vector bundle morphism, then bracket $\{,\}_\Psi$ is a Leibniz bracket on the manifold D. Moreover,

Theorem 24: *Let $(H,D,\mathcal{V})$ be a GNHS such that $\mathrm{d}H|_x\in T_xD^o$ (or equivalently, $\mathrm{d}H_D|_x=0$) only if $\mathrm{d}H|_x=0$. Then, $(H,D,\mathcal{V})$ defines a Leibniz system on D with bracket $\Pi^\sharp=\mathrm{j}^*_{\mathcal{V}^\flat}\omega_D^\sharp\mathrm{j}_{\mathcal{N}^\flat}$, being $\mathcal{N}$ an admissible distribution.*

Proof: We must prove that for every Hamiltonian function $H\in C^\infty(T^*Q)$, and every submanifold $D\subset T^*Q$, there exists, fixing again a distribution $\mathcal{U}$ as above, a vector bundle morphism $\Psi:T^*D\to T^*_DT^*Q$ with range inside TD^o and satisfying $\Psi(\mathrm{d}H_D)=\mathrm{d}H|_D-\mathrm{j}_{\mathcal{U}^\flat}(\mathrm{d}H_D)$. In this way we are showing that the submanifold $\mathcal{N}^\flat=(\Psi+\mathrm{j}_{\mathcal{U}^\flat})(T^*D)$ is admissible. But this is always possible, in fact, we only need to consider a metric Φ on T^*D, and define Ψ in $\mathrm{d}H_D$ equal to $\mathrm{d}H|_D-\mathrm{j}_{\mathcal{U}^\flat}(\mathrm{d}H_D)$, and equal to zero on the Φ-orthogonal complement of $\mathrm{d}H_D$. The map Ψ is well

defined, since, by hypothesis of the theorem, when $\mathrm{d}H_D|_x=0$ then $\mathrm{d}H|_x=0$. ■

If we choose $\mathcal{U}=\mathcal{V}$ in (45), we have a family of brackets $\Pi_\Psi=\Pi+\pi_\Psi$,

$$\Pi(\alpha,\beta)=\Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\alpha),\mathrm{j}_{\mathcal{V}^\flat}(\beta)),\quad \pi_\Psi(\alpha,\beta)=\Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\alpha),\Psi(\beta)).$$

Note that Π defines an almost-Poisson bracket. Writing $\mathcal{W}=\mathcal{V}^\perp$, and recalling that $\mathfrak{p}_{\mathcal{V}^\perp}=\mathrm{j}^*_{\mathcal{V}^\flat}$, or equivalently $\mathfrak{p}^*_{\mathcal{W}}=\mathrm{j}_{\mathcal{V}^\flat}$, we have

$$\Pi(\alpha,\beta)=\Lambda_D(\mathfrak{p}^*_{\mathcal{W}}(\alpha),\mathfrak{p}^*_{\mathcal{W}}(\beta)).$$

This kind of brackets were first introduced by Marle,[2] and called *pseudo-Poisson* brackets. In Ref. 33 they were denoted $\{,\}_{nh}$. The latter describes dynamic for related systems only if $\mathrm{d}H|_D=\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}H_D)$, as happens for systems with linear constraints and obeying D'Alembert's principle, and for systems with homogeneous constraints and obeying Chetaev's principle (see Theorems 17 and 21). The term we must add to describe the dynamics correctly

$$\pi_\Psi(\mathrm{d}f,\mathrm{d}H_D)=\Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f),\Psi(\mathrm{d}H_D))=\Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f),\mathrm{d}H|_D-\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}H_D)),$$

was called $R_H(f)$ in Ref. 33.

We want to emphasize that, given an arbitrary triple $(H,D,\mathcal{V})$, there is not in general a *naturally* related admissible pair $(\mathcal{U},\Psi)$. Nevertheless, as we have seen in the preceding section, for linear and homogeneous constraints we do have *natural* pairs $(\mathcal{K},0)$ and $(\mathcal{L},0)$, denoting by 0 the null function. In these cases, as we have seen before, such pairs give rise to Leibniz brackets. In the following section we shall see that systems with affine constraints also have a naturally related admissible pair, but the bracket it defines is not a Leibniz one.

Leibniz systems and GNHS: We have seen in the last theorem that (under a technical assumption) every GNHS is a Leibniz system. Now, we shall prove the converse statement.

Theorem 25: *Let* (h,D,Π) *be a Leibniz system. Then*, *there exists a manifold* Q, *an embedding* $i:D\hookrightarrow T^*Q$, *a function* $H\in C^\infty(T^*Q)$ *and a distribution* $\mathcal{V}\subset T_DT^*Q$, *satisfying*

(i) $H\circ i=h$,
(ii) *the decomposition* $T_DT^*Q=TD\oplus\mathcal{V}^\perp$ *holds*,
(iii) *there exists a distribution* $\mathcal{N}$ *along* D *such that*

$$T_DT^*Q=TD\oplus\mathcal{N}^\perp,\quad \mathrm{d}H|_D\in\mathcal{N}^\flat,\quad \textit{and}\quad \Pi^\sharp=\mathrm{j}^*_{\mathcal{V}^\flat}\omega_D^\sharp\mathrm{j}_{\mathcal{N}^\flat}.$$

In other words, *every Leibniz system is defined by a GNHS* $(H,D,\mathcal{V})$ *and a convenient admissible submanifold. Moreover*, H *can be chosen to be hyperregular and* $\mathcal{V}$ *such that* $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V})=\mathcal{V}$ [*recall Eq.* (17)]. *Accordingly*, (h,D,Π) *can be derived as being the Hamiltonian side of a triple* (L,C_K,C_V).

Proof: Consider a Leibniz system (h,D,Π). Let us define $Q=D$, and let us see D as the null section $i:D\hookrightarrow T^*Q$ of the cotangent bundle T^*Q. In these terms, D is given in coordinates by points (q,p) such that $p=0$. Define $\mathcal{V}=\ker(\pi_*)|_D$, being $\pi:T^*Q\to Q$ the canonical projection. Note that $TD,\mathcal{V}\subset T^*_DT^*Q$ are Lagrangian distributions along D, with respect to the canonical 2-form ω of T^*Q. In coordinates we have

$$TD=TD^\perp=\{(q,p,\dot q,\dot p):p=0\ \textit{and}\ \dot p=0\},\tag{46}$$

and

$$\mathcal{V}=\mathcal{V}^\perp=\{(q,p,\dot q,\dot p):p=0\ \textit{and}\ \dot q=0\}.\tag{47}$$

It is clear that $T_DT^*Q=TD\oplus\mathcal{V}^\perp$ and also $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V})=\mathcal{V}$.

Now, let us consider the map

$$\Psi = \omega_D^\flat i_* \Pi^\sharp : T^*D \to T^*_D T^*Q,$$

and a related distribution

$$\mathcal{N}^\flat = (\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat})(T^*D) \subset T^*_D T^*Q.$$

Note that range of $\omega_D^\flat i_* \Pi^\sharp$ is TD^o, since $TD^\flat = (TD^\perp)^o = TD^o$. Then, $i^*|_{\mathcal{N}^\flat}$ is a bijection between T^*D and its range, in fact

$$i^*\big|_{\mathcal{N}^\flat}(\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat}) = i^* \mathrm{j}_{\mathcal{V}^\flat} = \mathrm{id}_{T^*D},$$

and for all $\nu \in \mathcal{N}^\flat$, since $\nu = (\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat})(d)$ for some $d \in T^*D$,

$$(\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat}) i^*\big|_{\mathcal{N}^\flat}(\nu) = (\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat}) i^* (\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat})(d)$$

$$= (\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat})(d) = \nu.$$

As a consequence, decomposition $T_D T^*Q = TD \oplus \mathcal{N}^\perp$ holds, and the related map $\mathrm{j}_{\mathcal{N}^\flat} = (i^*|_{\mathcal{N}^\flat})^{-1}$ is given by

$$\mathrm{j}_{\mathcal{N}^\flat} = \omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat}.$$

Moreover, since range of $\omega_D^\sharp \mathrm{j}_{\mathcal{V}^\flat}$ is $\mathcal{V} = \mathcal{V}^\perp$ (and consequently $\mathrm{j}^*_{\mathcal{V}^\flat} = \mathfrak{p}_{\mathcal{V}^\perp}$ is null there), and $\mathrm{j}^*_{\mathcal{V}^\flat} i_* = \mathfrak{p}_{\mathcal{V}^\perp} i_* = \mathrm{id}_{TD}$, it follows that

$$\mathrm{j}^*_{\mathcal{V}^\flat} \omega_D^\sharp \mathrm{j}_{\mathcal{N}^\flat} = \mathrm{j}^*_{\mathcal{V}^\flat} \omega_D^\sharp (\omega_D^\flat i_* \Pi^\sharp + \mathrm{j}_{\mathcal{V}^\flat}) = \mathrm{j}^*_{\mathcal{V}^\flat} (i_* \Pi^\sharp + \omega_D^\sharp \mathrm{j}_{\mathcal{V}^\flat})$$

$$= \mathrm{j}^*_{\mathcal{V}^\flat} i_* \Pi^\sharp + \mathrm{j}^*_{\mathcal{V}^\flat} \omega_D^\sharp \mathrm{j}_{\mathcal{V}^\flat} = \Pi^\sharp.$$

Let us see that a hyperregular Hamiltonian H such that $H \circ i = h$ and $\mathrm{d}H|_D \in \mathcal{N}^\flat$ can be constructed. Consider a metric Φ on T^*Q, and define the Hamiltonian function

$$H(\alpha_q) = \tfrac{1}{2}\Phi(\alpha_q, \alpha_q) + \Pi(\alpha_q, \mathrm{d}h_q) + h \circ \pi(\alpha_q), \quad \alpha_q \in T^*Q.$$

In coordinates,

$$H(q,p) = \frac{1}{2} p_i \Phi^{ij}(q) p_j + p_i \Pi^{ij}(q) \frac{\partial h}{\partial q^j}(q) + h(q),$$

being $\Phi^{ij}(q)$ and $\Pi^{ij}(q)$ the matrix elements on a point q of the bilinear maps Φ and Π. It is clear that $H \circ i = h$, and it can be shown that

$$\mathrm{d}H|_D = \omega_D^\flat i_* \Pi^\sharp(\mathrm{d}h) + \mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}h) = \mathrm{j}_{\mathcal{N}^\flat}(\mathrm{d}h).$$

This easily follows from Eqs. (46) and (47), and the fact that

$$\frac{\partial H}{\partial q^i}(q,0) = \frac{\partial h}{\partial q^i}(q) \quad \textit{and} \quad \frac{\partial H}{\partial p_i}(q,0) = \Pi^{ij}(q) \frac{\partial h}{\partial q^j}(q).$$

Summing up, from (h, D, Π) we have constructed a GNHS $(H, D, \mathcal{V})$ and a related admissible pair $(\mathcal{V}, \Psi)$, such that $H \circ i = h$ and the derived bracket coincides exactly with Π. The fact that H is hyperregular and $\mathfrak{s}^{-1}\mathfrak{s}(\mathcal{V}) = \mathcal{V}$ ensures that $(H, D, \mathcal{V})$ has a Lagrangian counterpart. ■

B. Local construction for the linear and affine cases

When $\mathbb{F}H(D)$ is an affine subbundle of TQ, then

$$\mathcal{K} = \pi_*^{-1}(\mathbb{F}H(D))\big|_D = \pi_*^{-1}(\mathbb{F}H(D)_{\text{vec}} + \nu)\big|_D = \mathcal{K}_{\text{vec}} + \sigma,$$

with σ a fixed section of $T_D T^*Q$ such that $\pi_*(\sigma) - v \in \mathbb{F}H(D)_{\text{vec}}$. Let us suppose $\mathcal{K}_{\text{vec}}$ is a complement of $TD^\perp$ in $T_D T^*Q$ (e.g., if H is normal, as follows from Lemma 15). Then, there exists a unique section σ inside $TD^\perp$ such that $\mathcal{K} = \mathcal{K}_{\text{vec}} + \sigma$. In what follows, σ will always denote such a section. We know from Lemma 16 that $\mathrm{d}H\big|_D \in \mathcal{K}^\flat$. On the other hand, $\mathcal{K}^\flat = \mathcal{K}_{\text{vec}}^\flat + \sigma^\flat$ with $\sigma^\flat \in TD^o$.Accordingly we can write

$$\mathcal{K}^\flat = \mathrm{j}_{\mathcal{K}^\flat}(T^*D), \quad \mathrm{j}_{\mathcal{K}^\flat} = \Sigma + \mathrm{j}_{\mathcal{K}_{\text{vec}}^\flat},$$

being $\Sigma : T^*D \to T_D^* T^*Q : \alpha \mapsto (\sigma^\flat)_x$ for all $x \in D$ and $\alpha \in T_x^* D$. Thus, $\mathcal{K}$ satisfies admissibility conditions (a) and (b). Note also [from (44)]

$$\sigma = \Sigma(\mathrm{d}H_D) = \omega_D^\sharp(\mathrm{d}H\big|_D - \mathrm{j}_{\mathcal{K}_{\text{vec}}^\flat}(\mathrm{d}H_D)). \tag{48}$$

Using all that, the next result follows straightforwardly.

Proposition 26: *Given a triple* $(H, D, \mathcal{V})$ *such that* $\mathbb{F}H(D)$ *is an affine subbundle of* TQ, *and* $T_D T^*Q = TD \oplus \mathcal{K}_{\text{vec}}^\perp$, *the dynamics of the system is described in terms of the bracket*

$$\{f,g\} = \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathrm{j}_{\mathcal{K}^\flat}(\mathrm{d}g))$$

$$= \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \mathrm{j}_{\mathcal{K}_{\text{vec}}^\flat}(\mathrm{d}g)) + \Lambda_D(\mathrm{j}_{\mathcal{V}^\flat}(\mathrm{d}f), \sigma^\flat),$$

or equivalently

$$\{f,g\} = \{f,g\}_{\text{bilin}} + \langle \mathrm{d}f, \mathrm{j}_{\mathcal{V}^\flat}^*(\sigma)\rangle, \quad \{f,g\}_{\text{bilin}} = \langle \mathrm{d}f, \mathrm{j}_{\mathcal{V}^\flat}^* \omega_D^\sharp \mathrm{j}_{\mathcal{K}_{\text{vec}}^\flat}(\mathrm{d}g)\rangle, \tag{49}$$

being σ *the section of* $TD^\perp$ *that enables us to write* $\mathcal{K} = \mathcal{K}_{\text{vec}} + \sigma$.

Remark 27: *Note that*, *if* D *is coisotropic*, *i.e.*, $TD^\perp \subset TD$, *then* $\sigma \in TD$ *and consequently*

$$\{f,g\} = \{f,g\}_{\text{bilin}} + \langle \mathrm{d}f, \sigma\rangle.$$

The bracket above is related to the admissible pair $(\mathcal{K}_{\text{vec}}, \Sigma)$ and, clearly, it is naturally associated to $(H, D, \mathcal{V})$. Of course, we can define a Leibniz bracket to describe the dynamic of these systems, as we have shown in Theorem 25.

Local procedure: In order to give an explicit description of brackets (49), we shall build in local coordinates the maps $\mathfrak{p}_{\mathcal{V}^\perp} = \mathrm{j}_{\mathcal{V}^\flat}^*$ and $\mathrm{j}_{\mathcal{K}_{\text{vec}}^\flat}$. We focus on systems with variational constraints that do not depend on momenta ($l = 0$ case). In the D'Alembert's linear case $\mathcal{V} = \mathcal{K}_{\text{vec}} = \mathcal{K}$, we obtain the bracket of van der Schaft and Maschke.[9] It is worth mentioning that this procedure represents an alternative to that introduced in Ref. 33, to describe equations of motion for systems with affine kinematic constraints.

Let us consider a triple (L, C_K, C_V), such that $C_K = C_K^{\text{vec}} + v$, being v a section, and C_K^{vec} and C_V distributions on Q. We shall assume $\dim C_K = \dim C_V$. Then, in coordinates, C_K and C_V are given by equations of the form

$$w_i^a(q)\dot{q}^i = \gamma^a(q) \quad \text{and} \quad v_i^a(q)\delta q^i = 0, \quad a = 1, \ldots, k,$$

respectively. Of course, C_K^{vec} is given by $w_i^a(q)\dot{q}^i = 0$. On the Hamiltonian side we have the submanifold $D = \mathbb{F}L(C_K)$ given in coordinates by points (q,p) such that

$$w_i^a \frac{\partial H}{\partial p_i}(q,p) = \gamma^a, \quad a = 1, \ldots, k. \tag{50}$$

Related distributions $\mathcal{K}_{\text{vec}}$ and $\mathcal{V}$ read

$$\mathcal{K}_{\text{vec}} = \{(q,p,x,y):(q,p) \in D, w_i^a x^i = 0\} \tag{51}$$

and

$$\mathcal{V} = \{(q,p,x,y):(q,p) \in D, v_i^a x^i = 0\}. \tag{52}$$

We shall assume H is normal and $TD \cap \mathcal{V}^\perp = 0$, or equivalently $C_K^{(0)} \cap C_V = 0$ [recall Eq. (30)]. These facts ensure that there exist

$$v_a^i \quad \text{and} \quad Y_\alpha^i, \quad a = 1, \ldots, k \quad \text{and} \quad \alpha = 1, \ldots, n-k, \tag{53}$$

such that

$$v_i^a v_b^i = \delta_b^a, \quad v_i^a Y_\alpha^i = 0, \quad \text{and} \quad w_i^a v_b^i = \varphi_b^a \text{ is invertible}. \tag{54}$$

The last property is a direct consequence of Eq. (31). Moreover, if we define

$$\widetilde{p}_\alpha = Y_\alpha^i p_i \quad \text{and} \quad \hat{p}_a = v_a^i p_i, \tag{55}$$

then Eqs. (50) can be solved in terms of $\widetilde{p}$'s, i.e., we can write

$$\hat{p}_a = \hat{p}_a(q^i, \widetilde{p}_\alpha), \quad a = 1, \ldots, k.$$

It follows from the last assertion that we can choose local coordinates $(q, \widetilde{p})$ for D such that the embedding $i: D \hookrightarrow T^*Q$ is given by $i(q,\widetilde{p}) = (q, \widetilde{p}, \hat{p}(q,\widetilde{p}))$. Given an arbitrary element

$$X = \mu^i \frac{\partial}{\partial q^i} + \nu_\alpha \frac{\partial}{\partial \widetilde{p}_\alpha} + \varpi_a \frac{\partial}{\partial \hat{p}_a} \tag{56}$$

of $T_D T^*Q$, since elements of $\mathcal{V}^\perp$ are of the form $Y = \varpi_a \partial / \partial \hat{p}_a$, it follows that

$$\mathfrak{p}_{\mathcal{V}^\perp}(X) = \mathfrak{j}^*_{\mathcal{V}^\flat}(X) = \mu^i \frac{\partial}{\partial q^i} + \nu_\alpha \frac{\partial}{\partial \widetilde{p}_\alpha}, \tag{57}$$

seeing $\mathfrak{p}_{\mathcal{V}^\perp}$ as a map onto TD. Then, $\mathfrak{j}^*_{\mathcal{V}^\flat}: T_D T^*Q \to TD$ is locally given by a $(2n-k) \times 2n$ matrix

$$\mathbb{V} = \begin{pmatrix} \mathbb{I}_{2n-k} & \mathbb{O}_{(2n-k)\times k} \end{pmatrix}, \tag{58}$$

where $\mathbb{I}_r$ denotes the $r \times r$ identity matrix, and $\mathbb{O}_{r\times s}$ the $r \times s$ null matrix. On the other hand, in the same coordinates, $\omega^\sharp: T^*T^*Q \to TT^*Q$ is given by the $2n \times 2n$ matrix

$$\mathbb{J} = \begin{pmatrix} \{q,q\}_o & \{q,\widetilde{p}\}_o & \{q,\hat{p}\}_o \\ \{\widetilde{p},q\}_o & \{\widetilde{p},\widetilde{p}\}_o & \{\widetilde{p},\hat{p}\}_o \\ \{\hat{p},q\}_o & \{\hat{p},\widetilde{p}\}_o & \{\hat{p},\hat{p}\}_o \end{pmatrix}, \tag{59}$$

where $\{,\}_o$ denotes the canonical Poisson bracket. Of course, to obtain $\omega_D^\sharp$, we only need to consider the restriction $\mathbb{J}|_D$ of $\mathbb{J}$ to D. Now, let us derive local expressions for $\mathfrak{j}_{\mathcal{K}_{\text{vec}}^\flat}: T^*D \to T_D^* T^*Q$ and the section σ. We can do that simultaneously by using Eq. (48). The idea is to calculate $\mathrm{d}H_D$ in terms of $\mathrm{d}H|_D$, for generic H, and then invert the relation to obtain

$$\mathrm{d}H|_D = \mathfrak{j}_{\mathcal{K}_{\text{vec}}^\flat}(\mathrm{d}H_D) + \sigma^\flat.$$

Writing

$$\widetilde{H}(q,\widetilde{p},\hat{p}) = H(q, p(q,\widetilde{p},\hat{p})),$$

this will give us

$$\left.\begin{pmatrix} \dfrac{\partial \tilde{H}}{\partial q^j} \\ \dfrac{\partial \tilde{H}}{\partial \tilde{p}_\beta} \\ \dfrac{\partial \tilde{H}}{\partial \hat{p}_b} \end{pmatrix}\right|_D = \mathbb{K} \cdot \begin{pmatrix} \dfrac{\partial H_D}{\partial q^j} \\ \dfrac{\partial H_D}{\partial \tilde{p}_\beta} \end{pmatrix} + \begin{pmatrix} s_i \\ s^\alpha \\ s^a \end{pmatrix}, \tag{60}$$

being $\mathbb{K}$ a $2n \times (2n-k)$ rectangular matrix representing $\mathrm{j}_{\mathcal{K}^\flat_{\mathrm{vec}}}$, and s_i, s^α, s^a the coordinates of $\sigma^\flat$ with respect to such coordinates. Accordingly, the section σ can be obtained as

$$\sigma = \begin{pmatrix} \sigma^i \\ \sigma_\alpha \\ \sigma_a \end{pmatrix} = \mathbb{J}\Big|_D \cdot \begin{pmatrix} s_i \\ s^\alpha \\ s^a \end{pmatrix}. \tag{61}$$

Now let us start calculating. First, writing (50) in terms of $\tilde{H}$ we have

$$w_i^a \left(\left.\frac{\partial \tilde{H}}{\partial \tilde{p}_\alpha}\right|_D Y^i_\alpha + \left.\frac{\partial \tilde{H}}{\partial \hat{p}_b}\right|_D v^i_b \right) = \gamma^a. \tag{62}$$

Since $w_i^a v^i_b = \varphi^a_b$ is invertible (by construction), we can write

$$\left.\frac{\partial \tilde{H}}{\partial \hat{p}_a}\right|_D = \gamma^b (\varphi^{-1})^a_b - l^a_\alpha \left.\frac{\partial \tilde{H}}{\partial \tilde{p}_\alpha}\right|_D, \quad \text{being } l^a_\alpha = (\varphi^{-1})^a_b w^b_i Y^i_\alpha. \tag{63}$$

Using that, we have

$$\frac{\partial H_D}{\partial q^i} = \left.\frac{\partial \tilde{H}}{\partial q^i}\right|_D + \left.\frac{\partial \tilde{H}}{\partial \hat{p}_a}\right|_D \frac{\partial \hat{p}_a}{\partial q^i}$$

$$= \left.\frac{\partial \tilde{H}}{\partial q^i}\right|_D - l^a_\alpha \frac{\partial \hat{p}_a}{\partial q^i} \left.\frac{\partial \tilde{H}}{\partial \tilde{p}_\alpha}\right|_D + \gamma^b (\varphi^{-1})^a_b \frac{\partial \hat{p}_a}{\partial q^i}$$

and

$$\frac{\partial H_D}{\partial \tilde{p}_\alpha} = \left.\frac{\partial \tilde{H}}{\partial \tilde{p}_\alpha}\right|_D + \left.\frac{\partial \tilde{H}}{\partial \hat{p}_a}\right|_D \frac{\partial \hat{p}_a}{\partial \tilde{p}_\alpha}$$

$$= \left(\delta^\alpha_\beta - l^a_\beta \frac{\partial \hat{p}_a}{\partial \tilde{p}_\alpha}\right) \left.\frac{\partial \tilde{H}}{\partial \tilde{p}_\beta}\right|_D + \gamma^b (\varphi^{-1})^a_b \frac{\partial \hat{p}_a}{\partial \tilde{p}_\alpha}.$$

Since decomposition $T^*_D T^* Q = TD^o \oplus \mathcal{K}^\flat_{\mathrm{vec}}$ holds (which in the present case follows from normality of H), it can be shown that the matrix

$$\psi^\alpha_\beta = \delta^\alpha_\beta - l^a_\beta \frac{\partial \hat{p}_a}{\partial \tilde{p}_\alpha} \tag{64}$$

is invertible. Then, we can write derivatives of $\widetilde{H}$ restricted to D in terms of those of H_D as (i.e., $\mathrm{d}H|_D$ as a function of $\mathrm{d}H_D$)

$$\left.\frac{\partial \widetilde{H}}{\partial q^i}\right|_D = \frac{\partial H_D}{\partial q^i} + [\Lambda_1]_{i\alpha}\frac{\partial H_D}{\partial \widetilde{p}_\alpha} + s_i,$$

$$\left.\frac{\partial \widetilde{H}}{\partial \widetilde{p}_\alpha}\right|_D = [\Lambda_2]^\alpha_\beta \frac{\partial H_D}{\partial \widetilde{p}_\beta} + s^\alpha,$$

$$\left.\frac{\partial \widetilde{H}}{\partial \hat{p}_a}\right|_D = [\Lambda_3]^a_\alpha \frac{\partial H_D}{\partial \widetilde{p}_\alpha} + s^a,$$

being

$$[\Lambda_1]_{i\alpha} = (\psi^{-1})^\beta_\alpha I^a_\beta \frac{\partial \hat{p}_a}{\partial q^i}, \quad [\Lambda_2]^\alpha_\beta = (\psi^{-1})^\alpha_\beta,$$

$$[\Lambda_3]^a_\alpha = -(\psi^{-1})^\beta_\alpha I^a_\beta, \tag{65}$$

and

$$s_i = -\gamma^b(\varphi^{-1})^a_b\left([\Lambda_1]_{i\alpha}\frac{\partial \hat{p}_a}{\partial \widetilde{p}_\alpha} + \frac{\partial \hat{p}_a}{\partial q^i}\right),$$

$$s^\alpha = -\gamma^b(\varphi^{-1})^a_b[\Lambda_2]^\alpha_\beta \frac{\partial \hat{p}_a}{\partial \widetilde{p}_\beta},$$

$$s^a = -\gamma^b(\varphi^{-1})^c_b\left([\Lambda_3]^a_\alpha \frac{\partial \hat{p}_c}{\partial \widetilde{p}_\alpha} - \delta^a_c\right). \tag{66}$$

Accordingly, having Eq. (60) in mind, the matrix $\mathbb{K}$ is given by

$$\mathbb{K} = \begin{pmatrix} \mathbb{I}_n & \Lambda_1 \\ \mathbb{O}_{(n-k)\times n} & \Lambda_2 \\ \mathbb{O}_{k\times n} & \Lambda_3 \end{pmatrix}, \tag{67}$$

and components $\sigma^i, \sigma_\alpha, \sigma_a$ follows from (61).

With all that, the bilinear part of bracket (49), given by $\mathrm{j}^*_{\mathcal{V}^\flat}\omega_D^\sharp \mathrm{j}_{\mathcal{K}^\flat_{\mathrm{vec}}}$, is

$$\{f,g\}_{\mathrm{bilin}} = \left(\frac{\partial f}{\partial q}\frac{\partial f}{\partial \widetilde{p}}\right)\cdot \mathbb{V}\cdot \mathbb{J}|_D \cdot \mathbb{K}\cdot \begin{pmatrix} \dfrac{\partial g}{\partial q} \\ \dfrac{\partial g}{\partial \widetilde{p}} \end{pmatrix}. \tag{68}$$

In the D'Alembertian case, i.e., when $\mathcal{V}=\mathcal{K}_{\mathrm{vec}}$, or equivalently $C_V = C_K^{\mathrm{vec}}$, since we can take $v_i^a = w_i^a$, we have [recall (54)]

$$\varphi^a_b = \delta^a_b, \quad I^a_\alpha = 0 \text{ and } \psi^\alpha_\beta = \delta^\alpha_\beta.$$

Thus,

$$\mathbb{K}=\begin{pmatrix} \mathbb{I}_n & \mathbb{O}_{n\times(n-k)} \\ \mathbb{O}_{(n-k)\times n} & \mathbb{I}_{n-k} \\ \mathbb{O}_{k\times n} & \mathbb{O}_{k\times(n-k)} \end{pmatrix}=\begin{pmatrix} \mathbb{I}_{2n-k} \\ \mathbb{O}_{k\times(2n-k)} \end{pmatrix}=\mathbb{V}^t,$$

and

$$\mathbb{V}\cdot\mathbb{J}|_D\cdot\mathbb{K}=\mathbb{V}\cdot\mathbb{J}|_D\cdot\mathbb{V}^t$$

gives exactly the antisymmetric matrix appearing in Ref. 9.

Finally, adding the term containing the section σ, since

$$\mathbb{V}^t\cdot\begin{pmatrix} \sigma^i \\ \sigma_\alpha \\ \sigma_a \end{pmatrix}=\begin{pmatrix} \sigma^i \\ \sigma_\alpha \end{pmatrix},$$

the total bracket becomes [see Eq. (49)]

$$\{f,g\}=\{f,g\}_{\text{bilin}}+\left(\frac{\partial f}{\partial q^i}\frac{\partial f}{\partial\tilde{p}_\alpha}\right)\cdot\begin{pmatrix} \sigma^i \\ \sigma_\alpha \end{pmatrix},$$

and equations of motion read

$$\dot{q}^i=\{q^i,H_D\}_{\text{bilin}}+\sigma^i,\quad \dot{\tilde{p}}_\alpha=\{\tilde{p}_\alpha,H_D\}_{\text{bilin}}+\sigma_\alpha.$$

Summing up, given a GNHS $(H,D,\mathcal{V})$ such that H is normal and $T_DT^*Q=TD\oplus\mathcal{V}^\perp$ holds, in order to write down the bracket (49) we must

(1) define v_a^i and Y_α^i obeying (54), and coordinates $(q,\tilde{p},\hat{p})$ given in (55);
(2) construct the function $\hat{p}=\hat{p}(q,\tilde{p})$ [using (62) to set $\hat{p}$ as a function of $q,\tilde{p}$],
(3) calculate matrices $\mathbb{V}$, $\mathbb{J}$ and $\mathbb{J}|_D$ [see (58) and (59)],
(4) calculate matrix $\mathbb{K}$ in terms of φ, l, and ψ [see (54), (63)–(65), and (67)];
(5) construct the section's components σ^i,σ_α from (61) and (66).

Note that all above objects only depend on data w_i^a, γ^a, and v_i^a.

Brackets for the inverted pendulum: Let us come back to the inverted pendulum. Suppose again that we have affine kinematic constraints given by $\dot{x}-\rho(\theta)\dot{\theta}=\gamma(\theta)$, and variational constraints $\delta x=0$. Then, the number of equations is $k=1$, and vectors w_i^a and v_i^a are $w=(1,-\rho)$ and $v=(1,0)$, respectively. From steps (1) and (2) we have

$$\tilde{p}=p_\theta,\quad \hat{p}=p_x,\quad \hat{p}(x,\theta,\tilde{p})=\chi(\theta)\tilde{p}+\phi(\theta)$$

[see (22) and (23)], and matrices $\mathbb{V}$, $\mathbb{J}$, and $\mathbb{J}|_D$ of step (3) are given by

$$\mathbb{V}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}\quad\text{and}\quad \mathbb{J}=\mathbb{J}|_D=\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}.$$

Since φ, l, and ψ are in this case

$$\varphi=1,\quad l=-\rho,\quad \psi=1+\rho\chi,$$

it follows that

$$[\Lambda_1]_i = -\frac{\rho}{1+\rho\chi}\frac{\partial \hat{p}}{\partial q^i}, \quad \Lambda_2 = \frac{1}{1+\rho\chi}, \quad \Lambda_3 = \frac{\rho}{1+\rho\chi}$$

and accordingly [see step (4)]

$$\mathbb{K} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & -\dfrac{\rho\Delta}{1+\rho\chi} \\ 0 & 0 & \dfrac{1}{1+\rho\chi} \\ 0 & 0 & \dfrac{\rho}{1+\rho\chi} \end{pmatrix},$$

being

$$\Delta = \tilde{p}\frac{\mathrm{d}\chi}{\mathrm{d}\theta} + \frac{\mathrm{d}\phi}{\mathrm{d}\theta}. \tag{69}$$

Thus,

$$\mathbb{V}\cdot\mathbb{J}|_D\cdot\mathbb{K} = \begin{pmatrix} 0 & 0 & \dfrac{\rho}{1+\rho\chi} \\ 0 & 0 & \dfrac{1}{1+\rho\chi} \\ 0 & -1 & \dfrac{\rho\Delta}{1+\rho\chi} \end{pmatrix}.$$

Now, following step (5), we have

$$s_i = -\frac{\gamma}{1+\rho\chi}\frac{\partial \hat{p}}{\partial q^i}, \quad \tilde{s} = -\frac{\gamma\chi}{1+\rho\chi}, \quad \hat{s} = \frac{\gamma}{1+\rho\chi},$$

and so

$$\sigma = \frac{\gamma}{1+\rho\chi}\begin{pmatrix} 1 \\ -\chi \\ \Delta \end{pmatrix}.$$

In conclusion, the *natural* bracket related to the inverted pendulum with affine constraints is

$$\{f,g\} = \frac{\partial f}{\partial x}\frac{\rho}{1+\rho\chi}\frac{\partial g}{\partial \tilde{p}} + \frac{\partial f}{\partial \theta}\frac{1}{1+\rho\chi}\frac{\partial g}{\partial \tilde{p}} - \frac{\partial f}{\partial \tilde{p}}\left(\frac{\partial g}{\partial \theta} - \frac{\rho\Delta}{1+\rho\chi}\frac{\partial g}{\partial \tilde{p}}\right)$$

$$+ \frac{\gamma}{1+\rho\chi}\left(\frac{\partial f}{\partial x} - \chi\frac{\partial f}{\partial \theta} + \Delta\frac{\partial f}{\partial \tilde{p}}\right).$$

Note that for virtual constraints, where $\rho(\theta) = -L\cos\theta$ and $\gamma(\theta) = 0$, we have a Leibniz bracket. In such a case, it follows from Eq. (23) that

$$\chi(\theta) = \frac{m(l\sin\theta + L\cos\theta)}{mLl\cos\theta\sin\theta - I}, \quad \phi(\theta) = 0,$$

and accordingly [see (69)]

$$\Delta(\theta,\tilde{p}) = \tilde{p}\frac{\chi(\theta-\pi/2)(mLl\cos\theta\sin\theta+I)-\chi(\theta)mLl\cos 2\theta}{mLl\cos\theta\sin\theta-I}.$$

Geodesics and Killing tensors in mechanics

I. M. Benn[a)]

(Received 4 July 2005; accepted 3 January 2006; published online 17 February 2006)

Killing tensors give polynomial constants of the geodesic motion. The trajectories of a conservative mechanical system correspond to geodesics when the kinetic energy metric is conformally scaled to the Jacobi metric. Alternatively, the trajectories may be related to geodesics of some higher-dimensional warped product manifold. These two different ways of relating mechanical trajectories to geodesics are reviewed and compared. It is shown how a relation between Killing tensors on configuration space and the potential gives rise to Killing tensors on both the Jacobi and warped product manifolds. © *2006 American Institute of Physics.*

I. INTRODUCTION

The simplest mechanical system is that of a free point particle. That is, a particle whose motion in a (pseudo)-Riemannian configuration space is determined by the kinetic energy Lagrangian T, which is essentially the metric tensor. The trajectories in configuration space are just geodesics.

More general than the free mechanical systems are the conservative ones, where the kinetic energy Lagrangian is modified by the addition of a potential, $L=T-V$. Whereas the trajectories are clearly not geodesics of the kinetic energy metric, they are geodesics (or more accurately may be reparametrized to be geodesics) of a conformally related metric, the Jacobi metric.[1] The Jacobi metric is obtained by a scaling that not only involves the potential V, but the total energy $E=T+V$, so that the geodesics of a given metric describe only the trajectories of a fixed energy.

There is another, less well known, way of representing the trajectories of a conservative mechanical system as geodesics. The configuration space may be extended in dimension, and the kinetic energy metric and potential used to construct a warped (pseudo)-Riemannian product structure, in such a way that geodesics on this warped product project to trajectories on configuration space. This approach was introduced by Eisenhart[2] who added an extra dimension to configuration space to represent trajectories as geodesics.

There are several reasons why it may be useful to recognize trajectories of a mechanical system as geodesics. One is related to the matter of stability. The behavior of nearby geodesics is governed by the curvature, through the Jacobi equation. Thus the stability of any mechanical system that can be formulated as a geodesic one is amenable to examination by computing the curvature tensor. This has been the motivation of Refs. 3–5. Arnold[6] has shown how one can approach the hydrodynamics of an ideal fluid by recognizing the motion as geodesic for an appropriate metric.

Another reason why it is useful to recognize a mechanical system as a geodesic one is related to Killing tensors. For a geodesic system polynomial constants of the motion are given by Killing tensors. Thus the observation that many mechanical systems can be formulated as geodesic ones gives Killing tensors a wider range of applicability than might be immediately obvious. This

[a)]Electronic mail: ian.benn@newcastle.edu.au

observation is made in (for example) Ref. 7. One approach then, to finding integrable systems, is to find manifolds admitting nontrivial Killing tensors. This approach has been followed, in two dimensions, by Rosquist and Pucacco.[8]

As well as leading to constants of the geodesic motion, Killing tensors are also related to higher-order symmetries of the Laplacian.[9] In order to have a higher-order symmetry it is certainly necessary to have a Killing tensor, but it is not clear that this is sufficient.[10] To clarify this matter it is useful to look at examples. However, in general, nontrivial Killing tensors are hard to come by. In this regard it is useful to observe that, formulated as geodesic systems, known examples of superintegrable systems provide us with a source of examples of manifolds with nontrivial Killing tensors.

In this paper a condition is established that enables Killing tensors to be constructed on a warped product manifold from Killing tensors on the base. Since geodesics on warped products project to curves on the base that can be interpreted as Newtonian curves, this condition on Killing tensors can be interpreted as a (generalized) Bertrand-Darboux equation relating the Killing tensor to the potential. Recently Jelonek[11] has shown how Killing tensors can arise naturally on Riemannian warped products, and so it is interesting to see how the geometry of warped products provides a link to classical mechanics and integrable systems.

Since Killing tensors are totally symmetric tensors, we begin in Sec. II by introducing necessary notation and conventions for the totally symmetric tensor algebra. In Sec. III we review some properties of Killing tensors that we will need later. Here conformal Killing tensors are also mentioned, anticipating the conformal scaling in mechanics that gives the Jacobi metric. We examine conditions relating Killing tensors and the conformal factor that enable Killing tensors to be constructed on the conformally related manifold.

In Sec. IV we use the preceding formalism to show how Killing tensors on configuration space can give rise to Killing tensors with respect to the Jacobi geometry. The previously established condition for this is, in the mechanical context, a relation between the Killing tensor and the potential that can be recognized as a generalized Bertrand-Darboux equation.

Section V reviews some properties of warped products. In Sec. VI it is shown how Killing tensors on the base can lead to Killing tensors on the warped product. The necessary condition, relating the Killing tensor on the base and the warping function, can be recognized as the generalized Bertrand-Darboux equation if we choose to identify the projection of geodesics onto the base with Newtonian curves. The Eisenhart geometry is just a special case of a warped product with one-dimensional fiber.

Sections V and VI can be read independent of Secs. III and IV: we present some results on Killing tensors on warped products that can be taken without any mention of mechanics. Clearly however, the results presented in Sec. VI parallel those presented for conformally related metrics in Sec. III. In the final section we discuss the exact relation between the results of these different sections.

II. THE TOTALLY SYMMETRIC TENSOR ALGEBRA

We are going to consider Killing tensors, which are totally symmetric tensors. Thus some conventions for the totally symmetric tensor algebra are introduced here first. (It can be noted by anyone more familiar with the exterior algebra that all the conventions and notation here have exterior analogues, only there an extra sign comes from the sign of the permutation.)

The symmetrizing map $\mathcal{S}$ maps any tensor to a totally symmetric one,

$$(\mathcal{S}S)(X_1,X_2,\ldots,X_p)=\frac{1}{p!}\sum_{\sigma} S(X_{\sigma(1)},X_{\sigma(2)},\ldots,X_{\sigma(p)}), \tag{1}$$

where σ is an element of the permutation group. The map $\mathcal{S}$ is a projection operator,

$$\mathcal{S} \circ \mathcal{S} = \mathrm{Id}. \tag{2}$$

We can define a multiplication on symmetric tensors by taking the tensor product and then symmetrizing

$$S \odot T = \mathcal{S}(S \otimes T). \tag{3}$$

This symmetric tensor product makes the totally symmetric tensors into a commutative associative algebra.

If X is some vector field then the contraction map C_X just maps a 1-form A to $A(X)$. The contraction map can be extended to a map on covariant tensors by requiring it to act as a derivation on tensor products. It then follows that $\mathcal{S}C_X = C_X\mathcal{S}$ and so C_X maps totally symmetric tensors to totally symmetric tensors of one lower degree. We have

$$C_X(S \odot T) = C_X S \odot T + S \odot C_X T, \tag{4}$$

$$C_X C_Y = C_Y C_X, \tag{5}$$

$$(C_{X_1} S)(X_2, X_3, \ldots, X_p) = pS(X_1, X_2, \ldots, X_p), \tag{6}$$

$$\theta^a \odot C_{X_a} S = pS, \tag{7}$$

where p is the degree of S, and $\{\theta^a\}$ is dual to $\{X_a\}$.

When we have a metric g (and we always will have when considering Killing tensors) we can define a trace by an invariant double contraction,

$$\mathrm{Tr}\, S = g^{ab} C_{X_a} C_{X_b} S = C_{X^a} C_{X_a} S. \tag{8}$$

The covariant derivative operator, with respect to a vector field X, ∇_X, acts as a derivation on the tensor algebra. Since ∇_X commutes with $\mathcal{S}$ then it is also a derivation on the symmetric tensor algebra. We may define the divergence of a symmetric tensor by following differentiation with contraction:

$$\mathrm{div}\, S = C_{X^a} \nabla_{X_a} S. \tag{9}$$

The covariant derivative of a tensor S, ∇S, is a tensor of one higher covariant degree. The symmetrized covariant derivative of a symmetric tensor may be defined by

$$\nabla \odot S = \mathcal{S}(\nabla S). \tag{10}$$

If $\{\theta^a\}$ is dual to $\{X_a\}$ then

$$\nabla \odot S = \mathcal{S}(\nabla_{X_a} S \otimes \theta^a) = \nabla_{X_a} S \odot \theta^a. \tag{11}$$

It then follows that $\nabla\odot$ acts as a derivation on the symmetric tensor algebra.

III. KILLING TENSORS

Killing vectors generate isometries. So if K is a Killing vector of the metric g then the Lie derivative of g with respect to K must vanish, $\mathcal{L}_K g = 0$. This can be recast as a differential equation for K; Killing's equation,

$$g(\nabla_X K, Y) + g(\nabla_Y K, X) = 0, \tag{12}$$

where ∇ is the (pseudo)-Riemannian connection of g. If $K^\flat$ is the 1-form metrically related to K then Killing's equation requires the symmetrized derivative of $K^\flat$ to vanish,

$$\nabla_X K^\flat(Y) + \nabla_Y K^\flat(X) = 0, \tag{13}$$

$$\text{or } \nabla \odot K^\flat = 0. \tag{13'}$$

A Killing tensor obeys a generalization of Killing's equation. It is a totally symmetric (covariant) tensor whose symmetrized covariant derivative vanishes. That is,

$$\nabla \odot S = 0. \tag{14}$$

In generalizing Killing's equation from an equation for a vector field to one for a tensor, the clear geometrical interpretation is lost. However, one immediate consequence is that Killing tensors give constants of the geodesic motion. If C is geodesic, and S is Killing, then it immediately follows from (14) that $S(\dot{C},\dot{C},\ldots,\dot{C})$ is constant along C,

$$\dot{C}(S(\dot{C},\dot{C},\ldots,\dot{C})) = 0. \tag{15}$$

(It is important to note here that a geodesic is a curve that parallel transports its tangent vector, $\nabla_{\dot{C}}\dot{C}=0$. A curve satisfying $\nabla_{\dot{C}}\dot{C}=f\dot{C}$ for some function f may be reparameterized to become geodesic. Such a curve will be called pregeodesic. Although this terminology is usual it is not universal, with some authors calling geodesic that which is here called pregeodesic.)

The space of Killing tensors is closed under the symmetrized tensor product. Since Killing vectors, and the metric tensor, are certainly Killing tensors, we can always form higher degree Killing tensors from sums of their symmetrized tensor products. Such Killing tensors are called trivial, or reducible. Killing tensors are also closed under a nonassociative product, the Schouten bracket (or symmetric Schouten concomitant), as will be discussed below.

So far we have taken Killing tensors to be covariant, for then it makes sense to symmetrize the covariant derivative. However, since the notion of Killing tensor relies upon the existence of a metric, we can always use that metric to type change tensors. [The connection in Killing's equation is the (pseudo) Riemannian one, and here only torsion-free metric compatible connections will be considered.] The totally symmetric contravariant tensors on M naturally correspond to functions on T^*M that are polynomial in the fiber coordinate. That is, in the context of mechanics, polynomial in the momenta. Thus the symmetric contravariant tensor S corresponds to the function F_S defined by $F_S(\omega)=S(\omega,\omega,\ldots,\omega)$. In local coordinates, $F_S=S^{ab\cdots}p_a p_b\cdots$.

In particular, the kinetic energy Hamiltonian, T, is (up to a factor of 2) the function corresponding to the metric tensor g,

$$T = \tfrac{1}{2} g^{ab} p_a p_b. \tag{16}$$

The associative algebra of symmetric tensors on M, under the symmetrized tensor product, is isomorphic to the algebra of polynomial functions on T^*M under multiplication. The canonical symplectic structure of T^*M defines a Poisson bracket on functions. Functions on T^*M that are polynomial in the momenta are closed under the Poisson bracket. The natural correspondence between polynomial functions and symmetric tensors then enables a bracket to be induced on symmetric tensors. This is the Schouten bracket. That is, the Lie algebra of polynomial functions on T^*M, under the Poisson bracket, is isomorphic to the Lie algebra of symmetric contravariant tensors on M under the Schouten bracket.

The condition that a contravariant tensor S is Killing can be expressed in the following equivalent ways:

$$[S,g] = 0, \tag{17}$$

$$\{F_S,T\} = 0, \tag{18}$$

$$X_T F_S = 0. \tag{19}$$

In (17) [,] denotes the Schouten bracket,[12] with {, } denoting the Poisson bracket in (18). The equivalence of (17) and (18) is just the stated isomorphism between symmetric tensors, under the Schouten bracket, and polynomial functions, under the Poisson bracket. In (19) X_T is the Hamiltonian vector field of the kinetic energy Hamiltonian. Equation (19) gives perhaps the clearest geometrical interpretation of Killing tensors: they are tensors that correspond to polynomial functions that are invariant under the geodesic flow.

A conformal Killing tensor satisfies a conformally covariant generalization of (14). Namely, for a degree-p tensor S,

$$\nabla \odot S = \phi \odot g, \tag{20}$$

where ϕ is some totally symmetric tensor of degree $p-1$. In fact ϕ can be expressed in terms of S and its derivatives by (repeatedly) taking the trace of (20). For example, if S is of degree 2 then we get, in n-dimensions,

$$(n+4)\phi = \nabla \odot \mathrm{Tr}\, S + 2\ \mathrm{div}\, S. \tag{21}$$

For S of degree 3, for example, we arrive at a similar expression by taking another trace of (20).

Sometimes a definition of conformal Killing tensors is taken that further requires them to be trace-free (as discussed in Ref. 13, for example). The reason for this is that (20) is satisfied by any multiple of the metric tensor. In fact if S is any solution to (20) (with the degree of S two or more) then, for an arbitrary symmetric tensor ρ, so is

$$S' = S + \rho \odot g \tag{22}$$

with

$$\phi' = \phi + \nabla \odot \rho. \tag{23}$$

This arbitrariness in solutions to (20) can be removed by requiring the trace to vanish. Here the trace-free requirement will not be imposed on conformal Killing tensors, since it is useful to have the conformal Killing tensors include all the Killing ones (and these are not all trace-free).

It has already been stated that (20) is a conformally covariant generalization of (14). This will now be demonstrated. If $\hat{g}$ is a conformally related to g then the respective Riemannian connections are related by

$$\hat{g} = e^{2\lambda} g, \tag{24}$$

$$\hat{\nabla}_X Y = \nabla_X Y + (X\lambda)Y + (Y\lambda)X - g(X,Y)\mathrm{grad}\,\lambda \tag{25}$$

$$= \nabla_X Y + (X\lambda)Y + (Y\lambda)X - \hat{g}(X,Y)\widehat{\mathrm{grad}}\,\lambda. \tag{25'}$$

Then for ω a 1-form

$$\hat{\nabla} \odot \omega = \nabla \odot \omega + C_{\mathrm{grad}\,\lambda}\omega g - 2\ \mathrm{d}\lambda \odot \omega,$$

from which it follows, from induction, that for S of degree p,

$$\hat{\nabla} \odot S = \nabla \odot S + C_{\mathrm{grad}\,\lambda} S \odot g - 2p\ \mathrm{d}\lambda \odot S. \tag{26}$$

From this it follows that, if the metric is scaled as in (24), and S is of degree p, then (20) is covariant under the following transformations:

$$\hat{S} = e^{2p\lambda} S, \tag{27}$$

$$\hat{\phi} = e^{2(p-1)\lambda}(\phi + C_{\text{grad }\lambda} S). \tag{28}$$

Now if K is a Killing vector of the metric g, then it will also be a Killing vector of a conformally related metric $\hat{g}$ only if the scale function is invariant under K. More generally, if S is any (covariant) Killing tensor of the metric g, then it is also Killing for the metric $\hat{g}=s^{2\lambda}g$ if $C_{\text{grad }\lambda}S=0$. However, there is a more general way in which we can obtain Killing tensors on $(M,\hat{g})$ from those on (M,g).

Proposition 1: Suppose that S is a degree p Killing tensor with respect to g, with $p \geqslant 2$, that additionally satisfies

$$e^{2(p-1)\lambda} C_{\text{grad }\lambda} S = -\hat{\nabla} \odot \Omega \tag{29}$$

for some symmetric tensor Ω. Then $\hat{S}=e^{2p\lambda}S+\Omega\odot\hat{g}$ is a Killing tensor with respect to $\hat{g}=e^{2\lambda}g$.

Proof: Since S is Killing with respect to g it is certainly conformal Killing. Then, from (27) and (28) $e^{2p\lambda}S$ is conformal Killing with respect to $\hat{g}=e^{2\lambda}g$ with $\hat{\phi}=e^{2(p-1)\lambda}C_{\text{grad }\lambda}S$. If we then assume the extra condition (29), then it follows from (22) and (23) that we can add a multiple of the metric to absorb this term. We thus arrive at a conformal Killing tensor with the $(p-1)$-tensor ϕ vanishing; that is, we get a Killing tensor.

The Proposition becomes simpler in the case of $p=2$. The tensor Ω in (29) is then just a function and $\hat{\nabla}\odot\Omega=\nabla\odot\Omega=\mathrm{d}\Omega$. So if S is a degree 2 Killing tensor with respect to g that satisfies

$$C_{\text{grad } e^{2\lambda}} S = -2\, \mathrm{d}\Omega \tag{30}$$

then

$$\hat{S} = e^{4\lambda} S + \Omega \hat{g} \tag{31}$$

is Killing with respect to $\hat{g}=e^{2\lambda}g$. The function Ω in (30) is clearly only defined up to a constant. This arbitrariness results in the Killing tensor $\hat{S}$ only being defined up to the addition of a multiple of the metric.

Now we look at the more general case in which $p>2$. Equation (29) involves a Killing tensor with respect to g, and the connection with respect to $\hat{g}$. We can alternatively express (29) in terms of g and its connection as

$$C_{\text{grad }\lambda}(S + \hat{\Omega}\odot g) = -\nabla\odot\hat{\Omega}, \tag{32}$$

where

$$\hat{\Omega} = e^{-2(p-1)\lambda}\Omega. \tag{33}$$

Rearranging things in terms of the scaling function $e^{2\lambda}$ we get

$$C_{\text{grad } e^{2\lambda}} S = -2\,\nabla\odot(e^{2\lambda}\hat{\Omega}) - C_{\text{grad } e^{2\lambda}}\hat{\Omega}\odot g. \tag{34}$$

Note that whereas (30) only involves the gradient of $e^{2\lambda}$, both $e^{2\lambda}$ and its gradient enter into (34). This will be of significance when we consider the Jacobi geometry, where solutions to (29) will, in general, only give constants of the motion for some fixed energy. To find constants of the motion for arbitrary energy we can restrict the solutions to (29) by imposing a further condition. To see how this can be done we consider the case in which S is of degree four. (It turns out that the results for even and odd degrees are slightly different, and so the case of $p=3$ will be covered afterwards.) Suppose that we have a degree-4 Killing tensor S satisfying (34) for some degree-2 $\hat{\Omega}$. Suppose that in addition we have

$$C_{\text{grad } e^{2\lambda}}\hat{\Omega} = -2\,\mathrm{d}\alpha$$

for some function α. We then have

$$C_{\text{grad } e^{2\lambda}}S = -2\,\nabla \odot (e^{2\lambda}\hat{\Omega} - \alpha g) = -2\,\nabla \odot \omega,$$

where

$$\omega = e^{2\lambda}\hat{\Omega} - \alpha g.$$

Contracting on ω gives

$$C_{\text{grad } e^{2\lambda}}\omega = -2e^{2\lambda}\,\mathrm{d}\alpha - 2\alpha\,\mathrm{d}e^{2\lambda} = -2d(\alpha e^{2\lambda}) = -2\,\mathrm{d}\beta$$

where

$$\beta = \alpha e^{2\lambda}.$$

Since we have assumed a solution to (29) we can construct a Killing tensor with respect to $\hat{g}$. It follows that this can be written in terms of ω and β as

$$\hat{S} = e^{8\lambda}S + e^{6\lambda}\omega \odot g + e^{4\lambda}\beta g \odot g.$$

Now it becomes clear how this result can be generalized to arbitrary even degree.

Proposition 2: If S is a Killing tensor of even degree p, and there exist symmetric tensors $\{\Omega_1, \Omega_2, \ldots, \Omega_{p/2}\}$ such that

$$C_{\text{grad } e^{2\lambda}}S = -2\,\nabla \odot \Omega_1,$$

$$C_{\text{grad } e^{2\lambda}}\Omega_i = -2\,\nabla \odot \Omega_{i+1}, \quad i = 1, \ldots, p/2 - 1$$

then

$$\hat{S} = e^{2p\lambda}S + e^{2(p-1)\lambda}\Omega_1 \odot g + \cdots + e^{p\lambda}\Omega_{p/2}\underbrace{g \odot \ldots \odot g}_{p/2 \text{ times}} \tag{35}$$

is Killing with respect to $\hat{g}$.

The proof follows from (26). Note that the conditions of Proposition 2 are a special case of those of Proposition 1, and that in Proposition 2 only the gradient of the scale function enters.

There is a similar result for Killing tensors of odd degree.

Proposition 3: If S is a Killing tensor of odd degree p, and there exist symmetric tensors $\{\Omega_1, \Omega_2, \ldots, \Omega_{(p-1)/2}\}$ such that

$$C_{\text{grad } e^{2\lambda}}S = -2\,\nabla \odot \Omega_1,$$

$$C_{\text{grad } e^{2\lambda}}\Omega_i = -2\,\nabla \odot \Omega_{i+1}, \quad i = 1, \ldots, (p-3)/2,$$

$$C_{\text{grad } e^{2\lambda}}\Omega_{(p-1)/2} = 0,$$

then

$$\hat{S} = e^{2p\lambda}S + e^{2(p-1)\lambda}\Omega_1 \odot g + \cdots + e^{(p+1)\lambda}\Omega_{(p-1)/2} \odot \underbrace{g \odot \cdots \odot g}_{(p-1)/2 \text{ times}} \tag{36}$$

is Killing with respect to $\hat{g}$.

Note that the last equation, $C_{\text{grad } e^{2\lambda}}\Omega_{(p-1)/2}=\Omega_{(p-1)/2}(\text{grad } e^{2\lambda})=0$, says that the 1-form $\Omega_{(p-1)/2}$ is metrically related to a vector field whose flows leave the conformal factor invariant.

IV. KILLING TENSORS IN THE JACOBI GEOMETRY

Suppose that $C:I\subset R\rightarrow(M,g)$ is some Newtonian curve, satisfying

$$\nabla_{\dot{C}}\dot{C}=-\text{ grad } V \tag{37}$$

for some potential V.

Then the total energy E is a constant of the motion,

$$E=T+V,$$

where $T=\frac{1}{2}g(\dot{C},\dot{C})$. Then the Jacobi metric $\hat{g}$ is obtained by conformally scaling g,

$$\hat{g}=e^{2\lambda}g, \tag{38}$$

where

$$e^{2\lambda}=E-V. \tag{39}$$

(Clearly we could include an overall constant in the scaling and not change the connection.) We then have, from (25),

$$\hat{\nabla}_{\dot{C}}\dot{C}=2\dot{C}\lambda\dot{C}. \tag{40}$$

Thus C is pregeodesic with respect to $\hat{g}$: that is, a reparametrization makes it geodesic. Since geodesics remain geodesic under an affine reparameterization, there is no unique parametrization that makes C geodesic. These affine reparametrizations of C correspond to a change in the strength of the potential in (37). Thus this way (or indeed any other way) of putting Newtonian curves into correspondence with geodesics is insensitive to any coupling constant that scales the strength of the potential.

If we have Killing tensors, with respect to $\hat{g}$, then we have polynomial constants of the motion. The precise relation is as follows.

Proposition 4: If $\hat{S}$ is a degree p Killing tensor with respect to the Jacobi metric $\hat{g}$, then $e^{-2p\lambda}\hat{S}(\dot{C},\ldots,\dot{C})$ is constant along C.

Proof: We have

$$\dot{C}(e^{-2p\lambda}\hat{S}(\dot{C},\ldots,\dot{C}))=-2p\dot{C}\lambda e^{-2p\lambda}\hat{S}(\dot{C},\ldots,\dot{C})+pe^{-2p\lambda}\hat{S}(\hat{\nabla}_{\dot{C}}\dot{C},\ldots,\dot{C})=0 \quad \text{by (40)}.$$

Now we can apply the results of the preceding section to the particular case of the Jacobi metric where we have $\hat{g}=(E-V)g$. A Killing tensor on M that satisfies the conditions of Proposition 1 will give a polynomial constant of the motion. Since the Jacobi metric is obtained by scaling with an energy-dependent conformal factor, this constant will, in general, depend upon the energy. When we have a Killing tensor on M satisfying the more restrictive conditions of Propositions 2 or 3, then we have a Killing tensor for each Jacobi metric, that is, a constant of the motion for any energy. So, for example, taking Propositions 2 and 4 together we see that if S is a Killing tensor on M of even degree p that satisfies

$$\begin{aligned} C_{\text{grad } V}S&=2\,\nabla\odot\Omega_1,\\ C_{\text{grad } V}\Omega_i&=2\,\nabla\odot\Omega_{i+1},\quad i=1,\ldots,p/2-1, \end{aligned} \tag{41}$$

then

$$\rho = S(\dot{C},\dot{C},\ldots,\dot{C}) + 2\Omega_1(\dot{C},\dot{C},\ldots,\dot{C}) + \cdots + 2^{p/2}\Omega_{p/2}. \tag{42}$$

is a constant of the motion. Here we arrived at this expression by examining conformal scaling of Killing tensors. Of course it can be verified directly from (37) and (41) [using (6)] that $\dot{C}\rho=0$.

Unfortunately its not easy to see how to find Killing tensors satisfying (41). There is always one trivial solution. We always have the trivial Killing tensor g, and for any V,

$$C_{\text{grad } V}g = 2\mathrm{d}V, \tag{43}$$

thus for any potential (41) is satisfied by taking $S=g$. In this case the constant of the motion given in (42) is just (twice) the total energy.

Things become a little simpler when $p=2$, for then (41) reduces to

$$C_{\text{grad } V}S = 2\mathrm{d}\Omega \tag{44}$$

which is locally equivalent to

$$d(C_{\text{grad } V}S) = 0, \tag{45}$$

which, for any given S, is a second-order PDE for V. In the case of R^n, with the standard metric, we know what all the Killing tensors look like: they are all trivial, being made from the Killing vectors and the metric. For example, in R^2 the Killing algebra consists of two translations and a rotation. By choosing a suitable basis for this Killing algebra, $\{T_1,T_2,R\}$, any Killing tensor can be written as

$$S = R^\flat \otimes R^\flat + aT_1^\flat \otimes T_1^\flat + bg \tag{46}$$

for constants a and b (where we assume S nonparallel). If we adapt coordinates $\{x,y\}$ such that

$$T_1 = \partial_x, \tag{47}$$

$$T_2 = \partial_y, \tag{48}$$

$$R = x\partial_y - y\partial_x, \tag{49}$$

then (45) becomes

$$3(yV_x - xV_y) + (y^2 - x^2 + a)V_{xy} + xy(V_{xx} - V_{yy}) = 0. \tag{50}$$

This is the Bertrand-Darboux equation.[14] Thus we refer to (41) as the (generalized) Bertrand-Darboux equation.

As an illustration of how (44) relates to known systems admitting quadratic constants of the motion we consider the Kepler problem. The Kepler problem has three nontrivial quadratic constants of the motion, forming the Runge-Lenz vector.[15,16] These constants correspond to three Killing tensors. Consider a Killing tensor such as

$$S_{12} = R_1^\flat \odot T_2^\flat - R_2^\flat \odot T_1^\flat, \tag{51}$$

where R_i generates rotations about the i axis and T_i generates translations along the i axis. Then we look for spherically symmetric solutions to (45),

$$C_{\partial_r}S = r\mathrm{d}x^3 - x^3\mathrm{d}r,$$

and so

$$d(C_{f(r)\partial_r}S) = ((rf)' + f)\mathrm{d}r \wedge \mathrm{d}x^3,$$

and so we have a solution to (45) if $f=Ar^{-2}$ which corresponds to the Kepler potential $V=C/r$.

Note that the first-order constants of the motion correspond to Killing symmetries that leave the potential invariant. That is, we have a vector field K such that

$$\mathcal{L}_K g = KV = 0. \tag{52}$$

Given such a first-order symmetry then for any solution to (44), for some S and Ω, then we have another solution for $\mathcal{L}_K S$ and $\mathcal{L}_K \Omega$. In the case of the Coulomb-Kepler potential, which has spherical symmetry, the three Killing tensors of the form given in (51) are related in this way,

$$\mathcal{L}_{R_1} S_{12} = -S_{13},$$

$$\mathcal{L}_{R_3} S_{12} = 0, \quad \text{etc}.$$

The constants corresponding to these three Killing tensors form the components of the Runge-Lenz vector.

V. GEODESICS AND WARPED PRODUCTS

Eisenhart[2] showed how Newtonian curves on configuration space corresponded to geodesics on a warped product manifold with one more dimension. We here briefly review some properties of warped product geometries. We consider the general case, rather than restricting the fiber to be one dimensional. First, this is no harder; indeed it can be easier to see what is going on by considering the more general setting. Second, it may be useful to regard the phase trajectories as geodesics with respect to some metric. (We will return to this point later.) Finally, Killing tensors on warped products are of interest irrespective of any connection with mechanics. (We refer again to Ref. 11.)

In this section notation and conventions will generally follow O'Neill.[17] Suppose that (B, g_B) and (F, g_F) are pseudo-Riemannian manifolds. Then if f is some function on B the warped product manifold $M = B \times_f F$ is the product manifold endowed with metric

$$G = \pi^* g_B + (f \circ \pi)^2 \sigma^* g_F, \tag{53}$$

where π and σ are the projections,

$$\pi : B \times_f F \to B, \tag{54}$$

$$\sigma : B \times_f F \to F. \tag{55}$$

Let $\mathcal{L}(B)$ denote the space of vector fields lifted from B to M, with $\mathcal{L}(F)$ denoting lifts from F. The connection on M, which will be denoted by D, can be related to those on B and F. If $X, Y \in \mathcal{L}(B)$ and $U, W \in \mathcal{L}(F)$ then

$$D_X Y = \nabla_X Y, \tag{56}$$

$$D_U X = D_X U = X(\ln f) U, \tag{57}$$

$$D_U W = \nabla_U W - \tfrac{1}{2} \operatorname{grad}(f^2) g_F(U, W). \tag{58}$$

[To simplify notation lifts are implied in several places in the above formulas. For example, in (56) we mean of course that the derivative of one lift with respect to another is the lift of the derivative.] Note that a warped product is conformally related to a Riemannian product. Thus one way of obtaining these connection relations is to use connection relations for conformally related metrics given in Eqs. (24) and (25).

Any curve $\Phi : I \to M$ can be decomposed into curves on B and F,

$$\Phi(s) = (\alpha(s), \beta(s)). \tag{59}$$

We can then use (56)–(58) to relate the acceleration of Φ to those of α and β. In particular, Φ is geodesic if

$$\nabla_{\dot\alpha}\dot\alpha - \tfrac{1}{2}\,\mathrm{grad}(f^2) g_F(\dot\beta,\dot\beta) = 0, \tag{60}$$

$$\nabla_{\dot\beta}\dot\beta + 2\dot\alpha(\ln f)\dot\beta = 0. \tag{61}$$

It follows that (again following O'Neill[17])

$$\dot\Phi(f^4 g_F(\dot\beta,\dot\beta)) = 0, \tag{62}$$

so if

$$f^4 g_F(\dot\beta,\dot\beta) = A \tag{63}$$

then A is constant along Φ. (The existence of this quadratic constant of the geodesic motion corresponds to a Killing tensor of course. We will return to this in the following section where Killing tensors in this geometry will be discussed.) So if we set

$$V = \frac{A}{2f^2} \tag{64}$$

then the geodesic equations on M are equivalent to the projected equations

$$\ddot\alpha = -\,\mathrm{grad}\, V, \tag{65}$$

$$\ddot\beta = (\dot\alpha \ln \phi)\dot\beta. \tag{66}$$

That is, the projection onto B corresponds to the motion of a particle moving in a potential, while the projection onto the fiber is a pregeodesic. For geodesic motion we always have the energy constant, and this can be related to the total energy of the curve projected onto the base:

$$G(\dot\Phi,\dot\Phi) = 2E = g_B(\dot\alpha,\dot\alpha) + f^2 g_F(\dot\beta,\dot\beta) = g_B(\dot\alpha,\dot\alpha) + \frac{A}{f^2} = 2(T+V). \tag{67}$$

Note that the potential V occurring in Newton's equations is of course only defined up to a constant. Changing this constant is equivalent to fixing the zero point of the total energy. We can only identify the natural geodesic energy with that of a Newtonian system when the potential is given by (64) (there being no freedom to add an arbitrary constant).

So far we have merely used some mechanical terminology as a convenience in discussing geodesics on warped products. Suppose now that we start with some Newtonian system, and ask to what extent the curves correspond to geodesics of some warped product. First, the potential must be of definite sign. So long as the potential is bounded this can always be achieved by the addition of a suitable constant. If that is the case then a warped product can be constructed, for any choice of fiber. Whatever the fiber all the Newtonian curves will be projections of geodesics. However, whatever the fiber, there will always be geodesics on the warped product that project to geodesics on configuration space. Moreover, whatever the fiber, there will always be infinitely many geodesics that project to the same Newtonian curve: there will always be at least one geodesic that projects to a given Newtonian curve whatever the starting point on the fiber.

The special case of a one-dimensional fiber corresponds to the metric originally considered by Eisenhart.[2] As noted in the preceding paragraph, the correspondence between geodesics and Newtonian curves is not one to one. This is at variance with statements made in Ref. 18.

Suppose that the configuration space has a positive definite metric (the prime example being R^n of course) and that the potential is negative definite (for example, the Newtonian gravitational potential). Then the Eisenhart metric is Lorentzian. The timelike geodesics project to negative energy elliptical orbits, the null geodesics project to parabolic orbits with the spacelike geodesics projecting to hyperbolic scattering orbits. Thus to describe all the Newtonian curves we need to consider timelike geodesics as well as spacelike and null ones, again contrary to what is stated in Ref. 18.

VI. KILLING TENSORS ON WARPED PRODUCTS

When examining the geodesic equations in the preceding section we noted that there was always a quadratic constant of the geodesic motion (in addition to the energy) and hence we always had a nontrivial Killing tensor. This is a special case of the following.

Proposition 5: If R is a degree-p Killing tensor on F then, for any warping function f, $S=(f\circ\pi)^{2p}\sigma^*R$ is a Killing tensor on M.

It follows from the connection relations (56)–(58) that

$$D\odot((f\circ\pi)^{2p}\sigma^*R)=(f\circ\pi)^{2p}\sigma^*\nabla\odot R. \tag{68}$$

The proposition is an immediate consequence.

In particular, since F always has the trivial Killing tensor g_F, we always have the Killing tensor $(f\circ\pi)^4\sigma^*g_F$ on M. We have already essentially noted this when we observed the geodesic constant in (63).

Clearly Killing vectors on B are not necessarily Killing on M. For the lift of a Killing vector K on B to be Killing on M the warping function f must be invariant under the flow of K. More generally, the pullback of a Killing tensor from B to M is not in general Killing, there being an additional requirement relating the Killing tensor to the warping function. However, there is a more general way in which Killing tensors on M can arise from those on B.

Proposition 6: If S is a Killing tensor on B of even degree p, and there exist symmetric tensors $\{\omega_1,\omega_2,\ldots,\omega_{p/2}\}$ such that

$$C_{\mathrm{grad}\,f^{-2}}S=2\nabla\odot\omega_1,$$

$$C_{\mathrm{grad}\,f^{-2}}\omega_i=2\nabla\odot\omega_{i+1},\quad i=1,\ldots,p/2-1,$$

then

$$T=\pi^*S+\pi^*\omega_1\odot(f\circ\pi)^4\sigma^*g_F+\cdots+\pi^*\omega_{p/2}\underbrace{(f\circ\pi)^4\sigma^*g_F\odot\cdots\odot(f\circ\pi)^4\sigma^*g_F}_{p/2\ \text{times}}$$

is a Killing tensor on M.

There is a similar result for Killing tensors of odd degree.

Proposition 7: If S is a Killing tensor on B of odd degree p, and there exist symmetric tensors $\{\omega_1,\omega_2,\ldots,\omega_{(p-1)/2}\}$ such that

$$C_{\mathrm{grad}\,f^{-2}}S=2\nabla\odot\omega_1,$$

$$C_{\mathrm{grad}\,f^{-2}}\omega_i=2\nabla\odot\omega_{i+1},\quad i=1,\ldots,(p-3)/2,$$

$$C_{\mathrm{grad}\,f^{-2}}\omega_{(p-1)/2}=0,$$

then

$$T = \pi^* S + \pi^* \omega_1 \odot (f \circ \pi)^4 \sigma^* g_F + \cdots + \pi^* \omega_{(p-1)/2} \underbrace{\odot (f \circ \pi)^4 \sigma^* g_F \odot \cdots \odot (f \circ \pi)^4 \sigma^* g_F}_{(p-1)/2 \text{ times}}$$

is a Killing tensor on M.

It follows from (56)–(58) that if S is a totally symmetric tensor on B then

$$D \odot \pi^* S = \pi^* \nabla \odot S - \tfrac{1}{2} \pi^* (C_{\text{grad } f^{-2}} S) \odot (f \circ \pi)^4 \sigma^* g_f. \tag{69}$$

Since we have already shown that $(f \circ \pi)^4 \sigma^* g_F$ is Killing, repeated use of (69) establishes the truth of both propositions.

We have seen, from Proposition 5, that the trivial Killing tensor g_F on F always leads to a (nontrivial) Killing tensor on M. In a similar way Proposition 6 shows how g_B always gives a Killing tensor on M. Since

$$C_{\text{grad } f^{-2}} g_B = 2 \mathrm{d} f^{-2}$$

for any warping function f, Proposition 6 enables a Killing tensor on M to be constructed. What we get is nothing other than G, the metric on M.

Any Killing tensor on M constructed from one on B, as in Propositions 6 or 7, gives a polynomial constant of the geodesic motion. This constant can be expressed in terms of the projection of the geodesic onto B, which we know can be interpreted as a Newtonian curve. Thus we arrive at the same constant as we previously obtained via the Jacobi geometry. For example, suppose that S is a Killing tensor of even degree satisfying the conditions of Proposition 6. Then if a geodesic Φ is projected as in (59), then ρ is constant along Φ where

$$\begin{aligned} \rho = T(\dot{\Phi}, \dot{\Phi}, \ldots, \dot{\Phi}) &= S(\dot{\alpha}, \ldots, \dot{\alpha}) + \omega_1(\dot{\alpha}, \ldots, \dot{\alpha})(f \circ \alpha)^4 g_F(\dot{\beta}, \dot{\beta}) + \cdots + \omega_{p/2} \underbrace{(f \circ \alpha)^4 g_F(\dot{\beta}, \dot{\beta}) \cdots}_{p/2 \text{ times}} \\ &= S(\dot{\alpha}, \ldots, \dot{\alpha}) + 2\Omega_1(\dot{\alpha}, \ldots, \dot{\alpha}) + \cdots + 2^{p/2} \Omega_{p/2}, \end{aligned}$$

where

$$\Omega_i = (A/2)^i \omega_i, \tag{70}$$

where A is defined by (63). This is the same expression given in (42). Note that (64) and (70) ensure that the conditions of Proposition 6 can be written as (41).

VII. DISCUSSION AND CONCLUSIONS

Sections V and VI have been written to be largely independent of Secs. III and IV. However, Propositions 6 and 7 are clearly related to Propositions 2 and 3. Since a Killing tensor on the Jacobi manifold, or one on the warped product, gives a polynomial constant of the Newtonian motion, any condition that enables a Killing tensor to be constructed on one space must enable a Killing tensor to be constructed on the other. However, there is a more direct way of seeing why these Propositions are related.

As was noted in Sec. V, a warped product is conformally related to a Riemannian product, and thus we can use the conformal scaling of the connections to establish the connection on a warped product. In a similar way we can use Proposition 2 (for example) to directly prove Proposition 6, as we will now show.

First suppose that we have a Killing tensor S on $\{B, g\}$ satisfying the conditions of Proposition 2, so that we can construct the Killing tensor $\hat{S}$ on $\{B, \hat{g}\}$. Then $\hat{S}$ also satisfies the conditions of Proposition 2 so that we can invert the relation between S and $\hat{S}$. Specifically we have the following:

$$C_{\widehat{\text{grad } e^{-2\lambda}}} \hat{S} = -2 \hat{\nabla} \odot \hat{\Omega}_1,$$

$$C_{\widehat{\text{grad}}\, e^{-2\lambda}\hat{\Omega}_i} = -2\hat{\nabla}\odot\hat{\Omega}_{i+1},$$

where

$$-\hat{\Omega}_1 = e^{(2p-6)\lambda}\left\{\Omega_1 + 2e^{-2\lambda}\Omega_2\odot g + \cdots + \frac{p}{2}e^{-(p-2)\lambda}\Omega_{p/2}\underbrace{g\odot\ldots\odot g}_{p/2-1\ \text{terms}}\right\},$$

$$\hat{\Omega}_2 = e^{2(p-6)\lambda}\{\Omega_2 + \cdots\},$$

and

$$S = e^{-2p\lambda}\hat{S} + e^{-2(p-1)\lambda}\hat{\Omega}_1\odot\hat{g} + e^{-2(p-2)\lambda}\hat{\Omega}_2\odot\hat{g}\odot\hat{g} + \cdots .$$

(Clearly the relation between the $\{\Omega_i\}$ and the $\{\hat{\Omega}_i\}$ is irritatingly complex.)

Second we note that any Killing tensor satisfying the conditions of Proposition 2 may be pulled back to one satisfying the conditions on a Riemannian (unwarped) product manifold. That is, if S is a Killing tensor on $\{B,g\}$ satisfying the conditions of Proposition 2 for some $\{\Omega_i\}$ and some function λ, then π^*S is a Killing tensor on $\{B\times F, \pi^*g+\sigma^*g_F\}$ satisfying the same conditions for $\{\pi^*\Omega_i, \lambda\circ\pi\}$.

Now we can establish Proposition 6 directly from Proposition 2. Suppose that S is a Killing tensor on $\{B,g\}$ satisfying Proposition 2 for some function $e^{2\lambda}=f^{-2}$. Then we can construct $\hat{S}$ that is Killing on $\{B,\hat{g}=f^{-2}g\}$. Then, for any $\{F,g_F\}$ we can pull back to get $\pi^*\hat{S}$ which is Killing on $\{B\times F,\hat{G}=(f\circ\pi)^{-2}\pi^*g+\sigma^*g_F\}$. Finally we may scale with the inverse scaling relations given above to produce a Killing tensor T on the warped product $\{B\times F, G=\pi^*g+(f\circ\pi)^2\sigma^*g_F\}$. What we get is

$$T = \pi^*S - \Omega_1\odot(f\circ\pi)^4\sigma^*g_F + \Omega_2\odot(f\circ\pi)^4\sigma^*g_F\odot(f\circ\pi)^4\sigma^*g_F + \cdots .$$

This is exactly what is given by Proposition 6 when we relate the definition of the $\{\Omega_i\}$ to the $\{\omega_i\}$.

Propositions 2 and 3 (or equivalently 6 and 7) give conditions for Killing tensors (possibly trivial) on one space, to give Killing tensors (not necessarily trivial) on another. However, unfortunately we do not know how to find such Killing tensors. In particular, whereas the propositions refer to Killing tensors of arbitrary degree, the complexity of actually finding such nontrivial tensors increases with the degree. Of course, as can readily be checked, if we have any tensors satisfying these conditions then we can form symmetrized tensor products that also satisfy the conditions.

In our discussions of warped products the details of the fiber have never played a role. The metric originally introduced by Eisenhart takes a one-dimensional fiber which is obviously minimal dimensionally, but in this context dimensions do not cost anything. Clearly the details of the fiber were irrelevant in our construction of Killing tensors from those on the base, in that we only assumed relations between tensors on the base and a function on the base. The recognition that the fiber is arbitrary suggests new possibilities. Perhaps, for a conservative mechanical system, one can construct a metric on phase space in such a way that the phase curves are geodesic. Presumably such a metric would make the phase space (at least locally) a pseudo-Riemannian warped product.

Because we have here looked at constants of the geodesic motion we have considered generalizations of Killing's equation to totally symmetric tensors. The totally antisymmetric generalizations, Killing-Yano tensors, have been much studied. They lead, for example, to symmetry operators for the Dirac equation. Given a Killing-Yano tensor one can construct a (symmetric) Killing tensor. (The Killing tensor of the Kerr geometry is related to a Killing-Yano tensor in this way.) It would be interesting to explore relations between Killing-Yano tensors and Killing tensors in this fruitful arena of warped products.

The main results presented here concern how Killing tensors on one manifold can give rise to Killing tensors on another; either conformally related, or equivalently a warped product. Mechanics need not have been mentioned. However, placing these geometrical constructions in the mechanical context offers the possibility of further symbiotic developments.

Test particles with acceleration-dependent Lagrangian

M. Toller[a)]
via Malfatti n. 8, I-38100 Trento, Italy

(Received 8 October 2005; accepted 9 January 2006; published online 28 February 2006)

We consider a classical test particle subject to electromagnetic and gravitational fields, described by a Lagrangian depending on the acceleration and on a fundamental length. We associate to the particle a moving local reference frame and we study its trajectory in the principal fiber bundle of all the Lorentz frames. We discuss in this framework the general form of the Lagrange equations and the connection between symmetries and conservation laws (the Noether theorem). We apply these results to a model, already discussed by other authors, which implies an upper bound to the proper acceleration and to another new model in which a similar quantity, called "pseudoacceleration," is bounded. With some simple choices of the fields, we illustrate some other interesting properties of the models and we show that unwanted features may appear, as unstable run-away solutions and unphysical values of the energy momentum or of the velocity. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2170486]

I. INTRODUCTION

At present, the only well established long range relativistic fields, that allow a classical (nonquantum) treatment, are the Maxwell electromagnetic field and the Einstein gravitational field. However, the existence of new long range fields, or of modifications of the above-mentioned ones is often suggested on the basis of theoretical speculations or of not yet well confirmed experimental results. Many crucial problems of present day physics and cosmology can be formulated in terms of long range fields, for instance a possible failure of the Lorentz symmetry can be attributed to a long range nonscalar field.

A long range field can be defined in terms of well chosen test particles. For instance, charged particles are needed to define the electromagnetic field and only spinning particles are affected by a torsion field.[1] We see that the investigations of long range classical fields and of test particles are intimately related. The aim of the present article is to give a contribution to this problem by discussing new kinds of test particles.

By definition, in a test particle model one disregards the influence of the particle on the field, namely several important effects, as the radiated energy, the radiation damping, the electromagnetic contribution to the mass, etc. However, these models are much simpler and permit a better undertanding of some general features of the theory, in particular its symmetry properties.

The test particle models may also suggest a way to introduce in the theory a fundamental length λ of the order of the Planck length with the aim of taking into account approximately some effect of quantum gravity. For instance, as it has been proposed by several authors,[2–10] an effect of quantum gravity should be an upper bound of the order of λ^{-1} to the proper acceleration of particles (we use the convention $c=1$). Note that the gravitational acceleration vanishes in a local inertial frame and a discussion of the maximal acceleration principle requires the presence of an electromagnetic field. More references are given in the report,[11] dedicated to a discussion and a

[a)]Electronic mail: toller@iol.it

comparison of various geometric descriptions of the maximal acceleration principle. Another effect of the fundamental length is the appearance of new degrees of freedom and of excited states of the particle.

In order to study the motion of a test particle, it is useful to associate to every point of its world line, parametrized by the variable τ, a moving local Lorentz frame (a tetrad) $s(\tau)$ and to consider the motion of the point $s(\tau)$ in the principal bundle $\mathcal{S}$ of all the local Lorentz frames. This point of view has been adopted in Refs. 12 and 13 in the framework of presymplectic dynamics[14] and in Refs. 15–17 starting from the balance equations of a field theory and following the ideas of Ref. 18.

The method of moving rest frames has been applied in Refs. 19–22 to Lagrangians depending on the acceleration and also on higher derivatives of the velocity. In the following we develop a more general formalism which is not restricted to rest moving frames.

The geometry based on the space $\mathcal{S}$ of the local Lorentz frames permits a formulation of a wide class of (possibly nonlocal) field theories[23] and particle theories. In the present article we concentrate our attention on the innovative particle models, without a specific consideration of fields different from classical electromagnetism and Einstein's gravitation. The general formalism, however, is ready for the introduction of more general classical fields. It has been remarked[24,25] that this geometry permits an elegant treatment of the upper bounds to the acceleration and the angular velocity of the frames and of the (possibly extended) associated particles.

An important issue is the description of the motion of a maximally accelerated particle in a Lagrangian or Hamiltonian formalism, since it is necessary for the construction of a quantum theory. It has been treated in Refs. 21 and 22 by means of the idea, already mentioned previously, of associating to the particle a moving local Lorentz frame. As it looks natural, rest frames of the particle were chosen, but we shall see in the following that this choice is too restrictive.

The report[26] contains a treatment of various kinds of test particles by means of Lagrangians that depend on the acceleration and on the angular velocity and, for dimensional reasons, must contain a parameter λ that can be interpreted as a fundamental length. This report also contains a treatment of a presymplectic formalism, which is more powerful for the treatment of some models. In the present article we concentrate our attention on Lagrangians not depending on the angular velocity of the moving frame.

In Sec. II we summarize the relevant aspects of the geometry of the fiber bundle $\mathcal{S}$ and of its generalizations. In Sec. III we develop a general Lagrangian dynamics for a point moving in this space. In Sec. IV we introduce the additional assumptions concerning a test particle subject to an Einstein-Maxwell field. In Sec. V we use the Noether theorem to find the conserved quantities corresponding to various kinds of symmetry properties of the system.

In Sec. VI we give a detailed discussion of the relation between the particle and the local reference frames associated to it. We show that, if the Lagrangian depends on the acceleration, the center of mass cannot coincide with the origin of the local frame, where the electric charge is assumed to be concentrated. In this situation, the concept of acceleration is ambiguous and, besides the proper acceleration of the point charge, we define a new different quantity, called pseudoacceleration.

As a first example, in Sec. VII we give two equivalent treatments of the ordinary spinless charged masssive particle. In Sec. VIII we apply the general methods developed in the preceding sections to the model treated in Refs. 21 and 22, based on rest frames. The model has upper bounds to the velocity and to the proper acceleration of the charge, but the energy-momentum four-vector may be spacelike. Moreover, even in the absence of external fields, the solutions present an unstable behavior (run-away solutions) when the initial conditions are slightly modified.

In Sec. IX we introduce a different model based on zero-momentum frames. It has the correct energy-momentum spectrum and an upper bound, which does not concern the acceleration, but the pseudoacceleration, requiring a slight reformulation of the maximal acceleration principle.

In Secs. X and XI we study further this new model by considering a particle in a constant electromagnetic field and we show that the solutions have good stability properties. In some

circumstances, the velocity of the charge may exceed the velocity light, but, since it rotates with a very large frequency, this effect is hardly observable. In Sec. XII we consider a particle in a simple curved space and, even if the curvature is small, we find a serious form of instability.

In Sec. XIII we analyze another model, with a physical energy-momentum spectrum, and the charge moving slower than light. However, the acceleration and the pseudoacceleration have no upper bounds. In Sec. XIV we draw some general conclusions and we suggest some remarks on the quantization.

II. THE BUNDLE OF LORENTZ FRAMES

In the absence of an electromagnetic field, a powerful method to treat the dynamics of a (possibly extended) particle is to consider, for each value of the parameter τ, a local Lorentz frame (tetrad) $s(\tau)$ in such a way that a "distinguished point" of the particle (not necessarily the center of mass) coincides with the origin of the frame (sometimes called a *moving frame*). We indicate by $\mathcal{S}$ the ten-dimensional bundle of the Lorentz frames of the space-time and we describe the motion of the particle by means of the line $\tau \rightarrow s(\tau) \in \mathcal{S}$.

Particle dynamics in this space has been introduced by Künzle[12] (see also Ref. 13) in the framework of the presymplectic formalism.[14] A treatment based on the balance equations for the densities of energy, momentum and relativistic angular momentum, strongly influenced by Dixon's work,[18] is given in Refs. 15–17. In the next section we develop a geometric Lagrangian formalism which avoids the introduction of coordinate systems in the space $\mathcal{S}$. It is more general than the Lagrangian formalism used in Ref. 21, because $s(\tau)$ is not assumed to be a rest frame.

The elements of $\mathcal{S}$ are orthonormal tetrads $\{e_0, \ldots, e_3\}$ of four vectors in the pseudo-Riemannian space-time manifold $\mathcal{M}$. We assume that $\mathcal{M}$ is time oriented and e_0 belongs to the future cone. We consider ten vector fields $A_0, \ldots, A_9$ in the manifold $\mathcal{S}$. The fields $A_0, \ldots, A_3$ generate parallel displacements of the tetrads along the directions of the tetrad vectors, $A_4 = A_{[23]}$, $A_5 = A_{[31]}$, $A_6 = A_{[12]}$ generate rotations around the spatial vectors of the tetrad and $A_7 = A_{[10]}$, $A_8 = A_{[20]}$, $A_9 = A_{[30]}$ generate Lorentz boosts along the same spatial vectors. The latin indices i, k, j, l, m, n take the values 0,…,3 and the greek indices α, β, γ take the values 0,…,9. We assume $A_{[ik]} = A_{[ki]}$ and, when necessary, we use the square brackets to indicate that an antisymmetric pair of Latin indices stands for a greek index.

The vector fields A_α can also be considered as first order differential operators and their commutators (Lie brackets) can be written in the form

$$[A_\alpha, A_\beta] = F^\gamma_{\alpha\beta} A_\gamma. \tag{1}$$

The quantities $F^\gamma_{\alpha\beta} = -F^\gamma_{\beta\alpha}$, are called *structure coefficients* and in the absence of gravitation they are the structure constants of the Poincaré group. In the presence of gravitation, $F^{[jl]}_{ik}$ are the components of the curvature tensor and F^j_{ik} are the components of the torsion tensor, which vanishes in Einstein's theory.

The ten dimensional manifold $\mathcal{S}$ has a structure of principal fiber bundle[27] with base $\mathcal{M}$ and structural group $\mathrm{SO}^\uparrow(1,3)$, but the details of this structure are not needed in the next section. The only relevant feature is that $\mathcal{S}$ is a n-dimensional differentiable manifold in which n differentiable vector fields A_α are defined and that, for each point $s \in \mathcal{S}$, the vectors $A_\alpha(s)$ form a basis of the tangent space $T_s\mathcal{S}$. As a consequence, we can identify all the tangent spaces with a single n-dimensional vector space $\mathcal{T}$, which, in the absence of gravitation and other external fields, is the Lie algebra of the Poincaré group.

In the absence of gravitational field, $\mathcal{S}$ is the bundle of the Lorentz frames of the Minkowski space-time and the orthochronous Poincaré group $\mathcal{P}$ acts freely and transitively on $\mathcal{S}$. We choose a fixed frame $\hat{s}$ and represent univocally all the other frames in the form $s = g\hat{s}$ with $g \in \mathcal{P}$. In this way we may identify $\mathcal{S}$ and $\mathcal{P}$. The vector fields A_α generate the left translations of $\mathcal{P}$.

We shall also use the differential 1-forms ω^β defined by

$$\omega^{\beta}(A_{\alpha}) = \delta^{\beta}_{\alpha}. \tag{2}$$

The vectors $\omega^{\beta}(s)$ provide a basis in the cotangent space $T^{*}_{s}\mathcal{S}$.

More details on this kind of geometry can be found in Ref. 23. In this way we can also treat a large class of external fields, including torsion fields,[1] and, for $n > 10$, gauge fields,[28] including electromagnetic fields,[29] as it is explained in Sec. IV.

III. THE LAGRANGE EQUATIONS

We write the tangent vectors of the curve $\tau \to s(\tau) \in \mathcal{S}$, which describes the motion of the frame, in the form

$$\frac{ds(\tau)}{d\tau} = b^{\alpha}A_{\alpha}(s(\tau)) \in \mathcal{T} \tag{3}$$

and we consider the action principle

$$\delta\int_{\tau_1}^{\tau_2} L(b^{\alpha},s)d\tau = 0, \tag{4}$$

where the Lagrangian L is a homogeneous function of degree one of the "velocities" b^{α}.

In order to derive the dynamical equations, we consider a family, parametrized by ϵ, of varied trajectories $(\epsilon,\tau) \to s(\epsilon,\tau)$ with the usual properties

$$s(0,\tau) = s(\tau), \quad s(\epsilon,\tau_1) = s(\tau_1), \quad s(\epsilon,\tau_2) = s(\tau_2). \tag{5}$$

We put

$$\frac{\partial s(\epsilon,\tau)}{\partial\epsilon} = a^{\alpha}A_{\alpha}. \tag{6}$$

If $\phi(s)$ is a differentiable auxiliary function, we have

$$\frac{\partial\phi(s)}{\partial\epsilon} = a^{\alpha}A_{\alpha}\phi, \quad \frac{\partial\phi(s)}{\partial\tau} = b^{\alpha}A_{\alpha}\phi, \tag{7}$$

$$\frac{\partial^2\phi(s)}{\partial\epsilon\partial\tau} = a^{\alpha}A_{\alpha}(b^{\beta}A_{\beta}\phi) = b^{\alpha}A_{\alpha}(a^{\beta}A_{\beta}\phi). \tag{8}$$

From the last equality we obtain

$$((a^{\alpha}A_{\alpha}b^{\beta})A_{\beta} - (b^{\alpha}A_{\alpha}a^{\beta})A_{\beta} + a^{\alpha}b^{\beta}[A_{\alpha},A_{\beta}])\phi = 0, \tag{9}$$

namely

$$\left(\frac{\partial b^{\gamma}}{\partial\epsilon} - \frac{\partial a^{\gamma}}{\partial\tau} + a^{\alpha}b^{\beta}F^{\gamma}_{\alpha\beta}\right)A_{\gamma}\phi = 0, \tag{10}$$

and, since ϕ is arbitrary,

$$\frac{\partial b^{\gamma}}{\partial\epsilon} = \frac{\partial a^{\gamma}}{\partial\tau} - a^{\alpha}b^{\beta}F^{\gamma}_{\alpha\beta} \tag{11}$$

and finally (disregarding higher order terms in ϵ)

$$\delta b^{\alpha} = \epsilon\left(\frac{\partial b^{\alpha}}{\partial\epsilon}\right)_{\epsilon=0} = \epsilon\left(\frac{da^{\alpha}}{d\tau} - a^{\beta}b^{\gamma}F^{\alpha}_{\beta\gamma}\right)_{\epsilon=0} = \epsilon b^{\gamma}(A_{\gamma}a^{\alpha} - a^{\beta}F^{\alpha}_{\beta\gamma})_{\epsilon=0}. \tag{12}$$

By means of the last formula, one can write, performing a partial integration,

$$\delta\int_{\tau_1}^{\tau_2} L d\tau = \epsilon\int_{\tau_1}^{\tau_2}\left(\frac{\partial L}{\partial b^\alpha}\left(\frac{da^\alpha}{d\tau} - a^\beta b^\gamma F^\alpha_{\beta\gamma}\right) + a^\alpha A_\alpha L\right)d\tau$$

$$= \epsilon\int_{\tau_1}^{\tau_2}\left(-\frac{d}{d\tau}\frac{\partial L}{\partial b^\alpha} - \frac{\partial L}{\partial b^\beta}b^\gamma F^\beta_{\alpha\gamma} + A_\alpha L\right)a^\alpha d\tau + \epsilon\left[\frac{\partial L}{\partial b^\alpha}a^\alpha\right]_{\tau_1}^{\tau_2}. \tag{13}$$

The last term vanishes as a consequence of the conditions (5) and, considering that a^α is an arbitrary function of τ, we obtain the Euler-Lagrange dynamical equations

$$\dot{p}_\alpha = \frac{dp_\alpha}{d\tau} = b^\gamma p_\beta F^\beta_{\gamma\alpha} - A_\alpha L, \tag{14}$$

where

$$p_\alpha = -\frac{\partial L}{\partial b^\alpha}. \tag{15}$$

If we assume that L does not depend directly on s, the last term in Eq. (14) is not present and this equation is exactly the one obtained in Ref. 16 in the pole approximation by integrating the balance equations (the quantities $F^\gamma_{\alpha\beta}$ are defined there with a different sign).

The momenta p_α defined by Eq. (15) are homogeneous functions of degree zero of the velocities b^α, namely they depend only on the ratios $(b^0)^{-1}b^\alpha$ (and possibly on s). It follows that they must satisfy at least a primary constraint.[30] Other primary constraints may exist and we write them in the form

$$\Phi_\rho(p_\alpha, s) = 0, \quad \rho = 0, \ldots, m-1. \tag{16}$$

Since L is a homogeneous function, the Euler theorem gives, taking Eq. (15) into account,

$$L + p_\alpha b^\alpha = 0 \tag{17}$$

and by differentiation we obtain

$$b^\alpha dp_\alpha + (A_\alpha L)\omega^\alpha = 0. \tag{18}$$

The differentials dp_α and the forms ω^α are arbitrary, apart from the constraints

$$\frac{\partial\Phi_\rho}{\partial p_\alpha}dp_\alpha + (A_\alpha\Phi_\rho)\omega^\alpha = 0, \quad \rho = 0, \ldots, m-1 \tag{19}$$

and from Eq. (18) we have

$$b^\alpha = \sum_\rho \alpha^\rho \frac{\partial\Phi_\rho}{\partial p_\alpha}, \tag{20}$$

$$A_\alpha L = \sum_\rho \alpha^\rho A_\alpha \Phi_\rho. \tag{21}$$

Equation (20) inverts, as far as possible, Eq. (15). At this level, the functions $\alpha^\rho(\tau)$ are arbitrary and, if they are not determined by the dynamical equations, they parametrize the gauge transformations of the system. There is at least one kind of gauge transformation, namely a redefinition of the parameter τ.

If, according to the dynamical equations (14), the quantities Φ_ρ are not conserved, the conditions $\dot{\Phi}_\rho = 0$ determine partially the functions α^ρ or give rise to secondary constraints. Some simplification can be obtained from the following consequence of the above-derived equations:

$$\sum_{\rho} \alpha^{\rho}\dot{\Phi}_{\rho} = \sum_{\rho} \alpha^{\rho}\left(\frac{\partial \Phi_{\rho}}{\partial p_{\alpha}}\dot{p}_{\alpha} + A_{\alpha}\Phi_{\rho}b^{\alpha}\right) = b^{\alpha}(\dot{p}_{\alpha} + A_{\alpha}L) = b^{\alpha}b^{\beta}p_{\gamma}F^{\gamma}_{\beta\alpha} = 0. \tag{22}$$

It follows that if $\alpha^0 \neq 0$ and the secondary constraints $\dot{\Phi}_{\rho}=0$ for $\rho=1,\ldots,m-1$ are satisfied, Φ_0 is conserved. In particular, if there is only one primary constraint, it is conserved and there are no secondary constraints.

If one is able to express all the quantities b^{α} and $\dot{p}_{\alpha}$ as smooth functions of s and p_{α} (satisfying some constraints), we say that the equations of motion are in *normal form* and one can apply the theorems on the (local) existence and uniqueness of the solutions. In fact, if one introduces a local system of coordinates q^{α} in the space $\mathcal{S}$, it follows from Eq. (3) that the quantities $\dot{q}^{\alpha}$ are smooth functions of the quantities b^{α}.

IV. EINSTEIN-MAXWELL FIELDS

Now we consider a test particle moving in an Einstein gravitational field and a Maxwell electromagnetic field. In order to describe the electromagnetic field, we adopt the procedure indicated in Refs. 16, 28, and 29, namely we introduce a principal fiber bundle $\mathcal{S}$ with base $\mathcal{M}$ and structural group $\mathrm{SO}^{\uparrow}(1,3)\times\mathrm{U}(1)$ which includes the electromagnetic gauge group. Then the manifold $\mathcal{S}$ has dimension $n=11$ and we have to introduce a new vector field, that we indicate by $A_{\bullet}$ (in order to avoid a two-digit index $\alpha=10$), which generates the global electromagnetic gauge transformations. We use the notation

$$b^{\alpha}A_{\alpha} = b^{i}A_{i} + \tfrac{1}{2}b^{[ik]}A_{[ik]} + b^{\bullet}A_{\bullet}, \quad b^{[ik]} = -b^{[ki]}. \tag{23}$$

The 11-dimensional manifold $\mathcal{S}$ can also be considered as a principal fiber bundle with structural group U(1) and base $\mathcal{S}_0$, the 10-dimensional bundle of the Lorentz frames considered up to now. We shall consider later the projection $\mathcal{S}\to\mathcal{S}_0$ along the fibers generated by the vector field $A_{\bullet}$.

The structure coefficients $F^{\alpha}_{[ik]\beta}$ coincide with the structure constants of the Poincaré algebra. They can be written in the form

$$F^{[mn]}_{[ik][jl]} = \delta^{m}_{i}g_{kj}\delta^{n}_{l} - \delta^{m}_{k}g_{ij}\delta^{n}_{l} - \delta^{m}_{i}g_{kl}\delta^{n}_{j} + \delta^{m}_{k}g_{il}\delta^{n}_{j} - \delta^{n}_{i}g_{kj}\delta^{m}_{l} + \delta^{n}_{k}g_{ij}\delta^{m}_{l} + \delta^{n}_{i}g_{kl}\delta^{m}_{j} - \delta^{n}_{k}g_{il}\delta^{m}_{j}, \tag{24}$$

$$F^{l}_{[ik]j} = \delta^{l}_{i}g_{kj} - \delta^{l}_{k}g_{ij}, \tag{25}$$

$$F^{m}_{[ik][jl]} = 0, \quad F^{[mn]}_{[ik]j} = 0. \tag{26}$$

We also assume that the torsion F^{j}_{ik} vanishes.

The structure coefficients $F^{\bullet}_{ik}=F_{ik}$ represent the electromagnetic field strength and $F^{\beta}_{\alpha\bullet}=F^{\bullet}_{[ik]\alpha}=0$. The electromagnetic interaction Lagrangian is

$$L_I = eb^{\bullet}, \tag{27}$$

where e is the electric charge.

By means of these equations, we can write Eq. (14) in the more explicit form

$$\dot{p}_i = -b_i{}^k p_k + F_i, \quad F_i = b^k G_{ik} - A_i L, \quad G_{ik} = \tfrac{1}{2}p_{[jl]}F^{[jl]}_{ki} + eF_{ik}, \tag{28}$$

$$\dot{p}_{[ik]} = b_i p_k - b_k p_i - b_i{}^j p_{jk} - b_k{}^j p_{ij} - A_{[ik]}L, \tag{29}$$

$$\dot{p}_{\bullet} = 0, \quad p_{\bullet} = -e, \tag{30}$$

where $F_{ki}^{[jl]}$ is the Riemann curvature tensor which describes the gravitational field. As we discuss in the next section, the quantities p^i and $-p_{ik}$ are interpreted as the energy, the momentum and the relativistic angular momentum of the particle, measured in the local reference frame s. The quantity $-p_{\bullet}$ is the conserved electric charge.

It is often convenient to use a three-dimensional vector formalism. We introduce the vectors

$$\mathbf{b} = (b^1, b^2, b^3), \quad \mathbf{b}' = (b^{[23]}, b^{[31]}, b^{[12]}), \quad \mathbf{b}'' = (b^{[10]}, b^{[20]}, b^{[30]}), \tag{31}$$

$$\mathbf{p} = -(p_1, p_2, p_3), \quad \mathbf{p}' = -(p_{[23]}, p_{[31]}, p_{[12]}), \quad \mathbf{p}'' = -(p_{[10]}, p_{[20]}, p_{[30]}), \tag{32}$$

$$\mathbf{f} = -(b^0)^{-1}(F_1, F_2, F_3), \tag{33}$$

$$\mathbf{E} = (F_{01}, F_{02}, F_{03}), \quad \mathbf{B} = (F_{32}, F_{13}, F_{21}), \tag{34}$$

$$\hat{\mathbf{E}} = (G_{01}, G_{02}, G_{03}), \quad \hat{\mathbf{B}} = (G_{32}, G_{13}, G_{21}), \tag{35}$$

and we obtain, if L does not depend on s,

$$\dot{p}_0 = -\mathbf{b}'' \cdot \mathbf{p} + \mathbf{b} \cdot \mathbf{f}, \tag{36}$$

$$\dot{\mathbf{p}} = -\mathbf{b}' \times \mathbf{p} - p_0 \mathbf{b}'' + b^0 \mathbf{f}, \tag{37}$$

$$\dot{\mathbf{p}}' = -\mathbf{b} \times \mathbf{p} - \mathbf{b}' \times \mathbf{p}' - \mathbf{b}'' \times \mathbf{p}'', \tag{38}$$

$$\dot{\mathbf{p}}'' = p_0 \mathbf{b} - b^0 \mathbf{p} - \mathbf{b}' \times \mathbf{p}'' + \mathbf{b}'' \times \mathbf{p}', \tag{39}$$

$$\mathbf{f} = \hat{\mathbf{E}} + (b^0)^{-1} \mathbf{b} \times \hat{\mathbf{B}}. \tag{40}$$

The dimension of the phase space, namely the number of parameters necessary to define the initial conditions, is given by $2n=22$ minus the number of primary and secondary constraints [including the constraint (30)] minus the number of the arbitrary gauge parameters (including the usual electromagnetic gauge transformations).

It is instructive to consider, besides the flat Minkowski space time, the spaces of constant curvature

$$F_{ik}^{[jl]} = \rho(\delta_i^j \delta_k^l - \delta_k^j \delta_i^l). \tag{41}$$

$\mathcal{M}$ is a de Sitter space time if $\rho > 0$, and an anti-de Sitter space time for $\rho < 0$. From Eq. (28) we obtain

$$G_{ik} = -\rho p_{[ik]} + eF_{ik}, \tag{42}$$

or, in the vector notation,

$$\hat{\mathbf{E}} = -\rho \mathbf{p}'' + e\mathbf{E}, \quad \hat{\mathbf{B}} = -\rho \mathbf{p}' + e\mathbf{B}. \tag{43}$$

V. NOETHER'S THEOREM

In order to treat the connection between symmetries and conservation laws (Noether's theorem), we consider a vector field

$$Y(s) = a^{\alpha}(s)A_{\alpha}(s) \tag{44}$$

and the corresponding one-parameter diffeomorphism group $\exp(\epsilon Y)$, which transforms the trajectory $s(\tau)$ into the trajectories $s(\epsilon,\tau)$. If this transformation does not change the action, the expression (13) vanishes and, taking the dynamical equations into account, we obtain the conservation law

$$a^{\alpha}p_{\alpha} = \text{constant}. \tag{45}$$

We assume that L does not depend on s and consider two kinds of applications of this general theorem, which use two different kinds of symmetry properties. In the first case we require

$$[Y,A_{\beta}] = (a^{\alpha}F^{\gamma}_{\alpha\beta} - A_{\beta}a^{\gamma})A_{\gamma} = 0 \tag{46}$$

and from Eq. (12) we see that $\delta b^{\alpha}=0$, and therefore $\delta L=0$. Note that the validity of the conservation law (45) does not depend on the form of the function $L(b^{\alpha})$.

In a second case we assume Eqs. (24)–(26) and consider the infinitesimal Lorentz transformation generated by $A_{[ik]}$. From Eq. (12) we obtain

$$\delta b^{\alpha} = -\epsilon F^{\alpha}_{[ik]\gamma}b^{\gamma}, \tag{47}$$

namely an infinitesimal Lorentz transformation of the quantities b^{α}. If the Lagrangian is invariant under this transformation, the quantity $p_{[ik]}$ is conserved. In particular, if the Lagrangian is a Lorentz scalar function of b^{α} all the six quantities $p_{[ik]}$ are conserved. If the Lagrangian is only a rotational scalar, only the three quantities $p_{[rs]}$ with $r,s=1,2,3$ are conserved. These conservation laws depend on the invariance properties of the Lagrangian and on the form of the structure coefficients $F^{\alpha}_{[ik]\gamma}$. They are also valid in the presence of arbitrary gravitational and electromagnetic fields.

Now we consider the simplest application of the first kind. As we have seen in Sec. II, in the absence of gravitational and electromagnetic fields, $\mathcal{S}$ is the bundle of the Lorentz frames of the Minkowski space time and choosing a fixed frame $\hat{s}$, can be identified with the orthochronous Poincaré group $\mathcal{P}$. The vector fields A_{α} generate the left translations of $\mathcal{P}$, but one can also introduce the vector fields $\hat{A}_{\alpha}$, which generate the right translations, interpreted as Poincaré transformations of the fixed frame $\hat{s}$. They commute with A_{α} and are given by

$$Y = \hat{A}_{\alpha}(g) = D^{\beta}{}_{\alpha}(g)A_{\beta}(g), \tag{48}$$

where $D(g)$ is the adjoint representation of $\mathcal{P}$, which has the property

$$A_{\alpha}D^{\beta}{}_{\gamma}(g) = -F^{\beta}_{\alpha\delta}D^{\delta}{}_{\gamma}(g). \tag{49}$$

It follows from the Noether theorem that the quantities

$$\hat{p}_{\alpha} = D^{\beta}{}_{\alpha}(g(\tau))p_{\beta}(\tau) \tag{50}$$

are conserved. Since they are defined starting from the symmetry under spacetime translations and infinitesimal Lorentz transformations of $\hat{s}$, they have to be interpreted as the components of the energy momentum and the relativistic angular momentum measured in the fixed frame $\hat{s}$.

We indicate an element of $\mathcal{P}$ by $(\Lambda,x)=(\Lambda,0)(1,x)$, where x is the translation four vector and Λ is the Lorentz matrix acting on the contravariant components of the four vectors. If we use the explicit form of the adjoint representation, we obtain the equations

$$\hat{p}_i = \Lambda^k{}_i p_k, \quad \hat{p}_{[ik]} = \Lambda^j{}_i\Lambda^l{}_k p_{[jl]} - x_i\hat{p}_k + x_k\hat{p}_i, \tag{51}$$

which show that the quantities $p_{\beta}(\tau)$ are correctly interpreted as the components of the energy momentum and the relativistic angular momentum measured in the moving frame $s(\tau)$, as we anticipated in the preceding section. The mass μ and the spin σ of the particle are given by the

familiar Poincaré invariant expressions and take the same form when written as functions of $\hat{p}_\beta(\tau)$ or of $p_\beta(\tau)$. In particular we have

$$\mu^2 = p^i p_i, \quad \sigma^2\mu^2 = -S^k S_k, \quad S^k = 2^{-1}\epsilon^{kijl} p_{[ij]} p_l. \tag{52}$$

This interpretation is also valid if an electromagnetic field is present. In fact, from Eqs. (31)–(40) we see that the influence of the electromagnetic field on the derivatives $\dot{p}_\alpha$ is just the one expected for a point charge centered at the origin, if the quantities p_α represent the components of the kinetic energy momentum and relativistic angular momentum. This problem is also discussed in Ref. 20.

The exact definition of the energy momentum and of the relativistic angular momentum of an extended particle in a curved space time is somehow ambiguous[16,18] and in this case the interpretation of p_α can be considered as a definition.

VI. FRAMES AND PARTICLES

In order to interpret the solutions of the dynamical equations, we have to clarify the connection between the Lorentz frames $s(\tau)$ and the physical particle. We indicate by $\pi: \mathcal{S} \to \mathcal{M}$ the projection which associates to the tetrad $s \in \mathcal{S}$ its origin $x = \pi(s) \in \mathcal{M}$. The projection of the curve $\tau \to s(\tau)$ is the world line $\tau \to \pi(s(\tau)) = x(\tau)$ in the space-time manifold $\mathcal{M}$. From Eq. (3), remembering that the vector fields A_i generate the parallel displacements along the four vectors $e_i(\tau)$ of the tetrad $s(\tau)$, we have

$$\dot{x}(\tau) = \frac{dx(\tau)}{d\tau} = b^i(\tau) e_i(\tau). \tag{53}$$

If τ is the proper time, namely if $b_i b^i = 1$, the quantities b^i are the components of the four velocity of the origin of $s(\tau)$, with respect to the same frame.

The tetrad $s(\tau + d\tau)$ differs from the parallel transported tetrad by an infinitesimal Lorentz transformation with parameters $b^{[ik]} d\tau$. This means that the covariant derivatives of the tetrad four vectors are given by

$$\frac{De_i(\tau)}{d\tau} = -b_i^{\ k}(\tau) e_k(\tau), \tag{54}$$

and we obtain the formula

$$a(\tau) = \frac{D\dot{x}(\tau)}{d\tau} = \dot{b}^i e_i - b^i b_i^{\ k} e_k = (\dot{b}^i + b^i_{\ k} b^k) e_i. \tag{55}$$

If τ is the proper time, a is the covariant acceleration four vector and its components in the moving frame $s(\tau)$ are given by

$$a^i = \dot{b}^i + b^i_{\ k} b^k. \tag{56}$$

A *rest frame* is defined by the condition $\mathbf{b} = 0$ and the four velocity of the origin of the frame is equal to the tetrad vector e_0, which is time-like by definition. If τ is the proper time, we also have $b^0 = 1$, and $d\tau$ is a time measured in the rest frame. We have

$$a = \frac{De_0}{d\tau} = b^{[r0]} e_r, \quad a^0 = 0, \quad \mathbf{a} = \mathbf{b}''. \tag{57}$$

The vector $\mathbf{a}$ represents the acceleration of the origin of a rest frame measured in the same frame. If the parameter τ is arbitrary, we can write the more general formula

$$\mathbf{a} = (b^0)^{-1} \mathbf{b}''. \tag{58}$$

We can introduce more specific moving frames by requiring the stronger conditions

$$\mathbf{b}=0, \quad b^{[20]}=b^{[30]}=b^{[31]}=0. \tag{59}$$

In a Lagrangian model they can be imposed by introducing six Lagrangian multipliers. In this case $s(\tau)$ is a Frenet frame and the quantities $k_1=b^{[01]}$, $k_2=b^{[12]}$, $k_3=b^{[23]}$ are the geometric invariants of the world line, which depend on the acceleration and its first and second derivatives.[19,21] The Lagrangian depends on these invariants as in the models considered in Ref. 19.

Now we consider frames defined by nonpurely geometric, but dynamical requirements. The condition $\mathbf{p}=0$ defines a *zero-momentum frame*. It implies that the energy momentum is a timelike four vector. In the case of a free particle, the center of mass is at rest in this frame, but this is not true in general. In a zero-momentum frame $\mathbf{p}'$ represents by definition the spin of the particle. One can still consider the vector (58) but it does not represent the acceleration of the origin $x(\tau)$ and not even the acceleration of the center of mass. We call it the *pseudoacceleration*. From Eq. (37) we have

$$\mathbf{a}=p_0^{-1}\mathbf{f}. \tag{60}$$

Note that p_0 in a zero-momentum frame is the invariant mass and this formula coincides with the Newton formula, valid for a point particle. If the particle is extended, this formula remains valid if we replace the acceleration by the pseudoacceleration. This may be considered as the physical meaning of the pseudoacceleration.

In order to describe the position of the center of mass, we have to introduce for each tetrad a system of coordinates in a suitable open set of $\mathcal{M}$, for instance a system of normal coordinates. In the absence of gravitation, namely in special relativity theory, one can associate to every local frame s a Lorentzian coordinate system in the flat Minkowski spacetime and the space coordinates of the center of mass at zero time in this frame can be written in the form[31]

$$\mathbf{y}=-p_0^{-1}\mathbf{p}''. \tag{61}$$

The condition $\mathbf{p}''=0$ means that the trajectory of the center of mass crosses the origin. A frame with this property is called a *central frame*. This definition can be extended to the case in which gravitation is present. From Eq. (39) we see that, if the spin is zero, a zero-momentum central frame is also a rest frame.

The definition $\mathbf{p}''=0$ is not Lorentz invariant and it is often replaced by the condition

$$p_{[ik]}p^k=0, \tag{62}$$

proposed by Dixon.[18] A frame with this property is called a *Dixon frame*. It can always be obtained from a central zero-momentum frame by means of a Lorentz transformation.

The models treated in the following sections concern extended particles which contain a point charge. In this case, instead of working with central or Dixon frames, it is convenient to assume that the charge lies at the origin of $s(\tau)$. More in general, if the charge is not pointlike, one can require that the electric dipole moment with repect to the frame $s(\tau)$ vanishes.

VII. AN ORDINARY SPINLESS PARTICLE

It is instructive to consider first some Lagrangians that do not contain $\mathbf{b}'$ and $\mathbf{b}''$ and describe a pointlike spinless particle with mass m and charge e. The simplest Lagrangian of this kind is

$$L=-mb^0+eb^\bullet. \tag{63}$$

Since it is linear in the "velocities" b^α, all the momenta p_α are fixed by 11 primary constraints, namely we have $p_0=m$, $p_\bullet=-e$ and the other momenta vanish. As a consequence, the spin vanishes and the center of mass coincides with the charge. From the dynamical equations (36)–(39) we obtain

$$\mathbf{b}=0, \quad m\mathbf{a}=m(b^0)^{-1}\mathbf{b}''=\mathbf{f}=e\mathbf{E}. \tag{64}$$

We see that the frames $s(\tau)$ are zero-momentum rest central frames and that the acceleration is given by the usual formula. The time evolution of the quantities b^0, $\mathbf{b}'$, and $b^\bullet$ is not determined by the dynamical equations, the model has gauge invariances described by five parameters and the phase space has dimension six. If we impose the gauge fixing condition $\mathbf{b}'=0$, the frame is Fermi-Walker transported and if we assume $b^0=1$ the parameter τ is the usual relativistic proper time. If $\mathbf{E}=0$, the frame is parallel transported and the world line of the particle is a geodesic.

In view of the following developments, it is interesting to treat with more detail a charged particle in a constant electromagnetic field in the absence of gravitation. The field is invariant under spacetime translations, but it changes if a Lorentz transformation is applied to the frame. If $b^0=1$, we have

$$\dot{\mathbf{E}}=\mathbf{b}''\times\mathbf{B}-\mathbf{b}'\times\mathbf{E}, \quad \dot{\mathbf{B}}=-\mathbf{b}''\times\mathbf{E}-\mathbf{b}'\times\mathbf{B}. \tag{65}$$

Of course, the Lorentz invariants

$$I=\|\mathbf{E}\|^2-\|\mathbf{B}\|^2, \quad J=\mathbf{E}\cdot\mathbf{B} \tag{66}$$

are constant.

The derivatives (65) vanish if we choose the gauge fixing condition

$$\mathbf{b}'=-em^{-1}\mathbf{B}. \tag{67}$$

The components of the field and all the quantities b^α are constant and we say that this is a "stationary" solution. It follows that the projection of the trajectory on the ten-dimensional space $\mathcal{S}_0$, identified with the Poincaré group $\mathcal{P}$, is given by a one-parameter subgroup, namely

$$g(\tau)=\exp(\tau b^\alpha\widetilde{A}_\alpha)g(0), \tag{68}$$

where $\widetilde{A}_\alpha$ form a basis in the Lie algebra of $\mathcal{P}$ and $\exp(\cdot)$ is the exponential mapping of the group.[32]

We also consider the Lorentz invariant Lagrangian

$$L=-m((b^0)^2-\|\mathbf{b}\|^2)^{1/2}+eb^\bullet. \tag{69}$$

We obtain

$$p_0=mb^0((b^0)^2-\|\mathbf{b}\|^2)^{-1/2}, \quad \mathbf{p}=m((b^0)^2-\|\mathbf{b}\|^2)^{-1/2}\mathbf{b}, \tag{70}$$

$$\mathbf{p}'=\mathbf{p}''=0, \quad p_\bullet=-e \tag{71}$$

and the constraint

$$p_0^2-\|\mathbf{p}\|^2=m^2. \tag{72}$$

It is sufficient to consider the dynamical equations (37), since Eqs. (36), (38), and (39) are consequences of the other equations. We see that the quantities b^0, $\mathbf{b}'$, $\mathbf{b}''$, and $b^\bullet$ are not determined and they are gauge parameters. In particular, the Lorentz transformations assume the character of gauge transformations. We may fix the gauge partially by assuming that $\mathbf{p}=0$ and we obtain exactly the equations of the preceding model. The dynamics of the particle is the same, but in the second model there is more freedom in the choice of the moving frame.

Alternatively, we may require $\mathbf{b}'=\mathbf{b}''=0$, namely that the moving frame is parallel transported, and, also assuming $b^0=1$, Eq. (37) takes the familiar form

$$\dot{\mathbf{p}}=\mathbf{f}. \tag{73}$$

VIII. A MODEL WITH A MAXIMAL ACCELERATION

For dimensional reasons, a Lagrangian which is a homogeneous function of degree one of the velocities b^α and contains a fundamental length λ must contain, besides b^0 and $\mathbf{b}$, some of the quantities $\lambda\mathbf{b}'$ or $\lambda\mathbf{b}''$. In the following we consider Lagrangians that depend on $\mathbf{b}''$, but not on $\mathbf{b}'$, and we treat first a model with a maximal proper acceleration equivalent to the one treated in Ref. 21.

It is easy to obtain an upper limit for the quantity $(b^0)^{-1}\mathbf{b}''$, but, as we have seen in Sec. VI, this quantity coincides with the proper acceleration only if $s(\tau)$ are rest frames, namely if $\mathbf{b}=0$. This constraint is implicit in the formalism of Ref. 21, but in the framework of the preceding sections we have to enforce it by means of the Lagrange multipliers $\boldsymbol{\eta}$. A simple Lagrangian of this kind, that does not contain $\mathbf{b}'$, is given by

$$L = -m((b^0)^2 - \lambda^2\|\mathbf{b}''\|^2)^{1/2} + \boldsymbol{\eta}\cdot\mathbf{b} + eb^\bullet. \tag{74}$$

We obtain the equations

$$\mathbf{b} = 0, \quad \mathbf{p} = \boldsymbol{\eta}, \quad \mathbf{p}' = 0, \quad p_\bullet = -e. \tag{75}$$

The first equality means that we are dealing with rest frames and the second shows that $\mathbf{p}$ can be chosen freely in the initial conditions, even in contrast with the usual requirements on the energy-momentum spectrum. The third formula does not imply that the spin vanishes, because the spin is defined as the angular momentum in a zero-momentum frame, that in general is not a rest frame.

The other momenta are given by

$$\begin{aligned} p_0 &= mb^0((b^0)^2 - \lambda^2\|\mathbf{b}''\|^2)^{-1/2}, \\ \mathbf{p}'' &= m\lambda^2((b^0)^2 - \lambda^2\|\mathbf{b}''\|^2)^{-1/2}\mathbf{b}'' \end{aligned} \tag{76}$$

and satisfy the scalar primary constraint

$$p_0^2 - \lambda^{-2}\|\mathbf{p}''\|^2 = m^2, \tag{77}$$

which, in agreement with Eq. (22), is conserved and does not give rise to secondary constraints. We consider only solutions with $p_0 \geqslant m$ and, as a consequence, $b^0 > 0$. From the preceding formulas one obtains the relations

$$\mathbf{a} = (b^0)^{-1}\mathbf{b}'' = \lambda^{-2}p_0^{-1}\mathbf{p}'' = -\lambda^{-2}\mathbf{y} = \lambda^{-1}(\|\mathbf{p}''\|^2 + \lambda^2 m^2)^{-1/2}\mathbf{p}'', \tag{78}$$

which show that the acceleration $\|\mathbf{a}\|$ has the upper bound λ^{-1} and the distance $\|\mathbf{y}\|$ of the center of mass from the origin has the upper bound λ.

The dynamical equation (36) follows from Eq. (39) and the scalar constraint (77). Equation (38) is automatically satisfied and from Eqs. (37) and (39) we obtain

$$\dot{\mathbf{p}} = -p_0\mathbf{b}'' + b^0\mathbf{f} - \mathbf{b}' \times \mathbf{p}, \quad \dot{\mathbf{p}}'' = -b^0\mathbf{p} - \mathbf{b}' \times \mathbf{p}''. \tag{79}$$

There are no secondary constraints.

As in the simple model considered in the preceding section, the time evolution of the quantities b^0, $\mathbf{b}'$, and $b^\bullet$ is not determined by the dynamical equations and the model has gauge invariances. Since there are five primary constraints and five arbitrary gauge variables, the phase space has dimension twelve. We can impose the gauge fixing conditions $b^0=1$, $\mathbf{b}'=0$ and we get the simpler dynamical equations

$$\dot{\mathbf{p}} = -\lambda^{-2}\mathbf{p}'' + \mathbf{f}, \quad \dot{\mathbf{p}}'' = -\mathbf{p}. \tag{80}$$

This system is in normal form.

We obtain

$$\frac{d}{d\tau}(p_0^2 - \|\mathbf{p}\|^2) = -2\mathbf{f}\cdot\mathbf{p}. \tag{81}$$

Even if initially the four momentum is time-like, by applying a suitable force $\mathbf{f}$, it may become space-like. This means that one cannot simply discard as unphysical the states with space-like four momentum.

We see from Eqs. (28), (35), and (40), that, when the particle is subject to gravitational fields only, if $\mathbf{p}'=\mathbf{p}''=0$ we have $\mathbf{f}=0$. It follows that $\mathbf{p}''=\mathbf{b}''=\mathbf{p}=0$ is a solution which describes an ordinary spinless particle with mass $p_0=m$ moving according to the laws of general relativity. We show in the following that, even in the absence of external fields, there are many other solutions, as it is expected, since the phase space has dimension larger than six.

It is shown in Refs. 21 and 22 that, in space times of constant curvature and in the absence of other external fields, the dynamical equations can be solved exactly. In fact, from Eqs. (43) and (80) we obtain

$$\ddot{\mathbf{p}}'' = (\rho + \lambda^{-2})\mathbf{p}''. \tag{82}$$

For $\rho > -\lambda^{-2}$ it has exponential solutions and for $\rho < -\lambda^{-2}$ it has periodic solutions. Considering with more detail the case $\rho=0$, namely a flat spacetime, the general solution has the form

$$\mathbf{p}'' = \mathbf{u}\exp(\lambda^{-1}\tau) + \mathbf{v}\exp(-\lambda^{-1}\tau). \tag{83}$$

The acceleration $\|\mathbf{a}\|$ and the distance $\|\mathbf{y}\|$ of the center of mass from the origin of the moving frame are given by Eq. (78). For generic initial conditions, they approach their maximum values when time increases or decreases, in particular

$$\lim_{\tau\to\infty} \mathbf{a} = \lambda^{-1}\|\mathbf{u}\|^{-1}\mathbf{u}, \quad \mathbf{u} \neq 0. \tag{84}$$

For $\mathbf{u}=\mathbf{v}=0$, we obtain $\mathbf{p}''=\mathbf{a}=0$, namely the uniform motion that is expected for an ordinary particle in the absence of external forces. This solution, however, is unstable, since small changes of the initial conditions lead to solutions with a large acceleration in the past or in the future. We have

$$p_0^2 - \|\mathbf{p}\|^2 = m^2 + 4\lambda^{-2}\mathbf{u}\cdot\mathbf{v} \tag{85}$$

and we see that for some solutions the energy-momentum four vector is spacelike. The accelerated solutions recall the run-away solutions of the Lorentz-Dirac equation,[33] with the important difference that in our case we are considering test particles and disregarding the radiated energy.

In a flat spacetime one can easily compute the motion of the origin of $s(\tau)$, namely of the point charge associated with the extended particle. In the generic case, it approaches soon the velocity of light with respect to a fixed frame. Of course, the center of mass follows a linear world line and its distance from the charge becomes large in the fixed frame. In the moving frame, however, as an effect of the Lorentz transformation, it remains small.

If, instead of considering a test particle, we take into account effects depending on higher powers of the charge e, it is possible that the radiated energy (bremsstrahlung) prevents the unstable behavior described previously. In the following sections, however, we try a different solution of this problem.

IX. A MODEL WITH A MAXIMAL PSEUDOACCELERATION

In order to avoid the unphysical energy-momentum spectrum and the unstable behavior of the model described in the preceding section, a reasonable attempt is to consider zero-momentum frames instead of rest frames. This can be obtained by dropping the Lagrange multipliers from Eq. (74) namely by assuming

$$L = -m((b^0)^2 - \lambda^2\|\mathbf{b}''\|^2)^{1/2} + eb^\bullet. \tag{86}$$

Besides Eq. (30) we obtain the vector constraints

$$\mathbf{p} = 0, \quad \mathbf{p}' = 0, \tag{87}$$

showing that $s(\tau)$ is a zero-momentum frame and the particle is spinless. It is clear that the four-momentum p is necessarily timelike. Equation (76), the scalar constraint (77) and Eq. (78) of the preceding section are still valid and, in this case too, we consider only solutions with $p_0 \geqslant m$ and, as a consequence, $b^0 > 0$. Equation (78), however, does not give an upper bound to the acceleration, but to the pseudoacceleration **a** defined in Sec. VI.

The relation

$$p_0 = m(1 - \lambda^{-2}\|\mathbf{y}\|^2)^{-1/2} \tag{88}$$

shows that p_0 can be interpreted as a confining potential that binds the charge to the center of mass. When a force is applied to the charge, $\|\mathbf{y}\|$ and p_0 increase and this explains intuitively why the pseudoacceleration remains bounded.

As in the model of the preceding section, the dynamical equation (36) follows from Eq. (39) and the scalar constraint (77), Eq. (38) is automatically satisfied and from Eqs. (37) and (39) we obtain

$$p_0\mathbf{b}'' = b^0\mathbf{f}, \quad \dot{\mathbf{p}}'' = p_0\mathbf{b} - \mathbf{b}' \times \mathbf{p}''. \tag{89}$$

In this case too we have gauge symmetries. If we impose the gauge fixing conditions $b^0 = 1$ and $\mathbf{b}' = 0$, we get the simplified equations

$$\mathbf{p}'' = \lambda^2 p_0\mathbf{b}'' = \lambda^2\mathbf{f} = \lambda^2(\hat{\mathbf{E}} + \mathbf{b} \times \hat{\mathbf{B}}), \tag{90}$$

$$\dot{\mathbf{p}}'' = p_0\mathbf{b}. \tag{91}$$

Note that the four-vector $(b^0, \mathbf{b})$, proportional to the four-velocity of the charge measured in the frame $s(\tau)$, is not necessarily time-like and in Sec. X we find examples in which it is actually space-like. It follows that its time component in some other fixed reference frame $\hat{s}$ may vanish or even become negative. This means that the charge "moves backwards in time," namely, more exactly, the time coordinate with respect to the frame $\hat{s}$ is a decreasing function of the parameter τ. A further discussion will be given in Sec. XIV.

As we have remarked in the preceding section, if there is only a gravitational field, but no other external fields, the equalities $\mathbf{p}' = \mathbf{p}'' = 0$ imply that $\mathbf{f} = 0$. It follows that the equalities $\mathbf{f} = \mathbf{p}'' = \mathbf{b}'' = \mathbf{b}' = \mathbf{b} = 0$ define solutions in which $s(\tau)$ is a parallel transported rest frame. These solutions describe an ordinary spinless particle with mass $p_0 = m$ moving according to the laws of general relativity, but in general there are other different solutions with $\mathbf{p}'' \neq 0$. In a space of constant curvature ρ, as we see from Eq. (43), we have $\mathbf{f} = -\rho\mathbf{p}''$ and if $\rho \neq -\lambda^{-2}$, we have necessarily $\mathbf{f} = \mathbf{p}'' = 0$ and the only solutions are the ones described previously. In this case, the phase space has dimension six.

If $\hat{\mathbf{B}} \neq 0$, from Eq. (90) we obtain the secondary constraint

$$(\hat{\mathbf{E}} - \lambda^{-2}\mathbf{p}'') \cdot \hat{\mathbf{B}} = 0. \tag{92}$$

We have eight primary constraints, one secondary constraint and five arbitrary gauge variables. It follows that, if there are no tertiary constraints, the dimension of the phase space is eight. If $\hat{\mathbf{B}} = 0$ in the whole space $\mathcal{S}$, as in the constant curvature models treated previously, Eq. (90) gives the three secondary constraints

$$\mathbf{p}'' = \lambda^2 \hat{\mathbf{E}} \tag{93}$$

and the phase space has dimension six, as in the free case.

X. A PARTICLE IN A CONSTANT ELECTROMAGNETIC FIELD

It is useful to consider, as in Sec. VII, a particle in a flat space time with a constant electromagnetic field. Some results will be approximately valid for slowly varying fields. We consider first the case in which the invariants (66) have the properties $I \geqslant 0$, $J=0$ and in the frame $s(0)$ we have $\mathbf{B}=0$. If we choose the gauge $\mathbf{b}'=0$, we see from Eqs. (65) and (90) that $\dot{\mathbf{E}}=\dot{\mathbf{B}}=0$. It follows that along the whole trajectory $\mathbf{E}$, $\mathbf{p}''$, and $\mathbf{b}''$ are constant, $\mathbf{B}=0$ and $\mathbf{b}=0$. The frame $s(\tau)$ is a rest frame that moves with a constant acceleration given by

$$\mathbf{b}'' = (m^2 + \lambda^2 \|e\mathbf{E}\|^2)^{-1/2} e\mathbf{E}. \tag{94}$$

We see that, in this case, the singular manifold defined by $\mathbf{B}=0$ is invariant, namely all the trajectories crossing it are completely contained in it. The acceleration remains bounded even if the electric field is very large. As in the case of Sec. VII, $s(0)$ determines the initial conditions completely and the solution is stationary.

If in the frame $s(0)$ we have $\mathbf{B} \neq 0$, we must also specify two components of $\mathbf{p}''$ in order to describe the initial condition completely. We show, however, that there is a finite number of stationary solutions starting from $s(0)$ in which all the components of the field and all the quantities b^α and p_α are constant and $s(\tau)$ is given by the exponential formula (68). The other, nonstationary, solutions will be treated perturbatively in the next section.

We assume first that $\mathbf{E} \times \mathbf{B} \neq 0$, since the case in which this vector vanishes needs a separate treatment. If we require that the derivatives in Eqs. (65) and (89) vanish, we obtain after some calculation,

$$\mathbf{b} = a\mathbf{E} \times \mathbf{B},$$

$$\mathbf{b}' = p_0^{-1} e(-(1 - a\|\mathbf{B}\|^2)\mathbf{B} + a(\mathbf{B} \cdot \mathbf{E})\mathbf{E}),$$

$$\mathbf{b}'' = p_0^{-1} e((1 - a\|\mathbf{B}\|^2)\mathbf{E} + a(\mathbf{B} \cdot \mathbf{E})\mathbf{B}), \tag{95}$$

$$p_0^2 = m^2 + \lambda^2 e^2((1 - a\|\mathbf{B}\|^2)^2 \|\mathbf{E}\|^2 + a(2 - a\|\mathbf{B}\|^2)(\mathbf{E} \cdot \mathbf{B})^2).$$

The second Eq. (89) is satisfied if

$$a p_0^2 = \lambda^2 e^2((1 - a\|\mathbf{B}\|^2)^2 + a^2(\mathbf{B} \cdot \mathbf{E})^2), \tag{96}$$

namely, by substituting the expression for p_0^2,

$$\begin{aligned} f(a) &= (1 - a\|\mathbf{B}\|^2)((1 - a\|\mathbf{B}\|^2)(1 - a\|\mathbf{E}\|^2) - a^2(\mathbf{E} \cdot \mathbf{B})^2) - \lambda^{-2} e^{-2} m^2 a \\ &= (1 - a\|\mathbf{B}\|^2)(1 - a\|\mathbf{B}\|^2 - a\|\mathbf{E}\|^2 + a^2\|\mathbf{E} \times \mathbf{B}\|^2) - \lambda^{-2} e^{-2} m^2 a = 0. \end{aligned} \tag{97}$$

This is, in general, a third degree algebraic equation in the variable a, that has one or three real solutions. The polynomial function $f(a)$ has the following properties:

$$f(a) > 0 \quad \text{for } a \leqslant 0, \quad f(0) = 1,$$

$$f(a) < 0 \quad \text{for } \|\mathbf{E}\|^{-2} \leqslant a \leqslant \|\mathbf{B}\|^{-2},$$

$$f(a) < 0 \quad \text{for } \|\mathbf{B}\|^{-2} \leqslant a \leqslant \|\mathbf{B}\|^{-2}(1 + \lambda^{-2} e^{-2} m^2 (\|\mathbf{E}\|^2 + \|\mathbf{B}\|^2)^{-1}),$$

$$f'(a) < -\lambda^{-2}e^{-2}m^2 \quad \text{for } 0 \leqslant a \leqslant \min(\|\mathbf{E}\|^{-2}, \|\mathbf{B}\|^{-2}). \tag{98}$$

It follows that $f(a)$ has only one zero in the interval

$$0 < a < \min(\lambda^2 e^2 m^{-2}, \|\mathbf{E}\|^{-2}, \|\mathbf{B}\|^{-2}) \tag{99}$$

and, possibly, two zeros in the half line

$$a \geqslant \|\mathbf{B}\|^{-2}(1 + \lambda^{-2}e^{-2}m^2(\|\mathbf{E}\|^2 + \|\mathbf{B}\|^2)^{-1}). \tag{100}$$

If a lies in the interval, (99) we have $\|\mathbf{b}\|^2 < 1$, namely the velocity of the charge is smaller than the velocity of light. We see in the following that, for some values of the fields, if we choose a solution in the half line (100), the charge may move faster than light. Note that if $\|\mathbf{b}\|^2 = \lambda^2\|\mathbf{b}' \times \mathbf{b}''\|^2 > 1$, since $\lambda\|\mathbf{b}''\| < 1$, we have $\lambda\|\mathbf{b}'\| > 1$, namely the frame $s(\tau)$ rotates, with all the dynamical vector variables, with an angular velocity larger than λ^{-1}. If λ is very small, one can only observe an average value of the velocity $\mathbf{b}$, that is negligible, since $\mathbf{b}$ is orthogonal to the angular velocity $\mathbf{b}'$.

Note that the fields $\mathbf{E}$ and $\mathbf{B}$ are measured with respect to the moving frame $s(\tau)$ and if the particle is very fast can be much larger than the fields measured in the laboratory frame. Even if we take this remark into account, if λ is of the order of Planck's length, in all the experimental situations we have

$$\|\mathbf{E}\|, \|\mathbf{B}\| \ll \lambda^{-1}e^{-1}m. \tag{101}$$

Under these conditions, the smallest solution of Eq. (97) is given by the approximate formula

$$a_1 \approx \lambda^2 e^2 m^{-2}. \tag{102}$$

Note that when $\lambda \to 0$, this solution tends to zero and the other two solutions either become complex or tend to infinity. In this limit we obtain, as it is expected, the ordinary model of Sec. VII.

We have to consider the special case in which $\mathbf{B} \neq 0$ and $\mathbf{E} \times \mathbf{B} = 0$, namely $\mathbf{E} = k\mathbf{B}$. We obtain the following conditions for the stationary solutions

$$\mathbf{b} = 0, \quad \mathbf{b}' = h\|\mathbf{B}\|^{-1}\mathbf{B}, \quad p_0\mathbf{b}'' = e\mathbf{E}, \quad p_0^2 = m^2 + \lambda^2\|e\mathbf{E}\|^2, \tag{103}$$

where h is an arbitrary constant that describes just a choice of the rotational gauge. Note that Eq. (94) is also valid in this more general situation.

It is interesting to see if these equations can be obtained as a limit of Eqs. (95) for $\|\mathbf{E} \times \mathbf{B}\| \to 0$. Equation (97) tends to the second degree equation

$$(1 - a\|\mathbf{B}\|^2)(1 - a\|\mathbf{E}\|^2 - a\|\mathbf{B}\|^2) - \lambda^{-2}e^{-2}m^2a = 0 \tag{104}$$

and one of the three solutions of Eq. (97) tends to infinity, more exactly we have

$$a_3 \approx (\|\mathbf{E}\|^2 + \|\mathbf{B}\|^2)\|\mathbf{E} \times \mathbf{B}\|^{-2}. \tag{105}$$

It follows that for this solution we have $\|\mathbf{b}\| \to \infty$, showing that there are stationary solutions with the charge moving faster than light. The other two (necessarily positive) solutions are given by

$$a_{1,2} = (2\|\mathbf{B}\|^2(\|\mathbf{E}\|^2 + \|\mathbf{B}\|^2))^{-1}(\|\mathbf{E}\|^2 + 2\|\mathbf{B}\|^2 + \lambda^{-2}e^{-2}m^2 \pm \Delta^{1/2}), \tag{106}$$

where

$$\Delta = (\|\mathbf{E}\|^2 + \lambda^{-2}e^{-2}m^2)^2 + 4\lambda^{-2}e^{-2}m^2\|\mathbf{B}\|^2 > 0. \tag{107}$$

The corresponding values of the parameter h are

$$h_{1,2} = p_0^{-1} e\|\mathbf{B}\|(a_\pm(\|\mathbf{E}\|^2 + \|\mathbf{B}\|^2) - 1) = e(2p_0\|\mathbf{B}\|)^{-1}(\|\mathbf{E}\|^2 + \lambda^{-2}e^{-2}m^2 \pm \Delta^{1/2}). \tag{108}$$

Only for these values of the gauge parameter h the solutions (103) can be obtained as limits of the solutions (95).

XI. PERTURBATIONS AND STABILITY

The next step is to study perturbatively trajectories slightly different from the stationary ones described previously. Since the infinitesimal perturbations satisfy linear differential equations with constant coefficients, we look for complex exponential solutions, namely we write

$$b^\alpha \to b^\alpha + \Re(\delta b^\alpha \exp(z\tau)), \tag{109}$$

where the constant quantities z and δb^α are complex. A similar notation is used for the other variables. The derivatives with respect to τ can be replaced by the factor z. We are not interested in perturbations with $z=0$, which give other already known stationary solutions. For $z \neq 0$ we obtain new nonstationary solutions, but also stationary solutions, modified by an infinitesimal time-dependent gauge transformation.

From Eq. (65) we obtain

$$\begin{aligned} z\delta\mathbf{E} &= \mathbf{b}'' \times \delta\mathbf{B} - \mathbf{B} \times \delta\mathbf{b}'' - \mathbf{b}' \times \delta\mathbf{E} + \mathbf{E} \times \delta\mathbf{b}', \\ z\delta\mathbf{B} &= -\mathbf{b}'' \times \delta\mathbf{E} + \mathbf{E} \times \delta\mathbf{b}'' - \mathbf{b}' \times \delta\mathbf{B} + \mathbf{B} \times \delta\mathbf{b}'. \end{aligned} \tag{110}$$

Since the invariants (66) are not affected by the perturbation, we also require the relations

$$\mathbf{E} \cdot \delta\mathbf{E} = \mathbf{B} \cdot \delta\mathbf{B}, \quad \mathbf{E} \cdot \delta\mathbf{B} = -\mathbf{B} \cdot \delta\mathbf{E}, \tag{111}$$

which, however, are not independent from Eqs. (110).

From the other dynamical equations we have

$$\begin{aligned} \delta\mathbf{p}'' &= \lambda^2 e(\delta\mathbf{E} + \mathbf{b} \times \delta\mathbf{B} - \mathbf{B} \times \delta\mathbf{b}), \\ z\delta\mathbf{p}'' &= p_0\delta\mathbf{b} + \mathbf{b}\,\delta p_0 - \mathbf{b}' \times \delta\mathbf{p}'' + \mathbf{p}'' \times \delta\mathbf{b}', \\ \delta\mathbf{p}'' &= \lambda^2\mathbf{b}''\delta p_0 + \lambda^2 p_0\delta\mathbf{b}'', \\ \delta p_0 &= \lambda^2 p_0^3 m^{-2}\mathbf{b}'' \cdot \delta\mathbf{b}''. \end{aligned} \tag{112}$$

After the elimination of the variables δp_0, $\delta\mathbf{p}''$, and $\delta\mathbf{b}$, we obtain a system of nine homogeneous linear equations in the twelve unknown variables $\delta\mathbf{E}$, $\delta\mathbf{B}$, $\delta\mathbf{b}''$, and $\delta\mathbf{b}'$.

For all the values of z this system has three linearly independent solutions which represent rotational gauge transformations. They are given by

$$\delta\mathbf{E} = \mathbf{E} \times \mathbf{r}, \quad \delta\mathbf{B} = \mathbf{B} \times \mathbf{r}, \quad \delta\mathbf{b}'' = \mathbf{b}'' \times \mathbf{r}, \quad \delta\mathbf{b}' = \mathbf{b}' \times \mathbf{r} + z\mathbf{r}, \tag{113}$$

where $\mathbf{r}$ is an arbitrary infinitesimal complex vector. Note that unless

$$z^2 = -\|\mathbf{b}'\|^2, \tag{114}$$

the vector $\delta\mathbf{b}'$ can take arbitrary values and when we look for physically relevant perturbations we can choose the gauge $\delta\mathbf{b}'=0$. We obtain in this way a homogeneous linear system of nine equation in nine unknowns, which has nonvanishing solutions only if its determinant $\det M(z)$ vanishes. If z satisfies Eq. (114), there is a pure gauge perturbation with $\delta\mathbf{b}'=0$, and this implies that $\det M(\pm i\|\mathbf{b}'\|)=0$. If we disregard this uninteresting solution, the other nonvanishing solutions of the algebraic equation $\det M(z)=0$ correspond to physically relevant perturbations.

If $\mathbf{E}\times\mathbf{B}\neq 0$, it is convenient to use the projections of all the vectors on the basis formed by the vectors $\mathbf{E}$, $\mathbf{B}$, and $\mathbf{E}\times\mathbf{B}$. Equation (111) permits the elimination of two unknowns and we have to calculate the determinant of a 7×7 matrix. It has almost thousand terms and one has to use a computer algebra program.[34] We find that the determinant $\det M(z)$ contains only the powers z^6, z^4, and z^2, and, since we know that it vanshes for $z^2=-\|\mathbf{b}'\|^2$, we can find the other, physically relevant, solution of the equation $\det M(z)=0$ by means of Ruffini's rule. With an appropriate choice of the variables, the computer calculation gives the unexpectedly simple result

$$-z^2=\omega^2=\lambda^{-4}p_0^2\|e\mathbf{B}\|^{-2}+4\lambda^{-2}m^2p_0^{-2}>0, \tag{115}$$

where p_0^2 is given by Eq. (95). We see that $z=\pm i\omega$ is pure imaginary and this means that the stationary solutions are stable with respect to linear perturbations. The perturbations have a frequency $\omega/2\pi$, that when $\|e\mathbf{B}\|\to 0$, tends to infinity explaining why a degree of freedom disappears for $\|e\mathbf{B}\|=0$. If we use Eq. (101), we see that the frequency $\omega/2\pi$ is much larger than the Planck frequency λ^{-1}.

In order to extend our results to the case in which $\mathbf{E}\times\mathbf{B}=0$ a separate discussion, that does not require computer algebra, is needed. From Eqs. (103), (111), and (112) we find

$$\mathbf{B}\cdot\delta\mathbf{E}=\mathbf{B}\cdot\delta\mathbf{B}=\mathbf{B}\cdot\delta\mathbf{p}''=\mathbf{B}\cdot\delta\mathbf{b}=0,\quad \delta p_0=0. \tag{116}$$

As in the general case, we choose $\delta\mathbf{b}'=0$.

After some calculations we obtain

$$z(\delta\mathbf{B}-\lambda^2kep_0^{-1}\|\mathbf{B}\|^2\delta\mathbf{p}'')=-\mathbf{b}'\times(\delta\mathbf{B}-\lambda^2kep_0^{-1}\|\mathbf{B}\|^2\delta\mathbf{p}'') \tag{117}$$

and if $z^2\neq-\|\mathbf{b}'\|^2$ we have

$$\delta\mathbf{p}''=\lambda^{-2}(ke)^{-1}p_0\|\mathbf{B}\|^{-2}\delta\mathbf{B}. \tag{118}$$

By substituting this formula and Eq. (103) into Eq. (110), we obtain a linear homogeneous system of the form

$$z\begin{pmatrix}\delta\mathbf{E}\\ \delta\mathbf{B}\end{pmatrix}=\|\mathbf{B}\|^{-1}A\begin{pmatrix}\mathbf{B}\times\delta\mathbf{E}\\ \mathbf{B}\times\delta\mathbf{B}\end{pmatrix}, \tag{119}$$

where the matrix A is given by

$$A=\begin{pmatrix}-h & \lambda^{-2}m^2p_0^{-1}\|\mathbf{eE}\|^{-1}\\ -p_0^{-1}\|\mathbf{eE}\| & -h+\lambda^{-2}p_0\|\mathbf{e}B\|^{-1}\end{pmatrix}. \tag{120}$$

Since the vectors $\delta\mathbf{E}$ and $\delta\mathbf{B}$ must be perpendicular to $\mathbf{B}$, by iterating this formula we obtain

$$z^2\begin{pmatrix}\delta\mathbf{E}\\ \delta\mathbf{B}\end{pmatrix}=-A^2\begin{pmatrix}\delta\mathbf{E}\\ \delta\mathbf{B}\end{pmatrix}. \tag{121}$$

One can easily show that this linear system has nonvanishing solutions if

$$z^2=-(h_{1,2}-h)^2, \tag{122}$$

where the quantities $h_{1,2}$ are given by Eq. (108). From the same equation and Eq. (115) we obtain the identity

$$h_2-h_1=\omega. \tag{123}$$

We see that, in this case too, the stationary trajectories are stable, but the frequency of the perturbations depends on the gauge parameter h. There are two independent perturbations with different angular velocities and only their difference is invariant under the rotational gauge and

physically relevant. If we choose $h=h_{1,2}$, in both cases we obtain the solution $z^2=0$ and the solutions given by Eq. (115), namely the limits of the solutions found for $\mathbf{E}\times\mathbf{B}\neq 0$.

XII. A PARTICLE IN A SIMPLE GRAVITATIONAL FIELD

In order to understand the properties of the model in a gravitational field, it is instructive to consider, besides the spacetimes with constant curvature we have already examined in Sec. IX, another simple model, namely the stationary Einstein cosmological model[35] with spatial curvature ρ. The curvature tensor in the frame $s(\tau)$ takes the form

$$F_{ik}^{[jl]}=\rho(\delta_i^j\delta_k^l-\delta_k^j\delta_i^l-\delta_i^j v_k v^l+\delta_k^j v_i v^l+\delta_i^l v_k v^j-\delta_k^l v_i v^j),\quad v_k v^k=1,\quad \rho>0, \tag{124}$$

where, in a cosmological interpretation, $v=(v_0,\mathbf{v})$ is the four velocity with respect to the frame $s\in\mathcal{S}$ of a privileged frame in which the matter and radiation distribution is isotropic.

From Eq. (28) we obtain

$$G_{ik}=-\rho(p_{[ik]}+v^j p_{[ji]}v_k-v^j p_{[jk]}v_i), \tag{125}$$

or, in the vector notation,

$$\hat{\mathbf{E}}=\rho(\|\mathbf{v}\|^2\mathbf{p}''-(\mathbf{v}\cdot\mathbf{p}'')\mathbf{v}),\quad \hat{\mathbf{B}}=\rho v_0\mathbf{v}\times\mathbf{p}''. \tag{126}$$

Equations (90) and (91) give the result

$$(\lambda^{-2}\rho^{-1}-\|\mathbf{v}\|^2)\mathbf{p}''+(\mathbf{v}\cdot\mathbf{p}'')\mathbf{v}=p_0^{-1}v_0\dot{\mathbf{p}}''\times(\mathbf{v}\times\mathbf{p}''), \tag{127}$$

and constraint (92) is identically satisfied. We assume that $\|\mathbf{v}\|^2<\lambda^{-2}\rho^{-1}$. If $\mathbf{v}\times\mathbf{p}''=0$ we must have $\mathbf{p}''=0$, otherwise we obtain

$$\mathbf{v}\cdot\dot{\mathbf{p}}''=-p_0v_0^{-1}(\lambda^{-2}\rho^{-1}-\|\mathbf{v}\|^2),\quad \dot{p}_0=\lambda^{-2}v_0^{-1}(\mathbf{v}\cdot\mathbf{p}''). \tag{128}$$

The component of $\dot{\mathbf{p}}''$ normal to the vectors $\mathbf{v}$ and $\mathbf{p}''$ is not determined by the dynamical equations, namely there is a gauge symmetry. We fix the gauge by means of the condition

$$\dot{\mathbf{p}}''\cdot\mathbf{v}\times\mathbf{p}''=0. \tag{129}$$

One can show that the covariant space-time derivatives $A_i v^k$ vanish and it follows that the derivatives of v^k with respect to the parameter τ are given only by the boost of the Lorentz frame, namely

$$\dot{\mathbf{v}}=-v_0\mathbf{b}''=-\lambda^{-2}p_0^{-1}v_0\mathbf{p}'',\quad \dot{v}_0=-(\mathbf{v}\cdot\mathbf{b}'')=-\lambda^{-2}p_0^{-1}(\mathbf{v}\cdot\mathbf{p}''). \tag{130}$$

From the preceding equations it follows

$$0\leqslant\|\mathbf{v}\times\mathbf{p}''\|^2=\lambda^2(p_0^2-m^2)\|\mathbf{v}\|^2-\lambda^4v_0^2(\dot{p}_0)^2, \tag{131}$$

$$\frac{dw}{d\tau}=0,\quad w=p_0v_0\geqslant m. \tag{132}$$

The conserved quantity w is the energy measured in a privileged frame. We also obtain

$$\frac{d^2}{d\tau^2}\log p_0=-\lambda^{-2}v_0^{-2}(\lambda^{-2}\rho^{-1}+1-w^2m^2p_0^{-4}). \tag{133}$$

If w is not extremely large, the right-hand side is negative, $p_0(\tau)$ has a maximum for $\tau=\tilde{\tau}$ and violates the inequality $p_0\geqslant m$ outside a given interval. A stronger limitation is given by Eq. (131). It is clear that τ cannot vary in the whole real line.

For a detailed discussion, it is convenient to introduce some simplifications. We disregard higher powers of the adimensional quantity $\lambda^2\rho_0$, which is extremely small in all the interesting cases and we also disregard higher powers of $\tau-\tilde{\tau}$. We put $p_0(\tilde{\tau})=\tilde{p}_0$, $v_0(\tilde{\tau})=\tilde{v}_0$, $\mathbf{v}(\tilde{\tau})=\tilde{\mathbf{v}}$ and we obtain the approximate solution

$$p_0(\tau) \approx \tilde{p}_0(1 - 2^{-1}\lambda^{-4}\rho^{-1}\tilde{v}_0^{-2}(\tau-\tilde{\tau})^2), \tag{134}$$

$$\dot{p}_0(\tau) \approx -\tilde{p}_0\lambda^{-4}\rho^{-1}\tilde{v}_0^{-2}(\tau-\tilde{\tau}). \tag{135}$$

From Eq. (131) we see that τ must belong to the interval

$$|\tau-\tilde{\tau}| < 2^{-1}\Delta\tau \approx (1 - m^2\tilde{p}_0^{-2})^{1/2}\lambda^3\rho\tilde{v}_0\|\tilde{\mathbf{v}}\|. \tag{136}$$

This inequality shows that it was consistent to disregard higher powers of $\tau-\tau_0$ together with higher powers of $\lambda^2\rho$. In this interval we have

$$0 \leqslant \tilde{p}_0 - p_0(\tau) \leqslant 2^{-1}\lambda^2\rho\tilde{p}_0(1 - m^2\tilde{p}_0^{-2})\|\tilde{\mathbf{v}}\|^2 \tag{137}$$

and the quantities p_0, $\|\mathbf{p}''\|$, v_0, and $\mathbf{v}$ can be considered as constant.

It follows from Eq. (131) that at the end points of the interval (136) $\mathbf{p}''$ is parallel to $\mathbf{v}$ and by taking Eq. (129) into account, we see that the vector $\mathbf{p}''$ moves approximately on a half circumference in a plane containig the vector $\mathbf{v}$. From Eq. (128) we see that the projection of $\dot{\mathbf{p}}''$ in the direction of $\mathbf{v}$ is constant and it follows that the component of $\dot{\mathbf{p}}''$ normal to $\mathbf{v}$ tends to infinity at the end points.

The connection between τ and the "cosmic" time t, measured in the privileged rest frames defined by $\mathbf{v}=0$, is

$$\frac{dt}{d\tau} = v_i b^i = v_0 - \mathbf{v}\cdot\mathbf{b} = (\lambda^{-2}\rho^{-1} + 1)v_0^{-1} \tag{138}$$

and it follows that the interval (136) measured in terms of the time t is

$$\Delta t \approx 2\lambda(1 - m^2 p_0^{-2})^{1/2}\|\mathbf{v}\|, \tag{139}$$

namely it is, in general, very small. Note that it does not depend on the curvature ρ, but only on the four-vector v that defines the privileged frames.

The singularities at the end points of the interval (136) can be avoided by using, instead of the parameter τ defined by the condition $b^0=1$, another parameter and we can also try to extend the solution outside the interval. This is possible only if, generalizing our Lagrangian formalism, we accept negative values of b^0, namely negative values of the square root in Eq. (76). We do not try to give in this article a physical meaning to this extension, for instance in terms of antiparticles.

In any case, we have shown that, in the presence of an arbitrarily small gravitational field, the geodisic world lines, corresponding to the initial condition $\mathbf{p}''=0$, are badly unstable, since an arbitrarily small change of $\mathbf{p}''$ leads to completely different, physicaly unacceptable, solutions.

XIII. ANOTHER MODEL

In the preceding sections we have examined two models that imply an upper bound to acceleration or to pseudoacceleration. However, these models have unwanted properties, in particular the energy momentum or the four velocity of the charge may become spacelike and unstable solutions may appear. In order to show that it is not easy to avoid all these problems, we consider a model containing a fundamental length, in which both the energy momentum and the four velocity are necessarily timelike, as in the ordinary model of Sec. VII. A simple and natural Lagrangian with these properties is

$$L = -m((b^0)^2 - \|\mathbf{b}\|^2 - \lambda^2\|\mathbf{b}''\|^2)^{1/2} + eb^\bullet. \tag{140}$$

The canonical momenta are given by

$$\mathbf{p}' = 0, \quad p_\bullet = -e, \tag{141}$$

$$p_0 = mb^0((b^0)^2 - \|\mathbf{b}\|^2 - \lambda^2\|\mathbf{b}''\|^2)^{-1/2},$$

$$\mathbf{p} = m((b^0)^2 - \|\mathbf{b}\|^2 - \lambda^2\|\mathbf{b}''\|^2)^{-1/2}\mathbf{b}, \tag{142}$$

$$\mathbf{p}'' = m\lambda^2((b^0)^2 - \|\mathbf{b}\|^2 - \lambda^2\|\mathbf{b}''\|^2)^{-1/2}\mathbf{b}'',$$

and satisfy the scalar primary constraint

$$(p_0)^2 - \|\mathbf{p}\|^2 - \lambda^{-2}\|\mathbf{p}''\|^2 = m^2, \tag{143}$$

which assures that the energy momentum is timelike.

We adopt the gauge fixing conditions $b^0=1$ and $\mathbf{b}'=0$ and we obtain the formulas

$$\mathbf{b} = p_0^{-1}\mathbf{p} = (\lambda^{-2}\|\mathbf{p}''\|^2 + \|\mathbf{p}\|^2 + m^2)^{-1/2}\mathbf{p}, \tag{144}$$

$$\mathbf{b}'' = \lambda^{-2}p_0^{-1}\mathbf{p}'' = \lambda^{-1}(\|\mathbf{p}''\|^2 + \lambda^2\|\mathbf{p}\|^2 + \lambda^2 m^2)^{-1/2}\mathbf{p}'', \tag{145}$$

which assure that $\|\mathbf{b}\|<1$ and $\|\mathbf{b}''\|<\lambda^{-1}$. Note, however, that $s(\tau)$ is neither a rest frame nor a zero-momentum frame and $\mathbf{b}''$ cannot be interpreted as the acceleration or the pseudoacceleration of the particle.

The dynamical equation (36) follows from Eq. (39) and the scalar constraint (143). Equation (38) is automatically satisfied and from Eqs. (37) and (39) we obtain

$$\dot{\mathbf{p}} = -p_0\mathbf{b}'' + \mathbf{f} = -\lambda^{-2}\mathbf{p}'' + \mathbf{f}, \quad \dot{\mathbf{p}}'' = p_0\mathbf{b} - \mathbf{p} = 0. \tag{146}$$

We see that $\mathbf{p}''$ is conserved. If it vanishes, the dynamical equations coincide exactly with the equations of the ordinary model of Sec. VII in its last version and there is no upper bound to the acceleration or to the pseudoacceleration.

XIV. CONCLUSIONS

We have developed a general Lagrangian formalism for the description of test particles in gravitational and electromagnetic fields. It is based on a moving Lorentz frame associated to the particle and it is useful for the introduction of Lagrangians that depend on a fundamental length λ and to discuss a possible upper bound to the proper acceleration. Other interesting effects may be suggested by a detailed discussion of suitable models.

The test particles introduced in this way present some features characteristic of extended objects, in particular, additional degrees of freedom are present, the charge, assumed to be concentrated at the origin of the moving frame, does not necessarily coincide with the center of mass, the energy-momentum four-vector is not necessarily parallel to the four-velocity and the definition of the acceleration is somehow ambiguous.

We have considered with more detail three Lagrangians depending on the acceleration of the frame, but not on its angular velocity, discussing, in particular, the following requirements.

(1) The energy momentum four vector lies in the future cone;
(2) The velocity of the point charge is smaller than the velocity of light, namely the four velocity is time-like;
(3) The solutions have good stability properties; and
(4) There is an upper bound to the acceleration or to some related quantity as the pseudoacceleration defined in Sec. VI.

We have not been able to find a model that satisfies all these requirements and it is reasonable to conjecture that such a model does not exist within the formalism we have considered. Perhaps one should introduce new degrees of freedom that have not a geometric interpretation in terms of a moving frame.

The model described in Sec. VIII, based on rest frames, has an unphysical energy-momentum spectrum and has unstable run-away solutions even in the absence of external fields.

The model introduced in Sec. IX, based on the zero-momentum frames, has unstable solutions when a nonconstant curvature is present and, under some circumstances, the velocity of the charge may become arbitrarily large. Nevertheless, it has some interesting properties. It always has a time-like energy momentum four vector and it has good stability properties if only a slowly varying electromagnetic field is present.

An electric charge faster than light may be embarrassing, but does not seem to contradict the general principles of Maxwell's theory. The charge describes a singular distribution inside the particle of the electric current four vector, that is not required to be time-like. Moreover, in the absence of curvature, the velocity vector rotates very fast and one can only observe its average value.

In a constant electromagnetic field the second model has "stationary" solutions, similar to the trajectories of an ordinary point particle with some small corrections, but, since the model has additional degrees of freedom, more complicated solutions exist, obtained by adding to a stationary solution a periodic perturbation with a frequency $\omega/2\pi$ much larger than λ^{-1}.

In a quantized version of the model, according to Bohr's correspondence principle, this frequency is approximately interpreted as the frequency of the radiation emitted when an excited state of the particle decays. Since the frequency is defined in the zero momentum frame, the energy $\hbar\omega$ has to be interpreted as the additional mass of the excited state. This mass is very large and in ordinary conditions there is not enough energy to excite the periodic degrees of freedom and they are "frozen," as it happens, for instance, to the nuclear degrees of freedom in low-energy atomic physics. These features of the quantized model may provide some very simplified insights into the connection between ordinary and "transplanckian" physics.

The model presented in Sec. XIII has no problem with the properties of the energy momentum and of the four velocity, but the presence of the fundamental length λ in the Lagrangian does not impose any limitation to the acceleration.

Of course, a more precise physical discussion requires a formal quantization procedure of the models, based on Dirac's treatment of constrained systems. In particular, the ground state energy corresponding to the additional (internal) degrees of freedom, which cannot be evaluated by means of the correspondence principle, could give an unacceptably large contribution to the mass. The treatment of many particle states should be given in terms of free quantum fields. For the model of Sec. VIII these problems are treated in Ref. 36 and we shall discuss some other models elsewhere.

(Received 12 August 2005; accepted 9 December 2005; published online 8 February 2006)

In a recent study we have obtained correction terms to the large N asymptotic expansions of the eigenvalue density for the Gaussian unitary and Laguerre unitary ensembles of random $N\times N$ matrices, both in the bulk and at the soft edge of the spectrum. In the present study these results are used to similarly analyze the eigenvalue density for Gaussian and Laguerre random matrix ensembles with orthogonal and symplectic symmetry. As in the case of unitary symmetry, a matching is exhibited between the asymptotic expansion of the bulk density, expanded about the edge, and the asymptotic expansion of the edge density, expanded into the bulk. In addition, aspects of the asymptotic expansion of the smoothed density, which involves delta functions at the endpoints of the support, are interpreted microscopically. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2165254]

I. INTRODUCTION

Perhaps the best known result in random matrix theory is the Wigner semicircle law (see e.g., Ref. 17). Consider a real symmetric matrix, with elements on the diagonal i.i.d. random variables having finite variance and similarly the elements above the diagonal. The Wigner semicircle law tells us that after appropriate scaling, the limiting eigenvalue density is given by the semicircle functional form

$$\rho_W(\lambda)=\begin{cases}\dfrac{2}{\pi}(1-\lambda^2)^{1/2}, & |\lambda|<1,\\ 0, & |\lambda|\geqslant 1.\end{cases} \tag{1.1}$$

As a concrete example, the Gaussian orthogonal ensemble (GOE) of real symmetric matrices is specified by its diagonal entries being distributed according to the normal distribution $N[0,1]$ and its upper triangular entries according to $N[0,1/\sqrt{2}]$. Let $\rho^{(N)}(\lambda)$ denote the eigenvalue density for $N\times N$ matrices from the GOE. After the scaling $\sqrt{2N}\rho^{(N)}(\sqrt{2N}\lambda)\mapsto N\rho(\lambda)$ the $N\to\infty$ limiting form of $\rho^{(N)}(\lambda)$ is given by (1.1).

The functional form (1.1) has implications with respect to averaging a so-called linear statistic $A=\Sigma_{j=1}^{N}a(\lambda_j)$ over the spectrum of random real symmetric matrices. Thus, if the $N\to\infty$ scaling is such that $(\alpha_N/N)\rho^{(N)}(\alpha_N\lambda)\to\rho_W(\lambda)$, $a(\alpha_N\lambda)\to\tilde{a}(\lambda)$ for some α_N then

$$\langle A \rangle := \int_{-\infty}^{\infty} \rho^{(N)}(\lambda) a(\lambda)\, d\lambda \sim N \int_{-1}^{1} \rho_W(\lambda) \tilde{a}(\lambda)\, d\lambda. \tag{1.2}$$

The result (1.2) immediately draws attention to corrections to the Wigner semicircle law. Indeed in studies of the full distribution of linear statistics averaged over the GOE and certain of its generalizations, it is necessary to compute the $O(1)$ term in the asymptotic expansion of (1.2).[8] For this one seeks the asymptotic expansion of $\bar{\rho}^{(N)}(\lambda)$, where $\bar{\rho}^{(N)}(\lambda)$ is the signed measure (smoothed density) such that

$$\int_{-\infty}^{\infty} \rho^{(N)}(\lambda) a(\lambda)\, d\lambda = \int_{-\infty}^{\infty} \bar{\rho}^{(N)}(\lambda) a(\lambda)\, d\lambda$$

to all orders in the corresponding asymptotic expansions. In the case of the GOE itself the $O(1)$ term is known,[16,2,8] and one has

$$\frac{\sqrt{2N}}{N} \bar{\rho}^{(N)}(\sqrt{2N}\lambda) \sim \rho_W(\lambda) + \frac{1}{N}\left(\frac{1}{4}\big(\delta(\lambda-1) + \delta(\lambda+1)\big) - \frac{1}{2\pi} \frac{1}{\sqrt{1-\lambda^2}} \chi_{|\lambda|<1} \right) \tag{1.3}$$

where $\chi_T = 1$ if T is true and $\chi_T = 0$ otherwise.

The correction term in (1.3) exhibits a most remarkable feature, namely delta functions at the edge of the support of the spectrum. The appearance of the delta functions at a microscopic level, when one seeks directly the asymptotic expansion of $(\sqrt{2N}/N)\rho^{(N)}(\sqrt{2N}\lambda)$ rather than the asymptotics of the smoothed quantity $\bar{\rho}^{(N)}(\lambda)$ has not, to the best of our knowledge, been previously studied. One of the purposes of this paper is to undertake such a study for the Gaussian and Laguerre ensembles in random matrix theory. Each of the three symmetry classes, orthogonal ($\beta=1$), unitary ($\beta=2$), and symplectic ($\beta=4$) will be considered. For the Gaussian ensemble it is known[8] that (1.3) then generalizes to read

$$\frac{\sqrt{2N}}{N} \bar{\rho}^{(N)}(\sqrt{2N}\lambda) \sim \rho_W(\lambda) + \frac{1}{N}\left(\frac{1}{\beta} - \frac{1}{2} \right)\left(\frac{1}{2}\big(\delta(\lambda-1) + \delta(\lambda+1)\big) - \frac{1}{\pi} \frac{1}{\sqrt{1-\lambda^2}} \chi_{|\lambda|<1} \right). \tag{1.4}$$

Our task is to relate this expansion to the asymptotic expansion of the density itself.

The expansion (1.4) clearly shows both a bulk effect and an edge effect. This is in keeping with there being both a (global) bulk regime, and an edge regime which must be treated separately in the asymptotic analysis. As these expansions relate to the same quantity, one would expect there to be a matching in an appropriate limit. This topic, initiated in Ref. 7 for the GUE and LUE, is another main theme of the present work.

We begin in Sec. II by recalling the results from Ref. 7 relating to the asymptotic expansions of the global bulk density, and the soft edge density, in the GUE and LUE. We then proceed to write down higher order terms in these asymptotic expansions (obtained from the method of Ref. 7). These higher order terms are then used to further investigate the matching phenomenon alluded to above.

In Sec. III formulas required in the study of the asymptotics of the density in the Gaussian and Laguerre ensembles with orthogonal and symplectic symmetry are gathered. These formulas are used in Sec. IV to study the corresponding global density asymptotic expansions, and in Sec. V to study the soft edge density asymptotic expansions. In Sec. VI we use the results of Secs. II, IV and V to study our main topics of interest, namely the matching between the bulk and edge asymptotic expansions, and the microscopic origin of the delta functions in (1.4) and its Laguerre analogue.

II. THE GAUSSIAN AND LAGUERRE ENSEMBLES WITH UNITARY SYMMETRY

A. Definitions and summary of known results

The Gaussian unitary ensemble consists of the set of Hermitian matrices with diagonal entries distributed according to the normal distribution $N[0,1/\sqrt{2}]$ and with upper triangular entries distributed according to $N[0,1/2]+iN[0,1/2]$. The corresponding eigenvalue pdf is given by

$$\frac{1}{C}\prod_{l=1}^{N} e^{-x_l^2} \prod_{1\leqslant j<k\leqslant N} (x_k - x_j)^2, \tag{2.1}$$

where here and below C denotes *some* normalization constant.

The Laguerre unitary ensemble can be specified by matrices $X=A^\dagger A$ where A is a $n\times m$ ($n \geqslant m$) complex Gaussian matrix with entries distributed according to $N[0,1/\sqrt{2}]+iN[0,1/\sqrt{2}]$. All the eigenvalues are non-negative and have the joint distribution

$$\frac{1}{C}\prod_{l=1}^{m} x_l^{\alpha} e^{-x_l} \prod_{1\leqslant j<k\leqslant m} (x_k - x_j)^2, \tag{2.2}$$

where $\alpha=n-m$.

The eigenvalue pdf's (2.1) and (2.2) are special cases of the functional form

$$\mathrm{UE}_N(g_2) := \frac{1}{C}\prod_{l=1}^{N} g_2(x_l) \prod_{1\leqslant j<k\leqslant N} (x_k - x_j)^2 \tag{2.3}$$

defining a general matrix ensemble with unitary symmetry in terms of its eigenvalue pdf. Thus

$$\mathrm{Ev}(\mathrm{GUE}_N) = \mathrm{UE}_N(e^{-x^2}), \quad \mathrm{Ev}(\mathrm{LUE}_N) = \mathrm{UE}_N(x^{\alpha}e^{-x}),$$

where $\mathrm{Ev}(M)$ denotes the eigenvalue pdf of the matrix ensemble M.

It is a basic result in random matrix theory (see, e.g., Ref. 4) that the eigenvalue density for the ensemble (2.3) can be written in terms of the monic polynomials $\{p_n(x)\}$ orthogonal with respect to the weight $g_2(x)$. Thus with $(p_n,p_n)_2$ denoting the corresponding normalizations we have

$$\rho(x;\mathrm{UE}_N(g_2)) = g_2(x)\sum_{j=0}^{N-1} \frac{(p_j(x))^2}{(p_j,p_j)_2}. \tag{2.4}$$

In a recent study Kalisch and Braak[9] have obtained the leading correction term to the Wigner semicircle law for the asymptotic expansion of (2.4) in the case of the GUE.

Proposition 1: Let $-1<X<1$ *be fixed. One has*

$$\frac{1}{N}\rho(X;\mathrm{UE}_N(e^{-2Nx^2})) \sim \rho_W(X) - \frac{2\cos(2N\pi P_{\mathrm{W}}(X))}{\pi^3\rho_{\mathrm{W}}^2(X)}\frac{1}{N} + \mathrm{O}\left(\frac{1}{N^2}\right), \tag{2.5}$$

where $\rho_W(x)$ *is given by* (1.1) *and*

$$P_W(x) = 1 + \frac{x}{2}\rho_{\mathrm{W}}(x) - \frac{1}{\pi}\mathrm{Arccos}\, x. \tag{2.6}$$

The methods in Ref. 9 are particular to the Gaussian ensembles, relying on an integral formula coming from the supersymmetry method. Subsequently the present authors[7] have introduced a different strategy which reclaims (2.5), and furthermore applies equally well to the Laguerre case, for which the following result was obtained.

Proposition 2: Let $0<X<1$ *be fixed. We have*

$$\frac{1}{N}\rho(X;\mathrm{UE}_N(x^\alpha e^{-4Nx})) \sim \rho_{\mathrm{MP}}(X) - \left(\frac{\cos((2N+\alpha)\pi P_{\mathrm{MP}}(X) - \alpha\pi(1+X\rho_{\mathrm{MP}}(X)))}{\pi^3 X^2 \rho_{\mathrm{MP}}^2(X)} - \frac{\alpha}{\pi^2 X \rho_{\mathrm{MP}}(X)}\right)\frac{1}{N} + O\left(\frac{1}{N^2}\right), \tag{2.7}$$

where

$$\rho_{\mathrm{MP}}(x) := \frac{2}{\pi}\sqrt{\frac{1}{x}-1}, \quad P_{\mathrm{MP}}(x) = 1 + x\rho_{\mathrm{MP}}(x) - \frac{2}{\pi}\mathrm{Arccos}\sqrt{x} \tag{2.8}$$

(*the subscript MP denotes Marčenko-Pastur, who first derived the limit law giving the leading term in this expression*).

The strategy of Ref. 7 was to use integral representations of the product of orthogonal polynomials which result from the Christoffel-Darboux summation of (2.4). In addition to yielding the asymptotics of the global bulk density, it also gave asymptotics of the density at the so-called soft edge. This is the name given to the boundary of the support at leading order, with the feature that the density, appropriately scaled, is nonzero on both sides of this boundary.

Proposition 3: Let ξ be fixed. For the GUE

$$\frac{1}{2N^{2/3}}\rho\left(1 + \frac{\xi}{2N^{2/3}}; \mathrm{UE}_N(e^{-2Nx^2})\right) = [\mathrm{Ai}'(\xi)]^2 - \xi[\mathrm{Ai}(\xi)]^2 - \frac{1}{20}(3\xi^2[\mathrm{Ai}(\xi)]^2 - 2\xi[\mathrm{Ai}'(\xi)]^2 - 3\mathrm{Ai}(\xi)\mathrm{Ai}'(\xi))\frac{1}{N^{2/3}} + O\left(\frac{1}{N}\right), \tag{2.9}$$

while for the LUE

$$\frac{1}{(2N)^{2/3}}\rho\left(1 + \frac{\xi}{(2N)^{2/3}}; \mathrm{UE}_N(x^\alpha e^{-4Nx})\right) = ([\mathrm{Ai}'(\xi)]^2 - \xi[\mathrm{Ai}(\xi)]^2) + \frac{\alpha}{2^{1/3}}[\mathrm{Ai}(\xi)]^2\frac{1}{N^{1/3}} + \frac{2^{1/3}}{10}(3\xi^2[\mathrm{Ai}(\xi)]^2 - 2\xi[\mathrm{Ai}'(\xi)]^2 + (2-5\alpha^2)\mathrm{Ai}(\xi)\mathrm{Ai}'(\xi))\frac{1}{N^{2/3}} + O\left(\frac{1}{N}\right). \tag{2.10}$$

B. Matching of the bulk and edge expansions

We pursue the matching phenomenon observed in Ref. 7 between the asymptotic expansion of the bulk density, expanded about the soft edge, and the asymptotic expansion of the edge density, expanded into the bulk. Explicitly, it was found that setting

$$X = 1 + \xi/2N^{2/3} \quad (\xi < 0) \tag{2.11}$$

in the asymptotic expansion (2.5) multiplied by $N^{2/3}/2$, and then expanding in N, a matching is obtained with the $\xi \to -\infty$ asymptotic expansion on the right-hand side of (2.9). This was checked on terms in ξ in the latter accessible by expanding the former; on this point we note that terms of all orders in inverse powers of N in (2.5), will after substitution of (2.11) contribute to each term in the expansion of (2.9). A similar matching was observed between the bulk LUE density expanded with the substitution (2.11), and the $\xi \to -\infty$ asymptotic expansion of the $O(1)$ and $O(N^{-1/3})$ terms of the edge density (2.10).

Based on this evidence, the hypothesis was put forward in Ref. 7 that the matching persists between all terms in ξ, and at all orders in inverse (fractional) powers of N. Here we probe this

hypothesis further by extending the asymptotic expansions (2.5), (2.7), (2.9), and (2.10). As explained in Ref. 7, the orthogonal polynomial method readily allows for the computation of higher order terms, which we compute to be given as follows.

Proposition 4: The $O(1/N^2)$ *term in* (2.5) *is*

$$\left(\frac{1}{16\pi(1-X^2)^{5/2}}+\frac{X(15+2X^2)\sin[2N\pi P_{\mathrm{W}}(X)]}{48\pi(1-X^2)^{5/2}}\right)\frac{1}{N^2}; \tag{2.12}$$

the $O(1/N^3)$ *term in* (2.5) *is*

$$\frac{180+981X^2+60X^4+4X^6}{2304\pi(1-X^2)^4}\cos[2N\pi P_W(X)]\frac{1}{N^3}; \tag{2.13}$$

the oscillatory $O(1/N^4)$ *term in* (2.5) *is*

$$-X\frac{323\,190+647\,055X^2+20\,358X^4+6084X^6-1112X^8}{829\,440\pi(1-X^2)^{11/2}}\sin[2N\pi P_W(X)]\frac{1}{N^4}; \tag{2.14}$$

the $O(1/N^2)$ *term in* (2.7) *is*

$$\begin{aligned}&\left(\left(\frac{\alpha}{8\pi(1-X)^2}\right)\cos[2N\pi P_{\mathrm{MP}}(X)-2\alpha\,\mathrm{Arccos}\sqrt{X}]\right.\\&+\left(\frac{-3+12X+8X^2+12(-1+X)(-1+2X)\alpha^2}{192\pi(1-X)^{5/2}X^{3/2}}\right)\sin[2N\pi P_{\mathrm{MP}}(X)-2\alpha\,\mathrm{Arccos}\sqrt{X}]\\&\left.+\frac{1+4(-1+X)\alpha^2}{64\pi(1-X)^{5/2}X^{3/2}}\right)\frac{1}{N^2};\end{aligned} \tag{2.15}$$

the $O(1/N)$ *term in* (2.9) *is*

$$\left(\left(-\frac{\xi}{12}+\frac{3\xi^4}{40}+\frac{\xi^7}{48}\right)(\mathrm{Ai}(\xi))^2-\frac{3\xi^2}{40}\mathrm{Ai}(\xi)\mathrm{Ai}'(\xi)+\left(\frac{1}{12}-\frac{\xi^3}{20}-\frac{\xi^6}{48}\right)(\mathrm{Ai}'(\xi))^2\right)\frac{1}{N}; \tag{2.16}$$

the $O(1/N)$ *term in* (2.10) *is*

$$\alpha\left(\left(-\frac{7\xi}{15}+\frac{\alpha^2\xi}{6}\right)(\mathrm{Ai}(\xi))^2-\frac{\xi^2}{5}\mathrm{Ai}(\xi)\mathrm{Ai}'(\xi)+\left(-\frac{1}{6}+\frac{\alpha^2}{6}\right)(\mathrm{Ai}'(\xi))^2\right)\frac{1}{N}. \tag{2.17}$$

Considering first the GUE, we now substitute (2.11) in (2.5) extended by (2.12), (2.13), (2.14). Expanding the asymptotic series (an operation we denote by $\dot{\sim}$) gives the new asymptotic series in N,

$$\begin{aligned}&\frac{1}{N^{2/3}}\rho\left(1+\frac{\xi}{2N^{2/3}};\mathrm{UE}_N(e^{-2Nx^2})\right)\\&\quad\dot{\sim}\left(\frac{2\sqrt{|\xi|}}{\pi}+\frac{1}{16\pi|\xi|^{5/2}}+\left(-\frac{1}{2\pi|\xi|}+\frac{1225}{2304\pi\xi^4}\right)\cos(4|\xi|^{3/2}/3)-\frac{17\sin(4|\xi|^{3/2}/3)}{48\pi|\xi|^{5/2}}\right)\\&\qquad+\left(-\frac{|\xi|^{3/2}}{4\pi}+\frac{5}{128\pi|\xi|^{3/2}}+\left(-\frac{43}{480\pi}-\frac{23\,695}{331\,776\pi|\xi|^3}\right)\cos(4|\xi|^{3/2}/3)\right.\\&\qquad\left.+\left(\frac{233}{4608}-\frac{|\xi|^3}{20}\right)\frac{\sin(4|\xi|^{3/2}/3)}{\pi|\xi|^{3/2}}\right)\frac{1}{N^{2/3}}+O\left(\frac{1}{N^{4/3}}\right).\end{aligned} \tag{2.18}$$

On the other hand, making use of the asymptotic series[12]

$$\mathrm{Ai}(-z) \sim \pi^{-1/2} z^{-1/4} \left(\sin(\zeta + \pi/4) \sum_{k=0}^{\infty} (-1)^k c_{2k} \zeta^{-2k} - \cos(\zeta + \pi/4) \sum_{k=0}^{\infty} (-1)^k c_{2k+1} \zeta^{-2k-1} \right), \tag{2.19}$$

where

$$\zeta = \frac{2}{3} z^{3/2}, \quad c_0 = 1, \quad c_k = \frac{(2k+1)(2k+3)\cdots(6k-1)}{(216)^k k!} \quad (k \geqslant 1),$$

the $\xi \to -\infty$ expansion of the $O(1)$ and $O(1/N^{2/3})$ terms in (2.9) can readily be computed. Agreement is found with all terms in (2.18) except the one involving the fraction 23 695/331 776. Thus, even though no terms $O(1/N)$ have yet appeared, whereas (2.16) has a term at this order, the evidence is still in favor of a matching between all terms in ξ, and at all orders in inverse powers of N. However this matching cannot be fully exhibited at any order in N in the expansion of (2.9) without knowledge of all terms in the asymptotic expansion of (2.5).

As already mentioned, a similar matching phenomenon was observed in Ref. 7 in the case of the LUE, and conjectured to hold at general orders as for the GUE. Further evidence for this conjecture can be obtained by substituting (2.11) in (2.7) extended by (2.15), expanding as a series in inverse powers of N, and comparing against the $\xi \to -\infty$ expansion of (2.10). The former operation gives

$$\begin{aligned} &\frac{1}{N^{2/3}} \rho \left(1 + \frac{\xi}{2N^{2/3}}; \mathrm{UE}_N(x^\alpha e^{-4Nx}) \right) \\ &\quad \dot{\sim} \left(\frac{2^{2/3}|\xi|^{1/2}}{\pi} - \frac{\cos(4|\xi|^{3/2}/3)}{2^{4/3}\pi|\xi|} \right) + \frac{\alpha(1 + \sin(4|\xi|^{3/2}/3))}{2^{2/3}\pi|\xi|^{1/2}N^{1/3}} \\ &\qquad + \frac{1}{160\pi|\xi|^{3/2}N^{2/3}} \big(5 - 20\alpha^2 + 80|\xi|^3 + 40(-1 + 2\alpha^2)|\xi|^{3/2} \cos(4|\xi|^{3/2}/3) \\ &\qquad + (5 - 20\alpha^2 + 16|\xi|^3)\sin(4|\xi|^{3/2}/3) \big) + O\left(\frac{1}{N} \right). \end{aligned} \tag{2.20}$$

The latter operation gives agreement with this expansion at $O(1)$, $O(1/N^{1/3})$ and for the terms involving factors of $|\xi|^3$ at $O(1/N^{2/3})$. This is consistent with the matching hypothesis.

III. THE GAUSSIAN AND LAGUERRE ENSEMBLES WITH ORTHOGONAL AND SYMPLECTIC SYMMETRY—GENERAL FORMULAS

The Gaussian orthogonal ensemble has already been defined in the Introduction. At the level of an eigenvalue pdf, the GOE can be defined by the joint distribution

$$\frac{1}{C} \prod_{l=1}^{N} e^{-x_l^2/2} \prod_{1 \leqslant j < k \leqslant N} |x_k - x_j|.$$

Likewise the Gaussian symplectic ensemble, Laguerre orthogonal ensemble and Laguerre symplectic ensemble can be specified either in terms of the distribution of certain classes of random matrices (real symmetric matrices in the cases of orthogonal symmetry, and Hermitian matrices with real quaternion elements in the cases of symplectic symmetry), or in terms of the functional form of the eigenvalue pdf (see, e.g., Ref. 4). Here we will note only the latter, which in the case of the GSE reads

$$\frac{1}{C}\prod_{l=1}^{N} e^{-2x_l^2} \prod_{1\leqslant j<k\leqslant N} (x_k - x_j)^4;$$

for the LOE reads

$$\frac{1}{C}\prod_{l=1}^{N} x_l^{\alpha/2} e^{-x_l/2} \prod_{1\leqslant j<k\leqslant N} |x_k - x_j|;$$

and for the LSE reads

$$\frac{1}{C}\prod_{l=1}^{N} x_l^{2\alpha} e^{-2x_l} \prod_{1\leqslant j<k\leqslant N} (x_k - x_j)^4.$$

For the Laguerre ensembles one requires the eigenvalues to be positive and thus $x_l > 0$ ($l = 1, \ldots, N$). Thus we see that if we define a matrix ensemble with orthogonal and symplectic symmetry by the eigenvalue pdf's,

$$\mathrm{OE}_N(g_1) := \frac{1}{C}\prod_{l=1}^{N} g_1(x_l) \prod_{1\leqslant j<k\leqslant N} |x_k - x_j|$$

and

$$\mathrm{SE}_N(g_4) := \frac{1}{C}\prod_{l=1}^{N} g_4(x_l) \prod_{1\leqslant j<k\leqslant N} (x_k - x_j)^4,$$

respectively, then we have

$$\mathrm{Ev}(\mathrm{GOE}_N) = \mathrm{OE}_N(e^{-x^2/2}), \quad \mathrm{Ev}(\mathrm{LOE}_N) = \mathrm{OE}_N(x^{\alpha/2} e^{-x/2}),$$

$$\mathrm{Ev}(\mathrm{GSE}_N) = \mathrm{SE}_N(e^{-2x^2}), \quad \mathrm{Ev}(\mathrm{LSE}_N) = \mathrm{SE}_N(x^{2\alpha} e^{-x}). \tag{3.1}$$

In Ref. 1, the eigenvalue densities for the ensembles $\mathrm{OE}(g_1)$ and $\mathrm{SE}(g_4)$ were computed for all the so-called classical weights

$$g_1(x) = \begin{cases} e^{-x^2/2}, & \text{Gaussian}, \\ x^{(\alpha-1)/2} e^{-x/2} \ (x > 0), & \text{Laguerre}, \\ (1-x)^{(a-1)/2}(1+x)^{(b-1)/2} (-1 < x < 1), & \text{Jacobi}, \\ (1+x^2)^{-(\alpha+1)/2}, & \text{Cauchy}, \end{cases} \tag{3.2}$$

$$g_4(x) = \begin{cases} e^{-x^2}, & \text{Hermite}, \\ x^{\alpha+1} e^{-x}, & \text{Laguerre}, \\ (1-x)^{a+1}(1+x)^{b+1}, & \text{Jacobi}, \\ (1+x^2)^{-(\alpha-1)}, & \text{Cauchy} \end{cases} \tag{3.3}$$

in terms of a formula depending on the symmetry class only. Thus for ensembles $\mathrm{OE}_N(g_1)$ with classical weights (3.2) one has

$$\rho(x;\mathrm{OE}_N(g_1(x))) = \rho(x;\mathrm{UE}_{N-1}(g_2(x))) + \frac{c_{N-2}}{(p_{N-2},p_{N-2})_2(p_{N-1},p_{N-1})_2} g_1(x)p_{N-1}(x)\frac{1}{2}\int_{-\infty}^{\infty} \mathrm{sgn}(x-t)p_{N-2}(t)g_1(t)\,\mathrm{d}t, \tag{3.4}$$

while for ensembles $\mathrm{SE}_N(g_4)$ with classical weights (3.3) one has

$$\rho(x;\mathrm{SE}_N(g_4(x))) = \frac{1}{2}\rho(x;\mathrm{UE}_{2N}(g_2)) - g_1(x)\frac{c_{2N-1}p_{2N}(x)}{2(p_{2N},p_{2N})_2(p_{2N-1},p_{2N-1})_2}\int_x^{\infty} g_1(t)p_{2N-1}(t)\,\mathrm{d}t. \tag{3.5}$$

In (3.4) and (3.5),

$$g_2(x) = \begin{cases} e^{-x^2}, & \text{Hermite}, \\ x^{\alpha}e^{-x}, & \text{Laguerre}, \\ (1-x)^a(1+x)^b, & \text{Jacobi}, \\ (1+x^2)^{-\alpha}, & \text{Cauchy} \end{cases} \tag{3.6}$$

while

$$\frac{c_j}{(p_j,p_j)_2} = \begin{cases} 1, & \text{Hermite}, \\ \frac{1}{2}, & \text{Laguerre}. \end{cases} \tag{3.7}$$

The quantities $\{p_n(x)\}$ are the monic classical orthogonal polynomials with respect to the weights (3.6), and $(p_n,p_n)_2$ the corresponding normalizations. Thus in the Gaussian case

$$p_n(x) = 2^{-n}H_n(x), \quad (p_n,p_n)_2 = \pi^{1/2}2^{-n}n! \tag{3.8}$$

while in the Laguerre case

$$p_n(x) = (-1)^n n!\, L_n^{\alpha}(x), \quad (p_n,p_n)_2 = \Gamma(n+1)\Gamma(\alpha+n+1). \tag{3.9}$$

Essential tools in our subsequent analysis of the asymptotic forms of (3.4) and (3.5) are particular asymptotic formulas for the Hermite and Laguerre polynomials. Consider first the bulk region. In the case of the Hermite polynomials, the formula is due to Plancherel and Rotach.[13] It tells us that with

$$x = (2n+1)^{1/2}\cos\phi, \quad \epsilon \leqslant \phi \leqslant \pi - \epsilon,$$

we have

$$e^{-x^2/2}H_n(x) = 2^{n/2+1/4}(n!)^{1/2}(\pi n)^{-1/4}(\sin\phi)^{-1/2}(\sin((n/2+1/4)(\sin 2\phi - 2\phi) + 3\pi/4) + O(n^{-1})).$$

Setting

$$\sqrt{2N}X = (2(N+m)+1)^{1/2}\cos\phi$$

with $-1 < X < 1$ fixed we deduce from this that for m fixed

$$H_{N+m}(\sqrt{2N}X) = \left(\frac{2}{\pi}\right)^{1/4}\frac{2^{m/2+N/2}}{(1-X^2)^{1/4}}N^{m/2-1/4}(N!)^{1/2}e^{NX^2}g_{m,N}^{(H)}(X)\left(1+O\left(\frac{1}{N}\right)\right), \tag{3.10}$$

where

$$g_{m,N}^{(H)}(x) := \cos\left(Nx\sqrt{1-x^2} + (N+1/2)\mathrm{Arcsin}\,x - N\pi/2 - m\,\mathrm{Arccos}\,x\right). \tag{3.11}$$

The Plancherel-Rotach formula (3.10) was extended by Moecklin to the Laguerre polynomials.[10] With

$$x = (4n + 2\alpha + 2)\cos^2 \phi, \quad \epsilon \leqslant \phi \leqslant \pi/2 - \epsilon n^{-1/2}$$

it reads

$$e^{-x/2}L_n^{(\alpha)}(x) = (-1)^n(\pi \sin \phi)^{-1/2}x^{-\alpha/2-1/4}n^{\alpha/2-1/4} \times (\sin((n + (\alpha + 1)/2)(\sin 2\phi - 2\phi) + 3\pi/4) + (nx)^{-1/2}O(1)).$$

Setting

$$4nX = (4(n + m) + 2\alpha + 2)\cos^2 \phi$$

with m fixed and $\epsilon/n < X < 1$ we deduce from this that

$$x^{\alpha/2}e^{-x/2}L_{n+m}^{(\alpha)}(x)|_{x=4nX} = (-1)^{n+m}(2\pi\sqrt{X(1-X)})^{-1/2}n^{\alpha/2-1/2}\left(g_{m,n}^{(L)}(X) + O\left(\frac{1}{n}\right)\right), \tag{3.12}$$

where

$$g_{m,n}^{(L)}(X) := \sin(2n(\sqrt{X(1-X)} - \operatorname{Arccos}\sqrt{X}) - (2m + \alpha + 1)\operatorname{Arccos}\sqrt{X} + 3\pi/4). \tag{3.13}$$

We turn our attention now to the (soft) spectrum edge. In the Hermite case, the formula of Plancherel and Rotach tells us that with

$$x = (2N)^{1/2} + 2^{-1/2}N^{-1/6}t \tag{3.14}$$

we have

$$\exp(-x^2/2)H_N(x) = \pi^{1/4}2^{N/2+1/4}(N!)^{1/2}N^{-1/12}\{\mathrm{Ai}(t) + O(N^{-2/3})\},$$

where $\mathrm{Ai}(t)$ denotes the Airy function. It follows from this that with x again related to t by (3.14),

$$\exp(-x^2/2)H_{N+m}(x) = (2N)^{m/2}\pi^{1/4}2^{N/2+1/4}(N!)^{1/2}N^{-1/12}\left\{\mathrm{Ai}(t) - \frac{m}{N^{1/3}}\mathrm{Ai}'(t) + O(N^{-2/3})\right\}. \tag{3.15}$$

In the Laguerre case, Szegö[15] gives that with

$$x = 4N + 2\alpha + 2 + 2(2N)^{1/3}t \tag{3.16}$$

we have

$$e^{-x/2}L_N^{\alpha}(x) = (-1)^N 2^{-\alpha-1/3}N^{-1/3}(\mathrm{Ai}(t) + O(N^{-2/3})).$$

It then follows that for fixed p,

$$e^{-x/2}L_{N+p}^{\alpha}(x)|_{x=4N+2(2N)^{1/3}\xi} = (-1)^{N+p}2^{-\alpha-1/3}N^{-1/3}\left(\mathrm{Ai}(\xi) - \frac{2p + \alpha + 1}{(2N)^{1/3}}\mathrm{Ai}'(\xi) + O(N^{-2/3})\right). \tag{3.17}$$

IV. ASYMPTOTIC EXPANSIONS IN THE BULK

A. GOE and GSE in the bulk

As with the GUE, the asymptotic expansion of the bulk density for the GOE and GSE has been carried out by Kalisch and Braak.[9] But as their method is particular to the Gaussian case, we give an alternative method which can be extended to the Laguerre case.

Consider first the GOE. Substituting the appropriate formula from (3.7) and (3.8), in (3.4) we see after minor manipulation that

$$\rho(x;\mathrm{OE}_N(e^{-x^2/2})) = \rho(x;\mathrm{UE}_{N-1}(e^{-x^2})) + \frac{e^{-x^2/2}H_{N-1}(x)}{2^{N-1}\pi^{1/2}(N-2)!}\int_0^x e^{-t^2/2}H_{N-2}(t)\,\mathrm{d}t. \tag{4.1}$$

Also, making use of (2.4) shows

$$\rho(x;\mathrm{UE}_{N-1}(e^{-x^2})) = \rho(x;\mathrm{UE}_N(e^{-x^2})) - \frac{2^{-(N-1)}e^{-x^2}}{\pi^{1/2}(N-1)!}(H_{N-1}(x))^2. \tag{4.2}$$

From (4.1) and (4.2) the following asymptotic formula for the bulk eigenvalue density is obtained.

Proposition 5: Let $-1<X<1$ *be fixed. We have*

$$\frac{1}{N}\rho(X;\mathrm{OE}_N(e^{-Nx^2})) \sim \frac{2}{\pi}\sqrt{1-X^2} - \frac{1}{2\pi N\sqrt{1-X^2}} + O\left(\frac{1}{N^2}\right). \tag{4.3}$$

Proof: First we note that

$$\rho(X;\mathrm{OE}_N(e^{-Nx^2})) = \sqrt{2N}\rho(\sqrt{2N}X;\mathrm{OE}_N(e^{-x^2/2})), \tag{4.4}$$

and we proceed to analyze the large N form of the right-hand side using (4.1). In relation to the latter, by a simple change of variables,

$$\int_0^{\sqrt{2N}X} e^{-t^2/2}H_{N-2}(t)\,\mathrm{d}t = \left.\sqrt{2N}\int_0^X e^{-t^2/2}H_{N-2}(t)\right|_{t=\sqrt{2N}T}\mathrm{d}T,$$

while making use of (3.10) shows

$$\sqrt{2N}\int_0^X e^{-t^2/2}H_{N-2}(t)\Big|_{t=\sqrt{2N}T}\mathrm{d}T \sim \sqrt{2N}\left(\frac{2}{\pi}\right)^{1/4}\frac{2^{-1+N/2}}{(1-T^2)^{1/4}}N^{-5/4}(N!)^{1/2}\int_0^X \frac{g^{(H)}_{-2,N}(T)}{(1-T^2)^{1/4}}\mathrm{d}T. \tag{4.5}$$

The leading contribution to the integral for large N comes from the neighborhood of the endpoints $T=0$ and $T=X$. About $T=0$

$$g^{(H)}_{m,N}(T) \sim \cos(2NT - (N+m)\pi/2 + O(T^2)),$$

while about $T=X$,

$$\begin{aligned} g^{(H)}_{m,N}(T) \sim \cos(&NX\sqrt{1-X^2} + (N+1/2)\mathrm{Arcsin}\,X - N\pi/2 - m\,\mathrm{Arccos}\,X \\ &+ 2N\sqrt{1-X^2}(T-X) + O((T-X)^2)). \end{aligned}$$

Thus we have

$$\int_0^X \frac{g^{(H)}_{-2,N}(T)}{(1-T^2)^{1/4}}\mathrm{d}T \sim \frac{1}{2N(1-X^2)^{3/4}}\tilde{g}^{(H)}_{-2,N}(X), \tag{4.6}$$

where

$$\tilde{g}^{(H)}_{m,N}(x) := \sin(Nx\sqrt{1-x^2} + (N+1/2)\mathrm{Arcsin}\,x - N\pi/2 - m\,\mathrm{Arccos}\,x) \tag{4.7}$$

and use has been made of the fact that N is assumed even in (3.4).

We read off from (3.10) that

$$e^{-x^2}H_{N-1}(x)\big|_{x=\sqrt{2N}X} = \left(\frac{2}{\pi}\right)^{1/4}\frac{2^{-1/2+N/2}}{(1-X^2)^{1/4}}N^{-3/4}(N!)^{1/2}g^{(H)}_{-1,N}(X)\left(1+O\left(\frac{1}{N}\right)\right). \tag{4.8}$$

Making use of this together with (4.5), (4.6) and Stirling's formula we deduce

$$\frac{e^{-x^2/2}H_{N-1}(x)}{2^{N-1}\pi^{1/2}(N-2)!}\int_0^{\sqrt{2N}X} e^{-t^2/2}H_{N-2}(t)\mathrm{d}t$$
$$\sim \frac{1}{\pi\sqrt{2N}}\frac{g_{-1,N}^{(H)}(X)\tilde{g}_{-2,N}^{(H)}(X)}{(1-X^2)}\left(1+O\left(\frac{1}{N}\right)\right)$$
$$= \frac{1}{\pi\sqrt{2N}}\frac{g_{-1,N}^{(H)}(X)}{(1-X^2)}\left(X\tilde{g}_{-1,N}^{(H)}(X)+\sqrt{1-X^2}g_{-1,N}^{(H)}(X)\right)\left(1+O\left(\frac{1}{N}\right)\right), \tag{4.9}$$

where the equality follows from simple trigonometric identities.

For the second term in (4.2), use of (4.8) shows

$$-\frac{2^{-(N-1)}e^{-x^2}}{\pi^{1/2}(N-1)!}(H_{N-1}(x))^2\Big|_{x=\sqrt{2N}X} \sim -\frac{1}{\pi}\sqrt{\frac{2}{N}}\frac{(g_{-1,N}^{(H)}(X))^2}{\sqrt{1-X^2}}\left(1+O\left(\frac{1}{N}\right)\right). \tag{4.10}$$

And for the first term in (4.2) we know from (2.5) that

$$\rho(\sqrt{2N}X;\mathrm{UE}_N(e^{-x^2})) \sim \frac{\sqrt{2N}}{\pi}\sqrt{1-X^2}-\sqrt{\frac{2}{N}}\frac{\cos(2NX\sqrt{1-X^2}+2N\,\mathrm{Arcsin}\,X-N\pi)}{2\pi(1-X^2)}+O\left(\frac{1}{N^{3/2}}\right). \tag{4.11}$$

But

$$\cos(2NX\sqrt{1-X^2}+2N\,\mathrm{Arcsin}\,X-N\pi)=\sqrt{1-X^2}(2(\tilde{g}_{-1,N}^{(H)}(X))^2-1)-2X\tilde{g}_{-1,N}^{(H)}(X)g_{-1,N}^{(H)}(X). \tag{4.12}$$

Substituting (4.12) in (4.11), then adding this, (4.9) and (4.10), and recalling (4.4) gives (4.3). □

The result (4.3) agrees with that computed by Kalisch and Braak in Ref. 9 and is also consistent with (1.3). We remark that in Ref. 9 the $O(1/N^2)$ term is also given, being equal to

$$\frac{3+4X^2}{16\pi(1-X^2)^{5/2}N^2}-\frac{\cos((2N-1)\mathrm{Arcsin}\,X+2NX\sqrt{1-X^2})}{8\pi(1-X^2)^{5/2}N^2}. \tag{4.13}$$

In principle the present method offers a systematic approach to all correction terms. For this we need the explicit form of the higher order terms in (3.10), and these can in fact be calculated from the results in Ref. 13. However we have not pursued such calculations. We remark too that a calculation of the nonoscillatory portion of (4.13) is undertaken in Ref. 2; however the result obtained does not agree with (4.13).

We turn our attention now to the GSE. First we note that

$$\rho(X;\mathrm{SE}_N(e^{-4Nx^2}))=2\sqrt{N}\rho(2\sqrt{N}X;\mathrm{SE}_N(e^{-x^2})). \tag{4.14}$$

Regarding the right-hand side, making use of (3.7), (3.8) as well as the integral evaluation (see, e.g., Ref. 1)

$$2^{-N}\int_0^{\infty} e^{-t^2/2}H_N(t)\mathrm{d}t=\sqrt{\frac{\pi}{2}}\frac{N!}{2^N(N/2)!} \tag{4.15}$$

gives

$$\rho(x;\mathrm{SE}_N(e^{-x^2})) = \frac{1}{2}\rho(x;\mathrm{UE}_{2N}(e^{-x^2})) - \frac{e^{-x^2/2}H_{2N}(x)}{4\pi^{1/2}(2N-1)!}\left(\sqrt{\frac{\pi}{2}}\frac{(2N-1)!}{2^{2N-1}(N-1/2)!} - 2^{-(2N-1)}\int_0^x e^{-t^2/2}H_{2N-1}(t)\mathrm{d}t\right). \tag{4.16}$$

The asymptotic form of (4.16) can be calculated according to the strategy of the proof of Proposition 5 to give the following result for the bulk scaled density in the GSE.

Proposition 6: Let $-1<X<1$ *be fixed, and* $g^{(H)}_{0,2N}(X)$ *be given according to* (3.11). *We have*

$$\frac{1}{N}\rho(X;\mathrm{SE}_N(e^{-4Nx^2})) \sim \frac{2}{\pi}\sqrt{1-X^2} - \left(\frac{1}{\sqrt{2\pi N}} + \frac{(-1)^N}{2\pi N}\right)\frac{g^{(H)}_{0,2N}(X)}{(1-X^2)^{1/4}} + \frac{1}{4\pi N}\frac{1}{\sqrt{1-X^2}} + O\left(\frac{1}{N^{3/2}}\right). \tag{4.17}$$

Proof: Analogous to (4.5), it follows from (3.10) that

$$\int_0^{2\sqrt{N}X} e^{-t^2/2}H_{2N-1}(t)\mathrm{d}t \sim 2\sqrt{N}\left(\frac{2^{N-1}}{\pi^{1/4}N^{3/4}}((2N)!)^{1/2}\right)\int_0^X \frac{g^{(H)}_{-1,2N}(t)}{(1-t^2)^{1/4}}\mathrm{d}t,$$

while proceeding as in the derivation of (4.6) shows

$$\int_0^X \frac{g^{(H)}_{-1,2N}(t)}{(1-t^2)^{1/4}}\mathrm{d}t \sim \frac{1}{4N}\frac{1}{(1-X^2)^{3/4}}\tilde{g}^{(H)}_{-1,2N}(X) - \frac{(-1)^N}{4N}.$$

Thus, after making use too of Stirling's formula,

$$\left(\sqrt{\frac{\pi}{2}}\frac{(2N-1)!}{2^{2N-1}(N-1/2)!} - 2^{-(2N-1)}\int_0^{\sqrt{2N}X} e^{-t^2/2}H_{2N-1}(t)\mathrm{d}t\right) \sim (N-1/2)!\left(\frac{1}{\sqrt{2N}} - \frac{2}{\sqrt{\pi}}\left(\frac{1}{4N}\frac{1}{(1-X^2)^{3/4}}\tilde{g}^{(H)}_{-1,2N}(X) - \frac{(-1)^N}{4N}\right)\right).$$

Since (3.10) gives

$$e^{-x^2/2}H_{2N}(x)\big|_{x=2\sqrt{N}X} = \pi^{-1/4}\frac{2^N N^{-1/4}}{(1-X^2)^{1/4}}((2N)!)^{1/2}\left(g^{(H)}_{0,2N}(X) + O\left(\frac{1}{N}\right)\right)$$

we thus have that with $x=2\sqrt{N}X$ the final line in (4.16) has the asymptotic behavior

$$-\frac{1}{4\sqrt{\pi}}\frac{g^{(H)}_{0,2N}(X)}{(1-X^2)^{1/4}}\left(\sqrt{2} - \frac{1}{\sqrt{\pi N}}\left(\frac{1}{(1-X^2)^{3/4}}(X\tilde{g}^{(H)}_{0,2N}(X) + \sqrt{1-X^2}g^{(H)}_{0,2N}(X)) - (-1)^N\right)\right).$$

Further, we see from (2.5) and (3.11) that

$$\frac{1}{2}\rho(2\sqrt{N}X;\mathrm{UE}_{2N}(e^{-x^2})) \sim \frac{\sqrt{N}}{\pi}\sqrt{1-X^2} - \frac{\sqrt{1-X^2}(2(g^{(H)}_{0,2N}(X))^2-1) + 2X\tilde{g}^{(H)}_{0,2N}(X)g^{(H)}_{0,2N}(X)}{8\pi\sqrt{N}(1-X^2)} + O\left(\frac{1}{N^{3/2}}\right).$$

Adding these last two results, and recalling (4.16) and (4.14) gives the stated formula. □

In Ref. 9, at $O(1/N)$ only the nonoscillatory term is reported. We note too that the nonoscillatory term at $O(1/N)$ in (4.17) is consistent with (1.4) in the case $\beta=4$.

B. The LOE and LSE in the bulk

We now apply the same strategy to the Laguerre case. For the LOE, substituting the appropriate formula from (3.7) and (3.9), into (3.4) shows

$$\rho(x;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-x/2})) = \rho(x;\mathrm{UE}_{N-1}(x^\alpha e^{-x})) + \frac{(N-1)!}{4(\alpha+N-2)!}x^{(\alpha-1)/2}e^{-x/2}L_{N-1}^\alpha(x) \times \left(\int_0^\infty L_{N-2}^\alpha(t)t^{(\alpha-1)/2}e^{-t/2}\,\mathrm{d}t - 2\int_0^x L_{N-2}^\alpha(t)t^{(\alpha-1)/2}e^{-t/2}\,\mathrm{d}t\right) \tag{4.18}$$

while

$$\rho(x;\mathrm{UE}_{N-1}(x^\alpha e^{-x})) = \rho(x;\mathrm{UE}_N(x^\alpha e^{-x})) - \frac{(N-1)!}{\Gamma(N+\alpha)}(x^{\alpha/2}e^{-x/2}L_{N-1}^\alpha(x))^2. \tag{4.19}$$

Proposition 7: Let $0<X<1$. *We have*

$$\frac{1}{N}\rho(X;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-2Nx})) \sim \rho_{\mathrm{MP}}(X) - \frac{1}{2\pi N}\frac{1-\alpha}{\sqrt{X(1-X)}} + o(N^{-1}). \tag{4.20}$$

Proof: By a change of variables

$$\rho(X;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-2Nx})) = 4N\rho(4NX;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-x/2})), \tag{4.21}$$

so the task is to analyze the $N\to\infty$ asymptotics of the right-hand side of (4.18) with x replaced by $4NX$.

We know from Refs. 11 and 1 that

$$\int_0^\infty L_{N-2}^a(t)t^{(a-1)/2}e^{-t/2}\,\mathrm{d}t = \frac{\Gamma((N+1)/2)\Gamma(a+N-1)}{2^{a/2-3/2}\Gamma(N)\Gamma((a+N)/2)} \sim 2N^{(a-1)/2}. \tag{4.22}$$

Regarding the second integral in (4.18), we first write

$$\int_0^{4NX} L_{N-2}^a(t)t^{(a-1)/2}e^{-t/2}\,\mathrm{d}t = \left(\int_0^{4\epsilon} + \int_{4\epsilon}^{4NX}\right)L_{N-2}^a(t)t^{(a-1)/2}e^{-t/2}\,\mathrm{d}t,$$

where $0<\epsilon\ll 1$. In relation to the region $[4\epsilon,4NX]$, (3.12) tells us that for N even

$$L_{N-2}^\alpha(t)t^{a/2}e^{-t/2}\big|_{t\to 4NT} = (2\pi\sqrt{T(1-T)})^{-1/2}N^{(\alpha-1)/2}\left(g_{-2,N}^{(L)}(T) + O\left(\frac{1}{N}\right)\right).$$

Substituting in the integral and changing variables $T=s^2$ shows

$$\int_{4\epsilon}^{4NX} L_{N-2}^\alpha(t)t^{(\alpha-1)/2}e^{-t/2}\,\mathrm{d}t \sim (4N)^{1/2}N^{(\alpha-1)/2}\left(\frac{2}{\pi}\right)^{1/2}\int_{\sqrt{\epsilon/N}}^{\sqrt{X}}\frac{1}{\sqrt{s}(1-s^2)^{1/4}}g_{-2,N}^{(L)}(s^2)\mathrm{d}s. \tag{4.23}$$

In relation to the interval $t\in[0,4\epsilon]$, we know that for $N\to\infty$ (Ref. 15),

$$L_{N-2}^\alpha(t)t^{\alpha/2}e^{-t/2} \sim N^{\alpha/2}J_\alpha(2(Nt)^{1/2}),$$

where $J_n(z)$ denotes the Bessel function, and thus

$$\int_0^{4\epsilon} L_{N-2}^a(t)t^{(a-1)/2}e^{-t/2}\,\mathrm{d}t \sim N^{a/2}\int_0^{4\epsilon} J_\alpha(2(Nt)^{1/2})\frac{\mathrm{d}t}{\sqrt{t}}. \tag{4.24}$$

We expect the leading contributions to come from the neighborhood of the upper terminal $s=\sqrt{X}$ in (4.23), and the lower terminal $t=0$ in (4.24) [the integrands should connect smoothly from the lower terminal of (4.23) to the upper terminal of (4.24)]. Since about $s=\sqrt{X}$,

$$g^{(L)}_{-2,N}(s^2) \sim \sin(2N(\sqrt{X(1-X)} - \mathrm{Arcos}\sqrt{X}) - (\alpha-3)\mathrm{Arcos}\sqrt{X} + 3\pi/4 + 4N\sqrt{1-X}(s-\sqrt{X}))$$

we have

$$\int^{\sqrt{X}} \frac{g^{(L)}_{-2,N}(s^2)}{\sqrt{s}(1-s^2)^{1/4}}\mathrm{d}s \sim -\frac{1}{4N\sqrt{1-X}}\frac{\widetilde{g}^{(L)}_{-2,N}(X)}{X^{1/4}(1-X)^{1/4}},$$

where

$$\widetilde{g}^{(L)}_{m,N}(x) := \cos(2N(\sqrt{x(1-x)} - \mathrm{Arcos}\sqrt{x}) - (\alpha+1+2m)\mathrm{Arcos}\sqrt{x} + 3\pi/4).$$

Also

$$\int_0^\infty J_\alpha(t)\mathrm{d}t = 1,$$

so we have

$$\int_0 J_\alpha(2(Nt)^{1/2})\frac{\mathrm{d}t}{\sqrt{t}} \sim N^{-1/2}.$$

Reading off the asymptotic form of the factor $x^{a/2}e^{-x/2}L^a_{N-1}(x)|_{x=4NX}$ in (4.18) from (3.12) we deduce from this that

$$\rho(4NX;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-x/2})) \sim \rho(4NX;\mathrm{UE}_{N-1}(x^\alpha e^{-x})) - \frac{g^{(L)}_{-1,N}(X)\widetilde{g}^{(L)}_{-2,N}(X)}{8\pi NX(1-X)}.$$

It remains to determine the asymptotic form of (4.19). For this we use the analogue of (4.21) and (3.12), to obtain

$$\rho(4NX;\mathrm{UE}_{N-1}(x^\alpha e^{-x})) \sim \frac{1}{4N}\rho(X;\mathrm{UE}_N(x^\alpha e^{-2Nx})) - \frac{1}{2\pi}\sqrt{\frac{1}{X(1-X)}}(g_{-1,N}(X))^2.$$

Noting from the definitions and by a simple trigonometric identity that

$$\widetilde{g}^{(L)}_{-2,N}(X) = (2X-1)\widetilde{g}^{(L)}_{-1,N}(X) - 2\sqrt{(1-X)X}g^{(L)}_{-1,N}(X),$$

$$\widetilde{g}^{(L)}_{0,N}(X) = (2X-1)\widetilde{g}^{(L)}_{-1,N}(X) + 2\sqrt{(1-X)X}g^{(L)}_{-1,N}(X),$$

we therefore have

$$\rho(4NX;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-x/2})) \sim \frac{1}{4N}\rho(X;\mathrm{UE}_N(x^\alpha e^{-4Nx})) - \frac{1}{8\pi N}\frac{g^{(L)}_{-1,N}(X)\widetilde{g}^{(L)}_{0,N}(X)}{X(1-X)}. \tag{4.25}$$

Now, with

$$A_{N,\alpha}(X) := 2N(\sqrt{X(1-X)} - \mathrm{Arccos}\sqrt{X}) - \alpha\,\mathrm{Arccos}\sqrt{X} \tag{4.26}$$

we have that

$$g^{(L)}_{-1,N}(X) = \sin(A_{N,\alpha}(X) + \mathrm{Arccos}\sqrt{X} + 3\pi/4),$$

$$\tilde{g}^{(L)}_{0,N}(X) = \cos(A_{N,\alpha}(X) - \operatorname{Arccos}\sqrt{X} + 3\pi/4),$$

and thus

$$g^{(L)}_{-1,N}(X)\tilde{g}^{(L)}_{0,N}(X) = \tfrac{1}{2}(-\cos(2A_{N,\alpha}(X)) + 2\sqrt{X(1-X)}). \tag{4.27}$$

Substituting (4.27) in (4.25) and noting from (2.7) that

$$\frac{1}{4N}\rho(X;\mathrm{UE}_N(x^\alpha e^{-4Nx})) \sim \frac{1}{4}\rho_{\mathrm{MP}}(X) - \frac{\cos 2A_{N,\alpha}(X)}{16\pi X(1-X)N} + \frac{\alpha}{8\pi\sqrt{X(1-X)N}} \tag{4.28}$$

we obtain (4.20).

□

Consider now the LSE. Analogous to (4.21), by a change of variables

$$\rho(X;\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx})) = 8N\rho(8NX;\mathrm{SE}_N(x^{\alpha+1}e^{-x})),$$

while (3.5) together with the fact[11,1]

$$\int_0^\infty e^{-t/2}t^{(\alpha-1)/2}L^\alpha_{2N-1}(t)\mathrm{d}t = 0 \tag{4.29}$$

shows that

$$\rho(x;\mathrm{SE}_N(x^{\alpha+1}e^{-x})) = \frac{1}{2}\rho(x;\mathrm{UE}_{2N}(x^\alpha e^{-x})) - \frac{\Gamma(1+2N)}{4\Gamma(\alpha+2N)}e^{-x/2}x^{(\alpha-1)/2}L^\alpha_{2N}(x)\int_0^x e^{-t/2}t^{(\alpha-1)/2}L^\alpha_{2N-1}(t)\mathrm{d}t. \tag{4.30}$$

Proposition 8: Let $0<X<1$. *In terms of the notation* (3.13) and (4.26) *we have*

$$\frac{1}{N}\rho(X;\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx})) \sim \rho_{\mathrm{MP}}(X) - \frac{1}{2(\pi N)^{1/2}}\frac{g^{(L)}_{0,2N}(X)}{X^{3/4}(1-X)^{1/4}} + \frac{\alpha+1}{4\pi N\sqrt{X(1-X)}} + o(N^{-1}). \tag{4.31}$$

Proof: Following the strategy of the proof of Proposition 7 we find

$$\int_0^{8NX} e^{-t/2}t^{(\alpha-1)/2}L^\alpha_{2N-1}(t)\mathrm{d}t \sim (2N)^{(\alpha-1)/2} + \frac{(2N)^{\alpha/2}}{(2\pi)^{1/2}}\frac{\tilde{g}^{(L)}_{-1,2N}(X)}{2NX^{1/4}(1-X)^{3/4}}.$$

Also, (3.12) and Stirling's formula show

$$\frac{\Gamma(1+2N)}{4\Gamma(\alpha+2N)}e^{-x/2}x^{(\alpha-1)/2}L^\alpha_{2N}(x)\big|_{x=8NX} \sim \frac{1}{16(\pi N)^{1/2}(2N)^{(\alpha-1)/2}}\frac{g^{(L)}_{0,2N}(X)}{X^{3/4}(1-X)^{1/4}}.$$

Substituting in (4.30) gives

$$\rho(8NX;\mathrm{SE}_N(x^{\alpha+1}e^{-x})) \sim \frac{1}{16N}\rho(X;\mathrm{UE}_{2N}(x^\alpha e^{-8Nx})) - \frac{1}{16(\pi N)^{1/2}}\frac{g^{(L)}_{0,2N}(X)}{X^{3/4}(1-X)^{1/4}} - \frac{g^{(L)}_{0,2N}(X)\tilde{g}^{(L)}_{-1,2N}(X)}{32\pi NX(1-X)}. \tag{4.32}$$

Analogous to (4.27) we have

$$g^{(L)}_{0,2N}(X)\tilde{g}^{(L)}_{-1,2N}(X) = -\frac{1}{2}(\cos 2A_{2N,\alpha}(X) + 2\sqrt{X(1-X)}).$$

Substituting this together with (4.28) in (4.32) gives (4.31).

□

V. ASYMPTOTIC EXPANSIONS AT THE EDGE

A. The GOE and GSE

The scaled densities $\rho(X;\mathrm{OE}_N(e^{-NX^2}))$ and $\rho(X;\mathrm{SE}_N(e^{-4NX^2}))$ have to leading order their support on $(-1,1)$. We know from previous studies[5,6] that setting X as specified by (2.11) (with the restriction $\xi<0$ removed) and multiplying by $N^{1/3}$, the limit $N\to\infty$ exists and can be computed explicitly. Here we are interested in computing the first correction, as in the soft edge formula (2.9) for the GUE.

In the case of the GOE, we see from (4.4), (4.1), and (4.2) that in addition to the knowledge of (2.9), an asymptotic formula for $\rho(1+\xi/2N^{2/3};\mathrm{OE}_N(e^{-Nx^2}))$ can be obtained by making use of (3.15).

Proposition 9: We have

$$\frac{1}{2N^{2/3}}\rho\left(1+\frac{\xi}{2N^{2/3}};\mathrm{OE}_N(e^{-Nx^2})\right)=(\mathrm{Ai}'(\xi))^2-\xi(\mathrm{Ai}(\xi))^2+\frac{1}{2}\mathrm{Ai}(\xi)\left(1-\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t\right)+\frac{1}{2N^{1/3}}\mathrm{Ai}'(\xi)\times\left(1-\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t\right)+O\left(\frac{1}{N^{2/3}}\right). \tag{5.1}$$

Proof: Consider the integral in (4.1). We know from Ref. 1 that

$$\int_0^x e^{-t^2/2}H_N(t)\mathrm{d}t=\sqrt{\frac{\pi}{2}}\frac{N!}{(N/2)!}-\int_x^\infty e^{-t^2/2}H_N(t)\mathrm{d}t.$$

Replacing N by $N-2$, setting $x=(2N)^{1/2}+2^{-1/2}N^{-1/6}\xi$, making use of (3.15) and simplifying shows that

$$\int_0^{(2N)^{1/2}+2^{-1/2}N^{-1/6}\xi} e^{-t^2/2}H_{N-2}(t)\mathrm{d}t=\sqrt{\frac{\pi}{2}}\frac{(N-2)!}{(N/2-1)!}\left(1-\int_\xi^\infty \mathrm{Ai}(y)\mathrm{d}y+\frac{2}{N^{1/3}}\mathrm{Ai}(\xi)+O\left(\frac{1}{N^{2/3}}\right)\right). \tag{5.2}$$

Now using (3.15) with $m=-1$, and multiplying with the result (5.2) as required by (4.1) we obtain

$$\left(\frac{e^{-x^2/2}H_{N-1}(x)}{2^{N-1}\pi^{1/2}(N-2)!}\int_0^x e^{-t^2/2}H_{N-2}(t)\mathrm{d}t\right)\Bigg|_{x=(2N)^{1/2}+2^{-1/2}N^{-1/6}\xi}\sim\frac{N^{1/6}}{2^{1/2}}\left(\mathrm{Ai}(\xi)+\frac{1}{N^{1/3}}\mathrm{Ai}'(\xi)\right)\left(1-\int_\xi^\infty \mathrm{Ai}(y)\mathrm{d}y+\frac{2}{N^{1/3}}\mathrm{Ai}(\xi)\right).$$

According to (4.2), we also require the asymptotic formula

$$-\frac{2^{-N+1}}{\pi^{1/2}(N-1)!}(e^{-x^2/2}H_{N-1}(x))^2\Bigg|_{x=(2N)^{1/2}+2^{-1/2}N^{-1/6}\xi}\sim-\frac{\sqrt{2}}{N^{1/6}}(\mathrm{Ai}'(\xi))^2,$$

which follows from (3.15). Further

$$\rho((2N)^{1/2}+2^{-1/2}N^{-1/6}\xi;\mathrm{UE}_N(e^{-x^2}))=\frac{1}{(2N)^{1/2}}\rho(1+\xi/2N^{2/3};\mathrm{UE}_N(e^{-2Nx^2}))$$

[cf. (4.4)] so the asymptotic form of the first term on the right-hand side of (4.2) can be read off from (2.9). Doing this, and recalling (4.4), we deduce (5.1).

We turn our attention now to the GSE. We will analyze (4.16) rewritten to read

$$\rho(x;\mathrm{SE}_N(e^{-x^2})) = \frac{1}{2}\rho(x;\mathrm{UE}_{2N}(e^{-x^2})) - \frac{e^{-x^2/2}H_{2N}(x)}{2^{2N+1}\pi^{1/2}(2N-1)!}\int_x^\infty e^{-t^2/2}H_{2N-1}(t)\mathrm{d}t. \tag{5.3}$$

Proposition 10: We have

$$\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{2(2N)^{2/3}};\mathrm{SE}_N(e^{-4Nx^2})\right) \sim (\mathrm{Ai}'(\xi))^2 - \xi(\mathrm{Ai}(\xi))^2 - \frac{1}{2}\mathrm{Ai}(\xi)\left(\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t - \frac{1}{(2N)^{1/3}}\mathrm{Ai}(\xi) + O(N^{-2/3})\right). \tag{5.4}$$

Proof: By a simple change of variables

$$\rho\left(1+\frac{\xi}{2(2N)^{2/3}};\mathrm{SE}_N(e^{-4Nx^2})\right) = 2\sqrt{N}\rho((4N)^{1/2}+2^{-1/2}(2N)^{-1/6}\xi;\mathrm{SE}_N(e^{-x^2})), \tag{5.5}$$

so we seek the large N asymptotic form of (3.15) with $x\mapsto(4N)^{1/2}+2^{-1/2}(2N)^{-1/6}\xi$. Making use of (3.15) shows

$$\left(\frac{e^{-x^2/2}H_{2N}(x)}{2^{2N+1}\pi^{1/2}(2N-1)!}\int_x^\infty e^{-t^2/2}H_{2N-1}(t)\mathrm{d}t\right)\Bigg|_{x=(4N)^{1/2}+2^{-1/2}(2N)^{-1/6}\xi} \sim \frac{N^{1/6}}{2^{4/3}}\mathrm{Ai}(\xi)\left\{\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t - \frac{1}{(2N)^{1/3}}\mathrm{Ai}(X) + O(N^{-2/3})\right\}, \tag{5.6}$$

while it follows from (2.9) that

$$\frac{1}{2}\rho((4N)^{1/2}+2^{-1/2}(2N)^{-1/6}\xi;\mathrm{UE}_{2N}(e^{-x^2})) \sim \frac{(2N)^{1/6}}{\sqrt{2}}\left((\mathrm{Ai}'(\xi))^2 - \xi(\mathrm{Ai}(\xi))^2 + O\left(\frac{1}{N^{2/3}}\right)\right). \tag{5.7}$$

Substituting (5.7) and (5.6) in (5.3) and recalling (5.5) gives the stated result. □

B. The LOE and LSE

The soft edge scaling variables for the LOE and LSE are the same as those for the LUE, exhibited in (2.10). The leading correction term to the corresponding soft edge densities are given by the following result.

Proposition 11: We have

$$\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{(2N)^{2/3}};\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-2Nx})\right) \sim (\mathrm{Ai}'(\xi))^2 - \xi(\mathrm{Ai}(\xi))^2 + \frac{1}{2}\mathrm{Ai}(\xi)\left(1-\int_\xi^\infty \mathrm{Ai}(s)\mathrm{d}s\right) - \frac{(\alpha-1)}{2(2N)^{1/3}}\left[\mathrm{Ai}'(\xi)\left(1-\int_\xi^\infty \mathrm{Ai}(s)\mathrm{d}s\right) - (\mathrm{Ai}(\xi))^2\right] + O(N^{-2/3}) \tag{5.8}$$

and

$$\frac{2}{(4N)^{2/3}}\rho\left(1+\frac{\xi}{(4N)^{2/3}};\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx})\right)\sim(\mathrm{Ai}'(\xi))^2-\xi(\mathrm{Ai}(\xi))^2-\frac{1}{2}\mathrm{Ai}(\xi)\int_\xi^\infty \mathrm{Ai}(s)\mathrm{d}s$$
$$+\frac{\alpha+1}{2(4N)^{1/3}}\left((\mathrm{Ai}(\xi))^2+\mathrm{Ai}'(\xi)\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t\right)+O(N^{-2/3}). \tag{5.9}$$

Proof: Consider first the LOE. We rewrite (4.18) as

$$\rho(x;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-x/2}))=\rho(x;\mathrm{UE}_{N-1}(x^\alpha e^{-x}))+\frac{(N-1)!}{4(\alpha+N-2)!}x^{(\alpha-1)/2}e^{-x/2}L_{N-1}^\alpha(x)$$
$$\times\left(2\int_x^\infty L_{N-2}^\alpha(t)t^{(\alpha-1)/2}e^{-t/2}\,\mathrm{d}t-\int_0^\infty L_{N-2}^\alpha(t)t^{(\alpha-1)/2}e^{-t/2}\,\mathrm{d}t\right). \tag{5.10}$$

The asymptotic form of the final integral in (5.9) is known from (4.22). According to (4.21), we seek the asymptotic form of the remaining terms with

$$x=4N+2(2N)^{1/3}\xi.$$

For the first integral, use of (3.17) gives

$$\int_{4N+2(2N)^{1/3}\xi}^\infty L_{N-2}^\alpha(t)t^{(\alpha-1)/2}e^{-t/2}\,\mathrm{d}t\sim N^{(\alpha-1)/2}\left(\int_\xi^\infty \mathrm{Ai}(s)\mathrm{d}s-\frac{3-\alpha}{(2N)^{1/3}}\mathrm{Ai}(\xi)+O(N^{-2/3})\right).$$

The asymptotic form of the term outside the parenthetical integrals is given by (3.17) with $p=-1$. For the first term on the right-hand side of (5.10), use of (4.19), the analogue of (4.21), and (2.10) shows

$$\rho(4N+2(2N)^{1/3}\xi;\mathrm{UE}_{N-1}(x^\alpha e^{-x}))\sim\frac{1}{2(2N)^{1/3}}\left((\mathrm{Ai}'(\xi))^2-\xi(\mathrm{Ai}(\xi))^2+\frac{\alpha}{2^{1/3}}(\mathrm{Ai}(\xi))^2\frac{1}{N^{1/3}}\right)$$
$$-2^{-2/3}N^{-2/3}(\mathrm{Ai}(\xi))^2.$$

The asymptotic form of all terms have now been determined, and (5.8) follows.

In relation to the LSE, we use (4.29) to rewrite (4.30) to read

$$\rho(x;\mathrm{SE}_N(x^{\alpha+1}e^{-x}))=\frac{1}{2}\rho(x;\mathrm{UE}_{2N}(x^\alpha e^{-x}))+\frac{\Gamma(1+2N)}{4\Gamma(\alpha+2N)}e^{-x/2}x^{(\alpha-1)/2}L_{2N}^\alpha(x)\int_x^\infty e^{-t/2}t^{(\alpha-1)/2}L_{2N-1}^\alpha(t)\mathrm{d}t. \tag{5.11}$$

A simple change of variables gives

$$\rho\left(1+\frac{\xi}{(4N)^{2/3}};\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx})\right)=8N\rho(8N+2(4N)^{1/3}\xi;\mathrm{SE}_N(x^{\alpha+1}e^{-x})), \tag{5.12}$$

so we seek the asymptotic form of (5.11) with

$$x=8N+2(4N)^{1/3}\xi.$$

For this, we make use of (3.17) to deduce

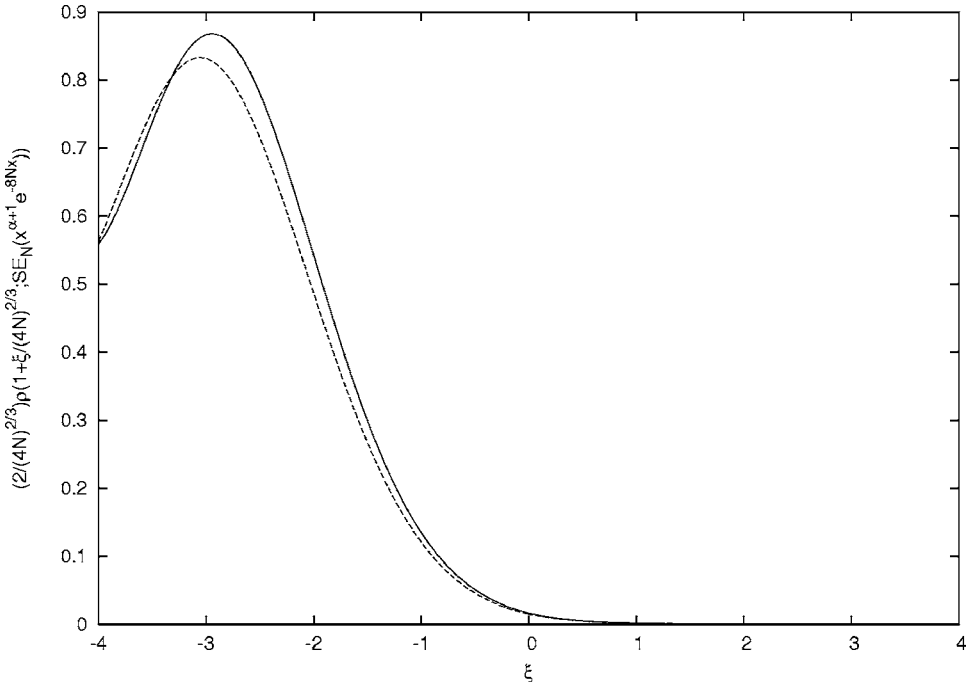

FIG. 1. Numerical comparison of the asymptotic expansion (5.9), shown as the dashed line, and the exact result for the LSE density given by (5.11) and (5.12), shown as the solid line, for the eigenvalue density near the soft edge of the LSE with $N=20$ and $\alpha=1/2$.

$$\frac{\Gamma(1+2N)}{4\Gamma(\alpha+2N)}e^{-x/2}x^{(\alpha-1)/2}L_{2N}^{\alpha}(x)\int_x^{\infty}e^{-t/2}t^{(\alpha-1)/2}L_{2N-1}^{\alpha}(t)\mathrm{d}t \sim -\frac{1}{8}2^{-2/3}N^{-1/3}\left(\mathrm{Ai}(\xi)-\frac{\alpha+1}{(4N)^{1/3}}\mathrm{Ai}'(\xi)\right)$$
$$\times\left(\int_{\xi}^{\infty}\mathrm{Ai}(s)\mathrm{d}s+\frac{\alpha-1}{(4N)^{1/3}}\mathrm{Ai}(\xi)+O(N^{-2/3})\right).$$

Further, making use of the analogue of (5.12) and recalling (2.10) shows

$$\frac{1}{2}\rho(8N+2(4N)^{1/3}\xi;\mathrm{UE}_{2N}(x^{\alpha}e^{-x})) \sim \frac{1}{4(4N)^{1/3}}\left((\mathrm{Ai}'(\xi))^2-\xi(\mathrm{Ai}(\xi))^2+\frac{\alpha}{2^{1/3}(2N)^{1/3}}(\mathrm{Ai}(\xi))^2\right.$$
$$\left.+O(N^{-2/3})\right).$$

The asymptotic form of all terms in (5.11) are now determined. After use of (5.12), (5.9) follows. □

Figure 1 provides a numerical comparison of the asymptotic expansion given by (5.9) with the exact result for the LSE density given by (5.11) and (5.12).

VI. CONSEQUENCES

A. Matching the bulk and edge expansions

1. The GOE and GSE

In Sec. II B the conjectured matching between the bulk asymptotic expansion expanded about the soft edge, and the asymptotic expansion of the edge density expanded into the bulk, for both the GUE and LUE was given further credence by its confirmation on further terms in the

asymptotic expansion. To study the matching in the case of orthogonal and symplectic symmetry, it is therefore convenient to express the corresponding asymptotic expansions in terms of the unitary symmetry expansions. We will consider first the Gaussian cases.

According to (4.3), (4.13), (2.5), (2.12),

$$\frac{1}{N}\rho(X;\mathrm{OE}_N(e^{-Nx^2})) \sim \frac{1}{N}\rho(X;\mathrm{UE}_N(e^{-Nx^2})) + \left(\frac{\cos[2N\pi P_{\mathrm{W}}(X)]}{4\pi(1-X^2)} - \frac{1}{2\pi\sqrt{1-X^2}}\right)\frac{1}{N} + \left(\frac{1+2X^2}{8\pi(1-X^2)^{5/2}} - \frac{X(21+2X^2)\sin[2N\pi P_{\mathrm{W}}(X)]}{48\pi(1-X^2)^{5/2}} - \frac{\cos[2N\pi P_{\mathrm{W}}(X)]}{8\pi(1-X^2)^2}\right)\frac{1}{N^2}; \tag{6.1}$$

according to (5.1) and (2.9)

$$\frac{1}{2N^{2/3}}\rho\left(1+\frac{\xi}{2N^{2/3}};\mathrm{OE}_N(e^{-Nx^2})\right) \sim \frac{1}{2N^{2/3}}\rho\left(1+\frac{\xi}{2N^{2/3}};\mathrm{UE}_N(e^{-2Nx^2})\right) + \frac{1}{2}\mathrm{Ai}(\xi)\left(1-\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t\right) + \frac{1}{2N^{1/3}}\mathrm{Ai}'(\xi)\left(1-\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t\right) + O\left(\frac{1}{N^{2/3}}\right); \tag{6.2}$$

according to (4.17) and (2.5)

$$\frac{1}{N}\rho(X;\mathrm{SE}_N(e^{-4Nx^2})) \sim \frac{1}{2N}\rho(X;\mathrm{UE}_{2N}(e^{-2Nx^2})) + \frac{\cos[4N\pi P_{\mathrm{W}}(X)]}{8\pi(1-X^2)N} \times \frac{1}{4\pi N\sqrt{1-X^2}} - \left(\frac{1}{\sqrt{2\pi N}} + \frac{1}{2\pi N}\right)\frac{\cos\left[2N\pi P_{\mathrm{W}}(X) + \frac{1}{2}\mathrm{Arcsin}\,X\right]}{(1-X^2)^{1/4}} + O(N^{-3/2}); \tag{6.3}$$

according to (5.4) and (2.9),

$$\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{2(2N)^{2/3}};\mathrm{SE}_N(e^{-4Nx^2})\right) \sim \frac{1}{2(2N)^{2/3}}\rho\left(1+\frac{\xi}{2(2N)^{2/3}};\mathrm{UE}_{2N}(e^{-4Nx^2})\right) - \frac{1}{2}\mathrm{Ai}(\xi)\int_\xi^\infty \mathrm{Ai}(t)\mathrm{d}t + \frac{(\mathrm{Ai}(\xi))^2}{2(2N)^{1/3}} + O\left(\frac{1}{N^{2/3}}\right); \tag{6.4}$$

substituting (2.11) in (6.1) and (6.3) and expanding as in (2.18) gives

$$\frac{1}{2N^{2/3}}\rho\left(1+\frac{\xi}{2N^{2/3}};\mathrm{OE}_N(e^{-Nx^2})\right) \dot{\sim} \frac{1}{2N^{2/3}}\rho\left(1+\frac{\xi}{2N^{2/3}};\mathrm{UE}_N(e^{-2Nx^2})\right) + \frac{3}{16\pi|\xi|^{5/2}} + \frac{23\sin(4|\xi|^{3/2}/3)}{96\pi|\xi|^{5/2}} + \frac{\cos(4|\xi|^{3/2}/3)}{8\pi|\xi|} - \left(\frac{1}{4\pi|\xi|^{1/2}} + \frac{\cos(4|\xi|^{3/2}/3)}{16\pi|\xi|^2}\right)\frac{1}{N^{1/3}} \tag{6.5}$$

and

$$\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{2(2N)^{2/3}};\mathrm{SE}_N(e^{-4Nx^2})\right)\dot{\sim}\frac{1}{2(2N)^{2/3}}\rho\left(1+\frac{\xi}{2(2N)^{2/3}};\mathrm{UE}_{2N}(e^{-4Nx^2})\right)$$
$$-\frac{1}{2}\frac{1}{\sqrt{\pi}}\frac{\sin\left(\frac{2}{3}|\xi|^{3/2}+\pi/4\right)}{|\xi|^{1/4}}+\frac{\cos\left(\frac{4}{3}|\xi|^{3/2}\right)}{8\pi|\xi|}$$
$$+\left(\frac{1}{4\pi|\xi|^{1/2}}+\frac{|\xi|^{1/4}\sin\left(\frac{2}{3}|\xi|^{3/2}-\pi/4\right)}{4\sqrt{\pi}}\right)\frac{1}{(2N)^{1/3}}+O(N^{-1/2}). \tag{6.6}$$

We now compare (6.5) and (6.6) to the $\xi\to-\infty$ expansion of (6.2) and (6.4), respectively. In relation to the latter, a straightforward calculation using the leading two terms of (2.19) shows that for $|\xi|\to\infty$,

$$\int_{|\xi|}^{\infty}\mathrm{Ai}(-t)\mathrm{d}t\sim\frac{1}{\sqrt{\pi}}\left(\frac{1}{|\xi|^{3/4}}\cos\left(\frac{2}{3}|\xi|^{3/2}+\pi/4\right)+\frac{41}{48}\frac{1}{|\xi|^{9/4}}\sin\left(\frac{2}{3}|\xi|^{3/2}+\pi/4\right)\right).$$

Using this, together with (2.19) itself, we find that (6.5) agrees with the $\xi\to-\infty$ expansion of (6.2) for the first two terms of the $O(1)$ part in (6.5), but the rational factor of $\frac{1}{8}$ should be $\frac{1}{4}$ for the third term. At $O(N^{-1/3})$ agreement is obtained with the first term. Similarly, we find that the first term at each order in (6.6) agrees with the $\xi\to-\infty$ expansion of (6.6). These results are all consistent with the matching hypothesis.

2. The LOE and LSE

As in the Gaussian cases, we begin by expressing the densities for the LOE and LSE in terms of the corresponding densities for the LUE.

According to (4.20) and (2.7),

$$\frac{1}{N}\rho(X;\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-2Nx}))\sim\frac{1}{N}\rho(X;\mathrm{UE}_N(x^{\alpha}e^{-4Nx}))+\left(\frac{\cos 2A_{N,\alpha}(X)}{4\pi X(1-X)}-\frac{1}{2\pi(X(1-X))^{1/2}}\right)\frac{1}{N}; \tag{6.7}$$

according to (5.8) and (2.10),

$$\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{(2N)^{2/3}};\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-2Nx})\right)\sim\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{(2N)^{2/3}};\mathrm{UE}_N(x^{\alpha}e^{-4Nx})\right)$$
$$+\frac{1}{2}\mathrm{Ai}(\xi)\left(1-\int_{\xi}^{\infty}\mathrm{Ai}(s)\mathrm{d}s\right)-\frac{(\alpha-1)}{2(2N)^{1/3}}\mathrm{Ai}'(\xi)\left(1-\int_{\xi}^{\infty}\mathrm{Ai}(s)\mathrm{d}s\right)-\frac{(\alpha+1)}{2(2N)^{1/3}}(\mathrm{Ai}(\xi))^2; \tag{6.8}$$

according to (4.31) and (2.7),

$$\frac{1}{N}\rho(X;\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx}))\sim\frac{1}{2N}\rho(X;\mathrm{UE}_{2N}(x^{\alpha}e^{-8Nx}))-\frac{1}{2(\pi N)^{1/2}}\frac{g^{(L)}_{0,2N}(X)}{X^{3/4}(1-X)^{1/4}}+\frac{\cos 2A_{2N,\alpha}(X)}{8\pi NX(1-X)}$$
$$+\frac{1}{4\pi N\sqrt{X(1-X)}}; \tag{6.9}$$

according to (5.9) and (2.10),

$$\frac{2}{(4N)^{2/3}}\rho\left(1+\frac{\xi}{(4N)^{2/3}};\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx})\right)\sim\frac{1}{(4N)^{2/3}}\rho\left(1+\frac{\xi}{(4N)^{2/3}};\mathrm{UE}_{2N}(x^{\alpha}e^{-8Nx})\right)$$
$$-\frac{1}{2}\mathrm{Ai}(\xi)\int_{\xi}^{\infty}\mathrm{Ai}(s)\mathrm{d}s+\frac{(\alpha+1)}{2(4N)^{1/3}}\mathrm{Ai}'(\xi)\int_{\xi}^{\infty}\mathrm{Ai}(t)\mathrm{d}t$$
$$-\frac{(\alpha-1)}{2(4N)^{1/3}}(\mathrm{Ai}'(\xi))^2. \tag{6.10}$$

Substituting (2.11) in (6.7) and (6.9) and expanding gives

$$\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{(2N)^{2/3}};\mathrm{OE}_N(x^{(\alpha-1)/2}e^{-2Nx})\right)\dot{\sim}\frac{1}{(2N)^{2/3}}\rho\left(1+\frac{\xi}{(2N)^{2/3}};\mathrm{UE}_N(x^{\alpha}e^{-4Nx})\right)+\frac{\cos(4|\xi|^{3/2}/3)}{4\pi|\xi|}$$
$$-\frac{(1+\alpha\sin(4|\xi|^{3/2}/3))}{2\pi\sqrt{|\xi|}}\frac{1}{(2N)^{1/3}} \tag{6.11}$$

and

$$\frac{2}{(4N)^{2/3}}\rho\left(1+\frac{\xi}{(4N)^{2/3}};\mathrm{SE}_N(x^{\alpha+1}e^{-8Nx})\right)\dot{\sim}\frac{1}{(4N)^{2/3}}\rho\left(1+\frac{\xi}{(4N)^{2/3}};\mathrm{UE}_{2N}(x^{\alpha}e^{-8Nx})\right)$$
$$+\frac{\sin(2|\xi|^{3/2}/3-3\pi/4)}{2\sqrt{\pi}|\xi|^{1/4}}+\frac{\cos(4|\xi|^{3/2}/3)}{4\pi|\xi|}$$
$$+\frac{1}{2(4N)^{1/3}\pi\sqrt{|\xi|}}\left(1+(1+\alpha)\sqrt{\pi}|\xi|^{3/4}\cos(2|\xi|^{3/2}-3\pi/4)\right.$$
$$\left.-\frac{\alpha}{2^{1/3}}\sin(4|\xi|^{3/2}/3)\right). \tag{6.12}$$

On the other hand, let us expand (6.8) and (6.10) for $\xi\to-\infty$. Doing so we find agreement with the first term at each order in (6.11) and (6.12), respectively, as consistent with the matching hypothesis.

B. Microscopic delta functions

The results of Secs. IV and V tell us the asymptotic expansion of the global density, and the soft edge density. Here we would like to relate these expansions to the result (1.4) and its Laguerre analogue.

Consider first the Gaussian cases. For $|\xi|$ large but otherwise arbitrary, we write

$$\int_{-\infty}^{\infty}\rho(x;\mathrm{ME}_N(e^{-\beta x^2/2}))a(x)\mathrm{d}x=\left(\int_{R_1}+\int_{R_2}\right)\rho(X;\mathrm{ME}_N(e^{-N\beta x^2}))\tilde{a}(X)\mathrm{d}X$$
$$=\int_{R_1}\rho(X;\mathrm{ME}_N(e^{-N\beta x^2}))\tilde{a}(X)\mathrm{d}X$$
$$+\frac{1}{2N^{2/3}}\left(\int_{-|\xi|}^{\infty}\rho(1+y/2N^{2/3};\mathrm{ME}_N(e^{-\beta Nx^2}))\tilde{a}(1+y/2N^{2/3})\mathrm{d}y\right.$$
$$\left.+\int_{-\infty}^{|\xi|}\rho(1-y/2N^{2/3};\mathrm{ME}_N(e^{-\beta Nx^2}))\tilde{a}(-1-y/2N^{2/3})\mathrm{d}y\right), \tag{6.13}$$

where $\mathrm{ME}_N=\mathrm{OE}_N$, UE_N, SE_N, respectively, $R_1=(-1+|\xi|/2N^{2/3},1-|\xi|/2N^{2/3})$ and $R_2=(-\infty,\infty)\backslash R_1$, $\tilde{a}(x)=a(Nx)$ and we have used the fact that ρ is even. Because

$$\rho^{\text{soft}}(y;\text{ME}_N(e^{-\beta N x^2})) := \lim_{N\to\infty} \frac{1}{2N^{2/3}} \rho(1 + y/2N^{2/3};\text{ME}_N(e^{-\beta N x^2})) \tag{6.14}$$

is an $O(1)$ quantity, we see that to leading order the second and third integrals in (6.13) contribute

$$(\widetilde{a}(1) + \widetilde{a}(-1)) \int_{-|\xi|}^{\infty} \rho^{\text{soft}}(y;\text{ME}_N(e^{-\beta N x^2}))\text{d}y. \tag{6.15}$$

However, in relation to the first integral on the right-hand side of (6.13), we know that terms which are different order in N in the asymptotic expansion of $\rho(X;\text{ME}_N(e^{-N\beta x^2}))$ can contribute at the same order upon the substitution (2.11). Unlike the situation at the edge, the asymptotic expansion of this integral does not therefore correspond directly to the asymptotic of the integrand, leaving us without a method of analysis. Nonetheless some insight into the microscopic origin of the delta functions in (1.4) can be obtained as a consequence of the functional form of (6.14) for $\beta=1,4$.

For $\beta=2$ we read off from (2.9),

$$\rho^{\text{soft}}(y;\text{UE}_N(e^{-2Nx^2})) = (\text{Ai}'(y))^2 - y(\text{Ai}(y))^2,$$

while (2.18) tells us that the leading $y\to-\infty$ behavior is $2\sqrt{|y|}/\pi$ so (6.15) diverges for $|\xi|\to\infty$. Because of the result (1.4) it must be that this is exactly canceled by a contribution from the bulk, and thus the edge terms (6.15) cancel.

For $\beta=1$ and 4 we observe from (5.1) and (5.4) that $\rho^{\text{soft}}(y;\text{UE}_N(e^{-2Nx^2}))$ appears as an additive component in the scaled soft edge density, together with a further term in both cases. The further term has the property that it is integrable for $y\to-\infty$. Thinking then of the decomposition (6.13) for $|\xi|$ large, and ignoring the contribution from the nonintegrable additive component, this then suggests that

$$\begin{aligned}\int_{-\infty}^{\infty} \rho(x;\text{OE}_N(e^{-x^2/2}))a(x)\text{d}x &\sim N\int_{-1}^{1} \rho_W(X)\widetilde{a}(X)\text{d}X - \frac{1}{2\pi}\int_{-1}^{1} \frac{\widetilde{a}(X)}{\sqrt{1-X^2}}\text{d}X \\ &+ (\widetilde{a}(1) + \widetilde{a}(-1))\frac{1}{2}\int_{-\infty}^{\infty} \text{Ai}(y)\left(1 - \int_{y}^{\infty} \text{Ai}(t)\text{d}t\right)\text{d}y,\end{aligned} \tag{6.16}$$

$$\begin{aligned}\int_{-\infty}^{\infty} \rho(x;\text{SE}_N(e^{-2x^2}))a(x)\text{d}x &\sim N\int_{-1}^{1} \rho_W(X)\widetilde{a}(X)\text{d}X + \frac{1}{4\pi}\int_{-1}^{1} \frac{\widetilde{a}(X)}{\sqrt{1-X^2}}\text{d}X \\ &- (\widetilde{a}(1) + \widetilde{a}(-1))\frac{1}{4}\int_{-\infty}^{\infty} \text{Ai}(y)\left(\int_{y}^{\infty} \text{Ai}(t)\text{d}t\right)\text{d}y.\end{aligned} \tag{6.17}$$

Here the bulk contributions are the leading two nonoscillatory terms exhibited in (4.3) and (4.17), respectively, and the edge contributions are the leading terms in (5.1) and (5.4), respectively, with the component corresponding to the $\beta=2$ edge deleted. Since

$$\text{Ai}(y)\left(1 - \int_{y}^{\infty} \text{Ai}(t)\text{d}t\right) = \frac{1}{2}\frac{d}{\text{d}y}\left(1 - \int_{y}^{\infty} \text{Ai}(t)\text{d}t\right)^2, \tag{6.18}$$

$$\text{Ai}(y)\int_{y}^{\infty} \text{Ai}(t)\text{d}t = -\frac{1}{2}\frac{d}{\text{d}y}\left(\int_{y}^{\infty} \text{Ai}(t)\text{d}t\right)^2 \tag{6.19}$$

we see from $\int_{-\infty}^{\infty}\text{Ai}(t)\text{d}t=1$ that the final integrals in (6.16) and (6.17) are both equal to $1/2$, thus reclaiming (1.4).

We consider now the Laguerre analogue of (1.4). Let us introduce the so-called chiral matrix ensembles $\mathrm{chME}_N(g(x))$ by the eigenvalue pdf,

$$\frac{1}{C}\prod_{l=1}^{N} g(x_l)x_l^{\beta/2}\prod_{1\leqslant j<k\leqslant N}|x_k^2-x_j^2|^\beta \quad (x_l>0). \tag{6.20}$$

The simple change of variables $x_j^2\mapsto x_j$ shows

$$\tfrac{1}{2}\rho(X;\mathrm{chME}_N(x^{2(a+(2-\beta)/4)}e^{-2N\beta x^2}))=X\rho(X^2;\mathrm{ME}_N(x^a e^{-2N\beta x})), \tag{6.21}$$

and thus that the Laguerre ensembles can be viewed as a Gaussian version of the chiral ensemble, generalized by the factor $x^{2(a+(2-\beta)/4)}$. We see from (6.21), (4.20), (2.7), and (4.31) that

$$\rho(X;\mathrm{chOE}_N(x^{a/2}e^{-2Nx^2}))\sim 2\rho_W(X)+\frac{1}{\pi N}\frac{a-1/2}{\sqrt{1-X^2}},$$

$$\rho(X;\mathrm{chUE}_N(x^a e^{-4Nx^2}))\sim 2\rho_W(X)+\frac{a}{\pi N\sqrt{1-X^2}},$$

$$\rho(X;\mathrm{chSE}_N(x^{2a}e^{-8Nx^2}))\sim 2\rho_W(X)+\frac{a+1/4}{\pi N\sqrt{1-X^2}},$$

where only nonoscillatory terms are included. In the case $a=0$ these expansions are precisely the same as for the corresponding Gaussian ensembles [the leading term in the chiral ensembles is $2\rho_W(X)$ rather than $\rho_W(X)$ because $X\in(0,1)$ rather than $(-1,1)$].

At the soft edge $X=1$ of the chiral ensembles, the fact that the scaled densities are the same as for the Gaussian ensembles tells us that there is a contribution

$$\frac{1}{2N}\left(\frac{1}{\beta}-\frac{1}{2}\right)\delta(X-1)$$

to the smoothed density. And, although not the focus of attention of the present work, for the Laguerre and thus chiral ensembles there is an edge effect at $X=0$ (the so-called hard edge[5]) which one expects to give a microscopic contribution

$$-\frac{a}{2N}\delta^+(X)$$

(see the next section), where $\int_0^\infty f(X)\delta^+(X)\mathrm{d}X=f(0)$. Consequently we expect the Laguerre analogue of (1.4) to be

$$\begin{aligned}\rho(X;\mathrm{chME}_N(x^{\beta a/2}e^{-2\beta Nx^2}))\sim{}& 2\rho_W(X)+\frac{a}{\pi N\sqrt{1-X^2}}-\frac{a}{2N}\delta^+(X)\\ &+\frac{1}{N}\left(\frac{1}{\beta}-\frac{1}{2}\right)\left(\delta(X-1)-\frac{1}{\pi}\frac{1}{\sqrt{1-X^2}}\right).\end{aligned} \tag{6.22}$$

C. Macroscopic balance

In this final section, we will show that the results (1.4), (6.22) are consistent with macroscopic considerations.

In a one-component log-gas, to leading order in N the electrostatic potential created by the particle density $\sigma(x)$ must balance the background potential $u(x)$, and thus the equation

$$u(x) + C = \int_{-c}^{c} \sigma(y) \log|x-y| \mathrm{d}y, \quad x \in (-c,c), \tag{6.23}$$

where C is *some* constant, must hold. This is to be solved subject to the particle conservation constraint

$$\int_{-c}^{c} \sigma(y) \mathrm{d}y = 1. \tag{6.24}$$

For example, with $u(x)=x^2$, (6.23) and (6.24) are satisfied with

$$\sigma(y) = \rho_W(y) \tag{6.25}$$

(see, e.g., Ref. 4). To the next order in N, fluctuations in the particle density create an electric field and thus a force density which must be balanced for the system to be stable. The balancing force is provided by the gradient of the pressure fluctuation, and leads to the refinement of (6.23) (Ref. 3),

$$u(x) + C = \int_{-c}^{c} \sigma(y) \log|x-y| \mathrm{d}y + \frac{1}{N}\left(\frac{1}{2} - \frac{1}{\beta}\right) \log \sigma(x), \quad x \in (-c,c) \tag{6.26}$$

which again is subject to (6.24). With $u(x)=x^2$, setting

$$\sigma(y) = \rho_W(y) + \frac{\mu(y)}{N} \tag{6.27}$$

we see that

$$C = \int_{-c}^{c} \mu(y) \log|x-y| \mathrm{d}y + \left(\frac{1}{2} - \frac{1}{\beta}\right) \log \rho_{\mathrm{W}}(x), \quad x \in (-c,c) \tag{6.28}$$

which must be solved subject to the constraint

$$\int_{-c}^{c} \mu(y) \mathrm{d}y = 0. \tag{6.29}$$

Differentiating (6.28) gives

$$0 = \mathrm{PV} \int_{-1}^{1} \frac{\mu(y)}{x-y} \mathrm{d}y - \left(\frac{1}{2} - \frac{1}{\beta}\right) \frac{x}{1-x^2}, \tag{6.30}$$

where PV denotes the principal value. Making use of the fact that

$$\mathrm{PV} \int_{-1}^{1} \frac{1}{x-y} \frac{1}{\sqrt{1-y^2}} \mathrm{d}y = 0, \quad x \in (-1,1)$$

(see, e.g., Ref. 14), we see that (6.30), (6.29) is solved by

$$\mu(y) = \left(\frac{1}{\beta} - \frac{1}{2}\right)\left(\frac{1}{2}(\delta(y-1) + \delta(y+1)) - \frac{1}{\pi} \frac{1}{\sqrt{1-y^2}}\right)$$

in agreement with (1.4).

The chiral ensemble (6.20) is a log-gas confined to $x>0$ with image charges in $x<0$. At leading order in N balance of the electric field requires

$$u(x) + C = \int_0^c \sigma(y) \log|x^2 - y^2| \mathrm{d}y, \quad x \in (-c, c), \tag{6.31}$$

subject to the constraint

$$\int_0^c \sigma(y) \mathrm{d}y = 0.$$

But (6.31) can be written

$$u(x) + C = \int_{-c}^c \sigma(y) \log|x - y| \mathrm{d}y$$

so we have essentially the previous situation. In particular, with $u(x) = 2x^2$, this shows (6.31) is satisfied with

$$\sigma(y) = 2\rho_W(y). \tag{6.32}$$

To next order in N the chiral ensembles in (6.22) have $u(x) = 2x^2 - (a/2N)\log x$, and the generalization of (6.28) reads

$$-\frac{a}{2}\log x + C = \int_{-1}^1 \mu(y) \log|x - y| \mathrm{d}y + \left(\frac{1}{2} - \frac{1}{\beta}\right) \log \rho_W(x).$$

With $\mu(y) \mapsto \mu(y) - (a/2)\delta(x)$ this is in fact identical to (6.28) and we thus reclaim (6.22).

(Received 20 October 2005; accepted 9 December 2005; published online 9 February 2006)

A chain rule and a subadditivity for the entropy of type β, which is one of the nonadditive entropies, were derived by Daróczy. In this paper, we study the further relations among Tsallis type entropies which are typical nonadditive entropies. The chain rule is generalized by showing it for Tsallis relative entropy and the nonadditive entropy. We show some inequalities related to Tsallis entropies, especially the strong subadditivity for Tsallis type entropies and the subadditivity for the nonadditive entropies. The subadditivity and the strong subadditivity naturally lead to define Tsallis mutual entropy and Tsallis conditional mutual entropy, respectively, and then we show again chain rules for Tsallis mutual entropies. We give properties of entropic distances in terms of Tsallis entropies. Finally we show parametrically extended results based on information theory. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2165744]

I. INTRODUCTION

For the probability distribution $p(x) \equiv p(X=x)$ of the random variable X, Tsallis entropy was defined in Ref. 1,

$$S_q(X) \equiv -\sum_x p(x)^q \ln_q p(x) \quad (q \neq 1) \tag{1}$$

with one parameter q as an extension of Shannon entropy, where q-logarithm function is defined by $\ln_q(x) \equiv (x^{1-q}-1)/(1-q)$ for any non-negative real number x and q. Tsallis entropy plays an essential role in nonextensive statistics so that many important results have been presented in mainly statistical physics.[2] In particular, see Refs. 3 and 4 for the recent results on Tsallis entropies. The field of the study on Tsallis entropy and related fields in statistical physics are often called Tsallis statistics or nonextensive statistical physics due to the nonextensivity Eq. (3) below. We easily find that $\lim_{q\to 1} S_q(X) = S_1(X) \equiv -\Sigma_x p(x) \log p(x)$, since q-logarithm converges to natural logarithm as $q \to 1$. After the celebrated discover by Tsallis, it was shown that Tsallis entropy can be uniquely formulated by the generalized Shannon-Khinchin's axioms in Refs. 5–7. The axiomatical characterization of Tsallis entropy was improved and that of Tsallis relative entropy was formulated in Ref. 8. It is a crucial difference of the fundamental property between Shannon entropy and Tsallis entropy that for two independent random variables X and Y, Shannon entropy $S_1(X)$ has an additivity,

$$S_1(X \times Y) = S_1(X) + S_1(Y), \tag{2}$$

however, Tsallis entropy $S_q(X), (q \neq 1)$ has a pseudoadditivity,

a)Electronic mail: furuichi@ed.yama.tus.ac.jp

$$S_q(X \times Y) = S_q(X) + S_q(Y) + (1-q)S_q(X)S_q(Y), \tag{3}$$

where $S_q(X \times Y)$ is Tsallis joint entropy, which will be defined below, for the direct product $X \times Y$ of two independent random variables X and Y. The independence between X and Y physically means that there is no interaction between two systems X and Y. This pseudoadditivity of Tsallis entropy in Eq. (3) originally comes from that of q-logarithm function $\ln_q(x)$. We pay attention to whether an additivity [such as Eq. (2)] of entropies for two independent random variables holds or not [such as Eq. (3)]. An entropy is called a nonadditive entropy if it does not satisfy the additivity such as Eq. (2), while an entropy is called an additive entropy if it satisfies the additivity specified in Eq. (2). The entropy of type β introduced by Daróczy in Ref. 9 (also called the structural a-entropy introduced by Havrda and Charvát in Ref. 10),

$$H_\beta(X) \equiv \frac{\sum_x (p(x)^\beta - p(x))}{2^{1-\beta}-1} \quad (\beta > 0, \beta \neq 1)$$

is a nonadditive entropy.

We are now interested in Tsallis entropy which is a typical nonadditive entropy. From Eq. (3), we easily find that we have a subadditivity of Tsallis entropies for two independent random variables X and Y in the case of $q \geqslant 1$ since Tsallis entropy is nonnegative. In the first of the section III, we will review a subadditivity of Tsallis entropies for general random variables X and Y in the case of $q \geqslant 1$.

From the entropy theoretical point of view, for the related entropies such as Tsallis conditional entropy and Tsallis joint entropy were introduced in Refs. 11–13 and then some interesting relations between them were derived. In this paper, in order to derive the relation between them, we adopt the following definition of Tsallis conditional entropy and Tsallis joint entropy.

Definition 1.1: For the conditional probability $p(x|y) \equiv p(X=x|Y=y)$ and the joint probability $p(x,y) \equiv p(X=x, Y=y)$, we define Tsallis conditional entropy and Tsallis joint entropy by

$$S_q(X|Y) \equiv -\sum_{x,y} p(x,y)^q \ln_q p(x|y) \quad (q \neq 1) \tag{4}$$

and

$$S_q(X,Y) \equiv -\sum_{x,y} p(x,y)^q \ln_q p(x,y) \quad (q \neq 1). \tag{5}$$

We note that the above definitions were essentially introduced in Ref. 9 by

$$H_\beta(X,Y) \equiv \frac{\sum_{x,y} (p(x,y)^\beta - p(x,y))}{2^{1-\beta}-1} \quad (\beta > 0,\ \beta \neq 1),$$

$$H_\beta(X|Y) \equiv \sum_y p(y)^\beta H_\beta(X|y) \quad (\beta > 0,\ \beta \neq 1),$$

except for the difference of the multiplicative function. And then a chain rule and a subadditivity,

$$H_\beta(X,Y) = H_\beta(X) + H_\beta(Y|X),$$

$$H_\beta(Y|X) \leqslant H_\beta(Y), \quad \beta > 1,$$

were shown in Theorem 8 of Ref. 9. In this paper, we call the entropy defined by Eq. (1), Eq. (4) or Eq. (5) Tsallis type entropy. It is remarkable that Eq. (4) can be easily deformed by

$$S_q(X|Y) = \sum_y p(y)^q S_q(X|y). \tag{6}$$

Note that for $q \neq 1$ we have $S_q(X|Y) = \Sigma_y p(y)^q S_q(X) \neq S_q(X)$ when X and Y are indepentent each other (i.e., $p(x|y) = p(x)$ for all x and y). Eq. (6) can be further regarded that the following expectation value:

$$E_q(X) \equiv \sum_i p_i^q x_i$$

depending on the parameter q is adopted. Since the expectation value $E_q(X)$ has a crucial lack that it does not hold $E_q(1) = 1$ for $q \neq 1$ in general, a slightly modified definition, the normalized Tsallis entropies such as

$$S_q^{\mathrm{nor}}(X) \equiv \frac{-\sum_x p(x)^q \ln_q p(x)}{\sum_x p(x)^q} \quad (q \neq 1) \tag{7}$$

are sometimes used,[12,13] and then important and meaningful results in physics are derived for the normalized nonadditive conditional entropy defined in Refs. 6 and 12. However, as pointed out in Ref. 14, the normalized Tsallis entropies are not stable, but the original Tsallis entropies are stable as experimental quantities so that it is meaningful to study the original Tsallis entropies from the physical point of view. Inspired by these pioneering works,[6,12,14] we therefore study the information theoretical properties of the original Tsallis type entropies without normalization in this paper. As advantages in information theoretical study, our approach shows chain rules and subadditivities of the Tsallis entropies and then naturally leads to define the Tsallis mutual entropy. Finally the rough meaning of the parameter q of the Tsallis entropy is given from the information theoretical viewpoint. Both entropies defined in Eq. (4) and Eq. (5) recover the usual Shannon entropies as $q \to 1$.

In the past, some parametrically extended entropies were introduced in the mathematical point of view. Especially, the Rényi entropy[15,16] (see also Ref. 17),

$$R_q(X) = \frac{1}{1-q} \log \sum_x p(x)^q \quad (q \neq 1) \tag{8}$$

is famous. For Tsallis entropy and Rényi entropy, we have the following relation:

$$R_q(X) = \frac{1}{1-q} \log\{1 + (1-q) S_q(X)\} \quad (q \neq 1). \tag{9}$$

It is notable that Rényi entropy has an additivity,

$$R_q(X \times Y) = R_q(X) + R_q(Y), \tag{10}$$

for two independent random variables X and Y. Although there exsits a simple transformation between Tsallis entropy and Rényi entropy, they have a different structure in regards to the matter of their additivities.

This paper is organized as follows. In Sec. II, we review a chain rule given in Ref. 9 and give its generalized results. We also give the chain rule for Tsallis relative entropy. In Sec. III, we review a subadditivity given in Ref. 9 and give its generalized results. In addition, we show several inequalities related to Tsallis entropies. In Sec. IV, we introduce Tsallis mutual entropy and then give its fundamental properties. In Sec. V, we discuss entropic distances and correlation coefficients due to Tsallis entropies. In Sec. VI, we give some applications of Tsallis entropies in the context of information theory. Related remarks and discussions are given in Sec. VII.

II. CHAIN RULES FOR TSALLIS ENTROPIES

It is important to study the so-called chain rule which gives the relation between a conditional entropy and a joint entropy in not only information theory[18] but also statistical physics. For these Tsallis entropies, the following chain rule holds as similar as the chain rule holds for the joint entropy of type β and the conditional entropy of type β.

Proposition 2.1 (Ref. 9):

$$S_q(X,Y) = S_q(X) + S_q(Y|X). \tag{11}$$

[Therefore immediately $S_q(X) \leqslant S_q(X,Y)$.]

Proof: From the formulas $\ln_q(xy) = \ln_q x + x^{1-q} \ln_q y$ and $\ln_q(1/x) = -x^{q-1} \ln_q x$, we have

$$\begin{aligned} S_q(X,Y) &= \sum_x \sum_y p(x,y) \ln_q \frac{1}{p(x,y)} = \sum_x \sum_y p(x,y) \ln_q \frac{1}{p(x)p(y|x)} \\ &= \sum_x p(x) \ln_q \frac{1}{p(x)} + \sum_x \sum_y p(x,y) p(x)^{q-1} \ln_q \frac{1}{p(y|x)} \\ &= -\sum_x p(x)^q \ln_q p(x) - \sum_x p(x)^q \sum_y p(y|x)^q \ln_q p(y|x) \\ &= S_q(X) + S_q(Y|X). \end{aligned}$$

■

From the process of the proof of Proposition 2.1, we can easily find that if X and Y are independent [i.e., $p(y|x) = p(y)$ for all x and y], then Eq. (11) recovers the pseudoadditivity Eq. (3),

$$\begin{aligned} S_q(X,Y) &= -\sum_x p(x)^q \ln_q p(x) - \sum_x p(x)^q \sum_y p(y)^q \ln_q p(y) \\ &= S_q(X) + \sum_x p(x)^q S_q(Y) = S_q(X) + S_q(Y) + (1-q) S_q(X) S_q(Y). \end{aligned}$$

As a corollary of the above Proposition 2.1, we have the following lemma.

Lemma 2.2: The following chain rules hold:

(1) $S_q(X,Y,Z) = S_q(X,Y|Z) + S_q(Z)$,
(2) $S_q(X,Y|Z) = S_q(X|Z) + S_q(Y|X,Z)$.

Proof: By using $\ln_q(y/x) = \ln_q y + y^{1-q} \ln_q(1/x)$, we have

$$S_q(X,Y|Z) = S_q(X,Y,Z) - S_q(Z).$$

In the similar way, we have

$$S_q(Y|X,Z) = S_q(X,Y,Z) - S_q(X,Z).$$

Also from the Proposition 2.1, we have

$$S_q(X,Y) = S_q(X) + S_q(Y|X).$$

Therefore we have

$$S_q(Y|X,Z) = S_q(X,Y,Z) - S_q(X,Z) = S_q(X,Y|Z) + S_q(Z) - \{S_q(X|Z) + S_q(Z)\} = S_q(X,Y|Z) - S_q(X|Z).$$

■

From (2) of Lemma 2.2, we have

$$S_q(X|Z) \leqslant S_q(X,Y|Z). \tag{12}$$

Remark 2.3: (2) of Lemma 2.2 can be generalized in the following formula:

$$S_q(X_1, \ldots, X_n|Y) = \sum_{i=1}^{n} S_q(X_i|X_{i-1}, \ldots, X_1, Y). \tag{13}$$

Theorem 2.4: Let $X_1, X_2, \ldots, X_n$ be the random variables obeying the probability distribution $p(x_1, x_2, \ldots, x_n)$. Then we have the following chain rule:

$$S_q(X_1, X_2, \ldots, X_n) = \sum_{i=1}^{n} S_q(X_i|X_{i-1}, \ldots, X_1). \tag{14}$$

Proof: We prove the theorem by induction on n. From Proposition 2.1, we have

$$S_q(X_1, X_2) = S_q(X_1) + S_q(X_2|X_1).$$

Assuming that Eq. (14) holds for some n, from Eq. (11) we have

$$\begin{aligned} S_q(X_1, \ldots, X_{n+1}) &= S_q(X_1, \ldots, X_n) + S_q(X_{n+1}|X_1, \ldots, X_n) \\ &= \sum_{i=1}^{n} S_q(X_i|X_{i-1}, \ldots, X_1) + S_q(X_{n+1}|X_n, \ldots, X_1), \end{aligned}$$

which means Eq. (14) holds for $n+1$. ■

In the rest of this section, we discuss the chain rule for Tsallis relative entropy. To do so, we use Tsallis relative entropy

$$D_q(U|V) \equiv -\sum_x u(x) \ln_q \frac{v(x)}{u(x)}, \tag{15}$$

defined for two probability distributions $u(x)$ and $v(x)$, and $q \geqslant 0$. See Refs. 19–22 for details of Tsallis relative entropy. Equation (15) is equivalent to the following forms:

$$D_q(U|V) = \frac{\sum_x (u(x) - u(x)^q v(x)^{1-q})}{1-q} \tag{16}$$

$$= \sum_x u(x)^q v(x)^{1-q} \ln_q \frac{u(x)}{v(x)}. \tag{17}$$

Along the line of the definition of Tsallis conditional entropy Eq. (4), we naturally define Tsallis conditional relative entropy such as

$$D_q(u(y|x)|v(y|x)) \equiv \sum_{x,y} u(x,y)^q v(x,y)^{1-q} \ln_q \frac{u(y|x)}{v(y|x)} \tag{18}$$

$$= \sum_x u(x)^q v(x)^{1-q} \sum_y u(y|x)^q v(y|x)^{1-q} \ln_q \frac{u(y|x)}{v(y|x)} \tag{19}$$

for two joint probability distributions $u(x,y)$ and $v(x,y)$, and two conditional probability distributions $u(y|x)$ and $v(y|x)$, based on the view of Eq. (17), neither Eq. (15) nor Eq. (16). Taking the limit as $q \to 1$, Eq. (18) recovers the usual conditional relative entropy. Then we have the following chain rule of Tsallis relative entropy for general (possibly *not* independent) case.

Theorem 2.5 (chain rule for Tsallis relative entropy):

$$D_q(u(x,y)|v(x,y)) = D_q(u(x)|v(x)) + D_q(u(y|x)|v(y|x)). \tag{20}$$

Proof: The proof follows by the direct calculations:

$$\begin{aligned}
D_q(u(x,y)|v(x,y)) &= -\sum_{x,y} u(x,y)\ln_q \frac{v(x,y)}{u(x,y)} = -\sum_{x,y} u(x,y)\ln_q \frac{v(x)v(y|x)}{u(x)u(y|x)} \\
&= -\sum_{x,y} u(x,y)\left\{ \ln_q \frac{v(x)}{u(x)} + \ln_q \frac{v(y|x)}{u(y|x)} + (1-q)\ln_q \frac{v(x)}{u(x)} \ln_q \frac{v(y|x)}{u(y|x)} \right\} \\
&= -\sum_{x,y} u(x,y)\left\{ \ln_q \frac{v(x)}{u(x)} + \left\{ \frac{u(x)}{v(x)} \right\}^{q-1} \ln_q \frac{v(y|x)}{u(y|x)} \right\} \\
&= D_q(u(x)|v(x)) - \sum_{x,y} \left\{ \frac{u(x)}{v(x)} \right\}^{q-1} u(x,y)\ln_q \frac{v(y|x)}{u(y|x)}. \\
&= D_q(u(x)|v(x)) + D_q(u(y|x)|v(y|x)).
\end{aligned}$$

■

Taking the limit as $q \to 1$, Theorem 2.5 recovers Theorem 2.5.3 in Ref. 18. It is known that for $u(y|x)=u(y)$ and $v(y|x)=v(y)$, Tsallis relative entropy has a pseudoadditivity,

$$D_q(u(x)u(y)|v(x)v(y)) = D_q(u(x)|v(x)) + D_q(u(y)|v(y)) + (q-1)D_q(u(x)|v(x))D_q(u(y)|v(y)). \tag{21}$$

From the process of the above proof, we find that the chain rule Eq. (20) recovers the pseudoadditivity Eq. (21) when $u(y|x)=u(y)$ and $v(y|x)=v(y)$.

III. SUBADDITIVITIES FOR TSALLIS ENTROPIES

From Eq. (3), for $q \geqslant 1$ and two independent random variables X and Y, the subadditivity holds,

$$S_q(X \times Y) \leqslant S_q(X) + S_q(Y).$$

It is known that the subadditivity for general random variables X and Y holds in the case of $q \geqslant 1$, thanks to the following proposition.

Proposition 3.1 (Ref. 9): The following inequality holds for two random variables X and Y, and $q \geqslant 1$,

$$S_q(X|Y) \leqslant S_q(X), \tag{22}$$

with equality if and only if $q=1$ and $p(x|y)=p(x)$ for all x and y.

Proof: We give the similar proof given in Ref. 9 as a version of Tsallis type entropies for the convenience of the reader. We define the function $\mathrm{Ln}_q(x) \equiv (x^q - x)/(1-q)$ for $q \geqslant 0$, $q \neq 1$, and $x \geqslant 0$. Then the function Ln_q is non-negative for $0 \leqslant x \leqslant 1, q > 1$ and concave in x for $q > 0, q \neq 1$. By the concavity of Ln_q, we have

$$\sum_y p(y)\mathrm{Ln}_q(p(x|y)) \leqslant \mathrm{Ln}_q\left(\sum_y p(y)p(x|y) \right).$$

Taking the summation of both sides on the above inequality on x, we have

$$\sum_y p(y) \sum_x \mathrm{Ln}_q(p(x|y)) \leqslant \sum_x \mathrm{Ln}_q(p(x)). \tag{23}$$

Since $p(y)^q \leqslant p(y)$ for any y and $q > 1$, and $\mathrm{Ln}_q(t) \geqslant 0$ for any $t \geqslant 0$ and $q > 1$, we have

$$p(y)^q \sum_x \mathrm{Ln}_q(p(x|y)) \leqslant p(y) \sum_x \mathrm{Ln}_q(p(x|y)).$$

Taking the summation of both sides on the above inequality on y, we have

$$\sum_y p(y)^q \sum_x \mathrm{Ln}_q(p(x|y)) \leqslant \sum_y p(y) \sum_x \mathrm{Ln}_q(p(x|y)). \tag{24}$$

By Eq. (23) and Eq. (24), we have

$$\sum_y p(y)^q \sum_x \mathrm{Ln}_q(p(x|y)) \leqslant \sum_x \mathrm{Ln}_q(p(x)).$$

Therefore we have $S_q(X|Y) \leqslant S_q(X)$. The equality holds when $q=1$ and $p(x|y)=p(x)$, which means X and Y are independent from each other. Thus the proof of the proposition was completed. ■

Equations (22) and (11) imply the subadditivity of Tsallis entropies.

Theorem 3.2 (Ref. 9): For $q \geqslant 1$, we have

$$S_q(X,Y) \leqslant S_q(X) + S_q(Y). \tag{25}$$

From Eq. (22) and Theorem 2.4, we have the following extended relation which is often called *independence bound on entropy* in information theory.

Theorem 3.3: Let $X_1, X_2, \ldots, X_n$ be the random variables obeying the probability distribution $p(x_1, x_2, \ldots, x_n)$. Then for $q \geqslant 1$, we have

$$S_q(X_1, \ldots, X_n) \leqslant \sum_{i=1}^{n} S_q(X_i) \tag{26}$$

with equality if and only if $q=1$ the random variables are independent from each other.

On the other hand, we easily find that for two independent random variables X and Y, and $0 \leqslant q < 1$, the superadditivity holds,

$$S_q(X \times Y) \geqslant S_q(X) + S_q(Y).$$

However, in general the superadditivity for two correlated random variables X and Y, and $0 \leqslant q < 1$ does not hold. Because we can show many counterexamples. For example, we consider the following joint distribution of X and Y:

$$p(x_1,y_1) = p(1-x), \quad p(x_1,y_2) = (1-p)y, \quad p(x_2,y_1) = px, \quad p(x_2,y_2) = (1-p)(1-y), \tag{27}$$

where $0 \leqslant p, x, y \leqslant 1$. Then each marginal distribution can be computed by

$$p(x_1) = p(1-x) + (1-p)y, \quad p(x_2) = px + (1-p)(1-y), \quad p(y_1) = p, \quad p(y_2) = 1-p. \tag{28}$$

In general, we clearly see X and Y are not independent from each other for the above example. Then the value of $\Delta \equiv S_q(X,Y) - S_q(X) - S_q(Y)$ takes both positive and negative so that there does not exist the complete ordering between $S_q(X,Y)$ and $S_q(X)+S_q(Y)$ for correlated X and Y in the case of $0 \leqslant q < 1$. Indeed, $\Delta = -0.287\,089$ when $q=0.8$, $p=0.6$, $x=0.1$, $y=0.1$, while $\Delta = 0.056\,2961$ when $q=0.8$, $p=0.6$, $x=0.1$, $y=0.9$.

Up to the above discussions, we have the possibility that the strong subadditivity holds in the case of $q \geqslant 1$. Indeed we can prove the following strong subadditivity for Tsallis type entropies.

Theorem 3.4: For $q \geqslant 1$, the strong subadditivity

$$S_q(X,Y,Z) + S_q(Z) \leqslant S_q(X,Z) + S_q(Y,Z) \tag{29}$$

holds with equality if and only if $q=1$ and, random variables X and Y are independent for a given random variable Z.

Proof: Theorem is proven by the similar way of Proposition 3.1. By the concavity of Ln_q, we have

$$\sum_y p(y|z)\mathrm{Ln}_q(p(x|y,z)) \leqslant \mathrm{Ln}_q\left(\sum_y p(y|z)p(x|y,z)\right).$$

Multiplying $p(z)^q$ to the both sides of the above inequality and then taking the summation on z and x, we have

$$\sum_{y,z} p(z)^q p(y|z)\sum_x \mathrm{Ln}_q(p(x|y,z)) \leqslant \sum_z p(z)^q \sum_x \mathrm{Ln}_q(p(x|z)) \tag{30}$$

since $\Sigma_y p(y|z)p(x|y,z)=p(x|z)$.

For any y, z and $q \geqslant 1$, we have $p(y|z)^q \leqslant p(y|z)$. Then by the non-negativity of the function Ln_q, we have

$$p(y|x)^q \sum_x \mathrm{Ln}_q(p(x|y,z)) \leqslant p(y|z)\sum_x \mathrm{Ln}_q(p(x|y,z)).$$

Multiplying $p(z)^q$ to both sides of the above inequality and then taking the summation on y and z, we have

$$\sum_{y,z} p(z)^q p(y|x)^q \sum_x \mathrm{Ln}_q(p(x|y,z)) \leqslant \sum_{y,z} p(z)^q p(y|z)\sum_x \mathrm{Ln}_q(p(x|y,z)). \tag{31}$$

From Eq. (30) and Eq. (31), we have

$$\sum_{y,z} p(y,z)^q \sum_x \mathrm{Ln}_q(p(x|y,z)) \leqslant \sum_z p(z)^q \sum_x \mathrm{Ln}_q(p(x|z)).$$

Thus we have

$$S_q(X|Y,Z) \leqslant S_q(X|Z), \tag{32}$$

which implies

$$S_q(X,Y,Z) - S_q(Y,Z) \leqslant S_q(X,Z) - S_q(Z),$$

by chain rules. The equality holds when $q=1$ and $p(x|y,z)=p(x|z)$, which means X and Y are independent from each other for a given Z. ■

We find that Eq. (29) recovers Eq. (25), by taking the random variable Z as a trivial one. This means that Eq. (29) is a generalization of Eq. (25). We have the further generalized inequality by the similar way of the proof of Theorem 3.4.

Theorem 3.5: Let $X_1, \ldots, X_{n+1}$ be the random variables. For $q>1$, we have

$$S_q(X_{n+1}|X_1, \ldots, X_n) \leqslant S_q(X_{n+1}|X_2, \ldots, X_n). \tag{33}$$

The subadditivity for Tsallis entropies conditioned by Z holds.

Proposition 3.6: For $q \geqslant 1$, we have

$$S_q(X,Y|Z) \leqslant S_q(X|Z) + S_q(Y|Z). \tag{34}$$

Proof: Summing $-2S_q(Z)$ to both sides in Eq. (29), we have

$$S_q(X,Y,Z) - S_q(Z) \leqslant S_q(X,Z) - S_q(Z) + S_q(Y,Z) - S_q(Z).$$

By chain rules, we have the proposition. ■

Proposition 3.6 can be generalized in the following.

Theorem 3.7: For $q \geqslant 1$, we have

$$S_q(X_1, \ldots, X_n|Z) \leqslant S_q(X_1|Z) + \cdots + S_q(X_n|Z). \tag{35}$$

In addition, we have the following propositions.

Proposition 3.8: For $q \geqslant 1$, we have

$$2S_q(X,Y,Z) \leqslant S_q(X,Y) + S_q(Y,Z) + S_q(Z,X).$$

Proof: For Eq. (22) and Eq. (32), we have

$$S_q(X|Y,Z) \leqslant S_q(X),$$

and

$$S_q(Z|X,Y) \leqslant S_q(Z|X).$$

Thus we have

$$S_q(X|Y,Z) + S_q(Z|X,Y) \leqslant S_q(X) + S_q(Z|X).$$

By chain rules, we have

$$S_q(X,Y,Z) - S_q(X,Y) + S_q(X,Y,Z) - S_q(Y,Z) \leqslant S_q(Z,X),$$

which implies the proposition. ■

Proposition 3.9: For $q > 1$, we have

$$S_q(X_n|X_1) \leqslant S_q(X_2|X_1) + \cdots + S_q(X_n|X_{n-1}).$$

Proof: From Eq. (14) and Eq. (32), we have

$$S_q(X_1, \ldots, X_n) \leqslant S_q(X_1) + S_q(X_2|X_1) + \cdots S_q(X_n|X_{n-1}).$$

Therefore we have

$$S_q(X_n|X_1) \leqslant S_q(X_2, \ldots, X_n|X_1) = S_q(X_1, \ldots, X_n) - S_q(X_1) \leqslant S_q(X_2|X_1) + \cdots + S_q(X_n|X_{n-1}),$$

by Eq. (11) and Eq. (12).

IV. TSALLIS MUTUAL ENTROPY

For normalized Tsallis entropies, the mutual information was defined in Ref. 13 with the assumption of its non-negativity. We define the Tsallis mutual entropy in terms of the original (*not* normalized) Tsallis type entropies. The inequality Eq. (22) naturally leads us to define Tsallis mutual entropy without the assumption of its non-negativity.

Definition 4.1: For two random variables X and Y, and $q > 1$, we define the Tsallis mutual entropy as the difference between Tsallis entropy and Tsallis conditional entropy such that

$$I_q(X;Y) \equiv S_q(X) - S_q(X|Y). \tag{36}$$

Note that we never use the term *mutual information* but use mutual entropy through this paper, since a proper evidence of channel coding theorem for information transmission has not ever been shown in the context of Tsallis statistics. From Eq. (11), Eq. (25), and Eq. (22), we easily find that $I_q(X;Y)$ has the following fundamental properties.

Proposition 4.2: (1) $0 \leqslant I_q(X;Y) \leqslant \min\{S_q(X), S_q(Y)\}$.

(2) $I_q(X;Y) = S_q(X) + S_q(Y) - S_q(X,Y) = I_q(Y;X)$.

Note that we have

$$S_q(X) \leqslant S_q(Y) \Leftrightarrow S_q(X|Y) \leqslant S_q(Y|X) \tag{37}$$

from the symmetry of Tsallis mutual entropy. We also define the Tsallis conditional mutual entropy

$$I_q(X;Y|Z) \equiv S_q(X|Z) - S_q(X|Y,Z) \tag{38}$$

for three random variables X, Y, and Z, and $q>1$.

In addition, $I_q(X;Y|Z)$ is non-negative, thanks to Eq. (32). For these quantities, we have the following chain rules.

Theorem 4.3: (1) For three random variables X, Y, and Z, and $q>1$, the chain rule holds,

$$I_q(X;Y,Z) = I_q(X;Z) + I_q(X;Y|Z). \tag{39}$$

(2) For random variables $X_1, \ldots, X_n$ and Y, the chain rule holds,

$$I_q(X_1, \ldots, X_n;Y) = \sum_{i=1}^{n} I_q(X_i;Y|X_1, \ldots, X_{i-1}). \tag{40}$$

Proof: (1) follows from the chain rules of Tsallis entropy,

$$I_q(X;Y|Z) = S_q(X|Z) - S_q(X|Y,Z) = S_q(X|Z) - S_q(X) + S_q(X) - S_q(X|Y,Z) = -I_q(X;Z) + I_q(X;Y,Z).$$

(2) follows from the application of Eq. (14) and Eq. (13),

$$\begin{aligned} I_q(X_1, \ldots, X_n;Y) &= S_q(X_1, \ldots, X_n) - S_q(X_1, \ldots, X_n|Y) \\ &= \sum_{i=1}^{n} S_q(X_i|X_{i-1}, \ldots, X_1) - \sum_{i=1}^{n} S_q(X_i|X_{i-1}, \ldots, X_1, Y) \\ &= \sum_{i=1}^{n} I_q(X_i;Y|X_1, \ldots, X_{i-1}). \end{aligned}$$

■

We have the following inequality for Tsallis mutual entropies by the strong subadditivity.

Proposition 4.4: For $q>1$, we have

$$I_Q(X;Z) \leqslant I_Q(X,Y;Z).$$

V. CORRELATION COEFFICIENTS AND DISTANCES FOR TSALLIS ENTROPIES

We discuss on the entropic distance between X and Y by means of Tsallis conditional entropy $S_q(X|Y)$. If $S_q(X|Y)=0=S_q(Y|X)$, then X and Y are called *equivalence* and denoted by $X \equiv Y$. Defining an entropic distance between X and Y as

$$d_q(X,Y) \equiv S_q(X|Y) + S_q(Y|X), \tag{41}$$

we have the following proposition.

Proposition 5.1: For $q>1$, d_q satisfies

(i) $d_q(X,Y)=0$ if and only if $X \equiv Y$,
(ii) $d_q(X,Y)=d_q(Y,X)$,
(iii) $d_q(X,Z) \leqslant d_q(X,Y)+d_q(Y,Z)$.

Proof: (i) and (ii) are clear from the definition of d_q. In the case of $n=3$ in Proposition 3.9, we have the triangle inequality:

$$S_q(X_3|X_1) \leqslant S_q(X_2|X_1) + S_q(X_3|X_2).$$

Setting $X_1=Z$, $X_2=Y$ and $X_3=X$ in the above inequality, we have

$$S_q(X|Z) \leqslant S_q(Y|Z) + S_q(X|Y). \tag{42}$$

In addition, exchanging X and Z in the above inequality, we have

$$S_q(Z|X) \leqslant S_q(Y|X) + S_q(Z|Y).$$

Summing both sides of the two above inequalities, we have the proposition. ■

$I_q(X;Y)$ represents a kind of correlation between X and Y. Following Ref. 23, we define a parametrically extended correlation coefficient in terms of Tsallis mutual entropy such that

$$\rho_q(X,Y) \equiv \frac{I_q(X;Y)}{S_q(X,Y)} \tag{43}$$

for $S_q(X)>0$, $S_q(Y)>0$, and $q>1$. Then we have the following proposition.

Proposition 5.2: For $q>1$, $S_q(X)>0$, and $S_q(Y)>0$, we have the following properties:

(i) $\rho_q(X,Y)=\rho_q(Y,X)$,
(ii) $0\leqslant\rho_q(X,Y)\leqslant 1$,
(iii) $\rho_q(X,Y)=0$ if and only if X and Y are independent of each other and $q=1$,
(iv) $\rho_q(X,Y)=1$ if and only if $X\equiv Y$.

Proof: (i) is clear from the definition of ρ_q. (ii) follows from $0\leqslant I_q(X;Y)\leqslant S_q(X)\leqslant S_q(X,Y)$. (iii) follows from Proposition 3.1. (iv) follows from $I_q(X;Y)=S_q(X,Y)\Leftrightarrow S_q(X|Y)=S_q(Y|X)=0$. ■

Again, we define an entropic distance between X and Y by

$$\tilde{d}_q(X,Y) \equiv 1 - \rho_q(X,Y). \tag{44}$$

Then we have the following proposition.

Proposition 5.3: For $q>1$, $S_q(X)>0$, $S_q(Y)>0$, and $S_q(Z)>0$, we have the following properties:

(i) $\tilde{d}_q(X,Y)=0$ if and only if $X\equiv Y$,
(ii) $\tilde{d}_q(X,Y)=\tilde{d}_q(Y,X)$,
(iii) $\tilde{d}_q(X,Z)\leqslant\tilde{d}_q(X,Y)+\tilde{d}_q(Y,Z)$.

Proof: (i) and (ii) follows from (iv) and (i) of Proposition 5.2, respectively. From chain rules and Eq. (42), we have

$$\begin{aligned}\frac{S_q(X|Z)}{S_q(X,Z)} &= \frac{S_q(X|Z)}{S_q(X|Z)+S_q(Z)} \leqslant \frac{S_q(X|Y)+S_q(Y|Z)}{S_q(X|Y)+S_q(Y|Z)+S_q(Z)} \\ &= \frac{S_q(X|Y)}{S_q(X|Y)+S_q(Y|Z)+S_q(Z)} + \frac{S_q(Y|Z)}{S_q(X|Y)+S_q(Y|Z)+S_q(Z)} \\ &\leqslant \frac{S_q(X|Y)}{S_q(X|Y)+S_q(Z)} + \frac{S_q(Y|Z)}{S_q(Y|Z)+S_q(Z)} = \frac{S_q(X|Y)}{S_q(X,Y)} + \frac{S_q(Y|Z)}{S_q(Y,Z)}.\end{aligned} \tag{45}$$

Exchanging X and Z, we have

$$\frac{S_q(Z|X)}{S_q(Z,X)} \leqslant \frac{S_q(Z|Y)}{S_q(Z,Y)} + \frac{S_q(Y|X)}{S_q(Y,X)}. \tag{46}$$

Summing both sides of two inequalities Eq. (45) and Eq. (46), we have (iii), since Tsallis joint entropy is symmetry. ■

We also define another correlation coefficient in terms of Tsallis mutual entropy by

$$\hat{\rho}_q(X,Y) \equiv \frac{I_q(X;Y)}{\max\{S_q(X),S_q(Y)\}} \tag{47}$$

for $S_q(X)>0$, $S_q(Y)>0$, and $q>1$. See Ref. 24. Then we have the following proposition.

Proposition 5.4: For $q>1$, $S_q(X)>0$, and $S_q(Y)>0$, we have the following properties:

(i) $\hat{\rho}_q(X,Y)=\hat{\rho}_q(Y,X)$,
(ii) $0\leqslant\hat{\rho}_q(X,Y)\leqslant 1$,
(iii) $\hat{\rho}_q(X,Y)=0$ if and only if X and Y are independent each other and $q=1$,
(iv) $\hat{\rho}_q(X,Y)=1$ if and only if $X\equiv Y$.

Proof: (i)–(iv) follow straightforwardly. ■

We also define an entropic distance between X and Y by

$$\hat{d}_q(X,Y) \equiv 1-\hat{\rho}_q(X,Y). \tag{48}$$

Then we have the following proposition.

Proposition 5.5: For $q>1$, $S_q(X)>0$, $S_q(Y)>0$, and $S_q(Z)>0$, we have the following properties:

(i) $\hat{d}_q(X,Y)=0$ if and only if $X\equiv Y$,
(ii) $\hat{d}_q(X,Y)=\hat{d}_q(Y,X)$,
(iii) $\hat{d}_q(X,Z)\leqslant\hat{d}_q(X,Y)+\hat{d}_q(Y,Z)$.

Proof: (i) and (ii) follows from Proposition 5.4. (iii) is proven by the similar way in Ref. 24. In order to show (iii), we can assume $S_q(Z)\leqslant S_q(X)$ without loss of generality. Then we prove (iii) in the following three cases.

(a) $S_q(Y)\leqslant S_q(Z)\leqslant S_q(X)$: From Eq. (37) and Eq. (42) we have

$$\begin{aligned}\hat{d}_q(X,Z) &= \frac{S_q(X|Z)}{S_q(X)} \leqslant \frac{S_q(X|Y)}{S_q(X)} + \frac{S_q(Y|Z)}{S_q(X)} \leqslant \frac{S_q(X|Y)}{S_q(X)} + \frac{S_q(Y|Z)}{S_q(Z)} \leqslant \frac{S_q(X|Y)}{S_q(X)} + \frac{S_q(Z|Y)}{S_q(Z)} \\ &= \hat{d}_q(X,Y) + \hat{d}_q(Y,Z).\end{aligned}$$

(b) $S_q(Z)\leqslant S_q(X)\leqslant S_q(Y)$: It is shown as similar as (a).
(c) $S_q(Y)\leqslant S_q(Z)\leqslant S_q(X)$: From Eq. (42), we have

$$\begin{aligned}\hat{d}_q(X,Z) &= \frac{S_q(X|Z)}{S_q(X)} = 1-\left(1-\frac{S_q(X|Z)}{S_q(X)}\right) \leqslant 1-\frac{S_q(X)}{S_q(Y)}\left(1-\frac{S_q(X|Z)}{S_q(X)}\right) \\ &= \frac{S_q(Y)-S_q(X)+S_q(X|Z)}{S_q(Y)} \leqslant \frac{S_q(Y)-S_q(X)+S_q(X|Y)+S_q(Y|Z)}{S_q(Y)} \\ &= \hat{d}_q(X,Y)+\hat{d}_q(Y,Z).\end{aligned}$$

■

VI. APPLICATIONS OF TSALLIS ENTROPIES

A. Generalized Fano's inequality

As an application of Tsallis conditional entropy, we give a generalized Fano's inequality.

Theorem 6.1: For $q>1$ and two random variables taking values in the finite (alphabet) set $\mathcal{X}$, the following inequality holds:

$$S_q(X|Y) \leqslant P(X \neq Y)\ln_q(|\mathcal{X}|-1) + s_q(P(X \neq Y)),$$

where s_q represents the Tsallis binary entropy,

$$s_q(p) \equiv -p^q \ln_q p - (1-p)^q \ln_q(1-p).$$

Proof: Define the random variables Z by

$$Z = \begin{cases} 0 & \text{if } X = Y, \\ 1 & \text{if } X \neq Y. \end{cases}$$

By chain rules, $S(Z|X,Y)=0$ and $S_q(Z|Y) \leqslant S_q(Z)=s_q(P(X \neq Y))$, we then have

$$\begin{aligned} S_q(X|Y) &= S_q(X|Y) + S_q(Z|X,Y) = S_q(X,Z|Y) = S_q(X|Y,Z) + S_q(Z|Y) \leqslant S_q(X|Y,Z) + S_q(Z) \\ &= S_q(X|Y=y,Z=0) + S_q(X|Y=y,Z=1) + s_q(P(X \neq Y)) \\ &= S_q(X|Y=y,Z=1) + s_q(P(X \neq Y)) \leqslant \ln_q(X \neq Y) + s_q(P(X \neq Y)), \end{aligned}$$

since the non-negativity of Tsallis relative entropy implies $-\Sigma_{i=1}^{n} p_i^q \ln_q p_i \leqslant \ln_q n$. ■

B. Entropy rate for Tsallis entropy

Moreover, we discuss on the Tsallis entropy rate.

Definition 6.2: The Tsallis entropy rate of a stochastic process $\mathbf{X} \equiv \{X_i\}$ is defined by

$$S_q(\mathbf{X}) \equiv \lim_{n\to\infty} \frac{S_q(X_1, \ldots, X_n)}{n}$$

if the limit exists.

$S_q(\mathbf{X})$ can be considered as Tsallis entropy per a symbol in the limit.

Theorem 6.3: For $q>1$ and a stationary stochastic process, the Tsallis entropy rate exists and is expressed by

$$S_q(\mathbf{X}) = \lim_{n\to\infty} S_q(X_n|X_1, \ldots, X_{n-1}).$$

Proof: By the stationary process and the inequality Eq. (33), we have

$$S_q(X_n|X_1, \ldots, X_{n-1}) = S_q(X_{n+1}|X_2, \ldots, X_n) \geqslant S_q(X_{n+1}|X_1, X_2, \ldots, X_n).$$

Thus $S_q(X_n|X_1, \ldots, X_{n-1})$ converges to a certain value s, since it is a monotone decreasing sequence with respect to n. That is,

$$\lim_{n\to\infty} S_q(X_n|X_1, \ldots, X_{n-1}) = s.$$

Moreover by the chain rule and Cesáro's theorem (e.g., see p. 64 of Ref. 18), we have

$$S_q(\mathbf{X}) \equiv \lim_{n\to\infty} \frac{S_q(X_1, \ldots, X_n)}{n} = \lim_{n\to\infty} \sum_{i=1}^{n} \frac{S_q(X_i|X_1, \ldots, X_{i-1})}{n} = s.$$

■

C. Generalized data processing inequality

Finally we prove the data processing inequality for Tsallis mutual entropy. Let X, Y, and Z be random variables. If the conditional probability distribution of the random variable Z depends only on the random variable Y, namely the random variable Z is independent of the random variable X, then it is called that X, Y, and Z form a simple Markov chain, and denoted by $X \to Y \to Z$.

Theorem 6.4: If $X \to Y \to Z$, then we have the inequality

$$I_q(X;Z) \leqslant I_q(X;Y) \tag{49}$$

for $q>1$, with equality if and only if $X \to Z \to Y$.

Proof: From Eq. (39), $I_q(X;Y,|Z)$ can be expanded in the following two ways:

$$I_q(X;Y) + I_q(X;Z|Y) = I_q(X;Y,Z) = I_q(X;Z) + I_q(X;Y|Z). \tag{50}$$

Since the non-negativity $I_q(X;Y|Z)$ and $I_q(X;Z|Y)=0$ because of the Markovity, we have $I_q(X;Z) \leqslant I_q(X;Y)$. If $I_q(X;Y|Z)=0$, namely $X \to Z \to Y$, then we have $I_q(X;Z)=I_q(X;Y)$. ■

We easily find that the following corollary holds.

Corollary 6.5: (1) If $Z=f(Y)$ with a certain mapping f, then $I_q(X;f(Y)) \leqslant I_q(X;Y)$, with equality if and only if f is a one-to-one mapping. (2) If $X \to Y \to Z$, then $I_q(X;Y|Z) \leqslant I_q(X;Y)$.

VII. REMARKS AND DISCUSSIONS

A. Chain rule and subadditivity for nonadditive entropies

In Ref. 7, the nonadditive entropies including Tsallis entropy and the entropy of type β was axiomatically characterized by the generalized Shannon-Khinchin axiom in the following manner. The function $\widetilde{S}_q(x_1,\ldots,x_n)$ is assumed to be defined for the n-tuple $(x_1,\ldots,x_n)$ belonging to

$$\Delta_n \equiv \left\{ (p_1,\ldots,p_n) | \sum_{i=1}^{n} p_i = 1, p_i \geqslant 0 (i=1,2,\ldots,n) \right\}$$

and to take a value in $R^+ \equiv [0,\infty)$. Then it was shown in Ref. 7 that four conditions *continuity, maximality, generalized Shannon additivity*, and *expandability* in Ref. 7 determine the function $\widetilde{S}_q : \Delta_n \to R^+$ such that

$$\widetilde{S}_q(x_1,\ldots,x_n) = \frac{\sum_{i=1}^{n} (x_i^q - x_i)}{\phi(q)}, \tag{51}$$

where $\phi(q)$ is characterized by the following conditions:

(i) $\phi(q)$ is continuous and $\phi(q)(1-q)>0$ for $q \neq 1$,
(ii) $\lim_{q\to 1} \phi(q)=0$ and $\phi(q) \neq 0$ for $q \neq 1$,
(iii) there exists $(a,b) \subset R^+$ such that $a<1<b$ and $\phi(q)$ is differentiable on $(a,1)$ and $(1,b)$,
(iv) there exists a positive constant number k such that $\lim_{q\to 1}[\mathrm{d}\phi(q)/\mathrm{d}q]=-1/k$.

Simple calculations show the nonextensivity

$$\widetilde{S}_q(X \times Y) = \widetilde{S}_q(X) + \widetilde{S}_q(Y) + \phi(q)\widetilde{S}_q(X)\widetilde{S}_q(Y)$$

for the nonadditive entropy $\widetilde{S}_q$. From the view of the generalization Eq. (51), we have the following chain rule.

Lemma 7.1: For the nonadditive entropy

$$\widetilde{S}_q(X) \equiv \frac{\sum_x (p(x)^q - p(x))}{\phi(q)}$$

and any continuous function $\phi(q)$, we have the chain rule

$$\widetilde{S}_q(X,Y) = \widetilde{S}_q(X) + \widetilde{S}_q(Y|X),$$

where the nonadditive joint entropy and the nonadditive conditional entropy are defined by

$$\widetilde{S}_q(X,Y) \equiv \frac{\sum_{x,y} (p(x,y)^q - p(x,y))}{\phi(q)}$$

and

$$\widetilde{S}_q(X|Y) \equiv \sum_y p(y)^q \widetilde{S}_q(X|y) = \sum_y p(y)^q \left\{ \frac{\sum_x (p(x|y)^q - p(x|y))}{\phi(q)} \right\},$$

respectively.

Proof: It follows immediately,

$$\widetilde{S}_q(Y|X) = \frac{\sum_{y,x} p(x)^q p(y|x)^q - \sum_x p(x)^q}{\phi(q)} = \frac{\sum_{x,y} (p(x,y)^q - p(x,y))}{\phi(q)} - \frac{\sum_x (p(x)^q - p(x))}{\phi(q)}$$
$$= \widetilde{S}_q(X,Y) - \widetilde{S}_q(X).$$

■

From the view of the generalization Eq. (51), Proposition 3.1 also generalized as follows.

Lemma 7.2: For the nonadditive entropy $\widetilde{S}_q(X)$ where $\phi(q)$ is continuous and $\phi(q)(1-q) > 0$ for $q \neq 1$, we have the inequality

$$\widetilde{S}_q(X|Y) \leqslant \widetilde{S}_q(X).$$

Proof: Since the function $\widetilde{\mathrm{Ln}}_q(x) \equiv (x^q - x)/\phi(q)$, $(q \geqslant 0, q \neq 1, x \geqslant 0)$ is non-negative for $0 \leqslant x \leqslant 1, q > 1$ and concave in x for $q > 0, q \neq 1$, the theorem follows as similar as the proof of Proposition 3.1. ■

Form Lemma 7.1 and Lemma 7.2, we have the subadditivity for nonadditive entropy.

Theorem 7.3. (Subadditivity for nonadditive entropy): For the nonadditive entropy $\widetilde{S}_q(X)$ where $\phi(q)$ is continuous and $\phi(q)(1-q) > 0$ for $q \neq 1$, we have the subadditivity

$$\widetilde{S}_q(X,Y) \leqslant \widetilde{S}_q(X) + \widetilde{S}_q(Y).$$

We note that we need the condition that $\phi(q)(1-q) > 0$ for $q \neq 1$ to prove Lemma 7.2, while we do not need any condition to prove Lemma 7.1.

B. Inequalities on pseudoadditivity

The pseudoadditivity Eq. (3) for independent random variables X and Y gives rise to the mathematical interest whether we have the complete ordering between the left-hand side and the right-hand side in Eq. (3) for two general random variables X and Y. Such a kind of problem was taken in the paper[25] for the normalized Tsallis type entropies which are different from the definitions of the Tsallis type entropies in the present paper. However, its inequality appeared in (3.5) of Ref. 25 was not true as we found the counter example in Ref. 26.

Unfortunately, in the present case, we also find the counter example for the inequalities between $S_q(X,Y)$ and $S_q(X) + S_q(Y) + (1-q)S_q(X)S_q(Y)$. In the same setting of Eq. (27) and Eq.

(28), $\delta \equiv S_q(X,Y) - \{S_q(X) + S_q(Y) + (1-q)S_q(X)S_q(Y)\}$ takes both positive and negative values for both cases $0 \leqslant q < 1$ and $q > 1$. Indeed, $\delta = 0.008\,466\,51$ when $q=1.8$, $p=0.1$, $x=0.1$, $y=0.8$, while $\delta = -0.011\,8812$ when $q=1.8$, $p=0.1$, $x=0.8$, $y=0.1$. Also, $\delta = 0.003\,990\,69$ when $q=0.8$, $p=0.1$, $x=0.8$, $y=0.1$, while $\delta = -0.012\,8179$ when $q=0.8$, $p=0.1$, $x=0.1$, $y=0.8$.

Therefore there does not exist the complete ordering between $S_q(X,Y)$ and $S_q(X)+S_q(Y)+(1-q)S_q(X)S_q(Y)$ for both cases $0 \leqslant q < 1$ and $q > 1$.

C. A remarkable inequality derived from subadditivity for Tsallis entropies

From Eq. (25), we have the following inequality:

$$\sum_{i=1}^{n} \left(\sum_{j=1}^{m} p_{ij} \right)^r + \sum_{j=1}^{m} \left(\sum_{i=1}^{n} p_{ij} \right)^r \leqslant \sum_{i=1}^{n} \sum_{j=1}^{m} p_{ij}^r + \left(\sum_{i=1}^{n} \sum_{j=1}^{m} p_{ij} \right)^r \tag{52}$$

for $r \geqslant 1$ and p_{ij} satisfying $0 \leqslant p_{ij} \leqslant 1$ and $\Sigma_{i=1}^{n} \Sigma_{j=1}^{m} p_{ij} = 1$. By setting $p_{ij} = a_{ij} / \Sigma_{i=1}^{n} \Sigma_{j=1}^{m} a_{ij}$ in Eq. (52), we have the following inequality as a corollary of Theorem 3.2.

Corollary 7.4: For $r \geqslant 1$ and $a_{ij} \geqslant 0$,

$$\sum_{i=1}^{n} \left(\sum_{j=1}^{m} a_{ij} \right)^r + \sum_{j=1}^{m} \left(\sum_{i=1}^{n} a_{ij} \right)^r \leqslant \sum_{i=1}^{n} \sum_{j=1}^{m} a_{ij}^r + \left(\sum_{i=1}^{n} \sum_{j=1}^{m} a_{ij} \right)^r. \tag{53}$$

It is remarkable that the following inequality holds:[27]

$$\sum_{i=1}^{n} \left(\sum_{j=1}^{m} a_{ij} \right)^r \geqslant \sum_{i=1}^{n} \sum_{j=1}^{m} a_{ij}^r \tag{54}$$

for $r \geqslant 1$ and $a_{ij} \geqslant 0$.

D. Difference between Tsallis entropy and Shannon entropy

We point out the difference between Tsallis entropy and Shannon entropy from the viewpoint of mutual entropy. In the case of $q=1$, the relative entropy between the joint probability $p(x,y)$ and the direct probability $p(x)p(y)$ is equal to the mutual entropy,

$$D_1((X,Y)|X \times Y) = S_1(X) - S_1(X|Y).$$

However, in the general case ($q \neq 1$), there exists the following relation:

$$\begin{aligned} D_q((X,Y)|X \times Y) = S_q(X) - S_q(X|Y) + \sum_{i,j} p(x_i,y_j)\{&p(x_i)^{q-1} \ln_q p(x_i) + p(y_j)^{q-1} \ln_q p(y_j) \\ &- p(x_i,y_j)^{q-1} \ln_q p(x_i)p(y_j)\}, \end{aligned} \tag{55}$$

which gives the crucial difference between the special case ($q=1$) and the general case ($q \neq 1$). The third term on the right-hand side of Eq. (55) vanishes if $q=1$. The existence of the third term of Eq. (55) means that we have two possibilities of the definition of Tsallis mutual entropy, that is, $I_q(X;Y) \equiv S_q(X) - S_q(X|Y)$ or $I_q(X;Y) \equiv D_q((X,Y)|X \times Y)$. We have adopted the former definition in the present paper, along with the definition of the capacity in the origin of information theory by Shannon.[28]

E. Another candidate of Tsallis conditional entropy

It is remarkable that Tsallis entropy $S_q(X)$ can be regarded as the expected value of $\ln_q[1/p(x)]$, that is, since $\ln_q(x) = -x^{1-q} \ln_q(1/x)$, it is expressed by

$$S_q(X) = \sum_x p(x) \ln_q \frac{1}{p(x)} \quad (q \neq 1), \tag{56}$$

where the convention $0 \ln_q(\cdot) = 0$ is set. Along with the view of Eq. (56), we may define Tsallis conditional entropy and Tsallis joint entropy in the following.

Definition 7.5: For the conditional probability $p(x|y)$ and the joint probability $p(x,y)$, we define Tsallis conditional entropy and Tsallis joint entropy by

$$\hat{S}_q(X|Y) \equiv \sum_{x,y} p(x,y) \ln_q \frac{1}{p(x|y)} \quad (q \neq 1) \tag{57}$$

and

$$S_q(X,Y) \equiv \sum_{x,y} p(x,y) \ln_q \frac{1}{p(x,y)} \quad (q \neq 1). \tag{58}$$

We should note that Tsallis conditional entropy defined in Eq. (57) is not equal to that defined in Eq. (4), while Tsallis joint entropy defined in Eq. (58) is equal to that defined in Eq. (5). If we adopt the above definitions Eq. (57) instead of Eq. (4), we have the following inequality.

Proposition 7.6: For $q > 1$, we have

$$S_q(X,Y) \leqslant S_q(X) + \hat{S}_q(Y|X).$$

For $0 \leqslant q < 1$, we have

$$S_q(X,Y) \geqslant S_q(X) + \hat{S}_q(Y|X).$$

Therefore we do not have the chain rule for $\hat{S}_q(Y|X)$ in general, namely we are not able to construct a parametrically extended information theory in this case.

VIII. CONCLUSION

As we have seen, we have found that the chain rules for the Tsallis type entropies hold as similar way of the proofs of the entropy of type β. This result was generalized from a few insights. Also we have proved the strong subadditivity of the Tsallis type entropies for the general two random variables in the case of $q > 1$. Moreover it has been shown that in general the superadditivity of Tsallis entropies does not hold in the case of $0 \leqslant q < 1$. Thus we could give important results for Tsallis entropies in the case of $q > 1$ from the information theoretical point of view. Therefore we have the possibility that the parametrically extended information theory will be constructed by starting from Tsallis entropy for $q > 1$. In other words, there is less possibility of such a construction in the case of $0 \leqslant q < 1$ if our stage is still in the usual probability theory, because the relation which should be satisfied in contrast to the usual information theory does not hold in the case of $0 \leqslant q < 1$. This gives us the rough meaning of the parameter q. That is, we found the crucial different results between $S_q(X)$ for $q > 1$ and $S_q(X)$ for $0 \leqslant q < 1$ from the information theoretical point of view. For $q > 1$, we showed that the Tsallis type entropies have the similar results to Shannon entropies. In other words, it has been shown that the definition of Tsallis conditional entropy Eq. (4) and Tsallis mutual entropy Eq. (36) have a possibility to be a pioneer to construct a nonadditive information theory.

Our results in the present paper are fundamental so that we are convinced that these results will help the progresses of nonextensive statistical physics and information theory. We are now studying the coding problem in nonadditive information theory and searching for the precise meaning of the parameter q.

Covariant equilibrium statistical mechanics

E. Lehmann[a)]
Tannenweg 19, D-75394 Oberreichenbach, Germany

(Received 22 October 2005; accepted 9 December 2005; published online 9 February 2006)

A manifest covariant equilibrium statistical mechanics is constructed starting with a $8N$ dimensional extended phase space which is reduced to the $6N$ physical degrees of freedom using the Poincaré-invariant constrained Hamiltonian dynamics describing the microdynamics of the system. The reduction of the extended phase space is initiated forcing the particles on energy shell and fixing their individual time coordinates with help of invariant time constraints. The Liouville equation and the equilibrium condition are formulated in respect to the scalar global evolution parameter which is introduced by the time fixation conditions. The applicability of the developed approach is shown for both, the perfect gas as well as the real gas. As a simple application the canonical partition integral of the monatomic perfect gas is calculated and compared with other approaches. Furthermore, thermodynamical quantities are derived. All considerations are shrinked on the classical Boltzmann gas composed of massive particles and hence quantum effects are discarded.

I. INTRODUCTION AND MOTIVATION

The motivation to investigate relativistic equilibrium statistical mechanics is given by theoretical reasons as well as by practical reasons. From the theoretical point of view equilibrium statistical mechanics must be brought into accordance with the principles of relativity like all other branches of physics. From the practical point of view there might be important relativistic effects at (very) high temperatures. Those effects may play a major role within cosmological problems. Hence, equilibrium statistical mechanics is also interesting in the framework of general relativity and as a proper base a manifest covariant approach of a special relativistic equilibrium statistical mechanics is demanded.

While the covariant generalization of kinetic equations as a major application of nonequilibrium statistical mechanics can be studied since many years with help of textbooks (see e.g., Ref. 1) the relativistic equilibrium statistical mechanics has not reached such stable states. (The interest on covariant kinetic equations was mainly driven by practical reasons, i.e., by applications in various fields like plasma physics, astrophysics, heavy ion reactions, etc.).

Although Jüttner presented already 1911 relativistic calculations concerning the perfect gas[2] (note, Jüttners calculations are relativistic but not covariant) the manifest covariant description of equilibrium statistical mechanics is still under consideration and a lot of attempts have been performed already to tackle the related problems. An overview about such problems may be studied in older papers and reviews like the ones of Hakim[3] and the one of Havas[4] as well as references therein.

In this paper we mainly focus on the problem that the phase space $\int d\Gamma$ must be conceived in an invariant fashion demanded, e.g., by the invariance of the entropy (i.e., $S=k \ln \Gamma$). ter Haar and Wergeland[5] have summarized very clearly the two possibilities which intuitively offer themselves:

(1) "Either one makes Γ explicitly invariant extending it from $6N$ to $8N$ dimensions. That

a)Electronic mail: lehmann.ewald@t-online.de

implies a many-time formulation of the underlying dynamics. For equilibrium theory, at any rate, this does not seem to be a suitable approach.

(2) Or, one retains (in the classical limit case) the usual phase space and considers the Lorentz transformations as canonical. This will certainly accomplish the desired invariance, but requires certain auxiliary reinterpretations."

The work of Balescu *et al.*[6] strongly enforces possibility (2) but applying the method on nonequilibrium statistical mechanics only.

The refusing statement of ter Haar and Wergeland concerning possibility (1) was certainly motivated by the fact that any straightforward attempt to formulate classical dynamics in a covariant fashion runs automatically into conflicts defined by the famous no-interaction theorem.[7] This theorem states that only a collection of noninteracting particles can be described within a Poincaré invariant fashion if a straightforward generalization of the usual dynamical description is applied. But the conflicts with the no-interaction theorem can be avoided within the framework of constrained Hamiltonian dynamics. This formalism is based on an algorithm which was introduced by Dirac[8] and Bergmann[9] in order to express a theory based on a singular Lagrangian in a generalized phase space approach with help of constraints. [A general and introductional overview about this formalism can be found in monographs and textbooks (see Ref. 10).] In this context the original $8N$ dimensional extended phase space given by N interacting relativistic particles can be reduced to $6N$ dimensions with the help of $2N$ constraints fixing the energies and the time coordinates of these N particles. Doing this a $6N$ dimensional hypersurface in the original $8N$ dimensional phase space is defined on which the system is allowed to move during its evolution. The evolution of the system is described in respect to a global scalar evolution parameter which is introduced by the time constraints relating the individual time coordinates to this parameter. This formalism is not changing the notion of simultaneity by a change of the frame of reference, means one gets an invariant notion of simultaneity as well as invariant world lines. This method has been successfully applied already in complicated non-equilibrium situations namely, in order to calculate heavy ion reactions at intermediate and high energies (Refs. 11 and 12).

Hence we do not agree that possibility (1) is not a suitable way and we propose in this paper an approach which uses the formalism of constrained Hamiltonian dynamics to describe the microdynamics of the system and which develops on this base an equilibrium statistical mechanics in a manifest covariant fashion.

A similar approach has been presented already by Hsu.[13] But this approach is based on the so-called common relativity (developed by the same author) which is a rather special formulation and interpretation of relativity. In contradiction to the work of Hsu we prefer in this paper to apply the usual framework and interpretion of relativity.

Another interesting approach following possibility (1) is the one of Horwitz *et al.*[14] which is based on the many-body theory of the relativistic mechanics proposed by Stückelberg.[15] The main characteristics of this method are the separation of the center of mass motion in the same way as in the nonrelativistic theory and the allowance of the particles being off-shell resulting finally in a new potential corresponding to the mass degree of freedom of the relativistic system. However, in our opinion, the extended phase space is not reduced in a satisfying way within this approach: phase space integrations are only performed keeping a common time interval Δt because no specific time fixations have been incorporated in this model [see, e.g., Eq. (3.25) in Ref. 14].

Furthermore, we would like to mention the paper of Tretyak.[16] This author used the front form of dynamics to investigate relativistic equilibrium statistical mechanics. But shrinking the phase space *ad hoc* to $6N$ dimensions this approach, although very elegant and useful, cannot be regarded to be manifest covariant.

The presentation of our approach in this paper is organized as follows.

In Sec. II we give a brief overview on the constrained Hamiltonian dynamics in a representation which is suitable for our purpose. In Sec. III we propose the formulation of a covariant equilibrium statistical mechanics using the framework explained in Sec. II. In Sec. IV we apply the developed approach to the canonical ensemble of the monatomic perfect gas. The obtained results are compared with other approaches. Finally, Sec. V contains some concluding remarks.

Some remarks on the used notation are at order.

Throughout the paper relativistic units are used, i.e., $\hbar=c=1$. The diagonal metric tensor has been chosen to be $(1,-1,-1,-1)$. The usual summation convention (i.e., summation of repeated indices in the same expression) is applied in the case with greek indices (representing tensor indices) which are running from 0 to 3. Italic indices indicate the particle index. Capital letters are used for quantities characterizing the complete system while lower case letters are used for quantities related to properties of single particles. The complete set of $8N$ phase space coordinates will be abbreviated by $(q^\mu,p^\mu)=(q_1^\mu,\ldots,q_N^\mu,p_1^\mu,\ldots,p_N^\mu)$. A contravariant 4-vector a^μ is defined as $a^\mu=(a^0,\mathbf{a})$. For the Poisson bracket of two dynamical phase space variables $A(q^\mu,p^\mu)$ and $B(q^\mu,p^\mu)$ the convention

$$\{A,B\}=\sum_i\left(\frac{\partial A}{\partial p_i^\mu}\frac{\partial B}{\partial q_{i\mu}}-\frac{\partial A}{\partial q_i^\mu}\frac{\partial B}{\partial p_{i\mu}}\right) \tag{1}$$

is used. As common within constrained Hamiltonian dynamics we also distinguish between weak equations and strong equations, assigned by $\approx$ and $=$, respectively. While strong equations hold throughout the extended phase space weak equations are demanded to be valid on the submanifold defined by the constraints. Note, weak equations should not be used before all interesting Poisson brackets have been worked out.

II. CONSTRAINED HAMILTONIAN DYNAMICS

The nonrelativistic equilibrium statistical mechanics contains as an essential part the description of the microdynamics using Hamiltonian dynamics, i.e., by classical propagation of particles under mutual interactions "at-a-distance." The generalization of this nonrelativistic particle dynamics to a manifest covariant particle dynamics is not trivial because, one must know how to treat action-at-a-distance in a covariant fashion. The conceptual problems in this field are formulated in the no-interaction theorem,[7] which states that only a collection of free particles can fulfill the following requirements:

(i) The many particle system is described in a Hamiltonian formulation with a canonical representation of the Poincaré group.
(ii) The world lines are invariant (World line condition).
(iii) The physical coordinates are identified with the canonical coordinates.

At least one of these requirements must be violated if one is going to allow an interaction between the particles which depends only on the trajectories of the particles.

In the 1970s three possibilities have been worked out to avoid this negative statement of the no-interaction theorem (an overview about the various attempts are collected in Ref. 17). The predictive relativistic mechanics, the singular Lagrange formalism and the constrained Hamiltonian dynamics. All these formalisms have in common that constraints are used to reduce the original $8N$-dimensional phase space, which is given by the space and time coordinates, the momenta and the energies of the N particles involved. The advantage of the constrained Hamiltonian dynamics is that one can choose these constraints more freely as in the other methods. Furthermore, one can define $2N$ constraints in a way obtaining the usual $6N$ dimensional phase space in the nonrelativistic limit, containing the physical dynamical degrees of freedom. The constrained Hamiltonian dynamics for particles under interaction was developed by Bergmann, Anderson, Goldberg,[9] Todorov,[18] Rohrlich,[19] Komar,[20] Sudarshan, Mokunda, Goldberg,[21] and Samuel.[22] These authors picked up the idea of Dirac[8] who has realized for the first time that constraints are not only reducing the degrees of freedom but can also determine the dynamics.

The model of Samuel contains as an important feature the cluster decomposition in a satisfying way for our purpose. The cluster decomposition, also called cluster separability, makes sure that when a system of interacting particles breaks into dynamical independent clusters, then the set of constraints must break into these dynamical independent clusters as well. The disadvantage of the model of Samuel is that it is not quantizable. But this is playing no role for our purpose

because, shrinking the considerations on the classical Boltzmann gas, we need only a classical Poincaré invariant description of particle dynamics in the framework of an action-at-a-distance theory which respects the cluster separability and the principle of causality.

In the following we demonstrate the concrete usage of this formalism to describe the microdynamics of the perfect gas as well as of the real gas composed of massive particles.

A. Microdynamics of the perfect gas

Modeling the microdynamics of the perfect relativistic gas a system of N noninteracting particles can be considered. The singular Lagrangian of such systems leads directly to N on-shell constraints (see, e.g., Ref. 23)

$$\varphi_i = \frac{1}{2m_i}(p_i^2 - m_i^2) \approx 0, \quad i = 1, \ldots, N, \tag{2}$$

with p_i^μ being the 4-momentum of particle i and m_i being its rest mass. In contradiction to an earlier work[12] and the common usage[10] the mass-shell constraints have been modified by the scalar factor $1/2m_i$. This modification provides several advantages.

First, the transition to the nonrelativistic limit is simplified and needs no further manipulations.

Second, this factor regulates the dimensions of the mass-shell constraints to be the one of an energy instead of an energy squared.

Third, and this is our major motivation, a straightforward performance of phase space integrals is guaranteed by this modification.

Since these primary constraints are first class, i.e., $\{\varphi_i, \varphi_j\} \approx 0$, no secondary constraints exist in this case. Nevertheless, the φ_i must be supplemented by N time fixation conditions which gauge the individual time coordinates parametrizing the world lines. Because noninteracting particles must not be correlated one often uses the simple gauging conditions

$$\chi_i = q_i^0 - \tau \approx 0, \quad i = 1, \ldots, N, \tag{3}$$

which force the time coordinates of the particles to be equal to the global scalar evolution parameter τ in any inertial system. These constraints are obviously not covariant.

But our aim in this paper is a manifest covariant reduction of the extended phase space and hence the constraints (3) are not satisfying in order to treat the relativistic perfect gas. Therefore, we define here another set of time fixations

$$\chi_i = \frac{p_i^\mu q_{i\mu}}{m_i} - \tau \approx 0, \quad i = 1, \ldots, N, \tag{4}$$

which are covariant and also do not create any correlation among the particles under consideration. The acting of these gauging conditions is easily recognized when considering it in the rest frame of a particle i: In this particular frame of reference $p_i^\mu = (m_i, \mathbf{0})$ and χ_i reduces to

$$\chi_i = q_{i0} - \tau \approx 0, \tag{5}$$

i.e., the time coordinates of the particles equal the global evolution parameter τ in their rest frame. In other words, using (4) the proper times of the particles are synchronized to τ within this covariant treatment. Note, both time fixations, (3) and (4) are first class, i.e., $\{\chi_i, \chi_j\} \approx 0$, but the complete set of $2N$ constraints is second class since $\{\varphi_i, \chi_j\} \not\approx 0$.

Because the canonical Hamiltonian derived by a Legendre transformation from the singular Lagrangian of a system of relativistic particles is identical vanishing[23] the Dirac Hamiltonian can be constructed by a linear combination of the τ-independent constraints,

$$H = \sum_{i=1}^{N} \lambda_i \varphi_i. \tag{6}$$

This Hamiltonian generates the equations of motion with respect to τ to be

$$\frac{\mathrm{d}q_i^\mu}{\mathrm{d}\tau} = \{H, q_i^\mu\} \approx \sum_{j=1}^{N} \lambda_j \frac{\partial \varphi_j}{\partial p_{i\mu}}, \tag{7}$$

$$\frac{\mathrm{d}p_i^\mu}{\mathrm{d}\tau} = \{H, p_i^\mu\} \approx -\sum_{j=1}^{N} \lambda_j \frac{\partial \varphi_j}{\partial q_{i\mu}}. \tag{8}$$

The Lagrange multipliers λ_i can be determined with the help of the consistency conditions

$$\frac{\mathrm{d}\psi_j}{\mathrm{d}\tau} = \frac{\partial \psi_j}{\partial \tau} + \{H, \psi_j\} \approx \frac{\partial \psi_j}{\partial \tau} + \sum_{i=1}^{N} \lambda_i \{\varphi_i, \psi_j\} \approx 0, \quad j = 1, \ldots, 2N; \tag{9}$$

which guarantee the validity of the constraints during the complete evolution of the system and which must be valid for the complete set of $2N$ constraints

$$\psi_j = \begin{cases} \varphi_j, & 0 < j \leqslant N, \\ \chi_{j-N}, & N < j \leqslant 2N. \end{cases} \tag{10}$$

Introducing the invertible $N \times N$-matrix C with elements $C_{ij} = \{\varphi_i, \chi_j\}$ the Lagrange multipliers are uniquely determined by

$$\lambda_i \approx -\sum_{j=1}^{N} \frac{\partial \chi_j}{\partial \tau} C_{ij}^{-1} \tag{11}$$

to be $\lambda_i = m_i / p_i^0$ if using (3) and $\lambda_i = m_i^2 / p_i^2$ if using (4).

In the following we will use the term *semicovariant approach* whenever the set of $2N$ constraints is assumed to consist of the N on-shell constraints (2) and the simple time fixations (3) because N covariant constraints are supplemented by N noncovariant constraints. Furthermore, we will use the term *full covariant approach* whenever the on-shell constraints (2) are combined with the covariant time fixations (4) to build the complete set of $2N$ constraints.

Using $p_i^0 = \epsilon_i + m_i$ the on-shell constraints reduce in the nonrelativistic limit ($\epsilon_i \ll m_i$) to

$$\varphi_i = \epsilon_i - \frac{\mathbf{p}_i^2}{2m_i} \approx 0. \tag{12}$$

Furthermore, the covariant time fixations (4) reduce to the simple time fixations (3) in the nonrelativistic limit and the global evolution parameter τ is identified with the absolute time t. Consequently, the usual nonrelativistic Hamiltonian dynamics is obtained as generated by the nonrelativistic Hamiltonian,

$$H^{(nr)} = \sum_{i=1}^{N} \frac{\mathbf{p}_i^2}{2m_i}. \tag{13}$$

B. Microdynamics of the real gas

In contradiction to ideal systems like the perfect gas real systems can only be understood if the intermolecular interactions are taken into account when describing the related microdynamics. Applying the formalism of the constrained Hamiltonian dynamics to the microdynamics of the real gas we therefore must consider a system of N particles in mutual interaction. In this case we prefer

to use a set of constraints quite similar to the constraints which have been successfully applied already within nonequilibrium situations when simulating heavy ion reactions (see Refs. 11 and 12). The first N constraints are chosen as on-shell constraints

$$\varphi_i = \frac{1}{2m_i}(p_i^2 - m_i^2 - \widetilde{V}_i) \approx 0, \quad i = 1, \ldots, N. \tag{14}$$

Note, as already discussed in Sec. II A, the on-shell constraints have been modified by the scalar factor $1/2m_i$. Regarding the potential part $\widetilde{V}_i$ this choice of the constraints requires that $\widetilde{V}_i$ should be a Lorentz scalar and therefore a function of Lorentz scalars. Defining a system with mutual two-body interactions, $\widetilde{V}_i$ should be given by a sum of these two-body interactions

$$\widetilde{V}_i = \sum_{j \neq i} \widetilde{V}_{ij}(q_{Tij}^2). \tag{15}$$

Using Eq. (15) we assume that the two-body interactions depend only on the Lorentz invariant squared transverse distance

$$q_{Tij}^2 = q_{ij}^2 - \frac{(q_{ij}^\mu p_{ij\mu})^2}{p_{ij}^2}, \tag{16}$$

with $q_{ij}^\mu = q_i^\mu - q_j^\mu$ being the four-dimensional distance and $p_{ij}^\mu = p_i^\mu + p_j^\mu$ the sum of the momenta of the two interacting particles i and j. This particular choice has two advantages.

First, in the common CMS of two interacting particles CMS_{ij} q_{Tij}^2 reduces to $-\mathbf{q}_{ij}^2$ which is quite natural since only in the CMS_{ij} particle i and particle j can be treated on the same footing. In addition, in the nonrelativistic limit the potential part $\widetilde{V}_i$ can be connected with the corresponding potential V_i used in the nonrelativistic theory: Using $p_i^0 = \epsilon_i + m_i$ and regarding the nonrelativistic limit ($\epsilon_i \ll m_i$) the on-shell constraints reduce to

$$\varphi_i = \epsilon_i - \frac{\mathbf{p}_i^2}{2m_i} - \frac{\widetilde{V}_i}{2m_i} \approx 0. \tag{17}$$

The comparison of (17) with the usual expression of the nonrelativistic energy suggests

$$\widetilde{V}_i = 2m_i V_i, \tag{18}$$

and the two-body potential acting among two particles i and j felt by particle i reads in the common CMS_{ij},

$$\widetilde{V}_{ij}(-\mathbf{q}_{ij}^2) = 2m_i V_{ij}(-\mathbf{q}_{ij}^2), \tag{19}$$

i.e., a nonrelativistic two-body potential can be generalized to be used in the relativistic theory. For instance, the widely used Lennard-Jones potential can be generalized replacing the squared distance $\mathbf{q}_{ij}^2$ by the Lorentz invariant squared transverse distance q_{Tij}^2 obtaining

$$\widetilde{V}_{ij}^{(\mathrm{LJ})}(q_{Tij}^2) = 2m_i \kappa \left[\left(\frac{\sigma}{\sqrt{q_{Tij}^2}} \right)^{12} - \left(\frac{\sigma}{\sqrt{q_{Tij}^2}} \right)^{6} \right] \tag{20}$$

with the two tuning parameters κ and σ having the dimensions of an energy and a length, respectively. Note, due to the second term on the right-hand side of Eq. (16) this generalized interaction is slightly implicit momentum dependent. Because of this term, which gives the longitudinal squared distance, the interaction depends not only on the distance of the two interacting particles but also on the direction of their center of mass motion in the rest frame of the real gas.

Since the on-shell constraints alone do not specify the world lines one needs additional N constraints which are fixing the relative times of the particles. Like in the model of Samuel[22] this second set of N constraints should fulfill the following conditions:

(1) $N-1$ of them should be Poincaré invariant in order to fulfill the required world line invariance.
(2) Causality must be respected.
(3) One must be consistent with cluster separability.
(4) A global evolution parameter must be defined.

These conditions can be fulfilled by defining the following set of N time fixations:

$$\chi_i = \frac{1}{m_{i\,j(\neq i)}} \sum \omega_{ij} p_{ij}^{\mu} q_{ij\mu} \approx 0, \quad i = 1, \ldots, (N-1), \tag{21}$$

$$\chi_N = P^{\mu} Q_{\mu} - \tau \approx 0 \tag{22}$$

with $P^{\mu} = P^{\mu}/\sqrt{P^2}$, $P^{\mu} = \Sigma_i p_i^{\mu}$, $Q^{\mu} = (1/N)\Sigma_i q_i^{\mu}$ and the dimensionless scalar weighting function

$$\omega_{ij} = \frac{1}{q_{ij}^2/\sigma^2} e^{(q_{ij}^2/\sigma^2)} \tag{23}$$

with σ being a characteristic interaction distance of the modeled interaction. Note, the scalar factor $1/m_i$ regulates the dimension of the time fixations to be the one of a length. The conditions (21) are motivated by studies in the framework of singular Lagrangians.[24] Using this methods one gets up to the weighting functions w_{ij} the same conditions as secondary constraints and the on-shell conditions as primary constraints in a natural way. The important fact for using the expression (23) as weighting function is that this scalar function respects the principle of causality, while the ones used in the singular Lagrangian theories and in the model of Samuel can violate this important physical restriction (see Ref. 11).

The constraints (21) take care that the times of interacting particles are not dispersed to much in their common CMS_{ij}. Furthermore, they specify the dynamics by fixing the times at which the forces must be calculated but they do not specify the global evolution parameter τ. This evolution parameter must be defined to be determined dynamically since the no-interaction theorem can only be avoided in this way and is defined by the gauging condition (22) in a way, that the individual times are increasing with increasing τ.

In the CMS of all particles involved τ is simply given by the average of all time coordinates

$$\tau = P^{\mu} Q_{\mu} \overset{\mathrm{CMS}}{\rightarrow} \frac{1}{N} \sum_{i=1}^{N} q_i^0. \tag{24}$$

This set of $2N$ constraints given by (14), (21), and (22) determines covariant world lines parametrized by the initial data at equal τ.

A linear combination of the $2N-1$ τ-independent constraints

$$\psi_i = \begin{cases} \varphi_i, & 0 < i \leqslant N, \\ \chi_{i-N}, & N < i \leqslant 2N-1 \end{cases} \tag{25}$$

constructs the Dirac Hamiltonian

$$H = \sum_{i=1}^{2N-1} \lambda_i \psi_i \tag{26}$$

which generates the equations of motion with respect to τ to be

$$\frac{\mathrm{d}q_i^\mu}{\mathrm{d}\tau} \approx \sum_{j=1}^{2N-1} \lambda_j \frac{\partial \psi_j}{\partial p_{i\mu}}, \tag{27}$$

$$\frac{\mathrm{d}p_i^\mu}{\mathrm{d}\tau} \approx -\sum_{j=1}^{2N-1} \lambda_j \frac{\partial \psi_j}{\partial q_{i\mu}}. \tag{28}$$

The Lagrange multipliers λ_i can be determined with the help of the consistency conditions

$$\frac{\mathrm{d}\psi_j}{\mathrm{d}\tau} = \frac{\partial \psi_j}{\partial \tau} + \{H, \psi_j\} \approx \frac{\partial \psi_j}{\partial \tau} + \sum_{i=1}^{2N-1} \lambda_i \{\psi_i, \psi_j\} \approx 0, \quad j = 1, \ldots, 2N; \tag{29}$$

and are finally given by

$$\lambda_i \approx -\frac{\partial \chi_N}{\partial \tau} C^{-1}_{i2N} \tag{30}$$

with C being the invertible $2N \times 2N$ matrix with elements $C_{ij} = \{\psi_i, \psi_j\}$.

The whole formalism has a well defined nonrelativistic limit as has been shown by Sorge.[11] In leading order of $1/c$ one gets for the first $2N-1$ constraints

$$\varphi_i = \epsilon_i - \frac{\mathbf{p}_i^2}{2m_i} - \frac{\tilde{V}_i}{2m_i} \approx 0, \quad i = 1, \ldots, N, \tag{31}$$

$$\chi_i = q_i^0 - q_N^0 \approx 0, \quad i = 1, \ldots, N-1 \tag{32}$$

which generate the same dynamics as the nonrelativistic many-body Hamiltonian

$$H^{(nr)} = \sum_{i=1}^{N} \left(\frac{\mathbf{p}_i^2}{2m_i} + V_i \right). \tag{33}$$

III. COVARIANT STATISTICAL MECHANICS IN THE FRAMEWORK OF CONSTRAINED HAMILTONIAN DYNAMICS

Regarding the constrained Hamiltonian dynamics as a proper formalism to describe a system of interacting particles in a covariant fashion we are to develop a manifest covariant statistical mechanics on its base. We start this development considering the extended phase space. In case of a system involving N particles this invariant phase space has $8N$ dimensions given by the N 4-momenta p_i^μ and the N 4-position-vectors $q_i^\mu (i = 1, \ldots, N)$.

The phase space distribution function $D(q^\mu, p^\mu, \tau)$ representing the statistical ensemble is assumed to depend on the complete set of $8N$ phase space coordinates and, in general, on the global evolution parameter τ which is introduced by certain time fixation conditions (compare Sec. II). Consequently, the Liouville equation and the equilibrium conditions must be discussed with respect to τ.

The Liouville equation is thus given by

$$\frac{\mathrm{d}D(q^\mu, p^\mu, \tau)}{\mathrm{d}\tau} = 0 \Leftrightarrow \frac{\partial D(q^\mu, p^\mu, \tau)}{\partial \tau} = \{D(q^\mu, p^\mu, \tau), H\}. \tag{34}$$

The microdynamics of the system is generated by the Hamiltonian

$$H = \sum_{i=1}^{M} \lambda_i \psi_i, \tag{35}$$

where $M=N$ in the case of the perfect gas and $M=2N-1$ in the case of the real gas using the constraints as introduced in Sec. II.

Hence we get

$$\frac{\partial D(q^\mu, p^\mu, \tau)}{\partial \tau} \approx \sum_{i=1}^{M} \lambda_i \{D(q^\mu, p^\mu, \tau), \psi_i\}. \tag{36}$$

The reduction of the invariant phase space volume element of the extended phase space

$$\mathrm{d}\Gamma_e = \prod_{i=1}^{N} d^4 q_i d^4 p_i. \tag{37}$$

is performed incorporating all $2N$ constraints by means of δ-functions, i.e.,

$$\mathrm{d}\Gamma = \prod_{i=1}^{N} d^4 q_i d^4 p_i \Theta(p_i^0)\, \delta(\varphi_i)\, \delta(\chi_i). \tag{38}$$

The Heaviside-Θ-function has been added in order to shrink on particles with positive energy which is useful if classical particles are considered only.

Equilibrium distribution functions are τ independent solutions of (34) and hence must fulfill the condition

$$\sum_{i=1}^{M} \lambda_i \{D(q^\mu, p^\mu), \psi_i\} \approx 0. \tag{39}$$

Using (38) the ensemble average (i.e., the classical expectation value) of a measurable quantity $A(p^\mu, q^\mu)$ at equilibrium is given by

$$\langle A \rangle = \frac{\int \prod_{i=1}^{N} d^4 q_i d^4 p_i \Theta(p_i^0)\, \delta(\varphi_i)\, \delta(\chi_i) A(p^\mu, q^\mu) D(q^\mu, p^\mu)}{\int \prod_{i=1}^{N} d^4 q_i d^4 p_i \Theta(p_i^0)\, \delta(\varphi_i)\, \delta(\chi_i) D(q^\mu, p^\mu)}. \tag{40}$$

We mention two simple (and widely used) possibilities to construct solutions of the Liouville equation fulfilling the equilibrium condition:

(i) Constant phase space distributions $D=\text{const}$.
(ii) Phase space distributions depending on quantities X_j which are conserved during the evolution in respect to τ, i.e., $\mathrm{d}X_j/\mathrm{d}\tau=0$.

Assuming $X_j \neq X_j(\tau)$ the condition

$$\sum_{i=1}^{M} \lambda_i \{X_j, \psi_i\} \approx 0 \tag{41}$$

must be valid in the case of such conserved quantities.

Beside the trivial uniform ensemble the microcanonical ensemble can be regarded to be the most typical example for the former case while the canonical as well as the grand canonical ensembles are examples of the latter case.

In the nonrelativistic theory the energy is playing a prominent role as the most important conserved quantity. In a relativistic generalization the energy must be replaced by the

4-momentum P^μ or even by the energy-momentum tensor $T^{\mu\nu}$ of the system. A fruitful alternate is the invariant energy $E=U_\mu P^\mu$ with U_μ being the 4-velocity of the system. In the comoving frame of reference (i.e., the rest frame of the system) we get $E=U_0P^0=P^0$, i.e., the invariant energy is nothing but the total (internal) energy of the system measured in its rest frame. We will use this invariant energy when generalizing the concepts of nonrelativistic statistical mechanics.

In the following we consider briefly the main equilibrium distributions.

(i) *Microcanonical ensemble*: Considering the classical (i.e., nonquantum mechanical) case only and applying our concept of the invariant energy E we can write the distribution function of the microcanonical ensemble using the δ-function (compare, e.g., Ref. 25) as

$$D_M = \frac{1}{Z_M}\delta(E-E_0) \tag{42}$$

with E_0 being the invariant energy of the closed system. The microcanonical partition integral Z_M (which is nothing but the phase space volume Γ) must be determined via

$$Z_M = \frac{1}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \Theta(p_i^0)\delta(\varphi_i)\delta(\chi_i)\delta(E-E_0). \tag{43}$$

The factor $1/N!$ respects the fact that the particles cannot be distinguished.

(ii) *Canonical ensemble*: Considering the canonical ensemble the condition

$$\sum_{i=1}^{M}\lambda_i\{E,\psi_i\} = \sum_{i=1}^{M}\lambda_i\{U_\mu P^\mu,\psi_i\} \approx 0 \tag{44}$$

is to be proved in order to use the ansatz

$$D_C(E) = \frac{1}{Z_C}e^{-\beta U_\mu P^\mu} \tag{45}$$

for the canonical distribution function with the canonical partition integral

$$Z_C = \frac{1}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \Theta(p_i^0)\delta(\varphi_i)\delta(\chi_i)e^{-\beta U_\mu P^\mu}. \tag{46}$$

(iii) *Grand canonical ensemble*: The grand canonical ensemble is characterized by another conserved quantity beside the energy namely, the particle number N. Hence, generalizing the canonical ensemble accordingly leads to

$$D_G(E,N) = \frac{1}{Z_G}e^{-\beta U_\mu P^\mu-\alpha N} \tag{47}$$

for the grand canonical distribution function with the grand canonical partition integral

$$Z_G = \frac{1}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \Theta(p_i^0)\delta(\varphi_i)\delta(\chi_i)e^{-\beta U_\mu P^\mu-\alpha N}. \tag{48}$$

(iv) *Related thermodynamics*: Let us briefly discuss the corresponding thermodynamics generated by our approach. Like in the next section, we shrink on the canonical ensemble. The formal properties of the thermodynamics are dominated by the introduction of the invariant energy E. As in the nonrelativistic theory the free energy can be determined with the help of the canonical partition integral Z_C by

$$F = -kT \ln Z_C. \tag{49}$$

Like the invariant energy E the free energy F (as all other thermodynamical potentials) is defined to be a scalar. Furthermore, the temperature T introduced by the parameter $\beta = 1/kT$ (k being the Boltzmann constant) is a scalar quantity and the introduction of a heat vector[26] is superfluous. (Of course, formally we get the same exponential factor [see Eq. (45)] but the 4-velocity of the system U_μ is now defining the invariant energy $E = U_\mu P^\mu$ and not used to define the heat vector $\Theta_\mu = U_\mu / T$ like in other approaches.[26] One can argue about this interpretation but the advantage defining an invariant energy is that this scalar quantity of the exponent can be demanded to be conserved during evolution in respect to τ, i.e., to fulfill Eq. (41).**)** Considering the usual relations defining other macroscopic state variables like the entropy

$$S = k \ln Z_C - \frac{1}{T} \frac{\partial \ln Z_C}{\partial \beta} \tag{50}$$

and the pressure

$$P = -\left(\frac{\partial F}{\partial V} \right)_T \tag{51}$$

we stress that both, the macroscopic state variables as well as the thermodynamical potentials are defined to be scalar quantities in our approach. Hence, an artifical extension of those quantities to higher rank tensors as often done when formulating relativistic thermodynamics (compare, e.g., Ref. 26) is not needed.

The average energy is given by

$$\langle E \rangle = -\frac{\partial \ln Z_C}{\partial \beta}, \tag{52}$$

and the specific heat can be determined with the help of it

$$c_V = \left(\frac{\partial \langle E \rangle}{\partial T} \right)_V. \tag{53}$$

Looking to the grand canonical ensemble we note that the chemical potential M introduced by the parameter $\alpha = \beta M = M/kT$ is a scalar as well in the approach considered.

IV. THE CANONICAL ENSEMBLE OF THE MONATOMIC PERFECT GAS

In this section we want to apply the formalism developed in the preceding sections. Unfortunately, concrete calculations [e.g., determining the canonical partition integral via Eq. (46)] are not easy to be performed due to the structure of the phase space volume element. (Especially, as in the nonrelativistic theory, calculations considering the real gas turn out to be complicated depending on the underlying model of intermolecular interactions.) Hence, as an example, we just apply the formalism to the canonical ensemble of the monatomic perfect gas. In order to determine the canonical partition integral using formula (46) we must prove the validity of condition (44).

By definition, the perfect gas is a system of noninteracting particles and as a consequence the Hamiltonian contains the simple mass shell constraints (2). Hence, the partial derivatives of φ_i with respect to $q_{j\mu}$ are vanishing and condition (44) is fulfilled in the case of the perfect gas.

Unfortunately, no analytical solution of the canonical partition integral (46) can be achieved within the full covariant approach. Hence, numerical solutions have been worked out as will be explained in Sec. IV B.

But before discussing these numerical results let us first present another approach, namely the semicovariant approach which provides analytical results and hence can be easily compared with other approaches known from the literature, e.g., the noncovariant Jüttner approach.[2]

A. Semicovariant approach

In the semicovariant approach the simple time fixation conditions (3) are used and the partition integral reads

$$Z_C = \frac{1}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \Theta(p_i^0)\,\delta\left(\frac{1}{2m_i}(p_i^2 - m_i^2)\right)\delta(q_i^0 - \tau)e^{-\beta U_\mu P^\mu}. \tag{54}$$

Using the properties

$$\delta(ax) = \frac{1}{|a|}\delta(x) \tag{55}$$

and

$$\delta(x^2 - a^2) = \frac{1}{2a}[\delta(x-a) - \delta(x+a)] \tag{56}$$

of the δ-function we get

$$Z_C = \frac{!}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \frac{m_i}{p_i^0}\delta(p_i^0 - \sqrt{\mathbf{p}_i^2 + m_i^2})\,\delta(q_i^0 - \tau)e^{-\beta U_\mu P^\mu}. \tag{57}$$

For the further concrete calculation we assume a comoving frame of reference (i.e., the rest frame of the gas). In this frame of reference we get

$$E = U_\mu P^\mu = U_\mu \sum_{i=1}^{N} p_i^\mu = \sum_{i=1}^{N} p_i^0 \tag{58}$$

and integrating the 0-components gives, according to the δ-functions,

$$Z_C = \frac{1}{N!}\int \prod_{i=1}^{N} d^3q_i d^3p_i \frac{m_i}{\sqrt{\mathbf{p}_i^2 + m_i^2}} e^{-\beta\sqrt{\mathbf{p}_i^2+m_i^2}} = \frac{V^N}{N!}\int \prod_{i=1}^{N} d^3p_i \frac{m_i}{\sqrt{\mathbf{p}_i^2 + m_i^2}} e^{-\beta\sqrt{\mathbf{p}_i^2+m_i^2}}, \tag{59}$$

where V represents the volume measured in the rest frame of the gas. The integral factorizes using spherical coordinates in momentum space and performing the angle integration gives

$$Z_C = \frac{V^N}{N!}\left[4\pi m \int_0^\infty \mathrm{d}\rho \frac{\rho^2}{\sqrt{\rho^2 + m^2}} e^{-\beta\sqrt{\rho^2+m^2}}\right]^N \tag{60}$$

with $\rho = \sqrt{\mathbf{p}^2}$. Note, the particle index becomes superfluous considering a monatomic gas of particles with mass $m_i = m$. The integral in this expression can be solved applying the transformation $\rho = m \sinh \xi$ (see, e.g., Ref. 27),

$$\int_0^\infty \mathrm{d}\rho \frac{\rho^2}{\sqrt{\rho^2 + m^2}} e^{-\beta\sqrt{\rho^2+m^2}} = \int_0^\infty \mathrm{d}\xi\, m^2 \sinh^2 \xi e^{-\beta m \cosh \xi} = \frac{m^2}{\beta m} K_1(\beta m) \tag{61}$$

with K_1 being the modified Bessel function of first order.

Finally, the canonical partition integral within this semicovariant approach is given by

$$Z_C = \frac{V^N}{N!}\left[\frac{4\pi m^3}{\beta m} K_1(\beta m)\right]^N. \tag{62}$$

Now we are able to list the analytical results of three different approaches,

$$Z_C = \begin{cases} \dfrac{V^N}{N!}\left[\dfrac{4\pi m^3}{\beta m}K_1(\beta m)\right]^N, & \text{semicovariant,} \\ \dfrac{V^N}{N!}\left[\dfrac{4\pi m^3}{\beta m}K_2(\beta m)\right]^N, & \text{Jüttner approach,} \\ \dfrac{V^N}{N!}\left[\left(\dfrac{2\pi m^2}{\beta m}\right)^{3/2}\right]^N, & \text{nonrelativistic (see e.g. Ref. 28).} \end{cases} \tag{63}$$

Comparing (62) with the result of Jüttner we realize that the only difference is the order of the modified Bessel function occurring in Z_C: Jüttner's approach contains $K_2(\beta m)$ instead of $K_1(\beta m)$.

We note further that this result is naturally quite similar to the one derived by Horwitz *et al.* [compare Eq. (3.25) in Ref. 14), especially regarding the functional dependence on β. But we stress that the phase space reduction regarding the time constraints in our semicovariant approach is already more satisfying and as a consequence, in contradiction to Ref. 14, no common time interval is remaining in the final result when applying the formalism of constrained Hamiltonian dynamics.

B. Full covariant approach

Evaluating the partition integral within the full covariant approach we apply the covariant time constraints (4) as specified in Sec. II A for a system of noninteracting particles and Eq. (46) reads

$$Z_C = \frac{1}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \Theta(p_i^0)\delta\left(\frac{1}{2m_i}(p_i^2 - m_i^2)\right)\delta\left(\frac{1}{m_i}q_i^\mu p_{i\mu} - \tau\right)e^{-\beta U_\mu P^\mu}. \tag{64}$$

Using the properties (55) and (56) of the δ-function we get

$$Z_C = \frac{1}{N!}\int \prod_{i=1}^{N} d^4q_i d^4p_i \frac{m_i^2}{p_i^{0^2}}\delta(p_i^0 - \sqrt{\mathbf{p}_i^2 + m_i^2})\delta\left(q_i^0 - \frac{1}{p_i^0}(\mathbf{qp} - m\tau)\right)e^{-\beta U_\mu P^\mu}. \tag{65}$$

Until now we have kept strictly the covariant fashion during the calculation. For the further concrete calculation the fixation of a defined frame of reference is demanded. Hence, for simplicity, we choose the rest frame of the gas to determine the invariant energy E as already applied within the semicovariant approach [see Eq. (58)] and get integrating the 0-components according to the δ-functions

$$Z_C = \frac{1}{N!}\int \prod_{i=1}^{N} d^3q_i d^3p_i \frac{m_i^2}{(\mathbf{p}_i^2 + m_i^2)}e^{-\beta\sqrt{\mathbf{p}_i^2+m_i^2}} = \frac{V^N}{N!}\int \prod_{i=1}^{N} d^3p_i \frac{m_i^2}{(\mathbf{p}_i^2 + m_i^2)}e^{-\beta\sqrt{\mathbf{p}_i^2+m_i^2}}. \tag{66}$$

The integral factorizes using spherical coordinates in momentum space and performing the angle integration gives

$$Z_C = \frac{V^N}{N!}\left[4\pi m^2 \int_0^\infty \mathrm{d}\rho \frac{\rho^2}{\rho^2 + m^2}e^{-\beta\sqrt{\rho^2+m^2}}\right]^N \tag{67}$$

with $\rho = \sqrt{\mathbf{p}^2}$. Note, as in Eq. (60), $m_i = m$ has been used again.

Unfortunately, no analytical solution of the integral in Eq. (67) is available. Hence, numerical solutions have been worked out for various monatomic gases.

In order to compare this numerical results obtained by the full covariant approach with the results of other approaches as listed in Eq. (63) we write the canonical partition integral of the monatomic gas in a generic representation:

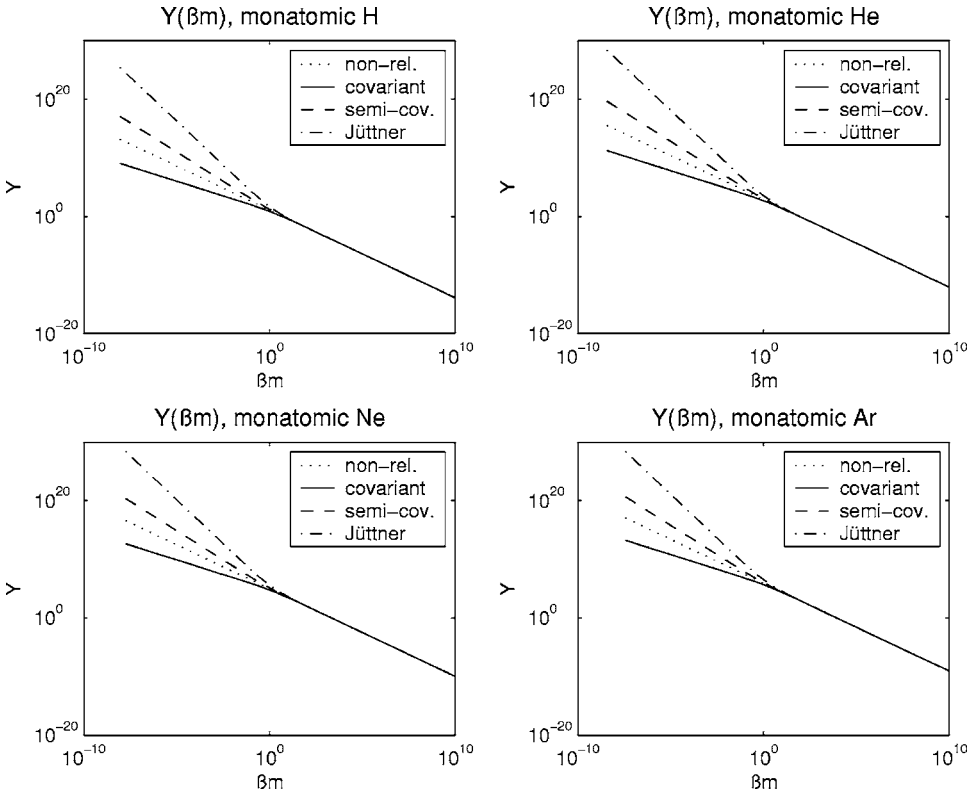

FIG. 1. Quantity Y as a function of βm for various approaches and different monatomic perfect gases.

$$Z_C = \frac{V^N}{N!}(e^{-\beta m}Y)^N. \tag{68}$$

The relativistic renormalization factor $e^{-\beta m}$ has been extracted explicitly in (68) for two reasons:

(1) This factor does not occur in the nonrelativistic partition integral.
(2) The numerical integration is simplified if this factor is extracted explicitly.

The nonanalytical integral occurring in the full covariant approach [see Eq. (67)] has been determined numerically using the Gauss-Laguerre method of 15th order. The results of the two other relativistic approaches (i.e., the Jüttner approach and the semicovariant approach) have been determined using the analytical expressions (i.e., evaluating the related modified Bessel functions K_1 and K_2) as well as using the same numerical integration method in order to justify the accuracy of the applied numerical method.

Figure 1 summarizes the results of calculations for different monatomic perfect gases namely, hydrogen, helium, neon, and argon. The comparison is focused on the quantity Y which determines the canonical partition integral via Eq. (68). As expected, the qualitative behavior is the same for all gases.

At low temperatures (nonrelativistic limit) all approaches give the same result as it should be. Even at higher temperatures ($T \leqslant 10^{12}$ K) (e.g., $T=10^{12}$ K corresponds roughly to $\beta m \simeq 10$ in case of hydrogen) no difference is visible among the various calculations. At extremely high temperatures ($T \geqslant 10^{12}$ K) relativistic effects are dominating the behavior. Compared to the nonrelativistic result the noncovariant Jüttner approach is showing a strong enhancement of the quantity Y in this regime. The semicovariant approach reduces this enhancement and the full covariant approach

turns the enhancement to a reduction even. Therefore, we conclude that a controlled manifest covariant reduction of the extended phase space reduces the value of the quantity Y and hence of the canonical partition integral.

In order to give an overview on the related thermodynamics of the monatomic perfect gas we finally list in dependence of the quantity Y the free energy

$$F = -kT \ln Z_C = -NkT\left(\ln \frac{V}{N} + \ln Y - \beta m + 1 \right), \tag{69}$$

the entropy

$$S = -\left(\frac{\partial F}{\partial T} \right)_V = k \ln Z_C + kT \frac{\partial \ln Z_C}{\partial T} = Nk\left(\ln \frac{V}{N} + \ln Y - \beta \frac{\partial \ln Y}{\partial \beta} + 1 \right), \tag{70}$$

the pressure

$$P = -\left(\frac{\partial F}{\partial V} \right)_T = kT \frac{\partial \ln Z_C}{\partial V} = \frac{NkT}{V}, \tag{71}$$

the average energy

$$\langle E \rangle = N\left(m - \frac{\partial \ln Y}{\partial B} \right), \tag{72}$$

and the specific heat

$$c_V = \left(\frac{\partial \langle E \rangle}{\partial T} \right)_V = \frac{N\beta}{T} \frac{\partial^2 \ln Y}{\partial \beta^2}. \tag{73}$$

Note, since the pressure turns out to be independent of Y all approaches give the same equation of state, namely the one of the nonrelativistic perfect gas,

$$PV = NkT. \tag{74}$$

Since the main differences among the various approaches are showing up at very high temperatures it is very useful to consider explicitly the following.

C. Ultrarelativistic limit

Since in the ultrarelativistic limit the rest mass is neglected in respect to the momentum and in respect to the energy it can be evaluated using $\sqrt{\mathbf{p}_i^2 + m_i^2} \to |\mathbf{p}_i|$ when deriving the integrals in Eqs. (67) and (60). Hence, it is even possible to derive analytical results in case of the full covariant approach since the partition integral simplifies drastically and we get in this limit ($\rho = |\mathbf{p}|$) for the various approaches,

$$Z_C^{(ur)} = \begin{cases} \dfrac{V^N}{N!}\left[4\pi m^2 \displaystyle\int_0^\infty \mathrm{d}\rho\, e^{-\beta\rho} \right]^N, & \text{full covariant,} \\ \dfrac{V^N}{N!}\left[4\pi m \displaystyle\int_0^\infty \mathrm{d}\rho\, \rho e^{-\beta\rho} \right]^N, & \text{semicovariant,} \\ \dfrac{V^N}{N!}\left[4\pi \displaystyle\int_0^\infty \mathrm{d}\rho\, \rho^2 e^{-\beta\rho} \right]^N, & \text{noncovariant (Jüttner).} \end{cases} \tag{75}$$

The integrals in (75) are easily determined with the help of the Γ-function according to

TABLE I. Thermodynamical quantities for the perfect gas in the ultrarelativistic limit.

Thermodynamical quantity	Full covariant	Semicovariant	Noncovariant (Jüttner approach)
$Z_C^{(ur)}$	$\frac{V^N}{N!}\left[\frac{4\pi m^3}{(\beta m)}\right]^N$	$\frac{V^N}{N!}\left[\frac{4\pi m^3}{(\beta m)^2}\right]^N$	$\frac{V^N}{N!}\left[\frac{8\pi m^3}{(\beta m)^3}\right]^N$
$F=-kT\ln Z_C$	$-NkT\left[\ln\frac{V}{N}+\ln(4\pi m^3)-\ln(\beta m)+1\right]$	$-NkT\left[\ln\frac{V}{N}+\ln(4\pi m^3)-2\ln(\beta m)+1\right]$	$-NkT\left[\ln\frac{V}{N}+\ln(8\pi m^3)-3\ln(\beta m)+1\right]$
$S=k\ln Z_C-\frac{1}{T}\partial\ln Z_C/\partial\beta$	$Nk\left[\ln\frac{V}{N}+\ln(4\pi m^3)-\ln(\beta m)+2\right]$	$Nk\left[\ln\frac{V}{N}+\ln(4\pi m^3)-2\ln(\beta m)+3\right]$	$Nk\left[\ln\frac{V}{N}+\ln(8\pi m^3)-3\ln(\beta m)+4\right]$
$\langle E\rangle=-\partial\ln Z_C/\partial\beta$	NkT	$2NkT$	$3NkT$
$c_V=\partial\langle E\rangle/\partial T$	Nk	$2Nk$	$3Nk$
$P=-\partial F/\partial V$	NkT/V	NkT/V	NkT/V

$$\int_0^\infty \mathrm{d}\zeta\,\zeta^n e^{-a\zeta}=\frac{\Gamma(n+1)}{a^{n+1}}. \tag{76}$$

Table I summarizes these results as well as some derived thermodynamical quantities in the case of the ultrarelativistic limit. Progressing from the noncovariant approach towards the full covariant approach via the semicovariant approach at a fixed β the canonical partition integral is decreasing as already mentioned when discussing Fig. 1. This behavior as well as the derivatives in respect to β are fixing the differences in the thermodynamical quantities, e.g., the entropy is reducing when progressing towards the full covariant approach. Especially, we want to focus on the average energy.

While Jüttners noncovariant calculations at the ultrarelativistic limit lead to $3NkT$ the semicovariant approach (as well as the method used in Ref. 14) leads to $2NkT$ and the full covariant treatment gives NkT. Thus, a controlled manifest covariant reduction of the extended phase space by N on-shell constraints reduces the average energy by a factor NkT and the final reduction by N time fixations by another factor NkT. Consequently, the specific heat is showing similar differences. As already mentioned by Horowitz *et al.*[14] no empirical evidence distinguishing between these results is available at the present time.

The following should be noted: Usually the noncovariant Jüttner approach in the ultrarelativistic limit is regarded to represent the classical photon gas. This approximate interpretation is not possible within our approach because the applied classical constrained Hamiltonian dynamics of massive particles cannot be used in the ultrarelativistic limit to approximate massless classical particle dynamics. This fact is showing up in the results and can be recognized inspecting $Z_C^{(ur)}$ (see Table I): In contradiction to the Jüttner approach $Z_C^{(ur)}$ remains mass dependant in the ultrarelativistic limit in case of the semicovariant and the full covariant approach.

D. Nonrelativistic limit

Finally, we examine the nonrelativistic limit of our approach. Since the covariant time fixations (4) reduce to the simple time fixations (3) in this limit the canonical partition integral within both approaches, semicovariant and full covariant, coincide according to Eq. (12) to be

$$Z_C^{(ur)} = \frac{1}{N!} \int \prod_{i=1}^{N} d^4q_i d^4p_i e^{-\beta E} \delta\left(\epsilon_i - \frac{\mathbf{p}_i^2}{2m_i} \right) \delta(q_i^0 - \tau). \tag{77}$$

Special care must be taken regarding the invariant energy E. In order to get a fair comparison in the nonrelativistic limit the rest masses of the particles must be subtracted from their energies getting in the comoving frame of reference

$$E = \sum_i^N (p_i^0 - m_i). \tag{78}$$

Using further $p_i^0 = \epsilon_i + m_i$ Eq. (77) simplifies to

$$Z_C^{(nr)} = \frac{V^N}{N!} \int \prod_{i=1}^{N} d^3p_i e^{-\beta(\mathbf{p}_i^2/2m_i)} = \frac{V^N}{N!} \left[\left(\frac{2\pi m^2}{\beta m} \right)^{3/2} \right]^N, \tag{79}$$

i.e., the nonrelativistic canonical partition integral.

Note, the same result can be achieved starting with the analytical result as obtained by the semicovariant approach. Supplementing Eq. (62) by a factor $e^{\beta N m}$ which covers the effect of the reduction of the energies by the rest masses [compare Eq. (78)], Eq. (62) transforms to

$$Z_C = \frac{V^N}{N!} e^{\beta N m} \left[\frac{4\pi m^3}{\beta m} K_1(\beta m) \right]^N. \tag{80}$$

In the nonrelativistic limit ($m \gg kT$) the asymptotic form of the modified Bessel function ($\beta m \to \infty$)

$$K_n(\beta m) \simeq \sqrt{\frac{\pi}{2\beta m}} e^{-\beta m} \left(1 + \frac{4n^2 - 1}{8\beta m} + \cdots \right) \tag{81}$$

can be applied. Since K_1 and K_2 coincide in the leading order the semicovariant approach and the noncovariant Jüttner approach provide the same result in the nonrelativistic limit namely, the nonrelativistic canonical partition integral (79) within this treatment.

V. SUMMARY AND CONCLUSION

A covariant equilibrium statistical mechanics has been formulated on the base of constrained Hamiltonian dynamics. The usage of this formalism to describe the microdynamics of the ensembles guarantees the manifest covariance of the developed approach.

Unfortunately, concrete calculations are not easily performed within this approach. As a simple application the canonical partition integral of the monatomic perfect gas has been evaluated numerically. Relativistic effects at very high temperatures have been observed.

The comparison of the obtained results with the results of the nonrelativistic theory show a decreasing partition integral at very high temperatures. In contradiction to this findings other relativistic approaches like the noncovariant calculations of Jüttner are showing an increased partition integral at these temperatures. It has been demonstrated that the full covariant treatment of the phase space is responsible for this significant difference. Considering the ultrarelativistic limit the same behavior is visible on a full analytical base. In the nonrelativistic limit the results coincide with the results obtained within the nonrelativistic theory.

As in the nonrelativistic theory the link to thermodynamics has been performed via the free energy. All thermodynamical potentials (like the internal energy, the free energy,…) as well as the thermodynamical state variables (like temperature, entropy, pressure,…) have been defined to be Lorentz scalars. This was achieved introducing the invariant internal energy $E=U_\mu P^\mu$ in the canonical distribution function. Regarding the ultrarelativistic limit the entropy, the average energy, and the specific heat are decreased in comparison to other approaches in this limit.

Unfortunately, the temperature regime which shows significant differences among the various approaches ($T \geqslant 10^{12}$ K) cannot be reached in experiments but may exist in cosmological events. Hence, it may be interesting to use the presented special relativistic approach as a base to develop a general relativistic equilibrium statistical mechanics being manifest covariant from first principle.

Solvable reaction-diffusion processes without exclusion

Masoud Alimohammadi[a)]
School of Physics, University of Tehran, North Karegar Ave., Tehran, Iran

(Received 16 November 2005; accepted 21 December 2005;
published online 22 February 2006)

For reaction-diffusion processes without exclusion, in which the particles can exist in the same site of a one-dimensional lattice, we study all the integrable models which can be obtained by imposing a boundary condition on the master equation of the asymmetric diffusion process. The annihilation process is also added. The Bethe ansatz solution and the exact N-particle conditional probabilities are obtained.
 [DOI: 10.1063/1.2168398]

I. INTRODUCTION

There are a variety of phenomena that can be explained by stochastic models, and their nonequilibrium behaviors can be understood by rather simple rules.[1–3] One of the important examples of these models are the reaction-diffusion processes on a one-dimensional lattice for which their dynamics are fully specified by their master equation.[4,5] A simple example of reaction-diffusion process is asymmetric simple exclusion process (ASEP),[2,6,7] which is known to be relevant to various fields of science like the kinetics of biopolymerization,[8,9] traffic models,[10] polymers in random media, dynamical models of interface growth,[11,12] noisy Burgers equation,[13] study of shocks,[14,15] sequence alignment,[16] and molecular motors.[17] For recent reviews, see for instance.[18–20]

The ASEP is a lattice model in which each particle hops to its right (left) nearest-neighboring site with a probability $D_R\,\mathrm{d}t(D_L\,\mathrm{d}t)$ in an infinitesimal interval $\mathrm{d}t$. In addition, particles are subject to hard-core exclusion: each site is either occupied only by one particle or empty. ASEP has been studied in Ref. 21 by introducing a master equation which describes the time evolution of probabilities $P(x_1,\ldots,x_N;t)$, when the particles are not in neighboring sites, and a so-called boundary condition, which specifies the situations in which the probabilities go outside the physical region $x_1<x_2<\cdots<x_N$. These happen when some of the particles are in adjacent sites and the master equation can not be applied to them. It has been shown that the model is integrable in the sense that the N-particle S-matrix is factorized into a product of two-particle S-matrices. The coordinate Bethe ansatz has been used in this proof. Note that the S-matrix can completely determine the dynamics of a Markovian process, i.e., the N-particle probabilities of a model.

By choosing other suitable boundary conditions, without changing the master equation, one may study the more complicated reaction-diffusion processes, even with long-range interaction. In Ref. 22, the so-called drop-push model has been studied by this method. In this model the particle hops to the next right site even if it is occupied. The particle hops to this site by pushing all the neighboring particles to their next right sites, with a rate depending on the number of right neighboring particles. The generalization of this model, by considering both the right and left hopping, has been done in Ref. 23. This method has been also applied to more-than-one-species situations, which become more complicated. The complexity arises from the above-mentioned factorization of N-particle scattering matrix. In these cases, the factorization demands the two-

a)Electronic mail: alimohmd@ut.ac.ir

particle *S*-matrices to satisfy the spectral Yang-Baxter equation. Various solvable multispecies models have been studied in this way, of which the most recent general cases have been discussed in Refs. 24 and 25.

All of the above studies have been restricted to interactions which include the hard-core exclusion. This made some simplification. In Refs. 26 and 27, an asymmetric diffusion model without exclusion has been shown to be integrable and to have the same *R*-matrix as that of the ASEP. In Ref. 28, it has been shown that the processes

$$mn \to m-l, n+l \quad \text{with rate } \frac{D_R}{[l]},$$

$$mn \to m+l, n-l \quad \text{with rate } \frac{D_R \gamma^l}{[l]}, \tag{1}$$

is integrable, in the sense of the above-mentioned two-particle factorization. The numbers "*m*," "*n*,"… indicate the particle numbers on a site, $\gamma = D_L/D_R$, and

$$[l] = \frac{1-\gamma^l}{1-\gamma}. \tag{2}$$

Note that in Ref. 28, the reaction rates of Eq. (1) are scaled by D_R. These processes are obtained by imposing the boundary condition

$$P_N(\ldots, x_j, x_j - 1, \ldots; t) = D_R P_N(\ldots, x_j - 1, x_j - 1, \ldots; t) + D_L P_N(\ldots, x_j, x_j, \ldots; t) (j = 1, \ldots, N-1), \tag{3}$$

on the master equation of ASEP,

$$\frac{\partial}{\partial t} P(x_1, \ldots, x_j, \ldots, x_N; t) = \sum_{j=1}^{N} D_R P(x_1, \ldots, x_{j-1}, x_j - 1, x_{j+1}, \ldots, x_N; t) + \sum_{j=1}^{N} D_L P(x_1, \ldots, x_{j-1}, x_j + 1, x_{j+1}, \ldots, x_N; t) - N P(x_1, \ldots, x_j, \ldots, x_N; t), \tag{4}$$

in which we have used a time scale so that $D_R + D_L = 1$. In the above equation, $P(x_1, \ldots, x_N; t)$ is the probability for finding at time t the particles at sites $x_1, \ldots, x_N$. We take these functions to define probabilities only in the physical region $x_1 \leqslant x_2 \leqslant \cdots \leqslant x_N$. In fact, in the domain $\Omega_N = x_1 \leqslant x_2 \leqslant \cdots \leqslant x_N \subset Z^N$, the function P is the probability defined above, whereas in Z^N/Ω_N it is defined by the master equation (4), but it is not a probability. The master equation (4) is only valid for

$$x_i < x_{i+1}, \tag{5}$$

since for $x_i = x_{i+1}$, there will be terms with $x_i = x_{i+1} + 1$ on the right-hand side of Eq. (4), which is out of the physical region. One can, however, assume that (4) is valid for all physical region $x_i \leqslant x_{i+1}$, and impose a certain boundary condition for $x_i = x_{i+1}$. The boundary condition (3) leads to interactions (1).

In this paper we want to study all possible boundary conditions for single-species systems and derive all the integrable one-dimensional reaction-diffusion processes without exclusion which can be obtained by this method. The scheme of the paper is the following. In Sec. II, we show that there are two types of boundary conditions when $D_R \neq 0$ and $D_L \neq 0$. The first is one considered in Ref. 28, i.e., Eq. (3), which we call the **type 1** model, and the second one is

$$D_R P(x, x-1) + D_L P(x+1, x) = P(x, x). \tag{6}$$

Here we have suppressed all the other coordinates for simplicity. We show that the interactions of this **type 2** model are

$$mn \to m-1,n+1 \quad \text{with rate } D_R,$$

$$mn \to m+1,n-1 \quad \text{with rate } D_L. \tag{7}$$

This is the reactions (1), restricted to $l=1$. In other words, to have an integrable model, it is not necessary to have the simultaneous hoppings of any number of particles from a common site to the neighboring site [as indicated in (1)], but the one particle hoppings can also lead to integrable models. Note that the reactions (7) is not a subset of processes (1).

In the totally asymmetric case with $D_L=0$, we show in Sec. III that there is a new boundary condition which is a linear combination of boundary conditions (3) and (6), i.e.,

$$P(x,x-1)=\lambda P(x,x)+\mu P(x-1,x-1). \tag{8}$$

It is shown that this **type 3** model contains the reactions

$$mn \to m-l,n+l, \tag{9}$$

with rates

$$r_l=\frac{1}{1+\frac{\lambda}{\mu}+\cdots+\left(\frac{\lambda}{\mu}\right)^{l-1}}. \tag{10}$$

This is an interesting one-parameter family of interactions.

In Sec. IV, we generalize the boundary conditions (3), (6), and (8) to include annihilation to the processes (1), (7), and (9), respectively. The resulting models are rather involved. To be specific, we consider $D_L=0$ case of (3), and show that the boundary condition

$$P(x,x-1)=\mu P(x-1,x-1) \quad (\mu<1) \tag{11}$$

describes the reactions

$$mn \to m-l,n+l \quad \text{with rate } \mu^{l-1},$$

$$n \to \begin{cases} n-1 \\ n-2 \\ \cdots \end{cases} \quad \text{with total rates } n-\sum_{l=0}^{n-1}\mu^l. \tag{12}$$

The second reactions are the annihilation processes. We call this model the **type 4** model. It must be mentioned that we cannot extend our investigation to include the creation processes. The main reason is that if we do so, the evolution equation of n-particle sector will not become closed and will depend on the more-than-n-particle configurations.

The Bethe ansatz solution for different models is discussed in Sec. V and the exact N-point conditional probabilities of type 4 model is obtained in Sec. VI. Some interesting physical quantities are also obtained. Finally we discuss the multispecies extension of these processes in the last section and show that this generalization is not possible for the reactions without exclusion.

II. REACTIONS WITH $D_L \neq 0$ AND $D_R \neq 0$

Consider the master equation (4) for the two particle sector, when the particles are at site $x_1=x_2=x$,

$$\dot{P}(x,x)=D_RP(x-1,x)+D_RP(x,x-1)+D_LP(x+1,x)+D_LP(x,x+1)-2P(x,x). \tag{13}$$

The second and third probabilities on the right-hand side of the above equation are out of the physical region, and must be defined through some boundary conditions. There are only two

possibilities which are consistent in more-than-two-particle sectors. The first one is

$$\mu' P(x,x-1) = D_R P(x-1,x-1) + D_L P(x,x), \tag{14}$$

and the second one is

$$D_R P(x,x-1) + D_L P(x+1,x) = \lambda' P(x,x). \tag{15}$$

In the first choice, we take any unphysical terms of Eq. (13) as a linear combination of physical functions, and in the second choice, we take the whole unphysical terms as a linear combination of the physical probabilities. The right-hand sides of Eqs. (14) and (15) are the only allowed combinations which one can write. This was discussed in Ref. 25 for ASEP cases. In fact, one can use any other parameters α and β instead of D_R and D_L in Eq. (14), with condition $\alpha+\beta=1$. Also one can add two other terms $\mu P(x-1,x-1)$ and $\nu P(x+1,x+1)$ to the right-hand side of Eq. (15), but it can be shown that for obtaining a consistent description in more-than-two-particle sectors, one must take $\mu=\nu=0$ (see Sec. III of Ref. 25 for more details in the ASEP case).

To obtain the range of parameters μ' and λ', one can use Eq. (4) to show that

$$\begin{aligned}\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1\leqslant x_2} P(x_1,x_2;t) &= -\sum_x P(x,x;t) + D_R\sum_x P(x,x-1;t) + D_L\sum_x P(x+1,x;t)\\ &= -\sum_x P(x,x;t) + \sum_x P(x,x-1;t).\end{aligned} \tag{16}$$

For boundary condition (14), Eq. (16) results in

$$\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1\leqslant x_2} P(x_1,x_2;t) = \left(\frac{1}{\mu'}-1\right)\sum_x P(x,x;t), \tag{17}$$

and for boundary condition (15), it results in

$$\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1\leqslant x_2} P(x_1,x_2;t) = (\lambda'-1)\sum_x P(x,x;t). \tag{18}$$

In the first step, let us exclude the annihilation processes and therefore it is assumed that the number of particles is constant in time. In this way, the Eqs. (17) and (18) lead to

$$\mu' = 1 \quad [\text{for boundary condition (14)}],$$

$$\lambda' = 1 \quad [\text{for boundary condition (15)}]. \tag{19}$$

Equation (14) exactly becomes the one studied in Ref. 28, i.e., Eq. (3), and it induces the reactions (1), but the second one, Eq. (15), is new. To obtain the reaction introduced by this boundary condition, with $\lambda'=1$, we first consider $\dot{P}(x,x)$ in Eq. (13). Using Eqs. (15) and (19), one finds

$$\dot{P}(x,x) = D_R P(x-1,x) + D_L P(x,x+1) - P(x,x), \tag{20}$$

which is the evolution equation of the following two-particle reactions:

$$10 \to 01 \quad \text{with rate } D_R,$$

$$01 \to 10 \quad \text{with rate } D_L. \tag{21}$$

Remember $D_R+D_L=1$. Generally, for n particles existing at a common site x, one finds from (4),

$$\frac{\partial}{\partial t}P(\underbrace{x,\ldots,x}_{n}) = D_R P(x-1,\underbrace{x,\ldots,x}_{n-1}) + D_L P(\underbrace{x,\ldots,x}_{n-1},x+1)$$
$$+\sum_{j=2}^{n} D_R P(x_1=x,\ldots,x_{j-1}=x,x_j=x-1,x_{j+1}=x,\ldots,x_n=x)$$
$$+\sum_{j=2}^{n} D_L P(x_1=x,\ldots,x_{j-2}=x,x_{j-1}=x+1,x_j=x,\ldots,x_n=x) - nP(\underbrace{x,\ldots,x}_{n})$$
$$= D_R P(x-1,\underbrace{x,\ldots,x}_{n-1}) + D_L P(\underbrace{x,\ldots,x}_{n-1},x+1) - P(\underbrace{x,\ldots,x}_{n}), \tag{22}$$

which is obviously the evolution equation of reactions (7).

III. TOTALLY ASYMMETRIC DIFFUSION WITH $D_L=0$

In $D_L=0$, the boundary condition (3) and (6) becomes

$$P(x,x-1) = P(x-1,x-1),$$

$$P(x,x-1) = P(x,x), \tag{23}$$

respectively, which describe the interactions

$$mn \to m-l,n+l \quad \text{with rate } 1 \tag{24}$$

and

$$mn \to m-1,n+1 \quad \text{with rate } 1, \tag{25}$$

respectively. But as was first noted in Ref. 22 for ASEP, the linear combination of these two boundary conditions may result in a integrable model. So we consider

$$P(x,x-1) = \lambda P(x,x) + \mu P(x-1,x-1), \tag{26}$$

as the boundary condition for the following master equation:

$$\frac{\partial}{\partial t}P(x_1,\ldots,x_N;t) = \sum_{j=1}^{N}[P(x_1,\ldots,x_{j-1},x_j-1,x_{j+1}\ldots,x_N;t) - P(x_1,\ldots,x_N;t)]. \tag{27}$$

First we note that

$$\frac{\partial}{\partial t}\sum_{x_2}\sum_{x_1\leqslant x_2} P(x_1,x_2;t) = (\lambda+\mu-1)\sum_{x} P(x,x;t), \tag{28}$$

from which the conservation of number of particles results

$$\lambda+\mu=1. \tag{29}$$

To obtain the resulting reactions, besides the diffusion $10\to01$ with rate 1, we first consider $\dot{P}(x,x)$. Using (26) and (27), it is found that

$$\dot{P}(x,x) = P(x-1,x) + \mu P(x-1,x-1) - (2-\lambda)P(x,x), \tag{30}$$

which represents the reaction $20\to02$, with rate $\mu=1-\lambda$, as the source and sink of this state. To find the reactions in the general case, we first prove a lemma.

Lemma: Equation (26) implies, for arbitrary n, the following:

$$P(\underbrace{x,\ldots,x}_{n},x-1)=r_{n+1}P(\underbrace{x-1,\ldots,x-1}_{n+1})+(1-r_{n+1})P(\underbrace{x,\ldots,x}_{n+1}), \tag{31}$$

with r_n defined through (10).

Proof: We proceed by induction. For $n=1$, (31) reduces to (26). Assuming (31) is correct for $n-1$, then using (26), we have

$$\begin{aligned}P(\underbrace{x,\ldots,x}_{n},x-1)&=\lambda P(\underbrace{x,\ldots,x}_{n+1})+\mu P(\underbrace{x,\ldots,x}_{n-1},x-1,x-1)\\&=\lambda P(\underbrace{x,\ldots,x}_{n+1})+\mu[r_nP(\underbrace{x-1,\ldots,x-1}_{n+1})\\&\quad+(1-r_n)P(\underbrace{x,\ldots,x}_{n},x-1)],\end{aligned} \tag{32}$$

so

$$P(\underbrace{x,\ldots,x}_{n},x-1)=r_{n+1}P(\underbrace{x-1,\ldots,x-1}_{n+1})+s_{n+1}P(\underbrace{x,\ldots,x}_{n+1}), \tag{33}$$

where

$$r_{n+1}=\frac{\mu r_n}{1-\mu(1-r_n)},\quad s_{n+1}=\frac{\lambda}{1-\mu(1-r_n)}. \tag{34}$$

It is seen that $r_{n+1}+s_{n+1}=1$. The value of r_n can be found by solving the first equation of (34), which can be written as

$$r_{n+1}^{-1}=1+\frac{\lambda}{\mu}r_n^{-1}. \tag{35}$$

Using $r_2^{-1}=(1/\mu)=1+(\lambda/\mu)$, (35) leads to Eq. (10) for r_n's. This proves the lemma. □

We now consider the evolution of $P(\underbrace{x,\ldots,x}_{n})$.
Using (27) and (31), we find

$$\begin{aligned}\frac{\partial}{\partial t}P(\underbrace{x,\ldots,x}_{n})&=\sum_{j=1}^{n}P(x_1=x,\ldots,x_{j-1}=x,x_j=x-1,x_{j+1}=x,\ldots,x_n=x)-nP(\underbrace{x,\ldots,x}_{n})\\&=\sum_{j=1}[r_jP(x_1=x-1,\ldots,x_j=x-1,x_{j+1}=x,\ldots,x_n=x)+(1-r_j)P(\underbrace{x,\ldots,x}_{n})]-nP(\underbrace{x,\ldots,x}_{n})\\&=\sum_{j=1}r_jP(x_1=x-1,\ldots,x_j=x-1,x_{j+1}=x,\ldots,x_n=x)-\left(\sum_{j=1}^{n}r_j\right)P(\underbrace{x,\ldots,x}_{n}).\end{aligned} \tag{36}$$

This equation shows that a collection of j particles hops from site $x-1$ to site x with rate r_j, and this proves that the induced reactions of the boundary condition (8) are those indicated in (9).

At $\lambda=1$ ($\mu=0$), Eq. (10) results in $r_l=\delta_{l1}$. So the reactions are

$$mn\to m-1,n+1,\quad \text{with rate } 1. \tag{37}$$

This is nothing but Eq. (25). At $\lambda=0$ ($\mu=1$), Eq. (10) gives $r_l=1$ for all l's. So the reactions are those shown in (24). In fact, at $\lambda=0$, all the multiparticle hoppings occur with equal rate 1. By increasing λ, the greater number of simultaneous hoppings happen with lower rates, until at $\lambda=1$, in which only the one-particle hopping is allowed.

IV. ANNIHILATION-DIFFUSION PROCESSES

Adding annihilation to the preceding reactions, results in the decreasing of the number of particles with time. Therefore the parameters μ', λ', and (λ,μ) in Eqs. (14), (15), and (26) become

$$\mu' > 1 \quad [\text{for boundary condition (14)}],$$

$$\lambda' < 1 \quad [\text{for boundary condition (15)}],$$

$$\mu + \lambda < 1 \quad [\text{for boundary condition (26)}]. \tag{38}$$

These are obtained from Eqs. (17), (18), and (28), respectively. Note that the annihilation interactions only appear in sink terms of the master equation, since if we consider an initial state with n particles, no annihilation process can lead to a n-particle state at any later time t.

To obtain the corresponding interactions of either of boundary conditions, we begin with (15) with $\lambda' < 1$. Considering $\dot{P}(x,x)$, one finds

$$\dot{P}(x,x) = D_R P(x-1,x) + D_L P(x,x+1) - (2-\lambda')P(x,x), \tag{39}$$

which shows the annihilation rate $1-\lambda'$ for the state of two particle at a common site. In general case, one finds, similar to Eq. (22),

$$\frac{\partial}{\partial t}P(\underbrace{x,\ldots,x}_{n}) = D_R P(x-1,\underbrace{x,\ldots,x}_{n-1}) + D_L P(\underbrace{x,\ldots,x}_{n-1},x+1) - [n-(n-1)\lambda']P(\underbrace{x,\ldots,x}_{n}), \tag{40}$$

which is the evolution equation of the following reactions:

$$mn \to m-1, n+1 \quad \text{with rate } D_R,$$

$$mn \to m+1, n-1 \quad \text{with rate } D_L,$$

$$n \to \begin{cases} n-1 \\ n-2 \\ \cdots \end{cases} \quad \text{with total rates } (n-1)(1-\lambda'). \tag{41}$$

In the case of boundary condition (26) with $\lambda+\mu<1$, it is not easy to obtain a compact form for interaction rates in the general case. For example, in two- and three-particle sectors, considering $\dot{P}(x,x)$ and $\dot{P}(x,x,x)$, one finds

$$mn \to m-1, n+1 \quad \text{with rate } 1,$$

$$mn \to m-2, n+2 \quad \text{with rate } \mu,$$

$$mn \to m-3, n+3 \quad \text{with rate } \frac{\mu^2}{1-\lambda\mu},$$

$$2 \to 1 \quad \text{with rate } \alpha = 1-(\lambda+\mu),$$

$$3 \to \begin{cases} 2 \\ 1 \end{cases} \quad \text{with total rates } \frac{\alpha(\mu^2+\alpha\mu+2)}{1-\lambda\mu}. \tag{42}$$

In this case, we have a two-parameter family of interactions.

When we consider the boundary condition (14) with $\mu' > 1$, again we can not find the compact relations and it is better to restrict ourselves to the subset of totally asymmetric reactions with $D_L = 0$. This means that we take

$$P(x, x-1) = \mu P(x-1, x-1) \quad (\mu < 1) \tag{43}$$

as the boundary condition ($\mu = 1/\mu'$). Considering the general case $P(x, \ldots, x)$, results in

$$\begin{aligned} \frac{\partial}{\partial t} P(\underbrace{x, \ldots, x}_{n}) &= \sum_{j=1}^{n} P(x_1 = x, \ldots, x_{j-1} = x, x_j = x-1, x_{j+1} = x, \ldots, x_n = x) - nP(\underbrace{x, \ldots, x}_{n}) \\ &= \sum_{j=1}^{n} \mu^{j-1} P(x_1 = x-1, \ldots, x_j = x-1, x_{j+1} = x, \ldots, x_n = x) - nP(\underbrace{x, \ldots, x}_{n}). \end{aligned} \tag{44}$$

This equation shows that the sources are the simultaneous hoppings of j particles ($j = 1, \ldots, n$) from the common site $x-1$ to x, with rates μ^{j-1}. So the sinks are also these hoppings and the remaining rate of the sink terms in Eq. (44), i.e., $n - \Sigma_{j=0}^{n-1} \mu^j$, is due to the annihilations of these n particles at site x. So, it is proved that the boundary condition (43) induces the reactions (12).

V. BETHE ANSATZ SOLUTION

Now we try to solve the resulting evolution equations, in all the discussed cases, by the following Bethe ansatz:

$$P(\mathbf{x}; t) = e^{-E_N t} \psi(\mathbf{x}), \tag{45}$$

where $\mathbf{x} = (x_1, \ldots, x_N)$, and

$$\psi(\mathbf{x}) = \sum_{\sigma} A_\sigma e^{i\sigma(\mathbf{p})\cdot\mathbf{x}}. \tag{46}$$

The summation runs over the elements of permutation group of N object. Inserting (46) in master equation (4), results in

$$E_N = \sum_{k=1}^{N} (1 - D_R e^{-ip_k} - D_L e^{ip_k}). \tag{47}$$

To determine A_σ, we must insert the expression (46) in the boundary conditions. For the type 2 model, for instance, we must use Eq. (6), which results in

$$D_R \psi(\ldots, x_i = x, x_{i+1} = x-1, \ldots) + D_L \psi(\ldots, x_i = x+1, x_{i+1} = x, \ldots) = \psi(\ldots, x_i = x, x_{i+1} = x, \ldots), \tag{48}$$

and using (46), gives

$$[D_R e^{-i\sigma(p_{k+1})} + D_L e^{i\sigma(p_k)} - 1] A_\sigma + [D_R e^{-i\sigma(p_k)} + D_L e^{i\sigma(p_{k+1})} - 1] A_{\sigma\sigma_k} = 0. \tag{49}$$

σ_k is an element of permutation group which only interchanges p_k and p_{k+1},

$$\sigma_k : (p_1, \ldots, p_k, p_{k+1}, \ldots, p_N) \to (p_1, \ldots, p_{k+1}, p_k, \ldots, p_N). \tag{50}$$

Equation (49) gives $A_{\sigma\sigma_k}$ in terms of A_σ as follows:

$$A_{\sigma\sigma_k} = S^{(2)}(\sigma(p_k), \sigma(p_{k+1})) A_\sigma, \tag{51}$$

where

$$S^{(2)}(z_1,z_2) = -\frac{D_R z_2 + D_L z_1^{-1} - 1}{D_R z_1 + D_L z_2^{-1} - 1}, \tag{52}$$

where $z_k = e^{-ip_k}$. Equation (51) allows one to compute all A_σ's in terms of A_1, which is set to unity.

The same procedure can be applied to other boundary conditions. For example for type 3 model, boundary condition (8), one finds

$$S^{(3)}(z_1,z_2) = -\frac{\lambda + \mu(z_1+z_2) - z_2}{\lambda + \mu(z_1+z_2) - z_1}, \tag{53}$$

and for boundary condition (15), with $\lambda' < 1$,

$$S(z_1,z_2) = -\frac{D_R z_2 + D_L z_1^{-1} - \lambda'}{D_R z_1 + D_L z_2^{-1} - \lambda'}. \tag{54}$$

These solutions can be used, in principle, to calculate the conditional probabilities $P(x_1,\ldots,x_N;t|y_1,\ldots,y_N;0)$. This is the probability of finding the particles at time t at sites $x_1,\ldots,x_N$, if at $t=0$, they were at sites $y_1,\ldots,y_N$, respectively. But unfortunately, the standard method, used for example, in Refs. 21–25, cannot be used here. This is because the initial condition

$$P(\mathbf{x};0|\mathbf{y};0) = \delta_{\mathbf{x},\mathbf{y}} \tag{55}$$

is satisfied by the standard expression

$$P(\mathbf{x};t|\mathbf{y};0) = \int \frac{d^N p}{(2\pi)^N} e^{-E_N t} e^{-i\mathbf{p}\cdot\mathbf{y}} \psi(\mathbf{x}), \tag{56}$$

only when $y_i < y_{i+1}$ and $x_i < x_{i+1}$. This condition is only satisfied by exclusion processes and for processes without exclusion, we must look for other methods.

VI. *N*-PARTICLE CONDITIONAL PROBABILITIES

In some special cases, it is possible to calculate the conditional probabilities in terms of a specific determinant. This was first proved in Ref. 21, and then used for other cases in Refs. 22 and 23. Now we want to check that this method does work here, and as a specific example, we consider the type 4 model with the boundary condition (11).

We set the following ansatz for N-particle conditional probabilities:

$$P(\mathbf{x};t|\mathbf{y};0) = e^{-Nt} \det[G(\mathbf{x};t|\mathbf{y};0)], \tag{57}$$

where G is a $N\times N$ matrix with elements

$$G_{ij}(\mathbf{x};t|\mathbf{y};0) = g_{i-j}(x_i - y_j;t). \tag{58}$$

Inserting (57) in Eqs. (27) and (11), results in

$$\frac{\partial}{\partial t} G_i(x;t) = G_i(x-1;t),$$

$$G_{i-1}(x;t) = \mu G_{i-1}(x-1;t) + \beta G_i(x-1;t), \tag{59}$$

where G_i denotes the ith row of matrix G, and β is an arbitrary constant. In terms of functions $g_p(n;t)$, (59) becomes

$$\frac{\partial}{\partial t} g_p(n;t) = g_p(n-1;t),$$

$$g_p(n;t) = \mu g_p(n-1;t) + \beta g_{p+1}(n-1;t). \tag{60}$$

Introducing the z-transform

$$\tilde{g}_p(z,t) = \sum_{n=-\infty}^{\infty} z^n g_p(n;t), \tag{61}$$

we find

$$\frac{\partial}{\partial t}\tilde{g}_p(z,t) = z\tilde{g}_p(z,t) \Rightarrow \tilde{g}_p(z,t) = e^{zt}\tilde{g}_p(z,0),$$

$$\tilde{g}_{p+1}(z,t) = \frac{1-\mu z}{\beta z}\tilde{g}_p(z,t). \tag{62}$$

The second equation yields

$$\tilde{g}_p(z,0) = \left(\frac{1-\mu z}{\beta z}\right)^p \tilde{g}_0(z,0). \tag{63}$$

Using $P(x;0|y;0) = g_0(x-y;0) = \delta_{x,y}$, one finds $\tilde{g}_0(z,0) = 1$. Finally

$$\tilde{g}_p(z,t) = e^{zt}\left(\frac{1-\mu z}{z}\right)^p, \tag{64}$$

in which we choose $\beta = 1$. The functions $g_p(n;t)$ can be obtained by expanding the generating functions $\tilde{g}_p(z,t)$. For $p \geqslant 0$, the expansion yields

$$g_p(n;t) = \sum_{m=0}^{p} \binom{p}{m} (-\mu)^m \frac{t^{n+p-m}}{(n+p-m)!}, \tag{65}$$

and for negative p, it yields

$$g_{-|p|}(n;t) = \sum_{m=0}^{n-|p|} \binom{|p|+m-1}{m} \mu^m \frac{t^{n-|p|-m}}{(n-|p|-m)!}. \tag{66}$$

We have thus obtained the explicit relation for conditional probabilities.

It can be checked that the resulting function satisfies the desired initial condition. At $t=0$, where $x_i = y_i$, we have $g_{-|p|}(0;t) = 0$ and $g_0(n;0) = \delta_{n,0}$, which result $P(\mathbf{x};0|\mathbf{x};0) = 1$. Also it may be interesting to obtain the rate of decay of a delta function distribution. Suppose at $t=0$, there are N particles at the same site y. We want to obtain the probability of finding all the particles at their initial positions at later time t, i.e., $P(\mathbf{y};t|\mathbf{y};0)$, where $\mathbf{y} = (y,\ldots,y)$. Using $g_{-|p|}(0;t) = 0$ and $g_0(0;t) = 1$, we obtain

$$P(\mathbf{y};t|\mathbf{y};0) = e^{-Nt}\det[G(\mathbf{y};t|\mathbf{y};0)] = e^{-Nt}, \tag{67}$$

which is independent of μ! It is an interesting result. At $\mu = 1$, where there is no annihilation, the rate of simultaneous hoppings of particles are all 1, irrespective of the number of particles. By decreasing μ, the rates of simultaneous hoppings decrease with increasing the number of particles [see Eq. (12)]. At the same time, the rate of annihilation increases in such a way that the total decaying rate remains constant.

The above determinant method can be applied to any model which its boundary condition equation contains only two terms. Otherwise it does not lead to the consistent relations for matrix elements $g_p(n;t)$'s. So for $D_R = 0$ *or* $D_L = 0$ cases of boundary conditions (3) and (6), and $\lambda = 0$ *or*

$\mu=0$ cases of boundary condition (8), this method leads to explicit expressions for N-particle conditional probabilities.

VII. CONCLUSION

In the preceding sections, we use all the allowed generalizations of the boundary condition in the asymmetric reaction-diffusion processes without exclusion, to obtain several integrable models for one-species cases. The further natural generalization, which has been discussed in many papers for the ASEP case, is the multispecies extensions of these models. In multispecies studies, one considers a p-species system with particles $A_1,\ldots,A_p$. The basic objects are the probabilities $P_{\alpha_1\ldots\alpha_N}(x_1,\ldots,x_N;t)$ for finding at time t the particles of type α_1 at x_1, particle of type α_2 at x_2, etc. The master equation, instead of (4), is Ref. 25,

$$\begin{aligned}\frac{\partial}{\partial t}P_{\alpha_1\ldots\alpha_N}(x_1,\ldots,x_j,\ldots,x_N;t) &= \sum_{j=1}^{N} D_R P_{\alpha_1\ldots\alpha_N}(x_1,\ldots,x_{j-1},x_j-1,x_{j+1},\ldots,x_N;t)\\ &\quad+\sum_{j=1}^{N} D_L P_{\alpha_1\ldots\alpha_N}(x_1,\ldots,x_{j-1},x_j+1,x_{j+1},\ldots,x_N;t)\\ &\quad- NP_{\alpha_1\ldots\alpha_N}(x_1,\ldots,x_j,\ldots,x_N;t).\end{aligned} \tag{68}$$

Now if we want to use this equation for reactions without exclusion, the problem will arise when some of the particles are in the same position. Consider, for example, the two-species case $P_{\alpha_1\alpha_2}(x,x)$. It is seen that Eq. (68) has the term $P_{\alpha_1\alpha_2}(x-1,x)$, as the source term of the desired state, but does not contain $P_{\alpha_2\alpha_1}(x-1,x)$, which is as important as the first term. In fact, this is the source of many difficulties that arise in multispecies extension of reaction-diffusion processes which have no exclusion. So it seems that the integrable models discussed in the preceding sections are *all* that one can obtain in this context.

(Received 26 October 2005; accepted 9 December 2005; published online 10 February 2006)

Noncommutative differential calculus on quantum Minkowski space is not separated with respect to the standard generators, in the sense that partial derivatives of functions of a single generator can depend on all other generators. It is shown that this problem can be overcome by a separation of variables. We study the action of the universal L-matrix, appearing in the coproduct of partial derivatives, on generators. Powers of the resulting quantum Minkowski algebra valued matrices are calculated. This leads to a nonlinear coordinate transformation which essentially separates the calculus. A compact formula for general derivatives is obtained in form of a chain rule with partial Jackson derivatives. It is applied to the massive quantum Klein-Gordon equation by reducing it to an ordinary q-difference equation. The rest state solution can be expressed in terms of a product of q-exponential functions in the separated variables. © *2006 American Institute of Physics.*

I. INTRODUCTION

A. Quantum theory on noncommutative space-time

Much of the development of quantum theories on noncommutative space-times was and still is driven by the question whether noncommutative geometry might lead to an ultraviolet regularization of quantum field theory, as it was suggested by Heisenberg as early as 1938.[1] For the simplest conceivable examples of noncommutative geometries, where the commutator of the coordinates is constant, these hopes for regularization were met with disappointment. Such theories exhibit a mixing of ultraviolet and infrared cutoff scales,[2,3] which has been understood recently on the level of renormalization.[4] For that reason these simple noncommutative spaces, while interesting objects on their own, hardly seem to improve the divergent behavior of quantum field theory at all. The natural next step is to turn again to more complicated noncommutative spaces, such as quantum spaces with Lie type or homogeneous commutation relations.

Quantum Minkowski space is one of the most realistic examples of a quantum deformation of space-time[5] with a rich and fairly well understood mathematical structure: It is four dimensional in the sense that it is generated as algebra by four coordinates such that the ordered monomials are a Poincaré-Birkhoff-Witt basis. The time coordinate is central, which is important for a causal interpretation of quantum theory.[6] By construction, it is a module algebra with respect to the quantum Poincaré algebra,[7] so it has a well-defined quantum symmetry structure.[8] The action of the generators of the inhomogeneous part of the quantum Poincaré algebra, the momenta, on quantum Minkowski space induces a first order covariant differential calculus[9].

With these key mathematical structures present, it was possible to mimic much of the construction of quantum theory on commutative space-time within an algebraic and representation theoretic approach. Sections of noncommutative space-time were studied by spectral theory of

noncommutative coordinates, yielding discrete space-time lattices.[10] Free elementary particles were constructed as irreducible representations of the quantum Poincaré algebra, including Wigner representations of spin.[11] The free particles were shown to obey quantum wave equations which project reducible quantum Lorentz spinor representations on their irreducible subrepresentations.[12] The coupling of free fields to gauge fields was studied systematically within noncommutative gauge theory.[13–17] Quantum statistics of the tensor representation of a second quantized free theory was studied within the framework of braided tensor categories[18] using Drinfeld twists.[19] Only a small selection of the numerous contributions to this program can be cited here. At the time of this writing, many mathematical aspects of free quantum theory on quantum Minkowski space are understood, and the construction of interaction terms on the level of single particle field equations is known. What is not known is how to solve these field equations by noncommutative wave functions, not even for the free case. However, this will be indispensable if free particles are to be coupled by multiplying their noncommutative wave functions within the algebra of quantum space-time, in order to modify the concept of locality on a fundamental level.

We remark, that there are other approaches involving wave equations on noncommutative space-time which are inequivalent to the ones considered here: In Ref. 20 a q-deformed relativistic wave equation was constructed using a q-deformation of the Clifford algebra. This approach yields q-wave equations which are similar to the ones considered here. However, in Ref. 12 it was shown that, from a representation theoretic viewpoint, an additional twisting of the γ-matrices by the universal $\mathcal{R}$-matrix is needed if the q-partial derivatives are to be identified with the q-momenta. In Ref. 21 the construction of deformed wave equations also relied on covariance arguments. But there, a certain deformation of the conformal symmetry algebra was considered which does not contain the standard q-Poincaré algebra as subalgebra. For this reason the wave equations derived in Ref. 21 are different from the ones considered here. In Ref. 22 q-deformed cospinors were used in order to construct q-deformed wave equations. However, these are really cowave equations which are mathematically quite different objects. Finally, a number of authors has used various abstract differential calculi on quantum spaces[23–25] in order to construct q-differential equations. In these cases covariance with respect to the full q-Poincaré algebra, which determined the q-wave equations of Ref. 12 uniquely, was not the guiding principle and is, therefore, not satisfied in general.

B. Noncommutative differential calculus

The free wave equations on quantum Minkowski space can be determined uniquely on a purely representation theoretic level. To give the simplest example, just as in the undeformed case, the momentum square $p_\mu p^\mu$ is central within the quantum Poincaré algebra. Therefore, it must be represented within the irreducible representation corresponding to a free particle by a multiple of the identity operator,

$$p_\mu p^\mu = m^2, \tag{1}$$

m^2 being the square of the particle's mass. This line of reasoning does not depend in any way on how the momenta act on noncommutative wave functions, that is, on elements of quantum Minkowski space.

In order to interpret Eq. (1) as Klein-Gordon equation on noncommutative space-time we must let the momenta act on noncommutative wave functions. Momenta then correspond to partial derivatives, $p^\mu = i\partial^\mu$, defined by the noncommutative first order differential calculus. This yields a wave equation given by a noncommutative partial differential equation,

$$\partial_\mu \partial^\mu \triangleright \psi = -m^2 \psi, \tag{2}$$

where ψ is an element of the algebra of quantum Minkowski space. The triangle notation is used to distinguish the action from the multiplication in the quantum Heisenberg algebra. There is a considerable amount of literature on first order differential calculi on noncommutative algebras, mostly on quantum groups[26] and to some extent on homogeneous quantum spaces.[27,28] Most

mathematical work has concentrated on the construction, structural analysis, and classification of differential calculi. However, hardly any literature on the subject has dealt with concrete calculations within these differential calculi. On quantum Minkowski space a differential calculus has been known for some time, and can be deduced most elegantly from the coproduct of momenta.[9] The coproduct defines the action of partial derivatives on noncommutative functions, recursively. While the recursion relations can be used to expand the derivatives in terms of nested summations and partition functions, as it was carried out in a very detailed manner in Ref. 29, this does not solve the main computational problem which arises with wave equations like Eq. (2).

Trying to solve Eq. (2) by a brute force calculation with a general ansatz for the wave function should work in principle, but turns out to run into considerable computational complexity. Moreover, the solutions thus obtained in terms of recursion relations do not give much structural insight in the solutions which, after all, are the noncommutative counterpart of something as simple and basic as plane waves. Why is this computation so difficult? It can be shown that just as in the commutative case the space of solutions of the massive Klein-Gordon Eq. (2) is generated, as representation of the quantum Poincaré algebra, by a rest state, which satisfies[12]

$$\partial^0 \triangleright \psi = im\psi, \quad \partial^A \triangleright \psi = 0, \tag{3}$$

where A is a three vector index of spatial coordinates. In the commutative case we could now infer that ψ is a function of the time coordinate x_0 alone, thus reducing Eq. (3) to an ordinary differential equation in one coordinate x_0. Not so in the noncommutative case, where the partial derivatives of a function in x_0 depend on all coordinates x_μ, which makes the solution of Eq. (3) so involved. In analogy to partial differential equations in non-Cartesian coordinates we will describe this mixing of dependencies by saying that within the noncommutative calculus the standard variables are not separated.

It is now obvious to ask, whether new variables can be found which separate the differential calculus, such that Eq. (3) becomes easily solvable. The main purpose of this paper is to show that this question has a positive answer.

C. Structure, main results, notation

The paper is organized as follows: In Sec. II the structure of the differential calculus on quantum Minkowski space is reviewed. We recall the commutation relations, general structure of the quantum Lorentz algebra, universal $\mathcal{R}$-matrix, and the definition of the coproduct of momenta in order to make this paper self-contained and fix conventions and notation unambiguously.

Section III contains the bulk of the paper: the computation of derivatives of arbitrary elements in the quantum Minkowski algebra. We first develop a notation and calculus in order to deal with functions of the algebra valued 4×4 matrices which come from the action of the universal L-matrices appearing in the definition of the coproduct of momenta. The computation problem is the calculation of powers of algebra valued matrices, which can then be used to calculate the derivatives of arbitrary functions of the noncommutative coordinates. We do this calculation in two steps: In the first step we deal with polynomials of the noncentral variables. The main result is Proposition 1, Eqs. (69) and can be written in the concise form of a chain rule, where the outer derivatives are partial Jackson derivatives. In the second step we calculate derivatives of functions of the central coordinates, time and four length. The partial derivatives of functions in the time generator are complicated and depend on all other generators. However, we are able to give a noncommutative coordinate transformation such that the derivatives of functions in the central generators are disentangled and take the form of a chain rule, too. This is the main result of the paper, presented in Proposition 3, Eq. (97). The results of these two steps can be combined to yield a compact formula for the derivatives of arbitrary elements of the algebra, given in Eq. (101).

In Sec. IV we apply the formulas for the derivations to the initial problem of finding the momentum eigenstate solutions of the massless and massive quantum Klein-Gordon equation, viewed as differential equations within the noncommutative differential calculus. We show that the separation of variables of the preceding section separates the differential equations completely.

This reduces the partial differential equations to single variable equations involving Jackson derivatives, which are easily solved. The solutions are given in Eqs. (110) and (117) in terms of q-exponential functions.

Following the conlusion in Sec. V, the appendix finally contains a few more technical results which are used in the paper. This makes this paper reasonably self-contained and will be useful for a reader who wishes to reproduce the calculations in detail.

Notation: Throughout the paper q denotes a real positive deformation parameter, such that for $q \to 1$ we retrieve the undeformed, commutative limit. We will often use the abbreviations $\lambda := q - q^{-1}$ and symmetrized and standard quantum numbers,

$$[n] = \frac{q^n - q^{-n}}{q - q^{-1}}, \quad (n)_{q^2} = \frac{q^{2n} - 1}{q^2 - 1}, \tag{4}$$

where n is a natural number. Repeated upper and lower indices are summed over $x_\mu x^\mu \equiv \sum_\mu x_\mu x^\mu$.

II. DIFFERENTIAL CALCULUS ON QUANTUM MINKOWSKI SPACE

A. Quantum Minkowski space

Quantum Minkowski space has first been constructed as braided product of two copies of the quantum plane.[5] We will need the definition in terms of generators which are decomposed into the scalar time coordinate and the three vector of space coordinates.

Definition 1: The algebra generated by the four generators x_0, x_-, x_+, and x_3, divided by the relations

$$x_- x_0 = x_0 x_-, \quad x_+ x_0 = x_0 x_+, \quad x_3 x_0 = x_0 x_3,$$

$$q^{-1} x_- x_3 - q x_3 x_- = -\lambda x_- x_0, \quad q^{-1} x_3 x_+ - q x_+ x_3 = -\lambda x_+ x_0, \tag{5}$$

$$x_- x_+ - x_+ x_- - \lambda x_3 x_3 = -\lambda x_3 x_0,$$

is called the algebra of quantum Minkowski space, denoted by $\mathcal{X}$.

Here, x_0 is the time coordinate, while x_-, x_+, and x_3 are the space coordinates with su_2-weight indices $\{-,3,+\} \equiv \{-1,0,1\}$. The commutation relations (5) can be written in more sophisticated forms, e.g., in terms of q-Clebsch-Gordon coefficients or in terms of an R-matrix as we will recall in the next section.

The center of $\mathcal{X}$ is generated by x_0 and the four-square

$$x^2 := (x_0)^2 + q^{-1} x_- x_+ + q x_+ x_- - (x_3)^2. \tag{6}$$

Since we will not use 2 as index, x^2 cannot be confused with any one of the coordinates. The four-square can also be written as

$$x^2 = x_\mu x_\nu \eta^{\mu\nu} \tag{7}$$

in terms of the q-Minkowski metric defined by

$$\eta^{00} = 1, \quad \eta^{-+} = q^{-1}, \quad \eta^{-+} = q, \quad \eta^{33} = -1, \tag{8}$$

all other components vanishing. The metric defines upper four-vector indices by

$$x^\mu := \eta^{\mu\nu} x_\nu. \tag{9}$$

Note, that $x^2 = x_\mu x^\mu$ but $x^2 \neq x^\mu x_\mu$ because $\eta^{\mu\nu}$ is not symmetric.

B. Quantum Lorentz algebra

By construction $\mathcal{X}$ is a module algebra with respect to the quantum Lorentz algebra $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$. There are several essentially isomorphic forms of $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$ in use.[30,9,31,32] In the chiral decomposition form $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$ is given, as algebra, by the tensor square of quantum $\mathcal{U}(\mathrm{su}_2)$,

$$\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C})) = \mathcal{U}_q(\mathrm{su}_2) \otimes \mathcal{U}_q(\mathrm{su}_2). \tag{10}$$

The definition of $\mathcal{U}_q(\mathrm{su}_2)$ is recalled in the appendix. The chiral decomposition implies that the irreducible representations of $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$ can be labelled by the highest weights of the two tensor factors. For example, the structure morphism of the four-vector representation is given on this chiral form by

$$\rho^{(1/2,1/2)} := \rho^{1/2} \otimes \rho^{1/2}, \tag{11}$$

where $\rho^{1/2}$ is the fundamental representation of $\mathcal{U}_q(\mathrm{su}_2)$ with highest weight or spin $j=\frac{1}{2}$.

The quantum Lorentz algebra is quasitriangular. In the chiral form (10) the universal $\mathcal{R}$-matrix of $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$ can be expressed in terms of the well-known universal $\mathcal{R}$-matrix of $\mathcal{U}_q(\mathrm{su}_2)$. There are two inequivalent universal $\mathcal{R}$-matrices,[18]

$$\mathcal{R}_{\mathrm{I}} = \mathcal{R}_{41}^{-1}\mathcal{R}_{31}^{-1}\mathcal{R}_{24}\mathcal{R}_{23}, \quad \mathcal{R}_{\mathrm{II}} = \mathcal{R}_{41}^{-1}\mathcal{R}_{13}\mathcal{R}_{24}\mathcal{R}_{23}, \tag{12}$$

where $\mathcal{R}$ is the universal $\mathcal{R}$-matrix of $\mathcal{U}_q(\mathrm{su}_2)$ given in Eq. (A6), and where we have used the tensor leg notation $\mathcal{R}_{23}=1\otimes\mathcal{R}\otimes 1$, etc. The four-vector representations of the universal $\mathcal{R}$-matrices are denoted by

$$\begin{aligned} R_{\mathrm{I}}{}^{\mu\nu}{}_{\sigma\tau} &:= (\rho^{(1/2,1/2)} \otimes \rho^{(1/2,1/2)})(\mathcal{R}_{\mathrm{I}})^{\mu\nu}{}_{\sigma\tau}, \\ R_{\mathrm{II}}{}^{\mu\nu}{}_{\sigma\tau} &:= (\rho^{(1/2,1/2)} \otimes \rho^{(1/2,1/2)})(\mathcal{R}_{\mathrm{II}})^{\mu\nu}{}_{\sigma\tau}. \end{aligned} \tag{13}$$

With the R-matrices the commutation relations (5) can be written in the compact form

$$x_\sigma x_\tau = x_\mu x_\nu R_{\mathrm{I}}{}^{\mu\nu}{}_{\tau\sigma}. \tag{14}$$

This implies that the $\mathcal{X}$-algebra has the Poincaré-Birkhoff-Witt property, because the R-matrices satisfy the Yang-Baxter equation. From the decomposition of the R-matrices into eigenspaces we can, furthermore, derive the relation

$$(1 + q\hat{R}_{\mathrm{II}})(1 - \hat{R}_{\mathrm{I}}) = 0, \tag{15}$$

where the hat denotes swapping the two upper indices $\hat{R}^{\mu\nu}{}_{\tau\sigma}=R^{\nu\mu}{}_{\tau\sigma}$. We will need this formula later.

The disadvantage of the chiral form (10) is that the inner tensor factors of the coproduct are twisted with the $\mathcal{R}$-matrix of $\mathcal{U}_q(\mathrm{su}_2)$. Since the $\mathcal{R}$-matrix is given by an infinite series, which exists only as formal power series, some of the generators of $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$ have a complicated coproduct which then exists only as formal power series, too. Therefore, it is also convenient to use the Drinfeld double form,[33] where $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C}))$ is represented as Drinfeld double of the Hopf-dually paired $\mathcal{U}_q(\mathrm{su}_2)$ and $\mathrm{SU}_q(2)^{\mathrm{op}}$.

C. Noncommutative differential calculus

The generators of q-momenta are required to transform as four-vector with respect to q-Lorentz transformations. The fact that q-momenta transform in the same way as the coordinate generators of q-Minkowski space implies that they must satisfy the same commutation relations as well. This leads to the definition of the q-momentum algebra as the algebra generated by p_0, p_-, p_+, p_3 with commutation relations (5), replacing x with p everywhere.

Noncommutative partial derivatives

$$\partial_\mu := ip_\mu \tag{16}$$

are defined by the action of the momentum generators on the q-Minkowski algebra of space functions. Partial derivatives of the coordinates must be dimensionless numbers from the base field of complex numbers (including the deformation parameter q). Just as in the undeformed case the only tensor in the base field with two four-vector indices is the metric. We conclude that the action of partial derivatives on coordinates is given by

$$\partial_\mu \triangleright x_\nu = \eta_{\mu\nu} \Leftrightarrow \partial^\mu \triangleright x_\nu = \delta^\mu_\nu. \tag{17}$$

This action on the generators extends to the entire algebra of q-Minkowski space by the coproduct of momenta,[9]

$$\Delta(p^\mu) := p^\mu \otimes 1 + (\kappa \otimes 1)\mathcal{R}_{\mathrm{II}}{}^{-1}(1 \otimes p^\mu)\mathcal{R}_{\mathrm{II}} = p^\mu \otimes 1 + \kappa L^\mu{}_\nu \otimes p^\nu. \tag{18}$$

Here $\mathcal{R}_{\mathrm{II}}$ is the second of the universal $\mathcal{R}$-matrices of the q-Lorentz algebra given in Eq. (12). The L-matrix is the four-vector half-representation of this $\mathcal{R}$-matrix

$$L^\mu{}_\nu := \mathcal{R}_{\mathrm{II}[1]}\rho^{(1/2,1/2)}(\mathcal{R}_{\mathrm{II}[2]})^\mu{}_\nu, \tag{19}$$

where we have used a Sweedler-type notation for $\mathcal{R}_{\mathrm{II}} = \mathcal{R}_{\mathrm{II}[1]} \otimes \mathcal{R}_{\mathrm{II}[2]}$. Finally, κ is a grouplike scaling operator,

$$p_\mu \kappa = q\kappa p_\mu, \quad x_\mu \kappa = q^{-1}\kappa x_\mu, \quad \Delta(\kappa) = \kappa \otimes \kappa. \tag{20}$$

The action (17) of partial q-derivatives together with the coproduct (18) defines a q-Lorentz-covariant differential calculus on q-Minkowski space. Letting p^μ act on $x_\nu f$, $f \in \mathcal{X}$, we obtain

$$p^\mu \triangleright (x_\nu f) = -i\delta^\mu_\nu f + qR_{\mathrm{II}}{}^{\nu'\mu}{}_{\nu\mu'} x_{\nu'}(p^{\mu'} \triangleright f), \tag{21}$$

from which we can deduce the q-deformed Heisenberg commutation relations

$$p^\mu x_\nu - qR_{\mathrm{II}}{}^{\nu'\mu}{}_{\nu\mu'} x_{\nu'} p^{\mu'} = -i\delta^\mu_\nu, \tag{22}$$

which are of the type originally introduced by Wess and Zumino.[28]

In order to show that Eqs. (17) and (18) define a differential calculus which is well defined on the algebra $\mathcal{X}$, that is, which does not depend on the ordering of the coordinate generators, we must check if the action of the momenta is consistent with commutation relations (5) defining $\mathcal{X}$. This is best done using the R-matrix form (14),

$$p^\lambda \triangleright (x_\sigma x_\tau - x_\mu x_\nu R_{\mathrm{I}}{}^{\mu\nu}_{\tau\sigma}) = (p^\lambda \triangleright x_\nu x_\mu)(\delta^\nu_\tau \delta^\mu_\sigma - \hat{R}_{\mathrm{I}}{}^{\nu\mu}_{\tau\sigma}) = x_\rho(\delta^\lambda{}_\nu \delta^\rho{}_\mu + q\hat{R}_{\mathrm{II}}{}^{\lambda\rho}{}_{\nu\mu})(\delta^\nu_\tau \delta^\mu_\sigma - \hat{R}_{\mathrm{I}}{}^{\nu\mu}_{\tau\sigma}) = 0, \tag{23}$$

where in the last step we have used Eq. (15).

In principle, the action (17) of the partial derivatives on generators together with the coproduct (18) of momenta defines the action of partial derivatives on arbitrary elements of quantum Minkowski space. Note, however, that this definition is recursive. It does not yield formulas for the partial derivatives of a basis of the noncommutative space algebra, such as the Poincaré-Birkhoff-Witt basis of ordered monomials,

$$\mathcal{B}_{\mathrm{PBW}} := \{(x_0)^{n_0}(x_-)^{n_-}(x_+)^{n_+}(x_3)^{n_3} | n_0, n_-, n_+, n_3 \in \mathbb{N}_0\}. \tag{24}$$

To derive such a formula is one of the goals of the next section.

III. COMPUTATION IN NONCOMMUTATIVE CALCULUS

A. *L*-matrix calculus

Let us first consider the simple case of a power of one single generator, $f=x_\alpha^n$, $\alpha\in\{0,-,+,3\}$, $n\in\mathbb{N}$. Using the coproduct (18) we get by induction

$$\partial^\mu\triangleright x_\alpha^n=\sum_{k=0}^{n-1}q^k(L^\mu{}_\nu\triangleright x_\alpha^k)(\partial^\nu\triangleright x_\alpha)x_\alpha^{n-k-1}, \tag{25}$$

where the factor q^k comes from the action of the scaling operator (20),

$$\kappa\triangleright x_\alpha^k=\kappa_{(1)}x_\alpha^kS(\kappa_{(2)})=\kappa x_\alpha^k\kappa^{-1}=q^kx_\alpha^k. \tag{26}$$

By construction, the L-matrix is a comultiplicative quantum matrix, $\Delta(L^\mu{}_\nu)=L^\mu{}_\sigma\otimes L^\sigma{}_\nu$. So we get for the action of L on a power

$$L^\mu{}_\nu\triangleright x_\alpha^k=(L^\mu{}_{\sigma_1}\triangleright x_\alpha)(L^{\sigma_1}{}_{\sigma_2}\triangleright x_\alpha)\cdots(L^{\sigma_{k-1}}{}_\nu\triangleright x_\alpha). \tag{27}$$

Since each $L^{\sigma_k}{}_{\sigma_{k+1}}\triangleright x_\alpha$ are $\mathcal{X}$-valued 4×4-matrices, the right-hand side is the matrix product of such matrices. This suggests to introduce an index-free notation.

Definition 2: Let $L^\mu{}_\nu$ be the L-matrix defined in Eq. (19), *∂^μ the partial derivatives defined in* (16), *$f\in\mathcal{X}$ an element of the algebra of quantum Minkowski space. Then we denote by L_f the $\mathcal{X}$-valued 4×4-matrix and by ∇f the $\mathcal{X}$-valued four-vector with entries*

$$(L_f)^\mu{}_\nu:=L^\mu{}_\nu\triangleright f\quad\textit{and}\quad(\nabla f)^\mu:=\partial^\mu\triangleright f, \tag{28}$$

respectively.

To illustrate this, we have, for example,

$$(L_f^2\nabla f)^\mu=(L^\mu{}_\nu\triangleright f)(L^\nu{}_\sigma\triangleright f)(\partial^\sigma\triangleright f). \tag{29}$$

In this index-free notation Eq. (27) is written as $L\triangleright x_\alpha^k=L_{x_\alpha}^k$, such that Eq. (25) becomes

$$\nabla x_\alpha^n=\sum_{k=0}^{n-1}q^kL_{x_\alpha}^k(\nabla x_\alpha)x_\alpha^{n-k-1}. \tag{30}$$

We recall that by definition (17) of the action of partial derivatives on the generators we have for the components of the gradient

$$(\nabla x_\alpha)^\mu=\partial^\mu\triangleright x_\alpha=\delta_\alpha^\mu, \tag{31}$$

where $\mu,\alpha\in\{0,-,+,3\}$.

The computationally difficult part of (30) is the evaluation of powers of the algebra-valued matrices L_{x_α}. For example, for $(L_{x_0})^\mu{}_\nu$ we get with respect to four-vector indices $\mu,\nu\in\{0,-,+,3\}$,

$$L_{x_0} = \frac{1}{[2]} \begin{pmatrix} \frac{[4]}{[2]} x_0 & q\lambda x_- & q\lambda x_+ & q\lambda x_3 \\ -\frac{\lambda}{q^2} x_+ & \frac{[4]}{[2]} x_0 - \frac{\lambda^2}{q} x_3 & 0 & \lambda x_+ \\ \lambda x_- & 0 & \frac{[4]}{[2]} x_0 - q\lambda^2 x_3 & -\lambda x_- \\ \frac{\lambda}{q} x_3 & -q\lambda x_- & \frac{\lambda}{q} x_+ & \frac{[4]}{[2]} x_0 - \lambda^2 x_3 \end{pmatrix}. \tag{32}$$

A brute force calculation of the powers $L_{x_0}^n$ of this algebra valued matrix is not feasible as it would require a reordering of an exponentially increasing number of terms to the Poincaré-Birkhoff-Witt basis (or any other ordering). Similar matrices and their eigenvalues have been studied elsewhere[34,35] but it can be seen that L_0 is not of the exact type considered there so the results do not carry over easily.

B. Block decomposition of *L*-matrices

The computational problem of computing the powers of the $\mathcal{X}$-valued L_{x_α}-matrices can be simplified by considering the L-matrix (19) not with respect to four-vector indices running through $\{0, -, +, 3\}$ as in Eq. (32), but with respect to pairs of indices of the two spin-$\frac{1}{2}$ representations of the chiral decomposition $\mathcal{U}_q(\mathrm{sl}_2(\mathbb{C})) = \mathcal{U}_q(\mathrm{su}_2) \otimes \mathcal{U}_q(\mathrm{su}_2)$ of the q-Lorentz algebra, each labelled by the weights $\{-\frac{1}{2}, +\frac{1}{2}\} = \{-, +\}$. We recall that the generators of quantum Minkowski space in this $(\frac{1}{2}, \frac{1}{2})$-spinor basis labelled by indices $\{--, -+, +-, ++\}$ are related to those in the four-vector basis by

$$\begin{aligned} x_{--} &= [2]^{1/2} x_-, \\ x_{-+} &= q^{1/2}(x_3 - x_0), \\ x_{+-} &= q^{-1/2} x_3 + q^{3/2} x_0, \\ x_{++} &= [2]^{1/2} x_+. \end{aligned} \tag{33}$$

Using formula (12) for the universal $\mathcal{R}_{\mathrm{II}}$-matrix in terms of the $\mathcal{R}$-matrix of $\mathcal{U}_q(\mathrm{su}_2)$ and definition (19) of the L-matrix, we calculate the L-matrix with respect to the spinor basis,

$$(L)^{ij}{}_{kl} = (\mathrm{id} \otimes \mathrm{id} \otimes \rho^{1/2} \otimes \rho^{1/2})(\mathcal{R}_{\mathrm{II}})^{ij}{}_{kl} = (L_-^{1/2})^j{}_{j'} (L_+^{1/2})^i{}_{i'} \otimes (L_+^{1/2})^{j'}{}_l (L_+^{1/2})^{i'}{}_k = B^j{}_l (L_+^{1/2})^i{}_k, \tag{34}$$

where all indices run through $\{-\frac{1}{2}, +\frac{1}{2}\} = \{-, +\}$. Here $B = (B^j{}_l)$ is the matrix of "boosts" which generate the $\mathrm{SU}_q(2)^{\mathrm{op}}$ Hopf subalgebra of the Drinfeld double form of the q-Lorentz algebra,[33] and $L_+^{1/2}$ the L_+-matrix[27] of the $\mathcal{U}_q(\mathrm{su}_2)$ subalgebra of rotations,

$$B = \begin{pmatrix} a & b \\ c & d \end{pmatrix}, \quad L_+^{1/2} = \begin{pmatrix} K^{-1/2} & q^{-1/2}\lambda K^{-1/2} E \\ 0 & K^{1/2} \end{pmatrix}, \tag{35}$$

with respect to the $\{-, +\}$ basis. The explicit form of the boosts in the chiral decomposition of the q-Lorentz algebra is given in Eq. (A7).

The decomposition (34) of the L-matrix into boosts and rotations yields a natural block matrix decomposition of the $\mathcal{X}$-valued 4×4-matrices L_{x_α} as defined in Eq. (28). For the four-vector index α it turns out to be convenient to use instead of x_3 the light cone coordinate

$$x_{3\backslash 0} := x_3 - x_0, \tag{36}$$

which is essentially the x_{-+}-coordinate in the spinor basis (33) of quantum Minkowski space. And for the block decomposition it is convenient to define $\mathcal{X}$-valued 2×2-matrices by the action of the boosts

$$(B_f)^i{}_j := B^i{}_j \triangleright f, \quad f \in \mathcal{X}, \tag{37}$$

using the same index-free notation as introduced in Eq. (28). Since $B^i{}_j$ is a comultiplicative quantum matrix, $\Delta(B^i{}_j) = B^i{}_k \otimes B^k{}_j$, the matrices B_{x_α} satisfy the same commutation relations (5) as x_α. Explicitly, the B_{x_α}-matrices can be computed to

$$B_{x_0} = \begin{pmatrix} \dfrac{[4]}{[2]^2}x_0 + \dfrac{\lambda}{q[2]}x_3 & q^{-1/2}\lambda[2]^{-1/2}x_+ \\ -q^{1/2}\lambda[2]^{-1/2}x_- & \dfrac{[4]}{[2]^2}x_0 - \dfrac{q\lambda}{[2]}x_3 \end{pmatrix},$$

$$B_{x_-} = \begin{pmatrix} x_- & q^{-1/2}\lambda[2]^{-1/2}x_{3\backslash 0} \\ 0 & x_- \end{pmatrix},$$

$$B_{x_+} = \begin{pmatrix} x_+ & 0 \\ -q^{1/2}\lambda[2]^{-1/2}x_{3\backslash 0} & x_+ \end{pmatrix}, \tag{38}$$

$$B_{x_{3\backslash 0}} = \begin{pmatrix} q^{-1}x_{3\backslash 0} & 0 \\ 0 & qx_{3\backslash 0} \end{pmatrix},$$

with respect to spin-$\frac{1}{2}$ indices running through $\{-, +\}$. In terms of these matrices the L_{x_α}-matrices can be expressed as

$$L_{x_0} = \begin{pmatrix} B_{x_0} & 0 \\ 0 & B_{x_0} \end{pmatrix},$$

$$L_{x_-} = \begin{pmatrix} qB_{x_-} & q^{-1/2}\lambda[2]^{1/2}B_{x_3} \\ 0 & q^{-1}B_{x_-} \end{pmatrix},$$

$$L_{x_+} = \begin{pmatrix} q^{-1}B_{x_+} & 0 \\ 0 & qB_{x_+} \end{pmatrix}, \tag{39}$$

$$L_{x_{3\backslash 0}} = \begin{pmatrix} B_{x_{3\backslash 0}} & q^{-1/2}\lambda[2]^{1/2}B_{x_+} \\ 0 & B_{x_{3\backslash 0}} \end{pmatrix},$$

with respect to the index structure $(--, -+, +-, ++)$.

C. Calculating powers of *L*-matrices

In the form of Eq. (39) the L_{x_α} matrices are upper block triangular. This makes the computation of their powers a lot easier. L_{x_0} and L_{x_+} are even block diagonal, so we immediately get

$$L^n_{x_0} = \begin{pmatrix} B^n_{x_0} & 0 \\ 0 & B^n_{x_0} \end{pmatrix}, \quad L^n_{x_+} = \begin{pmatrix} q^{-n}B^n_{x_+} & 0 \\ 0 & q^n B^n_{x_+} \end{pmatrix}. \tag{40}$$

For the calculation of $L^n_{x_-}$ and $L^n_{x_{3\backslash 0}}$ we must use the commutation relations (5) for the B_{x_α} matrices. We thus get by induction

$$\begin{aligned} L^n_{x_-} &= \begin{pmatrix} q^n B^n_{x_-} & q^{-1/2}\lambda[2]^{1/2}\left(q^{n-1}\dfrac{[2n]}{[2]}B_{x_{3\backslash 0}} + [n]B_{x_0}\right)B^{n-1}_{x_-} \\ 0 & q^{-n}B^n_{x_-} \end{pmatrix}, \\ L^n_{x_{3\backslash 0}} &= \begin{pmatrix} B^n_{x_{3\backslash 0}} & q^{-1/2}\lambda[2]^{1/2}q^{n-1}[n]B_{x_+}B^{n-1}_{x_{3\backslash 0}} \\ 0 & B^n_{x_{3\backslash 0}} \end{pmatrix}. \end{aligned} \tag{41}$$

Now we have expressed the powers of L_{x_α} matrices in terms of powers of the B_{x_α} matrices. It remains to calculate the powers of the B_{x_α}-matrices. Since $B_{x_{3\backslash 0}}$ is diagonal we immediately get

$$B^n_{x_{3\backslash 0}} = \begin{pmatrix} q^{-n}x^n_{3\backslash 0} & 0 \\ 0 & q^n x^n_{3\backslash 0} \end{pmatrix}. \tag{42}$$

For the powers of the matrices $B_{x_\pm}$, which are block triangular, we use again the commutation relations (5) to obtain by induction

$$\begin{aligned} B^n_{x_-} &= \begin{pmatrix} x^n_- & q^{-1/2}\lambda[2]^{-1/2}q^{n-1}[n]x_{3\backslash 0}x^{n-1}_- \\ 0 & x^n_- \end{pmatrix}, \\ B^n_{x_+} &= \begin{pmatrix} x^n_+ & 0 \\ -q^{1/2}\lambda[2]^{-1/2}q^{1-n}[n]x_{3\backslash 0}x^{n-1}_+ & x^n_+ \end{pmatrix}. \end{aligned} \tag{43}$$

The calculation of the powers of B_{x_0} is more difficult because it is not triangular. Using q-Pauli matrices (A5), B_{x_0} of Eqs. (38) can be written more compactly as

$$B_{x_0} := \frac{[4]}{[2]^2}x_0 - \frac{\lambda}{[2]}\tilde{\sigma}_A x^A, \tag{44}$$

where the index A is summed over $\{-, 3, +\}$. The q-Pauli matrices satisfy the relation

$$\tilde{\sigma}_A\tilde{\sigma}_B = g_{BA} - \tilde{\sigma}_C\varepsilon_B{}^C{}_A, \tag{45}$$

where the quantum metric and epsilon tensor are defined by quantum Clebsch-Gordon coefficients as

$$\begin{aligned} g^{AB} &:= -\sqrt{[3]}C_q(1,1,0;A,B,0), \\ \varepsilon^{AB}{}_C &:= -\sqrt{\frac{[4]}{[2]}}C_q(1,1,1;A,B,C). \end{aligned} \tag{46}$$

Contracting Eq. (45) with $x^A x^B$ and using the commutation relations (5) of the coordinates, which can be written as $x_A x_B \varepsilon^{AB}{}_C = -\lambda x_C x_0$, we derive

$$\tilde{\sigma}_A\tilde{\sigma}_B x^A x^B = (g_{BA} - \tilde{\sigma}_C\varepsilon_B{}^C{}_A)x^A x^B = x_A x^A + \lambda x_0\tilde{\sigma}_A x^A. \tag{47}$$

This can be used to compute the square of Eq. (44),

$$B_{x_0}^2 = \frac{[4]^2}{[2]^2}(x_0)^2 - 2\frac{\lambda[4]}{[2]^3}x_0\tilde{\sigma}_A x^A + \frac{\lambda^2}{[2]^2}\tilde{\sigma}_A\tilde{\sigma}_B x^A x^B$$
$$= \frac{[4]^2}{[2]^4}(x_0)^2 - 2\frac{\lambda[4]}{[2]^3}x_0\tilde{\sigma}_A x^A + \frac{\lambda^2}{[2]^2}(x_A x^A + \lambda x_0\tilde{\sigma}_A x^A) = [2]x_0 B_{x_0} - (x_0)^2 - \frac{\lambda^2}{[2]^2}x^2. \quad (48)$$

Together with Eq. (40) we conclude that L_{x_0} satisfies the polynomial equation

$$0 = L_{x_0}^2 - [2]x_0 L_{x_0} + \left((x_0)^2 + \frac{\lambda^2}{[2]^2}x^2\right) = L_{x_0}^2 - 2bL_{x_0} + c, \quad (49)$$

where we have introduced the abbreviations

$$b := \frac{[2]}{2}x_0, \quad c := (x_0)^2 + \frac{\lambda^2}{[2]^2}x^2, \quad (50)$$

which are both in the center of $\mathcal{X}$. Equation (49) enables us to derive formulas for arbitrary powers of L_{x_0}. This is most elegantly done by considering the generating function of the powers $(1 - L_{x_0}z)^{-1} = 1 + L_{x_0}z + L_{x_0}^2 z^2 + \dots$, where z is a formal parameter. First we rewrite (49) as

$$(1 - L_{x_0}^2 z^2) - 2bz(1 - L_{x_0}z) - (1 - 2bz + cz^2) = 0 \quad (51)$$

and divide it by $(1 - L_{x_0}z)$ and $(1 - 2bz + cz^2)$, yielding

$$\frac{1}{1 - L_{x_0}z} = \frac{1 + (L_{x_0} - 2b)z}{1 - 2bz + cz^2}. \quad (52)$$

The right-hand side can be expanded in powers of z, observing that it contains the generating function for Chebyshev polynomials of the second kind,

$$\frac{1}{1 - 2yt + t^2} = \sum_{n=0}^{\infty} U_n(y)t^n, \quad (53)$$

where we must set $y = b/\sqrt{c}$ and $t = \sqrt{c}z$. We thus obtain

$$L_{x_0}^n = U_n(b/\sqrt{c})c^{n/2} + U_{n-1}(b/\sqrt{c})c^{(n-1)/2}(L_{x_0} - 2b) = -U_{n-2}(b/\sqrt{c})c^{n/2} + U_{n-1}(b/\sqrt{c})c^{(n-1)/2}L_{x_0} \quad (54)$$

for $n \geqslant 2$. The fact that $U_n(y)$ is a polynomial of degree n which contains either only even or only odd powers of y implies that $U_n(1/y)y^n$ is a quadratic polynomial in y. Therefore, the right-hand side of Eq. (54) contains only even positive powers of $\sqrt{c}$, that is, does not contain inverses or square roots of c and, hence, yields well-defined elements of the algebra $\mathcal{X}$. Together with Eqs. (40)–(43) this completes our calculation of powers of the L_{x_α} matrices.

D. Calculating derivatives

1. Choice of basis and partial Jackson derivatives

With the formulas for the powers of the L_α matrices the derivatives of arbitrary elements $f \in \mathcal{X}$ could be computed by calculating the derivatives of the Poincaré-Birkhoff-Witt basis of $\mathcal{X}$. However, it turns out to be more convenient to work in a slightly different basis. Observe that from definition (7) of the q-Lorentz invariant length and the commutation relations (5) we can deduce the relation

$$[2]x_-x_+ = x^2 + q^2(x_{3\backslash 0})^2 + q\lambda x_0 x_{3\backslash 0}. \tag{55}$$

Using this relation, all products of equal powers of x_- and x_+ in the Poincaré-Birkhoff-Witt basis can be substituted by powers of x^2. We thus obtain a basis of ordered monomials which contains powers of x^2 and either powers of x_- or x_+. To be more precise, we have a basis of $\mathcal{X}$,

$$\mathcal{B} = \mathcal{B}_- \cup \mathcal{B}_+, \tag{56}$$

where

$$\begin{aligned} \mathcal{B}_- &:= \{(x_\mu x^\mu)^i (x_0)^j (x_{3\backslash 0})^k (x_-)^l | i,j,k,l \in \mathbb{N}_0\}, \\ \mathcal{B}_+ &:= \{(x_\mu x^\mu)^i (x_0)^j (x_+)^l (x_{3\backslash 0})^k | i,j,k,l \in \mathbb{N}_0\}. \end{aligned} \tag{57}$$

Note, that $\mathcal{B}_-$ and $\mathcal{B}_+$ have a nonempty intersection, the monomials for which $l=0$. But this will not be a problem here. Let us introduce a more suggestive notation for sums of monomials in a particular order.

Definition 3: Let $x_1, \ldots, x_n \in \mathcal{X}$ be *elements of the algebra of quantum Minkowski space. Then we will denote by* $f(x_1, \ldots, x_n)$ *linear combinations of ordered products of monomials in* $x_1, \ldots, x_n \in \mathcal{X}$. *That is*,

$$f(x_1, \ldots, x_n) \in \mathrm{Span}\{(x_1)^{k_1} \cdots (x_n)^{k_n} | k_1, \ldots, k_n \in \mathbb{N}_0\}. \tag{58}$$

With this notation the statement that $\mathcal{B}_- \cup \mathcal{B}_+$ is a basis of quantum Minkowski space can be written as

$$f(x_0, x_+, x_{3\backslash 0}, x_-) = f_-(x^2, x_0, x_{3\backslash 0}, x_-) + f_+(x^2, x_0, x_+, x_{3\backslash 0}), \tag{59}$$

decomposing an arbitrary element of $\mathcal{X}$ into two parts containing powers in either x_- or x_+.

It is important to have a notation which keeps track of the ordering of generators because the formulas for derivatives are most elegantly expressed in terms of partial Jackson derivatives which depend on the ordering. Recall, that the Jackson derivative or q-derivative of a function $f = f(x_\alpha)$ in a single variable x_α is defined as difference quotient,

$$\frac{\partial_{q^2} f}{\partial_{q^2} x_\alpha} := \frac{f(q^2 x_\alpha) - f(x_\alpha)}{q^2 x_\alpha - x_\alpha}. \tag{60}$$

For monomials $f(x_\alpha) = (x_\alpha)^k$, this yields

$$\frac{\partial_{q^2} (x_\alpha)^k}{\partial_{q^2} x_\alpha} = (k)_{q^2} (x_\alpha)^{k-1}, \tag{61}$$

where $(k)_{q^2}$ is the usual q-number defined in Eq. (4). This formula naturally generalizes to a partial Jackson derivative on monomials of several noncommutative variables.

Definition 4: Let $x_1, \ldots, x_n \in \mathcal{X}$ *be elements of the algebra of quantum Minkowski space (or any other algebra). We define the partial Jackson derivative with respect to one of these elements* x_α *on ordered monomials by*

$$\frac{\partial_{q^2}}{\partial_{q^2} x_\alpha} ((x_1)^{k_1} \cdots (x_n)^{k_n}) := (k_\alpha)_{q^2} (x_1)^{k_1} \cdots (x_\alpha)^{k_\alpha - 1} \cdots (x_n)^{k_n}, \tag{62}$$

and extend it linearly to arbitrary linear combinations of such monomials. This defines partial Jackson derivatives on general functions $f = f(x_1, \ldots, x_n)$ *in the sense of Definition 3*.

It must be emphasized that the partial Jackson derivatives depend on the particular order and are not well defined on the algebra. For example, within the algebra we have the commutation relation $x_{3\backslash 0} x_+ - q^2 x_+ x_{3\backslash 0} = 0$, but

$$\frac{\partial_{q^2}}{\partial_{q^2}x_+}(x_{3\backslash 0}x_+ - q^2 x_+ x_{3\backslash 0}) = x_{3\backslash 0} - q^2 x_{3\backslash 0} \neq 0. \tag{63}$$

This is why we have defined the notation $f=f(x_+,x_{3\backslash 0})$ to not just denote elements of the algebra but to denote in addition a specific ordering of the variables. With this notation the action of partial Jackson derivatives is defined unambiguously.

We break up the calculation of derivatives in two steps. First, we calculate the derivatives of noncentral variables, x_-, $x_{3\backslash 0}$, x_+. Working within the basis $\mathcal{B}$ we can limit the considerations in this first step to polynomial functions $f=f(x_{3\backslash 0},x_-)$ and $f=f(x_+,x_{3\backslash 0})$ which depend either on x_- or on x_+. This calculation is rather straightforward. In a second step we consider polynomial functions $f=f(x^2,x_0)$ of the center of $\mathcal{X}$. This calculation is much more involved.

2. Functions of noncentral coordinates

We begin the calculation of the derivatives of the basis $\mathcal{B}$ by reading off Eqs. (38) and (39) that the L_α matrices possess some algebra valued eigenvalues,

$$\begin{aligned} L_{x_A} \nabla x_A &= q x_A \nabla x_A, \\ L_{x_{3\backslash 0}} \nabla x_- &= q^{-1} x_{3\backslash 0} \nabla x_-, \\ L_{x_+} \nabla x_{3\backslash 0} &= q^{-1} x_+ \nabla x_{3\backslash 0}, \end{aligned} \tag{64}$$

for $A \in \{-,+,3\backslash 0\}$ (no summation over A). We recall that ∇x_α is the index free notation for $(\nabla x_\alpha)^\mu = \partial^\mu \triangleright x_\alpha = \delta^\mu_\alpha$.

Inserting the first of these eigenvalue equations into Eq. (30) we obtain for powers of the generators

$$\nabla x_A^n = \sum_{k=0}^{n} q^{2k} x_A^k (\nabla x_A) x_A^{n-k-1} = (n)_{q^2} x_A^{n-1} \nabla x_A, \tag{65}$$

for $A \in \{-,+,3\backslash 0\}$, where $(n)_{q^2}$ denotes the quantum number (4). From Eq. (65) we can deduce that the derivative of any polynomial $f=f(x_A)$ in a single one of the generators x_A can be expressed in terms of the Jackson derivative by

$$\nabla f(x_A) = \frac{\partial_{q^2} f}{\partial_{q^2} x_A} \nabla x_A \Leftrightarrow \partial^\mu \triangleright f(x_A) = \frac{\partial_{q^2} f}{\partial_{q^2} x_A} \delta^\mu_A. \tag{66}$$

Using the second of Eqs. (64) we get

$$\nabla(x_{3\backslash 0}^k x_-^n) = (\nabla x_{3\backslash 0}^k) x_-^n + q^k L_{3\backslash 0}^k (\nabla x_-^n) = (k)_{q^2} x_{3\backslash 0}^{k-1} x_-^n \nabla x_{3\backslash 0} + x_{3\backslash 0}^k (n)_{q^2} x_-^{n-1} \nabla x_-, \tag{67}$$

and analogously for the derivative of $x_+^k x_{3\backslash 0}^n$,

$$\nabla(x_+^k x_{3\backslash 0}^n) = (k)_{q^2} x_+^{k-1} x_{3\backslash 0}^n \nabla x_+ + x_+^k (n)_{q^2} x_{3\backslash 0}^{n-1} \nabla x_{3\backslash 0}. \tag{68}$$

From Eqs. (67) and (68) we can deduce the following result.

Proposition 1: Let $f=f(x_{3\backslash 0},x_-)$ and $f=f(x_+,x_{3\backslash 0})$ be ordered polynomials in the notation of Definition 3. Then their partial derivatives are expressed in terms of partial Jackson derivatives as

$$\nabla f(x_{3\backslash 0},x_-) = \frac{\partial_{q^2} f}{\partial_{q^2} x_{3\backslash 0}} \nabla x_{3\backslash 0} + \frac{\partial_{q^2} f}{\partial_{q^2} x_-} \nabla x_-, \tag{69a}$$

$$\nabla f(x_+, x_{3\backslash 0}) = \frac{\partial_{q^2} f}{\partial_{q^2} x_+} \nabla x_+ + \frac{\partial_{q^2} f}{\partial_{q^2} x_{3\backslash 0}} \nabla x_{3\backslash 0}. \tag{69b}$$

3. Functions of four-length

Next, we calculate the derivative of powers of the coordinate four-square x^2. Since x^2 is a Lorentz scalar the L-matrix acts with the counit ε,

$$L^\mu{}_\nu \triangleright x^2 = \varepsilon(L^\mu{}_\nu) x^2 = \delta^\mu_\nu x^2. \tag{70}$$

By the same reasoning which led to Eq. (30) we obtain for powers of the four-square

$$\nabla (x^2)^n = \sum_{k=0}^{n-1} q^{2k} (x^2)^{n-1} \nabla x^2 = (n)_{q^2} (x^2)^{n-1} \nabla x^2. \tag{71}$$

Again, for a general function $f = f(x^2)$ this can be written in terms of a Jackson derivative by

$$\nabla f(x^2) = \frac{\partial_{q^2} f}{\partial_{q^2}(x^2)} \nabla x^2. \tag{72}$$

It remains to compute the derivative of x^2, which for representation theoretic reasons we expect to be proportional to the coordinate four vector x^μ. After straightforward calculations we, indeed, find

$$(\nabla x^2)^\mu = q^{-1}[2] x^\mu. \tag{73}$$

4. Functions of time

Like the calculation of powers of L_{x_0}, the calculation of derivatives of powers of the time coordinate is more difficult. In order to calculate the derivative of $(x_0)^n$ we first observe that, since x_0 is central in the space algebra we can write Eq. (30) in the form

$$\nabla x_0^n = \frac{(qL_{x_0})^n - (x_0)^n}{qL_{x_0} - x_0} \nabla x_0, \tag{74}$$

which is similar to a q-difference quotient. We can get rid of the matrix in the denominator,

$$\frac{(qL_{x_0})^n - (x_0)^n}{qL_{x_0} - x_0} = \frac{(q^n L_{x_0}^n - x_0^n)(q^{-1} L_{x_0} - x_0)}{(qL_{x_0} - x_0)(q^{-1} L_{x_0} - x_0)} = -\frac{[2](q^{n-1} L_{x_0}^{n+1} - q^n L_{x_0}^n x_0 - q^{-1} L_{x_0} x_0^n - x_0^{n+1})}{\lambda^2 x^2}, \tag{75}$$

where in the second step we have used Eq. (49). The powers of L_{x_0} in the numerator have been calculated in Eq. (54). From explicit expression (32) of L_{x_0} we deduce

$$(L_{x_0} \nabla x_0)^\mu = q x_0 \delta_0^\mu - \frac{\lambda}{q[2]} x^\mu. \tag{76}$$

Putting things together we obtain

$$(\nabla x_0^n)^\mu = \frac{[2]}{\lambda} \left(\frac{U_n c^{n/2} q^{n-2} - U_{n-1} c^{(n-1)/2} q^{n-1} x_0 - x_0^n}{x^2} \right) x^\mu + U_{n-1} c^{(n-1)/2} q^{n-1} \delta_0^\mu, \tag{77}$$

where $U_n = U_n(b/\sqrt{c})$ denotes the Chebyshev polynomials of the second kind with the same argument as in Eq. (54).

In order to generalize the formulas to general functions $f = f(x_0)$ we first note that we can deduce from Eq. (74),

$$\nabla f(x_0) = \frac{f(qL_{x_0}) - f(x_0)}{qL_{x_0} - x_0} \nabla x_0, \tag{78}$$

which could be viewed as matrix valued generalization of the Jackson derivative. In order to compute this expression we need to generalize formula (54) for the powers of L_{x_0} to general functions. The result is given by the following.

Proposition 2: Let L_{x_0} be the $\mathcal{X}$-valued 4×4-matrix given by Eq. (32). Let b and c be defined as in Eq. (50). *Define*

$$\tau_\pm := b \pm \sqrt{b^2 - c} = \frac{1}{2}\left([2]x_0 \pm \lambda \sqrt{(x_0)^2 - \frac{4}{[2]^2}(x^2)}\right), \tag{79}$$

and

$$\Pi_\pm := \frac{1}{2}\left(1 \pm \frac{L_{x_0} - b}{\sqrt{b^2 - c}}\right). \tag{80}$$

Then for any polynomial function f in one variable we have

$$f(L_{x_0}) = f(\tau_+)\Pi_+ + f(\tau_-)\Pi_-. \tag{81}$$

Proof: First, we note that Chebyshev polynomials of the second kind can be written as

$$U_{n-1}(x) = \frac{(x + \sqrt{x^2 - 1})^n - (x - \sqrt{x^2 - 1})^n}{2\sqrt{x^2 - 1}}. \tag{82}$$

For $x = b/\sqrt{c}$ this identity takes the form

$$U_{n-1}(b/\sqrt{c})c^{(n-1)/2} = \frac{\tau_+^n - \tau_-^n}{\tau_+ - \tau_-}, \tag{83}$$

with $\tau_\pm$ defined as in the proposition. Inserting (83) into (54) yields for an arbitrary function

$$f(L_{x_0}) = \frac{f(\tau_+) - f(\tau_-)}{\tau_+ - \tau_-}(L_{x_0} - b) + \frac{1}{2}(f(\tau_+) + f(\tau_-)), \tag{84}$$

which can be written using $\Pi_\pm$ in the form of Eq. (81). □

The $\mathcal{X}$-valued matrices $\Pi_\pm$ arise here naturally because they are orthogonal, complementary idempotents,

$$\Pi_\pm^2 = \Pi_\pm, \quad \Pi_+\Pi_- = 0 = \Pi_-\Pi_+, \quad \Pi_+ + \Pi_- = 1. \tag{85}$$

This property ensures that Eq. (81) is consistent with the algebra structure of functions, because it can be immediately verified that $(fg)(L_{x_0}) = f(L_{x_0})g(L_{x_0})$.

We can now insert Eq. (84) into Eq. (78) to obtain

$$\nabla f(x_0) = \frac{f(q\tau_+) - f(x_0)}{q\tau_+ - x_0}\Pi_+ \nabla x_0 + \frac{f(q\tau_-) - f(x_0)}{q\tau_- - x_0}\Pi_- \nabla x_0 \tag{86}$$

for the derivative of an arbitrary function of the time coordinate. For this formula to be explicit it remains to calculate

$$(\Pi_\pm \nabla x_0)^\mu = \frac{\frac{1}{2}\left(\pm x_0 + \sqrt{(x_0)^2 - \frac{4}{[2]^2}(x^2)}\right)\delta_0^\mu \mp \frac{1}{q[2]}x^\mu}{\sqrt{(x_0)^2 - \frac{4}{[2]^2}(x^2)}}. \tag{87}$$

Finally, we can combine the previous result (72) for the derivative of functions of the four-length $x^2 = x_\mu x^\mu$ and (86) for the derivative of functions of the time coordinate x_0 into a formula for functions $f = f(x^2, x_0)$ of both variables,

$$\begin{aligned}\nabla f(x^2,x_0) = {} & \frac{f(q^2x^2,x_0) - f(x^2,x_0)}{q^2x^2 - x^2}\nabla x^2 + \frac{f(q^2x^2,q\tau_+) - f(q^2x^2,x_0)}{q\tau_+ - x_0}\Pi_+ \nabla x_0 \\ & + \frac{f(q^2x^2,q\tau_-) - f(q^2x^2,x_0)}{q\tau_- - x_0}\Pi_- \nabla x_0.\end{aligned} \tag{88}$$

This formula can be further simplified to

$$\nabla f(x^2,x_0) = \frac{f(q^2x^2,q\tau_+) - f(x^2,x_0)}{q\tau_+ - x_0}\Pi_+ \nabla x_0 + \frac{f(q^2x^2,q\tau_-) - f(x^2,x_0)}{q\tau_- - x_0}\Pi_- \nabla x_0. \tag{89}$$

5. Separation of variables

We have seen that the derivatives of functions of $x_\pm$, $x_{3\backslash 0}$, and x^2 can be written in terms of Jackson q-derivatives. Derivatives of functions of the time coordinate, however, do not have this property but depend on the four-length x^2, as well. In the language of partial differential equations, the partial derivative ∂^μ is not separated with respect to the standard time coordinate of quantum Minkowski space. We will now show that there is a nonlinear transformation of coordinates such that the partial derivatives are separated in the new coordinates.

These new coordinates $\xi_\pm = \xi_\pm(x^2, x_0)$ are given by

$$\xi_\pm = \frac{1}{2}\left(x_0 \pm \sqrt{(x_0)^2 - \frac{4}{[2]^2}(x^2)}\right). \tag{90}$$

In terms of the new variables $\tau_\pm$ is expressed as

$$\begin{aligned}\tau_+ &= q\xi_+ + q^{-1}\xi_-, \\ \tau_- &= q^{-1}\xi_+ + q\xi_-.\end{aligned} \tag{91}$$

The back transform is given by

$$\begin{aligned}x_0 &= \xi_+ + \xi_-, \\ x^2 &= [2]^2\xi_+\xi_-.\end{aligned} \tag{92}$$

A function $f = f(x^2, x_0)$ is expressed in terms of the new variables by the transformed function

$$\tilde{f}(\xi_+,\xi_-) := f(x^2(\xi_+,\xi_-), x_0(\xi_+,\xi_-)) = f([2]^2\xi_+\xi_-, \xi_+ + \xi_-), \tag{93}$$

for which the quotients of Eq. (89) take the form of Jackson derivatives

$$\frac{f(q^2x^2,q\tau_+)-f(x^2,x_0)}{q\tau_+-x_0}=\frac{\tilde{f}(q^2\xi_+,\xi_-)-\tilde{f}(\xi_+,\xi_-)}{q^2\xi_+-\xi_+},$$
$$\frac{f(q^2x^2,q\tau_+)-f(x^2,x_0)}{q\tau_+-x_0}=\frac{\tilde{f}(\xi_+,q^2\xi_-)-\tilde{f}(\xi_+,\xi_-)}{q^2\xi_--\xi_-}. \tag{94}$$

In order to completely rewrite Eq. (89) in q-derivative form we still must rewrite the expressions $\Pi_\pm\nabla x_0$. Towards this end, we must understand on what the projection operators $\Pi_\pm$ actually project.

Key to understanding the operators $\Pi_\pm$ is the calculation of the derivatives of the new coordinates viewed as functions of x^2 and x_0. Inserting these functions $\xi_\pm=\xi_\pm(x^2,x_0)$ into formula (89) and using the formula

$$\sqrt{\tau_\pm^2-\frac{4}{[2]^2}(x^2)}=\frac{1}{2}\left(\pm\lambda x_0+[2]\sqrt{(x_0)^2-\frac{4}{[2]^2}(x^2)}\right), \tag{95}$$

we obtain after long calculations the compact result

$$\nabla\xi_\pm=\Pi_\pm\nabla x_0. \tag{96}$$

In this sense $\Pi_\pm$ can be viewed as generalized Jacobian of the coordinate transformation (90). We thus arrive at the main result of this paper:

Proposition 3: Let $f=f(\xi_+,\xi_-)$ be a general polynomial function in $\xi_\pm$. Then

$$\nabla f(\xi_+,\xi_-)=\frac{\partial_{q^2}f}{\partial_{q^2}\xi_+}\nabla\xi_++\frac{\partial_{q^2}f}{\partial_{q^2}\xi_-}\nabla\xi_-. \tag{97}$$

6. General functions

Finally, we can combine this result with formulas (69) for derivations of functions of the noncentral variables. A general polynomial in $\mathcal{X}$ can be written as a sum of products of functions $g=f(\xi_+,\xi_-)$ and $h=h_+(x_+,x_{3\backslash 0})+h(x_{3\backslash 0},x_-)$. Using the coproduct (18) we obtain for the derivative of the product

$$\nabla(fg)=(\nabla f)g+(\kappa L\triangleright f)\nabla g, \tag{98}$$

where we can derive from Proposition 2 the formula

$$\kappa L\triangleright g(\xi_+,\xi_-)=\Pi_+g(q^2\xi_+,\xi_-)+\Pi_-g(\xi_+,q^2\xi_-). \tag{99}$$

Inserting Eq. (99) into (98) we must observe that $\Pi_\pm$ does not commute with the noncentral observables. In order to write down the end result, we first define for a general linear combination of the basis $\mathcal{B}$ the matrix valued object

$$\delta f:=\Pi_+(f|_{\xi_+\mapsto q^2\xi_+}-f)+\Pi_-(f|_{\xi_-\mapsto q^2\xi_-}-f). \tag{100}$$

This definition does not depend on the ordering because ξ_+ and ξ_- are both central. Putting things together we obtain for a general $f\in\mathrm{Span}\,\mathcal{B}$

$$\begin{aligned}\nabla f=&\frac{\partial_{q^2}f}{\partial_{q^2}\xi_+}\nabla\xi_++\frac{\partial_{q^2}f}{\partial_{q^2}\xi_-}\nabla\xi_-+\frac{\partial_{q^2}f}{\partial_{q^2}x_+}\nabla x_++\frac{\partial_{q^2}f}{\partial_{q^2}x_{3\backslash 0}}\nabla x_{3\backslash 0}+\frac{\partial_{q^2}f}{\partial_{q^2}x_-}\nabla x_-+\frac{\partial_{q^2}(\delta f)}{\partial_{q^2}x_+}\nabla x_+\\&+\frac{\partial_{q^2}(\delta f)}{\partial_{q^2}x_{3\backslash 0}}\nabla x_{3\backslash 0}+\frac{\partial_{q^2}(\delta f)}{\partial_{q^2}x_-}\nabla x_-.\end{aligned} \tag{101}$$

The first two lines look like a generalized chain rule with partial Jackson derivatives as outer

derivatives. The partial Jackson derivatives in the last line are to be understood not to act on the projections $\Pi_\pm$ contained in δf. By definition of δf the last line vanishes for $q \to 1$ and the first two lines reproduce the usual chain rule.

IV. SOLUTIONS OF QUANTUM WAVE EQUATIONS

In order to give an application of the separation of variables and the formulas for derivations, let us now come back to the initial problem of calculating solutions of the quantum Klein-Gordon equation (2). It can be shown that, just as in the commutative case, the space of solutions is generated as representation of the quantum algebra by a momentum eigenstate.[12] However, unlike in the commutative case, there is only a finite number of such momentum eigenstates. In the massless case it is the light cone state, defined by

$$p_0 \triangleright \psi = k\psi, \quad p_3 \triangleright \psi = k\psi, \quad p_\pm \triangleright \psi = 0, \tag{102}$$

where $k \in \mathbb{R}$ is related to helicity. In the massive case it is the rest state

$$p_0 \triangleright \psi = m\psi, \quad p_3 \triangleright \psi = 0, \quad p_\pm \triangleright \psi = 0, \tag{103}$$

where $m \in \mathbb{R}$ is the mass. The difficult part is to calculate these states within the noncommutative differential calculus as solutions of quantum differential equations. All other solutions of the quantum Klein-Gordon equation can then be obtained by quantum Lorentz transformations, which are well known and straightforward to calculate.

A. The massless case

Let us start with the massless case which turns out to be quite simple. As q-differential equation Eq. (102) reads

$$\partial^0 \triangleright \psi = ik\psi, \quad \partial^3 \triangleright \psi = -ik\psi, \quad \partial^\pm \triangleright \psi = 0, \tag{104}$$

where we have raised the indices with the q-Minkowski metric, e.g., $\partial^3 = -\partial_3$. Using the coordinate free notation and the lightcone coordinate $x_{3\backslash 0}$ to be a function of the light cone coordinate $x_{3\backslash 0} = x_3 - x_0$, we can write Eq. (104) as

$$\nabla\psi = -ik\psi \nabla x_{3\backslash 0}. \tag{105}$$

Since $x_{3\backslash 0}$ is one of the variables separating the noncommutative differential calculus, we can conclude that (105) can be solved by a function $\psi = \psi(x_{3\backslash 0})$ of $x_{3\backslash 0}$ alone. Using the formulas (69) for the derivatives we obtain

$$\nabla\psi(x_{3\backslash 0}) = \frac{\partial_{q^2}\psi}{\partial_{q^2} x_{3\backslash 0}} \nabla x_{3\backslash 0} = -ik\psi \nabla x_{3\backslash 0}, \tag{106}$$

which is equivalent to

$$\frac{\partial_{q^2}\psi}{\partial_{q^2} x_{3\backslash 0}} = -ik\psi(x_{3\backslash 0}). \tag{107}$$

This equation is solved by the well-known q-exponential function

$$\exp_q(z) \equiv e_q^z := \sum_{n=1}^{\infty} \frac{z^n}{(n)_{q^2}!}, \tag{108}$$

where the q-factorial is defined in the obvious way as

$$(n)_{q^2}! = (n)_{q^2}(n-1)_{q^2}\cdots(1)_{q^2}. \tag{109}$$

With the q-exponential the general solution of Eq. (107) and, hence, of Eq. (104) can be written as

$$\psi = Ce_q^{-ik(x_3-x_0)}, \tag{110}$$

where C is a normalization constant.

B. The massive case

Let us now turn to the massive case where the calculation of the rest state is more involved. As q-differential function the defining eigenvalue equation (103) reads

$$\partial^0 \triangleright \psi = im\psi, \quad \partial^A \triangleright \psi = 0, \tag{111}$$

where the index runs through $A=-,3,+$. In index free notation we can write this as

$$\nabla\psi = im\psi\nabla x_0. \tag{112}$$

Since the time coordinate x_0 is not one of the variables which separates the noncommutative differential calculus, we cannot conclude that Eq. (112) can be solved by a function in x_0 alone. Since the eigenvalue equation is invariant with respect to quantum rotations we can conclude, though, that ψ must be a function of the scalars with respect to quantum rotations x_0 and x^2. In order to solve Eq. (112) we must separate it with the separating coordinates ξ_- and ξ_+. Using Eq. (97) and $x_0=\xi_-+\xi_-$ we obtain

$$\nabla\psi(\xi_+,\xi_-) = \frac{\partial_{q^2}\psi}{\partial_{q^2}\xi_+}\nabla\xi_+ + \frac{\partial_{q^2}\psi}{\partial_{q^2}\xi_-}\nabla\xi_- = im(\psi\nabla\xi_+ + \psi\nabla\xi_-), \tag{113}$$

which can be rewritten as

$$\left(\frac{\partial_{q^2}\psi}{\partial_{q^2}\xi_+} - im\psi\right)\nabla\xi_+ + \left(\frac{\partial_{q^2}\psi}{\partial_{q^2}\xi_-} - im\psi\right)\nabla\xi_- = 0. \tag{114}$$

The differential equation is now separated so we can make the ansatz

$$\psi(\xi_+,\xi_-) = \psi_+(\xi_+)\psi_-(\xi_-), \tag{115}$$

which solves Eq. (114) if

$$\frac{\partial_{q^2}\psi_+}{\partial_{q^2}\xi_+} = im\psi_+, \quad \frac{\partial_{q^2}\psi_-}{\partial_{q^2}\xi_-} = im\psi_-. \tag{116}$$

We see that the separation of variables of the differential calculus by the new coordinates $\xi_\pm$ leads to a complete separation of the wave equation. Equations (116) are again solved by the q-exponential function (108). As end result we obtain

$$\psi = Ce_q^{im\xi_+}e_q^{im\xi_-} = Ce_q^{(im/2)[x_0+\sqrt{(x_0)^2-(4/[2]^2)(x^2)}]}e_q^{(im/2)[x_0-\sqrt{(x_0)^2-(4/[2]^2)(x^2)}]}, \tag{117}$$

where C is a normalization constant. This rest state is a solution of the massive quantum Klein-Gordon equation (2). All other solutions can be obtained from this one by quantum Lorentz transformations.[36]

V. CONCLUSION

The separation of variables (97) by a nonlinear coordinate transformation (90) seems to be the most intriguing result presented in this paper. We do not yet understand on a fundamental level

what property of quantum Minkowski space is responsible for the existence of such a transformation. Nor do we know if and how this can be generalized to other quantum spaces.

In definition (90) of the separating variables a square root expression appears which, strictly speaking, is not an element of the algebra of Minkowski space proper. In order to make all statements completely rigorous we have to enlarge $\mathcal{X}$ by a central square root element α satisfying

$$\alpha^2 = [2]^2(x_0)^2 - 4(x^2). \tag{118}$$

Alternatively, one could think of the coordinates being represented by operators on a Hilbert space as in Ref. 10. In this case the square root would be defined through functional calculus for normal operators. In the expansion of solution (117) of the quantum Klein-Gordon equation the square root drops out. There, it can be seen as an auxiliary object which makes the notation of a certain generating function more compact. Anyway, it is clear that this mathematical subtlety does not affect the results of this paper.

Finally, we would like to note that expressions for derivatives within the noncommutative calculus can also be derived in a straightforward manner using the recursion relations defined by the commutation relations of momenta and coordinates. While this approach circumvents to some degree the mathematical machinery we have introduced here, it produces lengthy formulas which do not give the structural insight desirable for solving noncommutative differential equations. Even when free field equation can be solved by brute force, using computer algebra, for example, the results turn to be quite complicated. But if already something as basic as the wave function of a free particle were described by complicated expressions, some fundamental questions of quantum field theory, such as independence of in and out states, would become very hard to tackle. In this respect we believe results of the type presented here to be not just a matter of computational convenience but an indispensable requirement for the further development of quantum theory on quantum Minkowski space.

APPENDIX

Definition 5: The Hopf $*$-algebra generated by E, F, K, and K^{-1} *with relations*

$$KK^{-1} = 1 = K^{-1}K, \quad KEK^{-1} = q^2E,$$
$$KFK^{-1} = q^{-2}F, \quad [E,F] = \lambda^{-1}(K - K^{-1}), \tag{A1}$$

Hopf structure

$$\Delta(E) = E \otimes K + 1 \otimes E, \quad \Delta(F) = F \otimes 1 + K^{-1} \otimes F,$$
$$\Delta(K) = K \otimes K, \quad \varepsilon(E) = 0 = \varepsilon(F), \quad \varepsilon(K) = 1, \tag{A2}$$
$$S(E) = -EK^{-1}, \quad S(F) = -KF, \quad S(K) = K^{-1},$$

and $*$-structure

$$E^* = FK, \quad F^* = K^{-1}E, \quad K^* = K \tag{A3}$$

is called $\mathcal{U}_q(\mathrm{su}_2)$, the q-deformation of the enveloping algebra $\mathcal{U}(\mathrm{su}_2)$.[37,38]

Another useful set of generators is given by angular momentum three-vector $\{J_A\} = \{J_-, J_3, J_+\}$ which is a vector operator with respect to the Hopf adjoint action of $\mathcal{U}(\mathrm{su}_2)$ on itself,[12]

$$J_- := q[2]^{-1/2}KF,$$

$$J_3 := [2]^{-1}(q^{-1}EF - qFE), \tag{A4}$$

$$J_+ := -[2]^{-1/2}E.$$

The spin-$\frac{1}{2}$ representation of the antipode of this vector operator yields by $\tilde{\sigma}_A := -[2]\rho^{\frac{1}{2}}(SJ_A)$ a variant of the q-Pauli matrices which we will need here. Explicitly, we obtain

$$\tilde{\sigma}_- = [2]^{1/2}\begin{pmatrix} 0 & q^{1/2} \\ 0 & 0 \end{pmatrix}, \quad \tilde{\sigma}_+ = [2]^{1/2}\begin{pmatrix} 0 & 0 \\ -q^{-1/2} & 0 \end{pmatrix}, \quad \tilde{\sigma}_3 = \begin{pmatrix} -q^{-1} & 0 \\ 0 & q \end{pmatrix} \tag{A5}$$

with respect to the $\{-, +\}$ basis. $\mathcal{U}_q(\mathrm{su}_2)$ is quasitriangular with universal $\mathcal{R}$-matrix[39]

$$\mathcal{R} = e^{\hbar(H\otimes H)/2}\sum_{n=0}^{\infty} e^{\hbar n(n-1)/2}\frac{(e^{\hbar} - e^{-\hbar})^n}{[n]!}(E^n \otimes F^n), \tag{A6}$$

where $\hbar := \ln q$. The quantum Lorentz algebra contains a $\mathrm{SU}_q(2)^{\mathrm{op}}$ Hopf subalgebra,[33] the generators of which are given explicitly by

$$a := K^{1/2} \otimes K^{-1/2},$$

$$b := q^{-1/2}\lambda K^{1/2} \otimes K^{-1/2}E,$$

$$c := -q^{1/2}\lambda FK^{1/2} \otimes K^{-1/2}, \tag{A7}$$

$$d := K^{-1/2} \otimes K^{1/2} - \lambda^2 FK^{1/2} \otimes K^{-1/2}E.$$

Generalized quantum entropy

Xinhua Hu[a] and Zhongxing Ye[b]
Department of Mathematics, Shanghai Jiao Tong University, Shanghai 200240, People's Republic of China

(Received 1 November 2005; accepted 9 December 2005; published online 13 February 2006)

The generalized quantum entropies are introduced in this paper. Some important properties such as nonnegativity, continuity, and concavity are proved. But different from the Von Neumann entropy, the subadditivity and additivity fail for the quantum unified (r,s)-entropy in general. © *2006 American Institute of Physics.*

I. INTRODUCTION

The successful application of Shannon's information quantities in information theory and coding theory has stimulated the investigation of more information measures. People have made much efforts in applying information theory to other fields and further extended Shannon's information measures in variable senses. There are various generalizations of Shannon's entropy.

For a discrete probability distribution $P=(p_1,p_2,\ldots,p_d)$ with $0\leqslant p_j\leqslant 1$ and $\Sigma_{j=1}^{d}p_j=1$. Let us consider the following generalized entropies:

Rényi entropy of order r,[1]

$$H_r(P)=(1-r)^{-1}\log\left(\sum_{j=1}^{d}p_j^r\right),\quad r>0,\quad r\neq 1. \tag{1}$$

Entropy of degree r (Tsallis entropy),[2]

$$H^r(P)=(1-r)^{-1}\left(\sum_{j=1}^{d}p_j^r-1\right),\quad r>0,\quad r\neq 1. \tag{2}$$

Entropy of type r,[3]

$${}_rH(P)=(r-1)^{-1}\left[\left(\sum_{j=1}^{d}p_j^{1/r}\right)^r-1\right],\quad r>0,\quad r\neq 1. \tag{3}$$

It is easy to verify that

$$\lim_{r\to 1}H_r(P)=\lim_{r\to 1}H^r(P)=\lim_{r\to 1}{}_rH(P)=H(P),$$

where

$$H(P)=-\sum_{j=1}^{d}p_j\log p_j \tag{4}$$

is the well-known Shannon entropy.

[b]Electronic mail: zxye@sjtu.edu.cn

Among multitude of information entropies, Shannon entropy, Rényi entropy and Tsallis entropy have found utility in a wide range of physical problems. Shannon entropy is well known to be successfully applied to modern information theory, and is frequently used in such areas as economics, geophysics, biology, medical diagnosis, and astronomy;[4] Rényi entropy is routinely measured in numerous situations ranging from coding theory and cryptography;[5] a possible generalization of Boltzmann-Gibbs statistical mechanics was proposed on the basis of Tsallis entropy, and Tsallis nonextensive formalism of statistical mechanics has been designed to treat those systems which cannot be treated within Boltzmann-Gibbs formalism owing to the presence of long-range interactions, spatio-temporal complexity, fractal dynamics and so on.[6]

However the above four entropies can be obtained easily as limiting or particular cases from the following entropy which is called (r,s)-entropy[7,8] involving two real parameters r and s:

$$H_r^s(P) = [(1-r)s]^{-1}\left[\left(\sum_{j=1}^{d} p_j^r\right)^s - 1\right], \quad r>0, \quad r\neq 1, \quad s\neq 0. \tag{5}$$

When $r=\alpha$, $s=(\beta-1)/(\alpha-1)$, $\alpha>0$, $\beta>0$, $\alpha\neq 1$, $\beta\neq 1$, then this reduces to Sharma and Mittal's entropy of order α and degree β.[9] The (r,s)-entropy (5) includes the entropies (1) and (4) as limiting cases. The entropies (2) and (3) are particular cases of (5). This can be written in composite form with the entropy of order r as follows:

$$H_r^s(P) = [(1-r)s]^{-1}[e^{(1-r)s\cdot H_r(P)} - 1], \quad r>0, \quad r\neq 1, \quad s\neq 0. \tag{6}$$

Let us write the continuous version of the above five entropies with respect to the parameters r,s as follows:

$$E_r^s(P) = \begin{cases} H_r^s(P) & \text{if } r\neq 1, \quad s\neq 0, \\ H_r(P) & \text{if } r\neq 1, \quad s=0, \\ H^r(P) & \text{if } r\neq 1, \quad s=1, \\ {}_rH(P) & \text{if } r\neq 1, \quad s=1/r, \\ H(P) & \text{if } r=1. \end{cases} \tag{7}$$

for all $r>0$ and for any s. $E_r^s(P)$is called the unified (r,s)-entropy.[7,8]

The Von Neumann entropy is the quantum version of the Shannon entropy. In Sec. II we review the definition of the Von Neumann entropy and define its various generalizations. The main results of this paper are presented in Sec. III. Some important properties of quantum unified (r,s)-entropy are proved.

II. QUANTUM ENTROPY

Von Neumann defined the entropy of a quantum state ρ by the formula[10,11]

$$S(\rho) = -\operatorname{tr}(\rho\log\rho), \tag{8}$$

where ρ is any density operator, i.e., positive operator on a complex separable Hilbert space $\mathcal{H}$ having a unit trace. The generalized entropies also have their quantum versions as follows.

Quantum Rényi entropy of order r,

$$S_r(\rho) = (1-r)^{-1}\log[\operatorname{tr}(\rho^r)], \quad r>0, \quad r\neq 1. \tag{9}$$

Quantum entropy of degree r (quantum Tsallis entropy),

$$S^r(\rho) = (1-r)^{-1}[\operatorname{tr}(\rho^r) - 1], \quad r>0, \quad r\neq 1. \tag{10}$$

Quantum entropy of type r,

$${}_rS(\rho) = (r-1)^{-1}\{[\operatorname{tr}(\rho^{1/r})]^r - 1\}, \quad r>0, \quad r\neq 1. \tag{11}$$

Quantum (r,s)-entropy,

$$S_r^s(\rho) = [(1-r)s]^{-1}\{[\mathrm{tr}(\rho^r)]^s - 1\}, \quad r > 0, \quad r \neq 1. \tag{12}$$

Quantum unified (r,s)-entropy,

$$E_r^s(\rho) = \begin{cases} S_r^s(\rho) & \text{if } r \neq 1, \quad s \neq 0, \\ S_r(\rho) & \text{if } r \neq 1, \quad s = 0, \\ S^r(\rho) & \text{if } r \neq 1, \quad s = 1, \\ {}_rS(\rho) & \text{if } r \neq 1, \quad s = 1/r, \\ S(\rho) & \text{if } r = 1. \end{cases} \tag{13}$$

for all $r>0$ and for any s.

Using the spectral decomposition theorem and noting $\mathrm{tr}(U\rho U^\dagger)=tr(\rho)$, where U is unitary, we can easily verify that

$$\lim_{r\to 1} S_r(\rho) = \lim_{r\to 1} S^r(\rho) = \lim_{r\to 1} {}_rS(P) = S(\rho).$$

III. PROPERTIES OF THE QUANTUM UNIFIED (r,s)-ENTROPY

Proposition 1: The quantum unified (r,s)-entropy is non-negative, i.e., $E_r^s(\rho)\geqslant 0$, where ρ is any density operator. The equality holds if and only if the state is pure.

Proof: The Von Neumann entropy $S(\rho)\geqslant 0$ (Refs. 10 and 11) and the quantum Rényi entropy $S_r(\rho)\geqslant 0$ (Ref. 12) are well known. Now we prove $S_r^s(\rho)\geqslant 0$. One has $x^r \leqslant (\text{resp.}\geqslant)x$ for $x \in [0,1]$ with equality iff $x=0$ or $x=1$ when $r>1$(resp.$0<r<1$). Since the eigenvalues p_j of ρ lie in $[0,1]$, we conclude the operator inequality $\rho^r \leqslant (\text{resp.}\geqslant)\rho$, where equality holds iff ρ is pure, i.e., a one-dimensional projection. It then follows that $\mathrm{tr}(\rho^r)\leqslant(\text{resp.}\geqslant)1$ with equality iff ρ is pure. Noting the sign of $(1-r)s$ in different cases, we complete the proof.

Proposition 2: In a finite dimension d, $E_r^s(\rho)$ is bounded, i.e.,

$$E_r^s(\rho) \leqslant \begin{cases} \log(\mathrm{rank}\,\rho) & \text{if } r = 1, \\ (1-r)^{-1}\log(\mathrm{rank}\,\rho) & \text{if } r \neq 1, \quad s = 0, \\ [(1-r)s]^{-1}[(\mathrm{rank}\,\rho)^{(1-r)s} - 1] & \text{if } r \neq 1, \quad s \neq 0. \end{cases} \tag{14}$$

Equality holds in the inequality if and only if ρ is an equidistribution of order rank ρ.

Proof: To prove the upper bounds of (14) we use Hölder's inequality. For $0<r<1$,

$$\mathrm{tr}(\rho^r) = \sum_{j=1}^{\mathrm{rank}\,\rho} p_j^r \leqslant \left(\sum_{j=1}^{\mathrm{rank}\,\rho} (p_j^r)^{1/r}\right)^r \left(\sum_{j=1}^{\mathrm{rank}\,\rho} 1^{1/(1-r)}\right)^{1-r} = (\mathrm{rank}\,\rho)^{1-r}, \tag{15}$$

where p_j is the eigenvalue of ρ, Equality holds iff p_j is constant for $j=1,2,\ldots,\mathrm{rank}\,\rho$, i.e., $p_j = (\mathrm{rank}\,\rho)^{-1}$. When $s>0$ or $s<0$, we have the same result as follows:

$$S_r^s(\rho) \leqslant [(1-r)s]^{-1}[(\mathrm{rank}\,\rho)^{(1-r)s} - 1], \tag{16}$$

which is the third inequality in (14). For $r>1$, the inequality in (15) is reversed but the conditions for equality are the same. When $s\neq 0$, the proof is similar. From (6) and (16), we have $S_r(\rho) = [(1-r)s]^{-1}\log[(1-r)s\cdot S_r^s(\rho)+1]$ and thus $S_r(\rho)\leqslant\log(\mathrm{rank}\,\rho)$. For $r=1$, Von Neumann entropy is at most $\log(\mathrm{rank}\,\rho)$.[10,11] This completes the proof.

Noting that $\mathrm{rank}(\rho)\leqslant d$ and letting $d\to\infty$, we have the following conclusions.

Corollary 1: In an infinite dimension

(i) for $0<r<1, s<0$ or $r>1, s>0$, $0\leqslant E_r^s(\rho)<[(r-1)s]^{-1}$;
(ii) for $0<r<1, s>0$ or $r>1, s<0$, $0\leqslant E_r^s(\rho)\leqslant\infty$.

Concavity is another important property of $E_r^s(\rho)$ similar to the Von Neumann entropy. To prove this property, we have the following lemma.

Lemma 1: Let $G_r^s(\rho)=[\mathrm{tr}(\rho^r)]^s$, $r>0, s\neq 0$, then

(i) $G_r^s(\rho)$ is a concave function of the density operator ρ for $0<r<1$, $s>0$, $rs\leqslant 1$;
(ii) $G_r^s(\rho)$ is a convex function of the density operator ρ for $r\geqslant 1$, $rs\geqslant 1$ or $0<r<1, s<0$.

Proof: We apply Minkowski's inequality to positive operators: Let ρ,σ be positive operators, and $1<r<\infty$, then

$$[\mathrm{tr}(\rho+\sigma)^r]^{1/r}\leqslant [tr(\rho)^r]^{1/r}+[\mathrm{tr}(\sigma)^r]^{1/r}. \tag{17}$$

Case 1: when $r\geqslant 1$, from (17), we have

$$[\mathrm{tr}(\lambda\rho+\mu\sigma)^r]^{1/r}\leqslant \lambda[\mathrm{tr}(\rho)^r]^{1/r}+\mu[\mathrm{tr}(\sigma)^r]^{1/r},$$

where $\lambda\geqslant 0$, $\mu\geqslant 0$, $\lambda+\mu=1$. If $rs>1$, we have

$$[\mathrm{tr}(\lambda\rho+\mu\sigma)^r]^s\leqslant [\lambda(\mathrm{tr}(\rho)^r)^{1/r}+\mu(\mathrm{tr}(\sigma)^r)^{1/r}]^{rs}\leqslant \lambda[\mathrm{tr}(\rho)^r]^s+\mu[\mathrm{tr}(\sigma)^r]^s. \tag{18}$$

Equation (18) is obtained from the convexity of the function $y=x^{rs}$, $rs\geqslant 1$. Therefore $G_r^s(\rho)$ is a convex function for $r>1$ with $rs\geqslant 1$.

Case 2: when $0<r<1$, the inequality in (17) is reversed,

$$[\mathrm{tr}(\rho+\sigma)^r]^{1/r}\geqslant [\mathrm{tr}(\rho)^r]^{1/r}+[\mathrm{tr}(\sigma)^r]^{1/r},$$

where $\lambda\geqslant 0, \mu\geqslant 0, \lambda+\mu=1$. We consider the following two cases:

(a) when $0<rs<1$, we have

$$[\mathrm{tr}(\lambda\rho+\mu\sigma)^r]^s\geqslant [\lambda(\mathrm{tr}(\rho)^r)^{1/r}+\mu(\mathrm{tr}(\sigma)^r)^{1/r}]^{rs}\geqslant \lambda[\mathrm{tr}(\rho)^r]^s+\mu[\mathrm{tr}(\sigma)^r]^s.$$

So $G_r^s(\rho)$ is a concave function for $0<r<1$, $0<rs<1$.

(b) When $rs<0$, i.e., $s<0$, (18) is also true. Therefore $G_r^s(\rho)$ is a convex function for $0<r<1$ with $rs<0$. This complete the proof.

Concavity of $E_r^s(\rho)$ follows from Lemma 1 and the sign of $(1-r)s$.

Proposition 3: Suppose ρ and σ are density operators and $0\leqslant\lambda\leqslant 1$. Then

$$E_r^s(\lambda\rho+(1-\lambda)\sigma)\geqslant \lambda E_r^s(\rho)+(1-\lambda)E_r^s(\sigma), \tag{19}$$

for all r and s satisfying either $0<r\leqslant 1, rs\leqslant 1$ or $r\geqslant 1, rs\geqslant 1$.

Remarks:

(i) For $r=1$, the Von Neumann entropy is a concave function.[10]
(ii) For $r>0, r\neq 1, s=0$, the quantum Rényi entropy fails for concavity.[12]
(iii) For $r>0, r\neq 1, s=1$, the quantum Tsallis entropy is a concave function.[13]

There is an upper bound for the convex combination.

Proposition 4: Setting $F_r^s(\lambda)=[(1-r)s]^{-1}[\lambda^{rs}+(1-\lambda)^{rs}-1]$, $0\leqslant\lambda\leqslant 1$, we have the following:

(i) For $r>1$, $s\geqslant 1$ or $0<r<1$, $0<s<1$ or $r>1$, $s<0$,

$$E_r^s(\lambda\rho+(1-\lambda)\sigma)\leqslant \lambda^{rs}E_r^s(\rho)+(1-\lambda)^{rs}E_r^s(\sigma)+F_r^s(\lambda). \tag{20}$$

(ii) In particular, for $r>1$, $s\geqslant 1$,

$$E_r^s(\lambda\rho+(1-\lambda)\sigma)\leqslant \lambda E_r^s(\rho)+(1-\lambda)E_r^s(\sigma)+F_r^s(\lambda). \tag{21}$$

Proof: It is clear that for positive numbers a and b,

$$(a+b)^s \geqslant a^s + b^s \quad \text{if } s \geqslant 1, \quad (a+b)^s \leqslant a^s + b^s \quad \text{if } 0 < s < 1 \quad \text{or } s < 0.$$

By using the trace inequalities:[14] for positive operators ρ and σ,

$$\mathrm{tr}((\rho+\sigma)^r) \geqslant [\text{resp. } \leqslant]\mathrm{tr}(\rho^r) + \mathrm{tr}(\sigma^r), \quad \text{for } r \geqslant 1[\text{resp.} 0 < r < 1].$$

Noting the sign of $(1-r)s$, we can complete the proof.

Remarks: From Corollary 1, some properties of $F_r^s(\lambda)$ follow:

(i) $(\lambda-\lambda^{rs})E_r^s(\rho)+[(1-\lambda)-(1-\lambda)^{rs}]E_r^s(\sigma) < F_r^s(\lambda)$ for $r>1$, $s>1$,
(ii) $(\lambda-\lambda^{rs})E_r^s(\rho)+[(1-\lambda)-(1-\lambda)^{rs}]E_r^s(\sigma) > F_r^s(\lambda)$ for $0<r<1$, $s<0$,

where ρ and σ are arbitrary density operators.

Using the method of mathematical induction, we obtain the following.

Corollary 2: Suppose $\rho=\Sigma_{i=1}^n p_i\rho_i$, where $\{p_i, 1 \leqslant i \leqslant n\}$ is a probability distribution, and ρ_i are density operators. If $r \geqslant 1$, $s \geqslant 1$ then

$$\sum_{i=1}^n p_i E_r^s(\rho_i) \leqslant E_r^s(\rho) \leqslant \sum_{i=1}^n p_i E_r^s(\rho_i) + F_r^s(p_1, p_2, \ldots, p_n), \tag{22}$$

where $F_r^s(p_1, p_2, \ldots, p_n)=[(1-r)s]^{-1}(p_1^{rs}+p_2^{rs}+\cdots+p_n^{rs}-1)$.

We can define the generalized Holevo bound denoted by χ and

$$\chi = E_r^s\left(\sum_{i=1}^n p_i\rho_i\right) - \sum_{i=1}^n p_i E_r^s(\rho_i). \tag{23}$$

The Holevo χ quantity is very useful in quantum information.[10]

Let ρ and σ be density operators, we say ρ majorizes σ and write it as $\rho \succ \sigma$ which means that the spectrum of the operator ρ majorizes the spectrum of the operator σ. That is, if ρ and σ have eigenvalues $\lambda_1 \geqslant \lambda_2 \geqslant \cdots \geqslant \lambda_d$ and $\mu_1 \geqslant \mu_2 \geqslant \cdots \geqslant \mu_d$, respectively, then $\Sigma_{j=1}^l \lambda_j \geqslant \Sigma_{j=1}^l \mu_j$ for all $1 \leqslant l \leqslant d$. If $\rho \succ \sigma$ then $E_r^s(\rho) \leqslant E_r^s(\sigma)$ which is called Schur concavity.

Proposition 5: The quantum unified (r,s)-entropy does not satisfy Schur concavity, moreover, if ρ majorizes σ, i.e., $\rho \succ \sigma$ then $E_r^s(\rho) \geqslant E_r^s(\sigma)$.

To prove this proposition, we need a lemma.

Lemma 2: If $\lambda_i \geqslant \mu_i \geqslant 0$, $i=1,2,\ldots,d$, then for $r>1$ or $r<0$,

$$\left(\sum_{i=1}^d \lambda_i\right)^r - \sum_{i=1}^d \lambda_i^r \geqslant \left(\sum_{i=1}^d \mu_i\right)^r - \sum_{i=1}^d \mu_i^r. \tag{24}$$

For $0<r<1$, the inequality in (24) is reversed.

Proof: See Ref. 8.

Proof of Proposition 5: If λ_i and μ_i are eigenvalues of density operators ρ and σ, respectively, then by Lemma 2 we obtain that if $\rho \succ \sigma$ then $\mathrm{tr}(\rho^r) \leqslant \mathrm{tr}(\sigma^r)$ for $r>1$ and $\mathrm{tr}(\rho^r) \geqslant \mathrm{tr}(\sigma^r)$ for $0<r<1$. For quantum (r,s)-entropy$(r>0, r\neq 1, s\neq 1)$, it is easy to verify $S_r^s(\rho) \geqslant S_r^s(\sigma)$. For the quantum Rényi entropy, the quantum Tsallis entropy and the quantum entropy of type r, the proof is similar by Lemma 2. For the Von Neumann entropy, Wehrl[11] gave the proof. This completes the proof of Proposition 5.

Suppose we vary the density operator ρ by a small amount. How much does $E_r^s(\rho)$ change? We know the Von Neumann entropy satisfies Fannes's inequality.[15] With respect to the trace distance $\|\rho-\sigma\| = \frac{1}{2}\mathrm{tr}|\rho-\sigma|$, $E_r^s(\cdot)$ is Lipschitz under certain conditions.

Proposition 6 (*Lipschitz continuity*): For $r>1$ and $s \geqslant 1$

$$|E_r^s(\rho) - E_r^s(\sigma)| \leqslant r(r-1)^{-1}\|\rho-\sigma\|. \tag{25}$$

Proof: Applying the generalized Klein's inequality,[16] we obtain, for $\rho \leqslant \sigma$,

$$\mathrm{tr}[(\rho-\sigma)f'(\sigma)] \leqslant \mathrm{tr}[f(\rho)-f(\sigma)] \leqslant \mathrm{tr}[(\rho-\sigma)f'(\rho)],$$

where $f(x)=x^r$, $r>1$, $x\in(0,1]$ is a convex function. So

$$|\mathrm{tr}(\rho^r)-\mathrm{tr}(\sigma^r)| \leqslant r\cdot\max\{|\mathrm{tr}[(\rho-\sigma)\rho^{r-1}|,|\mathrm{tr}[(\rho-\sigma)\sigma^{r-1}|\}.$$

By the spectral decomposition, we may decompose $\rho-\sigma=Q-R$, where Q and R are positive operators with orthogonal support, $\|\rho-\sigma\|=\mathrm{tr}(Q)+\mathrm{tr}(R)$, so

$$|\mathrm{tr}[(\rho-\sigma)\rho^{r-1}| = |\mathrm{tr}[(Q-R)\rho^{r-1}| \leqslant \mathrm{tr}(Q\rho^{r-1})+\mathrm{tr}(R\rho^{r-1}) \leqslant \mathrm{tr}(Q+R) = \|\rho-\sigma\|.$$

By symmetry between density operators ρ and σ, we also have $|\mathrm{tr}[(\rho-\sigma)\sigma^{r-1}| \leqslant \|\rho-\sigma\|$.

Therefore

$$|\mathrm{tr}(\rho^r)-\mathrm{tr}(\sigma^r)| \leqslant r\cdot\|\rho-\sigma\| \quad (r>1).$$

The derivative sx^{s-1} of the map $x\to x^s$ is bounded on $[0,1]$, so that this map is Lipschitz with constant $s\geqslant 1$. Hence

$$|[\mathrm{tr}(\rho^r)]^s-[\mathrm{tr}(\sigma^r)]^s| \leqslant s\cdot|\mathrm{tr}(\rho^r)-\mathrm{tr}(\sigma^r)| \leqslant sr\cdot\|\rho-\sigma\|.$$

The Lipschitz continuity of $E_r^s(\rho)$ follows from the above inequalities.

We now turn to properties of the quantum unified (r,s)-entropy for composite system. We recall that the familiar Von Neumann entropy $S(\rho)$ satisfies (see, e.g., Refs. 10 and 11),

$$S(\rho_{AB}) \leqslant S(\rho_A\otimes\rho_B) = S(\rho_A)+S(\rho_B), \tag{26}$$

for any state ρ_{AB} on $\mathcal{H}_A\otimes\mathcal{H}_B$, where $\rho_A=\mathrm{tr}_B(\rho_{AB})$ and $\rho_B=\mathrm{tr}_A(\rho_{AB})$.

The inequality in (26) is known as the subadditivity property of entropy; it is customarily paraphrased by saying that since all correlations between the subsystems present in ρ_{AB} are lost in the state $\rho_A\otimes\rho_B$ (when ρ_{AB} is not a product state) the entropy should increase. The equality holds iff $\rho_{AB}=\rho_A\otimes\rho_B$. Unfortunately, subadditivity of the form $S(\rho_{AB})\leqslant S(\rho_A)+S(\rho_B)$ and additivity of the form $S(\rho_{AB})=S(\rho_A)+S(\rho_B)$ fail for quantum unified (r,s)-entropy in general.

Proposition 7: Suppose ρ and σ are density operators, and $\rho\otimes\sigma$ is a product state, then

$$E_r^s(\rho\otimes\sigma) = E_r^s(\rho)+E_r^s(\sigma)+(1-r)sE_r^s(\rho)E_r^s(\sigma), \tag{27}$$

$$E_r^s(\rho\otimes\sigma) \leqslant E_r^s(\rho)+E_r^s(\sigma), \quad 0<r<1, \quad s<0 \text{ or } r\geqslant 1, \quad s\geqslant 0, \tag{28}$$

$$E_r^s(\rho\otimes\sigma) \geqslant E_r^s(\rho)+E_r^s(\sigma), \quad r>1, \quad s<0 \text{ or } 0<r<1, \quad s>0. \tag{29}$$

With equalities if and only if either of the states ρ,σ is pure.

Proof: When $r\neq 1$, $s\neq 0$, Direct computation gives (27)

$$S_r^s(\rho\otimes\sigma)-S_r^s(\rho)-S_r^s(\sigma) = [(1-r)s]^{-1}\{[\mathrm{tr}(\rho\otimes\sigma)^r]^s-[\mathrm{tr}(\rho)^r]^s-[\mathrm{tr}(\sigma)^r]^s+1\}$$

$$=[(1-r)s]^{-1}[(\mathrm{tr}(\rho^r))^s-1][(\mathrm{tr}(\sigma^r))^s-1]$$

$$=(1-r)s\cdot S_r^s(\rho)S_r^s(\sigma),$$

When $r\neq 1$, $s=0$ and $r=1$, the quantum Rényi entropy and the Von Neumann entropy, respectively, satisfy the additivity property.[10–12] The inequalities in (28) and (29) are clear. This completes the proof.

Due to (27), one has in general $E_r^s(\rho_{AB})\neq E_r^s(\rho_A)+E_r^s(\rho_B)$, moreover subadditivity of the form $E_r^s(\rho_{AB})\leqslant E_r^s(\rho_A)+E_r^s(\rho_B)$ fails due to (29). However under certain conditions, the subadditivity

inequality is true. For example, for $r>1$, the quantum Tsallis entropy satisfies the subadditivity property.[13] Because of the generality of quantum unified (r,s)-entropy, it is hard to obtain the subadditivity property.[17–19]

Proposition 8: If a composite system $\mathcal{H}_A \otimes \mathcal{H}_B$ is in a pure state ρ_{AB}, then

$$E_r^s(\rho_A) = E_r^s(\rho_B). \tag{30}$$

Proof: From the Schmidt decomposition we know that eigenvalues of density operators of systems $\mathcal{H}_A$ and $\mathcal{H}_B$ are the same. The entropy is determined by the eigenvalues, so $E_r^s(\rho_A) = E_r^s(\rho_B)$.

It is clear in this case, $0 = E_r^s(\rho_{AB}) \leqslant E_r^s(\rho_A) + E_r^s(\rho_B)$.

We study the geometrical optics generated by a refractive index of the form $n(x,y)=1/y$ $(y>0)$, where y is the coordinate of the vertical axis in an orthogonal reference frame in $\mathbb{R}^2$. We thus obtain what we call "hyperbolic geometrical optics" since the ray trajectories are geodesics in the Poincaré-Lobachevsky half-plane $\mathbb{H}^2$. Then we prove that the constant phase surface are horocycles and obtain the *horocyclic waves*, which are closely related to the classical Poisson kernel and are the analogs of the Euclidean plane waves. By studying the transport equation in the Beltrami pseudosphere, we prove (i) the conservation of the flow in the entire strip $0<y\leqslant 1$ in $\mathbb{H}^2$, which is the limited region of physical interest where the ray trajectories lie; (ii) the nonuniform distribution of the density of trajectories: the rays are indeed focused toward the horizontal x axis, which is the boundary of $\mathbb{H}^2$. Finally the process of ray focusing and defocusing is analyzed in detail by means of the sine-Gordon equation. © *2006 American Institute of Physics.*

I. INTRODUCTION

It is well known that the geometrical optics approximation of the wave equation is related to the asymptotic form of the integral representation of the field (if such exists), which is an exact solution of the wave problem. Suppose, for instance, that the field in a uniform medium can be written as an expansion in plane waves; the evaluation of this integral by the stationary phase method yields an asymptotic series. Then the leading term of this asymptotic expansion, which is composed by an amplitude and a phase, can be extracted to yield the approximation. The ray trajectories are the lines orthogonal to the constant phase surface and are described by the eikonal equation; the amplitude satisfies the transport equation, whose physical meaning is related to the conservation of the flow. In the simplest case of uniform medium, whose refractive index n is a real constant, the rays are straight lines which are characterized by the following properties:

(i) They are geodesics of the Euclidean space.
(ii) Phase and amplitude are real-valued functions.
(iii) They can be derived by the Fermat's principle.

Constrained by these properties the methods of geometrical optics are rather limited and fail to explain several phenomena as, for instance, the diffraction by a compact and opaque obstacle, that is the existence of non-null field in the geometrical shadow which, for this reason, is usually referred to as the classically (or geometrically) forbidden region.

In the decade 1950–1960 Keller[1–3] wrote several papers where he introduced the so-called geometrical theory of diffraction (GTD). The latter can be regarded as an extension of geometrical optics, which accounts for diffraction by introducing the diffracted rays in addition to the usual

rays of geometrical optics. After these seminal works there has been a steady flow of papers addressing various aspects of the theory. On the one hand papers oriented to pure and applied electromagnetic theory, like radiation and scattering of waves, antenna design, waveguide theory and so on;[3] on the other hand, a highly theoretical and mathematically sophisticated theory of propagation of singularities and diffraction of waves on manifolds.[4] In spite of these efforts and a wide literature on these topics, not all the cases of interest have been studied. An example is what we could call the "hyperbolic geometrical optics," that is the geometrical optics generated by the rays in the specific case of a refractive index of the form $n(x,y)=1/y$ $(y>0)$, where y denotes a spatial coordinate, say vertical, in an appropriate orthogonal reference frame in $\mathbb{R}^2$. As far as we know, this problem has never been treated, except for some very marginal remarks (see, for instance, Ref. 5), in spite of its intrinsic geometrical interest and some possible applications to the physics of nonuniform optical fibers. It is precisely the main purpose of the present paper to fill this gap.

Let us return to the Keller's program of widening, from a geometrical viewpoint, the arena of Euclidean geometrical optics. With this in mind we adopt, first of all, the Jacobi's form of the principle of least action (instead of Fermat's), which concerns with the path of the system point rather than with its time evolution.[6] More precisely, the Jacobi's principle (generally applied in mechanics) can be formulated as follows: If there are no forces acting on the body, then the system travels along the shortest path length in the configuration space. Here we assume a wide extension of the Jacobi's principle, which can be formulated as follows: the geodesics associated with the Riemannian metric $n(x,y)\sqrt{\mathrm{d}x^2+\mathrm{d}y^2}$, i.e., the paths making the functional $\int n(x,y)\sqrt{\mathrm{d}x^2+\mathrm{d}y^2}$ stationary, are nicknamed rays. In other words, in place of Fermat's principle which reads $\delta\int_{P_0}^{P_1}\mathrm{d}t=0$, where $\mathrm{d}t$ is the travel time measure, and P_0 and P_1 are prescribed starting and end points of the path, we write

$$\delta\int_{P_0}^{P_1} n(x,y)\sqrt{\mathrm{d}x^2+\mathrm{d}y^2}=0, \tag{1}$$

or, equivalently,

$$\delta\int_{x_0}^{x_1} F(x,y,y')\mathrm{d}x=0, \quad (F(x,y,y')=n(x,y)\sqrt{1+y'^2}), \tag{2}$$

where $y'=\tan\alpha$, α being the angle that the tangent to the curve $y=y(x)$ forms with the x axis.

The simplest realization of this Jacobi's principle consists in identifying n^2 with the Riemann metric tensor g_{ij}, *whenever this identification is admissible*. This identification requires great caution, indeed; the form $g_{ij}\,\mathrm{d}x^i\,\mathrm{d}x^j$ must be symmetric and positive definite, and this poses a strict restriction. For instance, consider a refractive index (or, in mechanics, a potential) of the following form: $n^2=1-V/E$, where E is the energy of the incoming particle and V is the height of the potential, with $V>E$ as in the case of the tunnel effect. In this situation the geometric interpretation of the trajectory as a real-valued geodesic in a Riemannian manifold is no longer possible. The only chance remains to extend the admissible values of the phase to imaginary and/or complex values and, consequently, to speak of complex rays in the sense of Landau.[7]

But let us return to the cases where this identification is admissible. As we already mentioned, it is obviously possible in the case of a uniform nonabsorbing medium: in this case we simply obtain a physical realization of Euclidean geometry. But it is also certainly admissible when the refractive index is of the form introduced above, i.e., $n(x,y)=1/y$ $(y>0)$, where y denotes the coordinate of the vertical axis in an orthogonal reference frame in $\mathbb{R}^2$. In this case we are led to the Lobachevskian metric: $\mathrm{d}s^2=(\mathrm{d}x^2+\mathrm{d}y^2)/y^2$. Then the rays are geodesics in the hyperbolic half-plane (Poincaré half-plane), i.e., Euclidean half-circles with centers on the x axis (horizontal axis), or Euclidean straight lines normal to the x axis. Let us recall that the refractive index n is defined as $n=c/v_{\mathrm{ph}}$, where c is the light speed in vacuum, and v_{ph} is the phase velocity of radiation of a specific frequency in a specific material. Therefore $n\geqslant 1$, and in the case $n(x,y)=1/y$ only the

strip $0<y\leqslant 1$ has physical interest; hence the actual rays will lie necessarily in this band. Accordingly, hereafter, the only optical paths considered will be the Euclidean half-circles with centers on the x axis and radius R bounded by $0<R\leqslant 1$.

The subsequent step in developing an optical geometry consists in finding the constant phase surfaces and, accordingly, describing the analog of the Euclidean plane wave. This problem will be solved in Sec. II, studying some geometrical properties of horocycles and introducing what we call *horocyclic waves*, which play in hyperbolic geometrical optics the same role as the plane waves do in the Euclidean one. At this point we have the main ingredients needed for writing the geometrical approximation of the wave function; what it is still missing is an analysis of the amplitude and of the related flux density. This latter problem can be analyzed at two different levels. First we prove that the flow of rays is conserved: once a pointlike source is fixed, no ray will be absorbed or created. This result will be proved in Sec. II. A more subtle question is the following: Is the flow of the ray trajectories homogeneous or do the rays focus? This issue, besides its intrinsic geometrical interest, could in our opinion be of some interest in possible applications to the propagation in optical fibers with nonuniform refractive index.[8] This problem will be analyzed in detail in Sec. III. First we study the transport equation in the Beltrami pseudosphere, and prove that the flow of ray trajectories is not homogeneous, but there is a focusing of rays on the horizontal x axis. Glancing to possible applications to propagation in optical fibers this result suggests a conjecture indicating a strong ray focusing along the fiber axis, when the refractive index profile in the fiber is of hyperbolic type, instead of paraboliclike, as is customary. Next, this problem will be reconsidered by studying the variation of the angle that the tangent to the meridian of the Beltrami pseudosphere makes with the rotation axis of this surface, which can be indeed represented as a surface of revolution generated by a curve in $\mathbb{R}^3$. This leads to the sine-Gordon equation and provides a more precise description of the ray focusing and defocusing processes. This analysis is necessarily local, since the problem is worked out inside each horocycle; at the end of Sec. III, we show how to pass from a local description of the flow inside each horocycle to a global one.

Finally, in the Appendix , the geometric and algebraic ingredients which occur in Secs. II and III will be given. This appendix is split in three parts: the first part is devoted to the various models of hyperbolic geometry and to the conformal maps which allows the transformation between them; in the second part we study the group $\mathrm{SU}(1,1)$, which acts transitively on the non-Euclidean disk, and prove some relationships connecting the spherical functions to the horocyclic waves; the last part is devoted to the Beltrami pseudosphere.

II. THE FLOW IN THE STRIP $0<y\leqslant 1$

A. Variational minimization of the Jacobi's functional and the rays in hyperbolic geometrical optics

Let us consider the upper half-plane model of the hyperbolic two-dimensional space $\mathbb{H}^2$: i.e., $U=\{z=x+iy: y>0\}$ equipped with the metric d derived from the differential $\mathrm{d}s=|\mathrm{d}z|/\mathrm{Im}\, z$ (see the Appendix). Then we apply the typical methods of variational calculus to the Jacobi functional

$$J=\int_{P_0}^{P_1}\frac{\sqrt{(\mathrm{d}x)^2+(\mathrm{d}y)^2}}{y}$$

or, equivalently,

$$J=\int_{x_0}^{x_1}\frac{\sqrt{1+(y')^2}}{y}\mathrm{d}x$$

(P_0 and P_1 denote two points of the ambient space where light propagates). First we prove the following proposition, which refers to the whole upper half plane U.

Proposition 1: (*i*) *Let J be the following functional*:

$$J = \int_{x_0}^{x_1} \frac{\sqrt{1 + (y')^2}}{y} \mathrm{d}x, \tag{3}$$

and let F denote the integrand of (3). *The Euler-Lagrange equation for this functional reads*

$$yy'' + y'^2 + 1 = 0. \tag{4}$$

(*ii*) *The extremals of functional* (3) *are Euclidean half-circles with centers on the x axis, or Euclidean straight lines normal to the x axis lying in the half plane* $y>0$. *These are the geodesics in the hyperbolic geometry realized in the half plane* $y>0$.

(*iii*) *The Weierstrass condition for the functional* (3) *reads*

$$F_{y'y'} = \frac{1}{y(1 + y'^2)^{3/2}} > 0 \quad (y > 0), \tag{5}$$

and it is satisfied for any y'.

(*iv*) *There exists a field of extremals of functional* (3), *and the transversality condition becomes an orthogonality condition of these extremals to the curve* $\Phi(x,y)=const$ (*constant phase curve*), *which satisfies the following equation* (*eikonal equation*):

$$g^{ij} \frac{\partial \Phi}{\partial x_i} \frac{\partial \Phi}{\partial x_j} = 1, \tag{6}$$

where $x_1=x$, $x_2=y$, *and* g_{ij} *is the metric tensor.*

Proof: The proof makes use of standard procedures and can be found, for instance, in Ref. 5.□

Remark: Let us recall once again that the domain of physical interest where the optical paths necessarily lie (in view of the fact that $n \geqslant 1$) is the strip $0<y\leqslant 1$; therefore we shall consider only a subclass of the extremals of functional (3): i.e., the half-circles with centers on the x axis and radius bounded by $0<R\leqslant 1$.

B. Poisson kernel and horocyclic waves

Let us now give a more precise formulation of the physical problem. Suppose that a pointlike source of light is pushed to $-\infty$ on the (x,y) plane. For the sake of simplicity, here we limit ourselves to the scalar representation of light, and phenomena associated with polarization will not be considered. From Proposition 1 it follows that light rays are half-circles with centers on the x axis. For several reasons which will appear clear in what follows, it is convenient to map conformally the half-plane $y>0$ into the unit disk $|\zeta|<1$, which amounts to pass from the Poincaré half-plane model U to the Poincaré disk model D (see the Appendix and Fig. 1). The appropriate conformal mapping is given by $\zeta=i(z-i)/(z+i)$ ($z=x+iy$; $\zeta=\xi+i\eta$).

In the unit disk the light source will be located at $\zeta=i$. The band $y>1$ will be mapped, in the ζ-plane, into the disk tangent to the boundary B of D in i with Euclidean radius $\frac{1}{2}$, and represents the *forbidden region* for the light rays. The circular arcs lying in the half-plane $y>0$ and normal to the x axis will be mapped, in the unit disk, into circular arcs perpendicular to the boundary $|\zeta|=1$, which are precisely the geodesics of the hyperbolic geometry in the unit disk model.

From the transversality condition [see statement (iv) of Proposition 1], it follows that the constant phase curve is the curve that intersects orthogonally the extremals of functional (3): i.e., the geodesics. In the unit disk, parallel geodesics are geodesics corresponding to the same point $b=e^{i\phi}$ on the boundary B of D. Therefore, in the physical problem being treated, the circles tangent to the unit circle at the point b, which intersects orthogonally the pencil of *parallel straight lines* (i.e., arcs of circle orthogonal to B) are the constant phase curves, they are a family of *horocycles*, and are denoted by H_b.

We can now state the following proposition.

Proposition 2: (*i*) *The Poisson kernel*

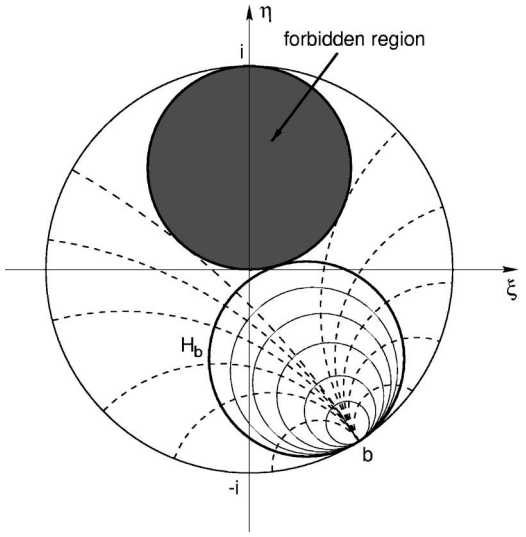

FIG. 1. Horocyclic flow outside the forbidden region in the Poincaré disk D.

$$P(\zeta,b)=\frac{1-|\zeta|^2}{1+|\zeta|^2-2|\zeta|\cos(\theta-\phi)} \quad (\zeta=|\zeta|e^{i\theta};b=e^{i\phi}), \tag{7}$$

is constant on each horocycle H_b with normal b.

(*ii*) *The function*

$$[P(\zeta,b)]^{\nu}=\left[\frac{1-|\zeta|^2}{1+|\zeta|^2-2|\zeta|\cos(\theta-\phi)}\right]^{\nu} \quad (\nu\in\mathbb{C}), \tag{8}$$

is an eigenfunction of the Laplace-Beltrami operator on the hyperbolic disk D corresponding to the eigenvalue $\nu(\nu-1)$.

(*iii*) *The hyperbolic waves* (*horocyclic waves*) *are represented by the following expression*:

$$e^{\nu\langle\zeta,b\rangle}=\left[\frac{1-|\zeta|^2}{1+|\zeta|^2-2|\zeta|\cos(\theta-\phi)}\right]^{\nu} \quad (\nu\in\mathbb{C}), \tag{9}$$

where $\langle\zeta,b\rangle$ is the hyperbolic distance between the origin of D and the horocycle of normal b passing through $\zeta\in D$.

(*iv*) *The conical functions $\mathcal{P}_{-1/2+i\lambda}(\cosh r)$* (*i.e., the first kind Legendre functions of index $\left(-\frac{1}{2}+i\lambda\right)$ $(\lambda\in\mathbb{R})$*) *can be represented by*

$$\mathcal{P}_{-\frac{1}{2}+i\lambda}(\cosh r)=\int_B e^{\left(\frac{1}{2}-i\lambda\right)\langle\zeta,b\rangle}\,db \quad (\lambda\in\mathbb{R},B=\{\zeta:|\zeta|=1\}), \tag{10}$$

and correspond to the fundamental series of the irreducible unitary representation of the group SU(1,1), *which acts transitively on the hyperbolic disk D.*

(*v*) *The following equality holds*:

$$\mathcal{P}_{-\frac{1}{2}+i\lambda}(\cosh r)=\mathcal{P}_{-\frac{1}{2}-i\lambda}(\cosh r) \quad (\lambda\in\mathbb{R}). \tag{11}$$

Proof: (i) The level lines of the Poisson kernel $P(\zeta,b)$ are the circles tangent to the unit circle at the point $b=e^{i\phi}$: i.e., the images of the horocycles H_b with normal b (see Ref. 9).

(ii) The Laplace-Beltrami operator Δ_D on the hyperbolic unit disk D is given by[10]

$$\Delta_D = \frac{1}{4}\left[1-(\xi^2+\eta^2)\right]^2\left(\frac{\partial^2}{\partial\xi^2}+\frac{\partial^2}{\partial\eta^2}\right). \tag{12}$$

If $\nu\in\mathbb{C}$ is any complex number, a direct computation gives[10]

$$\Delta_D P^\nu(\zeta,b) = \nu(\nu-1)P^\nu(\zeta,b). \tag{13}$$

(iii) In the Euclidean case the function $\mathbf{x}\to e^{ik(\mathbf{x},\boldsymbol{\omega})}$, where $k\in\mathbb{R}$, $\boldsymbol{\omega}\in\mathbb{S}^{(n-1)}$, $\mathbf{x}\in\mathbb{R}^n$, represents a plane wave with normal $\boldsymbol{\omega}$. It is indeed constant on each hyperplane perpendicular to $\boldsymbol{\omega}$, and furthermore is an eigenfunction of the Laplacian on $\mathbb{R}^n$. The geometric analog of the plane wave in the case of the hyperbolic disk D is the function represented by the equality (9) (see Ref. 11). In fact, it is an eigenfunction of the Laplace-Beltrami operator on D, as proved by statement (ii) [see Eq. (13)]. Further, setting $\theta=\phi$ in formulas (7) and (8), we have

$$\ln\frac{1-|\zeta|^2}{1+|\zeta|^2-2|\zeta|} = \ln\frac{1+|\zeta|}{1-|\zeta|} = d(0,\zeta) = \langle|\zeta|e^{i\phi},e^{i\phi}\rangle = \langle\zeta,b\rangle, \tag{14}$$

where $d(0,\zeta)=\ln[(1+|\zeta|)/(1-|\zeta|)]$ is the hyperbolic distance between the origin and the point $\zeta\in D$ (see the Appendix). Therefore, $\langle\zeta,b\rangle$ is the hyperbolic analog of $(\mathbf{x},\boldsymbol{\omega})$. In fact, in view of statement (i), $\langle\zeta,b\rangle$ is the distance between the origin and the horocycle of normal b passing through $\zeta\in D$, assuming that the origin falls outside the horocycle; $\langle\zeta,b\rangle$ is positive if the origin is external to the horocycle, while it is negative ($\langle\zeta,b\rangle=\ln[(1-|\zeta|)/(1+|\zeta|)]$) if the origin is internal to the horocycle.

(iv) If we set $\xi=\tanh(r/2)\cos\theta$, $\eta=\tanh(r/2)\sin\theta$, then $|\zeta|=\tanh(r/2)$. The Riemannian metric $\mathrm{d}s^2=4(\mathrm{d}\xi^2+\mathrm{d}\eta^2)/(1-\xi^2-\eta^2)^2$ becomes $\mathrm{d}s^2=\mathrm{d}r^2+\sinh^2 r\,\mathrm{d}\theta^2$. By the use of this substitution in the expression of the Poisson kernel (7) or (8), we have

$$\left[\frac{1-|\zeta|^2}{1+|\zeta|^2-2|\zeta|\cos(\theta-\phi)}\right]^\nu = \frac{1}{[\cosh r-\sinh r\cos(\theta-\phi)]^\nu} \quad (\nu\in\mathbb{C}), \tag{15}$$

and the integral sum of *horocyclic waves* [see statement (iii)] gives (see Ref. 11 and Proposition 6 in the Appendix):

$$\int_B e^{\nu\langle\zeta,b\rangle}\,\mathrm{d}b = \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{1}{\cosh r+\sinh r\cos\phi}\right)^\nu \mathrm{d}\phi = \mathcal{P}_{-\nu}(\cosh r) \quad (\nu\in\mathbb{C}), \tag{16}$$

where B is the boundary of the hyperbolic disk D, and $\mathcal{P}_{-\nu}(\cosh r)$ are the first kind Legendre functions.[12] Finally, setting $\nu=\frac{1}{2}-i\lambda$ ($\lambda\in\mathbb{R}$) we obtain the conical functions $\mathcal{P}_{-1/2+i\lambda}(\cosh r)$, which correspond to the fundamental series of the irreducible unitary representation of the group SU(1,1): i.e., the group of the matrices of the form[13] $\begin{pmatrix} a & c \\ \bar{c} & \bar{a}\end{pmatrix}$, $|a|^2-|c|^2=1$; $a,c\in\mathbb{C}$, which acts as a group of isometries of the hyperbolic disk D by means of the map

$$g(\zeta) = \frac{a\zeta+c}{\bar{c}\zeta+\bar{a}} \quad (\zeta\in D). \tag{17}$$

(v) Equality (11) is proved in the Appendix (see Proposition 6). □

Remark: It is well known that the classical Fourier transform refers to the decomposition of a function, belonging to an appropriate space, into exponentials of the form e^{ikx} (k real), which can also be viewed as the irreducible unitary representation of the additive group of real numbers. Analogously, the exponentials $e^{i(\mathbf{k},\mathbf{x})}$ are characters of the group $\mathbb{R}^2$. But the hyperbolic disk is not a group. Therefore a straightforward generalization of the exponential for D is not possible. Nevertheless, in view of the fact that the function $\mathcal{P}_{-\nu}(\cosh r)$ corresponds to the fundamental series of the irreducible unitary representation of the group SU(1,1) for $\nu=\frac{1}{2}-i\lambda$, the exponential

$e^{(1/2-i\lambda)\langle\zeta,b\rangle}$ $(\lambda \in \mathbb{R})$ represents the analog of the Euclidean exponential, and plays the same role in the hyperbolic Fourier analysis.[11]

C. Conservation of the flow

As already said in the Introduction, the ray trajectories are the lines orthogonal to the constant phase surface, and are described by the eikonal equation; moreover, $\langle\zeta,b\rangle$ is the hyperbolic distance between the origin and the horocycle H_b of normal b passing through ζ. Therefore, in close analogy with the Euclidean optical geometry, and recalling that $\mathcal{P}_{-1/2+i\lambda}(\cosh r) = \mathcal{P}_{-1/2-i\lambda}(\cosh r)$ $(\lambda \in \mathbb{R})$ [see statement (v) of Proposition 2], the expression of the analog of the Euclidean plane wave e^{ikx} $(k \in \mathbb{R})$ can be written as follows: $e^{(1/2-i\lambda)\langle\zeta,b\rangle}$ $(\lambda \in \mathbb{R})$. Thus the geometrical approximation of the wave function ψ can be obtained by multiplying $e^{(1/2-i\lambda)\langle\zeta,b\rangle}$times a function which represents the amplitude. Then we can state the following proposition.

Proposition 3: *The geometrical approximation of the wave function* ψ *reads*:

$$\psi(\zeta,\lambda,b) = A(\lambda)e^{\left(\frac{1}{2}-i\lambda\right)\langle\zeta,b\rangle} \quad (\lambda \in \mathbb{R}, \zeta \in D, b \in B), \tag{18}$$

and the flow in the entire strip $0 < y \leqslant 1$ *is conserved*.

Proof: Let σ be the conformal map

$$z = \sigma(\zeta) = -i\frac{\zeta+i}{\zeta-i}, \tag{19}$$

defined in the Appendix, that transfers the geometry of D into U. Since $\sigma(0)=i$ and $\sigma(i)=\infty$, then the image by σ of the horocycle H_i passing through $\zeta=0$ is the horizontal line $\widetilde{H}_\infty=\{x+iy : y=1\}$ in U (the horocycles in the Poincaré half-plane will be hereafter denoted by $\widetilde{H}_b$). The image by σ of the horocycle $H_{\sigma^{-1}(b)}$ tangent to H_i in D is the horocycle $\widetilde{H}_b$ of radius $1/2$ through $b \in \mathbb{R}$ and tangent to the horizontal line $\widetilde{H}_\infty$ (in order to avoid proliferation of notations, we denote by the same letter b both the points on the boundary B of D and the corresponding points belonging to the boundary of $\mathbb{H}^2$, i.e., belonging to $\mathbb{R}$).

We already saw that the horocycle $\widetilde{H}_b$ of normal b is perpendicular to each geodesic starting from b. To calculate the amplitude of the wave function, we must see how many geodesics perpendicular to $\widetilde{H}_b$ intersect $\widetilde{H}_b$, with the additional condition that these geodesics belong to the band $0 < y \leqslant 1$. This corresponds to find the amount of normal vectors at $\widetilde{H}_b$, with unit norm, that are tangent vectors of geodesics in the band $0 < y \leqslant 1$.

In general, if b is a point in $\mathbb{R}\cup\{\infty\}$ and T_1U is the unit tangent bundle of U, then the horocycle flow $h_{j,b}: T_1U \to T_1U$ is the flow which slides the inward normal vectors to each $\widetilde{H}_b$ to the right along $\widetilde{H}_b$ at unit speed. To find the equation of the flow $h_{j,b}$, first we consider the flow $h_{j,\infty}$ of geodesics perpendicular to the horocycle $\widetilde{H}_\infty$ of normal ∞. Then we choose a transformation M_b which maps the horocycle $\widetilde{H}_\infty$ into the horocycle $\widetilde{H}_b$. In particular, the map M_b transfers the flow $h_{j,\infty}$ into the flow $h_{j,b}$.

From the definition,

$$h_{j,\infty}(v_i) = \begin{pmatrix} 1 & j \\ 0 & 1 \end{pmatrix} v_i, \tag{20}$$

where v_i denotes the unit vector vertically upwards based at $i \in U$. This is because in the simplest case of horocycle flow $h_{j,\infty}$, the geodesics perpendicular to $\widetilde{H}_\infty$ are vertical lines and the isometry sending one vertical line into another vertical line is the horizontal translation. Therefore, the horocycle flow along $\widetilde{H}_\infty$ is simply the horizontal translation.

Let us now consider the transformation M_b such that $M_b(\infty)=b$. Then, the horocycle flow $h_{j,b}$ along $\widetilde{H}_b$ is the image of $h_{j,\infty}$ by M_b, hence

$$h_{j,b}(v) = M_b \begin{pmatrix} 1 & j \\ 0 & 1 \end{pmatrix} v. \tag{21}$$

It is clear from the definition that the amount of geodesics in the flow $h_{j,b}$ does not depend on the radius of the horocycle. Given two different points b_1 and b_2 in the boundary of the hyperbolic plane, then the composition of M_{b_1} and $M_{b_2}^{-1}$ sends the point b_2 in b_1. Moreover, $M_{b_1} \circ M_{b_2}^{-1}$ sends the horocycle flow h_{j,b_2} into the horocycle flow h_{j,b_1}. This proves that the amplitude of the wave does not depend on b and ζ.

Using Proposition 2, we obtain that there exists a function $A(\lambda)$ independent of ζ and b such that Eq. (18) is satisfied, and the conservation of the flow along the entire strip $0 < y \leqslant 1$ is proved. □

Remark: It is interesting to compare the propagation of light in vacuum with that within the strip $0 < y \leqslant 1$ belonging to $\mathbb{H}^2$. In vacuum each ray cuts orthogonally all the constant phase planes: i.e., each ray emerging from a plane cuts orthogonally all the other parallel planes. In $\mathbb{H}^2$ propagation proceeds in a completely different form. Take two horocycles lying in the strip $0 < y \leqslant 1$, and tangent at the point $z=(1+i)/2$: the first horocycle, denoted by $\widetilde{H}_0$, has normal $b_0 = 0$; the second one, denoted by $\widetilde{H}_1$, has normal $b_1 = 1$. Only one geodesic, denoted γ_t, lying in $\widetilde{H}_0$, cuts orthogonally $\widetilde{H}_1$; it emerges from $b_0=0$ and ends at $b_1=1$. All the geodesics $\gamma_>$, emerging from $b_0=0$ and lying in $\widetilde{H}_0$ above γ_t, cut orthogonally horocycles $\widetilde{H}_b$ with $b>1$; the geodesics $\gamma_<$, emerging from $b_0=0$ and lying in $\widetilde{H}_0$ below γ_t, cut orthogonally horocycles $\widetilde{H}_b$ with $b<1$. However, the density of the flow of geodesics entering orthogonally each horocycle equals the density of the flow of geodesics exiting orthogonally the same horocycle.

III. TRANSPORT EQUATION AND DISTRIBUTION OF THE DENSITY OF TRAJECTORIES

A. Transport equation in the Beltrami pseudosphere

Working out the problem in the space $\mathbb{H}^2$ allows us to describe each trajectory as a geodesic in the Poincaré plane (or disk), but this setting is not appropriate for describing the evolution of a bunch of trajectories. Hereafter we will switch to a representation more suitable for an effective characterization of the amplitude factor in the geometrical approximation of the field. To this aim, let us first recall the following well-known negative result due to Hilbert: there is no regular smooth isometric immersion $X: \mathbb{H}^2 \to \mathbb{R}^3$. However, one can look for a local immersion $X: \mathcal{U} \to \mathbb{R}^3$, where X is a continuous differentiable function, and $\mathcal{U} \subset \mathbb{H}^2$ is an open subset. We keep for $\mathcal{U}$ an open horocycle based at b. This local immersion can be realized by means of the Beltrami pseudosphere, denoted hereafter by P_b (see the Appendix and Fig. 2). In fact, let us consider in the hyperbolic disk D an infinite strip lying between two parallel straight lines emerging from the source point located on the absolute at $\zeta=-i$. Then we take on these parallel geodesics a pair of points A_0 and B_0, lying on a horocycle of normal $b_0=e^{-i\pi/2}=-i$ and cutting orthogonally these straight lines; A_0 and B_0 are spaced at distance of 2π. One is then led to consider the domain $(-i, A_0, B_0)$. The Beltrami surface cut along any of its generators can be isometrically mapped into the domain $(-i, A_0, B_0)$ (see Ref. 14). On a Lobachevskian plane there always exists reflection (i.e., a hyperbolic isometry) about an arbitrary straight line; in particular, reflecting the strip $(-i, A_0, B_0)$ about the straight line $(-i, A_0)$ we obtain a new strip isometric to the initial one and realized as a cut of the Beltrami surface in $\mathbb{R}^3$. Reflecting then this new strip $(-i, A_1, A_0)$ (the segment A_1A_0 has length 2π) about the straight line $(-i, A_1)$ we obtain the strip $(-i, A_2, A_1)$ with the same properties. Exactly the same procedure can be repeated on the other side of $(-i, A_0, B_0)$, leading to $(-i, B_2, B_1)$. We thus obtain strips of the form $(-i, A_k, A_{k-1})$ and $(-i, B_k, B_{k-1})$ $(1 \leqslant k < \infty)$; all segments (A_k, A_{k-1}) and (B_k, B_{k-1}) have the same length 2π. Working with the same procedure we can now construct the map of the open horocycle H_{b_0}, tangent at the boundary to the forbidden region (this latter represented by the horocycle H_i of normal i and passing through the origin), into a Beltrami funnel, such that each strip of the type $(-i, A_k, A_{k-1})$, $(-i, A_0, B_0)$, and $(-i, B_k, B_{k-1})$, $(1 \leqslant k < \infty)$ (referred, now, to the horocycle H_{b_0}), is mapped iso-

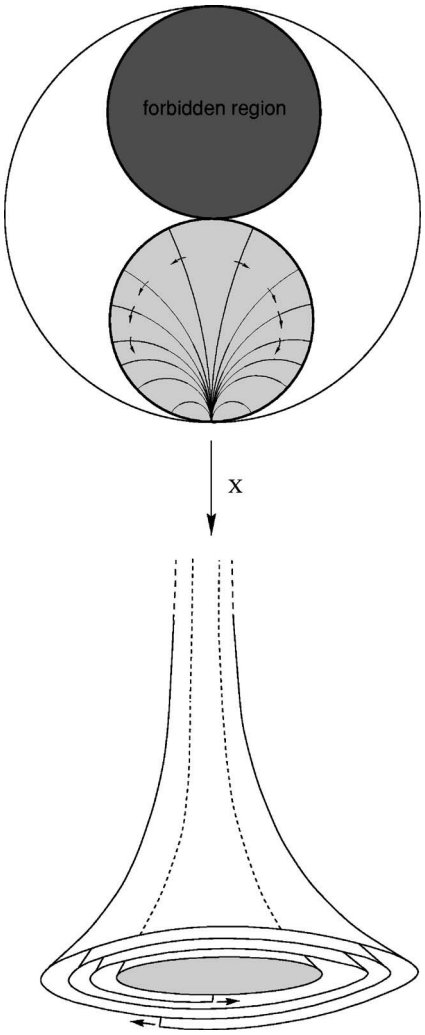

FIG. 2. Mapping of a horocycle in the disk D into a Beltrami pseudosphere.

metrically into the Beltrami surface, the horocycle H_{b_0} being wound infinitely many times into the Beltrami surface[14] (see Fig. 2). We can repeat the same procedure for each point $b \in B$, since there is a rotation (i.e., a hyperbolic isometry) sending each $b \in B$ onto b_0.

For an explicit equation of the immersion X, the reader is referred to Ref. 15.

In general, the Laplace-Beltrami operator Δ_M on a two-dimensional Riemannian manifold M with metric tensor g_{ij} ($g=|\det(g_{ij})|$, $g^{ij}=g_{ij}^{-1}$) is defined as follows:

$$\Delta_M = \frac{1}{\sqrt{g}}\left[\sum_{i=1}^{2}\frac{\partial}{\partial x_i}\left(\sum_{j=1}^{2} g^{ij}\sqrt{g}\frac{\partial}{\partial x_j}\right)\right]. \tag{22}$$

In the specific case of the hyperbolic metric associated with the refractive index $n(y)=1/y$ (see the Appendix), the Laplace-Beltrami operator reads

$$\Delta_{\mathrm{H}} = \frac{1}{n^2}\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right) = y^2\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right). \tag{23}$$

We then have the following proposition.

Proposition 4: (*i*) *The Helmholtz equation reads*

$$\Delta_{\mathbb{H}}\psi + k_{\mathbb{H}}^2\psi = 0, \tag{24}$$

where $k_{\mathbb{H}}^2 = \lambda^2 + \frac{1}{4}$ $(\lambda \in \mathbb{R})$.

(*ii*) *The geometrical approximation of the wave function* ψ (*for* $|\lambda| \to \infty$), *written in terms of the Beltrami coordinates* (*see the Appendix*), *reads*

$$\psi_{\pm}(\lambda, u) = C(\lambda) e^{u/2}\, e^{\mp i\lambda u} \quad (\lambda \in \mathbb{R}; u \geqslant 0). \tag{25}$$

Proof: (i) Let us consider the *horocyclic waves* which generate the conical functions $\mathcal{P}_{-1/2\pm i\lambda}(\cosh r)$, corresponding to the irreducible unitary representation of the SU(1,1) group, which acts transitively on the hyperbolic disk D. This amounts to put in the exponent $\nu \in \mathbb{C}$ of the Poisson kernel, $\nu = \frac{1}{2} \pm i\lambda$ $(\lambda \in \mathbb{R})$. Accordingly, the *horocyclic waves* read $e^{(1/2 \pm i\lambda)\langle \zeta, b\rangle}$ [see statements (iv) and (v) of Proposition 2]. From statement (ii) of Proposition 2 and Eq. (13) we get

$$\Delta_{\mathbb{H}} e^{\left(\frac{1}{2} \pm i\lambda\right)\langle \zeta, b\rangle} = -\left(\lambda^2 + \frac{1}{4}\right) e^{\left(\frac{1}{2} \pm i\lambda\right)\langle \zeta, b\rangle} = -k_{\mathbb{H}}^2 e^{\left(\frac{1}{2} \pm i\lambda\right)\langle \zeta, b\rangle}, \tag{26}$$

where $k_{\mathbb{H}}^2 = \lambda^2 + \frac{1}{4}$ $(\lambda \in \mathbb{R})$. Next, proceeding in close analogy with the Euclidean case, where the Euclidean plane wave plays the role of the *horocyclic wave*, we obtain Eq. (24).

(ii) Let us now go back to the mapping of the horocycle into the Beltrami funnel (without a cut) in $\mathbb{R}^3$, illustrated above. Next, we apply the Laplace-Beltrami operator to the wave function ψ, supposed to belong to $C^{\infty}(\mathcal{B})$ ($\mathcal{B}$ denoting the Beltrami pseudosphere); in (22) x_i $(i = 1, 2)$ stand for the Beltrami coordinates u, v. Recall that the first fundamental form in Beltrami coordinates reads [see part (C) of the Appendix]:

$$I = \mathrm{d}u^2 + e^{-2u}\, \mathrm{d}v^2 \quad (u \geqslant 0). \tag{27}$$

Accordingly, we have $g_{11} = 1$, $g_{22} = e^{-2u}$, $g_{12} = g_{21} = 0$, $g = |\det(g_{ij})| = e^{-2u}$, $g^{ij} = g_{ij}^{-1}$. Thus, we are led to the following equation:

$$\Delta_{\mathcal{B}}\psi + k_{\mathbb{H}}^2\psi = 0, \tag{28}$$

where $\Delta_{\mathcal{B}}$ is the Laplace-Beltrami operator, referred to the Beltrami pseudosphere. In this equation, we pass from the coordinates (ξ, η) of the hyperbolic disk D to the Beltrami coordinates (u, v) of the Beltrami pseudosphere. We illustrate with more details this passage. First we embed an open horocycle H_b of normal b and tangent to the *forbidden region* (represented by the horocycle H_i passing through the origin of D and with normal i; see Fig. 1) into a Beltrami pseudosphere. Notice that in the present analysis, as well as in Proposition 3, and in strict analogy with the classical Euclidean procedure, we consider the distance from the origin of the hyperbolic disk D (rather than from the point source located at $\zeta = i$) to the horocycle $H_{\zeta,b}$ (inside H_b) of normal b passing through a point ζ. Thus we have

$$\langle \zeta, b\rangle = d(0, H_b) + d(H_b, H_{\zeta,b}) := d_b + d(H_b, H_{\zeta,b}). \tag{29}$$

When we embed H_b into a Beltrami pseudosphere, the distance $d(H_b, H_{\zeta,b})$ between horocycles corresponds to the distance between different parallels $u = \text{const}$ inside the pseudosphere. Since H_b is fixed, then d_b is fixed too. Then, following the standard method of stationary phase, we look now for a solution of Eq. (28), of the following form:

$$\begin{aligned}\psi(\lambda, \mathbf{x}) &= \int A(\mathbf{x}, \ell\,) e^{\left(\frac{1}{2} - i\lambda\right)\langle \zeta, b\rangle}\, \mathrm{d}\ell\, = e^{\left(\frac{1}{2} - i\lambda\right)d_b} \int A(\mathbf{x}, \ell\,) e^{\left(\frac{1}{2} - i\lambda\right)d(H_b, H_{\zeta,b})}\, \mathrm{d}\ell \\ &= C(\lambda) \int A(\mathbf{x}, \ell\,) e^{\left(\frac{1}{2} - i\lambda\right)\Phi(\mathbf{x}, \ell)}\, \mathrm{d}\ell\,,\end{aligned} \tag{30}$$

where $\mathbf{x} = (x_1, x_2)$, $x_1 = u$, $x_2 = v$; ℓ is the pathlength inside the pseudosphere to the point of coordinate $\mathbf{x}$, $\Phi(\mathbf{x}, \ell\,)$ denotes the phase (recall the statements of Proposition 2).

The right-hand side (rhs) of equality (30) is an integral of oscillating type. The principal contribution to $\psi(\lambda,\mathbf{x})$, as $|\lambda|\to+\infty$, corresponds to the stationary point of Φ, in the neighborhood of which the exponential ceases to oscillate rapidly. These stationary points can be obtained from the equation $\partial\Phi/\partial\ell=0$ (provided that $\partial^2\Phi/\partial\ell^2\neq 0$). If the condition $\partial\Phi/\partial\ell=0$ is satisfied by a unique value ℓ_0 of ℓ, corresponding to the unique ray trajectory (geodesic) passing across the point of coordinates (u,v), we say that Φ has a critical nondegenerate point at $\ell=\ell_0$. Moreover, recalling that the manifolds with nonpositive curvature do not have conjugate points, we can state that all the critical points of Φ are nondegenerate. Then, by applying the Morse lemma on the representation of the functions all of whose critical points are nondegenerate, we obtain the following asymptotic evaluation of integral (30):

$$\psi(\lambda,\mathbf{x})=C(\lambda)e^{\frac{1}{2}\Phi(\mathbf{x},\ell_0)}e^{-i\lambda\Phi(\mathbf{x},\ell_0)}\sum_{m=0}^{\infty}\frac{A_m(\mathbf{x})}{(i\lambda)^m}. \tag{31}$$

The leading term of expansion (31) reads

$$\psi(\lambda,\mathbf{x})=C(\lambda)A_0(\mathbf{x})e^{\frac{1}{2}\Phi(\mathbf{x},\ell_0)}e^{-i\lambda\Phi(\mathbf{x},\ell_0)}, \tag{32}$$

where

$$A_0(\mathbf{x})=A(\mathbf{x},\ell_0)\left(\left|\frac{\partial^2\Phi}{\partial\ell^2}\right|^{-1/2}\right)_{\ell=\ell_0}\exp\left[i\,\frac{\pi}{4}\,\mathrm{sgn}\left(\frac{\partial^2\Phi}{\partial\ell^2}\right)\right]_{\ell=\ell_0}. \tag{33}$$

For simplicity, in the following we shall write the leading term of expansion (31) as $C(\lambda)A(\mathbf{x})e^{(1/2-i\lambda)\Phi(\mathbf{x})}$, dropping the zero subscripts. Substituting this expression into Eq. (28), collecting powers of $(i\lambda)$ and, finally, equating to zero their coefficients, two equations are obtained: the eikonal (or Hamilton-Jacobi) equation

$$g^{ij}\frac{\partial\Phi}{\partial x_i}\frac{\partial\Phi}{\partial x_j}=1, \tag{34}$$

and the transport equation

$$\frac{1}{\sqrt{g}}\sum_{i=1}^{2}\frac{\partial}{\partial x_i}\left[\sqrt{g}A^2e^{\Phi}\sum_{j=1}^{2}g^{ij}\frac{\partial\Phi}{\partial x_j}\right]=0. \tag{35}$$

Let us note that in the present problem the wave functions are radial, in view of the fact that we are considering a family of horocycles having all the same normal b. Therefore, $\psi(\lambda,\mathbf{x})$ [where $\mathbf{x}\equiv(u,v)$, u,v being the Beltrami coordinates, see the Appendix] does not depend on v. Then, Eq. (34) becomes

$$\left(\frac{\mathrm{d}\Phi}{\mathrm{d}u}\right)^2=1, \tag{36}$$

which gives the following expression of the phase: $\Phi^{(\pm)}=\pm u+c$ ($c=$const). Proceeding analogously with Eq. (35), we have

$$\frac{\mathrm{d}}{\mathrm{d}u}\left(A^2e^{\pm u}e^{-u}\frac{\mathrm{d}\Phi^{(\pm)}}{\mathrm{d}u}\right)=0. \tag{37}$$

Substituting in the leading term (32) the expressions of Φ and A, which derive from (36) and (37), the rhs of (25) follows. □

B. Sine-Gordon equation and the flow of trajectories

The analysis of propagation in the Beltrami pseudosphere has allowed us to study the distribution of the density of trajectories and, accordingly, the ray focusing along the horizontal axis. Another parameter, related once again to the Beltrami pseudosphere, and whose characterization is relevant in our description of the flow of trajectories, is the angle φ that the tangent to the meridian (in the Beltrami pseudosphere) makes with the z axis [see section (C) of the Appendix].

In the Appendix, the Beltrami pseudosphere is described in terms of the Beltrami coordinates u and v. Here we choose another parametrization (p,q) by setting

$$\mathrm{d}p = -\csc\varphi\,\mathrm{d}\varphi, \tag{38a}$$

$$\mathrm{d}q = -\mathrm{d}v. \tag{38b}$$

Integrating (38a), we obtain

$$\varphi = 2\tan^{-1}(e^{-p}), \tag{39}$$

and

$$\frac{\mathrm{d}\varphi}{\mathrm{d}p} = -\sin\varphi = \frac{1}{\cosh p}. \tag{40}$$

Next, substituting in formula (A31) of the Appendix (with $\rho=-1$) φ and v in terms of the parameters p and q, the position vector $\mathbf{r}$ of the pseudosphere can be rewritten as follows:

$$\mathbf{r}(p,q) = \begin{pmatrix} -\dfrac{1}{\cosh p}\cos q \\ \dfrac{1}{\cosh p}\sin q \\ p - \tanh p \end{pmatrix}, \tag{41}$$

where the downward vertex of the pseudosphere corresponds to $p\to-\infty$, while the rim corresponds to $p=0$. The parameters (p,q) can be related to the arc lengths (α,β) along asymptotic lines as follows:

$$p = \alpha + \beta,$$

$$q = \alpha - \beta. \tag{42}$$

Setting $\omega=2\varphi$, the first fundamental form reads

$$I = \mathrm{d}\alpha^2 + 2\cos\omega\,\mathrm{d}\alpha\,\mathrm{d}\beta + \mathrm{d}\beta^2, \tag{43}$$

which can be easily derived from the expression (A32) of the Appendix through the formulas (38a) and (42) (recalling that $\rho^2=1$). Moreover, from Gauss' and Weingarten's equations, it follows that ω, which is the angle between the asymptotic lines, satisfies the *classical* sine-Gordon equation, which reads

$$\frac{\partial^2\omega}{\partial\alpha\,\partial\beta} = \sin\omega. \tag{44}$$

This latter equation rewritten in terms of the coordinates p,q becomes

$$\frac{\partial^2\varphi}{\partial p^2} - \frac{\partial^2\varphi}{\partial q^2} = \sin\varphi\cos\varphi. \tag{45}$$

We can finally state the following proposition.

Proposition 5: (*i*) *The angle* φ, *that the tangent to the meridian of the pseudosphere makes with the z axis* (*i.e.*, *the rotation axis*), *is represented by the following formula*:

$$\varphi = 2\tan^{-1}(e^{-p}), \tag{46}$$

which is the so-called "*one-soliton*" *solution of the sine-Gordon equation* (45).

(*ii*) *The angle* φ *varies from* $\varphi=\pi/2$ *to* $\varphi=\pi$ *in the process of focusing*, *and from* $\varphi=\pi$ *to* $\varphi=\pi/2$ *in the process of defocusing*.

Proof: (i) The proof of this statement follows easily by direct calculation.

(ii) The downward vertical z axis of the pseudosphere we are considering is negatively oriented; then varying p from 0 to $-\infty$ [in Eq. (46)], φ varies from $\varphi=\pi/2$ to $\varphi=\pi$ (focusing). Next varying p from $-\infty$ to 0, φ varies from $\varphi=\pi$ to $\varphi=\pi/2$ (defocusing). □

So far in this section we have considered a local description of the flow in order to show that the density of the flow is not homogeneously distributed. We now want to recover a global description in the entire strip $0<y\leqslant 1$. But we have already remarked that the map of a horocycle into a pseudosphere excludes the boundary of the horocycle. Therefore this global description cannot be reached by considering only horocycles lying in the strip $0<y\leqslant 1$ and tangent to the line $y=1$. Recall, however, that while the *physical* geodesics, which lie within the strip $0<y\leqslant 1$ in $\mathbb{H}^2$, cannot enter the forbidden region $y>1$, this is not the case for horocycles, provided we limit ourselves to consider in these horocycles (i.e., those entering the forbidden region) those segments of geodesics which lie in the strip $0<y\leqslant 1$. In view of these considerations it is sufficient to consider horocycles $\widetilde{H}'_b \supset \widetilde{H}_b$ ($\widetilde{H}'_b$ entering the forbidden region), and, accordingly, the maps X'_b embedding $\widetilde{H}'_b$ into a Beltrami pseudosphere P'_b. We can thus obtain a sequence of Beltrami pseudospheres P'_b which, by varying b, allows us to connect in $\mathbb{R}^3$ the geodesics lying in the strip $0<y\leqslant 1$. We thus pass from a local to a global description.

IV. CONCLUSIONS AND DISCUSSION

In this paper we have presented the geometrical optics generated by a refractive index of hyperbolic type. The ray trajectories are geodesics in the Poincaré-Lobachevsky half-plane, and the horocyclic waves, which are related to the Poisson kernel, represent the analogs of the Euclidean plane waves. We thus obtain two main results.

(a) The flow in the entire strip $0<y\leqslant 1$ is conserved (see Proposition 3);
(b) inside each horocycle (by embedding horocycles in Beltrami pseudospheres) the ray focusing on each point b of the horizontal x axis: i.e., toward the boundary of $\mathbb{H}^2$, is shown.

The connection between hyperbolic geometry and optics of spatially nonuniform media can be made even tighter. In fact, it can be shown that the transfer matrix associated with lossless layered optical media is an element of the group SU(1,1), no matter how complicated the stepwise profile of the refractive index might be.[16–18] Therefore, the action of any lossless optical multilayer can be regarded as a Möbius transformation on the unit disk,[16] and therefore the natural geometric environment for these physical systems is the hyperbolic one. From this point of view, the geometrical optics description of light propagation in the "hyperbolic glass" discussed so far can be regarded as the study (in a spatially continuum setting) of the particular case of special interest, in which only motions along hyperbolic geodesics are allowed.

APPENDIX

(A) Let us consider the upper half-plane model of the hyperbolic two-dimensional space $U=\{z=x+iy : y>0\}$. Then the boundary ∂U of U is the real axis and infinity. On U we can define a

metric d derived from the differential $ds=|dz|/\Im z$ where dz is the standard Euclidean metric. The geodesics of U are vertical half-lines and Euclidean semicircles with center on the real axis. The group of the orientation preserving isometries of (U,d) is the Möbius group $\mathrm{PSL}_2(\mathbb{R})$, that is the group of the 2×2 matrices of real coefficients with determinant 1. The action on $U\cup\partial U$ is defined as $\gamma(z)=(az+b)/(cz+d)$, where $\begin{pmatrix} a & b \\ c & d \end{pmatrix}\in \mathrm{PSL}_2(\mathbb{R})$.

Another model of the hyperbolic two-dimensional space is the Poincaré disk $D=\{\zeta=\xi+i\eta:\xi^2+\eta^2<1\}$. The map

$$\zeta = i\frac{z-i}{z+i} \tag{A1}$$

{with inverse $z=-i[(\zeta+i)/(\zeta-i)]$} transfers the geometry of U into the geometry of D. In particular, the metric on D is given by the differential

$$d\zeta = \frac{2}{1-|\zeta|^2}d_E\zeta, \tag{A2}$$

where d_E is the standard Euclidean metric. In this model, the geodesics are circular arcs perpendicular to the boundary $|\zeta|=1$. Moreover, the group of the orientation preserving isometries of the Poincaré disk D is the group $\mathrm{SU}(1,1)$ of the maps of the following form:

$$\left\{\frac{a\zeta+\bar{c}}{c\zeta+\bar{a}}:|a|^2-|c|^2=1\right\}. \tag{A3}$$

(B) The group $G=\mathrm{SU}(1,1)$ admits two subgroups relevant for our analysis:

(1) The subgroup K of rotations

$$k_\theta=\begin{pmatrix} e^{i\frac{\theta}{2}} & 0 \\ 0 & e^{-i\frac{\theta}{2}} \end{pmatrix},$$

with $0\leqslant\theta<4\pi$.

(2) The subgroup A of matrices

$$a_r=\begin{pmatrix} \cosh\frac{r}{2} & \sinh\frac{r}{2} \\ \sinh\frac{r}{2} & \cosh\frac{r}{2} \end{pmatrix},$$

with $r\in\mathbb{R}$.

Let A^+ denote the set a_r with $r\geqslant 0$. Then the following decomposition holds.

Cartan decomposition:[10] Any element $g\in G$ can be decomposed as follows:

$$g=k_\theta a_r k_\phi \quad (r\geqslant 0, 0\leqslant\theta<4\pi, 0\leqslant\phi<2\pi), \tag{A4}$$

i.e., $G=KA^+K$. The decomposition is unique if $g\notin K$.

We now introduce the so-called *spherical functions* $\Phi_\nu(g)$ on G/K $[g\in G=\mathrm{SU}(1,1), \nu\in\mathbb{C}]$, which are defined as follows.[19]

Definition 1: *The spherical functions on* G/K $[G=\mathrm{SU}(1,1), K=\mathrm{SO}(2)]$ *are defined as follows*:

$$\Phi_\nu(g)=\int_B \left|\frac{d(g^{-1}\cdot b)}{db}\right|^\nu db \quad [g\in \mathrm{SU}(1,1), \nu\in\mathbb{C}], \tag{A5}$$

where B *is the boundary of the hyperbolic disk* D (*i.e.*, $B=\{\zeta:|\zeta|=1\}$).

We can then prove the following proposition.

Proposition 6: *The functions* $\Phi_\nu(g)$ *satisfy the following properties*:

(i)

$$\Phi_\nu(g) = \mathcal{P}_{-\nu}(\cosh r), \quad [g \in \mathrm{SU}(1,1), \nu \in \mathbb{C}], \tag{A6}$$

where $\mathcal{P}_{-\nu}(\cdot)$ *are the first kind Legendre functions*.

(ii)

$$\Delta_D \Phi_\nu(g) = \nu(\nu-1)\Phi_\nu(g), \quad [g \in \mathrm{SU}(1,1), \nu \in \mathbb{C}], \tag{A7}$$

where Δ_D *is the hyperbolic Laplace-Beltrami operator*.

(iii)

$$\mathcal{P}_{-\frac{1}{2}+i\lambda}(\cosh r) = \mathcal{P}_{-\frac{1}{2}-i\lambda}(\cosh r) \quad (\lambda \in \mathbb{R}). \tag{A8}$$

Proof: Let us consider the following integral $(1/2\pi)\int_0^{2\pi} f(e^{i\phi})\mathrm{d}\phi$ $[f \in L^1(B)]$, and evaluate how the Lebesgue measure $(1/2\pi)\mathrm{d}\phi$ changes when an element $g \in \mathrm{SU}(1,1)$ acts on B (boundary of D). Recalling that the action of g is $g\cdot\zeta = (a\zeta + c)/(\bar{c}\zeta + \bar{a})$ $(\zeta \in D)$ (see Proposition 2), we have $g \cdot e^{i\phi} = e^{i\chi} = (ae^{i\phi} + c)/(\bar{c}e^{i\phi} + \bar{a})$. We thus have[19]

$$\left|\frac{\mathrm{d}\phi}{\mathrm{d}\chi}\right| = |\bar{c}e^{i\chi} - a|^{-2} = |a|^{-2}\left|\frac{\bar{c}}{a}e^{i\chi} - 1\right|^{-2} = \left(1 - \frac{|c|^2}{|a|^2}\right)\left|\frac{\bar{c}}{a}e^{i\chi} - 1\right|^{-2}, \tag{A9}$$

since $|a|^2 - |c|^2 = 1$. Let us now note that $g\cdot 0 = c/\bar{a}$; on the other hand, in view of the Cartan decomposition, we have

$$g \cdot 0 = k_\theta a_r \cdot 0 = e^{i\theta}\tanh\left(\frac{r}{2}\right) = |\zeta| e^{i\theta}. \tag{A10}$$

Therefore $(1 - |c|^2/|a|^2) = 1 - |\zeta|^2$, and

$$\left|\frac{\bar{c}}{a}e^{i\chi} - 1\right|^{-2} = \frac{1}{|1 - |\zeta| e^{i(\chi-\theta)}|^2} = \frac{1}{1 + |\zeta|^2 - 2|\zeta|\cos(\chi - \theta)}. \tag{A11}$$

We thus have

$$\frac{1}{2\pi}\int_0^{2\pi} f(g \cdot e^{i\phi})\mathrm{d}\phi = \frac{1}{2\pi}\int_0^{2\pi} f(e^{i\chi})\left|\frac{\mathrm{d}\phi}{\mathrm{d}\chi}\right|\mathrm{d}\chi, \tag{A12}$$

and, in view of formulas (A9), (A10), (A11), (A12), we get

$$P(g\cdot 0, b) = \frac{1 - |\zeta|^2}{1 + |\zeta|^2 - 2|\zeta|\cos(\chi - \theta)} = \left|\frac{\mathrm{d}(g^{-1}\cdot b)}{\mathrm{d}b}\right|. \tag{A13}$$

Recalling Definition 1 we can write

$$\Phi_\nu(g) = \int_B \left|\frac{\mathrm{d}(g^{-1}\cdot b)}{\mathrm{d}b}\right|^\nu \mathrm{d}b = \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{1 - |\zeta|^2}{1 + |\zeta|^2 - 2|\zeta|\cos\phi}\right)^\nu \mathrm{d}\phi. \tag{A14}$$

Finally, writing $\tanh(r/2)$ in place of $|\zeta|$ [see formula (A10)], we obtain

$$\Phi_\nu(g) = \frac{1}{2\pi}\int_0^{2\pi}\frac{1}{(\cosh r + \sinh r\cos\phi)^\nu}\mathrm{d}\phi = \mathcal{P}_{-\nu}(\cosh r), \tag{A15}$$

where the last equality follows from the integral representation of the first kind Legendre functions.[12] Formula (A15) proves statement (i).

From formula (A15) it follows that the spherical functions $\Phi_\nu(g)$ are bi-k-invariant; indeed, using the Cartan decomposition, we have

$$\Phi_\nu(g) = \Phi_\nu(k_\theta a_r k_\phi) = \Phi_\nu(a_r) = \mathcal{P}_{-\nu}(\cosh r). \tag{A16}$$

Furthermore, we can prove that [see formulas (A13) and (A14)]

$$\Phi_\nu(E) = \int_B [P(E\cdot 0,b)]^\nu \, \mathrm{d}b = 1 = \mathcal{P}_{-\nu}(1). \tag{A17}$$

Let us now return to statement (ii) of Proposition 2, and recall that $P^\nu(\zeta,b)$ is an eigenfunction of the hyperbolic Laplace-Beltrami operator with eigenvalue $\nu(\nu-1)$. We then consider an integral of the following form:

$$\int_B [P(g\cdot 0,b)]^\nu \, \mathrm{d}b = \Phi_\nu(g). \tag{A18}$$

It can be proved that this integral superposition is still an eigenfunction of the hyperbolic Laplace-Beltrami operator Δ_D, having $\nu(\nu-1)$ as eigenvalue.[19] In particular, it follows that $\Phi_\nu(g)$ and $\Phi_{1-\nu}(g)$ $[g \in \mathrm{SU}(1,1)]$ are both eigenfunctions of Δ_D with the same eigenvalue, and therefore they coincide. We can thus state that $\mathcal{P}_{-1/2+i\lambda}(\cosh r) = \mathcal{P}_{-1/2-i\lambda}(\cosh r)$; statements (ii) and (iii) are thus proved.

Finally, from the representation of the Poisson kernel in terms of *horocyclic waves*, we have

$$\begin{aligned}\mathcal{P}_{-\frac{1}{2}+i\lambda}(\cosh r) &= \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{1}{\cosh r + \sinh r\cos\phi}\right)^{1/2-i\lambda}\mathrm{d}\phi \\ &= \frac{1}{2\pi}\int_0^{2\pi}\left(\frac{1-|\zeta|^2}{1+|\zeta|^2-2|\zeta|\cos\phi}\right)^{1/2-i\lambda}\mathrm{d}\phi = \int_B e^{\left(\frac{1}{2}-i\lambda\right)\langle\zeta,b\rangle}\,\mathrm{d}b \quad (\lambda\in\mathbb{R},\zeta\in D).\end{aligned} \tag{A19}$$

□

(C) In Sec. III, we have seen that it is possible to have a local isometric immersion from an horocycle to $\mathbb{R}^3$. The image of this immersion is a Beltrami pseudosphere. Now, we describe in more details the equation of the pseudosphere and its coordinates.

First, we want to recover the pseudosphere as a surface of revolution of a curve in $\mathbb{R}^3$. Let us recall that, in general, the position vector $\mathbf{r}$ of the surface of revolution generated by the rotation of a plane curve $z=\Phi(r)$ about the z axis is given by

$$\mathbf{r} = \begin{pmatrix} r\cos v \\ r\sin v \\ \Phi(r)\end{pmatrix}, \tag{A20}$$

where v varies between 0 and 2π. Here the circles $r=$const are the parallels and the curves $v=$const are the meridians. The first fundamental form associated with the surface (A20) is given by

$$I = \{1+[\Phi'(r)]^2\}\mathrm{d}r^2 + r^2\,\mathrm{d}v^2. \tag{A21}$$

We now rewrite the form (A21) as follows:

$$I = \mathrm{d}u^2 + r^2\,\mathrm{d}v^2, \tag{A22}$$

where

$$du = \sqrt{1 + [\Phi'(r)]^2}\,dr, \quad r = r(u). \tag{A23}$$

From the general Gauss' theory of surfaces, we have that the total curvature is given by[20]

$$K = -\frac{1}{r}\frac{d^2 r}{du^2}, \tag{A24}$$

whence the general pseudospherical surface of revolution with $K=-1/\rho^2$ adopts the form[20]

$$r(u) = c_1 \cosh\frac{u}{\rho} + c_2 \sinh\frac{u}{\rho}. \tag{A25}$$

In the case $c_1=c_2=c$, which corresponds to a parabolic pseudospherical surface of revolution, the meridians are given by

$$r(u) = ce^{u/\rho}, \tag{A26}$$

while

$$z = \Phi(r) = \int \sqrt{1 - \left(\frac{c}{\rho}\right)^2 e^{2u/\rho}}\,du. \tag{A27}$$

Then, the first fundamental form, with $c=1$, has the following expression:

$$I = du^2 + e^{2u/\rho}\,dv^2. \tag{A28}$$

The coordinates u,v are called *Beltrami coordinates*.

The substitution

$$\sin\varphi = \frac{c}{\rho}e^{u/\rho} \tag{A29}$$

in (A27) yields

$$z = \rho\left(\cos\varphi + \ln\left|\tan\frac{\varphi}{2}\right|\right). \tag{A30}$$

From formulas (A20), (A26), (A29), and (A30) we obtain

$$\mathbf{r} = \begin{pmatrix} \rho\sin\varphi\cos v \\ \rho\sin\varphi\sin v \\ \rho\left(\cos\varphi + \ln\left|\tan\frac{\varphi}{2}\right|\right) \end{pmatrix}, \tag{A31}$$

and the first fundamental form (in terms of φ and v) is

$$I = \rho^2\cot^2\varphi\,d\varphi^2 + \rho^2\sin^2\varphi\,dv^2. \tag{A32}$$

Equation (A31) is the parametric form of the parabolic pseudosphere, seen as surface of revolution about the z axis of the curve called *tractrix*, which satisfies the following property: the length of the tangent from the point where it touches the curve to the point where it intersects the z axis is constant and equal to $|\rho|$; φ is the angle that the tangent to the meridian makes with the z axis. The angle φ varies between 0 and π so that, keeping $\rho=1$, the related parabolic pseudosphere has vertices at $z=+\infty$ (corresponding to $\varphi=\pi$) and at $z=-\infty$ (corresponding to $\varphi=0$) and rim at $z=0$ (corresponding to $\varphi=\pi/2$). The curve is continuous and regular except at the point $z=0$, which is a cusp point. Choosing $\rho=-1$ and varying φ from 0 to π, we shall have the upward vertical z axis positively oriented (φ varying from 0 to $\pi/2$), and the downward vertical z axis negatively oriented (φ varying from $\pi/2$ to π). In accordance with the Hilbert's theorem, for

which it is impossible to embed the entire hyperbolic disk onto $\mathbb{R}^3$, and since we want the immersion from the horocycle to the pseudosphere to be regular, then the image must be contained either in the downward component or in the upward component of the pseudosphere; thus it does not contain the cuspidal rim. Accordingly, taking $\rho=-1$ once and for all, the first form, written in Beltrami coordinates, reads

$$I = \mathrm{d}u^2 + (e^{-u}\,\mathrm{d}v)^2 \quad (u \geqslant 0), \tag{A33}$$

and the tractrix is

$$\begin{aligned} x &= -\sin\varphi, \\ z &= -\left(\cos\varphi + \ln\left|\tan\frac{\varphi}{2}\right|\right). \end{aligned} \tag{A34}$$

Then, in Sec. III A we use the form (A33) with $u \geqslant 0$, varying φ from $\pi/2$ to 0 and, accordingly, $z \geqslant 0$ (see Fig. 2). In Sec. III B, where the coordinate u does not enter the game and we have chosen the coordinates p and q, it is convenient to vary φ from $\pi/2$ to π and, in accordance, taking the downward vertical axis negatively oriented, i.e., $z \leqslant 0$.

(Received 24 October 2005; accepted 19 December 2005;
published online 22 February 2006)

The necessary conditions are derived for existence of a bi-Hamiltonian structure for a given hydrodynamic type system. One of the conditions is the vanishing of its Haantjes tensor. A theorem is proved on the canonical forms of the generic bi-Hamiltonian systems. The Schouten (2,1)-tensor S_i^{jk} is connected with any Hamiltonian system of hydrodynamic type. The complete symmetry of the (3,0)-tensor S^{ijk} is demonstrated. The necessary conditions for existence of a single nondegenerate Hamiltonian structure are obtained in terms of the special differential k-forms $\Omega_{p_1\cdots p_k}(u_1,\ldots,u_k)$. © *2006 American Institute of Physics.*
[DOI: 10.1063/1.2167920]

I. INTRODUCTION

We present new applications of the Schouten (2,1)-tensor S_i^{jk} (Ref. 1) that exists for any (2,0)-tensor g^{ij} and any (1,1)-tensor A_k^j satisfying the equation

$$g^{i\alpha}A_\alpha^j = A_\alpha^i g^{\alpha j}. \tag{1.1}$$

Equation (1.1) naturally arises in the theory of bi-Hamiltonian dynamical systems[2–8]

$$\dot{x}^i = P_1^{i\alpha}\frac{\partial H_1(x)}{\partial x^\alpha} = P_2^{i\alpha}\frac{\partial H_2(x)}{\partial x^\alpha} \tag{1.2}$$

and in the theory of Hamiltonian systems of hydrodynamic type[9–11]

$$\frac{\partial u^i}{\partial t} = \sum_{j=1}^{n} A_j^i(u^1,\ldots,u^n)\frac{\partial u^j}{\partial x}. \tag{1.3}$$

For systems (1.3), $u^i = u^i(t,x)$ are unknown functions and $A_j^i(u)$ form a (1,1)-tensor on a manifold M^n with charts of local coordinates $u^1,\ldots,u^n$.

For a bi-Hamiltonian dynamical system (1.2), the (2,0)-tensor g^{ij} is one of the Poisson structures P_1^{ij} or P_2^{ij} and the (1,1)-tensor A_k^j is the recursion operator $A_k^j = P_1^{j\alpha}(P_2^{-1})_{\alpha k}$ provided that the Poisson structure P_2^{ij} is nondegenerate.

For the Hamiltonian systems (1.3) with a local or nonlocal structure of Poisson brackets, the (1,1)-tensor $A_j^i(u)$ is given by the formula

$$A_j^i(u) = g^{i\alpha}(u)\frac{\partial^2 f(u)}{\partial u^\alpha\,\partial u^j} + b_j^{i\alpha}(u)\frac{\partial f(u)}{\partial u^\alpha} + Kf(u)\delta^i_j, \tag{1.4}$$

where symmetric (2,0)-tensor $g^{ij}(u)$ and coefficients $b_j^{ik}(u)$ are connected by certain nonlinear equations that follow from the Jacobi identity;[9–11] $f(u)$ is the density of the Hamiltonian functional. Equation (1.1) holds for all Hamiltonian system (1.3) and (1.4) and thus allows to relate with them the Schouten (2,1)-tensor S_i^{jk}.[12]

In the paper, we show that for any Hamiltonian system (1.3) and (1.4) the corresponding Schouten (3,0)-tensor $S^{ijk}=g^{i\alpha}S^{jk}_{\alpha}$ is completely symmetric, even when the (2,0)-tensor g^{jk} is degenerate and the Hamiltonian structure is nonlocal, $K\neq 0$. In Ref. 12, we proved the symmetry of S^{ijk} for some special cases. The symmetry implies certain algebraic identities for the Nijenhuis and Haantjes tensors of the (1,1)-tensor $A^i_j(u)$.

We derive necessary conditions for existence of bi-Hamiltonian structures (1.4) having two different (2,0)-tensors g_1^{jk} and g_2^{jk}. Since the tensors $g_1^{ij}(u)$ and $g_2^{ij}(u)$ are not given *a priori*, the necessary conditions are formulated for the (1,1)-tensor $A^i_j(u)$ only, namely in terms of its Nijenhuis and Haantjes tensors[13,14] and in terms of the special differential k-forms $\Omega_{p_1\cdots p_k}(u_1,\ldots,u_k)$ introduced in this paper.

For the bi-Hamiltonian systems (1.3) and (1.4) with nondegenerate (2,0)-tensor g_2^{jk} and the (1,1)-tensor $B^i_j=g_1^{i\alpha}(g_2^{-1})_{\alpha j}$ having distinct eigenvalues we prove that the Haantjes (1,2)-tensor H^i_{jk} necessarily vanishes. For hyperbolic systems (1.3) with real and distinct eigenvalues of the (1,1)-tensor $A^i_j(u)$, this implies the existence of Riemann invariants for the system (1.3) and (1.4) and hence its integrability by the generalized hodograph transform.[15] For the generic bi-Hamiltonian systems with complex eigenvalues of $A^i_j(u)$, we prove a theorem on their canonical forms.

II. SCHOUTEN TENSORS FOR BI-HAMILTONIAN SYSTEMS

For any (1,1)-tensor A^i_k and the (2,0)-tensor g^{jk} on the manifold M^n satisfying Eq. (1.1), Schouten introduced the (2,1)-tensor,

$$S^{jk}_i=A^{\alpha}_i\frac{\partial g^{jk}}{\partial x^{\alpha}}-g^{j\alpha}\frac{\partial A^k_i}{\partial x^{\alpha}}-g^{\alpha k}\frac{\partial A^j_i}{\partial x^{\alpha}}+g^{j\alpha}\frac{\partial A^k_{\alpha}}{\partial x^i}-A^j_{\alpha}\frac{\partial g^{\alpha k}}{\partial x^i}. \tag{2.1}$$

In Ref. 12, we show that the Schouten tensor has the following invariant meaning: for any vector field $u(x)=u^i(x)$ on the manifold M^n the (2,0)-tensor $(S_u)^{jk}=S^{jk}_i u^i$ has the form

$$S_u=L_{Au}g-AL_ug+gL_uA, \tag{2.2}$$

where L_u is the Lie derivative operator with respect to the vector field $u(x)$.

Suppose a system (1.3) has two Hamiltonian structures (1.4) with two different (2,0)-tensors g_1^{jk} and g_2^{jk}. Then two equations (1.1) hold,

$$g_1^{i\alpha}A^j_{\alpha}=A^i_{\alpha}g_1^{\alpha j},\quad g_2^{i\alpha}A^j_{\alpha}=A^i_{\alpha}g_2^{\alpha j}. \tag{2.3}$$

Hence for any parameter λ we have

$$g_{\lambda}^{i\alpha}A^j_{\alpha}=A^i_{\alpha}g_{\lambda}^{\alpha j}, \tag{2.4}$$

where $g_{\lambda}=\lambda g_1+g_2$. Suppose that for some λ the (2,0)-tensor g_{λ} is nondegenerate and define the (1,1)-tensor $B^i_{\lambda j}=g_1^{i\alpha}(g_{\lambda}^{-1})_{\alpha j}$. As is known, Eqs. (2.3) and (2.4) imply that the operators A^i_j and $B^j_{\lambda k}$ commute,

$$AB_{\lambda}=B_{\lambda}A. \tag{2.5}$$

Evidently we have $g_1=B_{\lambda}g_{\lambda}$. Hence for the corresponding Schouten tensor S_{1u} (2.2) we get

$$S_{1u}=L_{Au}(B_{\lambda}g_{\lambda})-AL_u(B_{\lambda}g_{\lambda})+B_{\lambda}g_{\lambda}L_uA.$$

Applying the Leibniz formula and Eq. (2.5), we find

$$S_{1u}=B_{\lambda}(L_{Au}g_{\lambda}-AL_ug_{\lambda}+g_{\lambda}L_uA)+(L_{Au}B_{\lambda}-AL_uB_{\lambda})g_{\lambda}. \tag{2.6}$$

The first parentheses here evidently is the Schouten tensor

$$S_{\lambda u} = L_{Au} g_\lambda - A L_u g_\lambda + g_\lambda L_u A = \lambda S_{1u} + S_{2u}.$$

The second parentheses for the two commuting operators A and B_λ is the Nijenhuis tensor.[13] Indeed, for any two vector fields U and V and (1,1)-tensor A we have $(L_U A)V = [U, AV] - A[U, V]$. Hence we have

$$(L_{Au} B_\lambda - A L_u B_\lambda)v = [Au, B_\lambda v] - B_\lambda [Au, v] - A[u, B_\lambda v] + A B_\lambda [u, v], \tag{2.7}$$

$$(L_{B_\lambda v} A - B_\lambda L_v A)u = [B_\lambda v, Au] - A[B_\lambda v, u] - B_\lambda [v, Au] + B_\lambda A[v, u]. \tag{2.8}$$

Formula (2.7) does not depend on a smooth continuation of vector v, and formula (2.8) does not depend on a continuation of vector u. Since $AB_\lambda = B_\lambda A$, these formulas differ only by sign. Therefore $\widetilde{N}_{\lambda u} = L_{Au} B_\lambda - A L_u B_\lambda$ is a tensor; its components are

$$\widetilde{N}^i_{\lambda jk} = A^\alpha_j \frac{\partial B^i_{\lambda k}}{\partial x^\alpha} - B^\alpha_{\lambda k} \frac{\partial A^i_j}{\partial x^\alpha} + B^i_{\lambda \alpha} \frac{\partial A^\alpha_j}{\partial x^k} - A^i_\alpha \frac{\partial B^\alpha_{\lambda k}}{\partial x^j}. \tag{2.9}$$

Thus Eq. (2.6) has the form

$$S^{jk}_{1i} = B^j_{\lambda \alpha} S^{\alpha k}_{\lambda i} + \widetilde{N}^j_{\lambda i \alpha} g^{\alpha k}_\lambda,$$

that gives the following relation between the two Schouten tensors:

$$S^{jk}_{1i} = B^j_{\lambda \alpha} (\lambda S^{\alpha k}_{1i} + S^{\alpha k}_{2i}) + \widetilde{N}^j_{\lambda i \alpha} (\lambda g^{\alpha k}_1 + g^{\alpha k}_2). \tag{2.10}$$

Equation (2.10) depends on an arbitrary parameter λ.

III. SHOUTEN TENSOR S^{ijk} FOR ANY HAMILTONIAN SYSTEM (1.3) IS COMPLETELY SYMMETRIC

(i) It is evident that the Schouten tensor (2.1) has also the form

$$S^{jk}_i = A^\alpha_i \frac{\partial g^{jk}}{\partial x^\alpha} - \frac{\partial (A^k_\alpha g^{j\alpha})}{\partial x^i} + g^{j\alpha} \left(\frac{\partial A^k_\alpha}{\partial x^i} - \frac{\partial A^k_i}{\partial x^\alpha} \right) + \left(\frac{\partial A^j_\alpha}{\partial x^i} - \frac{\partial A^j_i}{\partial x^\alpha} \right) g^{\alpha k}. \tag{3.1}$$

Therefore for any symmetric (2,0)-tensor g^{ij} the Schouten tensor (3.1) has the following symmetry:

$$S^{jk}_i = S^{kj}_i. \tag{3.2}$$

Hence the Schouten (3,0)-tensor $S^{ijk} = g^{i\alpha} S^{jk}_\alpha$ possesses the partial symmetry, $S^{ijk} = S^{ikj}$.

Let us consider a nonlinear system of hydrodynamic type

$$u^i_t = \sum_{j=1}^n A^i_j (u^1, \ldots, u^n) u^j_x, \tag{3.3}$$

where $u^i(t,x)$ are unknown functions. Note that for the systems of hydrodynamic type (3.3) the variables $u^1, \ldots, u^n$ play the role of the coordinates $x^1, \ldots, x^n$ of Sec. II.

The Poisson brackets structure for the Hamiltonian systems (3.3) is defined by the operator $I^{ij}(u)$ for the local[9] and nonlocal case $K \neq 0$,[10,11]

$$I^{ij}(u) = g^{ij}(u) \frac{\partial}{\partial x} + b^{ij}_k(u) u^k_x + K u^i_x \left(\frac{\partial}{\partial x} \right)^{-1} u^j_x. \tag{3.4}$$

The corresponding Hamiltonian systems (3.3) have the form

$$u_t^i = I^{i\alpha}(u)\frac{\partial f(u)}{\partial u^\alpha} = A_j^i(u^1, \ldots, u^n)u_x^j, \tag{3.5}$$

with the following (1,1)-tensors $A_j^i(u)$:

$$A_j^i(u) = g^{i\alpha}(u)\frac{\partial^2 f(u)}{\partial u^\alpha\, \partial\, u^j} + b_j^{i\alpha}(u)\frac{\partial f(u)}{\partial u^\alpha} + Kf(u)\delta^i_j, \tag{3.6}$$

where $f(u)$ is the density of the Hamiltonian functional.

(ii) First we study the Hamiltonian systems (3.5) and (3.6) with the nondegenerate (2,0)-tensor g^{jk}. As is known,[9–11] such (2,0)-tensor $g^{ij}(u)$ corresponds to a metric $g_{ij}(u)$ of constant curvature K. The corresponding (1,1)-tensor $A_j^i(u)$ (3.6) has the invariant form

$$A_j^i(u) = g^{i\alpha}f(u)_{;\alpha;j} + Kf(u)\delta^i_j, \tag{3.7}$$

where $(;\alpha)$ means the g_{ij}-covariant derivative with respect to variable u^α.

Proposition 1: For the (1,1)*-tensor* A_j^i (3.7) *and nondegenerate* (2,0)*-tensor* g^{ij}, *the Schouten* (3,0)*-tensor* S^{ijk} *is completely symmetric.*

Proof: For $K=0$, the metric $g_{ij}(u)$ is flat and hence is constant and diagonal in some coordinates $v^1, \ldots, v^n$, $g^{ij}(v)=q^i\delta^i_j$. The corresponding (1,1)-tensor (3.7) takes the form[9]

$$A_j^i(v) = q^i\frac{\partial^2 f(v)}{\partial v^i\, \partial\, v^j}. \tag{3.8}$$

Hence the definition (2.1) yields the following formula for the Schouten (3,0)-tensor:

$$S^{ijk} = -\,q^iq^jq^k\frac{\partial^3 f(v)}{\partial v^i\, \partial\, v^j\, \partial\, v^k}. \tag{3.9}$$

Tensor (3.9) is evidently symmetric in the coordinates $v^1, \ldots, v^n$, hence it is completely symmetric in any coordinates $u^1, \ldots, u^n$.

For $K \neq 0$, the proof is presented in paper.[12] □

Remark 1: Formulas (3.8) and (3.9) yield that if the Schouten (2,1)-tensor S_i^{jk} is zero for a nondegenerate Hamiltonian system (1.3) and (1.4) with $K=0$ then the system is linearizable in some coordinates $v^1, \ldots, v^n$.

Remark 2: Let us consider the invariant function $h(u)=A_j^i(u)A_i^j(u)=\mathrm{Tr}\,A^2(u)$. Formula (3.8) implies

$$h(v) = \sum_{i,j} q^iq^j\left(\frac{\partial^2 f(v)}{\partial v^i\, \partial\, v^j}\right)^2. \tag{3.10}$$

Hence if a system (1.3) has a Hamiltonian structure (1.4) with positive (or negative) definite metric g^{jk} and $K=0$ then necessarily $h(u)\geqslant 0$. Thus if $h(u)\leqslant 0$ then the metric g^{jk} must be indefinite.

(iii) The operator $I^{ij}(u)$ (3.4) defines a structure of Poisson brackets

$$\{\hat{F}_1(u), \hat{F}_2(u)\} = \int_{-\infty}^{\infty}\frac{\delta F_1(u)}{\delta u^i(x)}I^{ij}(u)\frac{\delta F_2(u)}{\delta u^j(x)}\mathrm{d}x \tag{3.11}$$

for the local functionals

$$\hat{F}_\gamma = \int_{-\infty}^{\infty} F_\gamma(u, u_x, u_{xx}, \dots)\mathrm{d}x.$$

The coefficients $g^{ij}(u)$ and $b_k^{ij}(u)$ (3.4) satisfy certain equations[9,11] that follow from the conditions that the Poisson brackets (3.11) are skew and the Jacobi identity holds. The skew-symmetricity condition for the Poisson brackets (3.11) is equivalent to the equations

$$g^{ij} = g^{ji}, \tag{3.12}$$

$$\frac{\partial g^{ij}}{\partial u^k} = b_k^{ij} + b_k^{ji}. \tag{3.13}$$

The Jacobi identity for the Poisson brackets (3.11) is equivalent to the relations[11]

$$b_\alpha^{ik} g^{\alpha j} = b_\alpha^{jk} g^{\alpha i}, \tag{3.14}$$

$$\left(\frac{\partial b_\alpha^{jr}}{\partial u^k} - \frac{\partial b_k^{jr}}{\partial u^\alpha}\right) g^{\alpha i} + b_\alpha^{ij} b_k^{\alpha r} - b_\alpha^{ir} b_k^{\alpha j} + K(g^{ij}\delta^r_k - g^{ir}\delta^j_k) = 0, \tag{3.15}$$

$$\sum_{\sigma,\tau}\left(\frac{\partial b_{\tau(k)}^{\sigma(i)\sigma(j)}}{\partial u^\alpha} - \frac{\partial b_\alpha^{\sigma(i)\sigma(j)}}{\partial u^{\tau(k)}}\right) b_{\tau(s)}^{\alpha\sigma(m)} + K(b_{\tau(k)}^{\sigma(m)\sigma(i)} - b_{\tau(k)}^{\sigma(i)\sigma(m)})\delta_{\tau(s)}^{\sigma(j)} = 0. \tag{3.16}$$

Here summation is taken with respect to index α and in (3.16) with respect to the three cyclic permutations σ of indices i, j, m and two transpositions τ of indices k and s.

For the (1,1)-tensor $A_j^i(u)$ (3.6), we have

$$A_\alpha^i g^{\alpha j} - g^{i\alpha} A_\alpha^j = (g^{i\beta} g^{j\alpha} - g^{i\alpha} g^{j\beta}) \frac{\partial^2 f(u)}{\partial u^\alpha \partial u^\beta} + (b_\alpha^{i\beta} g^{\alpha j} - b_\alpha^{j\beta} g^{\alpha i}) \frac{\partial f(u)}{\partial u^\beta}.$$

This expression is zero in view of Eqs. (3.12) and (3.14). Hence the (1,1)-tensor $A_j^i(u)$ (3.6) satisfies the equation[9] $g^{i\alpha} A_\alpha^j = A_\alpha^i g^{\alpha j}$ (1.1) and therefore the corresponding Schouten (2,1)-tensor S_i^{jk} (3.1) does exist and satisfies Eq. (3.2), $S_i^{jk} = S_i^{kj}$.

Theorem 1: *For any Hamiltonian system of hydrodynamic type* (3.5) and (3.6), *the Schouten (3,0)-tensor S^{ijk} is completely symmetric*.

Proof: In view of Eq. (1.1), formula (3.1) implies

$$S^{ijk} = g^{i\beta} S_\beta^{jk} = A_\alpha^i \frac{\partial g^{jk}}{\partial u^\beta} g^{\beta\alpha} + A_\alpha^j \left(\frac{\partial g^{i\alpha}}{\partial u^\beta} g^{\beta k} - \frac{\partial g^{\alpha k}}{\partial u^\beta} g^{\beta i}\right) + \left(\frac{\partial A_\alpha^k}{\partial u^\beta} - \frac{\partial A_\beta^k}{\partial u^\alpha}\right) g^{\alpha j} g^{\beta i} - \frac{\partial (g^{i\beta} A_\beta^j)}{\partial u^\alpha} g^{\alpha k}. \tag{3.17}$$

In view of (1.1), the last term in (3.17) is symmetric with respect to the indices i, j. Hence formula (3.17) yields

$$\begin{aligned} S^{ijk} - S^{jik} = {} & A_\alpha^i \left(\frac{\partial g^{jk}}{\partial u^\beta} g^{\beta\alpha} - \frac{\partial g^{j\alpha}}{\partial u^\beta} g^{\beta k} + \frac{\partial g^{\alpha k}}{\partial u^\beta} g^{\beta j}\right) - A_\alpha^j \left(\frac{\partial g^{ik}}{\partial u^\beta} g^{\beta\alpha} - \frac{\partial g^{i\alpha}}{\partial u^\beta} g^{\beta k} + \frac{\partial g^{\alpha k}}{\partial u^\beta} g^{\beta i}\right) \\ & + 2\left(\frac{\partial A_\alpha^k}{\partial u^\beta} - \frac{\partial A_\beta^k}{\partial u^\alpha}\right) g^{\alpha j} g^{\beta i}. \end{aligned} \tag{3.18}$$

Let us prove that the expression (3.18) vanishes. Using formulas (3.13) and (3.14), we find

$$\frac{\partial g^{jk}}{\partial u^\beta} g^{\beta\alpha} - \frac{\partial g^{j\alpha}}{\partial u^\beta} g^{\beta k} + \frac{\partial g^{\alpha k}}{\partial u^\beta} g^{\beta j} = 2b_\beta^{jk} g^{\beta\alpha}. \tag{3.19}$$

The formulas (3.6) and (3.13) imply

$$\frac{\partial A_\beta^k}{\partial u^\alpha} = g^{k\gamma} \frac{\partial^3 f(u)}{\partial u^\gamma \partial u^\beta \partial u^\alpha} + b_\beta^{k\gamma} \frac{\partial^2 f(u)}{\partial u^\gamma \partial u^\alpha} + b_\alpha^{k\gamma} \frac{\partial^2 f(u)}{\partial u^\gamma \partial u^\beta} + b_\alpha^{\gamma k} \frac{\partial^2 f(u)}{\partial u^\gamma \partial u^\beta} + \frac{\partial b_\beta^{k\gamma}}{\partial u^\alpha} \frac{\partial f(u)}{\partial u^\gamma} + K \frac{\partial f(u)}{\partial u^\alpha} \delta_\beta^k. \tag{3.20}$$

Here the sum of the first three terms is evidently symmetric with respect to the indices α, β; hence these summands can be cancelled in the last term of (3.18). Substituting the formulas (3.19) and (3.20) into (3.18), we find

$$S^{ijk} - S^{jik} = 2(A_\alpha^i b_\beta^{jk} - A_\alpha^j b_\beta^{ik}) g^{\beta\alpha} + 2\left(\frac{\partial^2 f(u)}{\partial u^\gamma \partial u^\alpha} b_\beta^{\gamma k} - \frac{\partial^2 f(u)}{\partial u^\gamma \partial u^\beta} b_\alpha^{\gamma k} \right) g^{\alpha j} g^{\beta i}$$
$$+ 2 \frac{\partial f(u)}{\partial u^\gamma} \left(\frac{\partial b_\alpha^{k\gamma}}{\partial u^\beta} - \frac{\partial b_\beta^{k\gamma}}{\partial u^\alpha} \right) g^{\alpha j} g^{\beta i} + 2K \left(\frac{\partial f(u)}{\partial u^\beta} \delta_\alpha^k - \frac{\partial f(u)}{\partial u^\alpha} \delta_\beta^k \right) g^{\alpha j} g^{\beta i}.$$

Substituting here expressions (3.6) and using Eqs. (3.14), we obtain

$$S^{ijk} - S^{jik} = 2 \frac{\partial^2 f(u)}{\partial u^\gamma \partial u^\alpha} [(g^{i\gamma} b_\beta^{\alpha k} - g^{i\alpha} b_\beta^{\gamma k}) g^{\beta j} + (g^{j\alpha} b_\beta^{\gamma k} - g^{j\gamma} b_\beta^{\alpha k}) g^{\beta i}] + 2 \frac{\partial f(u)}{\partial u^\gamma} g^{i\beta} \Bigg[\left(\frac{\partial b_\alpha^{k\gamma}}{\partial u^\beta} - \frac{\partial b_\beta^{k\gamma}}{\partial u^\alpha} \right) g^{\alpha j}$$
$$+ b_\alpha^{jk} b_\beta^{\alpha\gamma} - b_\alpha^{j\gamma} b_\beta^{\alpha k} + K(g^{kj} \delta_\beta^\gamma - g^{\gamma j} \delta_\beta^k) \Bigg] + 2Kf(u)(b_\beta^{jk} g^{\beta i} - b_\beta^{ik} g^{\beta j}). \tag{3.21}$$

The first square brackets in (3.21) vanishes in view of the equality of the mixed derivatives, $f_{,\gamma,\alpha} = f_{,\alpha,\gamma}$. The second square bracket is zero because it coincides with Eq. (3.15) after changing the indices k, γ, β, j into j, r, k, i, respectively. Finally the last bracket is zero in view of Eq. (3.14). Thus the equality $S^{ijk} = S^{jik}$ is proven. Together with the equality (3.2) this implies that the Schouten (3,0)-tensor S^{ijk} is completely symmetric. □

IV. TENSOR M^j_{ik} AND DIFFERENTIAL k-FORMS $\Omega_{p_1 \dots p_k}$

(i) The Haantjes (1,2)-tensor[14] is defined by the formula

$$H(u,v) = A^2 N(u,v) + N(Au,Av) - AN(Au,v) - AN(u,Av). \tag{4.1}$$

Here $N(u,v)$ is the Nijenhuis (1,2)-tensor[13]

$$N(u,v) = A^2[u,v] + [Au,Av] - A[Au,v] - A[u,Av], \tag{4.2}$$

where $[u,v]$ is the commutator of any two vector fields that continually extend the given tangent vectors. The Nijenhuis tensor (4.2) has the following components:

$$N_{jk}^i = A_j^\alpha \frac{\partial A_k^i}{\partial x^\alpha} - A_k^\alpha \frac{\partial A_j^i}{\partial x^\alpha} + A_\alpha^i \frac{\partial A_j^\alpha}{\partial x^k} - A_\alpha^i \frac{\partial A_k^\alpha}{\partial x^j}. \tag{4.3}$$

The components of the Haantjes tensor are

$$H_{jk}^i = A_\alpha^i A_\beta^\alpha N_{jk}^\beta + N_{\alpha\beta}^i A_j^\alpha A_k^\beta - A_\alpha^i N_{\beta k}^\alpha A_j^\beta - A_\alpha^i N_{j\beta}^\alpha A_k^\beta. \tag{4.4}$$

The skew-symmetricity of the Nijenhuis (1,2)-tensor, $N_{jk}^i = -N_{kj}^i$, evidently yields $H_{jk}^i = -H_{kj}^i$. Raising up indices j and k in (4.4) by contractions with the (2,0)-tensor $g^{\alpha\beta}$ and using Eq. (1.1), we obtain for the Haantjes (3,0)-tensor $H^{ijk} = H_{\alpha\beta}^i g^{\alpha j} g^{\beta k}$,

$$H^{ijk} = A_\alpha^i A_\beta^\alpha N^{\beta jk} + N^{i\alpha\beta} A_\alpha^j A_\beta^k - A_\alpha^i N^{\alpha\beta k} A_\beta^j - A_\alpha^i N^{\alpha j\beta} A_\beta^k.$$

(ii) Let us consider the (1,2)-tensor[16]

$$M(u,v) = N(Au,v) - AN(u,v), \tag{4.5}$$

that has the following components:

$$M^j_{ik} = N^j_{\alpha k}A^\alpha_i - A^j_\alpha N^\alpha_{ik}. \tag{4.6}$$

Contracting (4.6) with any tangent vector $V^i \in T_x(M^n)$, we obtain the operator

$$M_V = N_{AV} - AN_V. \tag{4.7}$$

For the operator H_V corresponding to the Haantjes tensor (4.1), (4.4), we find

$$H_V = N_{AV}A - AN_VA - AN_{AV} + A^2N_V = M_VA - AM_V. \tag{4.8}$$

Definition 1: For any two non-negative integers p and q, we define the differential 2-form

$$\Omega_{pq}(u,v) = \mathrm{Tr}(M_uA^pM_vA^q - M_vA^pM_uA^q), \tag{4.9}$$

where u,v are tangent vectors $u,v \in T_x(M^n)$. For any non-negative integers $p_1,\dots,p_k$ and tangent vectors $u_1,\dots,u_k$, we introduce the differential k-form

$$\Omega_{p_1\dots p_k}(u_1,\dots,u_k) = \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(M_{\tau(u_1)}A^{p_1},\dots,M_{\tau(u_k)}A^{p_k}), \tag{4.10}$$

where summation is taken over all permutations τ of k symbols.

It is evident that the forms (4.9) and (4.10) are skew-symmetric.

Definition 2: For any non-negative integer p we introduce a (1,3)-tensor L_p that defines for any three vectors v^j, w^k, u^m a vector

$$\begin{aligned} L_p(v,w,u) &= M(v,A^pM(w,u)) - M(w,A^pM(v,u)) \\ &= N(Av,A^pN(Aw,u)) - N(Aw,A^pN(Av,u)) + N(Aw,A^{p+1}N(v,u)) \\ &\quad - N(Av,A^{p+1}N(w,u)) + AN(w,A^pN(Av,u)) - AN(v,A^pN(Aw,u)) \\ &\quad + AN(v,A^{p+1}N(w,u)) - AN(w,A^{p+1}N(v,u)). \end{aligned} \tag{4.11}$$

It is evident that

$$L_p(v,w,u) = (M_vA^pM_w - M_wA^pM_v)u. \tag{4.12}$$

(iii) The (1,2)-tensor M^j_{ik} (4.6) leads to the following (3,0)-tensor

$$M^{jik} = M^j_{\beta\gamma}g^{\beta i}g^{\gamma k} = N^j_{\alpha\gamma}A^\alpha_\beta g^{\beta i}g^{\gamma k} - A^j_\alpha N^\alpha_{\beta\gamma}g^{\beta i}g^{\gamma k},$$

that in view of Eq. (1.1) has the form

$$M^{jik} = N^{j\beta k}A^i_\beta - A^j_\beta N^{\beta ik}, \tag{4.13}$$

where $N^{ijk}=N^i_{\alpha\beta}g^{\alpha j}g^{\beta k}$. The skew-symmetricity of the Nijenhuis (1,2)-tensor N^i_{jk} yields $N^{ijk} = -N^{ikj}$.

Lemma 1: The (3,0)*-tensor* M^{jik} *possesses the partial symmetry*,

$$M^{jik} = M^{kij}, \tag{4.14}$$

provided that the Schouten (3,0)*-tensor* S^{ijk} *is completely symmetric.*

Proof: In Ref. 12, we prove that the Schouten (2,1)-tensor S^{jk}_i (3.1) and the Nijenhuis (1,2)-tensor N^j_{ik} (4.3) satisfy the identity

$$S_u A - A S_u = N_u g - g N_u,$$

that has the following form in the components:

$$S_i^{j\alpha} A_\alpha^k - A_\alpha^j S_i^{\alpha k} = N_{i\alpha}^j g^{\alpha k} - g^{j\alpha} N_{i\alpha}^k. \tag{4.15}$$

As is shown in Ref. 12, for the completely symmetric Schouten tensor S^{ijk} identity (4.15) implies

$$N^{ijk} = S^{ij\alpha} A_\alpha^k - S^{ik\alpha} A_\alpha^j. \tag{4.16}$$

Equations (4.13) and (4.16) yield

$$M^{jik} = A_\beta^i (S^{j\beta\alpha} A_\alpha^k + S^{\alpha k\beta} A_\alpha^j) - S^{jk\alpha} A_\beta^i A_\alpha^\beta - S^{\alpha i\beta} A_\alpha^j A_\beta^k.$$

This expression obviously possesses symmetry (4.14). □

Remark 3: It is evident that Eq. (4.14) has the form

$$(M_{\alpha\beta}^j g^{\beta k} - M_{\alpha\beta}^k g^{\beta j}) g^{\alpha i} = 0.$$

Hence for any tangent vector V of the form $V^\alpha = g^{\alpha i}\omega_i$ we find for the operator M_V (4.7), $M_{V\beta}^j g^{\beta k} = M_{V\beta}^k g^{\beta j}$. This equality has the following matrix form:

$$M_V g = g M_V^t. \tag{4.17}$$

We denote L_{kx} a linear subspace $L_{kx} \subset T_x(M^n)$ consisting of all vectors $V^i = g_k^{i\alpha}\omega_\alpha$ where ω_α are arbitrary covectors, and $k = 1,2$.

Lemma 2: Suppose that a hydrodynamic type system (1.3) *is bi-Hamiltonian, so it has two Hamiltonian forms* (1.4) *with two* (2,0)*-tensors* g_1^{jk} *and* g_2^{jk}. *Assume that tensor* $g_\lambda^{jk} = \lambda g_1^{jk} + g_2^{jk}$ *is nondegenerate. Then the* (1,1)*-tensor* $B_{\lambda k}^j = g_1^{j\alpha}(g_\lambda^{-1})_{\alpha k}$ *commutes with all* (1,1)*-tensors* M_V *and A where* $V \in L_{1x} \cap L_{2x}$, *or* $V^i = g_1^{i\alpha}\omega_\alpha = g_2^{i\alpha}\eta_\alpha$.

Proof: For the two Hamiltonian structures (1.4), the commutativity equation (2.5) holds. For the two (2,0)-tensors g_1 and g_2 equations (4.17) yield

$$g_1 M_V^t = M_V g_1, \quad g_2 M_V^t = M_V g_2,$$

for vectors $V \in L_{1x} \cap L_{2x}$. Hence we find $g_\lambda M_V^t = M_V g_\lambda$ and the commutativity equation

$$B_\lambda M_V = M_V B_\lambda \tag{4.18}$$

follows. □

V. NECESSARY CONDITIONS FOR EXISTENCE OF A NONDEGENERATE HAMILTONIAN STRUCTURE

Theorem 2: *For existence of a nondegenerate Hamiltonian structure* (1.3) and (1.4) *the following necessary conditions must hold:*

- *(a) the differential 2-forms* $\Omega_{pq}(u,v)$ *(4.9) vanish for all p and q;*
- *(b) the differential k-forms* $\Omega_{p_1 \cdots p_k}(u_1, \ldots, u_k)$ *(4.10) vanish if (1)* $p_i = p_{k-i}$ *for* $k = 4m+2$, *and* $k = 4m+3$ *or if (2)* $p_i = p_{k-i+1}$ *for* $k = 4m$, *and* $k = 4m+3$.

Proof: (a) If a Hamiltonian structure (1.3) and (1.4) exists and has a nondegenerate (2,0)-tensor g^{jk}, then Eq. (4.17) holds for all vectors $V \in T_x(M^n)$. Hence for any two tangent vectors u and v we have

$$M_u^t = g^{-1} M_u g, \quad M_v^t = g^{-1} M_v g, \quad A^t = g^{-1} A g. \tag{5.1}$$

Using these equalities, we obtain for the 2-form $\Omega_{pq}(u,v)$ (4.9),

$$\begin{aligned}\Omega_{pq}(u,v) &= \mathrm{Tr}(M_u A^p M_v A^q - M_v A^p M_u A^q)^t \\ &= \mathrm{Tr}(A^{qt} M_v^t A^{pt} M_u^t - A^{qt} M_u^t A^{pt} M_v^t) \\ &= \mathrm{Tr}(g^{-1}(A^q M_v A^p M_u - A^q M_u A^p M_v) g) = \Omega_{pq}(v,u) = -\Omega_{pq}(u,v). \end{aligned} \tag{5.2}$$

Hence $\Omega_{pq}(u,v) \equiv 0$.

(b) At the same assumptions, applying equalities (5.1) we find for the k-form (4.10),

$$\begin{aligned}\Omega_{p_1 \dots p_k}(u_1, \dots, u_k) &= \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(M_{\tau(u_1)} A^{p_1} \cdots M_{\tau(u_k)} A^{p_k})^t \\ &= \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(A^{p_k t} M^t_{\tau(u_k)} \cdots A^{p_1 t} M^t_{\tau(u_1)}) \\ &= \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(g^{-1}(A^{p_k} M_{\tau(u_k)} \cdots A^{p_1} M_{\tau(u_1)}) g) \\ &= \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(M_{\tau(u_k)} A^{p_{k-1}} \cdots A^{p_1} M_{\tau(u_1)} A^{p_k}) \\ &= \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(M_{\tau(u_1)} A^{p_k} M_{\tau(u_k)} \cdots M_{\tau(u_2)} A^{p_1}). \end{aligned} \tag{5.3}$$

(1) Suppose that $p_i = p_{k-i}$. Then we get from (5.3),

$$\Omega_{p_1 \dots p_k}(u_1, \dots, u_k) = \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(M_{\tau(u_k)} A^{p_{k-1}} \cdots A^{p_1} M_{\tau(u_1)} A^{p_k}) = \mathrm{sign}(\sigma_1)\Omega_{p_1 \dots p_k}(u_1, \dots, u_k), \tag{5.4}$$

where σ_1 is the permutation $\sigma_1(j) = p - j + 1$. It is evident that $\mathrm{sign}(\sigma_1) = (-1)^{k(k-1)/2}$. Hence for $k = 4m+2$ and $k = 4m+3$ we have $\mathrm{sign}(\sigma_1) = -1$ and the equality (5.4) yields $\Omega_{p_1 \dots p_k}(u_1, \dots, u_k) \equiv 0$. This case is realized for the 2-forms $\Omega_{pq}(u,v)$ above.

(2) Suppose that $p_i = p_{k-i+1}$. Then we get from the last equality (5.3),

$$\Omega_{p_1 \dots p_k}(u_1, \dots, u_k) = \sum_\tau \mathrm{sign}(\tau)\mathrm{Tr}(M_{\tau(u_1)} A^{p_k} M_{\tau(u_k)} \cdots M_{\tau(u_2)} A^{p_1}) = \mathrm{sign}(\sigma_2)\Omega_{p_1 \dots p_k}(u_1, \dots, u_k), \tag{5.5}$$

where σ_2 is the permutation $\sigma_2(1) = 1$, $\sigma_2(j) = k - j + 2$. Hence $\mathrm{sign}(\sigma_2) = (-1)^{(k-1)(k-2)/2}$ and for $k = 4m$ and $k = 4m+3$ we get $\mathrm{sign}(\sigma_2) = -1$ and the equality (5.5) implies $\Omega_{p_1 \dots p_k}(u_1, \dots, u_k) \equiv 0$. □

VI. NECESSARY CONDITIONS FOR EXISTENCE OF BI-HAMILTONIAN STRUCTURES

Theorem 3: *Suppose that for a bi-Hamiltonian system* (1.3) and (1.4) *the* (2,0)*-tensor* $g_\lambda = \lambda g_1 + g_2$ *is nondegenerate for some* λ, *and the* (1,1)*-tensor* $B^i_{\lambda k}(u) = g_1^{j\alpha}(g_\lambda^{-1})_{\alpha k}$ *has distinct eigenvalues. Then the following necessary conditions hold:*

- *(a) the Haantjes tensor* $H(V,W)$ *(4.1), (4.4) vanishes for all tangent vectors* $V \in L_x = L_{1x} \cap L_{2x}$;
- *(b) the (1,3)-tensors* $L_p(v,w,u)$ *(4.11) vanish for all vectors* $v, w \in L_x$;
- *(c) the differential k-forms* $\Omega_{p_1 \dots p_k}(u_1, \dots, u_k)$ *(4.9), (4.10) vanish for all* $k \geqslant 2$ *and all tangent vectors* $u_1, \dots, u_k \in L_x$ *and all non-negative integers* $p_1, \dots, p_k$;
- *(d) If in addition* rank $g_2 = n$ *then* $H(U,W) = 0$ *for all* $U, W \in T_x(M^n)$. *If the eigenvalues of the (1,1)-tensor* $A^i_j(u)$ *are real and distinct, then the system (1.3) possesses Riemann invariants: there exist local coordinates* $v^1, \dots, v^n$ *where tensor* $A^i_j(v)$ *is diagonal* $A^i_j(v) = A^i(v)\delta^i_j$ *and the system has the form*

$$v^i_t = A^i(v^1, \dots, v^n) v^i_x. \tag{6.1}$$

In these local coordinates both (2,0)*-tensors* $g_1^{ij}(v)$ *and* $g_2^{ij}(v)$ *are diagonal.*

Proof: (a) Since the (1,1)-tensor $B^j_{\lambda k}$ has distinct eigenvalues, it can have only one zero eigenvalue. Hence the (2,0)-tensor g_1^{jk} has rank $\geqslant n-1$. Equations (2.5) and (4.18) imply that the operators A and M_V are diagonal in the basis of eigenvectors of the operators $B^j_{\lambda k}$. Hence operator A and all operators M_{V_1}, M_{V_2} commute with each other for $V_1, V_2 \in L_x$. Hence the commutators $H_V = M_V A - A M_V$ vanish for all vectors $V \in L_x$ and the Haantjes tensor $H(V,U)=0$ for all $V \in L_x$.

(b),(c) The commutativity of the operators A, M_v, M_w for $v, w \in L_x$ implies that the (1,3)-tensors $L_p(v,w,u)$ (4.11) and (4.12) vanish for $v, w \in L_x$. Analogously, all operators in the definitions of the k-forms (4.9), (4.10) commute, hence due to their skew-symmetricity the forms vanish for all $p_1, \ldots, p_k$.

(d) If rank $g_2 = n$, then $L_x = L_{1x}$. Since the Haantjes (1,2)-tensor $H(U,W)$ is skew and $\dim(L_{1x}) \geqslant n-1$, we obtain that the Haantjes (1,2)-tensor $H(U,W)$ vanishes. If the (1,1)-tensor $A^i_k(u)$ has real and distinct eigenvalues then the Nijenhuis-Haantjes theorem[13,14] for $H(U,W)=0$ yields that there are some local coordinates $v^1, \ldots, v^n$ where the (1,1)-tensor $A^i_j(v)$ is diagonal. In these coordinates the system (1.3) has diagonal form (6.1) with Riemann invariants $A^i(v^1, \ldots, v^n)$. In the coordinates $v^1, \ldots, v^n$, Eqs. (2.3) imply that both (2,0)-tensors $g_1^{jk}(v)$ and $g_2^{jk}(v)$are diagonal. □

Proposition 2: For the existence of two Hamiltonian structures (1.3) and (1.4) *with two degenerate* (2,0)*-tensors* g_1^{jk}, rank $g_1 = m_1$, *and* g_2^{jk}, rank $g_2 = m_2$, *provided that for some* λ *the tensor* $g_\lambda = \lambda g_1 + g_2$ *is nondegenerate, the following necessary condition must hold for tangent vectors* $u_1, \ldots, u_k$ *of some subspace* $L_x \subset T_x(M^n)$ *of dimension* $m_1 + m_2 - n$:

The differential k-forms $\Omega_{p_1,\ldots,p_k}(u_1, \ldots, u_k)$ (4.10) *vanish if* (1) $p_i = p_{k-i}$ *for* $k = 4m+2$, *and* $k = 4m+3$ *or if (2)* $p_i = p_{k-i+1}$ *for* $k = 4m$, *and* $k = 4m+3$.

Proof: Applying Lemma 2 of Sec. IV, we find that equations

$$M_V^t = g_\lambda^{-1} M_V g_\lambda, \quad A^t = g_\lambda^{-1} A g_\lambda$$

hold for all tangent vectors $V \in L_x = L_{1x} \cap L_{2x}$. It is evident that $\dim L_x \geqslant \dim L_{1x} + \dim L_{2x} - n = m_1 + m_2 - n$. Hence the same proof as in Theorem 2 gives the necessary condition for $u_1, \ldots, u_k \in L_x$. □

Remark 4: Theorem 3 implies that the necessary condition for the existence of two Hamiltonian structures in general position [when tensor $B(u) = g_1(u) g_2^{-1}(u)$ has n distinct eigenvalues] for a system (1.3) is the vanishing of the Haantjes (1,2)-tensor $H(U,W)$ for the (1,1)-tensor $A^i_j(u)$. Another necessary condition is the vanishing of the (1,3)-tensor $L(V,W,U)$ (4.11) and the skew-symmetric k-forms $\Omega_{p_1 \ldots p_k}(u_1, \ldots, u_k)$ (4.9), (4.10) for any non-negative integers $p_1, \ldots, p_k$.

VII. CANONICAL FORMS OF THE GENERIC BI-HAMILTONIAN SYSTEMS

Let $A^i_j(u)$ be a smooth real (1,1)-tensor on a smooth real manifold M^n.

Theorem 4: *Assume that for the* (1,1)*-tensor* $A^i_j(u)$ *its Haantjes* (1,2)*-tensor* (4.4) *vanishes. Then if the eigenvalues of the operators* $A^i_j(u)$ *are all distinct in some open domain* $\mathcal{D}^n \subset M^n$ *then there exist local coordinates* $x^1, \ldots, x^n$ *in* $\mathcal{D}^n$ *in which the tensor* $A^i_j(u)$ *has block-diagonal form with k nonzero* 2×2 *blocks and* $n-2k$ *nonzero* 1×1 *blocks, where* $2k$ *is the number of complex eigenvalues and* $n-2k$ *is the number of real eigenvalues of operator* $A^i_j(u)$.

Proof: Let $\lambda_1(u), \ldots, \lambda_{2k}(u)$ be the complex eigenvalues of $A^i_j(u)$ and $\lambda_{2k+1}(u), \ldots, \lambda_n(u)$ be the real ones. Since complex eigenvalues appear in conjugate pairs, we reorder them so that $\lambda_{2m}(u) = \overline{\lambda_{2m-1}(u)}$ for $m = 1, \ldots, k$. Let $e_{2m-1}(u)$ and $e_{2m}(u)$ be the corresponding smooth complex-valued eigenvector fields. The vectors $e_{2m-1}(u)$ and $e_{2m}(u)$ belong to the complexification of the tangent spaces $T_u(\mathcal{D}^n)$. It is evident that we can assume that they also are complex conjugates, $e_{2m}(u) = \overline{e_{2m-1}(u)}$. Let

$$e_{2m-1}(u) = v_m(u) + i w_m(u), \tag{7.1}$$

where $v_m(u), w_m(u) \in T_u(\mathcal{D}^n)$ are real-valued tangent vector fields. Then

$$e_{2m}(u) = \overline{e_{2m-1}(u)} = v_m(u) - iw_m(u). \tag{7.2}$$

For $\lambda_{2m-1}(u) = \alpha_m(u) + i\beta_m(u)$, the two complex equations $A(e_{2m-1}) = \lambda_{2m-1}e_{2m-1}$ and $A(e_{2m}) = \overline{\lambda}_{2m-1}e_{2m}$ are equivalent to the two real equations

$$A(v_m) = \alpha_m v_m - \beta_m w_m, \quad A(w_m) = \beta_m v_m + \alpha_m w_m. \tag{7.3}$$

For the $n-2k$ real eigenvalues $\lambda_j(u)$ we define smooth real eigenvector fields $e_j(u)$ where $j = 2k+1, \ldots, n$. It is evident that the vectors $v_m(u), w_m(u), e_j(u)$ form a basis in each tangent space $T_u(\mathcal{D}^n)$. Here $m = 1, \ldots, k$ and $j = 2k+1, \ldots, n$.

For any two eigenvector fields $e_p(u)$, $e_q(u)$, complex or real, Eqs. (4.1), (4.2) lead to the following formula:[16]

$$H(e_p, e_q) = (A - \lambda_p)^2 (A - \lambda_q)^2 [e_p, e_q], \tag{7.4}$$

where $[e_p, e_q]$ is the commutator of the vector fields and $p, q = 1, \ldots, n$. For the vanishing Haantjes tensor, the equations

$$(A - \lambda_p)^2 (A - \lambda_q)^2 [e_p, e_q] = 0 \tag{7.5}$$

hold for all pairs of eigenvector fields $e_p(u)$, $e_q(u)$. For the real ones, equation $H(e_p, e_q) = 0$ implies[13,14]

$$[e_j(u), e_\ell(u)] = a_{j\ell}(u) e_j(u) + b_{j\ell}(u) e_\ell(u), \tag{7.6}$$

with some real-valued functions $a_{j\ell}(u)$ and $b_{j\ell}(u)$. Hence the two-dimensional distribution generated by vector fields $e_j(u)$, $e_\ell(u)$ is involutive.[17]

For the generic case of distinct complex eigenvalues, Eq. (7.5) evidently yields

$$[e_p(u), e_q(u)] = g_{pq}(u) e_p(u) + h_{pq}(u) e_q(u), \tag{7.7}$$

where $g_{pq}(u)$ and $h_{pq}(u)$ are some smooth complex-valued functions. Let us consider three different cases.

(1) Two complex conjugate eigenvalues $\lambda_{2m-1}(u)$, $\lambda_{2m}(u)$. For the corresponding eigenvector fields (7.1) and (7.2), we find

$$[e_{2m-1}(u),\, e_{2m}(u)] = -2i[v_m(u),\, w_m(u)]. \tag{7.8}$$

Hence applying Eq. (7.7), we obtain

$$[v_m(u), w_m(u)] = a_m(u) v_m(u) + b_m(u) w_m(u), \tag{7.9}$$

with some real-valued functions $a_m(u)$ and $b_m(u)$. Hence the two-dimensional distribution in $T_u(\mathcal{D}^n)$ generated by the tangent vector fields $v_m(u)$ and $w_m(u)$ is involutive.

(2) One real, $\lambda_j(u)$, and one complex, $\lambda_{2m-1}(u)$ or $\lambda_{2m}(u)$, eigenvalues. Equation (7.7) together with Eq. (7.9) imply that the three-dimensional distribution in $T_u(\mathcal{D}^n)$ generated by $e_j(u)$, $v_m(u)$, and $w_m(u)$ is involutive.

(3) Two pairs of complex conjugate eigenvalues, $\lambda_{2m-1}(u)$, $\lambda_{2m}(u)$, and $\lambda_{2s-1}(u)$ or $\lambda_{2s}(u)$. Equations (7.7) along with two equations (7.9) for the indices m and s yield that the four-dimensional distribution in $T_u(\mathcal{D}^n)$ generated by the tangent vector fields $v_m(u)$, $w_m(u)$, $v_s(u)$, and $w_s(u)$ is involutive.

For every real eigenvalue $\lambda_j(u)$, $j = 2k+1, \ldots, n$, we consider the $(n-1)$-dimensional distribution in $T_u(\mathcal{D}^n)$ generated by the vector fields $e_\ell(u)$ and $v_m(u)$, $w_m(u)$ corresponding to all other eigenvalues $\lambda_p(u) \neq \lambda_j(u)$. The above results (1)–(3) show that the distribution is involutive. Applying Frobenius theorem,[17] we obtain that the distribution is integrable and hence there exists a smooth nondegenerate function $x^j(u)$ that is constant on the $(n-1)$-dimensional integral submanifolds of the distribution. Hence we get

$$\mathrm{d}x^j(e_p(u)) = f_j(u)\,\delta^j_p, \quad f_j(u) \neq 0, \tag{7.10}$$

where $f_j(u)$ is some nonzero smooth function. Therefore the $(n-1)$-dimensional linear subspace in $T_u(\mathcal{D}^n)$ defined by

$$\mathrm{d}x^j(V) = 0, \quad V \in T_u(\mathcal{D}^n) \tag{7.11}$$

is generated by the tangent vectors $e_\ell(u)$, $\ell \neq j$, and $v_m(u)$, $w_m(u)$. Hence the subspaces $\mathrm{d}x^j(V) = 0$ are invariant under the operators $A^i_j(u)$, in view of $A(e_\ell) = \lambda_\ell e_\ell$ and Eqs. (7.3).

For any pair of complex conjugate eigenvalues $\lambda_{2m}(u) = \overline{\lambda_{2m-1}(u)}$, we consider the $(n-2)$-dimensional distribution in $T_u(\mathcal{D}^n)$ generated by the tangent vectors $v_s(u)$, $w_s(u)$, $s \neq m$, and $e_j(u)$ corresponding to all other eigenvalues. The above results (1)–(3) prove that this distribution is involutive. Hence by Frobenius theorem it is integrable and there exist two smooth functionally independent functions $x^{2m-1}(u)$ and $x^{2m}(u)$ that are constant on the integral submanifolds for this distribution. Hence we have

$$\mathrm{d}x^{2m-1}(v_s(u)) = a_m(u)\,\delta^m_s, \quad \mathrm{d}x^{2m-1}(w_s(u)) = b_m(u)\,\delta^m_s,$$

$$\mathrm{d}x^{2m}(v_s(u)) = c_m(u)\,\delta^m_s, \quad \mathrm{d}x^{2m}(w_s(u)) = d_m(u)\,\delta^m_s, \tag{7.12}$$

$$\mathrm{d}x^{2m-1}(e_j(u)) = 0, \quad \mathrm{d}x^{2m}(e_j(u)) = 0,$$

where $a_m(u)$, $b_m(u)$, $c_m(u)$, $d_m(u)$ are some smooth functions and the corresponding 2×2 matrix is nondegenerate,

$$a_m(u)d_m(u) - b_m(u)c_m(u) \neq 0. \tag{7.13}$$

Equations (7.12) imply that the $(n-2)$-dimensional linear subspaces defined by the two equations

$$\mathrm{d}x^{2m-1}(V) = 0, \quad \mathrm{d}x^{2m}(V) = 0, \quad V \in T_u(\mathcal{D}^n) \tag{7.14}$$

are invariant under the linear operators $A^i_j(u)$.

Thus we have constructed n smooth functions $x^1, \ldots, x^n$ on the domain $\mathcal{D}^n$. Equations (7.10), (7.12), and (7.13) prove that the functions are functionally independent and hence can be considered as a system of local coordinates in $\mathcal{D}^n$. In the coordinates $x^1, \ldots, x^n$, we define the unit tangent vector fields $\mathbf{e}_1, \ldots, \mathbf{e}_n$: $\mathrm{d}x^p(\mathbf{e}_q) = \delta^p_q$.

For $\ell = 2k+1, \ldots, n$, the vector $\mathbf{e}_\ell$ generates the subspace $C\mathbf{e}_\ell$ that is the intersection of the linear subspaces $\mathrm{d}x^j(V) = 0$ (7.10), $\mathrm{d}x^{2m-1}(V) = 0$, $\mathrm{d}x^{2m}(V) = 0$ (7.14), for all $j \neq \ell$ and $m = 1, \ldots, k$. Each of these subspaces is invariant under the operator $A^i_j(u)$. Hence their intersection that is the one-dimensional subspace $C\mathbf{e}_\ell$ is also invariant. Hence the $\mathbf{e}_\ell$ is an eigenvector of the operator $A^i_j(u)$ and defines an invariant diagonal 1×1 block of $A^i_j(u)$. Formulas (7.10) imply that the corresponding eigenvalue is $\lambda_\ell(x)$.

For $s = 1, \ldots, k$, the two tangent vectors $\mathbf{e}_{2s-1}$ and $\mathbf{e}_{2s}$ generate the space $C_1\mathbf{e}_{2s-1} + C_2\mathbf{e}_{2s}$ that is the intersection of the linear subspaces $\mathrm{d}x^j(V) = 0$ (7.10), $\mathrm{d}x^{2m-1}(V) = 0$, $\mathrm{d}x^{2m}(V) = 0$ (7.14), for all $j = 2k+1, \ldots, n$ and $m \neq s$. Since each of these subspaces is invariant under $A^i_j(u)$, their intersection also is invariant. Hence the subspace $C_1\mathbf{e}_{2s-1} + C_2\mathbf{e}_{2s}$ defines an invariant diagonal 2×2 block of the operator $A^i_j(u)$ in the coordinates $x^1, \ldots, x^n$. Formula (7.12) yields that the invariant subspace $C_1\mathbf{e}_{2s-1} + C_2\mathbf{e}_{2s}$ corresponds to the pair of complex eigenvalues $\lambda_{2s-1}(x)$ and $\lambda_{2s}(x) = \overline{\lambda_{2s-1}(x)}$.

Hence the (1,1)-tensor $A^i_j(u)$ in the local coordinates $x^1, \ldots, x^n$ has canonical block-diagonal form with k 2×2 blocks in the subspaces $C_1\mathbf{e}_{2s-1} + C_2\mathbf{e}_{2s}$ and $n-2k$ 1×1 blocks in the subspaces $C\mathbf{e}_\ell$. □

Theorem 5: *A generic bi-Hamiltonian system* (1.3) *with nondegenerate* (2,0)*-tensor* g_2^{jk} *and operators* $B^i_k(u) = g_1^{j\alpha}(g_2^{-1})_{\alpha k}$ *and* $A^i_k(u)$ *having distinct eigenvalues, complex or real, has canonical block diagonal form in some coordinates* $v^1, \ldots, v^n$ *with* k *nonzero* 2×2 *blocks and* $n-2k$ *nonzero* 1×1 *blocks where* $2k$ *is the number of complex eigenvalues of the* (1,1)*-tensor* $A^j_k(u)$.

Theorem 5 follows from Theorems 3 and 4. Indeed, since operators $B^i_k(u)$ have distinct eigenvalues, Theorem 3 implies that the Haantjes tensor H^i_{jk} vanishes. Applying Theorem 4 to the (1,1)-tensor $A^i_j(u)$ with distinct eigenvalues and $H^i_{jk}=0$, we obtain that tensor $A^i_j(v)$ has the block diagonal form in some coordinates $v^1,\dots,v^n$ (denoted above as $x^1,\dots,x^n$). Hence the bi-Hamiltonian system (1.3) has the canonical block diagonal form in the coordinates $v^1,\dots,v^n$.

Remark 5: Theorem 4 contains as a special case (for $k=0$) the classical Nijenhuis–Haantjes theorem that was proved in Refs. 13 and 14 for the case of real and distinct eigenvalues of $A^i_j(u)$. Nijenhuis and Haantjes did not study the generic case of complex eigenvalues because they were concerned with a pure geometric problem on "X_{n-1}*-forming sets of eigenvectors*." For the bi-Hamiltonian systems (1.3), the generic case of complex eigenvalues of $A^i_j(u)$ is as important as the real case.

VIII. ALGEBRAIC IDENTITIES FOR THE BI-HAMILTONIAN SYSTEMS (1.3)

In Ref. 12, we prove that if the Schouten (3,0)-tensor S^{ijk} is completely symmetric, then the Nijenhuis (3,0)-tensor N^{ijk} satisfies the identities

$$N^{ikj}+N^{kji}+N^{jik}=0, \tag{8.1}$$

$$A^i_\alpha N^{\alpha jk}+A^j_\alpha N^{\alpha ki}+A^k_\alpha N^{\alpha ij}=0. \tag{8.2}$$

The corresponding Haantjes (3,0)-tensor H^{ijk} obeys the identity

$$H^{ijk}=A^i_\beta A^\beta_\alpha N^{\alpha jk}+A^j_\beta A^\beta_\alpha N^{\alpha ki}+A^k_\beta A^\beta_\alpha N^{\alpha ij} \tag{8.3}$$

and is completely skew-symmetric.

In Sec. III, we have shown that the Schouten (3,0)-tensor S^{ijk} is completely symmetric for all Hamiltonian systems of hydrodynamic type (1.3) and (1.4). Therefore the identities (8.1)–(8.3) hold for an arbitrary Hamiltonian system of hydrodynamics type with degenerate or nondegenerate symmetric (2,0)-tensor g^{ij}.

For a bi-Hamiltonian system (1.3) and (1.4), there are two sets of identities (8.1)–(8.3) for the two tensors $N^{ijk}_1=N^i_{\alpha\beta}g_1^{\alpha j}g_1^{\beta k}$ and $N^{ijk}_2=N^i_{\alpha\beta}g_2^{\alpha j}g_2^{\beta k}$. Suppose the (2,0)-tensor g_2^{jk} is nondegenerate and define $B^i_j=g_1^{i\alpha}(g_2^{-1})_{\alpha j}$.

Proposition 3: For the bi-Hamiltonian system (1.3) and (1.4)*, tensor* N^{ijk}_1 *satisfies the additional identities*

$$B^i_\gamma N_1^{\gamma kj}+B^k_\gamma N_1^{\gamma ji}+B^j_\gamma N_1^{\gamma ik}=0, \tag{8.4}$$

$$B^i_\gamma A^\gamma_\alpha N_1^{\alpha jk}+B^j_\gamma A^\gamma_\alpha N_1^{\alpha ki}+B^k_\gamma A^\gamma_\alpha N_1^{\alpha ij}=0, \tag{8.5}$$

$$B^i_\gamma H_1^{\gamma jk}=B^i_\gamma A^\gamma_\beta A^\beta_\alpha N_1^{\alpha jk}+B^j_\gamma A^\gamma_\beta A^\beta_\alpha N_1^{\alpha ki}+B^k_\gamma A^\gamma_\beta A^\beta_\alpha N_1^{\alpha ij}. \tag{8.6}$$

Proof: Let us contract the identity (8.1),

$$N_2^{ikj}+N_2^{kji}+N_2^{jik}=0,$$

for the tensor N_2^{ijk} with the tensor $(g_2^{-1})_{\alpha i}(g_2^{-1})_{\beta k}(g_2^{-1})_{\gamma j}$. After changing the indices we get the identity for the Nijenhuis tensor N^i_{jk},

$$(g_2^{-1})_{i\gamma}N^\gamma_{kj}+(g_2^{-1})_{k\gamma}N^\gamma_{ji}+(g_2^{-1})_{j\gamma}N^\gamma_{ik}=0. \tag{8.7}$$

Contracting this identity with the tensor $g_1^{\alpha i}g_1^{\beta k}g_1^{\delta j}$ and again changing notations, we arrive at the identity (8.4). The identities (8.5) and (8.6) follow in an analogous way. □

Identity (8.6) implies that along with the (3,0)-tensors H_1^{ijk} and H_2^{ijk} also the (3,0)-tensor $B^i_\gamma H_1^{\gamma jk}$ is completely skew-symmetric.

(Received 8 December 2005; accepted 12 December 2005; published online 27 February 2006)

We present a nonlinear realization of the 5-graded Lie algebra associated to a Kantor triple system. Any simple Lie algebra can be realized in this way, starting from an arbitrary 5-grading. In particular, we get a unified realization of the exceptional Lie algebras $\mathfrak{f}_4, \mathfrak{e}_6, \mathfrak{e}_7, \mathfrak{e}_8$, in which they are respectively related to the division algebras $\mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O}$. © *2006 American Institute of Physics.*

I. INTRODUCTION

The product in an associative but noncommutative algebra can be decomposed into one symmetric part, leading to a *Jordan algebra*, and one antisymmetric part, leading to a *Lie algebra*. A deeper relationship between these two important kinds of algebras is suggested by the Kantor-Koecher-Tits construction,[1–3] which associates a Lie algebra to any Jordan algebra, and it becomes more evident when generalizing Jordan algebras to *Jordan triple systems* (JTS). These can further be generalized to *Kantor triple systems* (KTS).

The Lie algebra associated to a Jordan algebra or a JTS is 3-graded, written $\mathfrak{g}_{-1}+\mathfrak{g}_0+\mathfrak{g}_1$ as a direct sum of subspaces, while the Lie algebra associated to a KTS is 5-graded, written $\mathfrak{g}_{-2}+\mathfrak{g}_{-1}+\mathfrak{g}_0+\mathfrak{g}_1+\mathfrak{g}_2$. We will discuss graded Lie algebras more in the following section. In Sec. III we will describe how triple systems may be obtained from graded Lie algebras and conversely construct the graded Lie algebras associated to these triple systems. Under certain conditions, we get back the original algebra, together with a nonlinear realization.

In Sec. III A we will consider Jordan triple systems and the associated 3-graded Lie algebras. In this case, the realization of the Lie algebra is said to be *conformal*. The operators act on $\mathfrak{g}_{-1}$ and are each either constant, linear or quadratic, according to the 3-grading. In the case of $\mathfrak{so}(2,d)$ we get the well-known realization of the conformal algebra in d dimensions, where the elements in the algebra are regarded as generators of translations (constant), Lorentz transformations together with dilatations (linear) and special conformal transformations (quadratic).

The main result of this paper, to be presented in Sec. III B, is a corresponding realization of the 5-graded Lie algebra associated to a Kantor triple system. This Lie algebra has earlier been defined as a special case of a *Kantor algebra*,[4] using a functor that associates a Lie algebra to any generalized Jordan triple system.[5] It has also been defined in a simpler but rather abstract way, as a direct sum of vector spaces together with the appropriate commutation relations.[6]

In our construction, the Lie algebra associated to a KTS consists of nonlinear operators acting on an extension of the KTS. The bracket arises naturally when we regard the operators as vector fields, which we will explain in Sec. II B. To our knowledge, such a construction has not appeared before. However, the concomitant realization of any simple 5-graded Lie algebra on its subspace $\mathfrak{g}_{-2}+\mathfrak{g}_{-1}$ has been obtained in Ref. 7, using a general formula for the Lie algebra of a homogeneous space.

[a)]Electronic mail: jakob.palmkvist@aei.mpg.de

The corresponding realization of the Lie algebra associated to a *Freudenthal triple system* (FTS) was given in Ref. 8, called *quasiconformal*, and led us to the present work. The difference is that our realization is based on an arbitrary 5-grading, while in Ref. 8 the subspaces $\mathfrak{g}_{\pm 2}$ must be one dimensional. The connection between these two realizations will be clarified in Sec. III C. As an example of interesting cases where the subspaces $\mathfrak{g}_{\pm 2}$ are not one dimensional, we will in Sec. IV show how the exceptional Lie algebras $\mathfrak{f}_4, \mathfrak{e}_6, \mathfrak{e}_7, \mathfrak{e}_8$ can be given 5-gradings related to the division algebras $\mathbb{R}, \mathbb{C}, \mathbb{H}, \mathbb{O}$, respectively. This construction, given in Ref. 6, together with our main result, leads to a unified realization of these exceptional Lie algebras.

II. GRADED LIE ALGEBRAS

We start with some definitions concerning graded Lie algebras in general, after which we will consider the cases of semisimple and simple algebras.

A Lie algebra $\mathfrak{g}$ is *graded* if it is the direct sum of subspaces $\mathfrak{g}_k \subset \mathfrak{g}$ for all integers k, such that

$$[\mathfrak{g}_i, \mathfrak{g}_j] \subseteq \mathfrak{g}_{i+j}$$

for all integers i, j. It is $(2\nu+1)$-graded for some integer $\nu \geqslant 1$ if $\mathfrak{g}_{\pm\nu} \neq 0$ and

$$|k| > \nu \Rightarrow \mathfrak{g}_k = 0.$$

(If $\mathfrak{g}_k = 0$ for all $k \neq 0$, then $\mathfrak{g}$ will not be regarded as a graded Lie algebra.) The grade k of an element $x \in \mathfrak{g}_k$ may be measured by a *characteristic element* $Z \in \mathfrak{g}$, satisfying

$$x \in \mathfrak{g}_k \Rightarrow [Z, x] = kx$$

for all integers k. A *graded involution* τ on $\mathfrak{g}$ is an automorphism of $\mathfrak{g}$ such that $\tau(\tau(x)) = x$ for all $x \in \mathfrak{g}$ and $\tau(\mathfrak{g}_k) = \mathfrak{g}_{-k}$ for all integers k. If we instead of the last condition have $\tau(\mathfrak{g}_k) = (-1)^k \mathfrak{g}_{-k}$, then τ will be called a *graded pseudoinvolution*.

A. Semisimple algebras

Let the graded Lie algebra $\mathfrak{g}$ be semisimple, complex, and finite dimensional. Then $\mathfrak{g}$ has a unique characteristic element Z that belongs to a Cartan subalgebra of $\mathfrak{g}$ contained in $\mathfrak{g}_0$. With respect to this Cartan subalgebra, the subspaces $\mathfrak{g}_k$ with $k \neq 0$ are spanned by step operators E^α corresponding to roots α such that

$$E^\alpha \in \mathfrak{g}_k \Leftrightarrow E^{-\alpha} \in \mathfrak{g}_{-k},$$

while $\mathfrak{g}_0$ is spanned by the Cartan elements H^i and the remaining step operators. It follows that $\mathfrak{g}$ is $(2\nu+1)$-graded for some integer $\nu \geqslant 1$ and the *Chevalley involution*

$$E^{\pm\alpha} \mapsto -E^{\mp\alpha}, \quad H^i \mapsto -H^i$$

is a graded involution on $\mathfrak{g}$. Not all real forms of $\mathfrak{g}$ inherit the grading, since these are spanned by complex linear combinations of the step operators and the Cartan elements. In particular, the compact form of $\mathfrak{g}$ cannot be graded.

If we expand a root β in the basis of simple roots α_j as $\beta = \beta^j \alpha_j$, then any set of simple roots $\alpha_{i_1}, \alpha_{i_2}, \ldots, \alpha_{i_n}$ generates a grading of $\mathfrak{g}$ where $\mathfrak{g}_k$ is spanned by all step operators E^β such that $\beta^{i_1} + \beta^{i_2} + \cdots + \beta^{i_n} = k$ and, if $k = 0$, the Cartan elements. Any 3-grading or 5-grading of a simple Lie algebra can be obtained in this way (possibly after an automorphism). If $\mathfrak{g}$ is simple and 3-graded or 5-graded, we also have $[\mathfrak{g}_i, \mathfrak{g}_j] = \mathfrak{g}_{i+j}$ for $i, j = \pm 1$ and (up to an automorphism) there is a unique 5-grading with one dimensional subspaces $\mathfrak{g}_{\pm 2}$, except for $\mathfrak{g} = \mathfrak{a}_1$. On the other hand, $\mathfrak{e}_8, \mathfrak{f}_4, \mathfrak{g}_2$ cannot be 3-graded. A table of all simple 3-graded and 5-graded Lie algebras can be found in Ref. 9.

B. Algebras of operators

We will now describe how any vector space U or pair of vector spaces V,W gives rise to an infinite dimensional graded Lie algebra $T(U)$ or $T(V,W)$ consisting of operators acting on U or $V\oplus W$.

With an operator f on a vector space U we mean a map $U\to U$. It is of order $p\geqslant 1$ if there is a symmetric p-linear map $F:U^p\to U$ such that

$$f(u)=F(u,\ldots,u)$$

for all $u\in U$, and of order 0 if there is a vector $v\in U$ such that $f(u)=v$ for all $u\in U$. We define the composition of f and another operator g on U by

$$(f\circ g)(u)=pF(g(u),u,\ldots,u)$$

or $f\circ g=0$ if f is of order 0.

For any integer $k\geqslant -1$, let $T_k(U)$ be the vector space consisting of all operators on U of order $k+1$. Furthermore, set $T_k(U)=0$ for all integers $k\leqslant -2$ and let $T(U)$ be the direct sum of all these vector spaces. Now $T(U)$, together with the bracket

$$[f,g]=f\circ g-g\circ f,$$

is a graded Lie algebra, isomorphic to the algebra of all vector fields $f^i\partial_i$ on U such that $f\in T(U)$. The isomorphism is given by $f\mapsto -f^i\partial_i$.

Similarly, for any pair of vector spaces V,W, we can define a graded Lie algebra $T(V,W)$ of operators on $V\oplus W$, isomorphic to the algebra of all vector fields $f^i\partial_i$ on $V\oplus W$ such that $f\in T(V,W)$. As a graded Lie algebra, $T(V,W)$ is the direct sum of subspaces $T_k(V,W)$ for all integers k, where $T_k(V,W)=0$ for $k\leqslant -3$.

With a *realization* of a Lie algebra $\mathfrak{g}$ on U or $V\oplus W$ we mean a homomorphism from $\mathfrak{g}$ to $T(U)$ or $T(V,W)$. If all elements are mapped on linear operators, it reduces to a linear *representation*. In the following section, we will see that any simple 3-graded or 5-graded Lie algebra $\mathfrak{g}$ can be described as a subalgebra of $T(\mathfrak{g}_{-1})$ or $T(\mathfrak{g}_{-1},\mathfrak{g}_{-2})$ and this description will thus give us a realization of the algebra.

III. TRIPLE SYSTEMS

In this section, we will clarify the connection between graded Lie algebras and triple systems. Jordan triple systems and Kantor triple systems correspond to general 3-graded and 5-graded algebras, respectively, while Freudenthal triple systems correspond to 5-graded algebras with one dimensional subspaces $\mathfrak{g}_{\pm 2}$.

A *triple system* (or *ternary algebra*) is a vector space U together with a linear map

$$U\times U\times U\to U,\quad (x,y,z)\mapsto (xyz)$$

called *triple product*. For any two elements u,v in a triple system U, we define the linear operator $\langle u,v\rangle$ on U by

$$\langle u,v\rangle(z)=(uzv)-(vzu).$$

Let $\mathfrak{g}$ be a graded Lie algebra with a graded involution τ. Then the vector space $\mathfrak{g}_{-1}$ together with the triple product

$$(xyz)=[[x,\tau(y)],z]$$

is a triple system, which will be called the triple system *derived* from $\mathfrak{g}$. We have the identity

$$(uv(xyz))-(xy(uvz))=((uvx)yz)-(x(vuy)z) \tag{3.1}$$

from the fact that τ is an involution and from the Jacobi identity, which also gives us

$$\langle u,v\rangle(z) = [[u,v],\tau(z)]$$

for all $u,v,z \in \mathfrak{g}_{-1}$.

A. Jordan triple systems

Let $\mathfrak{g}$ be a 3-graded Lie algebra with a graded involution. Since $[u,v]=0$ for any $u,v \in \mathfrak{g}_{-1}$ we have

$$\langle u,v\rangle(z) = 0 \tag{3.2}$$

in the triple system derived from $\mathfrak{g}$, which means that the triple product (uzv) is symmetric in u and v.

We define a *Jordan triple system* (JTS)[10] as a triple system where the identities (3.1) and (3.2) hold. Thus the triple system derived from a 3-graded Lie algebra with a graded involution is a JTS. Conversely, any Jordan triple system J gives rise to a 3-graded subalgebra of $T(J)$, spanned by the operators

$$u_a(x) = a,$$

$$s_{ab}(x) = (abx),$$

$$\tilde{u}_a(x) = -\tfrac{1}{2}(xax),$$

where $a,b,x \in J$. This is the Lie algebra $L(J)$ *associated* to the Jordan triple system J. From (3.1) and (3.2) we get the commutation relations

$$[s_{ab},s_{cd}] = s_{(abc)d} - s_{c(bad)}, \quad [s_{ab},u_c] = u_{(abc)},$$

$$[s_{ab},\tilde{u}_c] = -\tilde{u}_{(bac)}, \quad [u_a,\tilde{u}_b] = s_{ab},$$

and $[\tilde{u}_a,\tilde{u}_b]=0$. [We also have $[u_a,u_b]=0$ already from the definition of $T(J)$.] It follows that if J is derived from a simple 3-graded Lie algebra $\mathfrak{g}$ with a graded involution τ, then $\mathfrak{g}$ is isomorphic to $L(J)$ with the isomorphism

$$\begin{array}{r|ccc} +1 & \tau(a) & \mapsto & \tilde{u}_a \\ 0 & [a,\tau(b)] & \mapsto & [u_a,\tilde{u}_b] \\ -1 & a & \mapsto & u_a \end{array} \tag{3.3}$$

where $a,b \in \mathfrak{g}_{-1}$. This is the *conformal realization* of $\mathfrak{g}$ on $\mathfrak{g}_{-1}$.

B. Kantor triple systems

If $\mathfrak{g}$ is a 5-graded Lie algebra with a graded involution, then the identity

$$(uv(xyz)) - (xy(uvz)) = ((uvx)yz) - (x(vuy)z) \tag{3.4}$$

still holds in the triple system derived from $\mathfrak{g}$ but instead of $\langle u,v\rangle=0$ we now have the identity

$$\langle\langle u,v\rangle(x),y\rangle = \langle(yxu),v\rangle - \langle(yxv),u\rangle. \tag{3.5}$$

We define a *Kantor triple system* (KTS),[11] or a JTS *of second order*[5] as a triple system such that (3.4) and (3.5) hold. Thus the triple system derived from a 5-graded Lie algebra with a graded involution is a KTS, and so is any JTS.

Let K be a KTS and let L be the vector space spanned by all linear operators $\langle u,v\rangle$ on K, where $u,v \in K$. If K is derived from a simple 5-graded Lie algebra $\mathfrak{g}$ with a graded involution τ,

then we can identify not only K with $\mathfrak{g}_{-1}$, but also L with $\mathfrak{g}_{-2}$ by $\langle u,v\rangle=[u,v]$. In analogy with the construction of $L(J)$ in the preceding section we can now construct a 5-graded subalgebra of $T(K,L)$ spanned by the operators

$$K_{ab}(z+Z)=2\langle a,b\rangle,$$

$$U_a(z+Z)=a+\langle a,z\rangle,$$

$$S_{ab}(z+Z)=(abz)-\langle a,Z(b)\rangle,$$

$$\tilde{U}_a(z+Z)=-\tfrac{1}{2}(zaz)-\tfrac{1}{2}Z(a)+\tfrac{1}{6}\langle(zaz),z\rangle-\tfrac{1}{2}\langle Z(a),z\rangle,$$

$$\tilde{K}_{ab}(z+Z)=-\tfrac{1}{6}(z\langle a,b\rangle(z)z)-\tfrac{1}{2}Z(\langle a,b\rangle(z))+\tfrac{1}{12}\langle(z\langle a,b\rangle(z)z),z\rangle+\tfrac{1}{2}\langle Z(a),Z(b)\rangle, \tag{3.6}$$

where $a,b,z\in K$ and $Z\in L$. This is the Lie algebra $L(K)$ *associated* to the Kantor triple system K. We get the commutation relations

$$[S_{ab},S_{cd}]=S_{(abc)d}-S_{c(bad)},\quad [S_{ab},U_c]=U_{(abc)},$$

$$[S_{ab},K_{cd}]=K_{\langle c,d\rangle(b)a},\quad [U_a,U_b]=K_{ab},$$

$$[S_{ab},\tilde{U}_c]=-\tilde{U}_{(bac)},\quad [S_{ab},\tilde{K}_{cd}]=-\tilde{K}_{\langle c,d\rangle(a)b},$$

$$[U_a,\tilde{U}_b]=S_{ab},\quad [U_a,\tilde{K}_{cd}]=-\tilde{U}_{\langle c,d\rangle(a)},$$

$$[K_{ab},\tilde{U}_c]=U_{\langle a,b\rangle(c)},\quad [K_{ab},\tilde{K}_{cd}]=S_{\langle a,b\rangle(c)d}-S_{\langle a,b\rangle(d)c},$$

$$[\tilde{U}_a,\tilde{U}_b]=\tilde{K}_{ab},\quad [\tilde{K}_{ab},\tilde{K}_{cd}]=[\tilde{K}_{ab},\tilde{U}_c]=0.$$

It follows that if K is derived from a simple 5-graded Lie algebra $\mathfrak{g}$ with a graded involution τ, then $\mathfrak{g}$ is isomorphic to $L(K)$ with the isomorphism

$$\begin{array}{r|ccccc}
+2 & [\tau(a),\tau(b)] & \mapsto & [\tilde{U}_a,\tilde{U}_b] & = & \tilde{K}_{ab} \\
+1 & \tau(a) & \mapsto & \tilde{U}_a & & \\
0 & [a,\tau(b)] & \mapsto & [U_a,\tilde{U}_b] & = & S_{ab} \\
-1 & a & \mapsto & U_a & & \\
-2 & [a,b] & \mapsto & [U_a,U_b] & = & K_{ab}
\end{array} \tag{3.7}$$

where $a,b\in\mathfrak{g}_{-1}$. Then this isomorphism will be a realization of $\mathfrak{g}$ on its subspace $\mathfrak{g}_{-2}+\mathfrak{g}_{-1}$. The Lie algebra associated to a Kantor triple system can also be *defined* by the commutation relations above, and this is partly the definition given in Refs. 6 and 12, but it does not directly lead to a realization like (3.6). On the other hand, with our construction, we have to *derive* the commutation relations from the definition of the operators and the defining properties of a Kantor triple system. This requires long calculations and we will only give a few of them here. The full expressions are written out in Ref. 13. As an example, we have

$$
\begin{aligned}
[U_a,\tilde{U}_b](z+Z) &= \left\langle a,-\tfrac{1}{2}(zbz)-\tfrac{1}{2}Z(b)\right\rangle \\
&\quad +\tfrac{1}{2}(abz)+\tfrac{1}{2}(zba)+\tfrac{1}{2}\langle a,z\rangle(b) \\
&\quad -\tfrac{1}{6}\langle(abz),z\rangle-\tfrac{1}{6}\langle(zba),z\rangle-\tfrac{1}{6}\langle(zbz),a\rangle \\
&\quad +\tfrac{1}{2}\langle\langle a,z\rangle(b),z\rangle+\tfrac{1}{2}\langle Z(b),a\rangle \\
&=(abz)+\langle Z(b),a\rangle+\tfrac{3}{6}\langle\langle a,z\rangle(b),z\rangle \\
&\quad -\tfrac{1}{6}\langle(zba),z\rangle-\tfrac{1}{6}\langle(abz),z\rangle+\tfrac{2}{6}\langle(zbz),a\rangle \\
&=(abz)+\langle Z(b),a\rangle=S_{ab}(z+Z),
\end{aligned}
$$

where we have used

$$
\begin{aligned}
3\langle\langle a,z\rangle(b),z\rangle &= 2\langle\langle a,z\rangle(b),z\rangle+\langle\langle a,z\rangle(b),z\rangle \\
&=2(\langle(zba),z\rangle-2\langle(zbz),a\rangle) \\
&\quad +\langle(abz),z\rangle-\langle(zba),z\rangle \\
&=\langle(zba),z\rangle+\langle(abz),z\rangle-2\langle(zbz),a\rangle.
\end{aligned}
$$

Among the other commutators, $[U_a,U_b]$ and $[S_{ab},U_c]$ are easy to calculate, while $[\tilde{U}_a,\tilde{U}_b]$ and $[S_{ab},\tilde{U}_c]$ are much harder. It is convenient to first verify the identities

$$
\{((zbz)az)+2(za(zbz))\}_{ab}=(z\langle b,a\rangle(z)z), \tag{3.8}
$$

$$
\{(\langle x,y\rangle(b)az)\}_{ab}=(x\langle a,b\rangle(y)z)-(y\langle a,b\rangle(x)z), \tag{3.9}
$$

where we denote antisymmetrization by curly brackets, $\{f(a,b)\}_{ab}=f(a,b)-f(b,a)$ for any function f. We can also use (3.9) to rewrite the last term in $\tilde{K}_{ab}(z+Z)$ and show that the map (3.7) is well defined in the sense that $\tilde{K}_{ab}=\tilde{K}_{cd}$ if $[a,b]=[c,d]$. It turns out that

$$
\begin{aligned}
2\langle\langle u,v\rangle(a),\langle x,y\rangle(b)\rangle &= \langle(x\langle a,b\rangle(y)u),v\rangle-\langle(y\langle a,b\rangle(x)u),v\rangle \\
&\quad +\langle(y\langle a,b\rangle(x)v),u\rangle-\langle(x\langle a,b\rangle(y)v),u\rangle.
\end{aligned}
$$

The remaining nonzero commutation relations follow from the Jacobi identity. Finally, we can show that

$$
[[\tilde{K}_{ab},\tilde{U}_c],K_{xy}]=[[\tilde{K}_{ab},\tilde{U}_c],U_z]=0
$$

which gives us

$$
[\tilde{K}_{ab},\tilde{U}_c]=[\tilde{K}_{ab},\tilde{K}_{cd}]=0.
$$

C. Freudenthal triple systems

Let $\mathfrak{g}$ be a 5-graded Lie algebra and let T be an element in $\mathfrak{g}_2$. Then $\mathfrak{g}_{-1}$ together with the triple product

$$
(xyz)=[[x,[T,y]],z]
$$

is a triple system satisfying

$$
\langle x,y\rangle(z)=(yxz)-(xyz). \tag{3.10}
$$

Suppose now that the subspaces $\mathfrak{g}_{\pm 2}$ are one dimensional. If we extend the map

$$\mathfrak{g}_{-1} \to \mathfrak{g}_1, \quad x \mapsto [T,x]$$

to a graded pseudoinvolution τ on $\mathfrak{g}$, then for any $x,y \in \mathfrak{g}_{-1}$ there is a scalar α such that $\langle x,y\rangle \times(z)=\alpha z$. Thus we can identify the vector space spanned by all operators $\langle x,y\rangle$ where $x,y \in \mathfrak{g}_{-1}$ with the field over which the Lie algebra is defined, writing

$$\langle x,y\rangle(z) = \langle x,y\rangle z \tag{3.11}$$

and we can regard $\langle x,y\rangle$ as an antisymmetric bilinear form on the triple system rather than an operator. Since τ is not an involution but a pseudoinvolution, we now have the identity

$$(uv(xyz)) - (xy(uvz)) = ((uvx)yz) + (x(vuy)z) \tag{3.12}$$

with a changed sign of the last term, in comparison to (3.4). However, (3.5) still holds. We define a *Freudenthal triple system* (FTS) as a triple system with an antisymmetric bilinear form satisfying (3.5), (3.10), and (3.12). To sum up, we have

$$(uv(xyz)) = ((uvx)yz) + (x(vuy)z) + (xy(uvz)), \tag{3.13}$$

$$\langle x,y\rangle z = (xzy) - (yzx) = (yxz) - (xyz), \tag{3.14}$$

$$\langle u,v\rangle\langle x,y\rangle = \langle (yxu),v\rangle - \langle (yxv),u\rangle. \tag{3.15}$$

We note that (3.13) cannot be replaced by (3.4) or, in other words, that a KTS cannot satisfy (3.14) and (3.15) for some antisymmetric bilinear form (unless this is identically equal to zero, in which case the KTS reduces to a JTS).

Let F be a FTS and let L be the vector space spanned by all operators $\langle u,v\rangle$ on F where $u,v \in F$. If we change some of the signs in the definition of $\widetilde{K}_{ab}$ in (3.6), keep the definitions of all the other operators and simplify the expressions by (3.10)–(3.12), then we get

$$K_{ab}(z+\zeta) = 2\langle a,b\rangle,$$

$$U_a(z+\zeta) = a + \langle a,z\rangle,$$

$$S_{ab}(z+\zeta) = (abz) - \zeta\langle a,b\rangle, \tag{3.16}$$

$$\widetilde{U}_a(z+\zeta) = -\tfrac{1}{2}(zaz) - \tfrac{1}{2}\zeta a + \tfrac{1}{6}\langle (zzz),a\rangle - \tfrac{1}{2}\zeta\langle a,z\rangle,$$

$$\widetilde{K}_{ab}(z+\zeta) = \tfrac{1}{6}\langle a,b\rangle(zzz) + \tfrac{1}{2}\zeta\langle a,b\rangle z - \tfrac{1}{12}\langle a,b\rangle\langle (zzz),z\rangle + \tfrac{1}{2}\zeta^2\langle a,b\rangle,$$

where $a,b,z \in F$ and $\zeta \in L$. These operators span a subalgebra of $T(F,L)$ with the commutation relations

$$[S_{ab},S_{cd}] = S_{(abc)d} + S_{c(bad)}, \quad [S_{ab},U_c] = U_{(abc)},$$

$$[S_{ab},K_{cd}] = \langle c,d\rangle K_{ba}, \quad [U_a,U_b] = K_{ab},$$

$$[S_{ab},\widetilde{U}_c] = \widetilde{U}_{(bac)}, \quad [S_{ab},\widetilde{K}_{cd}] = \langle c,d\rangle\widetilde{K}_{ab},$$

$$[U_a,\widetilde{U}_b] = S_{ab}, \quad [U_a,\widetilde{K}_{cd}] = \langle c,d\rangle\widetilde{U}_a,$$

$$[K_{ab},\tilde{U}_c]=\langle a,b\rangle U_c,\quad [K_{ab},\tilde{K}_{cd}]=\langle a,b\rangle(S_{cd}-S_{dc}),$$

$$[\tilde{U}_a,\tilde{U}_b]=\tilde{K}_{ab},\quad [\tilde{K}_{ab},\tilde{K}_{cd}]=[\tilde{K}_{ab},\tilde{U}_c]=0.$$

It follows that if F is derived from a simple 5-graded Lie algebra $\mathfrak{g}$ with one dimensional subspaces $\mathfrak{g}_{\pm 2}$ and a graded pseudoinvolution as described above, then the map (3.7) is again an isomorphism. This is the *quasiconformal realization* of $\mathfrak{g}$ on $\mathfrak{g}_{-2}+\mathfrak{g}_{-1}$, given in Ref. 8 [where the factor of -2 in (17) and the opposite sign of the bracket lead to different coefficients in (29)].

Freudenthal triple systems where the antisymmetric bilinear form is nondegenerate are in a one-to-one correspondence to simple, complex, and finite-dimensional Lie algebras.[14] Since such a Lie algebra is also associated to a KTS, it follows that any nondegenerate FTS can be obtained from a KTS. Although Freudenthal triple systems are sufficient to obtain all simple finite-dimensional Lie algebras, the result in the following section shows that also Kantor triple systems may be useful.

IV. EXCEPTIONAL LIE ALGEBRAS

We end this paper with some comments on the exceptional Lie algebras $\mathfrak{f}_4,\mathfrak{e}_6,\mathfrak{e}_7,\mathfrak{e}_8$. These are associated to Kantor triple systems which in turn can be defined using the division algebras $\mathbb{R},\mathbb{C},\mathbb{H},\mathbb{O}$. We will briefly describe this construction, given in Ref. 6 and extended in Ref. 12.

Let $\mathbb{K}$ be one of the division algebras $\mathbb{R},\mathbb{C},\mathbb{H},\mathbb{O}$, consisting of real and complex numbers, quaternions and octonions,[15] respectively. Then the tensor product algebra $\mathbb{K}\otimes\mathbb{O}$ is a KTS with the triple product

$$(xyz)=x(y^*z)+z(y^*x)-y(x^*z),$$

where the conjugation in $\mathbb{K}\otimes\mathbb{O}$ is given from the conjugations in $\mathbb{K}$ and $\mathbb{O}$ simply by

$$(a,b)^*=(a^*,b^*).$$

The complex Lie algebras $L(\mathbb{K}\otimes\mathbb{O})$ associated to these triple systems are

$$L(\mathbb{R}\otimes\mathbb{O})=\mathfrak{f}_4,$$

$$L(\mathbb{C}\otimes\mathbb{O})=\mathfrak{e}_6,$$

$$L(\mathbb{H}\otimes\mathbb{O})=\mathfrak{e}_7,$$

$$L(\mathbb{O}\otimes\mathbb{O})=\mathfrak{e}_8.$$

Thus we obtain 5-gradings of these algebras, but the subspaces $\mathfrak{g}_{\pm 2}$ are not one dimensional. If we include also the *split forms* of $\mathbb{C},\mathbb{H},\mathbb{O}$ in a similar way and consider the real Lie algebras, we get all noncompact forms of $\mathfrak{f}_4,\mathfrak{e}_6,\mathfrak{e}_7,\mathfrak{e}_8$.[12]

The construction (3.6) of $L(K)$ for any Kantor triple system K now leads to a unified realization of the exceptional Lie algebras $\mathfrak{f}_4,\mathfrak{e}_6,\mathfrak{e}_7,\mathfrak{e}_8$. This would be an interesting subject of further studies.

(Received 14 November 2005; accepted 10 January 2006; published online 28 February 2006)

In this paper we discuss various aspects of open-closed homotopy algebras (OCHAs) presented in our previous paper, inspired by Zwiebach's open-closed string field theory, but that first paper concentrated on the mathematical aspects. Here we show how an OCHA is obtained by extracting the tree part of Zwiebach's quantum open-closed string field theory. We clarify the explicit relation of an OCHA with Kontsevich's deformation quantization and with the B-models of homological mirror symmetry. An explicit form of the minimal model for an OCHA is given as well as its relation to the perturbative expansion of open-closed string field theory. We show that our open-closed homotopy algebra gives us a general scheme for deformation of open string structures (A_∞ algebras) by closed strings (L_∞ algebras). © *2006 American Institute of Physics.* [DOI: 10.1063/1.2171524]

I. INTRODUCTION

In this paper we discuss various aspects of open-closed homotopy algebras (OCHAs) defined in our previous paper.[35] They are a kind of homotopy algebra inspired by Zwiebach's classical open-closed string field theory[74] and also related to the deformation quantization setup by Kontsevich.[40] In Ref. 35 we showed that an OCHA actually defines a homotopy invariant algebraic structure and also it gives us a general scheme for deformation of open string structures (A_∞ algebras) by closed strings (L_∞ algebras).

As tree closed strings and open strings are related to the conformal plane $\mathbb{C}$ with punctures and the upper half plane H with punctures on the boundary, respectively, tree open-closed strings are related to the upper half plane H with punctures both in the bulk and on the boundary, which appears recently in the context of deformation quantization.[40] In operad theory (see Ref. 53), the relevance of the little disk operad to closed string theory is known. The little interval operad and associahedra are relevant to open string theory. The Swiss-cheese operad,[69] that combines the little disk operad with the little interval operad, also is inspired by Kontsevich's approach to deformation quantization. Our OCHA should be homotopy equivalent to a part of an algebra over the Swiss-cheese operad. It should be very interesting to investigate the remaining structures (see Ref. 23, which is related to this direction).

We first present the definition of OCHAs together with recalling two typical homotopy algebras, A_∞ algebras and L_∞ algebras, in Sec. II.

In Sec. III, we give an alternate interpretation in terms of odd formal vector fields (often called homological vector fields) on a supermanifold, which we believe is a more acceptable description for physicists.

[a)]Electronic mail: kajiura@yukawa.kyoto-u.ac.jp
[b)]Electronic mail: jds@math.upenn.edu

The connection to classical open-closed string field theory by Zwiebach[74] is given in Sec. IV. It is known that classical closed string field theory has an L_∞ structure,[73,66,38] and classical open string field theory has an A_∞ structure.[11,74,55,31] We show that an OCHA is obtained by extracting the tree part of Zwiebach's quantum open-closed string field theory. Since in general homotopy algebras are something whose structures are governed by the underlying tree graph (operad) structure, the structures of quantum string field theories are something beyond the ordinary homotopy algebra (see loop homotopy algebras[50] for quantum closed string field theories). Thus, we can say that OCHAs are the maximal homotopy algebraic structures which string field theories should have. Namely,

$$\text{Quantum open-closed SFT} \supset \text{OCHA} \supset L_\infty \oplus A_\infty.$$

One of the key theorems in homotopy algebra is the minimal model theorem which was proven for A_∞ algebras by Kadeishvili.[30] It holds true also for L_∞ algebras in a similar way, and in our previous paper[35] we stated the minimal model theorem holds for OCHAs, too. In Sec. V we present an explicit way of constructing a minimal model for an OCHA, and explain its relation to the perturbative expansion of classical open-closed string field theory.

Section VI is devoted to explaining some deformation theory aspect of OCHAs. An open-closed homotopy algebra consists of a direct sum of graded vector spaces $\mathcal{H}=\mathcal{H}_c\oplus\mathcal{H}_o$. It has an L_∞ structure on $\mathcal{H}_c$ and reduces to an A_∞ algebra if we set $\mathcal{H}_c=0$. From such a viewpoint, an open-closed homotopy algebra gives a general scheme of deformation of the A_∞ algebra by $\mathcal{H}_c$, where the deformation space is parametrized by a moduli space of the L_∞ algebra on $\mathcal{H}_c$.[35] In Sec. VI A we recall this fact in a more explicit way than Ref. 35. After that, we explain the relation of this viewpoint to various aspects of string theory; Kontsevich's deformation quantization[40] in Sec. VI B, and open-closed B-models (cf. Ref. 26) in Sec. VI C.

II. OPEN-CLOSED HOMOTOPY ALGEBRA

An open-closed homotopy algebra, as we proposed in our previous paper,[35] is a homotopy algebra which combines two typical homotopy algebras, an A_∞ algebra and an L_∞ algebra. There are various equivalent ways of defining and/or describing strong homotopy algebras. In this paper, we shall present them in terms of multivariable operations in this section, and in Sec. III we shall reinterpret them in terms of the supermanifold description. For the equivalent coalgebra description and tree graph description, see Ref. 35. Here we recall just enough so that this paper can be read without having to read Ref. 35. The reader familiar with A_∞ algebras and L_∞ algebras can go directly to Definition 2.8.

We first begin with recalling A_∞ algebras and L_∞ algebras in Sec. II A. The definition of open-closed homotopy algebras are given in Sec. II B. In Sec. II C we define cyclic structures in open-closed homotopy algebras together with explaining some background of such structures.

We restrict our arguments to the case that the characteristic of the field k is zero. We further let $k=\mathbb{C}$ for simplicity.

A. A_∞ algebras and L_∞ algebras

Definition 2.1 [A_∞ *algebra* (*strong homotopy associative algebra*)[64]]: Let $\mathcal{H}_o$ be a $\mathbb{Z}$-graded vector space $\mathcal{H}_o=\oplus_{r\in\mathbb{Z}}\mathcal{H}_o^r$ and suppose that there exists a collection of degree one multilinear maps

$$\mathfrak{m} := \{m_k:(\mathcal{H}_o)^{\otimes k}\to\mathcal{H}_o\}_{k\geqslant 1}.$$

$(\mathcal{H}_o,\mathfrak{m})$ is called an A_∞ *algebra* when the multilinear maps m_k satisfy the following relations:

$$\sum_{k+l=n+1}\sum_{j=0}^{k-1}(-1)^{o_1+\cdots+o_j}m_k(o_1,\ldots,o_j,m_l(o_{j+1},\ldots,o_{j+l}),o_{j+l+1},\ldots,o_n)=0 \tag{2.1}$$

for $n\geqslant 1$, where o_i on (-1) denotes the degree of o_i. A *weak* A_∞ *algebra* $(\mathcal{H}_o,\mathfrak{m})$ consists of a

collection of degree one multilinear maps $\mathfrak{m} := \{m_k : (\mathcal{H}_o)^{\otimes k} \to \mathcal{H}_o\}_{k\geqslant 0}$ satisfying the corresponding relations

$$\sum_{k+l=n+1} \sum_{j=0}^{k-1} (-1)^{o_1+\cdots+o_j} m_k(o_1, \ldots, o_j, m_l(o_{j+1}, \ldots, o_{j+l}), o_{j+l+1}, \ldots, o_n) = 0$$

for $n \geqslant 0$.

Remark 2.2: The definition above is different from the original one[64] in the definition of the degree of the multilinear maps m_k. Both are in fact equivalent and related by *suspension*.[15,53] In Ref. 64, the m_k are multilinear maps on $\downarrow\mathcal{H}_o$ where $(\downarrow\mathcal{H}_o)^{r+1} = \mathcal{H}_o^r$; in algebraic topology the desuspension is denoted by $\downarrow$, which is equivalent to $[-1]$ in the algebraic geometry tradition: $\downarrow\mathcal{H}_o = \mathcal{H}_o[-1]$. Since it might be more familiar also in mathematical physics as in Sec. VI, in this paper we denote the suspension and desuspension by $[1]$ and $[-1]$, respectively.

For an A_∞ algebra $(\mathcal{H}_o, \mathfrak{m})$ (in the case $m_0 = 0$), the first three relations of the A_∞ condition (2.1) are

$$0 = m_1^2,$$

$$0 = m_1(m_2(o_1, o_2)) + m_2(m_1(o_1), o_2) + (-1)^{o_1} m_2(o_1, m_1(o_2)),$$

$$0 = m_1(m_3(o_1, o_2, o_3)) + m_3(m_1(o_1), o_2, o_3) + (-1)^{o_1} m_3(o_1, m_1(o_2), o_3) + (-1)^{o_1+o_2} m_3(o_1, o_2, m_1(o_3))$$

$$+ m_2(m_2(o_1, o_2), o_3) + (-1)^{o_1} m_2(o_1, m_2(o_2, o_3)).$$

The first equation, in the physics terminology, says m_1 is nilpotent; $(\mathcal{H}_o, m_1)$ defines a complex on the $\mathbb{Z}$-graded vector space $\mathcal{H}_o$. The second equation says the differential m_1 satisfies the Leibniz rule for the product m_2. The third equation means the product m_2 is associative up to the term including m_3. Thus, a differential graded algebra (DGA) is described as an A_∞ algebra on $\downarrow\mathcal{H}_o = \mathcal{H}_o[-1]$ with a differential m_1, a product m_2, and $m_3 = m_4 = \cdots = 0$.

Definition 2.3 (A_∞ *morphism*): For two A_∞ algebras $(\mathcal{H}_o, \mathfrak{m})$ and $(\mathcal{H}'_o, \mathfrak{m}')$, suppose that there exists a collection of degree zero (degree preserving) multilinear maps

$$f_k : \mathcal{H}_o^{\otimes k} \to \mathcal{H}'_o, \quad k \geqslant 1.$$

The collection $\{f_k\}_{k\geqslant 1} : (\mathcal{H}_o, \mathfrak{m}) \to (\mathcal{H}'_o, \mathfrak{m}')$ is called an A_∞ *morphism* iff it satisfies the following relations:

$$\sum_{1\leqslant k_1 < k_2 \ldots < k_i = n} m'_i(f_{k_1}(o_1, \ldots, o_{k_1}), f_{k_2-k_1}(o_{k_1+1}, \ldots, o_{k_2}) \cdots f_{n-k_{i-1}}(o_{k_{i-1}+1}, \ldots, o_n))$$
$$= \sum_{k+l=n+1} \sum_{j=0}^{k-1} (-1)^{o_1+\cdots+o_j} f_k(o_1, \ldots, o_j, m_l(o_{j+1}, \ldots, o_{j+l}), o_{j+l+1}, \ldots, o_n) \tag{2.2}$$

for $n \geqslant 1$. If $(\mathcal{H}_o, \mathfrak{m})$ and $(\mathcal{H}'_o, \mathfrak{m}')$ are *weak* A_∞ algebras, then a *weak* A_∞ morphism consists of multilinear maps $\{f_k\}_{k\geqslant 0}$, where $f_0 : \mathbb{C} \to A'$, satisfying the above conditions and in addition

$$f_1 \circ m_0 = \sum m'_k(f_0, \ldots, f_0).$$

As an A_∞ algebra can be thought of as a generalization of a differential graded algebra (DGA), an L_∞ algebra is a generalization of a differential graded Lie algebra (DGLA). As ordinary associative and Lie algebras are related by skew-symmetrization and the universal enveloping construction, there are corresponding relations for A_∞ algebras and L_∞ algebras.[42]

Definition 2.4 (*graded symmetry*): A *graded symmetric multilinear map* of a graded vector

space V to itself is a linear map $f: V^{\otimes n} \to V$ such that, for any $c_i \in V$ $1 \leqslant i \leqslant n$ and any $\sigma \in \mathfrak{S}_n$ (the permutation group of n elements), the relation

$$f(c_1, \ldots, c_n) = (-1)^{\epsilon(\sigma)} f(c_{\sigma(1)}, \ldots, c_{\sigma(n)}) \tag{2.3}$$

holds, where the sign $(-1)^{\epsilon(\sigma)}$ is the Koszul sign of the permutation σ.

Also we adopt the convention that tensor products of functions or operators have the signs built in; e.g., $(f \otimes g)(x \otimes y) = (-1)^{g \cdot x} f(x) \otimes g(y)$.

Definition 2.5 [L_∞ *algebra* (*strong homotopy Lie algebra*)[43]]: Let $\mathcal{H}_c$ be a graded vector space and suppose that a collection of degree one graded symmetric multilinear maps $\mathfrak{l} := \{l_k : \mathcal{H}_c^{\otimes k} \to \mathcal{H}_c\}_{l \geqslant 0}$ is given. $(\mathcal{H}_c, \mathfrak{l})$ is called a *weak* L_∞ *algebra* iff the multilinear maps satisfy the following relations:

$$\sum_{k+l=n+1} \sum_{\sigma \in \mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{l\,!\,(n-l)!} l_k(l_l(c_{\sigma(1)}, \ldots, c_{\sigma(l)}), c_{\sigma(l+1)}, \ldots, c_{\sigma(n)}) = 0 \tag{2.4}$$

for $n \geqslant 0$. If the relation is satisfied for $n \geqslant 1$ without the additional map $l_0 : \mathbb{C} \to \mathcal{H}_c^1 \subset \mathcal{H}_c$, then $(\mathcal{H}_c, \mathfrak{l})$ is called an L_∞ *algebra*.

Remark 2.6: L_∞ algebras are usually defined in a similar but different fashion, where the summation for the permutation $\mathfrak{S}_n$ in Eq. (2.4) is replaced by the summation over the unshuffle permutations (2.3). This unshuffled description would enable us to drop all the symmetrization factors in this paper. However, we take the one with all the permutations since it fits the dual description in the next section.

For an L_∞ algebra $(\mathcal{H}_c, \mathfrak{l})$, the first three relations of the L_∞ condition (2.4) are

$$0 = (l_1)^2,$$

$$0 = l_1(l_2(c_1, c_2)) + l_2(l_1(c_1), c_2) + (-1)^{c_1} l_2(c_1, l_1(c_2)),$$

$$0 = l_1(l_3(c_1, c_2, c_3)) + l_3(l_1(c_1), c_2, c_3) + (-1)^{c_1} l_3(c_1, l_1(c_2), c_3) + (-1)^{c_1 + c_2} l_3(c_1, c_2, l_1(c_3))$$

$$+ l_2(l_2(c_1, c_2), c_3) + (-1)^{c_1(c_2+c_3)} l_2(l_2(c_2, c_3), c_1) + (-1)^{c_3(c_1+c_2)} l_2(l_2(c_3, c_1), c_2).$$

As in the case of an A_∞ algebra, the first equation indicates that $(\mathcal{H}_c, l_1)$ defines a complex, while, after a shift in grading, the second equation implies the differential l_1 satisfies a Leibniz rule with respect to the Lie bracket l_2, and the third equation means the bracket l_2 satisfies the Jacobi identity up to the terms including l_3. Thus, a differential graded Lie algebra is described as an L_∞ algebra on $\downarrow \mathcal{H}_c = \mathcal{H}_c[-1]$ with a differential l_1, a Lie bracket l_2, and $l_3 = l_4 = \cdots = 0$.

Definition 2.7 (L_∞ *morphism*): For two weak L_∞ algebras $(\mathcal{H}_c, \mathfrak{l})$ and $(\mathcal{H}'_c, \mathfrak{l}')$, suppose that there exists a collection of degree zero (degree preserving) graded symmetric multilinear maps

$$f_k : \mathcal{H}_c^{\otimes k} \to \mathcal{H}'_c, \quad l \geqslant 0.$$

Here f_0 is a map from $\mathbb{C}$ to a degree zero subvector space of $\mathcal{H}_c$. The collection $\{f_k\}_{k \geqslant 0} : (\mathcal{H}_c, \mathfrak{l}) \to (\mathcal{H}'_c, \mathfrak{l}')$ is called a *weak* L_∞ *morphism* iff it satisfies the following relations:

$$\sum_{k+l=n+1} \sum_{\sigma \in \mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{l\,!\,(n-l)!} f_k(l_l \otimes \mathbf{1}_c^{\otimes n-l})(c_{\sigma(1)}, \ldots, c_{\sigma(n)}) = \sum_{k_1 + \cdots k_j = n} \sum_{\sigma \in \mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{k_1\,!\,k_2\,!\,\cdots k_j\,!\,\cdot j!} l'_j(f_{k_1} \otimes f_{k_2}$$
$$\otimes \cdots \otimes f_{k_j})(c_{\sigma(1)}, \ldots, c_{\sigma(n)}) \tag{2.5}$$

for $n \geqslant 0$. In particular, when $(\mathcal{H}_c, \mathfrak{l})$ and $(\mathcal{H}'_c, \mathfrak{l}')$ are L_∞ algebras, a weak L_∞ morphism $\{f_k\}_{k \geqslant 0} : (\mathcal{H}_c, \mathfrak{l}) \to (\mathcal{H}'_c, \mathfrak{l}')$ is called an L_∞ *morphism* if in addition $f_0 = 0$.

B. Open-closed homotopy algebra

Definition 2.8 (*open-closed homotopy algebra*[35]): Let $\mathcal{H}=\mathcal{H}_c\oplus\mathcal{H}_o$ be a graded vector space and $(\mathcal{H}_c,\mathfrak{l})$ be a weak L_∞ algebra. Consider a collection of multilinear maps

$$\mathfrak{n} := \{n_{k,l}:(\mathcal{H}_c)^{\otimes k}\otimes(\mathcal{H}_o)^{\otimes l}\to\mathcal{H}_o\}_{k,l\geqslant 0}$$

each of which is graded symmetric on $(\mathcal{H}_c)^{\otimes l}$. We call $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ a *weak open-closed homotopy algebra* (*weak OCHA*) when $\mathfrak{n}$ satisfies the following relations:

$$\begin{aligned}0=&\sum_{p+r=n}\sum_{\sigma\in\mathfrak{S}_n}\frac{(-1)^{\epsilon(\sigma)}}{p!\,r!}n_{1+r,m}(l_p(c_{\sigma(1)},\ldots,c_{\sigma(p)}),c_{\sigma(p+1)},\ldots,c_{\sigma(n)};o_1,\ldots,o_m)\\&+\sum_{p+r=n}\sum_{i+s+j=m}\sum_{\sigma\in\mathfrak{S}_n}\frac{(-1)^{\mu_{p,i}(\sigma)}}{p!\,r!}\\&\times n_{p,i+1+j}(c_{\sigma(1)},\ldots,c_{\sigma(p)};o_1,\ldots,o_i,n_{r,s}(c_{\sigma(p+1)},\ldots,c_{\sigma(n)};o_{i+1},\ldots,o_{i+s}),o_{i+s+1},\ldots,o_m).\end{aligned}\tag{2.6}$$

Here the sign exponent $\mu_{p,i}(\sigma)$ is given explicitly by

$$\mu_{p,i}(\sigma)=\epsilon(\sigma)+(c_{\sigma(1)}+\cdots+c_{\sigma(p)})+(o_1+\cdots+o_i)+(o_1+\cdots+o_i)(c_{\sigma(p+1)}+\cdots+c_{\sigma(n)}),\tag{2.7}$$

corresponding to the signs effected by the interchanges. In particular, if $l_0=n_{0,0}=0$, we call $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ an *open-closed homotopy algebra*. We can also write the defining equation (2.6) in the following shorthand expression:

$$\begin{aligned}0=&\sum_{p+r=n}\sum_{\sigma\in\mathfrak{S}_n}\frac{(-1)^{\epsilon(\sigma)}}{p!\,r!}(-1)^{\epsilon(\sigma)}n_{1+r,m}((l_p\otimes\mathbf{1}_c^{\otimes r}\otimes\mathbf{1}_o^{\otimes m})(c_{\sigma(1)},\ldots,c_{\sigma(n)};o_1,\ldots,o_m))\\&+\sum_{p+r=n}\sum_{i+s+j=m}\sum_{\sigma\in\mathfrak{S}_n}\frac{(-1)^{\epsilon(\sigma)}}{p!\,r!}n_{p,i+1+j}((\mathbf{1}_c^{\otimes p}\otimes\mathbf{1}_o^{\otimes i}\otimes n_{r,s}\otimes\mathbf{1}_o^{\otimes j})(c_{\sigma(1)},\ldots,c_{\sigma(n)};o_1,\ldots,o_m)),\end{aligned}$$

where the complicated sign is absorbed into this expression.

Remark 2.9: For an OCHA $(\mathcal{H},\mathfrak{l},\mathfrak{n})$, the substructure $(\mathcal{H}_c,\mathfrak{l})$ is by definition an L_∞ algebra and $(\mathcal{H}_o,\{n_{0,k}\})$ forms an A_∞ algebra. Furthermore, the substructure $(\mathcal{H},\{n_{1,q}\}_{q\geqslant 0})$ forms an A_∞ module over the A_∞ algebra $(\mathcal{H}_o,\mathfrak{m})$ in the sense of Refs. 49 and 67. Also, if $n_{p,0}=0$ for all $p\geqslant 1$, the substructure $(\mathcal{H},\{n_{p,1}\})$ makes $\mathcal{H}_o$ an L_∞ module over $(\mathcal{H}_c,\mathfrak{l})$.[42]

Now, let us denote $l_1=d_c$ and $n_{0,1}=d_o$. The first few relations which do not appear as A_∞ or L_∞ conditions are

$$0=d_on_{1,0}+n_{1,0}d_c,\tag{2.8}$$

$$0=d_on_{1,1}(c;o)+n_{1,1}(c;d_o(o))+n_{1,1}(d_c(c);o)+n_{0,2}(n_{1,0}(c),o)+(-1)^{c(o+1)}n_{0,2}(o,n_{1,0}(c)),\tag{2.9}$$

$$\begin{aligned}0=&d_on_{2,0}(c_1,c_2)+n_{2,0}(d_c(c_1),c_2)+(-1)^{c_1c_2}n_{2,0}(d_c(c_2),c_1)+n_{1,0}l_2(c_1,c_2)+(-1)^{c_1}n_{1,1}(c_1,n_{1,0}(c_2))\\&+(-1)^{c_2(1+c_1)}n_{1,1}(c_2,n_{1,0}(c_1)),\end{aligned}\tag{2.10}$$

$$0 = d_o n_{1,2}(c;o_1,o_2) + n_{1,2}(d_c(c);o_1,o_2) + (-1)^c n_{1,2}(c;d_o(o_1),o_2) + (-1)^{c+o_1} n_{1,2}(c;o_1,d_o(o_2))$$
$$+ n_{1,1}(c,n_{0,2}(o_1,o_2)) + n_{0,2}(n_{1,1}(c;o_1),o_2) + (-1)^{o_1(1+c)} n_{0,2}(o_1,n_{1,1}(c,o_2)) + n_{0,3}(n_{1,0}(c),o_1,o_2)$$
$$+ (-1)^{o_1(1+c)} n_{0,3}(o_1,n_{1,0}(c),o_2) + (-1)^{(o_1+o_2)(1+c)} n_{0,3}(o_1,o_2,n_{1,0}(c)), \tag{2.11}$$

$$0 = d_o n_{2,1}(c_1,c_2;o) + n_{2,1}(d_c(c_1),c_2;o) + (-1)^{c_1} n_{2,1}(c_1,d_c(c_2);o) + (-1)^{c_1+c_2} n_{2,1}(c_1,c_2;d_o(o))$$
$$+ n_{1,1}(l_2(c_1,c_2);o) + + (-1)^{c_1} n_{1,1}(c_1;n_{1,1}(c_2;o)) + (-1)^{c_2(c_1+1)} n_{1,1}(c_2;n_{1,1}(c_1;o))$$
$$+ n_{0,2}(n_{2,0}(c_1,c_2),o) + (-1)^{o(1+c_1+c_2)} n_{0,2}(o,n_{2,0}(c_1,c_2)) + (-1)^{c_2(1+c_1)} n_{1,2}(c_2;n_{1,0}(c_1),o)$$
$$+ (-1)^{(c_2+o)(1+c_1)} n_{1,2}(c_2;o,n_{1,0}(c_1)) + (-1)^{c_1} n_{1,2}(c_1;n_{1,0}(c_2),o)$$
$$+ (-1)^{c_1+o(1+c_2)} n_{1,2}(c_1;o,n_{1,0}(c_2)), \quad \dots . \tag{2.12}$$

Equation (2.8) implies $n_{1,0}$ is a chain map by an appropriate relative shift of the grading. On the other hand, in the case $n_{0,1}=0$, Eq. (2.9) is an extended Leibniz rule. Suppose that we have an OCHA with only nonzero structures $d_c, d_o, l_2, n_{1,1}, m_2 := n_{0,2}$. In Eq. (2.11) only the second line survives, which means that $\mathcal{H}_c$ acts on an algebra $(\mathcal{H}_o, m_2)$ by $n_{1,1}$ as derivations. Furthermore, in Eq. (2.12) only the second line survives, which implies that $\mathcal{H}_o$ represents a Lie algebra $(\mathcal{H}_c, l_2)$. Then $(\mathcal{H}, d_c, d_o, l_2, n_{1,1}, m_2)$ forms what is called a $\mathfrak{g}$ algebra or Leibniz pair (see Ref. 35 and references there).

Definition 2.10 (*open-closed homotopy algebra morphism*): For two weak OCHAs $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$ and $(\mathcal{H}', \mathfrak{l}', \mathfrak{n}')$, consider a collection $\mathfrak{f}$ of degree zero (degree preserving) multilinear maps

$$f_k : (\mathcal{H}_c)^{\otimes k} \to \mathcal{H}'_c \quad \text{for } k \geqslant 0,$$

$$f_{k,l} : (\mathcal{H}_c)^{\otimes k} \otimes (\mathcal{H}_o)^{\otimes l} \to \mathcal{H}'_o \quad \text{for } k,l \geqslant 0,$$

where f_k and $f_{k,l}$ are graded symmetric with respect to $(\mathcal{H}_c)^{\otimes k}$. We call $\mathfrak{f} : (\mathcal{H}, \mathfrak{l}, \mathfrak{n}) \to (\mathcal{H}', \mathfrak{l}', \mathfrak{n}')$ a *weak OCHA morphism* when $\{f_k\}_{k\geqslant 0} : (\mathcal{H}_c, \mathfrak{l}) \to (\mathcal{H}'_c, \mathfrak{l}')$ is a weak L_∞ morphism and $\{f_{k,l}\}_{k,l\geqslant 0}$ further satisfies the following relations:

$$\sum_{p+r=n} \sum_{\sigma\in\mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{p!\,r!} f_{1+r,m}((l_p \otimes \mathbf{1}_c^{\otimes r} \otimes \mathbf{1}_o^{\otimes m})(c_{\sigma(1)}, \dots, c_{\sigma(n)}; o_1, \dots, o_m))$$
$$+ \sum_{p+r=n} \sum_{i+s+j=m} \sum_{\sigma\in\mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{p!\,r!} f_{p,i+1+j}((\mathbf{1}_c^{\otimes p} \otimes \mathbf{1}_o^{\otimes i} \otimes n_{r,s} \otimes \mathbf{1}_o^{\otimes j})(c_{\sigma(1)}, \dots, c_{\sigma(n)}; o_1, \dots, o_m))$$
$$= \sum_{\substack{(r_1+\cdots+r_i)+(p_1+\cdots+p_j)=n \\ (q_1+\cdots+q_j)=m}} \sum_{\sigma\in\mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{i!\,(r_1!\cdots r_i!)(p_1!\cdots p_j!)} n'_{i,j}((f_{r_1} \otimes \cdots \otimes f_{r_i} \otimes f_{p_1,q_1}$$
$$\otimes \cdots \otimes f_{p_j,q_j})(c_{\sigma(1)}, \dots, c_{\sigma(n)}; o_1, \dots, o_m)). \tag{2.13}$$

The right-hand side is written explicitly as

$$n'_{i,j}((f_{r_1} \otimes \cdots \otimes f_{r_i} \otimes f_{p_1,q_1} \otimes \cdots \otimes f_{p_j,q_j})(c_{\sigma(1)}, \dots, c_{\sigma(n)}; o_1, \dots, o_m))$$
$$= (-1)^{\tau_{\vec{p},\vec{q}}(\sigma)} n'_{i,j}(f_{r_1}(c_{\sigma(1)}, \dots, c_{\sigma(r_1)}), \dots, f_{r_i}(c_{\sigma(\bar{r}_{i-1}+1)}, \dots, c_{\sigma(\bar{r}_i)});$$
$$\times f_{p_1,q_1}(c_{\sigma(\bar{r}_i+1)}, \dots, c_{\sigma(\bar{p}_1)}; o_1, \dots, o_{q_1}), \dots, f_{p_j,q_j}(c_{\sigma(\bar{p}_{j-1}+1)}, \dots, c_{\sigma(\bar{p}_j)}; o_{\bar{q}_{j-1}+1}, \dots, o_{\bar{q}_j})),$$

where $\bar{r}_k := r_1 + \cdots + r_k$, $\bar{p}_k := \bar{r}_i + p_1 + \cdots + p_k$, $\bar{q}_k := q_1 + \cdots + q_k$ and $\tau_{\vec{p},\vec{q}}(\sigma)$ is given by

$$\tau_{\vec{p},\vec{q}}(\sigma) = \sum_{k=1}^{j-1} (c_{\sigma(\bar{p}_k+1)} + \cdots + c_{\sigma(\bar{p}_{k+1})})(o_1 + \cdots + o_{\bar{q}_k}).$$

In particular, if $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ and $(\mathcal{H}',\mathfrak{l}',\mathfrak{n}')$ are OCHAs and if $f_0=f_{0,0}=0$, we call it an *OCHA morphism*.

Definition 2.11 (*quasi-isomorphism*): Suppose that two OCHAs $(\mathcal{H},\mathfrak{l},\mathfrak{n})$, $(\mathcal{H}',\mathfrak{l}',\mathfrak{n}')$ and an OCHA morphism $\mathfrak{f}:(\mathcal{H},\mathfrak{l},\mathfrak{n})\to(\mathcal{H}',\mathfrak{l}',\mathfrak{n}')$ are given. $\mathfrak{f}$ is called an *open-closed homotopy algebra quasi-isomorphism* if $f_1:\mathcal{H}_c\to\mathcal{H}_c'$ induces an isomorphism between the cohomology spaces of the complexes $(\mathcal{H}_c,l_1)$ and $(\mathcal{H}_c',l_1')$, and further $f_{0,1}:\mathcal{H}_o\to\mathcal{H}_o'$ induces an isomorphism between the cohomology spaces of the complexes $(\mathcal{H}_o,n_{0,1})$ and $(\mathcal{H}_o',n_{0,1}')$. In particular, if $f_1$and $f_{0,1}$ are isomorphisms, we call $\mathfrak{f}$ an open-closed homotopy algebra isomorphism.

C. Cyclic structures in OCHAs

Now we consider an additional structure, cyclicity, (cf. Ref. 16) on open-closed homotopy algebras. It is defined in terms of constant symplectic inner products. The string theory motivation for this additional structure is that punctures on the boundary of the disk inherit a cyclic order from the orientation of the disk and the operations are to respect this cyclic structure, just as the L_∞ structure reflects the symmetry of the punctures in the interior of the disk or on the sphere. Alternatively, a typical Lagrangian of a (quantum) field theory originally has such structure and in particular in the Batalin-Vilkovisky (BV) formalism,[3,4] such structure is defined in terms of an odd (degree minus one) symplectic structure on the corresponding supermanifold.[3,62,1,33] Both pictures are then combined with each other in string field theory as discussed in Sec. IV.

From such background, in Ref. 33 a "cyclicity" is defined for A_∞ algebras in terms of a degree minus one constant symplectic inner product, and it is shown that homotopy invariant properties of A_∞ algebras hold true also in the category of cyclic A_∞ algebras. However, in string theory or in particular topological string theory, there often exist cyclic structures defined by inner products having some different degree. For the arguments on homotopy invariant properties in Ref. 33, the degree of the inner product is not essential. Thus, we define cyclic structures with constant symplectic inner products of arbitrary fixed integer degrees.

Definition 2.12 (*constant symplectic structure*): Bilinear maps, $\omega_c:\mathcal{H}_c\otimes\mathcal{H}_c\to\mathbb{C}$ and $\omega_o:\mathcal{H}_o\otimes\mathcal{H}_o\to\mathbb{C}$, are called *constant symplectic structures* when they have fixed integer degrees $|\omega_c|,|\omega_o|\in\mathbb{Z}$ and are nondegenerate and skew-symmetric. Here skew-symmetric indicates that

$$\omega_c(c_2,c_1)=-(-1)^{c_1c_2}\omega_c(c_1,c_2),\quad \omega_o(o_2,o_1)=-(-1)^{o_1o_2}\omega_o(o_1,o_2)$$

for any $c_1,c_2\in\mathcal{H}_c$, $o_1,o_2\in\mathcal{H}_o$, and the degree of ω_c,ω_o implies that $\omega_c(c_1,c_2)=0$ except for $\deg(c_1)+\deg(c_2)+|\omega_c|=0$ and $\omega_o(o_1,o_2)=0$ except for $\deg(o_1)+\deg(o_2)+|\omega_o|=0$. We further denote the constant symplectic structure on $\mathcal{H}=\mathcal{H}_c\oplus\mathcal{H}_o$ by $\omega:=\omega_c\oplus\omega_o$.

Suppose that an open-closed homotopy algebra $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ is equipped with constant symplectic structures $\omega_c:\mathcal{H}_c\otimes\mathcal{H}_c\to\mathbb{C}$ and $\omega_o:\mathcal{H}_o\otimes\mathcal{H}_o\to\mathbb{C}$ as in Definition 2.12.

For $\{l_k\}_{k\geqslant 1}$ and $\{n_{p,q}\}_{p+q\geqslant 1}$, let us define two kinds of multilinear maps by

$$\mathcal{V}_{k+1}=\omega_c(l_k\otimes\mathbf{1}_c):(\mathcal{H}_c)^{\otimes(k+1)}\to\mathbb{C},\quad \mathcal{V}_{p,q+1}=\omega_o(n_{p,q}\otimes\mathbf{1}_o):(\mathcal{H}_c)^{\otimes p}\otimes(\mathcal{H}_o)^{\otimes(q+1)}\to\mathbb{C}$$

or more explicitly

$$\mathcal{V}_{k+1}(c_1,\ldots,c_{k+1})=\omega_c(l_k(c_1,\ldots,c_k),c_{k+1})$$

and

$$\mathcal{V}_{p,q+1}(c_1,\ldots,c_p;o_1,\ldots,o_{q+1})=\omega_o(n_{p,q}(c_1,\ldots,c_p;o_1,\ldots,o_q),o_{q+1}).$$

The degree of $\mathcal{V}_{k+1}$ and $\mathcal{V}_{p,q+1}$ are $|\omega_c|+1$ and $|\omega_o|+1$. Note that the degrees of $\mathcal{V}_{k+1}$ and $\mathcal{V}_{p,q+1}$ are zero when they come from odd constant symplectic structures $|\omega_c|=|\omega_o|=-1$.

Definition 2.13 (*cyclic open-closed homotopy algebra*): An open-closed homotopy algebra $(\mathcal{H},\omega,\mathfrak{l},\mathfrak{n})$ is called a *cyclic open-closed homotopy algebra* (COCHA) when $\mathcal{V}_{k+1}$ is graded symmetric with respect to any permutation of $(\mathcal{H}_c)^{\otimes(k+1)}$ and $\mathcal{V}_{p,q+1}$ has cyclic symmetry with respect to cyclic permutations of $(\mathcal{H}_o)^{\otimes(q+1)}$, that is, if

$$\mathcal{V}_{k+1}(c_1,\ldots,c_{k+1}) = (-1)^{\epsilon(\sigma)}\mathcal{V}_{k+1}(c_{\sigma(1)},\ldots,c_{\sigma(k+1)}), \quad \sigma \in \mathfrak{S}_{k+1}$$

and

$$\mathcal{V}_{p,q+1}(c_1,\ldots,c_p;o_1,\ldots,o_{q+1}) = (-1)^{o_1(o_2+\cdots+o_{q+1})}\mathcal{V}_{k+1,l}(c_1,\ldots,c_p;o_2,\ldots,o_{q+1},o_1).$$

The graded commutativity of $\mathcal{V}_{p,q+1}$ with respect to permutations of $(\mathcal{H}_c)^{\otimes p}$, that is,

$$\mathcal{V}_{p,q+1}(c_1,\ldots,c_p;o_1,\ldots,o_{q+1}) = (-1)^{\epsilon(\sigma)}\mathcal{V}_{p,q+1}(c_{\sigma(1)},\ldots,c_{\sigma(p)};o_1,\ldots,o_{q+1}), \quad \sigma \in \mathfrak{S}_p$$

automatically holds by the definition of $\mathfrak{n}$.

Note also that there are many situations where the inner products exist only for open strings. This is the case for the topological string situation in the B-model we will discuss later in Sec. VI C. For instance, on the topological open string side, there often exists a natural inner product coming essentially from an integral (trace) of products of two differential forms. The inner products of this kind in fact turn out to be skew-symmetric (symplectic) in our suspended notation (see Ref. 34). See also Ref. 57 for more general cyclic structures including nonskew inner products.

On the other hand, if we have ω_c and ω_o, nondegenerate inner products in both open and closed string sides, we can identify $\mathcal{H}$ with its linear dual, then reverse the process and define further maps

$$r_{p-1,q+1}:(\mathcal{H}_c)^{\otimes(p-1)} \otimes (\mathcal{H}_o)^{\otimes(q+1)} \to \mathcal{H}_c$$

with relations amongst themselves and with the operations already defined, which can easily be deduced from their definition. In particular, for $n_{1,0}:\mathcal{H}_c \to \mathcal{H}_o$ we have $r_{0,1}:\mathcal{H}_o \to \mathcal{H}_c$. Namely, for the cyclic case the fundamental object is the multilinear map $\mathcal{V}_{p,q+1}$ where $n_{p,q}$ and $r_{p-1,q+1}$ are equivalent under the relation above.

Physically, the multilinear map $\mathcal{V}_{p,q+1}$ is related to the (scattering) amplitudes of a disk with p closed strings and $(q+1)$ open strings insertions. Choosing an open string state as a root edge instead of a closed string state, that is, taking $n_{p,q}$ instead of $r_{p-1,q+1}$, for defining an OCHA is related to a standard compactification of the moduli spaces of the corresponding Riemann surface [a disk with p points interior and $(q+1)$ points on the boundary]. Also, in the next section we shall see that, due to this choice of the root edge, the OCHA structure $(\mathfrak{l},\mathfrak{n})$ can be singled out to be an odd vector field on the appropriate supermanifold.

Remark 2.14(*Category version*): As an A_∞ category is defined as a straightforward extension of an A_∞ algebra,[9] one can extend our open-closed homotopy algebra to its category version by replacing $\mathcal{H}_o$ by the space of morphisms of a category. This category extension corresponds to considering many D-branes on which open strings end. This is important for applying OCHAs to topological string theory, see Sec. VI C.

III. THE DUAL SUPERMANIFOLD DESCRIPTION

A. OCHAs and odd formal vector fields

For a graded vector space $\mathcal{H}=\mathcal{H}_c\oplus\mathcal{H}_o$, denote by $\{\mathbf{e}_{c,i}\}$ a basis of $\mathcal{H}_c$ and by $\{\mathbf{e}_{o,i}\}$ a basis of $\mathcal{H}_o$. For each $\mathbf{e}_{c,i}\in\mathcal{H}_c$ represent the dual base as ψ^i and similarly the dual base of $\mathbf{e}_{o,i}\in\mathcal{H}_o$ as ϕ^i. We set the degree of the dual basis by $\deg(\psi^i)=-\deg(\mathbf{e}_{c,i})$ and $\deg(\phi^i)=-\deg(\mathbf{e}_{o,i})$. We consider the formal power series ring in the variables $\{\phi^i\}$, $\{\psi^i\}$, and $\{\phi^i\}\sqcup\{\psi^i\}$, and denote them by $C(\phi)$, $C(\psi)$, and $C(\psi,\phi)$, respectively. We define $\{\psi^i\}$ to be associative and graded commutative and $\{\phi^i\}$ to be associative but noncommutative. More precisely, in the space of the formal power series of associative fields $\{\phi^i\}\sqcup\{\psi^i\}$, an element in $\{\psi^i\}$ is graded commutative with respect to all elements. Therefore, any element in $C(\psi,\phi)$ is represented as

$$a(\psi,\phi) = \sum_{k,l} a_{i_1\cdots i_k;j_1\cdots j_l}(\phi^{j_l}\cdots\phi^{j_1})(\psi^{i_k}\cdots\psi^{i_1}), \tag{3.1}$$

where the coefficient $a_{i_1\cdots i_k;j_1\cdots j_l}\in\mathbb{C}$ is graded symmetric with respect to $i_1\cdots i_k$. We can call

$(\mathcal{H}, C(\phi,\psi))$ the *formal supermanifold*[1,40] corresponding to an OCHA $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$. Though usually the term super indicates $\mathbb{Z}_2$ graded, we use it for $\mathbb{Z}$ graded objects. On the other hand, an A_∞ algebra is described on a formal noncommutative supermanifold $(\mathcal{H}_o, C(\phi))$,[31,33] and an L_∞ algebra is described on a formal graded commutative supermanifold $(\mathcal{H}_c, C(\psi))$.

For a weak OCHA $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$, express the collection of multilinear maps

$$l_k : (\mathcal{H}_c)^{\otimes k} \to \mathcal{H}_c, \quad n_{k,l} : (\mathcal{H}_c)^{\otimes k} \otimes (\mathcal{H}_o)^{\otimes l} \to \mathcal{H}_o,$$

in terms of the bases,

$$l_k(\mathbf{e}_{c,i_1}, \ldots, \mathbf{e}_{c,i_k}) = \mathbf{e}_{c,j} c^j_{i_1 \cdots i_k}, \quad c^j_{i_1 \cdots i_k} \in \mathbb{C},$$

$$n_{k,l}(\mathbf{e}_{c,i_1}, \ldots, \mathbf{e}_{c,i_k}; \mathbf{e}_{o,j_1}, \ldots, \mathbf{e}_{o,j_l}) = \mathbf{e}_{o,j} c^j_{i_1 \cdots i_k; j_1 \cdots j_l}, \quad c^j_{i_1 \cdots i_k; j_1 \cdots j_l} \in \mathbb{C}.$$

Correspondingly, let us define an odd formal vector field $\delta := \delta_S + \delta_D : C(\phi,\psi) \to C(\phi,\psi)$, where

$$\delta_S = \frac{\overleftarrow{\partial}}{\partial \psi^j} c^j(\psi) = \sum_{k \geqslant 0} \frac{1}{k!} \frac{\overleftarrow{\partial}}{\partial \psi^j} c^j_{i_1 \cdots i_k} \psi^{j_k} \cdots \psi^{j_1}, \quad c^j(\psi) \in C(\psi),$$

$$\delta_D = \frac{\overleftarrow{\partial}}{\partial \phi^j} c^j(\phi,\psi) = \sum_{k+l \geqslant 0} \frac{1}{k!} \frac{\overleftarrow{\partial}}{\partial \phi^j} c^j_{i_1 \cdots i_k; j_1 \cdots j_l} (\phi^{j_l} \cdots \phi^{j_1})(\psi^{j_k} \cdots \psi^{j_1}), \quad c^j(\phi,\psi) \in C(\phi,\psi). \tag{3.2}$$

We use right derivatives just for the sign problem; it is easy to relate this dual supermanifold description to the convention in the preceding section. Since $\mathfrak{l}$ and $\mathfrak{n}$ have degree one, δ also has degree one.

It acts on $C(\phi,\psi)$ as follows:

$$\begin{aligned} \delta(a(\phi,\psi)) = & \sum_{k,l} a_{i_1 \cdots i_k; j_1 \cdots j_l} \sum_{s=1}^{k} (-1)^{\beta_S(s-1)} (\phi^{j_l} \cdots \phi^{j_1})(\psi^{j_k} \cdots \delta_S(\psi^{j_s}) \cdots \psi^{j_1}) \\ & + \sum_{k,l} a_{i_1 \cdots i_k; j_1 \cdots j_l} \sum_{t=1}^{l} (-1)^{\beta_D(t-1)} (\phi^{j_l} \cdots \delta_D(\phi^{j_t}) \cdots \phi^{j_1})(\psi^{j_k} \cdots \psi^{j_1}), \end{aligned} \tag{3.3}$$

where $\delta_D(\phi^{j_t}) = c^{j_t}(\phi,\psi)$ and $\delta_S(\psi^{j_s}) = c^{i_s}(\psi)$. Then, $\beta_S(s-1)$ (respectively, $\beta_D(t-1)$) is the sign arising when δ_S (respectively, δ_D) acts from the right and passes the corresponding superfields and is given explicitly by

$$\beta_S(s-1) = \mathbf{e}_{c,i_1} + \cdots + \mathbf{e}_{c,i_{s-1}}, \quad \beta_D(t-1) = (\mathbf{e}_{c,i_1} + \cdots + \mathbf{e}_{c,i_k}) + \mathbf{e}_{o,j_1} + \cdots + \mathbf{e}_{o,j_{t-1}}.$$

The above $\delta(a(\phi,\psi))$ is further rewritten; in the first line ψ's in $\delta_D(\phi^{j_t})$ are brought to the right of ϕ's, and ψ's on each line of Eq. (3.3) are treated as graded symmetric. The $\delta(a(\phi,\psi))$ is expressed in the form in Eq. (3.1) again but with a different coefficient. In the supermanifold language, δ is called an (odd) *formal vector field* on the formal supermanifold. A formal manifold with such a δ is called a *Q-manifold* in Ref. 1 if $Q = \delta$ with $Q^2 = 0$.

Lemma 3.1: *The condition that* $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$ *is a weak OCHA is equivalent to*

$$(\delta)^2 = 0. \tag{3.4}$$

In particular, δ *defines an OCHA if the* $k=0$ *part of* δ_S *and* $k=l=0$ *part of* δ_D *in Eq.* (3.2) *are absent or zero.*

The equation above can be expanded as $(\delta_S)^2+[\delta_S,\delta_D]+(\delta_D)^2=0$, where $[\delta_S,\delta_D]=\delta_S(\delta_D)+\delta_D(\delta_S)$, $\delta_S(\delta_D)=(\overleftarrow{\partial}/\partial\phi^j)(\delta_S(c^j(\phi,\psi)))$. Note that $\delta_D(\delta_S)$ vanishes since δ_S does not include ϕ. Furthermore, one can see that

$$(\delta_S)^2=0, \quad \delta_S(\delta_D)+(\delta_D)^2=0$$

hold independently. The first one is just the dual of the L_∞ condition (2.4), and the second one is the dual description of the OCHA condition (2.6). The pair of the equations above can also be thought of as a deformation of δ_S by $\delta_S+\delta_D$, though we do not discuss this type of deformation in this paper.

A (weak) OCHA morphism in Definition 2.10 can also be rewritten in the same way. For the collection $\mathfrak{f}$ of degree zero multilinear maps,

$$f_l:(\mathcal{H}_c)^{\otimes l}\to\mathcal{H}'_c, \quad f_{k,l}:(\mathcal{H}_c)^{\otimes k}\otimes(\mathcal{H}_o)^{\otimes l}\to\mathcal{H}'_o,$$

let us now express f_k and $f_{k,l}$ as

$$f_k(\mathbf{e}_{c,i_1},\ldots,\mathbf{e}_{c,i_k})=\mathbf{e}_{c,j'}f^{j'}_{i_1\cdots i_k}, \quad f^{j'}_{i_1\cdots i_k}\in\mathbb{C},$$

$$f_{k,l}(\mathbf{e}_{c,i_1},\ldots,\mathbf{e}_{c,i_k};\mathbf{e}_{o,j_1},\ldots,\mathbf{e}_{o,j_l})=\mathbf{e}_{o,j'}f^{j'}_{i_1\cdots i_k;j_1\cdots j_l}, \quad f^{j'}_{i_1\cdots i_k;j_1\cdots j_l}\in\mathbb{C}. \tag{3.5}$$

They define the following coordinate transformation between the two supermanifolds $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ and $(\mathcal{H}',\mathfrak{l}',\mathfrak{n}')$:

$$\psi^{j'}=\mathfrak{f}^{j'}_*(\psi)=f^{j'}+f^{j'}_i\psi^i+f^{j'}_{i_1i_2}\psi^{i_2}\psi^{i_1}+\cdots+f^{j'}_{i_1\cdots i_n}\psi^{i_n}\cdots\psi^{i_1}+\cdots,$$

$$\phi^{j'}=\mathfrak{f}^{j'}_*(\phi,\psi)=\sum_{k,l\geqslant 0}f^{j'}_{i_1\cdots i_k;j_1\cdots j_l}(\phi^{j_l}\cdots\phi^{j_1})(\psi^{j_k}\cdots\psi^{j_1}). \tag{3.6}$$

This induces a pullback from $C(\phi',\psi')$ to $C(\phi,\psi)$,

$$\mathfrak{f}^*(a(\phi',\psi'))=a(\mathfrak{f}_*(\phi,\psi),\mathfrak{f}_*(\psi)),$$

where $\{\phi^i\}$ and $\{\phi^{i'}\}$ are the coordinates on $\mathcal{H}$ and $\mathcal{H}'$, respectively.

Lemma 3.2: *The condition that this* $\mathfrak{f}$ *is a weak OCHA morphism is then that the map between two formal supermanifolds* $\mathfrak{f}_*$ *is compatible with the actions of* δ *and* δ' *on both sides, that is,*

$$\mathfrak{f}^*\delta'(a(\phi',\psi'))=\delta\mathfrak{f}^*a(\phi',\psi') \tag{3.7}$$

holds for any $a(\phi',\psi')\in C(\phi',\psi')$. *In other words,* $\mathfrak{f}_*$ *is a morphism between Q manifolds. If in addition* $f^{j'}=f^{j'}_{\emptyset;\emptyset}=0$, $\mathfrak{f}_*$ *preserves the origin of the formal supermanifolds.* $\mathfrak{f}_*$ *is then an OCHA morphism in the situation that both* δ *and* δ' *define OCHAs.*

All these structures in the supermanifold description are dual to the coalgebra description explained in Ref. 35 in the following sense (see Ref. 33 for the A_∞ case). Let us introduce natural pairings

$$\langle\psi^i|\mathbf{e}_{c,j}\rangle=\delta^i_j, \quad \langle\phi^i|\mathbf{e}_{o,j}\rangle=\delta^i_j$$

and also the extended pairings

$$\langle(\phi^{j_l}\cdots\phi^{j_1})(\psi^{j_k}\cdots\psi^{j_1})|(\mathbf{e}_{c,i'_1}\cdots\mathbf{e}_{c,i'_k})\otimes(\mathbf{e}_{o,j'_1}\cdots\mathbf{e}_{o,j'_l})\rangle=\epsilon^{i_1\cdots i_k}_{i'_1\cdots i'_k}\delta^{j_1}_{j'_1}\cdots\delta^{j_k}_{j'_k}$$

for $k+l>1$, where $\epsilon^{i_1\cdots i_k}_{i'_1\cdots i'_k}:=\Sigma_{\sigma\in\mathfrak{S}_k}\epsilon(\sigma)\delta^{i_{\sigma(1)}}_{i'_1}\cdots\delta^{i_{\sigma(k)}}_{i'_k}$. We set the pairing to be zero if the number of elements ψ/ϕ and $\mathbf{e}_c/\mathbf{e}_o$ does not coincide. The space spanned by $(\mathbf{e}_{c,i_1}\cdots\mathbf{e}_{c,i_k})\otimes(\mathbf{e}_{o,j_1}\cdots\mathbf{e}_{o,j_l})$, $k+l\geqslant 1$, is what is denoted $C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)$ in Ref. 35. As the adjoint of the product on $C(\psi,\phi)$, a

coproduct $\Delta: C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)\to (C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o))\otimes (C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o))$ is defined; for $a,b \in C(\psi,\phi)$ and $x\in C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)$,

$$\langle b\cdot a|x\rangle = \sum_i \langle a|x_i^+\rangle\cdot\langle b|x_i^-\rangle, \quad \Delta := \sum_i (x_i^+\otimes x_i^-).$$

Thus, $C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)$ forms a coalgebra. Then, a codifferential $\mathfrak{l}+\mathfrak{n}: C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)\to C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)$ is given as the adjoint of $\delta=\delta_S+\delta_D$,

$$\langle a|(\mathfrak{l}+\mathfrak{n})(x)\rangle := \langle \delta(a)|x\rangle.$$

In a similar way, a coalgebra homomorphism $\mathfrak{f}: C(\mathcal{H}_c)\otimes T^c(\mathcal{H}_o)\to C(\mathcal{H}_c')\otimes T^c(\mathcal{H}_o')$ is obtained as the adjoint of the pullback $\mathfrak{f}^*: C(\phi',\psi')\to C(\phi,\psi)$. Thus, the coalgebra description given in Ref. 35 is obtained as the dual of the algebra description in terms of formal power series on supermanifolds.

B. Cyclicity and constant symplectic and/or Poisson structures

Next, we discuss the cyclicity (Definition 2.13). If cyclicity is imposed on the ϕ^i's, we indicate that by $C(\phi)_{\mathrm{cyc}}$ or $C(\phi,\psi)_{\mathrm{cyc}}$. Any element of $C(\phi,\psi)_{\mathrm{cyc}}\subset C(\phi,\psi)$ is represented in the form in Eq. (3.1) but the coefficient $a_{i_1\cdots i_k;j_1\cdots j_l}$ is in addition graded cyclic symmetric with respect to the indices $j_1\cdots j_l$. On this algebra, a constant Poisson structure is introduced naturally by dualizing the constant symplectic structures in Definition 2.12.

Definition 3.3 (*constant Poisson structure*): Suppose $\mathcal{H}_c$ and $\mathcal{H}_o$ have constant symplectic structures $\omega_c:\mathcal{H}_c\otimes\mathcal{H}_c\to\mathbb{C}$ and $\omega_o:\mathcal{H}_o\otimes\mathcal{H}_o\to\mathbb{C}$ (Definition 2.12). The corresponding Poisson brackets are denoted by

$$(\ ,\ )_c = \frac{\overleftarrow{\partial}}{\partial\phi^i}\omega_c^{ij}\frac{\overrightarrow{\partial}}{\partial\phi^j}, \quad (\ ,\ )_o = \frac{\overleftarrow{\partial}}{\partial\phi^i}\omega_o^{ij}\frac{\overrightarrow{\partial}}{\partial\phi^j}.$$

Here $\omega_c^{ij}\in\mathbb{C}$ and $\omega_o^{ij}\in\mathbb{C}$ are the inverse matrices of $\omega_{c,ij}:=\omega_c(\mathbf{e}_{c,i},\mathbf{e}_{c,j})$ and $\omega_{o,ij}:=\omega_o(\mathbf{e}_{o,i},\mathbf{e}_{o,j})$. That is, $\omega_{c,ij}\omega_c^{jk}=\omega_c^{kj}\omega_{c,ji}=\delta_i^k$ and $\omega_{o,ij}\omega_o^{jk}=\omega_o^{kj}\omega_{o,ji}=\delta_i^k$ hold. Thus $(\ ,\ )_c$ is a graded Poisson bracket for a graded commutative algebra and $(\ ,\ )_o$ is a Poisson bracket for the cyclic algebra as in Ref. 31. $C(\psi)_{\mathrm{cyc}}$ and $C(\phi)_{\mathrm{cyc}}$ form graded Poisson algebras with Poisson brackets $(\ ,\ )_c$ and $(\ ,\ )_o$, respectively. Furthermore, these two Poisson brackets can be combined naturally and extended to one on $C(\phi,\psi)_{\mathrm{cyc}}$.

A COCHA (Definition 2.13) is dualized as follows. For the collection of multilinear maps $\mathcal{V}_k$ and $\mathcal{V}_{k,l}$, let us define their coefficients by

$$\mathcal{V}_k(\mathbf{e}_{c,i_1},\ldots,\mathbf{e}_{c,i_k}) := \mathcal{V}_{i_1\cdots i_k}\in\mathbb{C}, \quad \mathcal{V}_{k,l}(\mathbf{e}_{c,i_1},\ldots,\mathbf{e}_{c,i_k};\mathbf{e}_{o,j_1},\ldots,\mathbf{e}_{o,j_l}) := \mathcal{V}_{i_1\cdots i_k;j_1\cdots j_l}\in\mathbb{C}.$$

Note that they are graded symmetric with respect to the indices $i_1\cdots i_k$ and cyclic with respect to the indices $j_1\cdots j_l$. Consider further a formal sum of polynomial functions S,

$$S(\phi,\psi)=S_S(\psi)+S_D(\phi,\psi), \quad S_S(\psi)\in C(\psi), \quad S_D(\phi,\psi)\in C(\phi,\psi)_{\mathrm{cyc}}, \tag{3.8}$$

where S_S and S_D are defined by

$$S_S(\psi)=\sum_{l\geqslant 2}\frac{1}{l!}\mathcal{V}_{i_1\cdots i_l}\psi^{i_l}\cdots\psi^{i_1}, \quad \mathcal{V}_{i_1\cdots i_l}\in\mathbb{C},$$

$$S_D(\phi,\psi)=\sum_{k\geqslant 0,l\geqslant 1,k+l\geqslant 2}\frac{1}{k!\,l}\mathcal{V}_{i_1\cdots i_k;j_1\cdots j_l}(\phi^{j_l}\cdots\phi^{j_1})(\psi^{i_k}\cdots\psi^{i_1}), \quad \mathcal{V}_{i_1\cdots i_k;j_1\cdots j_l}\in\mathbb{C}. \tag{3.9}$$

Then one can define the formal vector field δ acting on $C(\phi,\psi)_{\mathrm{cyc}}$ as follows:

$$\delta := \delta_S + \delta_D, \quad \delta_S = (\ ,S_S)_c, \quad \delta_D = (\ ,S_D)_o. \tag{3.10}$$

The condition $(\delta)^2=0$ coincides with the condition that $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ is a COCHA.

IV. ZWIEBACH'S OPEN-CLOSED STRING FIELD THEORY

String field theory is defined on a fixed conformal background of a space-time (target space) M to which world sheets of strings (Riemann surfaces) are mapped, where the conformal background is a background (metric, etc., of M) in which string world sheet theory has conformal symmetry. There exist several classes of string field theories corresponding to the classes of Riemann surfaces. The most general one is quantum open-closed string field theory,[74] which is associated to the most general class of Riemann surfaces: Riemann surfaces of arbitrary genus, possibly with boundaries and punctures.

It includes various substring field theories: classical open string field theories—associated to disks (one boundary and zero genus) with punctures only on the boundary, classical closed string field theories—associated to spheres (no boundary and genus zero) with punctures, quantum closed string field theories—associated to Riemann surfaces with punctures (and various genera) and without boundary, and so on. Genera and multiboundaries relate to closed and open string loops (in the sense of Feynman diagrams), respectively. We use the term classical (respectively, quantum) for theory without loops (respectively, with loops). In this section we shall explain that, extracting the tree open-closed part from Zwiebach's quantum open-closed string field theory,[74] one obtains an OCHA. Namely, an OCHA is a general homotopy algebraic structure for tree open-closed string field theory as L_∞ algebras (respectively, A_∞ algebras) are for tree closed (respectively, open) string field theories.

The quantum open-closed string field theory discussed by Zwiebach[74] is defined by all possible open-closed interaction vertices together with closed and open string kinetic terms satisfying the quantum BV master equation. The interaction term is expressed formally in the following form [Eq. (5.7) of Ref. 74]:

$$f(\mathcal{V}^{g,n}_{b,m}) = \left[\frac{1}{n!}\frac{1}{b!}\prod_{k=1}^{b}\frac{1}{m_k}\right]\int_{\mathcal{V}^{g,n}_{b,n}} \langle\Omega|\underbrace{|\Psi\rangle\cdots|\Psi\rangle}_{n}\prod_{k=1}^{b}\underbrace{|\Phi\rangle\cdots|\Phi\rangle}_{m_k}. \tag{4.1}$$

Here the kets $|\Psi\rangle\in\mathcal{H}_c$ and $|\Phi\rangle\in\mathcal{H}_o$ are the *closed string fields* and the *open string fields*, respectively. $\mathcal{V}^{g,n}_{b,m}\subset\bar{\mathcal{M}}^{g,n}_{b,m}$ is the appropriate subspace of the compactified moduli space of Riemann surfaces with genus g, n-interior punctures and b boundaries S^1 having $m_1,\ldots,m_b$ punctures on them. Equivalently, it has n-closed string punctures and m_i-open string insertions on the corresponding boundary S^1. The bra $\langle\Omega|$ denotes a differential form on $\bar{\mathcal{M}}^{g,n}_{b,m}$ which takes its value in $(\mathcal{H}^*_c)^{\otimes n}\otimes(\mathcal{H}^*_o)^{\otimes m_1}\otimes\cdots\otimes(\mathcal{H}^*_o)^{\otimes m_b}$. This data is determined by the conformal field theory for a fixed conformal background. Then, the combination $\int_{\mathcal{V}^{g,n}_{b,m}}\langle\Omega|$ defines a map

$$\int_{\mathcal{V}^{g,n}_{b,m}}\langle\Omega|:(\mathcal{H}_c)^{\otimes n}\otimes(\mathcal{H}_o)^{\otimes m_1}\otimes\cdots\otimes(\mathcal{H}_o)^{\otimes m_b}\to\mathbb{C}. \tag{4.2}$$

In terms of bases $\mathbf{e}_{c,i}$ and $\mathbf{e}_{o,j}$ of the *spaces of states* $\mathcal{H}_c$ and $\mathcal{H}_o$, the kets can be expressed as $|\Psi\rangle := \Sigma_i\mathbf{e}_{c,i}\psi^i$ and $|\Phi\rangle := \Sigma_j\mathbf{e}_{o,j}\phi^j$, and the coordinates ψ^i and ϕ^j play the role of fields. The degree of each basis element $\mathbf{e}_{c,i}$ or $\mathbf{e}_{o,j}$ is determined by the corresponding conformal field theory on the string world sheet and is related to the degree of field ψ^i or ϕ^j through the relations $\deg(\psi^i) = -\deg(\mathbf{e}_{c,i})$ and $\deg(\phi^i)=-\deg(\mathbf{e}_{o,i})$. The degrees $\deg(\psi^i)$ and $\deg(\phi^i)$ in turn denote the ghost numbers in the sense of the BV-formalism for the target space field theory. The map (4.2) is defined to be of degree zero because of a ghost number preserving condition on the string world sheets, naturally extended to the polynomials of ψ^i and ϕ^j. Then $f(\mathcal{V}^{g,n}_{b,m})$ in Eq. (4.1), which is the image of $|\Psi\rangle^{\otimes n}\otimes\Pi_{k=1}^{b}|\Phi\rangle^{\otimes m_k}$ by the map (4.2), belongs to a subspace of $C(\psi,\phi)$ whose elements are expressed in general in the form

$$a(\phi,\psi)=\sum_{k,l}\frac{1}{k!\,l!\,|J_1|\cdots|J_l|}a_{i_1\cdots i_k;J_1,\ldots,J_l}(\phi^{J_l}\cdots\phi^{J_1})(\psi^{j_k}\cdots\psi^{j_1}).$$

For the interaction terms, $|J_i|=m_i$ in the notation in Eq. (4.1). Here $J=(j_1,\ldots,j_{|J|})$ is the multi-index, $\phi^J=\phi^{j_{|J|}}\cdots\phi^{j_1}$. The coefficient $a_{i_1\cdots i_k;J_1,\ldots,J_l}\in\mathbb{C}$ is then graded symmetric with respect to the cyclic permutations of each multi-index $J=(j_1,\ldots,j_{|J|})$, all the permutations of $i_1\cdots i_k$, and those of $J_1,\ldots,J_l$. We denote the corresponding subspace by $C(\phi,\psi)_{\mathrm{qoc}}:=C_{\mathrm{sym}}(\psi)\otimes C_{\mathrm{sym}}(C(\phi)_{\mathrm{cyc}})\subset C(\phi,\psi)$, where qoc indicates quantum open-closed. Note that, by construction, the degree of $f(\mathcal{V}^{g,n}_{b,m})$ is zero. The closed string kinetic term and the open string kinetic term are expressed as follows:

$$\tfrac{1}{2}\langle\Psi,Q_c\Psi\rangle_c,\quad \tfrac{1}{2}\langle\Phi,Q_o\Phi\rangle_o \tag{4.3}$$

which also belong to $C(\phi,\psi)_{\mathrm{qoc}}$ and have degree zero. In our notation, $Q_c=l_1:\mathcal{H}_c\to\mathcal{H}_c$ and $Q_o=n_{0,1}:\mathcal{H}_o\to\mathcal{H}_o$. Physically, Q_c (respectively, Q_o) is called the *BRST operator* for closed (respectively, open) strings, where BRST is taken in the sense of the conformal field theory on the string world sheet. Their cohomologies then define the physical state spaces of strings. Also, the brackets are just the constant symplectic structures in Definition 2.12,

$$\langle\ ,\ \rangle_c=\omega_c:\mathcal{H}_c\otimes\mathcal{H}_c\to\mathbb{C},\quad \langle\ ,\ \rangle_o=\omega_o:\mathcal{H}_o\otimes\mathcal{H}_o\to\mathbb{C}.$$

Since these constant symplectic structures come from the BV formalism[3,4] in which string field theories are described, the degrees of ω_c and ω_o are set to be minus one. In such a superfield description of the BV formalism, they are called *odd symplectic structures*[62,1] since degree minus one implies *odd* in $\mathbb{Z}_2$ grading. The corresponding odd Poisson brackets

$$(\ ,\ )=(\ ,\ )_c+(\ ,\ )_o,\quad (\ ,\ )_c=\frac{\overleftarrow{\partial}}{\partial\psi^j}\omega_c^{ij}\frac{\overrightarrow{\partial}}{\partial\psi^j},\quad (\ ,\ )_o=\frac{\overleftarrow{\partial}}{\partial\phi^i}\omega_o^{ij}\frac{\overrightarrow{\partial}}{\partial\phi^j}$$

are what are called the *BV brackets*. Since they have degree one, $(\psi^j,\psi^j)_c=\omega_c^{ij}\neq 0$ only when the sum of the degree of ψ^j and the degree of ψ^j is equal to minus one. In the BV formalism,[3,4] two fields ψ^j and ψ^j having nonzero ω_c^{ij} make a pair of a *field* and an *antifield*. Of course these facts hold true similarly for open string fields (see Refs. 31 and 33). Both Poisson brackets are naturally combined and extended to $(\ ,\ )$ on $C(\phi,\psi)_{\mathrm{qoc}}$. Also, define second order operators as

$$\Delta=\Delta_c+\Delta_o,\quad \Delta_c=\frac{1}{2}(-1)^{\mathbf{e}_{c,i}}\omega_c^{ij}\frac{\overrightarrow{\partial}}{\partial\psi^j}\frac{\overrightarrow{\partial}}{\partial\psi^j},\quad \Delta_o=\frac{1}{2}(-1)^{\mathbf{e}_{o,i}}\omega_o^{ij}\frac{\overrightarrow{\partial}}{\partial\phi^i}\frac{\overrightarrow{\partial}}{\partial\phi^j}. \tag{4.4}$$

Since the BV brackets have degree one, we have $\deg(\Delta)=1$, while $(C(\psi),\Delta_c,\bullet,(\ ,\ )_c)$ and $(C(\phi)_{\mathrm{cyc}},\Delta_o,\bullet,(\ ,\ )_o)$ form BV algebras (see Refs. 3, 4, and 14).

Further $(C(\psi,\phi)_{\mathrm{qoc}},\Delta,\bullet,(\ ,\ ))$ forms a BV algebra, where $\bullet:C(\psi,\phi)_{\mathrm{qoc}}\otimes C(\psi,\phi)_{\mathrm{qoc}}\to C(\psi,\phi)_{\mathrm{qoc}}$ is the associative product, symmetric in the ψ's. We shall soon reduce them to the tree open-closed structures, so do not stress to explain the detail of the structure on the whole $C(\psi,\phi)_{\mathrm{qoc}}$ in this paper.

The action of quantum open-closed string field theory is then given by summing up the kinetic terms (4.3) and all the interaction terms (vertices) in Eq. (4.1),

$$S_{\mathrm{qoc}}(\phi,\psi)=\sum_{g,b,n}\frac{1}{n!\,b!\,|J_1|\cdots|J_b|}\mathcal{V}^g_{i_1\cdots i_n;J_1,\ldots,J_b}(\phi^{J_b}\cdots\phi^{J_1})(\psi^{j_n}\cdots\psi^{j_1}),$$

$$\mathcal{V}^{g}_{i_1\cdots i_n;J_1,\ldots,J_b} := \int_{\mathcal{V}^{g,n}_{b,m}} \langle\Omega|(\mathbf{e}_{c,i_1},\ldots,\mathbf{e}_{c,i_n};\mathbf{e}_{o,J_1},\ldots,\mathbf{e}_{o,J_b}), \tag{4.5}$$

where $\mathbf{e}_{o,J}=\mathbf{e}_{o,j_1}\cdots\mathbf{e}_{o,j_{|J|}}$ for $J=(j_1,\ldots,j_{|J|})$, and the summation $\Sigma_{g,b,n}$ is taken for all $g\geqslant 0$, $b\geqslant 0$ and $n\geqslant 0$ except for the cases $(g,b)=(0,0), n\leqslant 1$, $(g,n,b)=(0,0,1), |J_1|\leqslant 1$ and $(g,n,b)=(1,0,0)$. In particular, the terms with $(g,n,b)=(0,2,0)$ and $(g,n,b)=(0,0,1)$ with $|J_1|=2$ are the kinetic terms of closed strings and open strings, respectively.

A quantum open-closed string field theory $S_{\mathrm{qoc}}(\phi,\psi)$ is defined so that it satisfies the *quantum master equation*

$$\tfrac{1}{2}(S_{\mathrm{qoc}},S_{\mathrm{qoc}}) + \Delta S_{\mathrm{qoc}} = 0. \tag{4.6}$$

Note that ΔS_{qoc} is the term peculiar to the *quantum* string field theory. Δ_c increases g by one and Δ_o increases b by one for $b>0$. The quantum master equation splits into separate equations for each genus g and number of boundaries b. When we concentrate on the equations for $g=0$ and $b=0$ or 1, we get

$$(g,b)=(0,0), \quad 0=(S_S,S_S)_c, \tag{4.7}$$

$$(g,b)=(0,1), \quad 0=(\widetilde{S}_D,S_S)_c+\tfrac{1}{2}(\widetilde{S}_D,\widetilde{S}_D)_o, \tag{4.8}$$

where S_S and $\widetilde{S}_D$ consist of the corresponding terms in S_{qoc} in Eq. (4.5); explicitly, S_S is of the same form as S_S in Eq. (3.9) and $\widetilde{S}_D$ consists of S_D in Eq. (3.9) with additional terms corresponding to $(k,l)=(k,0)$ below,

$$S_S(\psi)=\sum_{l\geqslant 2}\frac{1}{l!}\mathcal{V}_{i_1\cdots i_l}\psi^{j_l}\cdots\psi^{j_1}\in C(\psi),$$

$$\widetilde{S}_D(\phi,\psi)=\sum_{k\geqslant 0,l\geqslant 0,2k+l\geqslant 2}\frac{1}{k!\;l}\mathcal{V}_{i_1\cdots i_k;j_1\cdots j_l}(\phi^{j_l}\cdots\phi^{j_1})(\psi^{j_k}\cdots\psi^{j_1})\in C(\phi,\psi)_{\mathrm{cyc}}. \tag{4.9}$$

Here we dropped the index g used in Eq. (4.5) since $g=0$. Namely, we denote

$$\mathcal{V}^{g=0}_{i_1\cdots i_l;\varnothing}=:\mathcal{V}_{i_1\cdots i_l}, \quad \mathcal{V}^{g=0}_{i_1\cdots i_l;J=(j_1,\ldots,j_l)}=:\mathcal{V}_{i_1\cdots i_l;j_1\cdots j_l}.$$

The action S_S corresponds to punctured spheres [since the corresponding Riemann surfaces have no boundary $(\varnothing)$], whereas $\widetilde{S}_D$ corresponds to disks with punctures both in the disks and on the boundary of the disks. Equation (4.8) is often called a *Maurer-Cartan equation*.

A classical (tree) open-closed string field theory[74] is then given by the action $S_{\mathrm{toc}}(\phi,\psi)=S_S(\psi)+\widetilde{S}_D(\phi,\psi)$ satisfying Eqs. (4.7) and (4.8), the Batalin-Vilkovisky[3,4] classical open-closed master equations. The identity (4.7) implies that S_S is just the action of the classical closed string field theory.[73] Namely, S_S has a cyclic L_∞ structure. For the operadic construction of the classical closed string field theory, see Ref. 38. The relevant operad is the L_∞ operad of nonplanar trees, where the composition of the trees corresponds to the *twist-sewing* of two S^1's parametrizing two closed strings and/or boundaries in a Riemann surface picture.[73,38]

Just in the same way as for Eq. (3.10), one can define the following formal vector fields acting on $C(\phi,\psi)_{\mathrm{cyc}}$:

$$\delta := \delta_S+\delta_D, \quad \delta_S=(\ ,S_S)_c, \quad \delta_D=(\ ,\widetilde{S}_D)_o. \tag{4.10}$$

The condition $(\delta)^2=0$ that $(\mathcal{H},\mathfrak{l},\mathfrak{n})$ is a cyclic OCHA is equivalent to the derivatives of the master equations (4.7) and (4.8),

$$0 = (\ ,(S_S,S_S)_c)_c,$$

$$0 = \left(\ ,(\widetilde{S}_D,S_S)_c + \tfrac{1}{2}(\widetilde{S}_D,\widetilde{S}_D)_o\right)_o.$$

Here note that, as has been explained in Eq. (4.9), $\widetilde{S}_D$ consists of S_D with the following additional terms:

$$\frac{1}{l!}\mathcal{V}_{j_1\cdots j_l;J=\emptyset}(\psi^{j_l}\cdots\psi^{j_1}) \tag{4.11}$$

each of which corresponds to a disk with punctures only in the bulk (the interior of the disk) and no punctures $J=\emptyset$ on the boundary. However, one can see that these terms drop out in Eq. (4.10): $(\ ,\widetilde{S}_D)_o=(\ ,S_D)_o$, since no open string field ϕ^i is included in Eq. (4.11). This is why we do not include the corresponding terms in the definition of (cyclic) OCHAs. Thus, a classical open-closed string field theory is a cyclic OCHA with the additional terms (4.11).

Of course, there exist situations in which these terms (4.11) are also important physically. For example, the terms (4.11) contribute to a constant term for open string field theory in discussing its deformation as in Sec. VI, and the constant term is relevant to D-brane mass, since the value of the action is believed to correspond to D-brane mass in open string field theory. But, it is enough to consider a cyclic OCHA structure in a classical open-closed string field theory at present if we examine its homotopy algebraic structures in the sense of the next section.

V. MAURER-CARTAN EQUATION, MINIMAL MODEL, AND TREE OPEN-CLOSED STRING AMPLITUDES

Homotopy algebras should have some homotopical properties.[7,51] One of the key theorems in homotopy algebra is the minimal model theorem. The minimal model theorem for A_∞ algebras was proved by Kadeishvili.[30] For the construction of minimal models of A_∞ structures, homological perturbation theory was developed by Refs. 17, 28, 18, 21, 19, and 20, for instance, and the form of a minimal model is then given explicitly in Refs. 54 and 41. Also, the existence of a stronger theorem, called the decomposition theorem in Refs. 33 and 36, is mentioned in Ref. 40 and proven by employing a kind of homological perturbation theory in Refs. 33 and 36 (see also Ref. 47). It is clear that the same arguments hold true for L_∞ algebras, and in our previous paper[35] we stated that they hold also for OCHAs.

In this section, we present the explicit form of a minimal model for an OCHA, which in the cyclic case can be thought of as the perturbative expansion of a classical open-closed string field theory.

Definition 5.1 (*minimal open-closed homotopy algebra*): An OCHA $(\mathcal{H}=\mathcal{H}_c\oplus\mathcal{H}_o,\mathfrak{l},\mathfrak{n})$ is called minimal if $l_1=0$ on $\mathcal{H}_c$ and $n_{0,1}=0$ on $\mathcal{H}_o$.

Theorem 5.2 (**Minimal model theorem for open-closed homotopy algebras**[35]): *For any OCHA, there exists a minimal OCHA and an OCHA quasi-isomorphism from the minimal OCHA to the original OCHA.*

The minimal model theorem holds also for COCHAs. Namely, for any COCHA, there exists a minimal COCHA and a COCHA quasi-isomorphism from the minimal COCHA to the original COCHA. This fact also follows from the explicit minimal model we shall construct here.

First of all, we fix a Hodge decomposition of the complex $(\mathcal{H},d=l_1+n_{0,1})$. Namely, for $d_c=l_1$ and $d_o=n_{0,1}$, we give Hodge decompositions of the complexes $(\mathcal{H}_c,d_c)$ and $(\mathcal{H}_o,d_o)$ separately, by fixing degree minus one (homotopy) operators $h_c:\mathcal{H}_c\to\mathcal{H}_c$ and $h_o:\mathcal{H}_o\to\mathcal{H}_o$,

$$d_ch_c+h_cd_c+\iota_c\circ\pi_c=\mathbf{1}_c,\quad d_oh_o+h_od_o+\iota_o\circ\pi_o=\mathbf{1}_o. \tag{5.1}$$

Here, π and ι indicate the projection to and the inclusion into the corresponding cohomologies. Thus, these data give a contraction (deformation retract) of $\mathcal{H}=\mathcal{H}_c\oplus\mathcal{H}_o$ as a graded vector space (see Ref. 35),

$$(H(\mathcal{H}) \underset{\pi}{\overset{\iota}{\rightleftarrows}} \mathcal{H}, h), \tag{5.2}$$

where $\iota := \iota_c + \iota_o$, $\pi := \pi_c + \pi_o$ and $h = h_c + h_o$.

We would like to follow the arguments in Refs. 31 and 33, where a minimal model is obtained by a process of solving the Maurer-Cartan equation for an A_∞ algebra. For OCHAs, the Maurer-Cartan equations are defined as follows.[35]

Definition 5.3 (*Maurer-Cartan equation*): For an OCHA $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$ and degree zero elements $\bar{c} \in \mathcal{H}_c$ and $\bar{o} \in \mathcal{H}_o$, we call the following pair of equations

$$0 = \sum_k \frac{1}{k!} l_k(\bar{c}, \ldots, \bar{c}), \quad 0 = \sum_{k,l} \frac{1}{k!} n_{k,l}(\bar{c}, \ldots, \bar{c}; \bar{o}, \ldots, \bar{o}) \tag{5.3}$$

the *Maurer-Cartan equations* for the OCHA $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$.

Remark 5.4: Recall that, for the cyclic A_∞ or L_∞ case, the Maurer-Cartan equations are just the equations of motions for the action (of the corresponding string field theory).[31,33] In field theory, the equations of motions are defined by the derivatives of the action with respect to the fields. For instance, for classical closed string field theory with the action S_S, the equations of motions are $0 = (\vec{\partial}/\partial\psi^i) S_S$ for each i. Here, since the BV bracket $(\ ,\ )_c := (\overleftarrow{\partial}/\partial\psi^i)\omega_c^{ij}(\vec{\partial}/\partial\psi^j)$ is nondegenerate, the equations of motions are equivalent to $0 = (\ , S_S)$ $(= \delta_S)$. Usually, we set degree nonzero fields to be zero and concentrate on the solutions for the fields of degree zero. Then, further identifying $\vec{\partial}/\partial\psi^i$ with $\mathbf{e}_c^i$ in $0 = \delta_S$, one obtains the Maurer-Cartan equations for the L_∞ algebra, which is the first equation in Eq. (5.3). However, note that, for a COCHA $(\mathcal{H}, \omega, \mathfrak{l}, \mathfrak{n})$, the zeroes of the corresponding odd formal vector field $\delta = \delta_S + \delta_D$ are not the same as solutions to the equations of motions $0 = (\ , S) = (\ , S)_c + (\ , S)_o$, or separately

$$0 = \frac{\overleftarrow{\partial}}{\partial\psi^i}\omega_c^{ij}\frac{\vec{\partial}}{\partial\psi^j}(S_S + S_D) = 0, \quad 0 = \frac{\overleftarrow{\partial}}{\partial\phi^i}\omega_o^{ij}\frac{\vec{\partial}}{\partial\phi^j}S_D = 0,$$

for the COCHA. Namely, the first equation above includes the term $(\ , S_D)_c$, the corresponding term of which is absent in the Maurer-Cartan equations (5.3) for the COCHA.

One can see that, if one solves the equations of motions, instead of solving the Maurer-Cartan equations, the resulting structure includes terms corresponding to $b > 1$.

If we apply the arguments in Refs. 31 and 33 to an OCHA, the Maurer-Cartan equations for an OCHA should be considered formally for the pair of string fields $(\Psi, \Phi) \in (\mathcal{H}_c \otimes \mathcal{H}_c^*, \mathcal{H}_o \otimes \mathcal{H}_o^*)$ instead of their degree zero parts $(\bar{c}, \bar{o}) \in (\mathcal{H}_c^0, \mathcal{H}_o^0)$.

Then, for instance for the L_∞ part, solving the Maurer-Cartan equation recursively one gets first an L_∞ quasi-isomorphism $\{f_k\}_{k\geqslant 1} : (H(\mathcal{H}_c))^{\otimes k} \to \mathcal{H}_c$. This somewhat physical procedure is closely related to the homological perturbation theory developed earlier, and in particular, $\mathfrak{f} := \oplus_k f_k \in \oplus_k \mathrm{Hom}((H(\mathcal{H}_c))^{\otimes k}, \mathcal{H}_c)$ is just what is called a *twisting cochain* τ (see Ref. 29 for the DGLA case). Then, substituting $\mathfrak{f}$ instead of Ψ into the initial Maurer-Cartan equation, one obtains an equation on $H(\mathcal{H}_c)$, which is in fact the Maurer-Cartan equation for the corresponding minimal L_∞ algebra, so one can read the minimal L_∞ structure from the Maurer-Cartan equation. For the case of an OCHA, its minimal model is obtained by first considering the Maurer-Cartan equation for the L_∞ algebra as above and, after that, considering the Maurer-Cartan equation for $\mathfrak{n}$.

For an L_∞ algebra $(\mathcal{H}_c, \mathfrak{l})$, a minimal L_∞ algebra and an L_∞ quasi-isomorphism $\{f_l\}_{l\geqslant 1} : (H(\mathcal{H}_c), \mathfrak{l}') \to (\mathcal{H}_c, \mathfrak{l})$ are constructed as follows.

We set $f_1 = \iota_c : H(\mathcal{H}_c) \to \mathcal{H}_c$, and assume that we have $\{f_l : (H(\mathcal{H}_c))^{\otimes l} \to \mathcal{H}_c\}_{l\geqslant 1}$ for $l \leqslant n-1$. Then, for $c_1', \ldots, c_n' \in H(\mathcal{H}_c)$, f_n is defined by

$$f_n(c_1', \ldots, c_n') = -h_c \sum_{k_1+\cdots+k_j=n} \sum_{\sigma\in\mathfrak{S}_n} \frac{(-1)^{\epsilon(\sigma)}}{k_1!\,k_2!\cdots k_j!\cdot j!} l_j(f_{k_1} \otimes f_{k_2} \otimes \cdots \otimes f_{k_j})(c'_{\sigma(1)}, \ldots, c'_{\sigma(n)}).$$

The minimal L_∞ structure is then determined by

$$l'_n(c'_1,\ldots,c'_n)=\pi_c\sum_{k_1+\cdots+k_j=n}\sum_{\sigma\in\mathfrak{S}_n}\frac{(-1)^{\epsilon(\sigma)}}{k_1!\,k_2!\cdots k_j!\cdot j!}l_j(f_{k_1}\otimes f_{k_2}\otimes\cdots\otimes f_{k_j})(c'_{\sigma(1)},\ldots,c'_{\sigma(n)}),$$

in particular, for $l=2$ one gets $l'_2=H(l_2):=\pi_c\circ l_2\circ(\iota_c)^{\otimes 2}$.

Once the L_∞ quasi-isomorphism $\{f_l\}_{l\geqslant 1}$ is given, we have an OCHA $(H(\mathcal{H}_c)\oplus\mathcal{H}_o,\mathfrak{l}',\mathfrak{n}'')$ for some $\mathfrak{n}''$. Next we should construct $\{f_{k,l}:(H(\mathcal{H}_c))^{\otimes k}\otimes(H(\mathcal{H}_o))^{\otimes l}\to H(\mathcal{H}_o)\}_{k+l\geqslant 1}$ and $\mathfrak{n}'=\{n'_{k,l}:(H(\mathcal{H}_c))^{\otimes k}\otimes(H(\mathcal{H}_o))^{\otimes l}\to H(\mathcal{H}_o)\}_{2k+l\geqslant 2}$; these are obtained in a similar way as follows. $f_{0,1}$ is given as inclusion $f_{0,1}=\iota_o:H(\mathcal{H}_o)\to\mathcal{H}_o$. $f_{r,s}$ and $f_{p,q}$ are ordered as $f_{r,s}<f_{p,q}$ if $r+s<p+q$ or $r<p$ for $r+s=p+q$. Then, a similar recursive procedure as above can be carried out also here. For $c'_1,\ldots,c'_n\in H(\mathcal{H}_c)$ and $o'_1,\ldots,o'_m\in H(\mathcal{H}_o)$, $f_{n,m}$ is determined by

$$\begin{aligned}&f_{n,m}(c'_1,\ldots,c'_n;o'_1,\ldots,o'_m)\\&\quad=-h_o\sum\frac{(-1)^{\epsilon(\sigma)}}{i!\,(r_1!\cdots r_i!)(p_1!\cdots p_j!)}n_{i,j}(f_{r_1}\otimes\cdots\otimes f_{r_i}\otimes f_{p_1,q_1}\otimes\cdots\otimes f_{p_j,q_j})\\&\qquad(c'_{\sigma(1)},\ldots,c'_{\sigma(n)};o'_1,\ldots,o'_m),\end{aligned}$$

where the summation Σ runs over all $r_1,\ldots,r_i,p_1,\ldots,p_j,q_1,\ldots,q_j$ such that $(r_1+\cdots+r_i)+(p_1+\cdots+p_j)=n$, $(q_1+\cdots+q_j)=m$, and also all $\sigma\in\mathfrak{S}_n$.

Then $\mathfrak{n}'=\{n'_{k,l}\}_{2k+l\geqslant 2}$ is obtained by replacing $-h_o$ above with π_o,

$$\begin{aligned}&n'_{n,m}(c'_1,\ldots,c'_n;o'_1,\ldots,o'_m)\\&\quad=\pi_o\sum\frac{(-1)^{\epsilon(\sigma)}}{i!\,(r_1!\cdots r_i!)(p_1!\cdots p_j!)}n_{i,j}(f_{r_1}\otimes\cdots\otimes f_{r_i}\otimes f_{p_1,q_1}\otimes\cdots\otimes f_{p_j,q_j})\\&\qquad(c'_{\sigma(1)},\ldots,c'_{\sigma(n)};o'_1,\ldots,o'_m),\end{aligned}$$

where the summation Σ stands for the same one as above. In particular, for $2k+l=2$ one gets $n'_{0,2}=H(n_{0,2}):=\pi_o\circ n_{0,2}\circ(\iota_o)^{\otimes 2}$ and $n'_{1,0}=H(n_{1,0}):=\pi_o\circ n_{1,0}\circ\iota_c$. In the equation above, we used the convention presented in Definition 2.10.

For a COCHA $(\mathcal{H},\omega,\mathfrak{l},\mathfrak{n})$, we do this construction by starting with an *orthogonal* Hodge decomposition with respect to the symplectic form ω. Namely, we give a decomposition

$$(H(\mathcal{H})\underset{\pi}{\overset{\iota}{\rightleftarrows}}\mathcal{H},h)$$

of $\mathcal{H}$ in Eq. (5.2) with a homotopy $h:\mathcal{H}\to\mathcal{H}$ satisfying $\omega(\mathbf{1}\otimes h)=\omega(h\otimes\mathbf{1})$, where $\mathbf{1}:=\mathbf{1}_c\oplus\mathbf{1}_o$. The existence of such a homotopy h follows from the nondegeneracy of ω and the cyclicity for the terms $\omega_c(l_1\otimes\mathbf{1}_c)$ and $\omega_o(n_{0,1}\otimes\mathbf{1}_o)$, and then $\omega(\mathbf{1}\otimes(\iota\circ\pi))=\omega((\iota\circ\pi)\otimes\mathbf{1})$ also holds. Then, for the COCHA $(\mathcal{H},\omega,\mathfrak{l},\mathfrak{n})$, forgetting the cyclic structure ω having already used it to fix the contraction (5.2), one can obtain a minimal model $(H(\mathcal{H}),\mathfrak{l}',\mathfrak{n}')$ as an OCHA by the construction we have seen above. The resulting minimal OCHA $(H(\mathcal{H}),\mathfrak{l}',\mathfrak{n}')$ is in fact cyclic with respect to the induced inner product $\omega':=\omega(\iota\otimes\iota)$ and the OCHA quasi-isomorphism a COCHA quasi-isomorphism.

To summarize we give the following.

Theorem 5.5: *$(H(\mathcal{H}),\mathfrak{l}',\mathfrak{n}')$ forms a minimal OCHA and $\mathfrak{f}:=\{\{f_l\}_{l\geqslant 1},\{f_{k,l}\}_{k+l\geqslant 1}\}$ is an OCHA quasi-isomorphism $\mathfrak{f}:(H(\mathcal{H}),\mathfrak{l}',\mathfrak{n}')\to(\mathcal{H},\mathfrak{l},\mathfrak{n})$.*

Theorem 5.6: *For a COCHA $(\mathcal{H},\omega,\mathfrak{l},\mathfrak{n})$ and an orthogonal Hodge decomposition with respect to ω, $(H(\mathcal{H}),\omega',\mathfrak{l}',\mathfrak{n}')$ forms a minimal COCHA and $\mathfrak{f}:=\{\{f_l\}_{l\geqslant 1},\{f_{k,l}\}_{k+l\geqslant 1}\}$ is a COCHA quasi-isomorphism $\mathfrak{f}:(H(\mathcal{H}),\omega',\mathfrak{l}',\mathfrak{n}')\to(\mathcal{H},\omega,\mathfrak{l},\mathfrak{n})$.*

Since the explicit forms are given, one can check the cyclicity directly in a similar way to that in the A_∞ case (see Ref. 33).

Remark 5.7 (*rooted planar tree graphs*): One can also present an alternate description of this

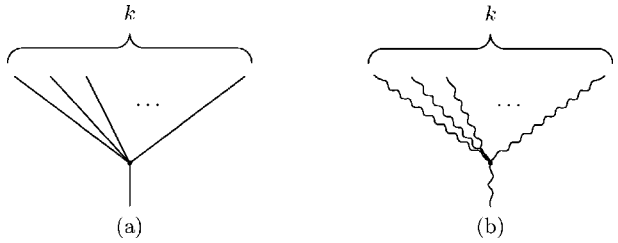

FIG. 1. (a) The k-corolla, the planar tree corresponding to the A_∞ structure $m_k=n_{0,k}$. (b) The k-corolla, the nonplanar tree corresponding to the L_∞ structure l_k.

minimal model in terms of rooted planar trees in a similar way as for A_∞ algebras (see Refs. 41, 31, 33, 52, 7, 11, 15, 16, 27, 36, 47, 51, and 60, etc.). This is related to Feynman graphs in field theory. For an A_∞ algebra $(\mathcal{H}_o,\{n_{0,k}\})$, it is convenient to associate $n_{0,k}$ to the k-corolla of planar rooted trees. An L_∞ algebra also has such a description, where the L_∞ structure l_k is associated with the k-corolla of nonplanar rooted trees (Fig. 1). In our OCHA, we need to introduce also $n_{k,l}$, to which we associate a mixed corolla as in Fig. 2. As stated previously, from a string theory viewpoint, l_k corresponds to the sphere with $(k+1)$-(closed string) punctures and $n_{k,l}$ corresponds to the disk with $(k+1)$-(open string) punctures on the boundary and l-(closed string) punctures in the bulk (interior) of the disk. In fact, one may think of the tubular neighborhood of these tree graphs as the corresponding world sheet, where we take strips and cylinders for the neighborhood of the straight lines and meandering lines, respectively. The minimal OCHA structure l'_k and $n'_{k,l}$ are then obtained by grafting corollas in all possible ways such that straight lines are grafted to straight and wiggly to wiggly (Fig. 3), where we assign to corollas the corresponding multilinear maps $l_k,n_{p,q}$, and to internal edges h_c, h_o, and so on. Physically, h_c and h_o are the propagators for closed string and open string, respectively.

Remark 5.8 (*string amplitude*): For a classical open-closed string field theory $S=S_S+S_D$, the string amplitudes are obtained as follows. Let $(\mathcal{H},\omega,\mathfrak{l},\mathfrak{n})$ be the corresponding COCHA, and suppose that its minimal COCHA $(H(\mathcal{H}),\omega',\mathfrak{l}',\mathfrak{n}')$ is constructed as above.

By definition, string field theory is constructed so that its perturbative expansion reproduces the corresponding world sheet string amplitudes. Thus,

$$\mathcal{V}'_{k+1} := \omega'_c(l'_k \otimes \mathbf{1}_c), \quad \mathcal{V}'_{k,l+1} = \omega'_o(n'_{k,l} \otimes \mathbf{1}_o) \tag{5.4}$$

just define the on-shell $(k+1)$-closed strings sphere amplitudes and k-closed $(l+1)$-open string disk amplitudes, respectively. Moreover, the n-closed string disk amplitude, which we denote $\mathcal{V}'_{n,0}$, is given by composing the L_∞ quasi-isomorphism with $\mathcal{V}_{k,0}$ as follows:

$$\mathcal{V}'_{n,0} = \sum_{i=1}^{n} \sum_{k_1+\cdots+k_i=n} \frac{1}{k_1!\cdots k_i!} \mathcal{V}_{i,0}(f_{k_1} \otimes \cdots \otimes f_{k_i})$$

for $\mathfrak{f}=\{f_k\}_{k\geqslant 1}$, the L_∞ quasi-isomorphism.

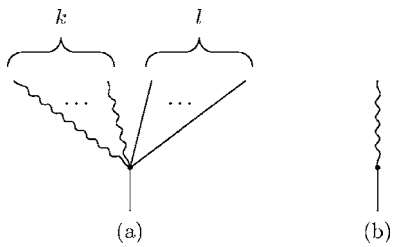

FIG. 2. (a) The (k,l)-corolla corresponding to $n_{k,l}$. (b) For the open-closed case, the (k,l)-corollas include the $(1,0)$-corolla corresponding to $n_{1,0}$.

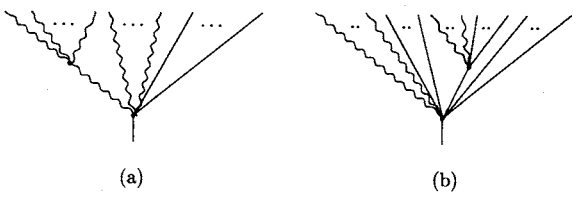

FIG. 3. Grafting of corollas. (a) Wiggly to wiggly. (b) Straight to straight.

Note also that we can prove the decomposition theorem for a (cyclic) OCHA,[35] which implies that all classical open-closed string field theories constructed on a fixed *conformal background* (the data of the conformal field theory on the Riemann surfaces) are isomorphic. From the field theory viewpoint, an OCHA morphism is a field transformation and in particular an OCHA isomorphism is a field redefinition. Since field theory actions related by a field redefinition are physically equivalent, one can say the decomposition theorem can prove the equivalence of all classical open-closed string field theories constructed on a fixed conformal background. (See Ref. 33 for the A_∞ case.)

VI. DEFORMATION OF A_∞ STRUCTURES AND THE FORMALITY THEOREM

For an L_∞ algebra $(\mathcal{H}_c,\mathfrak{l})$ and an A_∞ algebra $(\mathcal{H}_o,\mathfrak{m})$, if there exists an OCHA $(\mathcal{H}=\mathcal{H}_c \oplus \mathcal{H}_o,\mathfrak{l},\mathfrak{n})$ whose subalgebra $(\mathcal{H}_o,\{n_{0,k}\}_{k\geqslant 1})$ coincides with $(\mathcal{H}_o,\{m_k\}_{k\geqslant 1})$, one obtains deformations of the A_∞ algebra $(\mathcal{H}_o,\{m_k\}_{k\geqslant 1})$ parametrized by the L_∞ algebra $(\mathcal{H}_c,\mathfrak{l})$. On the other hand, the whole deformation space of the A_∞ algebra is also described by a moduli space of the L_∞ algebra(Coder$(T^c\mathcal{H}_o),\mathfrak{m},[\ ,\ ]))$, which we denote by $(\mathcal{H}_c',\mathfrak{l}')$. The maps $\{n_{k,l}\}$ for $k\geqslant 1$ define an L_∞ morphism from $(\mathcal{H}_c,\mathfrak{l})$ to $(\mathcal{H}_c',\mathfrak{l}')$. The defining equation for an OCHA (2.6) just converts to the defining equation for an L_∞ morphism (2.5).[35] In Sec. VI A we reexplain this in a more explicit way. Such structure appears in various aspects of mathematical physics; the relation to deformation quantization by Kontsevich[40] is explained in Sec. VI B, and the application to the open-closed topological B-model[26] from the viewpoint of the homological mirror symmetry setup[39] is discussed in Sec. VI C. Note also that, in string field theory, this picture is related to the arguments in Sec. 8 of Ref. 74.

A. Deformations of A_∞ structures from open-closed homotopy algebras

Definition 6.1 [(graded) Gerstenhaber bracket[12]]: For $\mathcal{H}_o$ a $\mathbb{Z}$-graded vector space, let $\mathrm{Hom}_k^r := \mathrm{Hom}^r(\mathcal{H}_o^{\otimes k},\mathcal{H}_o)$ be the space of degree r k-linear maps, and

$$\mathrm{Hom} := \oplus_r \mathrm{Hom}^r, \quad \mathrm{Hom}^r := \oplus_{k\geqslant 0} \mathrm{Hom}_k^r.$$

It is known that Hom is in one-to-one correspondence with the space of coderivations on $T^c(\mathcal{H}_o)$, Coder$(T^c(\mathcal{H}_o))$.[65] For two elements in Coder$(T^c(\mathcal{H}_o))$, the commutator of any two elements in fact belongs to Coder$(T^c(\mathcal{H}_o))$, and further satisfies the Jacobi identity. After a shift in degree, this induces a graded Lie bracket on Hom, which is the *Gerstenhaber bracket*. For $m\in\mathrm{Hom}_k^r$, $m'\in\mathrm{Hom}_{k'}^{r'}$ and $o_1,\ldots,o_{k+k'-1}\in\mathcal{H}_o$, the graded Lie bracket $[m,m']\in\mathrm{Hom}_{k+k'-1}^{r+r'}$ is defined by

$$[m,m'] = m\circ m' - (-1)^{r\cdot r'} m'\circ m,$$

$$m\circ m'(o_1,\ldots,o_{k+k'-1}) = \sum_{i=0}^{k-1} (-1)^{l'(o_1+\cdots+o_i)} m(o_1,\ldots,o_i,m'(o_{i+1},\ldots,o_{i+k'}),o_{i+k'+1},\ldots,o_{k+k'-1}).$$

Thus, (Hom,[,]) forms a *graded Lie algebra*.[12,65]

In the supermanifold description in Sec. III, this Gerstenhaber bracket corresponds to the graded Lie bracket of formal vector fields on the corresponding formal supermanifold.

Furthermore, let us denote by $\bar{m} \in \mathrm{Hom}^1$ the degree one element corresponding to a degree one coderivation in $(\mathcal{H}'_c, \mathfrak{l}') = \mathrm{Coder}(T(\mathcal{H}_o))$, that is, an A_∞ structure on $\mathcal{H}_o$. Then, it is clear that $[\bar{m}, \bar{m}] = 0$ holds and $(\mathrm{Hom}, d, [\ ,\ ])$ forms a DGLA with $d = [\bar{m},\ ]$.

Remark 6.2 (*suspension*): A DGLA is described as an L_∞ algebra through the suspension s. For the DGLA $(\mathrm{Hom}, d, [\ ,\ ])$, the suspension is a degree shifting operator

$$s : \mathrm{Hom} \to \mathrm{Hom}[1] =: \mathcal{H}'_c.$$

By this, a degree r element $m \in \mathrm{Hom}^r$ is mapped to be a degree $(r-1)$ element $s(m) \in \mathrm{Hom}[1]^{r-1} = \mathcal{H}'^{r-1}_c$. This actually converts the degree preserving bracket $[\ ,\ ] : \mathrm{Hom} \otimes \mathrm{Hom} \to \mathrm{Hom}$ into a degree one bilinear map $l'_2 : \mathcal{H}'_c \otimes \mathcal{H}'_c \to \mathcal{H}'_c$ defined by

$$l'_2(s(m), s(m')) := s((-1)^r [m, m']), \quad m \in \mathrm{Hom}^r, \quad m' \in \mathrm{Hom}^{r'}.$$

One can see that the graded anticommutativity $[m', m] = -(-1)^{rr'}[m, m']$ is in fact replaced by the graded commutativity in Eq. (2.3), $l'_2(s(m'), s(m)) = (-1)^{(r-1)(r'-1)} l'_2(s(m), s(m'))$, where l'_1 is given simply by $l'_1 = s\, \mathrm{d} s^{-1} = d$. Then $(\mathcal{H}'_c, \mathfrak{l}' = \{l'_1, l'_2, l'_3 = l'_4 = \cdots = 0\})$ forms an L_∞ algebra.

Now, let us express the open-closed multilinear maps as

$$n_{k,l}(c_1, \ldots, c_k; o_1, \ldots, o_l) =: (n^*_l(c_1, \ldots, c_k))(o_1, \ldots, o_l),$$

where $n^*_l(c_1, \ldots, c_k)$ belongs to $\mathrm{Hom}_k^{\deg(c_1)+\cdots+\deg(c_k)+1}$. By this, the second term of the OCHA relation (2.6) can be rewritten as

$$-(-1)^{(c_{\sigma(1)}+\cdots+c_{\sigma(l)}+1)} \frac{1}{2} [n^*_{m+1-k}(c_{\sigma(1)}, \ldots, c_{\sigma(l)}), n^*_k(c_{\sigma(l+1)}, \ldots, c_{\sigma(n)})](o_1, \ldots, o_m),$$

which, acting further with the suspension s on the equation above, yields

$$-\tfrac{1}{2} l'_2(s(n^*_{m+1-k})(c_{\sigma(1)}, \ldots, c_{\sigma(l)}), s(n^*_k)(c_{\sigma(l+1)}, \ldots, c_{\sigma(n)}))(o_1, \ldots, o_m).$$

Thus, one obtains

$$\sum_{k,l \geqslant 0} \sum_{p=0}^{m-k} \sum_{\sigma \in \mathfrak{S}_n} \frac{1}{2} \frac{(-1)^{\epsilon(\sigma)}}{l!\,(n-l)!} l'_2(s(n^*_{m+1-k})(c_{\sigma(1)}, \ldots, c_{\sigma(l)}), s(n^*_k)(c_{\sigma(l+1)}, \ldots, c_{\sigma(n)}))$$

$$= \sum_{\sigma \in \mathfrak{S}_n} \sum_{l=1}^{n} \frac{(-1)^{\epsilon(\sigma)}}{l!\,(n-l)!} s(n^*_m)(l_l(c_{\sigma(1)}, \ldots, c_{\sigma(l)}), c_{\sigma(l+1)} \ldots, c_{\sigma(n)}). \tag{6.1}$$

These are just the defining equations for an L_∞ morphism (2.5). By treating the $l=0$ and $l=n$ cases separately in the first line of the equation above, it becomes just the condition that the collection of multilinear maps $s(n^*_k) : (\mathcal{H}_c)^{\otimes^*} \to \mathrm{Hom}_k[1]$ forms an L_∞ morphism from $(\mathcal{H}_c, \mathfrak{l})$ to $(\mathcal{H}'_c, \mathfrak{l}')$. Here, note that $l'_1 = [\bar{m},\ ]$ and $\bar{m} = \Sigma_{l \geqslant 0} m_k$, the A_∞ structure included in $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$ as $m_l := n_{0,l}$. From these arguments, it is clear that the converse also holds.

Theorem 6.3 (**Ref.** 35)**:** *For an OCHA* $(\mathcal{H}, \mathfrak{l}, \mathfrak{n})$, *let* $(\mathcal{H}'_c, \mathfrak{l}')$ *denote the DGLA* $\mathrm{Coder}(T^c \mathcal{H}_o)$. *The OCHA structure gives an* L_∞ *morphism from* $(\mathcal{H}_c, \mathfrak{l})$ *to* $(\mathcal{H}'_c, \mathfrak{l}')$. *Conversely, if there exists an* L_∞ *algebra* $(\mathcal{H}_c, \mathfrak{l})$ *and an* L_∞ *morphism from it to the DGLA* $(\mathcal{H}'_c, \mathfrak{l}')$ *of an* A_∞ *algebra* $(\mathcal{H}_o, \mathfrak{m})$, *then one obtains an OCHA.*

For an L_∞ algebra $(\mathcal{H}_c, \mathfrak{l})$, let us denote by $\mathcal{MC}(\mathcal{H}_c, \mathfrak{l})$ the *solution space* of the Maurer-Cartan equation

$$\mathcal{MC}(\mathcal{H}_c, \mathfrak{l}) = \left\{ \bar{c} \in \mathcal{H}^0_c \,\middle|\, 0 = \sum_{k \geqslant 1} \frac{1}{k!} l_k(\bar{c}, \ldots, \bar{c}) \right\},$$

where $\mathcal{H}^0_c$ is the degree zero subvector space of $\mathcal{H}_c$. In addition, we have an equivalence relation $\sim$ called *gauge equivalence* between the solutions of the Maurer-Cartan equation. The moduli

space of the solution space of the Maurer-Cartan equation for $(\mathcal{H}_c, \mathfrak{l})$ is defined by

$$\mathcal{M}(\mathcal{H}_c, \mathfrak{l}) = \mathcal{MC}(\mathcal{H}_c, \mathfrak{l})/\sim . \tag{6.2}$$

Suppose that we have an L_∞ morphism $\mathfrak{f}: (\mathcal{H}_c, \mathfrak{l}) \to (\mathcal{H}'_c, \mathfrak{l}')$ between two L_∞ algebras. Then it is known that the L_∞ morphism $\mathfrak{f}$ induces a map $\mathfrak{f}: \mathcal{M}(\mathcal{H}_c, \mathfrak{l}) \to \mathcal{M}(\mathcal{H}'_c, \mathfrak{l}')$, and furthermore it is an isomorphism if $\mathfrak{f}$ is an L_∞ quasi-isomorphism (cf. Ref. 40). Similar facts hold also for A_∞ algebras and also for OCHAs,[35] but what is relevant here is just the L_∞ case.

Note that, for an L_∞ algebra (DGLA) $(\mathcal{H}'_c, \mathfrak{l}') = \mathrm{Coder}(T^c \mathcal{H}_o)$ as above, its moduli space $\mathcal{M}(\mathcal{H}'_c, \mathfrak{l}')$ is the moduli space of deformations of the A_∞ algebra in the space of weak A_∞ algebras. Thus, we have the following.

Corollary 6.4 (A_∞ *structure parameterized by the moduli space of* L_∞ *structures*[35]): *For an* L_∞ *algebra* $(\mathcal{H}_c, \mathfrak{l})$ *and an* A_∞ *algebra* $(\mathcal{H}_o, \mathfrak{m})$, *suppose there exists an OCHA* $(\mathcal{H} = \mathcal{H}_c \oplus \mathcal{H}_o, \mathfrak{l}, \mathfrak{n})$ *such that* $(\mathcal{H}_o, \{n_{0,k}\}) = (\mathcal{H}_o, \mathfrak{m})$. *Then, for each element* $c \in \mathcal{M}(\mathcal{H}_c, \mathfrak{l})$, *we have a weak* A_∞ *algebra which is a deformation of the original* A_∞ *algebra* $(\mathcal{H}_o, \mathfrak{m})$. *If* $\{n_{1,k}\}_{k \geqslant 0}: \mathcal{H}_c \to \mathcal{H}'_c$ *gives a quasi-isomorphism of complexes* $(\mathcal{H}_c, l_1) \to (\mathcal{H}'_c, l'_1)$, *then all the equivalence classes of deformations of* $(\mathcal{H}, \mathfrak{m})$ *as weak* A_∞ *algebras, described by* $\mathcal{M}(\mathcal{H}'_c, l'_1)$, *are in one-to-one correspondence with the space* $\mathcal{M}(\mathcal{H}_c, \mathfrak{l})$.

B. The construction of deformation quantization by Kontsevich

The deformation quantization problem is to construct a star product corresponding to the Poisson algebra on a manifold M. Namely, for a formal (deformation) parameter ν and a given Poisson algebra $(\mathcal{A} = C^\infty(M), \cdot, \{\ ,\ \})$, a bilinear, bidifferential ν-linear map $*: \mathcal{A}[[\nu]] \otimes \mathcal{A}[[\nu]] \to \mathcal{A}[[\nu]]$,

$$f * g = \sum_{r=0}^{\infty} m_r(f,g) \nu^r, \quad f, g \in \mathcal{A}[[\nu]] \tag{6.3}$$

is called a *deformation quantization* of M if $m_0(f,g) = f \cdot g$, the usual commutative product on $C^\infty(M)$, $m_1(f,g) = \frac{1}{2}\{f,g\}$ and the *star product* $*$ is associative.[5] (Notice here m_r is still a function of two variables and should not be confused with the m_l of an A_∞ algebra.) In Ref. 40, Kontsevich reformulated this problem in a homotopy algebraic setup. For any associative algebra $\mathcal{A}$, deformations as associative multiplications are controlled by the Hochschild complex, which is essentially $\mathrm{Coder}(T^c \mathcal{A})$ and hence a DGLA.[12] In fact, control is equally well exercised by any quasi-isomorphic DGLA or even L_∞ algebra.[60] The obstructions to existence and to equivalence are identified by the quasi-isomorphism. For the special case of $\mathcal{A} = C^\infty(M)$, the deformations relevant to deformation quantization are controlled by the subcomplex of multidifferential Hochschild cochains, which we denote $D_{\mathrm{poly}}(M)$ (Definition 6.5) and which is quasi-isomorphic to the full Hochschild complex. The smooth analog of the Hochschild-Kostant-Rosenberg theorem.[25] (an explicit proof can be found in Ref. 22) equates the Hochschild cohomology with $T_{\mathrm{poly}}(M)$, the space of polyvector fields, which possesses a DGLA structures with $d = 0$ and the Schouten-Nijenhuis bracket.

Kontsevich treated these DGLAs as L_∞ algebras and obtained the existence and the classification of deformation quantizations by constructing an L_∞ morphism between $T_{\mathrm{poly}}(M)$ and $D_{\mathrm{poly}}(M)$, which is in a sense a nonlinear generalization of a DGLA map. Moreover, the specific L_∞ morphism provides a specific star product. In this setting, the space of Poisson structures and the space of star products given by bidifferential operators are then described by the Maurer-Cartan equations of the corresponding DGLAs.

In this section, we shall first present these tools and then relate them to an OCHA.

Definition 6.5 [*DGLA of multidifferential operators for* $C^\infty(M)$]: For $\mathcal{A} = C^\infty(M)$, denote by $D^k_{\mathrm{poly}}(M)$ the space of multilinear maps from $\mathcal{A}^{\otimes(k+1)}$ to $\mathcal{A}$ of multidifferential operators. Then define $D_{\mathrm{poly}} = \oplus_{k \in \mathbb{Z}} D^k_{\mathrm{poly}}$ by

$$D^k_{\mathrm{poly}} = D^k_{\mathrm{poly}}(M)(k \geqslant -1), \quad D^k_{\mathrm{poly}} = 0(k < -1).$$

For d, we take the Hochschild coboundary operator. Namely, for any $C \in D^k_{\mathrm{poly}}$, d is given by

$$(\mathrm{d}C)(g_0, \ldots, g_{k+1}) = g_0 C(g_1, \ldots, g_{k+1}) - \sum_{r=0}^{k} (-1)^r C(g_0, \ldots, g_r g_{r+1}, \ldots, g_{k+1})$$

$$+ (-1)^k C(g_0, \ldots, g_k) g_{k+1}.$$

We take for $[\ ,\ ]$ the Gerstenhaber bracket.[12] Namely, for $C \in D^k_{\mathrm{poly}}$, $C' \in D^{k'}_{\mathrm{poly}}$, it is defined by

$$[C, C'] = C \circ C' - (-1)^{kk'} C' \circ C,$$

$$C \circ C'(g_0, \ldots, g_{k+k'}) = \sum_{r=0}^{k} (-1)^{rk'} C(g_0, \ldots, g_{r-1}, C'(g_r, \ldots, g_{r+k'}), g_{r+k'+1}, \ldots, g_{k+k'}).$$

Then $(D_{\mathrm{poly}}, [\ ,\ ], d)$ forms a DGLA.

One can see that d can be written as

$$(-1)^k (dC)(g_0, \ldots, g_{k+1}) = [\bar{m}, C], \quad C \in D^k_{\mathrm{poly}},$$

where $\bar{m}$ is the usual commutative product of functions $\bar{m}(f,g) = f \cdot g$. Though the operation $[\bar{m},\ ]$ is different in sign from the original d, $[\bar{m},\ ]$ also forms a DGLA on D_{poly} with $[\ ,\ ]$. So, we take this as d. This DGLA is described as a sub-DGLA of $(\mathrm{Hom}, d, [\ ,\ ])$. First, set $\mathcal{H}^{-1}_o = \mathcal{A}$ and $\mathcal{H}^k_o = 0$ otherwise. Then $C: \mathcal{A}^{\otimes(k+1)} \to \mathcal{A}$ has degree k as defined above. Namely, $D_{\mathrm{poly}}(M)$ is included in the restricted subvector space $\mathrm{Hom}_{\mathrm{sub}} = \oplus_k \mathrm{Hom}^{k-1}_k$ of Hom.

Let us state the necessary condition for the existence of a deformation quantization in the language of DGLAs here. If we write the star product (6.3) as $f * g = m(f,g)$, $m \in \mathrm{Hom}^1_2$, the associativity condition $(f*g)*h = f*(g*h)$ is expressed algebraically as $[m,m] = 0$. This just indicates that m defines a codifferential on $T^c(\mathcal{A})$ as previously or, equivalently, that m is associative. Since m should be obtained as a deformation of $\bar{m}$, writing $m = \bar{m} + \theta$, $\theta \in \nu D_{\mathrm{poly}}[[\nu]]$, one gets a Maurer-Cartan equation in the DGLA $(\nu D_{\mathrm{poly}}[[\nu]], d, [\ ,\ ])$,

$$\mathrm{d}\theta + \tfrac{1}{2}[\theta, \theta] = 0. \tag{6.4}$$

Definition 6.6 (DGLA of polyvector fields): For $k \geqslant -1$, set $T^k_{\mathrm{poly}}(M) := \Gamma(M, \wedge^{k+1} TM)$, and define $T_{\mathrm{poly}} = \oplus_k T^k_{\mathrm{poly}}$ by

$$T^k_{\mathrm{poly}} = T^k_{\mathrm{poly}}(M)(k \geqslant -1), \quad T^k_{\mathrm{poly}} = 0(k < -1).$$

Here, when $k = -1$ we set $T^{-1}_{\mathrm{poly}} = T^{-1}_{\mathrm{poly}}(M) = C^\infty(M)$. The differential d is defined by $d = 0$. Therefore, the cohomology of the complex of T^n_{poly} with respect to d coincides with T^n_{poly} itself. $[\ ,\ ]$ is taken to be the *Schouten-Nijenhuis bracket*.[61,56] For $\xi_s, \eta_t \in T^0_{\mathrm{poly}} = \Gamma(M, TM)$, the bracket of $\xi_0 \wedge \cdots \wedge \xi_k, \in T^k_{\mathrm{poly}}$ with $\eta_0 \wedge \cdots \wedge \eta_l \in T^l_{\mathrm{poly}}$, $k, l \geqslant 0$, is defined by

$$[\xi_0 \wedge \cdots \wedge \xi_k, \eta_0 \wedge \cdots \wedge \eta_l]$$
$$= \sum_{i=0}^{k} \sum_{j=0}^{l} (-1)^{s+t} [\xi_s, \eta_t] \wedge \xi_0 \wedge \cdots \wedge \xi_{s-1} \wedge \xi_{s+1} \wedge \cdots \wedge \xi_k \wedge \eta_0 \wedge \cdots \wedge \eta_{t-1} \wedge \eta_{t+1} \wedge \cdots \wedge \eta_l,$$

and for $k \geqslant 0$, $h \in T^{-1}_{\mathrm{poly}} = C^\infty(M)$, the bracket is

$$[\xi_0 \wedge \cdots \wedge \xi_k, h] = \sum_{r=0}^{k} (-1)^r \xi_r(h)(\xi_0 \wedge \cdots \wedge \xi_{r-1} \wedge \xi_{r+1} \wedge \cdots \wedge \xi_k).$$

We can define $\mathcal{H}_c^{k-1} := T^k_{\text{poly}}$ with this Schouten-Nijenhuis bracket.

Now, a bivector $\alpha = \Sigma_{i,j} \alpha^{ij} (\partial/\partial x_i) \wedge (\partial/\partial x_j) \in T^1_{\text{poly}}$ in the local expression represents the Poisson bracket by $\{f,g\} = \Sigma_{i,j} \alpha^{ij} (\partial f/\partial x_i)(\partial g/\partial x_j)$, where $(x_1, \ldots, x_n)$ are local coordinates of M. This bracket by definition satisfies all the axioms of a Poisson algebra except the Jacobi identity. The Jacobi identity is then described by

$$[\alpha, \alpha] = 0. \tag{6.5}$$

Since $d=0$, Eq. (6.5) is also the Maurer-Cartan equation. A bivector satisfying (6.5) is called a Poisson bivector. Similarly, a quantum deformation of the Poisson bivector is defined by $\alpha_{[\nu]} \in \nu T^1_{\text{poly}}[[\nu]]$ satisfying

$$[\alpha_{[\nu]}, \alpha_{[\nu]}] = 0. \tag{6.6}$$

In the expansion $\alpha_{[\nu]} = \nu\alpha_1 + \nu^2\alpha_2 + \cdots$, the original classical Poisson bivector α is α_1. In fact, expanding (6.6) in terms of powers of ν, one can see that the lowest identity reads $[\alpha_1, \alpha_1] = 0$.

Thus, the conditions that an element in $\nu T^1_{\text{poly}}[[\nu]]$ is a Poisson bracket and that an associative product on $C^\infty(M)[[\nu]]$ as an element in $\nu D^1_{\text{poly}}[[\nu]]$ are both described by Maurer-Cartan equations for DGLAs. Let us set two L_∞ algebras $(\mathcal{H}_c, \mathfrak{l})$ and $(\mathcal{H}'_c, \mathfrak{l}')$ as the suspension of DGLAs T_{poly} and D_{poly}, respectively. Namely, we have $\mathcal{H}_c^k = T^{k+1}_{\text{poly}}$ and $\mathcal{H}_c'^k = D^{k+1}_{\text{poly}}$. The Maurer-Cartan equations for DGLAs (6.6), (6.4) are of course rewritten as the Maurer-Cartan equations for L_∞ algebras through the suspension in Remark 6.2.

The existence and the classification of the deformation quantization follows from the formality theorem,[40] which claims the existence of an L_∞ quasi-isomorphism $\mathfrak{f}: (\mathcal{H}_c, \mathfrak{l}) \to (\mathcal{H}'_c, \mathfrak{l}')$. Note that this fact implies that the DGLA of Hochschild cochains is (homotopically) formal; in particular, the higher L_∞ structures vanish on its cohomologies. In order that $\mathfrak{f}$ is an L_∞ quasi-isomorphism, the chain map $f_1: (\mathcal{H}_c, d_c = 0) \to (\mathcal{H}'_c, d'_c)$ must be a quasi-isomorphism, that is, f_1 must induce an isomorphism on cohomologies. One may set

$$(f_1(\xi_{i_1} \wedge \cdots \wedge \xi_{i_k}))(g_1, \ldots, g_k) = \frac{1}{k!} \sum_{\sigma \in \mathfrak{S}} (-1)^{\epsilon(\sigma)} (\xi_{i_{\sigma(1)}} g_1) \cdots (\xi_{i_{\sigma(k)}} g_k).$$

Kontsevich constructs all the higher multilinear maps f_k explicitly as local expressions on $M = \mathbb{R}^n$ in terms of Feynman graphs, which are just those derived from a certain topological open-closed string theory as revealed explicitly by Cattaneo-Felder[8] (see for review Ref. 48).

When an L_∞ quasi-isomorphism $\mathfrak{f} = \{f_1, f_2, \ldots\}$ is given, it preserves the Maurer-Cartan equations, and the deformed Poisson bivector is given by the following nonlinear map:

$$\theta = \sum_{k=1}^{\infty} \frac{1}{k!} f_k(\alpha_{[\nu]}, \ldots, \alpha_{[\nu]}), \tag{6.7}$$

for $\alpha_{[\nu]} \in \mathcal{M}(\mathcal{H}_c, \mathfrak{l})$ and $\theta \in \mathcal{M}(\mathcal{H}'_c, \mathfrak{l}')$. Here the L_∞ quasi-isomorphism $\mathfrak{f}: (\mathcal{H}_c, \mathfrak{l}) \to (\mathcal{H}'_c, \mathfrak{l}')$ has been extended by tensoring with the formal power series $\nu\mathbb{C}[[\nu]]$. If we expand the deformation $m = \bar{m} + \theta, \theta \in \nu D_{poly}[[\nu]]$ as in Eq. (6.3):

$$m = \bar{m} + \nu m_1 + \nu^2 m_2 + \cdots$$

with $m_1 = (1/2)\alpha_1$, Kontsevich's quasi-isomorphism of L_∞ algebras then provides a choice for m_2 and in fact for all the m_i.

Now, let us summarize Kontsevich's deformation quantization in terms of OCHAs. First, we set $\mathcal{H}_c^{r-2} := \Gamma(M, \wedge^r TM)$. It forms a formal L_∞ algebra with l_2 the Schouten-Nijenhuis bracket, and $l_1 = l_3 = \cdots = 0$. For $\mathcal{H}_o$, we take $\mathcal{H}_o^{-1} := C^\infty(M)$ and $\mathcal{H}_o^k = 0$ for $k \neq -1$. The A_∞ structure is $n_{0,2} = \bar{m}$,

the usual commutative product of functions $C^\infty(M)$, and $n_{0,l}=0$ except for $l=2$. The multilinear maps of the L_∞ quasi-isomorphism are then identified as the adjoints$\{n_{k,l}:(\mathcal{H}_c)^{\otimes k}\otimes(\mathcal{H}_o)^{\otimes l}\to\mathcal{H}_o\}$ with $k\geqslant 1$. In particular, $n_{1,2}(\alpha_{[\nu]};f,g)=(1/2)\{f,g\}$, and $n_{1,k}(\xi_{i_1}\wedge\cdots\wedge\xi_{i_k};g_1,\ldots,g_k)=(1/k!)\Sigma_{\sigma\in\mathfrak{S}}(-1)^{\epsilon(\sigma)}(\xi_{i_{\sigma(1)}}g_1)\cdots(\xi_{i_{\sigma(k)}}g_k)$. These structures form a minimal OCHA on cohomology. Corollary 6.4 then implies that, for a fixed element of $\mathcal{MC}(\mathcal{H}_c,\mathfrak{l})$, an A_∞ structure is obtained. However, in this situation, since Hom is restricted to $\mathrm{Hom}_{\mathrm{sub}}=\oplus\,\mathrm{Hom}_r^{r-1}$ and the elements of Maurer-Cartan equations, especially $\mathcal{M}(\mathcal{H}_c',\mathfrak{l}')$are degree zero, the deformed A_∞ structure also has $m_2\in(\mathrm{Hom}_2[1])^0$ only, i.e., m_1 and higher product $m_3,m_4,\ldots$ are absent. Equivalently, when $\mathcal{H}_c$ is restricted to its degree zero part $\mathcal{H}_c^0$, $n_{k,l}$ vanishes except for $(k,l)=(k,2)$. This m_2 is just the star product, an associative but noncommutative product $C^\infty(M)\otimes C^\infty(M)\to C^\infty(M)$ of a deformation quantization. The next example below is a natural extension of this situation, but in the case that Hom is not restricted to $\mathrm{Hom}_{\mathrm{sub}}$.

C. Open-closed B-model

A natural extension of Kontsevich's deformation quantization setup is to the B-model side of homological mirror symmetry.[39]

The mirror symmetry, a symmetry between Calabi-Yau manifolds, can be interpreted as topological closed string physics. There are two types of topological string theories whose target spaces are Calabi-Yau manifolds. One is called the A-model, which depends only on the complexified symplectic structure and is independent of the complex structure of the Calabi-Yau manifold. Another one, the B-model in contrast depends only on the complex structure. For a given Calabi-Yau manifold M, the mirror symmetry conjecture is the existence of a mirror Calabi-Yau manifold $\hat{M}$ such that the A-model closed string on $\hat{M}$ is equivalent to the B-model closed string on M and vice versa.[71] Homological mirror symmetry is thought of as an open string version[72] of the mirror symmetry conjecture. open string theory in general includes some kind of D-branes, which form a D-brane category (see Ref. 45); the D-branes and open strings are identified with objects and morphisms between the objects. For the tree open string A-model, the corresponding category is Fukaya's A_∞ category,[9] which depends only on the complexified symplectic structure. On the other hand, what is constructed on the B-model side is a category of holomorphic vector bundles or coherent sheaves more generally. The homological mirror symmetry conjecture[39] then states that the Fukaya category on a Calabi-Yau manifold M is in some sense equivalent to the category of coherent sheaves on the mirror dual Calabi-Yau manifold $\hat{M}$. Now, the conjecture is checked successfully in the case M is an elliptic curve,[39,59,57] an Abelian variety,[10,41] a quartic surface,[63] and so on. For noncommutative two-tori, see Refs. 32, 37, and 34 and a related work.[58]

One of the original motivations to argue for this homological mirror symmetry conjecture[39] is that it might explain the (tree closed string parts of) mirror symmetry: the family (deformations) of tree open string A- (respectively, B-) models should be in one-to-one correspondence with that of tree closed string A-(respectively, B-) model, and the tree closed string structure should follow from the corresponding family of the tree open string structures. These concepts have their background in the open-closed string physics in our sense. Since the A side and B side should be mirror dual, they should have isomorphic structures in some sense. However, that which is directly related to us is the B-model side, since there the classical solution of string world sheet theory is only a constant map (no world sheet instanton) and the corresponding moduli spaces are just the usual ones of Riemann surfaces with boundaries and punctures.[71]

One can see that the tree open-closed B-model is just a particular example of the arguments in Sec. VI A, and gives a natural extension of that in the preceding section. However, the mathematical formulation of the tree open-closed B-model is not yet established completely, nor is there known the explicit formula as in the case of deformation quantization in the preceding section.

An interesting attempt and a partial result can be found in Hofman's work.[26] We can identify some set of multilinear maps $\{l_k,n_{p,q}\}$ on open and closed string observables for this situation. Of course we could have an infinite number of homotopy equivalent open-closed homotopy struc-

tures. For instance, for the tree closed string part, the world sheet action of the B-twisted topological string theory as given in Ref. 71 has the space of observables which is identified with the cohomology of $\oplus_{p,q}\Gamma(M,\wedge^p TM\otimes\wedge^q\overline{T^*M})$ with respect to the Dolbeault operator $\bar{\partial}$ and hence, in principle, one can compute closed string $(k+1)$-point functions (=scattering amplitudes) related to l_k. However, in general this is complicated; it is better if one can find a corresponding string field theory in a simple form. Such a string field theory is given by Ref. 6, where the B-twisted topological closed string field theory action consists of the kinetic term and a three point vertex only, and so a DGLA structure is associated to it. Note that the equations of motions are just the Maurer-Cartan equations defining deformations of the complex structures, with additional extended directions mentioned below. The string field theory gives, at least for tree level (genus zero), a simple way of calculating $(k+1)$-point functions in terms of Feynman rules, and this procedure just coincides with taking a minimal model of the DGLA from a homotopy algebraic point of view. (However, for the action given in Ref. 6, they use an inner product which is not nondegenerate in our sense. In particular, it vanishes on the cohomology. Together with an additional structure called a differential Gerstenhaber structure, the pull-back of this action with respect to the L_∞ quasi-isomorphism, or equivalently the superpotential or the collection of tree closed string amplitudes, has a Frobenius structure,[6,2] even though the minimal L_∞ structure is trivial, all $l_k=0$. We do not deal with this Frobenius structure in this paper.)

In a similar way, one can also consider open strings in the B-twisted topological string theory, and, in a similar spirit, one can construct a particular open string topological string field theory action,[72,6] called a holomorphic Chern-Simons action, a holomorphic version of the usual Chern-Simons action or Witten's bosonic open string field theory.[70] Thus, it has a structure of a differential graded associative algebra (DGA) with cyclicity, a cyclic A_∞ structure. Again, tree open string world sheet scattering amplitudes are obtained by taking the minimal model of the DGA.

Although the B-twisted topological string is controlled by such a simple DGLA or DGA for the closed or open string case, respectively, it is known that the same story does not hold for tree open-closed string in general.[74] Therefore, we consider here a minimal OCHA structure whose purely closed string part $\{l_k\}$ and purely open string part $\{m_k=n_{0,k}\}$ are given by taking the minimal models of the DGLA and DGA, respectively. For the closed string side, the corresponding DGLA structure is $(\Gamma(M,\wedge^\star TM\otimes\wedge^\star\overline{T^*M}),\bar{\partial},[\ ,\ ])$, where $[\ ,\ ]$ is the Schouten-Nijenhuis bracket, the one in Definition 6.6 extended to $\overline{T^*M}$ naturally. However, for closed strings, the $\partial\bar{\partial}$ lemma and the Tian-Todorovs lemma lead to the corresponding minimal L_∞ structure, given by the procedure in Sec. V, being trivial (see Refs. 6 and 2). Thus, we have $l_k=0$ for$k\geqslant 1$ for $\mathcal{H}_c^k=\oplus_{p+q-2=k}H^q(\wedge^p TM)$, and the corresponding moduli space is itself,

$$\mathcal{M}(\mathcal{H}_c,\mathfrak{l})=\mathcal{H}_c^0.$$

Here, we restrict $\mathcal{H}_c$ to its degree zero part only. It might be reasonable to think that one can deform in these $\mathcal{H}_c^0$ directions finitely in principle and that the other $\mathcal{H}_c^k$ directions provide fibers of an infinitesimal neighborhood. In fact, the whole deformation space $\mathcal{H}_c$ is called the extended moduli space in Barannikov-Kontsevich.[2] Note that $H^1(\wedge^1 TM)\in\mathcal{H}_c^0$ describes the complex structure deformations. This is the original deformation theory of complex structures, and the Barannikov-Kontsevich's setup can be thought of as an extension of it.

Next, for pure open string structure, we should stress what is taken for $\mathcal{H}_o$. The open string theory forms a D-brane category, which should be treated as an A_∞ category in our context. The objects, B-type D-branes, are the coherent sheaves on M. Thus, $\mathcal{H}_o$ is identified with the space of morphisms between them. A general construction of a minimal model in this situation is found in Refs. 44, 46, 68, and 45, and See Ref. 34 for an explicit construction in the noncommutative two-tori case. However, for simplicity, here we consider the case that the object is only the structure sheaf $\mathcal{O}(M)$. One can see that this simplified situation is enough for our purpose here under some appropriate assumptions. The differential is then simply $\bar{\partial}$, and one obtains a minimal model of DGA $(\mathcal{O}^{0,*}(M),\bar{\partial},\wedge)$, which we denote by $(\mathcal{H}_o,\bar{m}=\{n_{0,k}\}_{k\geqslant 2})$, where $\mathcal{H}_o^{k-1}=H^k(\mathcal{O}^{0,*}(M))$.

For this particular choice of $\mathcal{H}_o$, let us consider the space of multilinear maps $\mathrm{Hom} := \oplus \mathrm{Hom}_k^r$,

$$\mathrm{Hom}_k^r = \mathrm{Hom}^r(\mathcal{H}_o^{\otimes k}, \mathcal{H}_o).$$

Again, the result of Gerstenhaber-Schack,[13] in a similar way as the Hochschild-Konstant-Rosenberg theorem does in the preceding section, implies that the cohomology of $\mathrm{Hom} = \oplus_{k,r} \mathrm{Hom}_k^r$ coincides with $\mathcal{H}_c$ itself (see Ref. 39).

Alternatively, the existence of an L_∞ quasi-isomorphism from $(\mathcal{H}_c, \mathfrak{l})$ to $(\mathcal{H}_c', \mathfrak{l}')$ is guaranteed at least physically, since $\{n_{k,l}\}$ can be constructed as open-closed disk amplitudes of the open-closed B-model, where the string world sheet action is of the same form as the one for pure closed strings, and the space of observables are just those used in separate open-closed B-model. An open-closed disk amplitude is then obtained by the integral of a disk correlation function, calculated in the usual way in physics, over the moduli space of the corresponding disk with punctures, both in the interior and on the boundary.

Moreover, it was checked in Ref. 26 that $n_{1,q}$ given by this physical argument in fact gives the linear part of the L_∞ quasi-isomorphism f_1,

$$n_{1,k}(\xi_{i_1} \wedge \cdots \wedge \xi_{i_k}, f_1, \ldots, f_k) = \frac{1}{k!} \sum_{\sigma \in \mathfrak{S}} (-1)^{\epsilon(\sigma)} (\xi_{i_{\sigma(1)}} f_1) \cdots (\xi_{i_{\sigma(k)}} f_k),$$

where $\xi_i \in TM$ acts on $f_i \in \mathcal{H}_o$ as the Lie derivative. Also, in the spirit of homological mirror symmetry, since the collection $\{n_{k,l}\}$ gives an L_∞ quasi-isomorphism even with the restriction to the category of coherent sheaves to $\mathcal{O}(M)$, it does also in case the full category would be treated for the open string side.

To summarize, we set $\mathcal{H}_c^k = \oplus_{p+q-2=k} H^q(\wedge^p TM)$, $\mathcal{H}_o^{k-1} = H^k(\mathcal{O}^{0,*}(M))$, and $\mathrm{Hom}_k^r = \mathrm{Hom}^r(\mathcal{H}_o^{\otimes k}, \mathcal{H}_o)$. Then we have $l_k = 0$ on $\mathcal{H}_c$ and $n_{0,q}$ is the minimal A_∞ structure of DGA $(\mathcal{O}^{0,*}(M), \bar{\partial}, \wedge)$. The operation l' is defined as in Sec. VI A, that is, $l_1' = [\bar{m}, \ ]$ with $\bar{m} = \Sigma_{0,q} n_{0,q}$ and $\mathfrak{l}_2'$ is related to the commutator $[\ ,\ ]$ through the suspension.

The corresponding OCHA structure in this case reduces to the generalized WDVV relation discussed in Ref. 24. Namely, it corresponds to a minimal OCHA with trivial L_∞ structure. At present, the explicit form of multilinear maps $n_{p,q}$ of $p \geqslant 2$ and $q \geqslant 0$ are not known in general, though physically existence is guaranteed by the open-closed scattering amplitudes of disks in B-twisted topological string theory. There is an interesting restriction where we can understand the form of $n_{k,l}$. Hofman discussed in Ref. 26 that if we restrict $\mathcal{H}_c$ to $\wedge^p TM$, the situation reduces to a complex version of Kontsevich's deformation quantization and hence $n_{p,q}$ are obtained in a similar way.

An interesting difference from the deformation quantization setup in the preceding section is that, since $\mathrm{Hom} = \oplus \mathrm{Hom}_k^r$ is not restricted to $\mathrm{Hom}_{\mathrm{sub}}$, even if $r = 1$ we can have nontrivial deformed m_k. In particular, we could in general obtain a deformation of the A_∞ structure $\bar{m}$ to a weak A_∞ structure, which should be one of the interesting future directions to be investigated.

In this case, for the closed string part, the L_∞ structure is trivial, including the bracket, and hence the obstructions vanish. In a more general model, however, it should not be trivial, as discussed by Huebschmann-Stasheff.[29] It should be interesting to find such models which can be calculated explicitly.

published online 28 February 2006)

For applications of group theory in quantum mechanics, one generally needs explicit matrix representations of the spectrum generating algebras that arise in bases that reduce the symmetry group of some Hamiltonian of interest. Here we use vector coherent state techniques to develop an algorithm for constructing the matrices for arbitrary finite-dimensional irreps of the SO(5) Lie algebra in an SO(3) basis. The SO(3) subgroup of SO(5) is defined by regarding SO(5) as linear transformations of the five-dimensional space of an SO(3) irrep of angular momentum two. A need for such irreps arises in the nuclear collective model of quadrupole vibrations and rotations. The algorithm has been implemented in MAPLE, and some tables of results are presented. © *2006 American Institute of Physics.*

I. INTRODUCTION

A vector coherent state (VCS) representation is a representation of a group (or Lie algebra) on a space of vector-valued functions. It is a representation induced from a multidimensional representation of a subgroup. Such representations have been used widely in the construction of explicit representations of Lie algebras and Lie groups,[1–6] in the construction of shift tensors,[7] and for the computation of Clebsch–Gordan coefficients for reducing tensor product representations.[8,9]

The VCS construction for a representation of a group G involves two subgroups that play quite different roles. A so-called "intrinsic" subgroup (sometimes called the "core" subgroup) acts in a known way on a subspace of the representation of interest. A second "orbiter" subgroup acts upon this subspace to generate the larger representation of the group G. A prototypical example of the construction is that for the dynamical group of the rigid rotor given by the semidirect product $G=\mathbb{R}^5 \ltimes \mathrm{SO}(3)$ of an intrinsic $\mathbb{R}^5$ subgroup, which describes the quadrupole moments (hence the shape) of an object, and an orbiter group SO(3), corresponding to physical rotations of the object, which describes its possible orientations. The quantum mechanics of such a rotor are then described by the unitary irreducible representations (irreps) of G.[10]

The key requirement is that the Lie algebras of the intrinsic and orbiter groups, together with those elements of the complexified Lie algebra $\mathfrak{g}_{\mathbb{C}}$ of G that leave the intrinsic space invariant, span the complex extension of the Lie algebra. Finding such groups is often easier in the complex extension of G. In many cases there are then mathematically naturally choices of intrinsic and orbiter subgroups for which the VCS construction of an induced representation is straightforward. Unfortunately a mathematically natural choice often produces a representation in a basis that is not adapted to the symmetries of a physical problem. A goal of this paper is to show how to construct representations of $\mathfrak{so}(5)$ in a basis that reduces a physically relevant $\mathfrak{so}(3) \subset \mathfrak{so}(5)$ subalgebra.

---

[a]Current address: Institute for Quantum Information Science, University of Calgary, Calgary, Alberta T2N 1N4, Canada.

The group SO(5) and its Lie algebra $\mathfrak{so}(5)$ arise in many physical contexts. For example, they are needed for the classification of states in the Bohr–Mottelson model[11] and Interacting Boson model[12] of nuclear collective states. They arise in a charge-independent pairing theory and in the use of isospin for the classification of nuclear shell model basis states.[13,14] They have also been used for the study of algebraic many-body equations of motion methods[15] and high-temperature superconductivity.[16] Depending on the context, $\mathfrak{so}(5)$ irreps may be required in an $\mathfrak{su}(2)$ (e.g., isospin) or an $\mathfrak{so}(3)$ (angular momentum) basis. The isospin $\mathfrak{su}(2)$ algebra is embedded in $\mathfrak{so}(5)$ as a subalgebra $\mathfrak{su}(2)\subset\mathfrak{su}(2)\times\mathfrak{su}(2)\cong\mathfrak{so}(4)\subset\mathfrak{so}(5)$. Thus, the required $\mathfrak{so}(5)\supset\mathfrak{su}(2)$ irreps are given in a basis that reduces the Gel'fand chain $\mathrm{SO}(5)\supset\mathrm{SO}(4)\supset\mathrm{SO}(3)\supset\mathrm{SO}(2)$.[17] Such irreps were constructed years ago[14,18] and reconstructed more simply by VCS methods in Refs. 3 and 19. Note, however, that the $\mathfrak{so}(3)\subset\mathfrak{so}(4)$ subalgebra of the SO(3) group in the Gel'fand chain is not the same as the above-mentioned angular momentum algebra that generates a "geometrical" $\mathrm{SO}(3)\subset\mathrm{SO}(5)$ subgroup of rotations of an associated three-dimensional space; as a result the construction of $\mathfrak{so}(5)$ irreps in an angular-momentum basis is more challenging.

The so-called one-rowed representations that occur in the decomposition of the Hilbert space of the five-dimensional harmonic oscillator can be inferred in an $\mathfrak{so}(3)$ basis from the results of Chaćon, Moshinsky, and others[20–22] or from the SO(5) hyperspherical harmonics and Clebsch–Gordan coefficients given in Ref. 21. An explicit VCS (vector coherent state) construction of irreps with highest weights of the type $(v,0)$ and $(0,f)$ (this notation is explained below) was given by Rowe and Hecht.[22]

In this paper we give a systematic construction of the generic (v,f) irreps in an $\mathfrak{so}(3)$ basis. In addition to its obvious relevance to the representation theory of $\mathfrak{so}(5)$, the construction is a prototype for a relatively sophisticated application of VCS theory.

II. VECTOR COHERENT STATE REPRESENTATIONS

Vector coherent state (VCS) theory is a generalization of standard (scalar) coherent state theory.[23] It was introduced[1] for the purpose of providing an explicit systematic construction of the irreducible unitary representations of the compact and noncompact symplectic Lie algebras. Simplicity and efficiency were achieved in the construction by making use of the already well-known representation theory of the unitary subalgebras. Important aspects of the theory were also introduced independently by Deenen and Quesne in their *partial coherent state representations*.[24] Subsequently, VCS has been used to construct representations of a large number of Lie algebras, groups, and superalgebras (cf. Ref. 6 for a review). Early applications of VCS theory gave realizations of the so-called *holomorphic representations* (reviewed by Hecht[25]). A more general class of VCS representations was later used in the construction of $\mathfrak{su}(3)$ irreps in an $\mathfrak{so}(3)$ basis.[26] It has also been shown that VCS theory is compatible with the theory of induced representations[6] and the theory of geometric quantization.[27] A more general perspective on the theory was given in Ref. 28.

The construction of the finite-dimensional irreps of $\mathfrak{so}(5)$ in an $\mathfrak{so}(3)$ basis has much in common with the construction of irreps of $\mathfrak{su}(3)$ in an $\mathfrak{so}(3)$ basis. The $\mathfrak{su}(3)$ Lie algebra is spanned by the components of $\mathfrak{so}(3)$ tensors of angular momentum $L=1$ and $L=2$, while the $\mathfrak{so}(5)$ Lie algebra is spanned by $\mathfrak{so}(3)$ tensors of angular momentum $L=1$ and $L=3$. However, whereas for $\mathfrak{su}(3)$ it was possible to use scalar coherent state wave functions, a special case of VCS functions, it proves to be essential to use vector-valued wave functions for $\mathfrak{so}(5)$.

The VCS theory of $\mathfrak{su}(3)$ relies on the fact that the carrier space for an $\mathfrak{su}(3)$ irrep is spanned by the set of states generated by SO(3) rotations of a highest weight state. The carrier space for a generic irrep of $\mathfrak{so}(5)$ is generated by SO(3) rotations of a set of highest *grade* states.

A. Highest grade states for an $\mathfrak{so}(5)$ irrep

The $\mathfrak{so}(5)$ Lie algebra is semisimple, of rank 2, and has the root diagram shown in Fig. 1. It is conventional to separate the roots of a semisimple Lie algebra into positive and negative roots and to regard the corresponding root vectors as raising and lowering operators, respectively. Every irrep is then characterized by a highest weight state.

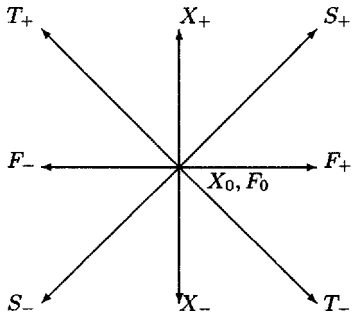

FIG. 1. Root diagram for the $\mathfrak{so}(5)$ Lie algebra.

Let α_1 be the root corresponding to the vector T_+ and α_2 be that corresponding to F_+. Then in the standard labeling scheme, the highest weight Λ for an irrep is given by two integers λ_1 and λ_2 such that $\Lambda=(\lambda_1+\frac{1}{2}\lambda_2)\alpha_1+(\lambda_1+\lambda_2)\alpha_2$. In keeping with the nuclear structure notation, we use the label $v=\lambda_1$ (the "seniority"), and find it convenient to introduce the half-integer $f=\frac{1}{2}\lambda_2$ since it also labels a $\mathfrak{u}(2)$ irrep, as is shown below. Thus, we label an $\mathfrak{so}(5)$ irrep (vf); the highest weight is then given by $\Lambda=(v+f)(\alpha_1+\alpha_2)+f\alpha_2$.

For present purposes, we separate the root vectors into grade raising, grade conserving, and grade lowering operators, as shown in Fig. 2. The horizontal grade-conserving root vectors $\{F_\pm, F_0, X_0\}$ then define what we shall refer to as an *intrinsic* or *core* $\mathfrak{u}(2)$ subalgebra. This grading of the $\mathfrak{so}(5)$ Lie algebra generates a grading of any irrep. Each irrep has a set of highest grade states $\{|(vf)m\rangle\}$ that are annihilated by the grade-raising operators $\hat{T}_+$, $\hat{X}_+$, and $\hat{S}_+$, and carry an irrep of the above-mentioned intrinsic $\mathfrak{u}(2)$ algebra; the highest grade states satisfy the equations

$$\hat{S}_+|(vf)m\rangle = \hat{X}_+|(vf)m\rangle = \hat{T}_+|(vf)m\rangle = 0, \tag{1}$$

$$\hat{X}_0|(vf)m\rangle = (v+f)|(vf)m\rangle, \quad \hat{F}_0|(vf)m\rangle = m|(vf)m\rangle, \tag{2}$$

$$\hat{F}_\pm|(vf)m\rangle = \sqrt{(f\mp m)(f\pm m+1)}|(vf)m\pm 1\rangle. \tag{3}$$

The weights for the highest grade states of a generic irrep of $\mathfrak{so}(5)$ are as illustrated in Fig. 2. A set of wave functions $\{\xi_m^{(vf)}; m=-f,\ldots,f\}$ for these highest grade states are regarded as *intrinsic* wave functions in the VCS construction—it is in the Hilbert space of these intrinsic functions that the VCS wave functions take their *vector* values.

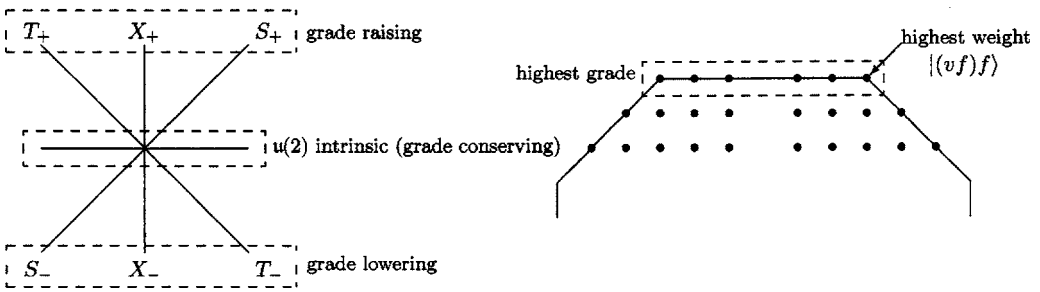

FIG. 2. The $\mathfrak{u}(2)$ intrinsic subalgebra and grade raising/lowering operators. The highest grade and highest weight of a generic $\mathfrak{so}(5)$ irrep are shown in the second digram.

B. Holomorphic VCS wave representations

Let $|\psi\rangle$ be a state in the carrier space of an $\mathfrak{so}(5)$ irrep (vf). Then a holomorphic VCS wave function is defined for this state by

$$\Psi(z) = \sum_m \xi_m^{(vf)} \langle (vf)m | e^{\hat{z}} | \psi \rangle, \tag{4}$$

where

$$\hat{z} = z_1 \hat{S}_+ + z_2 \hat{X}_+ + z_3 \hat{T}_+ \tag{5}$$

and $z=(z_1,z_2,z_3)$ is a set of complex numbers. The corresponding VCS representation Γ of the $\mathfrak{so}(5)$ Lie algebra is defined by

$$[\Gamma(X)\Psi](z) = \sum_m \xi_m^{(vf)} \langle (vf)m | e^{\hat{z}} \hat{X} | \psi \rangle, \quad X \in \mathfrak{so}(5). \tag{6}$$

Such holomorphic representations are natural generalizations of the familiar Bargmann–Segal representations[29] of the Heisenberg–Weyl algebras. They were the first to be considered in the formulation of VCS theory.[1] However, in practical applications they are not always the most useful. In particular, they do not reduce the $\mathfrak{so}(3) \subset \mathfrak{so}(5)$ angular momentum subalgebra.

C. VCS wave functions in an SO(3)-coupled basis

The group SO(3) can be embedded as a subgroup in SO(5) in many ways. We consider the SO(3) subgroup defined up to conjugation by regarding SO(5) as a group of orthogonal transformations of the five-dimensional carrier space for an $L=2$ irrep of SO(3). This embedding is motivated by the rotational properties of the five quadrupole degrees of freedom in the nuclear collective model. The construction of an SO(3)-coupled basis for a VCS irrep of $\mathfrak{so}(5)$ then parallels a similar construction of an SO(3)-coupled basis for a VCS irrep of $\mathfrak{su}(3)$.[26] The $\mathfrak{so}(5)$ construction makes use of the following theorem, which constrains the choice of the SO(3) subgroup.

Theorem 1: Provided no $\mathfrak{so}(3)$ angular momentum operator lies within the $\mathfrak{u}(2)$ intrinsic subalgebra, the set of states $\{\hat{R}(\Omega)|(vf)m\rangle; m=-f,\ldots,f; \Omega \in \mathrm{SO}(3)\}$ obtained by all SO(3) rotations of an orthonormal basis for the highest grade subspace spans the Hilbert space for the $\mathfrak{so}(5)$ irrep (vf).

Proof: The set of states generated by repeated application of the lowering operators $\{\hat{S}_-,\hat{X}_-,\hat{T}_-\}$ to the highest grade states spans the Hilbert space of the irrep. Now, if $\{\hat{L}_i; i=1,2,3\}$ is a Hermitian basis for the $\mathfrak{so}(3) \subset \mathfrak{so}(5)$ subalgebra, then each $\hat{L}_i$ can be expanded $\hat{L}_i = \hat{L}_i^- + \hat{L}_i^0 + \hat{L}_i^+$, where $\hat{L}_i^-$ is a grade lowering operator, $\hat{L}_i^0$ is of grade zero, and $\hat{L}_i^+$is a grade raising operator. By hermiticity, if $\hat{L}_i$ has a nonzero component $\hat{L}_i^+$, it must also have a nonzero $\hat{L}_i^-$ component. Thus, if no $\hat{L}_i$ lies in the zero grade $\mathfrak{u}(2)$ subalgebra, then each $\hat{L}_i$ must have a nonzero $\hat{L}_i^-$ component. By linear independence, it must be that the span of $\{\hat{L}_i^-\}$ equals the span of $\{\hat{S}_-,\hat{X}_-,\hat{T}_-\}$. **QED**

This theorem means that an arbitrary state $|\psi\rangle$ in an irrep (vf) is defined by the set of overlaps $\{\langle (vf)m|\hat{R}(\Omega)|\psi\rangle; m=-f,\ldots,+f; \Omega \in \mathrm{SO}(3)\}$, provided that the SO(3) subgroup is chosen as required by the theorem, which we assume from now on. It also means that, if $\{|(vf)\tau LM\rangle\}$ is an SO(3)-coupled basis for an $\mathfrak{so}(5)$ irrep and $\{|(vf)m\rangle\}$, with wave functions $\{\xi_m^{(vf)}\}$, is an orthonormal $\mathfrak{u}(2)$ basis of highest grade states for this irrep, then the basis states $\{|(vf)\tau LM\rangle\}$ have VCS wave functions given as vector-valued functions over SO(3) by

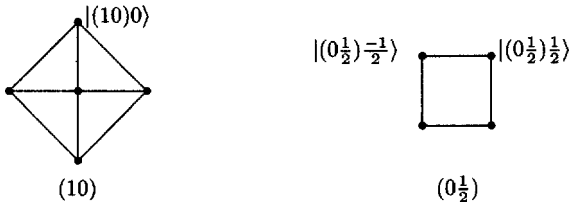

FIG. 3. The weight diagrams for the fundamental irreps (10) and $(0\frac{1}{2})$ with highest grade states labeled $|(vf)m\rangle$

$$\Phi^{(vf)}_{\tau LM}(\Omega) = \sum_m \xi^{(vf)}_m \langle (vf)m|\hat{R}(\Omega)|(vf)\tau LM\rangle. \tag{7}$$

These wave functions are very much like rotor-model wave functions.[11] Indeed, with basis states chosen to have good SO(3) transformation properties, they can be expanded

$$\Phi^{(vf)}_{\tau LM}(\Omega) = \sum_{mK} \xi^{(vf)}_m \langle (vf)m|(vf)\tau LK\rangle \mathcal{D}^L_{KM}(\Omega), \tag{8}$$

where $\mathcal{D}^L(\Omega)$ is a Wigner rotation matrix. It follows that a basis state $|(vf)\tau LM\rangle$ is characterized by the set of expansion coefficients,

$$b^{(vf)}_{mK}(\tau L) = \langle (vf)m|(vf)\tau LK\rangle. \tag{9}$$

The following gives a systematic procedure for determining these coefficients and for deriving the transformations of these coefficients by elements of the $\mathfrak{so}(5)$ Lie algebra as defined by the VCS representation

$$[\Gamma(X)\Phi^{(vf)}_{\tau LM}](\Omega) = \sum_m \xi^{(vf)}_m \langle (vf)m|\hat{R}(\Omega)\hat{X}|(vf)\tau LM\rangle, \quad X \in \mathfrak{so}(5). \tag{10}$$

III. REPRESENTATION SPACES FOR $\mathfrak{so}(5)$

A. A subspace of harmonic oscillator states

Irreps of $\mathfrak{so}(5)$ can be built up from its two fundamental irreps with highest weights (10) and $(0\frac{1}{2})$. The former is the fundamental five-dimensional irrep; the latter is the fundamental four-dimensional irrep. Both weight diagrams are shown in Fig. 3. These fundamental irreps are carried by the spaces generated by the raising operators $\{\eta^\dagger_\nu; \nu = 0, \pm 1, \pm 2\}$ of a five-dimensional harmonic oscillator with symmetry group U(5) and by the raising operators $\{\zeta^\dagger_m; m = \pm\frac{1}{2}, \pm\frac{3}{2}\}$ of a four-dimensional harmonic oscillator with symmetry group U(4), respectively. The operators $\{\eta^\dagger_\nu\}$ and $\{\zeta^\dagger_m\}$, together with the corresponding lowering operators, satisfy the usual boson commutation relations,

$$[\eta^\mu, \eta^\dagger_\nu] = \delta_{\mu\nu}\hat{I}, \quad [\eta^\mu, \eta^\nu] = [\eta^\dagger_\mu, \eta^\dagger_\nu] = 0, \tag{11}$$

$$[\zeta^m, \zeta^\dagger_n] = \delta_{mn}\hat{I}, \quad [\zeta^m, \zeta^n] = [\zeta^\dagger_m, \zeta^\dagger_n] = 0, \tag{12}$$

where we use the notation $\eta^\nu = (\eta^\dagger_\nu)^\dagger$ and $\zeta^m = (\zeta^\dagger_m)^\dagger$.

The invariants of U(5) and U(4) are given by their respective number operators,

$$\hat{n}_\eta = \eta^\dagger \cdot \eta = \sum_\nu \eta^\dagger_\nu \eta^\nu, \quad \hat{n}_\zeta = \zeta^\dagger \cdot \zeta = \sum_m \zeta^\dagger_m \zeta^m. \tag{13}$$

For the natural SO(3) embedding (defined to within conjugation), we can regard these number operators as coupled products, e.g.,

$$\hat{n}_\zeta = 2\sum_m \left(\tfrac{3}{2}, -m, \tfrac{3}{2}, m|0,0\right)\zeta_m^\dagger \zeta_{-m} = \sum_m (-1)^{3/2+m}\zeta_m^\dagger \zeta_{-m}, \tag{14}$$

where

$$\zeta_{-m} = (-1)^{3/2+m}\zeta^m.$$

Similarly, we can define

$$\eta_{-\nu} = (-1)^\nu \eta^\nu. \tag{15}$$

The fundamental five-dimensional irrep of the group SO(5) can be realized as the group of special orthogonal transformations of the creation operators $\{\eta_\nu^\dagger; \nu = 0, \pm 1, \pm 2\}$ that leave invariant the quantity $\eta^\dagger \cdot \eta^\dagger = \Sigma_\nu (-1)^\nu \eta_\nu^\dagger \eta_{-\nu}^\dagger$. This realization exhibits SO(5) as a subgroup of U(5). The four-dimensional fundamental irrep is a spinor irrep of SO(5). It can be realized as the group of special orthogonal transformations of the (boson) creation operators $\{\zeta_m^\dagger; m = \pm\frac{1}{2}, \pm\frac{3}{2}\}$ that leave invariant the quantity $\zeta^\dagger \cdot \zeta^\dagger = \Sigma_m (-1)^{3/2+m}\zeta_m^\dagger \zeta_{-m}^\dagger$. This realization exhibits USp(4), the two-fold cover of SO(5), as a subgroup of U(4). Because every irrep of a group is contained in a tensor product of copies of its fundamental irreps, it follows that every irrep of $\mathfrak{so}(5)$ can be realized on a subspace of the tensor product $\mathbb{H} = \mathbb{H}^{(5)} \otimes \mathbb{H}^{(4)}$, where $\mathbb{H}^{(n)}$ is the Hilbert space of an n-dimensional harmonic oscillator. Highest grade states for an $\mathfrak{so}(5)$ irrep in $\mathbb{H}$ are given by

$$|(vf)m\rangle = \frac{(\zeta_{3/2}^\dagger)^{f+m}(\zeta_{1/2}^\dagger)^{f-m}(\eta_2^\dagger)^v}{\sqrt{(f+m)!\,(f-m)!\,v!}}|0\rangle, \quad m = -f, \ldots, f. \tag{16}$$

B. A model space of VCS wave functions

A model space for a compact Lie group G is a representation of G that is a direct sum of irreps comprising precisely one copy from each equivalence class of irreps.[30] As emphasized by Biedenharn and Flath,[31] a model space provides a valuable framework for a realization of the tensor algebra of the group. We now show that a Hilbert space of VCS wave functions for the states of $\mathbb{H}$ provides a model space with very useful properties.

It follows from Eq. (7) that, provided the conditions of Theorem 1 are satisfied, any state $|\psi\rangle$ in $\mathbb{H}$ has VCS wave function Ψ given by

$$\Psi(\Omega) = \sum_{vfm} \xi_m^{(vf)} \langle (vf)m|\hat{R}(\Omega)|\psi\rangle. \tag{17}$$

Now observe that, if the wave functions $\{\xi_m^{(vf)}\}$ of the highest grade states are expressed in Bargmann form as the holomorphic functions,

$$\xi_m^{(vf)}(x,y) = \frac{x_1^{f+m}x_2^{f-m}y^v}{\sqrt{(f+m)!\,(f-m)!\,v!}}, \tag{18}$$

then, using Eq. (16), the $\mathfrak{u}(2)$-intertwining operator $\Sigma_{vfm}\xi_m^{(vf)}\langle (vf)m|$ can be expressed as

$$\sum_{vfm} \xi_m^{(vf)}\langle (vf)m| = \langle 0|e^{\hat{\mathfrak{X}}}, \tag{19}$$

where

$$\hat{\mathfrak{X}} = x_1\zeta^{3/2} + x_2\zeta^{1/2} + y\,\eta^2. \tag{20}$$

Thus, any state $|\psi\rangle$ in $\mathbb{H}$ has VCS wave function defined by

$$\Psi(\Omega) = \langle 0|e^{\hat{\mathfrak{X}}}\hat{R}(\Omega)|\psi\rangle. \tag{21}$$

Let $\mathcal{F}^{(vf)}$ denote the Hilbert space of VCS wave functions for an $\mathfrak{so}(5)$ irrep of highest weight (vf), relative to the inner product inherited from that of $\mathbb{H}$. The space of all VCS wave functions for states in $\mathbb{H}$ is then the direct sum

$$\mathcal{F} = \bigoplus_{(vf)} \mathcal{F}^{(vf)}, \tag{22}$$

of all such Hilbert spaces. Hence, by construction, it is a model space for $\mathfrak{so}(5)$. The following theorem, which generalizes a theorem of Rowe and Hecht,[22] shows that $\mathcal{F}$ is also a ring and that it can be generated from the VCS wave functions of the fundamental irreps (1,0) and $(0,\frac{1}{2})$.

Theorem 2: If $\Phi = \Phi_1 \odot \Phi_2$ is the *model product* of VCS wave functions defined by

$$\Phi(x,y,\Omega) = \Phi_1(x,y,\Omega)\Phi_2(x,y,\Omega), \tag{23}$$

then, if Φ_1 is in $\mathcal{F}^{(v_1f_1)}$ and Φ_2 is in $\mathcal{F}^{(v_2f_2)}$, the product Φ is in $\mathcal{F}^{(v_1+v_2,f_1+f_2)}$. Moreover, if $\mathcal{F}^{(v_1f_1)} \odot \mathcal{F}^{(v_2f_2)}$ denotes the linear span of model products of the functions of $\mathcal{F}^{(v_1f_1)}$ with the functions of $\mathcal{F}^{(v_2f_2)}$, then

$$\mathcal{F}^{(v_1f_1)} \odot \mathcal{F}^{(v_2f_2)} = \mathcal{F}^{(v_1+v_2,f_1+f_2)}. \tag{24}$$

Proof: Let $\hat{Z}_1^{(v_1f_1)}$ be a homogeneous polynomial of degree v_1 in the $\{\eta_\nu^\dagger\}$ raising operators and degree $2f_1$ in the $\{\zeta_m^\dagger\}$ raising operators, which creates a state with a VCS wave function,

$$\Phi^{(v_1f_1)}(\Omega) = \langle 0|e^{\hat{\mathfrak{X}}}\hat{R}(\Omega)\hat{Z}_1^{(v_1f_1)}|0\rangle. \tag{25}$$

Let

$$\hat{Z}_1^{(v_1f_1)}(\Omega) = \hat{R}(\Omega)\hat{Z}_1^{(v_1f_1)}\hat{R}(\Omega^{-1}) \tag{26}$$

denote the corresponding rotated operator. Then

$$\begin{aligned}\Phi^{(v_1f_1)}(\Omega) &= \langle 0|e^{\hat{\mathfrak{X}}}\hat{Z}_1^{(v_1f_1)}(\Omega)e^{-\hat{\mathfrak{X}}}|0\rangle \\ &= \langle 0|\left(\hat{Z}_1^{(v_1f_1)}(\Omega) + [\hat{\mathfrak{X}},\hat{Z}_1^{(v_1f_1)}(\Omega)] + \frac{1}{2!}[\hat{\mathfrak{X}},[\hat{\mathfrak{X}},\hat{Z}_1^{(v_1f_1)}(\Omega)]] + \cdots\right)|0\rangle.\end{aligned} \tag{27}$$

The successive terms in the sequence of multiple commutators inside the brackets are homogenous polynomials of decreasing degree in the raising operators. This sequence terminates with a polynomial of degree zero (a number) at the (v_1+2f_1)th term. Moreover, this last term is the only term in the sequence with a nonvanishing vacuum expectation value. It follows that

$$\Phi^{(v_1f_1)}(\Omega) = \frac{1}{(v_1+2f_1)!}[\underbrace{\hat{\mathfrak{X}},[\hat{\mathfrak{X}},[\cdots\hat{Z}_1^{(v_1f_1)}(\Omega)]]\cdots}_{v_1+2f_1 \text{ commutators}}]. \tag{28}$$

If $Z_2^{(v_2f_2)}$ is similarly defined for the wave function $\Phi_2^{(v_2f_2)}$, then the wave function $\Phi = \Phi_1^{(v_1f_1)} \odot \Phi_2^{(v_2f_2)}$ has values given by

$$\Phi(\Omega) = \langle 0|(e^{\hat{\mathfrak{X}}}\hat{Z}_1^{(v_1f_1)}(\Omega)e^{-\hat{\mathfrak{X}}})(e^{\hat{\mathfrak{X}}}\hat{Z}_2^{(v_2f_2)}(\Omega)e^{-\hat{\mathfrak{X}}})|0\rangle = \langle 0|e^{\hat{\mathfrak{X}}}\hat{R}(\Omega)\hat{Z}_1^{(v_1f_1)}\hat{Z}_2^{(v_2f_2)}|0\rangle. \tag{29}$$

The state $\hat{Z}_1^{(v_1f_1)}\hat{Z}_2^{(v_2f_2)}|0\rangle$ does not necessarily belong to an irreducible $\mathfrak{so}(5)$ subspace. However, it is of degree (v_1+v_2) and $2(f_1+f_2)$ in the $\{\eta_\nu^\dagger\}$ and $\{\zeta_m^\dagger\}$ operators, respectively, and, therefore, only the component of the state $\hat{Z}_1^{(v_1f_1)}\hat{Z}_2^{(v_2f_2)}|0\rangle$ that does lie within the irreducible SO(5) subspace of highest weight (v_1+v_2,f_1+f_2) will have nonzero overlap with $\langle 0|e^{\hat{\mathfrak{X}}}\hat{R}(\Omega)$.Thus, Φ is a VCS wave function for a state belonging to an SO(5) irrep of highest weight (v_1+v_2,f_1+f_2), as claimed by the theorem. The second part of the theorem follows from the observation that, if $\{\hat{Z}_\alpha^{(vf)}\}$ is a

basis for the linear space $P^{(vf)}$ of homogeneous polynomials of degree v in $\{\eta_\nu^\dagger\}$ and degree $2f$ in $\{\zeta_m^\dagger\}$, then the space $P^{(v_1+v_2,f_1+f_2)}$ is spanned by the products $\{\hat{Z}_{\alpha_1}^{(v_1f_1)}\hat{Z}_{\alpha_2}^{(v_2f_2)}\}$. **QED**

The theorem shows that $\mathcal{F}$ can be constructed from the two fundamental irreps, and that this process will generate all the irreps of $\mathfrak{so}(5)$. The importance of a model space is that, since it is multiplicity free, calculations performed in $\mathcal{F}$ are not complicated by any need to keep track of equivalent copies of the same $\mathfrak{so}(5)$ irreps.

IV. BASES FOR THE $\mathfrak{so}(5)$ LIE ALGEBRA

The VCS representations of $\mathfrak{so}(5)$ in an SO(3)-coupled basis make use of two bases for the $\mathfrak{so}(5)$ Lie algebra: a Cartan basis of root vectors and a basis of components of SO(3) tensors.

A. A Cartan basis

Starting from two copies of the (10) irrep, one spanned by the creation operators $\{\eta_\nu^\dagger\}$ and one spanned by the annihilation operators $\{\eta_\nu\}$, one can construct a realization of the $\mathfrak{so}(5)$ Lie algebra, which carries a (01) irrep, by taking an antisymmetric tensor product of the two. This gives the $\mathfrak{so}(5)$ root vectors of Fig. 1 as a subset of $\mathfrak{u}(5)$ operators,

$$\hat{S}_+ = \eta_1^\dagger\eta_2 - \eta_2^\dagger\eta_1 = \eta_1^\dagger\eta^{-2} + \eta_2^\dagger\eta^{-1}, \tag{30}$$

$$\hat{T}_+ = \eta_{-1}^\dagger\eta_2 - \eta_2^\dagger\eta_{-1} = \eta_{-1}^\dagger\eta^{-2} + \eta_2^\dagger\eta^{1}, \tag{31}$$

$$\hat{X}_+ = \sqrt{2}(\eta_2^\dagger\eta_0 - \eta_0^\dagger\eta_2) = \sqrt{2}(\eta_2^\dagger\eta^{0} - \eta_0^\dagger\eta^{-2}), \tag{32}$$

$$\hat{F}_+ = \sqrt{2}(\eta_1^\dagger\eta_0 - \eta_0^\dagger\eta_1) = \sqrt{2}(\eta_1^\dagger\eta^{0} + \eta_0^\dagger\eta^{-1}), \tag{33}$$

$$\hat{S}_- = (\hat{S}_+)^\dagger, \quad \hat{T}_- = (\hat{T}_+)^\dagger, \tag{34}$$

$$\hat{X}_- = (\hat{X}_+)^\dagger, \quad \hat{F}_- = (\hat{F}_+)^\dagger. \tag{35}$$

A basis for the Cartan subalgebra is given by

$$\hat{X}_0 = \tfrac{1}{2}[\hat{X}_+,\hat{X}_-] = \eta_2^\dagger\eta^2 - \eta_{-2}^\dagger\eta^{-2}, \tag{36}$$

$$\hat{F}_0 = \tfrac{1}{2}[\hat{F}_+,\hat{F}_-] = \eta_1^\dagger\eta^1 - \eta_{-1}^\dagger\eta^{-1}. \tag{37}$$

A realization of the $\mathfrak{so}(5)$ algebra as a subalgebra of $\mathfrak{u}(4)$ is similarly obtained from the symmetric tensor product of two copies of the $\left(0,\frac{1}{2}\right)$ irrep:

$$\hat{S}_+ = -\zeta_{3/2}^\dagger\zeta^{-3/2}, \quad \hat{T}_+ = \zeta_{1/2}^\dagger\zeta^{-1/2}, \tag{38}$$

$$\hat{X}_+ = \zeta_{1/2}^\dagger\zeta^{-3/2} - \zeta_{3/2}^\dagger\zeta^{-1/2}, \tag{39}$$

$$\hat{F}_+ = \zeta_{3/2}^\dagger\zeta^{1/2} + \zeta_{-1/2}^\dagger\zeta^{-3/2}, \tag{40}$$

$$\hat{X}_0 = \tfrac{1}{2}(\zeta_{3/2}^\dagger\zeta^{3/2} + \zeta_{1/2}^\dagger\zeta^{1/2} - \zeta_{-1/2}^\dagger\zeta^{-1/2} - \zeta_{-3/2}^\dagger\zeta^{-3/2}), \tag{41}$$

$$\hat{F}_0 = \tfrac{1}{2}(\zeta^\dagger_{3/2}\zeta^{3/2} - \zeta^\dagger_{1/2}\zeta^{1/2} + \zeta^\dagger_{-1/2}\zeta^{-1/2} - \zeta^\dagger_{-3/2}\zeta^{-3/2}). \tag{42}$$

B. An SO(3) tensor basis

Let $\{\hat{L}_k\}$ denote a set of angular momentum operators for the $\mathfrak{so}(3)$ subalgebra of $\mathfrak{so}(5)$ and let $\{d^\dagger_M; M=0,\pm1,\pm2\}$ and $\{p^\dagger_M; M=\pm\frac{1}{2},\pm\frac{3}{2}\}$ denote linear combinations of the $\{\eta^\dagger_\nu\}$ and $\{\zeta^\dagger_m\}$ operators, respectively, which satisfy the commutation relations

$$[\hat{L}_0, d^\dagger_M] = M d^\dagger_M, \quad [\hat{L}_\pm, d^\dagger_M] = \sqrt{(2 \mp M)(3 \pm M)}\, d^\dagger_{M\pm1}, \tag{43}$$

$$[\hat{L}_0, p^\dagger_M] = M p^\dagger_M, \quad [\hat{L}_\pm, p^\dagger_M] = \sqrt{\left(\tfrac{3}{2} \mp M\right)\left(\tfrac{5}{2} \pm M\right)}\, p^\dagger_{M\pm1}. \tag{44}$$

A basis for a realization of the $\mathfrak{so}(5)$ Lie algebra on the combined (tensor product) Hilbert spaces of the four- and five-dimensional harmonic oscillators is then provided by the $(L=1)$- and $(L=3)$-coupled operators,

$$\hat{L}_k = -\sqrt{10}[d^\dagger \otimes d]_{1k} - \sqrt{5}[p^\dagger \otimes p]_{1k}, \tag{45}$$

$$\hat{O}_\nu = -\sqrt{10}[d^\dagger \otimes d]_{3\nu} + \sqrt{5}[p^\dagger \otimes p]_{3\nu}, \tag{46}$$

where $[d^\dagger \otimes d]_{1k}$ signifies the SU(2)-coupled product,

$$[d^\dagger \otimes d]_{1k} = \sum_{mn} (2,n,2,m|1,k) d^\dagger_m d_n. \tag{47}$$

These operators satisfy the commutation relations

$$[\hat{L}_k, \hat{L}_l] = \sqrt{2}(1l,1k|1k+l)\hat{L}_{k+l}, \tag{48}$$

$$[\hat{L}_k, \hat{O}_\nu] = 2\sqrt{3}(3\nu,1k|3k+\nu)\hat{O}_{k+\nu}, \tag{49}$$

$$[\hat{O}_\mu, \hat{O}_\nu] = 2\sqrt{7}(3\nu,3\mu|1\mu+\nu)\hat{L}_{\mu+\nu} - \sqrt{6}(3\nu,3\mu|3\mu+\nu)\hat{O}_{\mu+\nu}. \tag{50}$$

Specification of the $\{d^\dagger_M\}$ and $\{p^\dagger_M\}$ operators in terms of the $\{\eta^\dagger_\nu\}$ and $\{\zeta^\dagger_m\}$ operators then defines the embedding of $\mathrm{SO}(3) \subset \mathrm{SO}(5)$ as the subgroup with Lie algebra $\mathfrak{so}(3)$ spanned by the $\{\hat{L}_k\}$ angular momentum operators. From now on, all references to SO(3) or $\mathfrak{so}(3)$ will mean this subgroup or its Lie algebra.

C. Relationships between the two bases

Many choices of relationship are possible. However, the simple relationship defined by $d^\dagger_M = \eta^\dagger_M$ and $p^\dagger_M = \zeta^\dagger_M$ is unsatisfactory because, for this choice, it is found that $\hat{L}_0 = 2\hat{X}_0 + \hat{F}_0$; this means that $\hat{L}_0$ lies in the intrinsic $\mathfrak{u}(2)$ subalgebra and the conditions for Theorem 1 are violated. A satisfactory relationship is given by setting

$$d^\dagger_M = e^{(\pi/4)(\hat{S}_+ - \hat{S}_-)} \eta^\dagger_M e^{-(\pi/4)(\hat{S}_+ - \hat{S}_-)}, \tag{51}$$

$$p^\dagger_M = e^{(\pi/4)(\hat{S}_+ - \hat{S}_-)} \zeta^\dagger_M e^{-(\pi/4)(\hat{S}_+ - \hat{S}_-)}. \tag{52}$$

This relationship gives

$$\eta^\dagger_2 = \sqrt{\tfrac{1}{2}}(d^\dagger_2 + d^\dagger_{-1}), \quad \eta^\dagger_{-2} = \sqrt{\tfrac{1}{2}}(d^\dagger_{-2} - d^\dagger_1), \tag{53}$$

$$\eta_0^\dagger = d_0^\dagger, \tag{54}$$

$$\eta_1^\dagger = \sqrt{\tfrac{1}{2}}(d_1^\dagger + d_{-2}^\dagger), \quad \eta_{-1}^\dagger = \sqrt{\frac{1}{2}}(d_{-1}^\dagger - d_2^\dagger), \tag{55}$$

and

$$\zeta_{\frac{3}{2}}^\dagger = \sqrt{\tfrac{1}{2}}(p_{3/2}^\dagger - p_{-3/2}^\dagger), \quad \zeta_{-3/2}^\dagger = \sqrt{\tfrac{1}{2}}(p_{-3/2}^\dagger + p_{3/2}^\dagger), \tag{56}$$

$$\zeta_{1/2}^\dagger = p_{1/2}^\dagger, \quad \zeta_{-1/2}^\dagger = p_{-1/2}^\dagger. \tag{57}$$

The relationship between the two bases for $\mathfrak{so}(5)$ is then given by

$$\hat{L}_0 = \tfrac{1}{2}(\hat{X}_0 - \hat{F}_0) - \tfrac{3}{2}(\hat{S}_+ + \hat{S}_-), \tag{58}$$

$$\hat{L}_\pm = 2\hat{T}_\pm + \sqrt{\tfrac{3}{2}}(\hat{F}_\pm + \hat{X}_\mp), \tag{59}$$

$$\hat{O}_0 = \tfrac{3}{2}(\hat{X}_0 - \hat{F}_0) + \tfrac{1}{2}(\hat{S}_+ + \hat{S}_-), \tag{60}$$

$$\hat{O}_{\pm 1} = \mp \sqrt{3}\hat{T}_\pm \pm \sqrt{\tfrac{1}{2}}(\hat{F}_\pm + \hat{X}_\mp), \tag{61}$$

$$\hat{O}_{\pm 2} = \tfrac{\sqrt{5}}{2}(\hat{X}_\pm - \hat{F}_\mp), \tag{62}$$

$$\hat{O}_{\pm 3} = \tfrac{\sqrt{5}}{2}(\mp \hat{X}_0 \mp \hat{F}_0 - \hat{S}_+ + \hat{S}_-), \tag{63}$$

where $\hat{L}_\pm = \mp \sqrt{2}\hat{L}_{\pm 1}$.

V. CONSTRUCTION OF VCS BASIS WAVE FUNCTIONS

Orthonormal basis states $\{|(vf)\tau LM\rangle\}$ for the (10) and $(0\frac{1}{2})$ irreps, for which the multiplicity index τ is redundant, are given by

$$|(10)2M\rangle = d_M^\dagger|0\rangle, \quad M = 0, \pm 1, \pm 2, \tag{64}$$

$$\left|\left(0\tfrac{1}{2}\right)\tfrac{3}{2}M\right\rangle = p_M^\dagger|0\rangle, \quad M = \pm\tfrac{1}{2}, \pm\tfrac{3}{2}. \tag{65}$$

Thus, from the definitions (18)–(21), the corresponding VCS wave functions are given by

$$\Psi_{2M}^{(10)}(\Omega) = \xi_0^{(10)}\langle 0|\eta^2\hat{R}(\Omega)d_M^\dagger|0\rangle = \sum_K \xi_0^{(10)}\langle 0|\eta^2 d_K^\dagger|0\rangle \mathcal{D}_{KM}^2(\Omega) = \tfrac{1}{\sqrt{2}}\xi_0^{(10)}[\mathcal{D}_{2M}^2(\Omega) + \mathcal{D}_{-1,M}^2(\Omega)], \tag{66}$$

and

$$\begin{aligned}\Psi_{\frac{3}{2}M}^{\left(0\frac{1}{2}\right)}(\Omega) &= \xi_{\frac{1}{2}}^{\left(0\frac{1}{2}\right)}\langle 0|\zeta^{3/2}\hat{R}(\Omega)p_M^\dagger|0\rangle + \xi_{-1/2}^{(01/2)}\langle 0|\zeta^{1/2}\hat{R}(\Omega)p_M^\dagger|0\rangle \\ &= \tfrac{1}{\sqrt{2}}\xi_{1/2}^{(01/2)}[\mathcal{D}_{3/2M}^{3/2}(\Omega) - \mathcal{D}_{-3/2,M}^{3/2}(\Omega)] + \xi_{-1/2}^{(01/2)}\mathcal{D}_{1/2M}^{3/2}(\Omega).\end{aligned} \tag{67}$$

From Eq. (18), it follows that

$$\xi_{m_1}^{(v_1 f_1)} \odot \xi_{m_2}^{(v_2 f_2)} = \sqrt{\frac{(f+m)!\,(f-m)!\,v!}{(f_1+m_1)!\,(f_1-m_1)!\,(f_2+m_2)!\,(f_2-m_2)!\,v_1!\,v_2!}}\,\xi_m^{(vf)}, \tag{68}$$

where

$$v = v_1 + v_2, \quad f = f_1 + f_2, \quad m = m_1 + m_2. \tag{69}$$

From the properties of the Wigner rotation matrices, it also follows that

$$\mathcal{D}_{K_1 M_1}^{L_1} \odot \mathcal{D}_{K_2 M_2}^{L_2} = \sum_{L=|L_1-L_2|}^{L_1+L_2} (L_2 M_2, L_1 M_1 | L M)(L_2 K_2, L_1 K_1 | L K)\mathcal{D}_{KM}^{L}, \tag{70}$$

where

$$K = K_1 + K_2, \quad M = M_1 + M_2. \tag{71}$$

Thus, Theorem 2 and these expressions lead naturally to an algorithm for constructing (nonorthonormal) basis wave functions for an arbitrary $\mathfrak{so}(5)$ irrep.

It is convenient to start by constructing a nonorthonormal basis of VCS wave functions of the form

$$\Phi_{\tau LM}^{(vf)} = \sum_{mK} \xi_m^{(vf)} b_{mK}^{(vf)}(\tau L)\mathcal{D}_{KM}^{L}, \tag{72}$$

with $b_{mK}^{(vf)}(\tau L)$ coefficients conveniently chosen to be real and normalized such that

$$\sum_{mK} b_{mK}^{(vf)}(\tau L) b_{mK}^{(vf)}(\sigma L) = \delta_{\tau\sigma}. \tag{73}$$

The functions Φ so normalized will be related to the orthonormal $\mathfrak{so}(5)$ functions Ψ in Sec. VII.

In order to carry out this basis construction efficiently, it is useful to know the values of the angular momentum and the multiplicity of their occurrence in any given irrep. In other words, we need to know the $\mathfrak{so}(5)\downarrow\mathfrak{so}(3)$ branching rules that give the $\mathfrak{so}(3)$ irreps contained in any given $\mathfrak{so}(5)$ irrep. The $\mathfrak{so}(5)\downarrow\mathfrak{so}(3)$ branching rules for irreps of the type $(v0)$ were conveniently summarized by Williams and Pursey[32] in the form

$$L = 2K,\ 2K-2,\ 2K-3,\ \ldots,K$$

$$K = v,\ v-3,\ v-6,\ \ldots,K_{\min}, \tag{74}$$

where $K_{\min}=0$, 1, or 2. The branching rules for the irreps of type $(0f)$ are given[33] by

$$L = 3K,\ 3K-2,\ 3K-3,\ \ldots,K$$

$$K = f,\ f-2,\ f-4,\ \ldots,K_{\min}, \tag{75}$$

where $K_{\min}=0$ or 1. The branching rules for a generic irrep can be inferred by use of character theory[34] or by a simple "peeling-off" program[35] that uses knowledge of the number of eigenvalues of the $\hat{L}_0$ operator. The $\mathfrak{so}(3)$ content of some low-dimensional $\mathfrak{so}(5)$ irreps is given in Table I.

A basis for any irrep of highest weight (vf) can now be built up by taking coupled products of the above basic wave functions. For example, for the (20) irrep,

$$\Phi_{LM}^{(20)} \propto [\Psi_2^{(10)} \odot \Psi_2^{(10)}]_{LM}, \quad L = 2,4, \tag{76}$$

gives

TABLE I. The $\mathfrak{so}(3)$ content of some low-dimensional $\mathfrak{so}(5)$ irreps; note that the spinor irreps are labeled in the table by $2L$ for convenience.

Genuine irreps		Spinor irreps	
(v,f)	L	(v,f)	$2L$
(1,0)	2	(0,1/2)	3
(0,1)	1,3	(1,1/2)	1,5,7
(2,0)	2,4	(0,3/2)	3,5,9
(1,1)	1,2,3,4,5	(1,3/2)	1,3,5,7,7,9,11,13
(0,2)	0,2,3,4,6	(2,1/2)	3,5,7,9,11
(3,0)	0,3,4,6	(0,5/2)	3,5,7,9,11,15
(2,1)	1,2,3,3,4,5,5,6,7	(1,5/2)	1,3,5,5,7,7,9,9,11,11,13,13,15,17,19
(1,2)	1,2,2,3,4,4,5,5,6,7,8	(2,3/2)	1,3,5,5,7,7,9,9,11,11,13,13,15,17
(0,3)	1,3,3,4,5,6,7,9	(3,1/2)	3,5,7,9,9,11,13,15
(4,0)	2,4,5,6,8	(0,7/2)	3,5,7,9,9,11,13,15,17,21

$$\Phi^{(20)}_{LM} \propto \xi^{(20)}_0 \sum_{K_1K_2} b^{(10)}_{0K_1}(2) b^{(10)}_{0K_2}(2)(2K_1,2K_2|L,K_1+K_2)\mathcal{D}^L_{K_1+K_2,M}$$
$$\propto \xi^{(20)}_0[(22,22|L4)\mathcal{D}^L_{4M} + 2(22,2,-1|L1)\mathcal{D}^L_{1M} + (2,-1,2,-1|L,-2)\mathcal{D}^L_{-2,M}]. \quad (77)$$

Thus, we obtain the results shown in Table II. Similarly, we have for the (01) irrep

$$\Phi^{(01)}_{LM} \propto \xi^{(01)}_1 \sum_{K_1K_2} b^{(01/2)}_{1/2K_1}\left(\tfrac{3}{2}\right) b^{(01/2)}_{1/2K_2}\left(\tfrac{3}{2}\right)\left(\tfrac{3}{2}K_1,\tfrac{3}{2}K_2|L,K_1+K_2\right)\mathcal{D}^L_{K_1+K_2,M}$$
$$+ \sqrt{2}\,\xi^{(01)}_0 \sum_{K_1K_2} b^{(01/2)}_{-1/2K_1}\left(\tfrac{3}{2}\right) b^{(01/2)}_{1/2K_2}\left(\tfrac{3}{2}\right)\left(\tfrac{3}{2}K_1,\tfrac{3}{2}K_2|L,K_1+K_2\right)\mathcal{D}^L_{K_1+K_2,M}$$
$$+ \xi^{(01)}_{-1} \sum_{K_1K_2} b^{(01/2)}_{-1/2K_1}\left(\tfrac{3}{2}\right) b^{(01/2)}_{-1/2K_2}\left(\tfrac{3}{2}\right)\left(\tfrac{3}{2}K_1,\tfrac{3}{2}K_2|L,K_1+K_2\right)\mathcal{D}^L_{K_1+K_2,M}, \quad (78)$$

which leads to a set of coefficients given in Table III.

TABLE II. The $b^{(v0)}_{0K}(\tau L)$ coefficients for some irreps of type $(v0)$. Note that here and in the following tables the coefficients are normalized according to Eq. (73) and their phases are chosen so that the leading nonzero coefficient for each (L,τ) is positive.

$(vf) = (10)$

	K	
L	2	−1
2	$1/\sqrt{2}$	$1/\sqrt{2}$

$(vf) = (20)$

	K		
L	4	1	−2
2	0	$2/\sqrt{5}$	$-1/\sqrt{5}$
4	$\sqrt{7/13}$	$\sqrt{2/13}$	$2/\sqrt{13}$

$(vf) = (30)$

	K			
L	6	3	0	−3
0	0	0	1	0
3	0	$\sqrt{2/5}$	$-\sqrt{1/2}$	$-\sqrt{1/10}$
4	0	$2\sqrt{5/32}$	$\sqrt{7/32}$	$-\sqrt{5/32}$
6	$\sqrt{77/124}$	$3\sqrt{7/620}$	$\sqrt{3/31}$	$2\sqrt{7/155}$

TABLE III. The $b^{(0f)}_{mK}(\tau L)$ coefficients for some irreps of type $(0f)$. Note that for an $\mathfrak{so}(5)$ irrep (vf) the coefficients among different $\mathfrak{so}(3)$ irreps can all be indexed by the same values of $K-m$, hence, this is used to label columns.

$(vf)=(0\frac{1}{2})$

		$K-m$	
L	m	1	-2
$\frac{3}{2}$	$+\frac{1}{2}$	$1/2$	$-1/2$

	$+\frac{1}{2}$	$2\sqrt{14/328}$	$-4\sqrt{1/328}$	$\sqrt{14/328}$	
	$-\frac{1}{2}$	$2\sqrt{21/328}$	$-2\sqrt{6/328}$		
	$-\frac{3}{2}$	$6\sqrt{2/328}$			

In general, we can form basis states for an irrep (vf) from the coupled products

$$[\Phi^{(v0)}_{\tau_2 L_2}\odot\Phi^{(0f)}_{\tau_1 L_1}]_{LM}=\sum_m \xi^{(v0)}_0\odot\xi^{(f0)}_m\sum_{K_1K_2} b^{(v0)}_{0K_2}(\tau_2L_2)b^{(0f)}_{mK_1}(\tau_1L_1)(L_1K_1,L_2K_2|L,K_1+K_2)\mathcal{D}^L_{K_1+K_2,M}. \tag{79}$$

Some examples are given in Table IV.

It is important to recognize that the basis $\{\Phi^{(vf)}_{\tau LM}\}$ is not orthonormal relative to the appropriate inner product for VCS wave functions. An orthonormal basis is one relative to which the VCS representations are unitary; i.e., for which the elements of the $\mathfrak{so}(5)$ Lie algebra are represented by Hermitian operators.

VI. VCS REPRESENTATION OF THE $\mathfrak{so}(5)$ ALGEBRA

According to Eq. (10), the action of the angular momentum operators on any SO(3)-coupled VCS wave functions of the form

TABLE IV. The $b^{(vf)}_{mK}(\tau L)$ coefficients for some generic irreps.

$(vf) = (1\frac{1}{2})$

	-1	$-2\sqrt{42/829}$	$2\sqrt{30/829}$		
5	$+1$	$\sqrt{70/313}$	0	$-\sqrt{3/313}$	$2\sqrt{7/313}$
	0	$2\sqrt{21/313}$	$2/\sqrt{313}$	$-2\sqrt{7/313}$	
	-1	$2\sqrt{14/313}$	$2\sqrt{10/313}$		

$$\Phi^{(vf)}_{\tau LM}(\Omega) = \sum_{mK} \xi^{(vf)}_m \langle (vf)m|(vf)\tau LK\rangle \mathcal{D}^L_{KM}(\Omega) = \sum_{mK} \xi^{(vf)}_m b^{(vf)}_{mK}(\tau L)\mathcal{D}^L_{KM}(\Omega) \tag{80}$$

is given by the standard action

$$[\Gamma(L_0)\Phi^{(vf)}_{\tau LM}](\Omega) = M\Phi^{(vf)}_{\tau LM}(\Omega), \tag{81}$$

$$[\Gamma(L_\pm)\Phi^{(vf)}_{\tau LM}](\Omega) = \sqrt{(L \mp M)(L \pm M + 1)}\,\Phi^{(vf)}_{\tau L,M\pm 1}(\Omega). \tag{82}$$

The action of the octupole operators is given by

$$[\Gamma(O_\nu)\Phi^{(vf)}_{\tau LM}](\Omega) = \sum_{mK\mu} \xi^{(vf)}_m \langle (vf)m|\hat{O}_\mu|(vf)\tau LK\rangle \mathcal{D}^3_{\mu\nu}(\Omega)\mathcal{D}^L_{KM}(\Omega), \tag{83}$$

or, in coupled form,

$$[\Gamma(O)\otimes \Phi^{(vf)}_{\tau L}]_{L'M} = \sum_{mK\mu} \xi^{(vf)}_m \langle (vf)m|\hat{O}_\mu|(vf)\tau LK\rangle (LK,3\mu|L',K+\mu)\mathcal{D}^{L'}_{K+\mu,M}. \tag{84}$$

Thus, it remains to determine the matrix elements $\{\langle (vf)m|\hat{O}_\mu|(vf)\tau LK\rangle\}$ to define an $\mathfrak{so}(5)$ irrep (vf). From the definition of the states $\{|(vf)m\rangle\}$ as highest grade states, cf. Eqs. (1)–(3), we have the identities

$$\langle (vf)m|\hat{S}_-|(vf)\tau LK\rangle = \langle (vf)m|\hat{X}_-|(vf)\tau LK\rangle = \langle (vf)m|\hat{T}_-|(vf)\tau LK\rangle = 0, \tag{85}$$

$$\langle (vf)m|\hat{X}_0|(vf)\tau LK\rangle = (v+f)\langle (vf)m|(vf)\tau LK\rangle, \quad \langle (vf)m|\hat{F}_0|(vf)\tau LK\rangle = m\langle vfm|(vf)\tau LK\rangle, \tag{86}$$

$$\langle (vf)m|\hat{F}_{\pm}|(vf)\tau LK\rangle = \sqrt{(f\pm m)(f\mp m+1)}\langle (vf)m\mp 1|(vf)\tau LK\rangle, \tag{87}$$

and from the standard action of the angular momentum operators on the states $\{|(vf)\tau LK\rangle\}$, we have

$$\langle (vf)m|\hat{L}_0|(vf)\tau LK\rangle = K\langle (vf)m|(vf)\tau LK\rangle, \tag{88}$$

$$\langle (vf)m|\hat{L}_{\pm}|(vf)\tau LK\rangle = \sqrt{(L\mp K)(L\pm K+1)}\langle (vf)m|(vf)\tau L,K\pm 1\rangle. \tag{89}$$

Equations (58) and (59) give the relationships

$$\hat{S}_+ = \frac{1}{3}(\hat{X}_0 - \hat{F}_0) - \hat{S}_- - \frac{2}{3}\hat{L}_0, \tag{90}$$

$$\hat{X}_+ = \sqrt{\frac{2}{3}}\hat{L}_- - 2\sqrt{\frac{2}{3}}\hat{T}_- - \hat{F}_-, \tag{91}$$

$$\hat{T}_+ = \frac{1}{2}\hat{L}_+ - \frac{1}{2}\sqrt{\frac{3}{2}}(\hat{F}_+ + \hat{X}_-), \tag{92}$$

which makes it possible to rewrite Eqs. (60)–(63) in the form

$$\hat{O}_0 = \frac{5}{3}(\hat{X}_0 - \hat{F}_0) - \frac{1}{3}\hat{L}_0, \tag{93}$$

$$\hat{O}_1 = -\frac{\sqrt{3}}{2}\hat{L}_+ + \frac{5}{2\sqrt{2}}(\hat{F}_+ + \hat{X}_-), \tag{94}$$

$$\hat{O}_{-1} = -\frac{1}{\sqrt{3}}\hat{L}_- + \frac{5}{\sqrt{3}}\hat{T}_-, \tag{95}$$

$$\hat{O}_2 = \sqrt{\frac{5}{6}}\hat{L}_- - \sqrt{\frac{10}{3}}\hat{T}_- - \sqrt{5}\hat{F}_-, \tag{96}$$

$$O_{-2} = \frac{\sqrt{5}}{2}\hat{X}_- - \frac{\sqrt{5}}{2}\hat{F}_+, \tag{97}$$

$$O_3 = -\frac{2\sqrt{5}}{3}\hat{X}_0 - \frac{\sqrt{5}}{3}\hat{F}_0 + \sqrt{5}\hat{S}_- + \frac{\sqrt{5}}{3}\hat{L}_0, \tag{98}$$

$$O_{-3} = \frac{\sqrt{5}}{3}\hat{X}_0 + \frac{2\sqrt{5}}{3}\hat{F}_0 + \sqrt{5}\hat{S}_- + \frac{\sqrt{5}}{3}\hat{L}_0. \tag{99}$$

We now have all of the $\mathfrak{so}(5)$ operators in terms of the basis operators $\{S_-, T_-, X_-, X_0, F_0, F_\pm, L_0, L_\pm\}$ with known algebraic actions on either the highest grade states or on

the $\mathfrak{so}(3)$-coupled states. Note that Theorem 1 ensures that this set is linearly independent and spans $\mathfrak{so}(5)$. This is a general feature of a useful VCS construction.

We obtain

$$\langle (vf)m|\hat{O}_0|(vf)\tau LK\rangle = \frac{1}{3}(5v+5f-5m-K)b^{(vf)}_{mK}(\tau L), \tag{100}$$

$$\langle (vf)m|\hat{O}_1|(vf)\tau LK\rangle = \tfrac{5}{2}\sqrt{\tfrac{1}{2}(f+m)(f-m+1)}\,b^{(vf)}_{m-1,K}(\tau L) - \tfrac{1}{2}\sqrt{3(L-K)(L+K+1)}\,b^{(vf)}_{m,K+1}(\tau L), \tag{101}$$

$$\langle (vf)m|\hat{O}_{-1}|(vf)\tau LK\rangle = -\sqrt{\tfrac{1}{3}(L+K)(L-K+1)}\,b^{(vf)}_{m,K-1}(\tau L), \tag{102}$$

$$\langle (vf)m|\hat{O}_2|(vf)\tau LK\rangle = \sqrt{\tfrac{5}{6}(L+K)(L-K+1)}\,b^{(vf)}_{m,K-1}(\tau L) - \sqrt{5(f-m)(f+m+1)}\,b^{(vf)}_{m+1,K}(\tau L), \tag{103}$$

$$\langle (vf)m|\hat{O}_{-2}|(vf)\tau LK\rangle = -\tfrac{1}{2}\sqrt{5(f+m)(f-m+1)}\,b^{(vf)}_{m-1,K}(\tau L), \tag{104}$$

$$\langle (vf)m|\hat{O}_3|(vf)\tau LK\rangle = -\tfrac{\sqrt{5}}{3}(2v+2f+m-K)b^{(vf)}_{mK}(\tau L), \tag{105}$$

$$\langle (vf)m|\hat{O}_{-3}|(vf)\tau LK\rangle = \tfrac{\sqrt{5}}{3}(v+f+2m+K)b^{(vf)}_{mK}(\tau L). \tag{106}$$

It follows that Eq. (84) has the explicit expansion given by

$$[\Gamma(O)\otimes\Phi^{(vf)}_{\tau L}]_{L'M} = \sum_{mKm'K'} b^{(vf)}_{mK}(\tau L)M^{(vf)}_{mKL,m'K'L'}\xi^{(vf)}_{m'}\mathcal{D}^{L'}_{K'M}, \tag{107}$$

where $M^{(vf)}$ is a matrix with nonzero entries,

$$\begin{aligned}
M^{(vf)}_{mKL,mKL'} &= \tfrac{1}{3}(5v+5f-5m-K)(LK,\,30|L'K) - \tfrac{1}{2}\sqrt{3(L+K)(L-K+1)}\,(LK-1,3\;1|L'K)\\
&\quad - \sqrt{\tfrac{1}{3}(L-K)(L+K+1)}\,(LK+1,3\;-1|L'K),\\
M^{(vf)}_{mKL,m+1K+1L'} &= \tfrac{5}{2}\sqrt{\tfrac{1}{2}(f-m)(f+m+1)}\,(LK,3\;1|L'K+1),\\
M^{(vf)}_{mKL,m-1K+2L'} &= -\sqrt{5(f+m)(f-m+1)}\,(LK,3\;2|L'K+2),\\
M^{(vf)}_{mKL,mK+3L'} &= \sqrt{\tfrac{5}{6}(L-K)(L+K+1)}\,(LK+1,3\;2|L'K+3) - \frac{\sqrt{5}}{3}(2v+2f+m-K)(LK,3\;3|L'K+3),\\
M^{(vf)}_{mKL,m+1K-2L'} &= -\tfrac{1}{2}\sqrt{5(f-m)(f+m+1)}\,(LK,3\;-2|L'K-2),\\
M^{(vf)}_{mKL,mK-3L'} &= \tfrac{\sqrt{5}}{3}(v+f+2m+K)(LK,3\;-3|L'K-3).
\end{aligned} \tag{108}$$

Now, if the basis wave functions $\{\Phi^{(vf)}_{\tau LM}\}$ are chosen, as defined in Sec. V, with $\{b^{(vf)}_{mK}(\tau L)\}$ coefficients that are real and satisfy Eq. (73), it follows that Eq. (107) can be expressed as

$$[\Gamma(O)\otimes\Phi^{(vf)}_{\tau L}]_{L'M}=\sum_{\sigma}\Phi^{(vf)}_{\sigma L'M}\mathcal{O}^{(vf)}_{\sigma L',\tau L}, \tag{109}$$

where

$$\mathcal{O}^{(vf)}_{\sigma L',\tau L}=\sum_{mKm'K'}b^{(vf)}_{mK}(\tau L)M^{(vf)}_{mKL,m'K'L'}b^{(vf)}_{m'K'}(\sigma L'). \tag{110}$$

Thus, together with Eqs. (81) and (82), these equations give the explicit transformations of the $\{\Phi^{(vf)}_{\tau LM}\}$ basis wave functions for any $\mathfrak{so}(5)$ irrep.

Unfortunately, these matrices do not satisfy the hermiticity conditions required of a unitary representation. This is because the $\{\Phi^{(vf)}_{\tau LM}\}$ basis is not orthonormal relative to the appropriate VCS inner product.

VII. THE MATRICES OF UNITARY IRREPS

We now suppose that $\{|(vf)\alpha LM\rangle\}$ is an orthonormal basis for an irrep (vf) and that the corresponding VCS wave functions have expansions

$$\Psi^{(vf)}_{\alpha LM}=\sum_{mK}\xi^{(vf)}_{m}\langle(vf)m|(vf)\alpha LK\rangle\mathcal{D}^{L}_{KM}=\sum_{mK}\xi^{(vf)}_{m}a^{(vf)}_{mK}(\alpha L)\mathcal{D}^{L}_{KM}. \tag{111}$$

Note that for an orthonormal basis we have called the expansion coefficients of the VCS wave functions $a^{(vf)}_{mK}$ in order to distinguish them from the $b^{(vf)}_{mK}$ coefficients of the nonorthonormal $\Phi^{(vf)}_{\sigma LM}$ basis. The Wigner–Eckart theorem for matrix elements in an orthonormal basis,

$$\langle(vf)\beta L'M'|\hat{O}_{\nu}|(vf)\alpha LM\rangle=\frac{1}{\sqrt{2L'+1}}(LM,3\nu|L'M')\langle(vf)\beta L'\|\hat{O}\|(vf)\alpha L\rangle \tag{112}$$

then implies that

$$[\Gamma(O)\otimes\Psi^{(vf)}_{\alpha L}]_{L'M'}=\frac{1}{\sqrt{2L'+1}}\sum_{\beta}\Psi^{(vf)}_{\beta L'}\langle(vf)\beta L'\|\hat{O}\|(vf)\alpha L\rangle. \tag{113}$$

It follows from Eq. (110) that if the orthornormal basis wave functions are expanded as

$$\Psi^{(vf)}_{\alpha LM}=\sum_{\sigma}\Phi^{(vf)}_{\sigma LM}K^{(vf)}_{\sigma\alpha}(L); \tag{114}$$

then the desired reduced matrix elements, relative to the orthonormal basis, are given by

$$\langle(vf)\beta L'\|\hat{O}\|(vf)\alpha L\rangle=\sqrt{2L'+1}\sum_{\sigma\tau}\overline{K}^{(vf)}_{\beta\tau}\mathcal{O}^{(vf)}_{\tau L',\sigma L}K^{(vf)}_{\sigma\alpha}, \tag{115}$$

where $\overline{K}^{(vf)}$ is the inverse of the matrix $K^{(vf)}$, i.e., it is defined such that

$$\sum_{\sigma}\overline{K}^{(vf)}_{\beta\sigma}K^{(vf)}_{\sigma\alpha}=\delta_{\alpha\beta}. \tag{116}$$

The $K^{(vf)}(L)$ matrices are chosen in VCS theory[1] such that the reduced matrix elements satisfy the hermiticity condition

$$\langle(vf)\alpha L'\|\hat{O}\|(vf)\beta L\rangle^{*}=(-1)^{L-L'}\langle(vf)\beta L\|\hat{O}\|(vf)\alpha L'\rangle, \tag{117}$$

required of a unitary representation. Such a transformation is found in two steps.[36]

First observe that the submatrices $\mathcal{O}(L)$ with elements

$$\mathcal{O}_{\sigma\tau}(L) = \mathcal{O}^{(vf)}_{\sigma L,\tau L} \tag{118}$$

are real and symmetric. Thus, we first make an orthogonal transformation

$$\tilde{\Phi}^{(vf)}_{\alpha LM} = \sum_{\sigma} \Phi^{(vf)}_{\sigma LM} \mathcal{K}^{(vf)}_{\sigma\alpha}(L), \tag{119}$$

which diagonalizes the $\mathcal{O}(L)$ matrices. The transformed matrix,

$$\tilde{\mathcal{O}}^{(vf)}_{\beta L',\alpha L} = \sum_{\sigma\tau} \mathcal{K}^{(vf)}_{\tau\beta}(L') \mathcal{O}^{(vf)}_{\tau L',\sigma L} \mathcal{K}^{(vf)}_{\sigma\alpha}(L), \tag{120}$$

then satisfies the equality

$$\tilde{\mathcal{O}}^{(vf)}_{\beta L,\alpha L} = \delta_{\alpha\beta} \mathcal{O}^{(vf)}_{\beta L,\beta L}. \tag{121}$$

Before proceeding, it is important to note that states of different L and M are automatically orthogonal by virtue of their transformation properties under $SO(3)$. Moreover, if the reduced matrices for $L=L'$ are diagonal, this subset of matrices automatically satisfies the hermiticity condition (117).

Thus, in general, it only remains to apply suitable scale factors to the basis vectors $\{\tilde{\Phi}^{(vf)}_{\alpha LM}\}$ to obtain an orthonormal basis. The required scale factors $\{k^{(vf)}_{\alpha L}\}$ must be such that

$$(k^{(vf)}_{\alpha L})^{-1} \tilde{\mathcal{O}}^{(vf)}_{\alpha L,\beta L'} k^{(vf)}_{\beta L'} = (-1)^{L-L'} (k^{(vf)}_{\beta L'})^{-1} \tilde{\mathcal{O}}^{(vf)}_{\beta L',\alpha L} k^{(vf)}_{\alpha L}. \tag{122}$$

The desired $K^{(vf)}$ matrices are then given by

$$K^{(vf)}_{\tau\alpha}(L) = \mathcal{K}^{(vf)}_{\tau\alpha}(L) k^{(vf)}_{\alpha L}, \tag{123}$$

with

$$\left| \frac{k^{(vf)}_{\alpha L}}{k^{(vf)}_{\beta L'}} \right|^2 = (-1)^{L-L'} \frac{\tilde{\mathcal{O}}^{(vf)}_{\alpha L,\beta L'}}{\tilde{\mathcal{O}}^{(vf)}_{\beta L',\alpha L}}. \tag{124}$$

Special consideration must be given to the relatively few irreps for which there is a multiplicity of states of $L=0$, $\frac{1}{2}$, or 1. This is because the $\mathcal{O}(L)$ matrices are identically zero for these L values. However, to ensure the orthogonality and correct normalization of, for example, the $L=0$ states it is sufficient to determine linear combinations of these states that satisfy the equations

$$\langle (vf)\alpha 0 \| \hat{O} \| (vf)\beta L \rangle = (-1)^L \langle (vf)\beta L \| \hat{O} \| (vf)\alpha 0 \rangle, \tag{125}$$

where $\{|(vf)\beta LM\rangle\}$ is a small subset of states that have already been orthonormalized.

VIII. SAMPLE RESULTS

In this section we tabulate the a coefficients $a^{(vf)}_{mK}(\tau L)$ of the unitary basis wave functions and the unitary SO(3)-reduced $\mathfrak{so}(5)$ matrix elements of the $\hat{O}$ operator for the simplest generic $\mathfrak{so}(5)$ irreps as well as the table for the first irrep with a multiplicity, namely $(1\frac{3}{2})$ [we index the multiple $\mathfrak{so}(3)$ irreps as L_τ]. Because of the SO(3) reduction, we need only provide values between states of different L, since the Wigner–Ekart theorem provides the rest. Note that the matrix elements of the $\hat{L}$ operator are easily computed using Eqs. (81) and (82), and so they are not included in the tables. Since the diagonalization of Eq. (119) must be done numerically, the values are given in floating point form. (See Tables V–VIII.)

IX. CONCLUDING REMARKS

As mentioned in the Introduction, the group SO(5) and its Lie algebra $\mathfrak{so}(5)$ arise in many physical contexts and, depending on the situation, their irreps are needed in different bases. In particular, they are needed in bases that reduce one of the following: (i) the U(2) subgroup whose Lie algebra is the grade-conserving intrinsic subalgebra shown in Fig. 2; (ii) the SO(4) subgroup generated by the S and T root vectors shown in Fig. 2; and (iii) the geometric SO(3) subgroup considered in this paper. VCS theory[1] has now been used in systematic ways to construct SO(5) irreps in all of these bases.

VCS theory was originally formulated to construct the holomorphic representations of the compact and noncompact discrete-series representations of the symplectic algebras. A first application constructed the irreps of the noncompact $\mathfrak{sp}(6,\mathbb{R})$ algebra [also called $\mathfrak{sp}(3,\mathbb{R})$] in a U(3) coupled basis. A next application, by Hecht and Elliott,[19] derived similar results for the compact $\mathfrak{sp}(4)$ algebra [isomorphic to $\mathfrak{so}(5)$] in a U(2)-coupled basis.

The common feature of the holomorphic VCS representations, which makes them particularly simple,[25] is their use of Abelian orbiter groups with Lie algebras spanned by commuting sets of grade-lowering (or grade-raising) operators to complement the grade-conserving intrinsic subgroups that generate highest- (or lowest-) grade intrinsic vectors for a VCS representation. A problem is that Abelian orbiter groups cannot be found in many important situations. For example, in constructing irreps of $\mathfrak{so}(5)$ in an $\mathfrak{so}(4)$-coupled basis, it is natural to use SO(4) as the intrinsic subgroup. However, the complementary $\mathfrak{so}(5)$ lowering operators (i.e., the operators F_- and X_- of Fig. 2) do not then commute. Fortunately, it was possible to extend the VCS construction[37] to accommodate this situation. It was also discovered[26] that VCS theory could be extended to give the much needed irreps of, for example, $\mathfrak{su}(3)$ in an $\mathfrak{so}(3)$ basis by using SO(3) itself as an orbiter group to complement an intrinsic U(2) group. This method was subsequently used[22] to construct the so-called one-rowed irreps of $\mathfrak{so}(5)$ [the irreps of type $(v,0)$ in the notation of this paper] for which only scalar-valued VCS wave functions are needed. The techniques have been further developed in this paper to give the generic $\mathfrak{so}(5)$ irreps in what is the most sophisticated explicit VCS construction of irreps to date.

Some novel features that considerably simplify the construction of VCS representations were introduced in Ref. 22 and further developed here. In particular, we have found that the Hilbert space $\mathcal{H}$ of all SO(5) VCS wave functions is a model space for SO(5), in the sense that it contains precisely one copy of every irrep. A particularly valuable feature of this model space is that it is a ring in as much as the product of any two VCS wave functions is another VCS wave function in $\mathcal{H}$. This observation greatly facilitates the construction of an $\mathrm{SO}(5)\supset\mathrm{SO}(3)$-coupled basis for $\mathcal{H}$; one has simply to construct multiple SO(3)-coupled products of the generating functions given by the VCS wave functions for the fundamental $(1,0)$ and $(0,\frac{1}{2})$ irreps. As a result, it is very easy to construct (nonorthonormal) basis wave functions for any $\mathfrak{so}(5)$ irrep. It is also shown that, once a basis has been determined, the matrices of the $\mathfrak{so}(5)$ Lie algebra in this basis can be determined

algebraically; cf. Eqs. (107) and (108). These results are remarkable in view of the fact that there is generally a multiplicity in the $SO(5) \supset SO(3)$ reduction of the representation space.

An important component of VCS theory is its incorporation of algorithms that go under the name of *K*-matrix theory,[36] whose purpose is to determine the inner product of a Hilbert space, transform a nonorthonormal basis into an orthonormal basis, and a nonunitary VCS irrep into a unitary representation whenever it is equivalent to a unitary irrep (or more generally to an isometric irrep when it is equivalent to an isometric irrep). For the irreps considered in this paper, a particularly simple version of the *K*-matrix transformation is given[36] by first finding an orthogonal basis in which off-diagonal matrix elements of the SO(5) octupole operator are zero between states of the same SO(3) angular momentum. This is simply achieved by diagonalization of subblocks of the octupole matrices. The renormalization factors needed to give an orthonormal basis can then be read off, as shown in Sec. VII. Unfortunately, this simple method does not work for states of angular momentum $L=0, \frac{1}{2}$, or 1, when there are multiple states of these L values. One must then resort to less simple *K*-matrix methods.

To summarize, the construction of the SO(3)-reduced matrices of the octupole operators in a generic $\mathfrak{so}(5)$ irrep is achieved in three simple steps: (i) the construction of basis wave functions with good SO(3) angular momentum quantum numbers; (ii) a calculation of the reduced matrix elements of the $\mathfrak{so}(5)$ octupole operators in this basis; and (iii) transforming these matrices to those of a unitary representation in an orthonormal basis.

Step (i) is simply achieved for a (vf) irrep by first computing the basis wave functions for the $(v0)$ and $(0f)$ irreps and then taking their SO(3)-coupled products, as indicated in Sec. V. Step (ii) is achieved by use of the analytical expressions given in Sec. VI in terms of SU(2) Clebsch–Gordan coefficients and the coefficients of the wave functions of step (i). Finally, step (iii) is achieved by the unitarization process described above and in Sec. VII. The routine has been coded in MAPLE, which is amenable to both algebraic and numeric computations. Steps (i) and (ii) are carried out algebraically; thus, the results in Tables II–IV are given in exact arithmetic. Step (iii), in which diagonalizations are used to orthogonalize states of a common angular momentum, is done numerically; thus the results given in Sec. VIII are floating point numbers. The current code has not been designed to handle large-dimensional irreps. However, should large irreps be of interest, the routine could be coded entirely in a numerical language such as FORTRAN, MATLAB, or C^{++}.

The representations of $\mathfrak{so}(5)$ in an SO(3)-coupled basis are of interest for several reasons. The so-called one-row irreps of type $(v0)$ feature in the Bohr–Mottelson and IBM-1 collective models and, consequently, have received much attention.[20–22] The generic irreps, constructed in this paper, show up in these collective models whenever the neutron and proton degrees of freedom are considered independently. They could also prove useful in the classification of shell-model states of fermions in an angular momentum $l=2$ orbital. Generic $\mathfrak{so}(5)$ irreps also show up in supersymmetric boson–fermion models.[38,39] For example, the irreps of the orthosymplectic $\mathfrak{osp}(5/4)$ superalgebra of Iachello's model contain irreps of the $\overline{\mathfrak{so}}(5)$ subalgebra in the chain:

$$\mathfrak{osp}(5/4) \supset \mathfrak{so}(5) \oplus \mathfrak{sp}(4) \supset \overline{\mathfrak{sp}}(4) \simeq \overline{\mathfrak{so}}(5), \tag{126}$$

where $\overline{\mathfrak{so}}(5)$ here signifies the subalgebra of $\mathfrak{so}(5) \oplus \mathfrak{sp}(4)$ obtained by adding the corresponding infinitesimal generators of the isomorphic $\mathfrak{so}(5)$ and $\mathfrak{sp}(4)$ algebras. The construction of VCS representations of orthosymplectic superalgebras was considered by LeBlanc and Rowe[40] in a natural extension of the holomorphic representations to include representations over Grassmann as well as complex variables. Thus, it would be useful for the development of supersymmetric models of coupled boson–fermion systems to extend the construction given in this paper for $\mathfrak{so}(5) \simeq \mathfrak{usp}(4)$ irreps in an SO(3) basis to the irreps of the orthosymplectic algebras.

It is interesting to note that, in the present construction of $\mathfrak{so}(5)$ irreps, the $\mathfrak{so}(5)$ algebra has been realized as a combination of $L=2$ and $L=3/2$ boson operators. The use of bosons of half-odd integer angular momentum is admittedly unusual in physics. But, in spite of the spin-statistics theorem, there is no algebraic reason forbidding their use in this way. The fact is that bilinear products of either boson or fermion operators of any given angular momentum obey

precisely the same commutation relations. However, the number of $\mathfrak{so}(5)$ irreps that can be built up with fermions is severely limited by the Pauli principle whereas with bosons there is no such limitation.

A major motivation for the present study was that the methods developed for $\mathfrak{so}(5)$ would serve as prototype examples of what can be done in more general situations. Constructing the irreps of a Lie algebra (or a Lie group) in a basis that reduces a noncanonical subgroup chain is generally much more challenging than in a basis that reduces a canonical subgroup chain. Thus, it is an order of magnitude simpler to construct $\mathfrak{so}(5)$ irreps in a canonical $\mathrm{SO}(5)\supset\mathrm{SO}(4)\supset\mathrm{SO}(3)$ basis than in the geometrical SO(3) basis considered in this paper. For example, analytical expressions are readily derived for the irreps of $\mathfrak{su}(3)$ in the canonical $\mathrm{SU}(3)\supset\mathrm{SU}(2)$ basis. But, prior to the development of apposite VCS techniques,[26] special *ad hoc* methods were needed to obtain these irreps in $\mathrm{SU}(3)\supset\mathrm{SO}(3)$ bases. A possible application of the methods developed in this paper might be to construct irreps of the exceptional Lie algebra $\mathfrak{g}_2$ in an $\mathrm{SU}(3)\supset\mathrm{SO}(3)$-coupled basis. This would appear to be possible by choosing intrinsic states that carry an irrep of a $\mathfrak{u}(2)$ subalgebra, corresponding to a pair of short $\mathfrak{g}_2$ roots, and employing SU(3) as the orbiter group. The construction of such irreps of $\mathfrak{g}_2$ is of physical interest as a step toward the construction of $\mathfrak{so}(7)$ irreps in a $G_2\supset\mathrm{SO}(3)$-coupled basis. The need for such irreps would surface if it were considered desirable to formulate a collective model of octupole dynamics analogous to Bohr's quadrupole model or to classify shell-model states of fermions in an angular momentum $l=3$ orbital.

(Received 13 October 2005; accepted 10 January 2006; published online 28 February 2006)

In this paper, we consider a generalized second-order nonlinear ordinary differential equation (ODE) of the form $\ddot{x}+(k_1x^q+k_2)\dot{x}+k_3x^{2q+1}+k_4x^{q+1}+\lambda_1x=0$, where k_i's, $i=1,2,3,4$, λ_1, and q are arbitrary parameters, which includes several physically important nonlinear oscillators such as the simple harmonic oscillator, anharmonic oscillator, force-free Helmholtz oscillator, force-free Duffing and Duffing–van der Pol oscillators, modified Emden-type equation and its hierarchy, generalized Duffing–van der Pol oscillator equation hierarchy, and so on, and investigate the integrability properties of this rather general equation. We identify several new integrable cases for arbitrary value of the exponent $q, q \in R$. The $q=1$ and $q=2$ cases are analyzed in detail and the results are generalized to arbitrary q. Our results show that many classical integrable nonlinear oscillators can be derived as subcases of our results and significantly enlarge the list of integrable equations that exists in the contemporary literature. To explore the above underlying results we use the recently introduced generalized extended Prelle-Singer procedure applicable to second-order ODEs. As an added advantage of the method, we not only identify integrable regimes but also construct integrating factors, integrals of motion, and general solutions for the integrable cases, wherever possible, and bring out the mathematical structures associated with each of the integrable cases.

I. INTRODUCTION

A. Overview of the problem

In a recent paper[1] we have shown that the force-free Duffing–van der Pol (DVP) oscillator,

$$\ddot{x} + (\alpha + \beta x^2)\dot{x} - \gamma x + x^3 = 0, \tag{1}$$

is integrable for the parametric restriction $\alpha=4/\beta$ and $\gamma=-3/\beta^2$. In Eq. (1) the overdot denotes differentiation with respect to t and α, β and γ are arbitrary parameters. Under the transformation

$$w = -xe^{(1/\beta)t}, \quad z = e^{-(2/\beta)t}, \tag{2}$$

Eq. (1) with restriction $\alpha=4/\beta$ and $\gamma=-3/\beta^2$ was shown to be transformable to the form

$$w'' - \frac{\beta^2}{2} w^2 w' = 0, \tag{3}$$

which can then be integrated.[1]

In a parallel direction, while performing the invariance analysis of a similar kind of problem, we find that not only the Eq. (1) but also its generalized version,

$$\ddot{x} + \left(\frac{4}{\beta} + \beta x^2\right)\dot{x} + \frac{3}{\beta^2} x + x^3 + \delta x^5 = 0, \quad \delta = \text{arbitrary parameter}, \tag{4}$$

is invariant under the same set of Lie point symmetries.[2] As a consequence one can use the same transformation (2) to integrate Eq. (4). The transformation (2) modifies Eq. (4) to the form

$$w'' - \frac{\beta^2}{2} w^2 w' + \delta w^5 = 0, \tag{5}$$

which is not so simple to integrate straightforwardly. However, we observe that this equation coincides with the second equation in the so-called modified Emden equation (MEE) hierarchy, investigated by Feix *et al.*,[3]

$$\ddot{x} + x^l \dot{x} + g x^{2l+1} = 0, \quad l = 1, 2, \ldots, n, \tag{6}$$

where g is an arbitrary parameter.

In fact, Feix *et al.*[3] have shown that through a direct transformation to a third-order equation the above Eq. (6) can be integrated to obtain the general solution for the specific choice of the parameter g, namely, for $g = 1/(l+2)^2$. For this choice of g, the general solution of (6) can be written as

$$x(t) = \left(\frac{(2 + 3l + l^2)(t + I_1)^l}{l(t + I_1)^{l+1} + (2 + 3l + l^2) I_2}\right)^{1/l}, \quad I_1, I_2 = \text{arbitrary constants}. \tag{7}$$

Consequently, Eq. (4) can be integrated under the specific parametric choice $\delta = 1/16$, and it belongs to the $l = 2$ case of the MEE hierarchy (6) with $g = 1/16$. Now the question arises as to whether there exist other new integrable second-order nonlinear differential equations which are linear in $\dot{x}$ and contain fifth and other powers of nonlinearity. As far as our knowledge goes, only few equations in this class have been shown to be integrable. For example, Smith had investigated a class of nonlinear equations coming under the category

$$\ddot{x} + f(x)\dot{x} + g(x) = 0, \tag{8}$$

with $f(x) = (n+2) b x^n - 2a$ and $g(x) = x(c + (b x^n - a)^2)$, where a, b, c, and n are arbitrary parameters. He had shown that Eq. (8) with this specific form of f and g admits explicit oscillatory solutions. However, one can also expect that there should be a number of integrable equations which also admit solutions which are both oscillatory and nonoscillatory types in the class

$$\ddot{x} + (k_1 x^q + k_2)\dot{x} + k_3 x^{2q+1} + k_4 x^{q+1} + \lambda_1 x = 0, \quad q \in R, \tag{9}$$

where k_i's, $i = 1, 2, 3, 4$, and λ_1 are arbitrary parameters. When $q = 1$, Eq. (9) becomes the generalized MEE

$$\ddot{x} + (k_1 x + k_2)\dot{x} + k_3 x^3 + k_4 x^2 + \lambda_1 x = 0, \tag{10}$$

and for $q = 2$ it becomes

$$\ddot{x} + (k_1 x^2 + k_2)\dot{x} + k_3 x^5 + k_4 x^3 + \lambda_1 x = 0. \tag{11}$$

We note that Eq. (4) is a special case of (11).

Needless to say, Eq. (9) is a unified model for several ground-breaking physical systems which includes simple harmonic oscillator, anharmonic oscillator, force-free Helmholtz oscillator, force-free Duffing oscillator, MEE hierarchy, generalized DVP hierarchy, and so on.

As noted earlier, there exists no rigorous mathematical analysis in the literature for the second-order nonlinear differential equations which contain fifth or higher degree nonlinearity in x and linearity in $\dot{x}$, and the results are very scarce on integrability or exact solutions. Our motivation to analyze this problem is not only to explore new integrable cases/systems of Eq. (9) but also to synthesize all earlier results under one approach.

Having described the problem and motivation, now we can start analyzing the integrability properties of Eq. (9). To identify the integrable regimes we employ the recently introduced extended Prelle-Singer procedure applicable to second-order ordinary differential equations (ODEs).[5–11] Through this method we not only identify integrable regimes but also construct integrating factors, integrals of motion, and general solution for the integrable cases, wherever possible.

B. Results

We unearth several new integrable equations for any real value of the exponent q in Eq. (9). In the following we summarize the results for the case $q=$*arbitrary* only and discuss in detail the $q=1$, $q=2$, and $q=$*arbitrary* cases separately in the following sections.

For the choice $q=$*arbitrary* we find that the following equations are completely integrable (after suitable reparametrizations), all of which appear to be new to the literature:

$$\ddot{x}+(k_1x^q+(q+2)k_2)\dot{x}+k_1k_2x^{q+1}+(q+1)k_2^2x=0, \tag{12}$$

$$\ddot{x}+((q+2)k_1x^q+k_2)\dot{x}+k_1^2x^{2q+1}+k_1k_2x^{q+1}+\lambda_1x=0, \tag{13}$$

$$\ddot{x}+(q+4)k_2\dot{x}+k_4x^{q+1}+2(q+2)k_2^2x=0, \tag{14}$$

$$\ddot{x}+((q+1)k_1x^q+k_2)\dot{x}+\frac{(r-1)}{r^2}[(q+1)k_1^2x^{2q+1}+(q+2)k_1k_2x^{q+1}+k_2^2x]=0, \quad r\neq 0, \tag{15}$$

$$\ddot{x}+((q+1)k_1x^q+(q+2)k_2)\dot{x}+(q+1)\left[\frac{(r-1)}{r^2}k_1^2x^{2q+1}+k_1k_2x^{q+1}+k_2^2x\right]=0, \quad r\neq 0, \tag{16}$$

where k_1, k_2, k_4, λ_1, and r are arbitrary parameters. We stress that the above results are true for any arbitrary values of q. We discuss the special cases, namely, $q=1$ and $q=2$ separately in detail in Secs. III and IV in order to put the results of q arbitrary case in proper perspective.

We show that the Eq. (12) is nothing but a generalization of the Duffing–van der Pol oscillator Eq. (1). In a recent work[1,9] three of the present authors have established the integrability of Eq. (12) with $q=2$. However, in this work we show that the generalized Eq. (12) itself is integrable. Equation (13) is nothing but the generalized MEE among which the hierarchy of Eq. (6), studied by Feix *et al.*,[3] can be identified as a subcase. In fact, the general solution constructed by Feix *et al.*, Eq. (7), can be derived straightforwardly as a subcase. Equation (13) also contains the family of equations studied by Smith.[4] In particular, the latter author has derived a general solution for the case $k_2^2<4\lambda_1$, which turns out to be an oscillatory one. However, in this work, we show that even for arbitrary values of k_2 and λ_1 one can construct the general solution. Interestingly, the system (14) generalizes several physically important nonlinear oscillators. For example, in the case $q=1$ and 2, Eq. (14) provides us the force-free Helmholtz and Duffing oscillators, respectively, whose nonlinear dynamics is well documented in the literature.[12–17] Here, we present certain integrable generalizations of these nonlinear oscillators. Equation (15) admits a conservative Hamiltonian for all values of the parameters r, k_1, and k_2 and any integer value of q. We also provide the explicit form of the Hamiltonian for all values of q. As a result we conclude that it is

a Liouville integrable system. As far as Eq. (16) is concerned we construct a time-dependent integral of motion and transform the latter to a time-independent Hamiltonian one, thereby ensuring its Liouville integrability.

The plan of the paper is as follows. In the following section we briefly describe the extended Prelle-Singer procedure applicable to second-order ODEs. In Sec. III, we consider the case $q=1$ in (9) and identify the integrable parametric choices of this equation through the extended PS procedure. To do so, first we identify the integrable cases where the system admits time-independent integrals and construct explicit conservative Hamiltonians for the respective parametric choices. We then identify the cases which admit explicit time-dependent integrals of motion. To establish the complete integrability of these cases we use our own procedure and transform the time-dependent integrals of motion into time-independent integrals of motion and integrate the latter and derive the general solution. In Sec. IV, we repeat the procedure for the case $q=2$ in Eq. (9) and identify the integrable systems. In Sec. V, we consider the case $q=$arbitrary in (9) and unearth several new integrable equations and their associated mathematical structures. Finally, we present our conclusions in Sec. VI.

II. GENERALIZED EXTENDED PRELLE-SINGER (PS) PROCEDURE

In this section we briefly recall the generalized extended or modified PS procedure before applying it to the specific problem in hand. Some time ago, Prelle and Singer[5] proposed a procedure for solving first-order ODEs that admits solutions in terms of elementary functions if such solutions exist. The attractiveness of the PS method is that if the given system of first-order ODEs has a solution in terms of elementary functions, then the method guarantees that this solution will be found. Very recently Duarte *et al.*[7,8] modified the technique developed by Prelle and Singer[5,6] and applied it to second-order ODEs. Their approach was based on the conjecture that if an elementary solution exists for the given second-order ODE then there exists at least one elementary first integral $I(t,x,\dot{x})$ whose derivatives are all rational functions of t, x, and $\dot{x}$. For a class of systems these authors have deduced first integrals and in some cases for the first time through their procedure.[7] Recently the present authors generalized the theory of Duarte *et al.*[7] in different directions and showed that for the second-order ODEs one can isolate even two independent integrals of motion[9–11] and obtain general solutions explicitly without any integration. This theory has also been illustrated for a class of problems.[1,9–11] The authors have also generalized the theory successfully to higher order ODEs.[10,18] For example, in the case of third-order ODEs the theory has been appropriately generalized to yield three independent integrals of motion unambiguously so that the general solution follows immediately from these integrals of motion.[18]

We stress that the PS procedure has many advantages over other methods. To name a few, we cite: (1) For a given problem if the solution exists it has been conjectured that the PS method guarantees to provide first integrals. (2) The PS method not only gives the first integrals but also the underlying integrating factors, that is, multiplying the equation with these functions we can rewrite the equation as a perfect differentiable function which upon integration gives the first integrals directly. (3) The PS method can be used to solve nonlinear as well as linear second-order ODEs. (4) As the PS method is based on the equations of motion rather than on Lagrangian or Hamiltonian description, the analysis is applicable to deal with both Hamiltonian and non-Hamiltonian systems.

A. PS method

Let us rewrite Eq. (9) in the form

$$\ddot{x} = -\left((k_1 x^q + k_2)\dot{x} + k_3 x^{2q+1} + k_4 x^{q+1} + \lambda_1 x\right) \equiv \phi(x,\dot{x}). \tag{17}$$

(In fact the method is applicable to a general situation where ϕ can be a rational function of the variables x, $\dot{x}$, and t; for details see for example Ref. 9 and for a related approach see Ref. 15.) Further, we assume that the ODE (17) admits a first integral $I(t,x,\dot{x})=C$, with C constant on the solutions, so that the total differential becomes

$$dI = I_t\,dt + I_x\,dx + I_{\dot{x}}\,d\dot{x} = 0, \tag{18}$$

where each subscript denotes partial differentiation with respect to that variable. Rewriting Eq. (17) in the form $\phi dt - d\dot{x} = 0$ and adding a null term $S(t,x,\dot{x})\dot{x}dt - S(t,x,\dot{x})dx$ to the latter, we obtain that on the solutions the 1-form

$$(\phi + S\dot{x})dt - S\,dx - d\dot{x} = 0. \tag{19}$$

Hence, on the solutions, the 1-forms (18) and (19) must be proportional. Multiplying (19) by the factor $R(t,x,\dot{x})$ which acts as the integrating factors for (19), we have on the solutions that

$$dI = R(\phi + S\dot{x})dt - RS\,dx - R\,d\dot{x} = 0. \tag{20}$$

Comparing Eq. (18) with (20) we have, on the solutions, the relations

$$I_t = R(\phi + \dot{x}S), \quad I_x = -RS, \quad I_{\dot{x}} = -R. \tag{21}$$

Then, the compatibility conditions, $I_{tx} = I_{xt}$, $I_{t\dot{x}} = I_{\dot{x}t}$, $I_{x\dot{x}} = I_{\dot{x}x}$, between Eqs. (21) provide us

$$S_t + \dot{x}S_x + \phi S_{\dot{x}} = -\phi_x + \phi_{\dot{x}}S + S^2, \tag{22}$$

$$R_t + \dot{x}R_x + \phi R_{\dot{x}} = -(\phi_{\dot{x}} + S)R, \tag{23}$$

$$R_x - SR_{\dot{x}} - RS_{\dot{x}} = 0. \tag{24}$$

Solving Eqs. (22)–(24), one can obtain expressions for S and R. It may be noted that any set of special solutions (S,R) is sufficient for our purpose. Once these forms are determined the integral of motion $I(t,x,\dot{x})$ can be deduced from the relation

$$I = r_1 - r_2 - \int \left[R + \frac{d}{d\dot{x}}(r_1 - r_2) \right] d\dot{x}, \tag{25}$$

where

$$r_1 = \int R(\phi + \dot{x}S)dt, \quad r_2 = \int \left(RS + \frac{d}{dx}r_1 \right) dx.$$

Equation (25) can be derived straightforwardly by integrating the Eq. (21).

The crux of the problem lies in finding the explicit solutions satisfying all three determining equations (22)–(24), since once a particular solution is known the integral of motion can be readily constructed. The difficulties in constructing admissible set of solutions (S,R) satisfying all three equations (22)–(24) and possible ways of obtaining the solutions have been discussed in detail in Ref. 9. In this context we wish to point out that our above method of finding solutions using Eqs. (22)–(25) is closely related to the integrating factor/first integral method of Bluman and Anco.[15] In fact in Refs. 15 and 16 effective Ansätze for solving the integrating factor determining equations are treated and the present method can also be considered as a generalization of the method developed in Refs. 15 and 16.

III. APPLICATION OF PS PROCEDURE TO EQ. (10)

Let us first consider the case $q=1$ in Eq. (9) or equivalently (10),

$$\ddot{x} + (k_1 x + k_2)\dot{x} + k_3 x^3 + k_4 x^2 + \lambda_1 x = 0. \quad \text{[Eq. (10)]}$$

Equation (10) itself includes several physically important models. For example, choosing $k_i = 0$, $i = 1, \ldots, 4$, we get the simple harmonic oscillator equation and the choice k_1, $k_2 = 0$ gives us the anharmonic oscillator equation. When k_1, $k_4 = 0$ Eq. (10) becomes the force-free Duffing oscillator

equation.[12] The choice k_2, k_4, $\lambda_1=0$ provides us the MEE.[19] In the limit $k_3=k_1^2/9$, $k_4=k_1k_2/3$, Eq. (10) becomes MEE with linear term which is another linearizable equation which we have studied extensively in Refs. 9 and 20. The restriction k_1, $k_3=0$ leads us to the force-free Helmhotz oscillator.[12,13] In the following we investigate whether the system (10) admits any other integrable case besides the above.

We solve Eq. (10) through the extended PS procedure in the following way. For a given second-order equation (10), the first integral I should be either a time-independent or time-dependent one. In the former case, it is a conservative system and we have $I_t=0$ and in the latter case we have $I_t\neq 0$. So, let us first consider the case $I_t=0$ and determine the null forms and the corresponding integrating factors, and from these we construct the integrals of motion and then we do extend the analysis for the case $I_t\neq 0$.

A. The case $I_t=0$

1. Null forms

In this case one can easily fix the null form S from the first equation in (21) as

$$S=\frac{-\phi}{\dot{x}}=-\frac{((k_1x+k_2)\dot{x}+k_3x^3+k_4x^2+\lambda_1x)}{\dot{x}}. \tag{26}$$

2. Integrating factors

Substituting this form of S, given in (26), into (23), we get

$$\dot{x}R_x-((k_1x+k_2)\dot{x}+k_3x^3+k_4x^2+\lambda_1x)R_{\dot{x}}=\left((k_1x+k_2)+\frac{((k_1x+k_2)\dot{x}+k_3x^3+k_4x^2+\lambda_1x)}{\dot{x}}\right)R. \tag{27}$$

Equation (27) is a first-order linear partial differential equation with variable coefficients. As we noted earlier any particular solution is sufficient to construct an integral of motion (along with the function S). To seek a particular solution for R one can make a suitable Ansatz instead of looking for the general solution. We assume R to be of the form

$$R=\frac{\dot{x}}{(A(x)+B(x)\dot{x})^r}, \tag{28}$$

where A and B are functions of their arguments, and r is a constant which are all to be determined. We demand the above form of Ansatz (28), due to the following reason. To deduce the first integral I we assume a rational form for I, that is, $I=[f(x,\dot{x})]/[g(x,\dot{x})]$, where f and g are arbitrary functions of x and $\dot{x}$ and are independent of t. Since we already assumed that I is independent of t, we have $I_x=(f_xg-fg_x)/g^2$ and $I_{\dot{x}}=(f_{\dot{x}}g-fg_{\dot{x}})/g^2$. From (21) one can see that $R=I_{\dot{x}}=(f_{\dot{x}}g-fg_{\dot{x}})/g^2$, $S=I_x/I_{\dot{x}}=(f_xg-fg_x)/(f_{\dot{x}}g-fg_{\dot{x}})$, and $RS=I_x$, so that the denominator of the function S should be the numerator of the function R. Since the denominater of S is $\dot{x}$ [*vide* Eq. (26)] we fixed the numerator of R as $\dot{x}$. To seek a suitable function in the denominator initially one can consider an arbitrary form $R=\dot{x}/[h(x,\dot{x})]$. However, it is difficult to proceed with this choice of h. So, let us assume that $h(x,\dot{x})$ is a function which is polynomial in $\dot{x}$. To begin with let us consider the case where h is linear in $\dot{x}$, that is, $h=A(x)+B(x)\dot{x}$. Since R is in rational form while taking differentiation or integration the form of the denominator remains the same but the power of the denominator decreases or increases by a unit order from that of the initial one. So, instead of considering h to be of the form $h=A(x)+B(x)\dot{x}$, one may consider a more general form $h=(A(x)+B(x)\dot{x})^r$, where r is a constant to be determined. Such a generalized form of h and so R leads to several new integrable cases as we see below.

Substituting (28) into (27) and solving the resultant equations, we arrive at the relation

$$r(\dot{x}(A_x + B_x\dot{x}) + \phi B) = (A + B\dot{x})\phi_{\dot{x}}. \tag{29}$$

Solving Eq. (29) with $\phi = -((k_1x+k_2)\dot{x}+k_3x^3+k_4x^2+\lambda_1 x)$, we find nontrivial forms for the functions A and B for two choices, namely (i) k_1, k_2 arbitrary and (ii) k_1=arbitrary, $k_2=0$ with restrictions on other parameters as given below. The respective forms of the functions and the restriction on the parameters are

(i) k_1, k_2: arbitrary

$$A(x) = \frac{(r-1)b_0}{r}\left(\frac{k_1}{2}x^2 + k_2x\right), \quad B(x) = b_0 = \text{constant}, \quad r = \text{constant},$$

$$k_3 = \frac{b_0(r-1)}{2r^2}k_1^2, \quad k_4 = \frac{3b_0(r-1)}{2r^2}k_1k_2, \quad \lambda_1 = \frac{b_0(r-1)k_2^2}{r^2}, \tag{30a}$$

(ii) k_1=arbitrary, $k_2=0$

$$A(x) = \frac{(r-1)b_0}{2r}k_1x^2 + \frac{r\lambda_1}{k_1}, \quad B(x) = b_0,$$

$$k_3 = \frac{b_0(r-1)}{2r^2}k_1^2, \quad k_4 = 0, \quad \lambda_1 = \text{arbitrary parameter (here)}. \tag{30b}$$

We note that the case (ii) cannot be derived from case (i) by taking $k_2=0$. For example, choosing $k_2=0$ in (30a) we get not only $k_4=0$ but also $\lambda_1=0$, whereas in the case (ii) we have the freedom λ_1=arbitrary, so the cases (30a) and (30b) are to be treated as separate. Making use of the forms of A and B from Eqs. (30a) and (30b) into (28), the integrating factor, "R," for the two cases can be obtained as

(i) k_1, k_2: arbitrary

$$R = \frac{\dot{x}}{\left[\frac{(r-1)}{r}\left(\frac{k_1}{2}x^2 + k_2x\right) + \dot{x}\right]^r}, \quad r \neq 0 \tag{31a}$$

(ii) k_1=arbitrary, $k_2=0$

$$R = \frac{\dot{x}}{\left[\frac{(r-1)}{2r}k_1x^2 + \frac{r\lambda_1}{k_1} + \dot{x}\right]^r}, \quad r \neq 0. \tag{31b}$$

We note that b_0 is a common parameter in the above and it is absorbed in the definition of R; see Eqs. (23) and (24). While deriving the above forms of R [Eqs. (31a) and (31b)] we assumed that $r \neq 0$ and for the choice $r=0$ we obtain a consistent solution only if both the parameters k_1 and k_2 become zero. Of course, this subcase can be treated as a trivial one since when $k_1, k_2=0$ the damping term in Eq. (10) vanishes and the system becomes an integrable anharmonic oscillator. In this trivial case we have the integrating factor of the form

(iii) k_1, $k_2=0$

$$R = \dot{x}, \quad r = 0. \tag{31c}$$

Finally, one has to check the compatibility of forms S and R with the third Eq. (24). We indeed verified that the sets

$$\text{(i)} \quad S = -\frac{\left((k_1x+k_2)\dot{x} + \frac{(r-1)}{r^2}\left(\frac{k_1^3}{2}x^2 + \frac{3k_1k_2}{2}x^2 + k_2^2x\right)\right)}{\dot{x}},$$

$$R = \frac{\dot{x}}{\left(\frac{(r-1)}{r}\left(\frac{k_1}{2}x^2 + k_2x\right) + \dot{x}\right)^r}, \quad k_1,k_2 = \text{arbitrary}, \quad r \neq 0 \tag{32a}$$

$$\text{(ii)} \quad S = -\frac{\left(k_1x\dot{x} + \frac{(r-1)}{2r^2}k_1^2x^3 + \lambda_1x\right)}{\dot{x}},$$

$$R = \frac{\dot{x}}{\left(\frac{(r-1)}{2r}k_1x^2 + \frac{r\lambda_1}{k_1} + \dot{x}\right)^r}, \quad k_1 = \text{arbitrary}, \quad k_2 = 0, \quad r \neq 0 \tag{32b}$$

and

$$\text{(iii)} \quad S = -\frac{(k_3x^3 + k_4x^2 + \lambda_1x)}{\dot{x}}, \quad R = \dot{x}, \quad k_1,k_2 = 0, \tag{32c}$$

satisfy Eq. (24) individually. As a consequence all three pairs form compatible sets of solution for the equations (22)–(24).

3. Integrals of motion

Having determined the explicit forms of S and R, one can proceed to construct integrals of motion using the expressions (25). The parametric restrictions (30a) and (30b) fix the equation of motion (10) to the following specific forms:

$$\text{(i)} \quad \ddot{x} + (k_1x+k_2)\dot{x} + \frac{(r-1)}{2r^2}(k_1^2x^3 + 3k_1k_2x^2 + 2k_2^2x) = 0, \quad r \neq 0, \tag{33a}$$

$$\text{(ii)} \quad \ddot{x} + k_1x\dot{x} + \frac{(r-1)k_1^2}{2r^2}x^3 + \lambda_1x = 0, \quad r \neq 0, \tag{33b}$$

$$\text{(iii)} \quad \ddot{x} + k_3x^3 + k_4x^2 + \lambda_1x = 0, \quad r = 0. \tag{33c}$$

In the above k_1, k_2, k_3, k_4, λ_1, and r are arbitrary parameters.

We note that the transformation $x = y - k_2/k_1$ transforms Eq. (33a) to the form

$$\ddot{y} + k_1y\dot{y} + \frac{(r-1)k_1^2}{2r^2}y^3 - \frac{(r-1)k_2^2}{2r^2}y = 0, \quad r \neq 0. \tag{34}$$

Equation (34) is obtained from Eq. (33b) by fixing $\lambda_1 = -[(r-1)k_2^2]/2r^2$. So, hereafter, we consider Eq. (33a) as a special case of Eq. (33b) and so discuss only Eq. (33b) as the general one. It may be noted that Eq. (33b) includes several known integrable cases. For example, the choice $r=3$ and $\lambda_1=0$ in Eq. (33b) yields the MEE.[19] On the other hand the choice $r=-1$ leads us to the equation $\ddot{x}+k_1x\dot{x}-k_1^2x^3+\lambda_1x=0$, which can be solved in terms of Weierstrass elliptic function.[21] *The other choices of r lead to new integrable cases* as we see below.

Substituting the forms of S and R [vide Eqs. (32b) and (32c)] into the general form of the integral of motion (25) and evaluating the resultant integrals, we obtain the following time independent first integrals for the cases (33b) and (33c):

$$\text{(iia)}\quad I_1=\left(\dot{x}+\frac{(r-1)}{2r}k_1x^2+\frac{r\lambda_1}{k_1}\right)^{-r}\left[\dot{x}\left(\dot{x}+\frac{k_1}{2}x^2+\frac{r^2\lambda_1}{(r-1)k_1}\right)+\frac{(r-1)}{r^2}\left(\frac{k_1}{2}x^2+\frac{r^2\lambda_1}{(r-1)k_1}\right)^2\right],\quad r\neq 0,1,2, \tag{35a}$$

$$\text{(iib)}\quad I_1=\frac{4k_1\dot{x}}{k_1^2x^2+4k_1\dot{x}+8\lambda_1}-\log(k_1^2x^2+4k_1\dot{x}+8\lambda_1),\quad r=2, \tag{35b}$$

$$\text{(iic)}\quad I_1=\dot{x}+\frac{k_1}{2}x^2-\frac{\lambda_1}{k_1}\log(k_1\dot{x}+\lambda_1),\quad r=1, \tag{35c}$$

$$\text{(iii)}\quad I_1=\frac{\dot{x}^2}{2}+\frac{k_3}{4}x^4+\frac{k_4}{3}x^3+\frac{\lambda_1}{2}x^2,\quad r=0. \tag{35d}$$

Note that in Eq. (35a), r can take any real value, except 0, 1, 2. In the above integrals I_1 given by Eqs. (35a)–(35c) correspond to the ODE (33b), while (35d) corresponds to Eq. (33c).

Due to the fact that the integrals of motion (35) are time independent, one can look for a Hamiltonian description for the respective equations of motion. In fact, we obtain the explicit Hamiltonian forms for all the above cases.

4. Hamiltonian description of (35)

Assuming the existence of a Hamiltonian

$$I(x,\dot{x})=H(x,p)=p\dot{x}-L(x,\dot{x}), \tag{36}$$

where $L(x,\dot{x})$ is the Lagrangian and p is the canonically conjugate momentum, we have

$$\frac{\partial I}{\partial\dot{x}}=\frac{\partial H}{\partial\dot{x}}=\frac{\partial p}{\partial\dot{x}}\dot{x}+p-\frac{\partial L}{\partial\dot{x}}=\frac{\partial p}{\partial\dot{x}}\dot{x},$$

$$\frac{\partial I}{\partial x}=\frac{\partial H}{\partial x}=\frac{\partial p}{\partial x}\dot{x}-\frac{\partial L}{\partial x}. \tag{37}$$

From (37) we identify

$$p=\int\frac{I_{\dot{x}}}{\dot{x}}\mathrm{d}\dot{x},$$

$$L=\int(p_x\dot{x}-I_x)\mathrm{d}x+\int\left[p-\frac{\mathrm{d}}{\mathrm{d}\dot{x}}\int(p_x\dot{x}-I_x)\mathrm{d}x\right]\mathrm{d}\dot{x}. \tag{38}$$

Plugging the expressions (36) into (38), one can evaluate the canonically conjugate momentum and the associated Lagrangian as well as the Hamiltonian. They read as follows:

(a) The canonical momenta:

$$\text{(iia,b)}\quad p=\frac{1}{r-1}\left(\dot{x}+\frac{(r-1)}{r}\frac{k_1}{2}x^2+\frac{r\lambda_1}{k_1}\right)^{1-r},\quad r\neq 0,1 \tag{39a}$$

$$\text{(iic)} \quad p = \log(k_1\dot{x} + \lambda_1), \quad r = 1 \tag{39b}$$

$$\text{(iii)} \quad p = \dot{x}, \quad r = 0. \tag{39c}$$

[Note in the above $r=2$ is included in Eq. (39a) itself.]

(b) The Lagrangian:

$$\text{(iia)} \quad L = \frac{1}{(2-r)(r-1)}\left(\dot{x} + \frac{(r-1)}{r}\frac{k_1x^2}{2} + \frac{r\lambda_1}{k_1}\right)^{2-r}, \quad r \neq 0,1,2 \tag{40a}$$

$$\text{(iib)} \quad L = \log(4k_1\dot{x} + 8\lambda_1 + k_1^2x^2), \quad r = 2 \tag{40b}$$

$$\text{(iic)} \quad L = \frac{\lambda_1}{k_1}\log(k_1\dot{x} + \lambda_1) + \dot{x}(\log(k_1\dot{x} + \lambda_1) - 1) - \frac{1}{2}k_1x^2, \quad r = 1 \tag{40c}$$

$$\text{(iii)} \quad L = \frac{\dot{x}^2}{2} - \frac{k_3}{4}x^4 - \frac{k_4}{3}x^3 - \frac{\lambda_1}{2}x^2, \quad r = 0. \tag{40d}$$

(c) The Hamiltonian:

$$\text{(iia)} \quad H = \left[\frac{((r-1)p)^{(r-2)/(r-1)}}{(r-2)} - p\left(\frac{(r-1)}{2r}k_1x^2 + \frac{r\lambda_1}{k_1}\right)\right], \quad r \neq 0,1,2 \tag{41a}$$

$$\text{(iib)} \quad H = \frac{2\lambda_1}{k_1}p + \frac{k_1}{4}x^2p + \log\left(\frac{4k_1}{p}\right), \quad r = 2 \tag{41b}$$

$$\text{(iic)} \quad H = \frac{1}{k_1}\left(e^p - \lambda_1 p + \frac{k_1^2}{2}x^2 - \lambda_1\right), \quad r = 1 \tag{41c}$$

$$\text{(iii)} \quad H = \frac{p^2}{2} + \frac{k_3}{4}x^4 + \frac{k_4}{3}x^3 + \frac{\lambda_1}{2}x^2, \quad r = 0. \tag{41d}$$

One can check that the Hamilton's equations of motion are indeed equivalent to the appropriate equation (10).

Since Eqs. (33b) and (33c) admit time-independent Hamiltonians, they can be classified as Liouville integrable systems. *The important fact we want to stress here is that for arbitrary values of r, including fractional values, Eq. (33b) is integrable*.

5. Canonical transformation for the Hamiltonian Eqs. (41)

Interestingly, we also identified suitable canonical transformation to standard particle in a potential description for the Hamiltonians (41). Now, introducing the canonical transformations

$$x = \frac{2rP}{k_1U}, \quad p = -\frac{k_1U^2}{4r}, \quad r \neq 0,1, \tag{42}$$

$$x = \frac{P}{k_1}, \quad p = -k_1U, \quad r = 1 \tag{43}$$

the Hamiltonian H in Eq. (41) can be recast in the standard form (after rescaling)

$$H=\begin{cases}\dfrac{1}{2}P^2+\dfrac{(1-r)}{(r-2)}\left(\dfrac{(r-1)k_1U^2}{4r}\right)^{(r-2)/(r-1)}+\dfrac{(r-1)\lambda_1}{4}U^2, & r\neq 0,1,2\\ \dfrac{1}{2}P^2+\dfrac{\lambda_1}{4}U^2+\log\left(\dfrac{32}{U^2}\right), & r=2\\ \dfrac{1}{2}P^2+e^{-k_1U}+\lambda_1k_1U, & r=1\\ \dfrac{1}{2}P^2+\dfrac{k_3}{4}U^4+\dfrac{\lambda_1}{2}U^2, & r=0.\end{cases} \tag{44}$$

It is straightforward to check that when U and P are canonical so are x and p (and vice versa), and the corresponding equations of motion turn out to be

$$\ddot{U}-2\left(\frac{(r-1)k_1}{4r}\right)^{(2-r)/(1-r)}U^{(3-r)/(1-r)}+\frac{(r-1)\lambda_1}{2}U=0,\quad r\neq 0,1 \tag{45a}$$

$$\ddot{U}-k_1e^{-U}+k_1\lambda_1=0,\quad r=1 \tag{45b}$$

$$\ddot{U}+k_3U^3+\lambda_1U=0,\quad r=0. \tag{45c}$$

One may note that the equations of motion now become standard-type anharmonic oscillator equations.

B. The case $I_t\neq 0$

In the previous subsection we considered the case $I_t=0$. As a consequence S turns out to be $-\phi/\dot{x}$. However, in the case $I_t=0$, the function S has to be determined from Eq. (22), that is,

$$S_t+\dot{x}S_x-((k_1x+k_2)\dot{x}+k_3x^3+k_4x^2+\lambda_1x)S_{\dot{x}}=(k_1\dot{x}+3k_3x^2+2k_4x+\lambda_1)-(k_1x+k_2)S+S^2. \tag{46}$$

Since it is too difficult to solve Eq. (46) for its general solution, we seek a particular solution for S, which is sufficient for our purpose. In particular, we seek a simple rational expression for S in the form

$$S=\frac{a(t,x)+b(t,x)\dot{x}}{c(t,x)+d(t,x)\dot{x}}, \tag{47}$$

where a, b, c, and d are arbitrary functions of t and x which are to be determined. Of course, the analysis of this form alone does not exhaust all possible cases of interest. We hope to make a more exhaustive study of Eq. (46) separately. Substituting (47) into (46) and equating the coefficients of different powers of $\dot{x}$ to zero, we get

$$db_x-bd_x-k_1d^2=0,$$

$$db_t-bd_t+cb_x-bc_x+a_xd-ad_x-2k_1cd-(3k_3x^2+2k_4x+\lambda_1)d^2+(k_1x+k_2)bd-b^2=0,$$

$$cb_t-bc_t+da_t-ad_t+ca_x-ac_x-k_1c^2-2(3k_3x^2+2k_4x+\lambda_1)cd+2(k_1x+k_2)ad-2ab=0,$$

$$ca_t - ac_t - (k_3x^3 + k_4x^2 + \lambda_1 x)(bc - ad) - (3k_3x^2 + 2k_4x + \lambda_1)c^2 + (k_1x + k_2)ac - a^2 = 0. \tag{48}$$

The determining equation for the functions a, b, c, and d have now turn out to be nonlinear. To solve these equations we further assume that the functions a, b, c, and d are polynomials in x with coefficients which are arbitrary functions in t. Substituting these forms into Eqs. (48) we obtain another enlarged set of determining equations for the unknowns and solving the latter consistently we obtain nontrivial solutions for the functions a, b, c, and d for four sets of parametric choices. We present the explicit forms of the associated null function S given by (47) and the parametric restrictions in Table I.

Now substituting the forms of S into Eq. (23) and solving the resultant equation, we obtain the corresponding forms of R. To solve the determining equation for R we again seek the same form of Ansatz (28) but with explicit t dependence on the coefficient functions, that is, $R = S_d/[(A(t,x)+B(t,x)\dot{x})^r]$, where S_d is the denominator of S. We report the resultant forms of R in Table I. Once S and R are determined then one has to verify the compatibility of this set (S,R) with the extra constraint Eq. (24). We find that the forms S and R given in Table I do satisfy the extra constraint equation and form a compatible solution. Now substituting S_i's and R_i's into Eq. (25) one can construct the associated integrals of motion. We report the integrals of motion (I) in Table I along with the forms S and R.

At this stage, we note that the first integral for the case (i) with $k_2, \lambda_1 = 0$ has been derived in Ref. 19 through Lie symmetry analysis. However, recently, we have derived[9] the first integral for arbitrary values of k_2 and λ_1. Case (ii) is new to the literature. The first integral for case (iii) was reported recently in Refs. 9, 12, and 13. The first integral for the case (iva) is new to the literature. The *case* $r=0$ discussed as (ivb) is nothing but the force-free Duffing oscillator whose integrability has been discussed in Refs. 12 and 14.

Since we obtained only one integral in each case [except case (i), where we have found a second explicit time-dependent integral; see Ref. 9], which are also time-dependent ones, we need to integrate them further to obtain the second integration constant and prove the complete integrability of the respective systems, which is indeed a difficult task.

In this connection we have introduced a new method[1,9] which can be effectively used to transform the time-dependent integral into a time-independent one, for a class of problems, so that the latter can be integrated easily. We invoke this procedure here in order to integrate the time-dependent first integrals and obtain the general solution for all the cases in Table I [except case (iv), see below]. For case (iv), we prove the Liouville integrability of it.

C. Method of transforming time-dependent first integral to time-independent one

Let us assume that there exists a first integral for Eq. (10) of the form

$$I = F_1(t,x,\dot{x}) + F_2(t,x). \tag{49}$$

Now let us split the function F_1 further in terms of two functions such that F_1 itself is a function of the product of the two functions, say, a perfect differentiable function $(\mathrm{d}/\mathrm{d}t)G_1(t,x)$ and another function $G_2(t,x,\dot{x})$, that is,

$$I = F_1\left(\frac{1}{G_2(t,x,\dot{x})}\frac{\mathrm{d}}{\mathrm{d}t}G_1(t,x)\right) + F_2(G_1(t,x)), \tag{50}$$

where F_1 is a function which involves the variables t, x, and $\dot{x}$, whereas F_2 should involve only the variable t and x. We note that while rewriting Eq. (49) in the form (50), we demand the function $F_2(t,x)$ in (49) automatically to be a function of $G_1(t,x)$. Now identifying the function G_1 as the new dependent variable and the integral of G_2 over time as the new independent variable, that is,

TABLE I. Parametric restrictions, null forms (S), integrating factors (R) and time dependent integrals of motion (I) of $\ddot{x}+(k_1x+k_2)\dot{x}+k_3x^3+k_4x^2+\lambda_1x=0$ (identified with the assumed Ansatz form of S and R).

Cases	Parametric restrictions	Null form (S)	Integrating factor (R)	Integrals of motion (I)
(i)	$k_3=\frac{k_1^2}{9}, \quad k_4=\frac{k_1k_2}{3}$ (k_1,k_2,λ_1: arbitrary)	$\frac{\left(\frac{k_1}{3}x^2-\dot{x}\right)}{x}$	$\frac{xe^{\mp\omega t}}{\left(\dot{x}-\frac{(k_2\pm\omega)}{2}x+\frac{k_1}{3}x^2\right)^2}$	(a) $I=e^{\mp\omega t}\left(\frac{3\dot{x}-\frac{3(-k_2\mp\omega)}{2}x+k_1x^2}{3\dot{x}-\frac{3(-k_2\pm\omega)}{2}x+k_1x^2}\right)$, $k_2,\lambda_1\neq 0, \quad \omega=(k_2^2-4\lambda_1)^{1/2}$ (b) $I=-t+\frac{x}{\left(\frac{k_2}{2}x+\frac{k_1}{3}x^2+\dot{x}\right)}, \quad k_2^2=4\lambda_1$

TABLE I. (*Continued.*)

Cases	Parametric restrictions	Null form (S)	Integrating factor (R)	Integrals of motion (I)
(iva)	$k_3=\frac{(r-1)k_1^2}{2r^2}, \quad k_4=\frac{k_1k_2}{3},$ $\lambda_1=\frac{2k_2^2}{9}, \quad r\neq 0$ (k_1,k_2,r: arbitrary)	$\frac{k_2}{3}+k_1x+\frac{3k_3x^3}{(3\dot{x}+k_2x)}$	$\frac{(k_2x+3\dot{x})e^{[2(2-r)k_2/3]t}}{\left(\frac{k_2}{3}x+rk_3x^2+\dot{x}\right)^r}$	$I=\left(\frac{k_3}{2}x^4+\left(\dot{x}+\frac{k_2}{3}x\right)\left(\dot{x}+\frac{k_2}{3}x+\frac{k_1}{2}x^2\right)\right)$ $\times\left(\dot{x}+\frac{k_2}{3}x+rk_3x^2\right)^{-r}e^{[(2(2-r))/3]k_2t}, \quad r\neq 2$
				$I=\frac{2}{3}k_2t+\log(4k_2x+3k_1x^2+12\dot{x})$ $-\frac{4(k_2x+3\dot{x})}{(4k_2x+3k_1x^2+12\dot{x})}, \quad r=2$
(ivb)	$k_1=0, \quad k_4=0,$ $\lambda_1=\frac{2k_2^2}{9}, \quad r=0$ (k_2,k_3: arbitrary)	$\frac{\left(\frac{k_2}{3}\dot{x}+\frac{k_2^2}{9}x+k_3x^3\right)}{\left(\dot{x}+\frac{k_2x}{3}\right)}$	$e^{(4/3)k_2t}\left(\dot{x}+\frac{k_2x}{3}\right)$	$I=e^{(4/3)k_2t}\left[\frac{\dot{x}^2}{2}+\frac{k_2}{3}x\dot{x}+\frac{k_2^2}{18}x^2+\frac{k_3}{4}x^4\right]$

$$w = G_1(t,x), \quad z = \int_o^t G_2(t',x,\dot{x})\mathrm{d}t', \tag{51}$$

one indeed obtains an explicit transformation to remove the time-dependent part in the first integral. We note here that the integration on the right-hand side of (51) leading to z can be performed provided the function G_2 is an exact derivative of t, that is, $G_2=(\mathrm{d}/\mathrm{d}t)z(t,x)=\dot{x}z_x+z_t$, so that z turns out to be a function t and x alone. In terms of the new variables, Eq. (50) can be modified to the form

$$I = F_1\left(\frac{\mathrm{d}w}{\mathrm{d}z}\right) + F_2(w). \tag{52}$$

In other words,

$$F_1\left(\frac{\mathrm{d}w}{\mathrm{d}z}\right) = I - F_2(w). \tag{53}$$

Now rewriting Eq. (52), one obtains a separable equation

$$\frac{\mathrm{d}w}{\mathrm{d}z} = f(w), \tag{54}$$

which can lead to the solution after an integration. Now rewriting the solution in terms of the original variables one obtains a general solution for the given equation.

In the following, using the above idea we integrate the first integrals given in Table I and deduce the second integration constant and general solution.

D. Application

Case (ia): $k_3=k_1^2/9$, $k_4=k_1k_2/3$, k_1, k_2 and λ_1: arbitrary.

The parametric restrictions given above fix the equation of motion (10) in the form

$$\ddot{x} + (k_1x + k_2)\dot{x} + \frac{k_1^2}{9}x^3 + \frac{k_1k_2}{3}x^2 + \lambda_1 x = 0. \tag{55}$$

Let us rewrite the first integral associated for this case [*vide* case (i) in Table I] in the form

$$I_1 = -\frac{k_1 e^{[(k_2\mp\omega)/2]t}x^2}{(3\dot{x} - [(-k_2\pm\omega)/2]3x + k_1x^2)}\left[\frac{\mathrm{d}}{\mathrm{d}t}\left(\left(\frac{-3}{k_1x} + \frac{-k_2\pm\omega}{2\lambda_1}\right)e^{[(-k_2\mp\omega)/2]t}\right)\right], \tag{56}$$

where $\omega=\sqrt{k_2^2-4\lambda_1}$. Comparing this with Eq. (50), and using (51), we obtain

$$w = \left(\frac{-3}{k_1x} + \frac{-k_2\pm\omega}{2\lambda_1}\right)e^{[(-k_2\mp\alpha)/2]t}, \quad z = \left(\frac{-3}{k_1x} + \frac{-k_2\mp\omega}{2\lambda_1}\right)e^{[(-k_2\pm\omega)/2]t}. \tag{57}$$

Substituting (57) into Eq. (55), the latter becomes the free particle equation, namely, $\mathrm{d}^2w/\mathrm{d}z^2=0$, whose general solution is $w=I_1z+I_2$, where I_1 and I_2 are integration constants. Rewriting w and z in terms of x and t, one gets

$$x(t) = \left(\frac{6\lambda_1(1-I_1e^{\omega t})}{k_1\omega(1+I_1e^{\omega t}) - (k_2\pm\omega)I_2e^{[(k_2\pm\omega)/2]t} - k_1k_2(1-I_1e^{\omega t})}\right), \tag{58}$$

where $\omega=\sqrt{k_2^2-4\lambda_1}$.

Interestingly one can consider several subcases. In the following we discuss some important ones which are being widely discussed in the current literature. In particular, the difference in

dynamics arises mainly depending on the sign of the parameter α $(=\sqrt{k_2^2-4\lambda_1})$. We consider the cases (i) $k_2^2<4\lambda_1$; (ii) $k_2^2>4\lambda_1$; and (iii) $k_2^2=4\lambda_1$ separately. The restriction $k_2^2<4\lambda_1$ reduces the solution (58) to the form[4]

$$x(t)=\frac{A\cos(\omega_0 t+\delta)}{\left(e^{(k_2/2)t}+\frac{2k_1A}{3(k_2^2+4\omega_0^2)}(2\omega_0\sin(\omega_0 t+\delta)-k_2\cos(\omega_0 t+\delta))\right)}, \tag{59}$$

where $\omega_0=\sqrt{4\lambda_1-k_2^2}/2$ and δ, A are arbitrary constants. A further restriction $k_2=0$ gives us the purely sinusoidally oscillating solution[20]

$$x(t)=\frac{A\sin(\omega_0 t+\delta)}{1-\left(\frac{k}{3\omega_0}\right)A\cos(\omega_0 t+\delta)}, \quad 0\leqslant A<\frac{3\omega_0}{k}, \quad \omega_0=\sqrt{\lambda_1}, \tag{60}$$

where A and δ are arbitrary constants. The associated equation of motion, namely $\ddot{x}+k_1x\dot{x}+(k_1^2/9)x^3+\lambda_1x=0$, admits very interesting nonlinear dynamics; see for example in Ref. 20.

On the other hand, in the limit $k_2^2>4\lambda_1$ the solution looks like a dissipative/frontlike one.[19] A further restriction $\lambda_1=0$ takes us to the solution of the form[11]

$$x(t)=\left(\frac{3k_2(I_1e^{k_2t}-1)}{k_1+k_2(3I_2+k_1I_1t)e^{k_2t}}\right). \tag{61}$$

Case (ib): $k_3=k_1^2/9$, $k_4=k_1k_2/3$, $k_2^2=4\lambda_1$, k_1 and k_2: arbitrary.

The third choice $k_2^2=4\lambda_1$ in (58) leads us to the solution

$$x(t)=\left(\frac{3(I_1+t)}{3I_2e^{(k_2/2)t}-\frac{2k_1}{k_2^2}(2+I_1k_2+k_2t)}\right). \tag{62}$$

Further parametric restriction k_2, $\lambda_1=0$ provides us the general solution of the form

$$x(t)=\left(\frac{6(I_1+t)}{k_1(I_1+t)^2+6I_2}\right). \tag{63}$$

The underlying equation, that is, $\ddot{x}+k_1x\dot{x}+(k_1^2/9)x^3=0$, is the $l=1$ integrable case of Eq. (6) with the solution (7) (see for example in Refs. 19 and 20).

Case (ii): $k_3=0$, $k_4=(k_1/4)(k_2\pm\sqrt{k_2^2-4\lambda_1})$, k_1, k_2, and λ_1: arbitrary.

In this case we have the equation of the form

$$\ddot{x}+(k_1x+k_2)\dot{x}+\frac{k_1}{4}(k_2\pm\sqrt{k_2^2-4\lambda_1})x^2+\lambda_1x=0. \tag{64}$$

The associated first integral reads [*vide* case (ii) in Table I]

$$I=\left(\dot{x}+\frac{k_2\mp\sqrt{k_2^2-4\lambda_1}}{2}x+\frac{k_1}{2}x^2\right)e^{[(k_2\pm\sqrt{k_2^2-4\lambda_1})/2]t}. \tag{65}$$

Note that Eq. (65) can be rewritten as a Riccati equation of the form[22]

$$\dot{x}=Ie^{[(-k_2\mp\sqrt{k_2^2-4\lambda_1})/2]t}-\left(\frac{k_2\mp\sqrt{k_2^2-4\lambda_1}}{2}\right)x-\frac{k_1}{2}x^2. \tag{66}$$

The general solution of the Riccati equation is known to be free from movable critical points and satisfies the Painlevé property. In this sense Eq. (64) can be considered as integrable in the Painlevé criteria sense. However, in the general case (66), it is not clear whether it can be

explicitly integrated further. However, for the special case $\lambda_1=2k_2^2/9$ it can be integrated as follows.

The restriction $\lambda_1=2k_2^2/9$ fixes the equation of motion (64) and the first integral (65) in the forms

$$\ddot{x}+(k_1x+k_2)\dot{x}+\frac{k_1k_2}{3}x^2+\frac{2k_2^2}{9}x=0, \tag{67}$$

and

$$I=\left(\dot{x}+\frac{k_2}{3}x+\frac{k_1}{2}x^2\right)e^{(2k_2/3)t}, \tag{68}$$

respectively. Now rewriting (68) in the form (50), we get

$$I=e^{(k_2/3)t}\left(\frac{d}{dt}(xe^{(k_2/3t)})\right)+\frac{k_1}{2}(xe^{(k_2/3)t})^2. \tag{69}$$

Identifying the dependent and independent variables from (69) and using the identities (51), we obtain the transformation

$$w=xe^{(k_2/3)t}, \quad z=-\frac{3}{k_2}e^{-(k_2/3)t}. \tag{70}$$

Using the transformation (70), the first integral (68) can be rewritten in the form

$$\hat{I}=w'+\frac{k_1}{2}w^2, \tag{71}$$

which in turn leads to the solution by an integration, that is,

$$w(z)=\sqrt{\frac{2I}{k_1}}\tanh\left[\sqrt{\frac{k_1I}{2}}(z-z_0)\right], \tag{72}$$

where z_0 is arbitrary constant. Rewriting (72) in terms of old variables we get

$$x(t)=\sqrt{\frac{2I}{k_1}}e^{-(k_2/3)t}\tanh\left[\frac{3}{k_2}\left(\sqrt{\frac{k_1I}{2}}\right)(e^{-(k_2/3)t_0}-e^{-(k_2/3)t})\right], \tag{73}$$

where t_0 is the second integration constant.

Case (iii): k_1, $k_3=0$, $\lambda_1=6k_2^2/25$, k_2 and k_4: arbitrary.

The corresponding equation of motion is

$$\ddot{x}+k_2\dot{x}+k_4x^2+\frac{6k_2^2}{25}x=0. \tag{74}$$

Rewriting the associated first integral I_1, given in case (iii) in Table I, in the form (49), we get

$$I=\frac{1}{2}\left(\dot{x}+\frac{2k_2}{5}x\right)^2e^{(6/5)k_2t}+\frac{k_4}{3}x^3e^{(6/5)k_2t}. \tag{75}$$

Now splitting the first term in Eq. (75) further in the form (50), we obtain

$$I = e^{2k_2t/5}\left(\frac{d}{dt}\left(\frac{1}{\sqrt{2}}xe^{2k_2t/5}\right)\right)^2 + \frac{k_4}{3}(xe^{(2/5)k_2t})^3. \tag{76}$$

Identifying the dependent and independent variables from (76) and using the relations (51), we obtain the transformation

$$w = \frac{1}{\sqrt{2}}xe^{2k_2t/5}, \quad z = -\frac{5}{k_2}e^{-(k_2t/5)}. \tag{77}$$

Using this transformation (77), the first integral (75) can be rewritten in the form

$$\hat{I} = w'^2 + \frac{\hat{k}_4}{3}w^3, \tag{78}$$

where $\hat{k}_4 = 2\sqrt{2}k_4$, which in turn leads to

$$w'^2 = 4w^3 - g_3, \tag{79}$$

where $z = 2\sqrt{3/\hat{k}_4}\hat{z}$ and $g_3 = -12I_1/\hat{k}_4$. The solution of this differential equation can be represented in terms of the Weierstrass function[12,13] $\varrho(\hat{z};0,g_3)$.

Case (iv): $k_3 = [(r-1)/2r^2]k_1^2$, $k_4 = k_1k_2/3$, $\lambda_1 = 2k_2^2/9$, k_1, k_2, and r: arbitrary (but not zero).

The above parameters fix the equation of motion (10) in the form

$$\ddot{x} + (k_1x + k_2)\dot{x} + \frac{(r-1)k_1^2}{2r^2}x^3 + \frac{k_1k_2}{3}x^2 + \frac{2k_2^2}{9}x = 0, \quad r \neq 0. \tag{80}$$

The associated first integral reads [*vide* case (iva) in Table I]

$$I = \begin{cases} \left(\frac{(r-1)}{4r^2}k_1^2x^4 + \left(\dot{x} + \frac{k_2}{3}x\right)\left(\dot{x} + \frac{k_2}{3}x + \frac{k_1}{2}x^2\right)\right)\left(\dot{x} + \frac{k_2}{3}x + \frac{(r-1)}{2r}k_1x^2\right)^{-r} e^{[2(2-r)/3]k_2t}, & r \neq 0,2 \\ \frac{2}{3}k_2t + \log(4k_2x + 3k_1x^2 + 12\dot{x}) - \frac{4(k_2x + 3\dot{x})}{(4k_2x + 3k_1x^2 + 12\dot{x})}, & r = 2. \end{cases} \tag{81}$$

Rewriting Eq. (81) in the form (50), we get

$$I = \begin{cases} \left(\frac{(r-1)k_1^2}{4r^2}(xe^{(k_2/3)t})^4 + \frac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/3)t})\left(\frac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/3)t})e^{(k_2/3)t} + \frac{k_1}{2}(xe^{(k_2/3)t})^2\right)e^{(k_2/3)t}\right) \\ \quad \times \left(\frac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/3)t})e^{(k_2/3)t} + \frac{k_1(r-1)}{2r}(xe^{(k_2/3)t})^2\right)^{-r}, & r \neq 0,2 \\ \frac{4\frac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/3)t})e^{(k_2/3)t}}{k_1(xe^{(k_2/3)t})^2 + 4\frac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/3)t})e^{(k_2/3)t}} - \log\left(k_1(xe^{(k_2/3)t})^2 + 4\frac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/3)t})e^{(k_2/3)t}\right), & r = 2. \end{cases} \tag{82}$$

Identifying the dependent and independent variables from (82) and the relations (51), we obtain the transformation

$$w = xe^{(k_2/3)t}, \quad z = -\frac{3}{k_2}e^{-(k_2/3)t}. \tag{83}$$

In terms of the new variables (83), the first integral I given above (82), can be written as

$$I = \begin{cases} \left(w' + \dfrac{(r-1)}{2r}k_1w^2\right)^{-r}\left[\dfrac{(r-1)}{4r^2}k_1^2w^4 + w'\left(w' + \dfrac{k_1}{2}w^2\right)\right], & r \neq 0,2 \\ \dfrac{4w'}{k_1w^2 + 4w'} - \log(k_1w^2 + 4w'), & r = 2. \end{cases} \tag{84}$$

On the other hand the transformation (83) modifies the equation (80) to the form

$$w'' + k_1ww' + \frac{(r-1)k_1^2}{2r^2}w^3 = 0, \quad r \neq 0, \quad \text{and } ' = \frac{\mathrm{d}}{\mathrm{d}z}. \tag{85}$$

Finally, for the case $r=0$, we have an equation of the form [*vide* case (ivb) in Table I], $\ddot{x} + k_2\dot{x} + k_3x^3 + (2/9)k_2^2x = 0$, which is nothing but the force-free Duffing oscillator equation. Again using the transformation (83), the associated time-dependent integral given in Table I can be rewritten as

$$I = \frac{w'^2}{2} + \frac{k_3}{4}w^4, \quad r = 0. \tag{86}$$

Though it is difficult to integrate the above time-independent first integrals (84), as they are in complicated forms, one can easily check that Eq. (86) ($r=0$) can be integrated in terms of Jacobian elliptic function[14] and the case $r=1$ is already discussed as case (ii) in this section. For the other cases one can give a Hamiltonian formulation as in Sec. III A 4 and write the corresponding Hamiltonian as

$$H = \begin{cases} \left[\dfrac{((r-1)p)^{(r-2)/(r-1)}}{(r-2)} - p\left(\dfrac{(r-1)}{2r}k_1w^2\right)\right], & r \neq 0,1,2 \\ \dfrac{k_1}{4}w^2p + \log\left(\dfrac{4k_1}{p}\right), & r = 2 \\ e^p + \dfrac{k_1}{2}w^2, & r = 1 \\ \dfrac{p^2}{2} + \dfrac{k_3}{4}w^4, & r = 0, \end{cases} \tag{87}$$

where

$$p = \begin{cases} \dfrac{1}{r-1}\left(\dfrac{(r-1)}{2r}k_1w^2 + w'\right)^{1-r}, & r \neq 0,1 \\ \log(w'), & r = 1 \\ w', & r = 0. \end{cases} \tag{88}$$

Thus one is ensured of Liouville integrability of system (85) and so (80) for all values of r. Further, following the analysis in the above Sec. III A 5, one can make a canonical transformation [*vide* Eqs. (42)–(44)] to standard nonlinear oscillator equations.

E. Summary of results for the $q=1$ case

To summarize the results obtained in this section, we have identified six integrable cases in Eq. (10), among which four of them were already known in the literature and the remaining two are new. In the following, we tabulate all of them for convenience.

1. Integrable equations already known in the literature

(1) $\ddot{x}+(k_1x+k_2)\dot{x}+\frac{k_1^2}{9}x^3+\frac{k_1k_2}{3}x^2+\lambda_1x=0$ [Eq. (55)],

(2) $\ddot{x}+(k_1x+k_2)\dot{x}+\frac{k_1k_2}{3}x^3+\frac{2k_2^2}{9}x=0$ [Eq. (67)],

(3) $\ddot{x}+k_2\dot{x}+k_4x^2+\frac{6k_2^2}{25}x=0$ [Eq. (74)],

(4) $\ddot{x}+k_3x^3+k_4x^2+\lambda_1x=0$ [Eq. (33c)],

We note that the dynamics and certain transformation properties of Eq. (55) have been studied in detail recently by three of the present authors in Refs. 9 and 11. In particular, we have shown that this equation admits certain unusual nonlinear dynamics.[20] The dynamics of Eqs. (67), (74), and (33c) can be found in Ref. 12.

2. New integrable equations

(1) $\ddot{x}+k_1x\dot{x}+k_3x^3+\lambda_1x=0$ [Eq. (33b)],

(2) $\ddot{x}+(k_1x+k_2)\dot{x}+k_3x^3+\frac{k_1k_2}{3}x^2+\frac{2k_2^2}{9}x=0$ [Eq. (80)],

where $r^2k_3=[(r-1)k_1^2]/2$ and k_1, k_2, λ_1, and r are arbitrary parameters. We note that (33b) includes the first equation of MEE hierarchy (6) as a subcase. Importantly, we showed that (33b) is a Hamiltonian system [see Eq. (41)] and so it is Liouville integrable. Equation (80) can be transformed to the integrable Eq. (85). Explicit general solution of certain special cases, namely, $r=3$ or $\frac{3}{2}$ and $r=-1$ or $\frac{1}{2}$ are reported in Ref. 21.

IV. GENERALIZED FORCE FREE DVP FORM OF EQUATIONS

Let us now consider the case $q=2$ in Eq. (9) or equivalently (11), that is,

$$\ddot{x}=-((k_1x^2+k_2)\dot{x}+k_3x^5+k_4x^3+\lambda_1x)\equiv\phi(x,\dot{x})\ \text{[Eq. (11)]}.$$

Interestingly, Eq. (11) includes another class of physically important nonlinear oscillators. For example, choosing $k_3=0$ one can get the force-free Duffing-van der Pol oscillator equation. With the choice k_2, k_4, $\lambda_1=0$, it coincides with the second equation in the MEE hierarchy equation. Equation (11) with the restriction $k_3=k_1^2/16$, $k_4=k_1k_2/4$, and $\lambda_1=[\omega_0^2+(k_2^2/4)]$, has been investigated in a different perspective in Ref. 4. However, the general equation of the form (11) has never been considered for an integrability test and so we perform the same here.

To identify integrals of motion and the general solution of Eq. (11) we again seek the PS procedure. As the calculations are similar to the $q=1$ case of Eq. (9) which was carried out in the previous section, in the following we give only the important steps.

A. The case $I_t=0$

By considering the same arguments given in Sec. III A 1, the null form S can be fixed easily in the form

$$S = -\frac{((k_1x^2+k_2)\dot{x}+k_3x^5+k_4x^3+\lambda_1 x)}{\dot{x}}. \tag{89}$$

The respective R equation becomes

$$\dot{x}R_x - ((k_1x^2+k_2)\dot{x}+k_3x^5+k_4x^3+\lambda_1 x)R_{\dot{x}} = \left((k_1x^2+k_2)+\frac{((k_1x^2+k_2)\dot{x}+k_3x^5+k_4x^3+\lambda_1 x)}{\dot{x}}\right)R. \tag{90}$$

To seek a particular form for R one may seek a suitable Ansatz. We assume R to be of the form (28) and investigate the system (90) as before. Following a similar procedure we find that a nontrivial particular solution for (90) exists in the form

$$R = \frac{\dot{x}}{\left(\frac{(r-1)}{r}\left(\frac{k_1}{3}x^3+k_2x\right)+\dot{x}\right)^r}, \tag{91}$$

where r, k_1, and k_2 are arbitrary parameters and the remaining parameters, k_3, k_4, and λ_1, are fixed by the relations

$$k_3 = \frac{(r-1)}{3r^2}k_1^2, \quad k_4 = \frac{4(r-1)}{3r^2}k_1k_2, \quad \lambda_1 = \frac{(r-1)}{r^2}k_2^2. \tag{92}$$

Further, we confirmed the compatibility of the functions S and R with the extra constraint (24) also. We note that, unlike the earlier case, $q=1$, we do not get a nontrivial solution for the parametric restriction k_2, $k_4=0$. The above restrictions fix Eq. (11) to the following specific forms:

$$\text{(ia)} \quad \ddot{x}+(k_1x^2+k_2)\dot{x}+\frac{(r-1)}{3r^2}k_1^2x^5+\frac{4(r-1)k_1k_2}{3r^2}x^3+\frac{(r-1)k_2^2}{r^2}x=0, \quad r\neq 0 \tag{93a}$$

$$\text{(ib)} \quad \ddot{x}+k_3x^5+k_4x^3+\lambda_1 x=0, \quad r=0. \tag{93b}$$

Now substituting (89) and (91) into (25) and evaluating the integrals, we obtain the first integrals in the form

$$\text{(ia)} \quad I_1 = \left(\dot{x}+\frac{(r-1)}{r}\left(\frac{k_1}{3}x^3+k_2x\right)\right)^{-r}\left[\dot{x}\left(\dot{x}+\frac{k_1}{3}x^3+k_2x\right)+\frac{(r-1)}{r^2}\left(\frac{k_1}{3}x^3+k_2x\right)^2\right], \quad r\neq 0,2, \tag{94a}$$

$$\text{(ib)} \quad I_1 = \frac{6\dot{x}}{(6\dot{x}+3k_2x+k_1x^3)}-\log(6\dot{x}+3k_2x+k_1x^3), \quad r=2, \tag{94b}$$

$$\text{(ii)} \quad I_1 = \frac{\dot{x}^2}{2}+\frac{k_3}{6}x^6+\frac{k_4}{4}x^4+\frac{\lambda_1}{2}x^2, \quad r=0. \tag{94c}$$

Further, as in the $q=1$ case in Sec. III A 4, the integrals (94) can be recast into the Hamiltonian form

$$\text{(ia)} \quad H = \left[\frac{((r-1)p)^{(r-2)/(r-1)}}{(r-2)}-\frac{(r-1)}{r}p\left(\frac{k_1}{3}x^3+k_2x\right)\right], \quad r\neq 0,1,2, \tag{95a}$$

$$\text{(ib)} \quad H = \frac{k_2}{2}xp + \frac{k_1}{6}x^3p + \log\left(\frac{6}{p}\right), \quad r = 2, \tag{95b}$$

$$\text{(ic)} \quad H = e^p + \frac{k_1}{3}x^3 + k_2x, \quad r = 1, \tag{95c}$$

$$\text{(ii)} \quad H = \frac{p^2}{2} + \frac{k_3}{6}x^6 + \frac{k_4}{4}x^4 + \frac{\lambda_1}{2}x^2, \quad r = 0, \tag{95d}$$

where the corresponding canonical momenta, respectively, are

$$\text{(ia,b)} \quad p = \frac{1}{(r-1)}\left(\dot{x} + \frac{(r-1)}{r}\left(\frac{k_1}{3}x^3 + k_2x\right)\right)^{(1-r)}, \quad r \neq 0,1, \tag{96a}$$

$$\text{(ic)} \quad p = \log \dot{x}, \quad r = 1, \tag{96b}$$

$$\text{(ii)} \quad p = \dot{x}, \quad r = 0. \tag{96c}$$

Note that in the above the parameters r, k_1, k_2, k_3, and λ_1 are all arbitrary. We also note here that unlike the $q=1$ case discussed in Sec. III, so far we have been unable to find suitable canonical transformations for the above Hamiltonian systems so that the standard "potential" equation results. The problem is being further investigated.

B. The case $I_t \neq 0$

Now let us study the case $I_t \neq 0$. In this case S has to be determined from Eq. (22), that is,

$$S_t + \dot{x}S_x - ((k_1x^2 + k_2)\dot{x} + k_3x^5 + k_4x^3 + \lambda_1x)S_{\dot{x}} = (2k_1x\dot{x} + 5k_3x^4 + 3k_4x^2 + \lambda_1) - (k_1x^2 + k_2)S + S^2. \tag{97}$$

As we did in the $q=1$ case of Eq. (9) we proceed to solve Eq. (97) with the same form of Ansatz (47). Doing so we find that Eq. (97) admits nontrivial forms of solutions for certain specific parametric restrictions. We report both the parametric values and their respective forms of S in Table II.

Now substituting the forms of S into Eq. (23) and solving the resultant equation we obtain the corresponding forms of R. Once S and R are determined then one has to verify the compatibility of this solution with the extra constraint (24). Then, one can substitute the null forms and integrating factors into (25) and construct the associated integrals of motion. We report the integrating factors (R) and time-dependent integrals of motion (I) in Table II.

The remaining task is to derive the general solution and establish the complete integrability of Eq. (11) for each parametric restriction. We again adopt the procedure given in Sec. III C and transform the time-dependent integrals into time-independent ones and integrate the latter and deduce the general solution. As the procedure is exactly the same we provide only the results in the following.

Case (ia): $k_3 = k_1^2/16$, $k_4 = k_1k_2/4$, k_1, k_2, and λ_1: arbitrary.

Substituting the parametric restrictions given above in Eq. (11), we get

$$\ddot{x} + (k_1x^2 + k_2)\dot{x} + \frac{k_1^2}{16}x^5 + \frac{k_1k_2}{4}x^3 + \lambda_1x = 0. \tag{98}$$

We observed that the first integral of this case (i) (see Table II), when rewritten, is nothing but the Bernoulli equation which can be integrated strightforwardly[22] and leads to the general solution of the form

TABLE II. Parametric restrictions, null forms (S), integrating factors (R), and time-dependent integrals of motion (I) of $\ddot{x}+(k_1x^2+k_2)\dot{x}+k_3x^5+k_4x^3+\lambda_1x=0$ (identified with the assumed Ansatz form of S and R).

Cases	Parametric restrictions	Null form (S)	Integrating factor (R)	Integrals of motion (I)
(i)	$k_3=\frac{k_1^2}{16}, \quad k_4=\frac{k_1k_2}{4}$ (k_1, k_2, λ_1: arbitrary)	$\frac{\frac{k_1}{2}x^3-\dot{x}}{x}$	$\frac{xe^{\mp\omega t}}{\left(\dot{x}-\frac{(k_2\pm\omega)}{2}x+\frac{k_1}{4}x^3\right)^2}$	(a) $I=e^{\mp\omega t}\left(\frac{4\dot{x}+2(k_2\pm\omega)x+k_1x^3}{4\dot{x}+2(k_2\mp\omega)x+k_1x^3}\right)$, $k_2,\lambda_1\neq 0, \quad \omega=(k_2^2-4\lambda_1)^{1/2}$ (b) $I=-t+\frac{x}{\left(\frac{k_2}{2}x+\frac{k_1x^3}{4}+\dot{x}\right)}, \quad k_2^2=4\lambda_1$
(ii)	$k_3=0, \quad k_4=\frac{k_1}{6}(k_2\pm\omega)$, ($k_1$, k_2, λ_1: arbitrary)	$\frac{1}{2}(k_2\mp\omega)+k_1x^2$	$e^{[(k_2\pm\omega)/2]t}$	$I=\left(\dot{x}+\frac{k_2\mp\omega}{2}x+\frac{k_1}{3}x^3\right)e^{[(k_2\pm\omega)/2]t}$, $\omega=(k_2^2-4\lambda_1)^{1/2}$
(iii)	$k_1, \quad k_3=0, \quad \lambda_1=\frac{2k_2^2}{9}$ (k_2, k_4: arbitrary)	$\left(\frac{\frac{k_2}{3}\dot{x}+\frac{k_2^2}{9}x+k_4x^3}{\dot{x}+\frac{k_2}{3}x}\right)$	$\left(\dot{x}+\frac{k_2}{3}x\right)e^{(4/3)k_2t}$	$I=e^{(4/3)k_2t}\left[\frac{\dot{x}^2}{2}+\frac{k_2}{3}x\dot{x}+\frac{k_2^2}{18}x^2+\frac{k_4}{4}x^4\right]$

TABLE II. (*Continued.*)

Cases	Parametric restrictions	Null form (S)	Integrating factor (R)	Integrals of motion (I)
(iva)	$k_3=\frac{(r-1)k_1^2}{3r^2}, \quad k_4=\frac{k_1k_2}{4},$ $\lambda_1=\frac{3k_2^2}{16}, \quad r\neq 0$ (k_1, k_2, r: arbitrary)	$\frac{k_2}{4}+k_1x^2+\frac{4k_3x^5}{(4\dot{x}+k_2x)}$	$\frac{(k_2x+4\dot{x})e^{\{[3(2-r)]/4\}k_2t}}{\left(\frac{k_2}{4}x+rk_3x^3+\dot{x}\right)^r}$	$I=\left(\frac{k_3}{3}x^6+\left(\dot{x}+\frac{k_2}{4}x\right)\left(\dot{x}+\frac{k_2}{4}x+\frac{k_1}{3}x^3\right)\right)$ $\times\left(\dot{x}+\frac{k_2}{4}x+rk_3x^3\right)^{-r}e^{\{[3(2-r)]/4\}k_2t}, \quad r\neq 2$ $I=\frac{3}{4}k_2t+\log(6k_2x+4k_1x^3+24\dot{x})$ $-\frac{6(k_2x+4\dot{x})}{(6k_2x+4k_1x^3+24\dot{x})}, \quad r=2$
(ivb)	$k_1=0, \quad k_4=0,$ $\lambda_1=\frac{3k_2^2}{16}, \quad r=0$ (k_2, k_3: arbitrary)	$\left(\frac{\frac{k_2}{4}\dot{x}+\frac{k_2^2}{16}x+k_3x^5}{\dot{x}+\frac{k_2}{4}x}\right)$	$e^{(3k_2/2)t}\left(\dot{x}+\frac{k_2}{4}x\right)$	$I=e^{(3k_2/2)t}\left(\frac{\dot{x}^2}{2}+\frac{k_2}{4}x\dot{x}+\frac{k_2^2}{32}x^2+\frac{k_3}{6}x^6\right)$

$$x(t)=\left(\frac{8k_2\lambda_1(e^{\omega t}-I_1)^2}{I_1^2k_1k_2(-k_2+\omega)-e^{2\omega t}k_1k_2(k_2+\omega)+8I_2k_2\lambda_1e^{(k_2+\omega)t}+8I_1k_1\lambda_1e^{\omega t}}\right)^{1/2}, \tag{99}$$

where $\omega=\sqrt{k_2^2-4\lambda_1}$. A subcase of Eq. (98), namely, $k_2^2<4\lambda_1$ has been studied by Smith[4,23] who showed that the corresponding equation of motion admits a damped oscillatory form of solution, namely,

$$x(t)=\frac{A\cos(\omega_0t+\delta)}{\left(e^{k_2t}-\frac{k_1A}{4k_2}+\frac{k_1A}{4(k_2^2+4\omega_0^2)}(2\omega_0\sin 2(\omega_0t+\delta)-k_2\cos 2(\omega_0t+\delta))\right)^{1/2}}, \tag{100}$$

where $\omega_0=\frac{1}{2}\sqrt{4\lambda_1+k_2^2}$ and δ, A are arbitrary constants.

On the other hand for $k_2^2>4\lambda_1$, the solution (99) becomes of dissipative type, having a frontlike structure. In particular, for $\lambda_1=0$ we get a solution of the form

$$x(t)=\left(\frac{2\sqrt{k_2}(I_1e^{k_2t}-1)}{(-k_1+2k_1I_1e^{k_2t}(2+k_2I_1te^{k_2t})+4k_2I_2e^{2k_2t})^{1/2}}\right). \tag{101}$$

Case (ib): $k_3=k_1^2/16$, $k_4=k_1k_2/4$, $k_2^2=4\lambda_1$, k_1 and k_2: arbitrary.

In this case we get the general solution of the form from (101) as

$$x(t)=\left(\frac{2(I_1+t)^2}{2e^{k_2t}I_2-\frac{k_1}{k_2^3}(2+I_1^2k_2^2+2k_2t+k_2^2t^2+2I_1k_2(1+k_2t))}\right)^{1/2}. \tag{102}$$

One may note that a subcase of this equation, namely, $k_2=\lambda_1=0$, leads us to the second equation in the MEE hierarchy (6) and the corresponding solution follows from Eq. (102) as

$$x(t)=\sqrt{6}\left(\frac{(I_1+t)^2}{6I_2+k_1t(3I_1^2+3I_1t+t^2)}\right)^{1/2}. \tag{103}$$

This form exactly coincides with the solution (7) for $l=2$.

Case (ii): $k_3=0$, $k_4=(k_1/6)(k_2\pm\sqrt{k_2^2-4\lambda_1})$, k_1, k_2 and λ_1: arbitrary.

The repective equation of motion and the first integral are (see Table II)

$$\ddot{x}+(k_1x^2+k_2)\dot{x}+\frac{k_1}{6}(k_2\pm\sqrt{k_2^2-4\lambda_1})x^3+\lambda_1x=0, \tag{104}$$

and

$$I=\left(\dot{x}+\frac{k_2\mp\sqrt{k_2^2-4\lambda_1}}{2}x+\frac{k_1}{3}x^3\right)e^{[(k_2\pm\sqrt{k_2^2-4\lambda_1})/2]t}. \tag{105}$$

Equation (105) can be rewritten as an Abel's equation in the form

$$\dot{x}=Ie^{[(-k_2\mp\sqrt{k_2^2-4\lambda_1})/2]t}-\left(\frac{k_2\mp\sqrt{k_2^2-4\lambda_1}}{2}\right)x-\frac{k_1}{3}x^3. \tag{106}$$

It is not clear whether Eq. (106) can be explicitly integrated in general. However, for the special case $\lambda_1=\frac{3}{16}k_2^2$ it can be integrated as follows.

The restriction $\lambda_1=\frac{3}{16}k_2^2$ fixes the equation of motion (104) and the first integral (105) in the forms

$$\ddot{x} + (k_1 x^2 + k_2)\dot{x} + \frac{k_1 k_2}{4} x^3 + \frac{3k_2^2}{16} x = 0, \tag{107}$$

and

$$I = \left(\dot{x} + \frac{k_2}{4} x + \frac{k_1}{3} x^3 \right) e^{(3k_2/4)t}, \tag{108}$$

respectively.

Now following our procedure given in Sec. III C one arrives at the general solution[1] as

$$z + z_0 = -\frac{a}{3I} \left[\frac{1}{2} \log\left(\frac{(w-a)^2}{w^2 + aw + a^2} \right) + \sqrt{3} \arctan\left(\frac{-w\sqrt{3}}{2a + w} \right) \right], \tag{109}$$

with $w = xe^{(k_2/4)t}$, $z = -(2/k_2)e^{-k_2/2t}$, and $a = \sqrt[3]{3I/k_1}$ and z_0 is the second integration constant. Rewriting w and z in terms of old variables one can get the explicit solution.

Case (iii): k_1, $k_3 = 0$, $\lambda_1 = 2k_2^2/9$, k_2 and k_4: arbitrary.

The parametric restrictions given above fix the equation of motion (11) to the force-free Duffing oscillator, namely, $\ddot{x} + k_2\dot{x} + k_4 x^3 + (2k_2^2/9)x = 0$. We have already discussed the general solution of this equation in Sec. III [*vide* case (iv)].

Case (iv): $k_3 = [(r-1)k_1^2]/3r^3$, $k_4 = k_1 k_2/4$, $\lambda_1 = 3k_2^2/16$, k_1, k_2, and r: arbitrary.

The equation of motion turns out to be

$$\ddot{x} + (k_1 x^2 + k_2)\dot{x} + \frac{(r-1)k_1^2}{3r^2} x^5 + \frac{k_1 k_2}{4} x^3 + \frac{3k_2^2}{16} x = 0, \quad r \neq 0. \tag{110}$$

Rewriting the associated first integral I, given in case (iv) in Table II, in the form (50), we get

$$I = \begin{cases} \left(\dfrac{(r-1)k_1^2}{9r^2} (xe^{(k_2/4)t})^6 + \dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) \left(\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) e^{(k_2/2)t} + \dfrac{k_1}{3}(xe^{(k_2/4)t})^3 \right) e^{(k_2/2)t} \right) \\ \quad \times \left(\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) e^{(k_2/2)t} + \dfrac{k_1(r-1)}{3r}(xe^{(k_2/4)t})^3 \right)^{-r}, \quad r \neq 0, 2, \\ \dfrac{6\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) e^{(k_2/2)t}}{k_1(xe^{(k_2/4)t})^3 + 6\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) e^{(k_2/2)t}} - \log\left(k_1(xe^{(k_2/4)t})^3 + 6\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) e^{(k_2/2)t} \right), \quad r = 2 \\ \dfrac{1}{2}\left(\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{(k_2/4)t}) \right)^2 e^{k_2 t} + \dfrac{k_3}{6}(xe^{(k_2/4)t})^6, \quad r = 0 \end{cases} \tag{111}$$

and identifying the dependent and independent variables from (111) and the relations (51), we obtain the transformation

$$w = xe^{(k_2/4)t}, \quad z = -\frac{2}{k_2} e^{-(k_2/2)t}. \tag{112}$$

In terms of the new variables (112) the first integral I given above (111), can be written as

$$I=\begin{cases}\left(w'+\dfrac{(r-1)}{3r}k_1w^3\right)^{-r}\left[w'\left(w'+\dfrac{k_1}{3}w^3\right)+\dfrac{(r-1)}{9r^2}k_1^2w^6\right], & r\neq 0,2\\ \dfrac{6w'}{k_1w^3+6w'}-\log(k_1w^3+6w'), & r=2,\\ \dfrac{w'^2}{2}+\dfrac{k_3}{6}w^6, & r=0.\end{cases}\tag{113}$$

On the other hand substituting the transformation (112) into the equation of motion (110), we get

$$w''+k_1w^2w'+\frac{(r-1)k_1^2}{3r^2}w^5=0,\quad r\neq 0,\quad '=\frac{\mathrm{d}}{\mathrm{d}z}.\tag{114}$$

In the case $r=0$, we have an equation of the form [*vide* case (ivb) in Table II]

$$\ddot{x}+k_2\dot{x}+k_3x^5+\frac{3k_2^2}{16}x=0.\tag{115}$$

We note that Eq. (114) is the $l=2$ case of Eq. (6). As we mentioned in the Introduction, the general solution of this equation can be obtained only for certain specific choices, namely, $[(r-1)k_1^2]/3r^2=1/16$. This in turn gives $r=4k_1$ or $\frac{4}{3}k_1$. The respective solutions for these values of r of Eq. (114) can be fixed from Eq. (7) with $l=2$. The other cases do not seem to be amenable to explicit integration. However, all of them can be recast in the Hamiltonian form as we see below.

As the first integrals (113) are now "time" independent ones, one can give a Hamiltonian formalism for all the integrals (113) by following the ideas given in Sec. III A 4. Doing so we obtain

$$H=\begin{cases}\left[\dfrac{((r-1)p)^{(r-2)/(r-1)}}{(r-2)}-\dfrac{(r-1)}{3r}k_1w^3p\right], & r\neq 0,1,2,\\ \dfrac{k_1}{6}w^3p+\log\left(\dfrac{6}{p}\right), & r=2\\ e^p+\dfrac{k_1}{3}w^3, & r=1\\ \dfrac{p^2}{2}+\dfrac{k_3}{6}w^6, & r=0\end{cases}\tag{116}$$

where

$$p=\begin{cases}\dfrac{1}{(r-1)}\left(w'+\dfrac{(r-1)}{3r}k_1w^3\right)^{(1-r)}, & r\neq 0,1\\ \log w', & r=1\\ \dfrac{p^2}{2}+\dfrac{k_3}{6}w^6, & r=0.\end{cases}\tag{117}$$

In this sense these cases may be considered as Liouville integrable systems. Finally, the $r=0$ case in Eq. (113) can be integrated in terms of Jacobian elliptic function (see for example in Ref. 24). Again, here, we have not been able to identify canonical transformations which can lead to the identification of suitable potential equations.

C. Summary of results in $q=2$ case

To summarize the results obtained for the $q=2$ case, we have identified six integrable cases in Eq. (11), among which three of them were already known in the literature and the remaining three are new. In the following, we tabulate both of them.

1. Integrable equations already known in the literature

$$(1)\ \ddot{x}+(k_1x^2+k_2)\dot{x}+\frac{k_1k_2}{4}x^3+\frac{3k_2^2}{16}x=0\ [\text{Eq. (107)}],$$

$$(2)\ \ddot{x}+k_2\dot{x}+k_3x^3+\frac{2k_2^2}{9}x=0, \tag{118}$$

$$(3)\ \ddot{x}+k_3x^5+k_4x^3+\lambda_1x=0\ [\text{Eq. (93b)}].$$

We mention that Eq. (107) is nothing but the force-free DVP whose integrability is established in Ref. 1 and Eq. (118) is nothing but the force-free Duffing oscillator.[12,14]

2. New integrable equations

$$(1)\ \ddot{x}+(k_1x^2+k_2)\dot{x}+k_3x^5+\frac{4(r-1)k_1k_2}{3r^2}x^3+\frac{(r-1)k_2^2}{r^2}x=0,\quad r\neq 0\ [\text{Eq. (93a)}],$$

$$(2)\ \ddot{x}+(k_1x^2+k_2)\dot{x}+\frac{k_1^2}{16}x^5+\frac{k_1k_2}{4}x^3+\lambda_1x=0\ [\text{Eq. (98)}],$$

$$(3)\ \ddot{x}+(k_1x^2+k_2)\dot{x}+k_3x^5+\frac{k_1k_2}{4}x^3+\frac{3k_2^2}{16}x=0\ [\text{Eq. (110)}],$$

where $r^2k_3=[(r-1)k_1^2]/3$ and k_1, k_2, λ_1, and r are arbitrary parameters. We proved that Eq. (93a) is a Liouville integrable one. As far as Eq. (98) is concerned we derived the general solution for arbitrary values of k_1, k_2, and λ_1. Finally, for Eq. (110), though we identified only one time-dependent integral, we have demonstrated that it can be transformed into a time-independent Hamiltonian, thereby ensuring its Liouville integrability.

V. EXTENDED PRELLE-SINGER METHOD TO GENERALIZED EQ. (9)

One can investigate the integrability properties of Eq. (9) by considering the cases $q=3,4,5,\ldots$, one by one and classifying the integrable equations. Since the procedure and the mathematical techniques in exploring the integrating factors (R), null forms (S), first integrals (I), and general solution are the same in each case we do not consider each case in detail. We straightaway move to the case $q=$*arbitrary*, that is, $q\in R$ and not necessarily an integer, and present the outcome of our investigations.

As we did earlier, we consider the cases $I_t=0$ and $I_t\neq 0$ separately for the choice $q=$*arbitrary* also. First let us consider the case $I_t=0$.

A. The case $I_t=0$

By considering the same arguments given in Sec. III A 1, the null form S and the integrating factor R can be fixed easily in the form

$$S=-\frac{((k_1x^q+k_2)\dot{x}+k_3x^{2q+1}+k_4x^{1+q}+\lambda_1x)}{\dot{x}},$$

$$R=\frac{\dot{x}}{\left(\frac{(r-1)}{r}\left(\frac{k_1}{(q+1)}x^{q+1}+k_2x\right)+\dot{x}\right)^r}, \tag{119}$$

where k_1 and k_2 are arbitrary and the remaining parameters, k_3, k_4, and λ_1, are related to the parameters k_1 and k_2 through the relations

$$k_3=\frac{(r-1)}{r^2}(q+1)\hat{k}_1^2,\quad k_4=\frac{(r-1)}{r^2}(q+2)\hat{k}_1k_2,\quad \lambda_1=\frac{(r-1)}{r^2}k_2^2, \tag{120}$$

where $\hat{k}_1=k_1/(q+1)$. The above restrictions fix Eq. (9) to the following specific forms:

$$\text{(ia)}\quad \ddot{x}+((q+1)\hat{k}_1x^q+k_2)\dot{x}+\frac{(r-1)}{r^2}[(q+1)\hat{k}_1^2x^{2q+1}$$
$$+(q+2)\hat{k}_1k_2x^{q+1}+k_2^2x]=0,\quad r\neq 0\ [\text{Eq. (15)}],$$
$$\text{(ib)}\quad \ddot{x}+k_3x^{2q+1}+k_4x^{q+1}+\lambda_1x=0,\quad r=0. \tag{121}$$

Now substituting (119) into (25) and evaluating the integrals, we obtain the first integrals of the form

$$\text{(ia)}\ I_1=\left(\dot{x}+\frac{(r-1)}{r}(\hat{k}_1x^{q+1}+k_2x)\right)^{-r}\left[\dot{x}(\dot{x}+\hat{k}_1x^{q+1}+k_2x)+\frac{(r-1)}{r^2}(\hat{k}_1x^{q+1}+k_2x)^2\right],\quad r\neq 0,2, \tag{122a}$$

$$\text{(ib)}\quad I_1=\frac{\dot{x}}{\left(\dot{x}+\frac{k_2}{2}x+\frac{\hat{k}_1}{2}x^{q+1}\right)}-\log\left(\dot{x}+\frac{k_2}{2}x+\frac{\hat{k}_1}{2}x^{q+1}\right),\quad r=2, \tag{122b}$$

$$\text{(ii)}\quad I_1=\frac{\dot{x}^2}{2}+\frac{k_3}{2(q+1)}x^{2(q+1)}+\frac{k_4}{(q+2)}x^{q+2}+\frac{\lambda_1}{2}x^2,\quad r=0. \tag{122c}$$

Further, using the above forms of the first integrals, one can show that the equation of motion (9), with the parametric restrictions (120), can also be derived from the Hamiltonians

$$\text{(ia)}\ H=\left[\frac{((r-1)p)^{(r-2)/(r-1)}}{(r-2)}-\frac{(r-1)}{r}p(\hat{k}_1x^{q+1}+k_2x)\right],\quad r\neq 0,1,2, \tag{123a}$$

$$\text{(ib)}\ H=\frac{k_2}{2}xp+\frac{\hat{k}_1}{2}x^{q+1}p+\log\left(\frac{2(q+1)}{p}\right),\quad r=2 \tag{123b}$$

$$\text{(ic)}\ H=e^p+\hat{k}_1x^{q+1}+k_2x,\quad r=1, \tag{123c}$$

$$\text{(ii)}\ H=\frac{p^2}{2}+\frac{k_3}{2(q+1)}x^{2(q+1)}+\frac{k_4}{(q+1)}x^{q+1}+\frac{\lambda_1}{2}x^2,\quad r=0, \tag{123d}$$

where the corresponding canonical momenta, respectively, are

$$\text{(ia,b)}\ p=\frac{1}{(r-1)}\left(\dot{x}+\frac{(r-1)}{r}(\hat{k}_1x^{q+1}+k_2x)\right)^{(1-r)},\quad r\neq 0,1, \tag{124a}$$

$$\text{(ic) } p = \log \dot{x}, \quad r = 1, \tag{124b}$$

$$\text{(ii) } p = \dot{x}, \; r = 0. \tag{124c}$$

With the above Hamiltonian formulation, for the parametric set (120), the integrability of the associated equation of motion is assured for these parametric cases through Liouville theorem.

B. The case $I_t \neq 0$

We use the same Ansatz and ideas which we followed for the $q=1$ and $q=2$ cases to determine the forms of S and R. As the procedure is exactly the same as in the earlier cases, we present the parametric restrictions and the respective form of expressions of the integrating factors, null forms, and integrals of motions in Table III without further discussion.

Since we derived only one integral, which is also a time-dependent one for each parametric restriction, we need to integrate each one of them further and obtain the second integration constant in order to prove the complete integrability of each of the cases reported in Table III. In the following we deduce the second integral and general solution by utilizing the procedure given in Sec. III C.

Case (ia): $k_3=k_1^2/(q+2)^2$, $k_4=k_1k_2/(q+2)$, k_1, k_2, and λ_1: arbitrary.

We have an equation of the form

$$\ddot{x} + ((q+2)\hat{k}_1 x^q + k_2)\dot{x} + \hat{k}_1^2 x^{2q+1} + \hat{k}_1 k_2 x^{q+1} + \lambda_1 x = 0 \text{ [Eq. (13)]},$$

where $k_1=(q+2)\hat{k}_1$. The corresponding first integral given in Table III is nothing but the Bernoulli equation which can be solved using the standard method.[22] The general solution turns out to be

$$x(t) = (e^{\omega t} - I_1)\left(e^{(q/2)(k_2+\omega)t}\left(I_2 + \hat{k}_1 q \int \left(\frac{e^{\omega t} - I_1}{e^{(1/2)(k_2+\omega)t}} \right)^q \mathrm{d}t \right) \right)^{-1/q}, \tag{125}$$

where $\omega=\sqrt{k_2^2-4\lambda_1}$. We note here that a subcase of the above, namely, $k_2^2<4\lambda_1$, has been studied by Smith,[4] who had shown that the corresponding system admits the general solution of the form

$$x(t) = A\cos(\omega_0 t + \delta)e^{-(k_2/2)t}\left(1 + q\hat{k}_1 A \int e^{(-qk_2/2)t}\cos^q(\omega_0 t + \delta)\mathrm{d}t \right)^{-1/q}, \tag{126}$$

where $\omega_0=\frac{1}{2}\sqrt{4\lambda_1+k_2^2}$ and δ, A are arbitrary constants. For $k_2^2>4\lambda_1$, the solution become a dissipative type/frontlike structure. In particular, for $\lambda_1=0$ the general solution takes the form

$$x(t) = (e^{k_2 t}I_1 - 1)\left[e^{qk_2 t}\left(I_2 + \hat{k}_1 q \int (I_1 - e^{-k_2 t})^q \mathrm{d}t \right) \right]^{-1/q}. \tag{127}$$

Case (ib): $k_3=k_1^2/16$, $k_4=k_1k_2/4$, $k_2=4\lambda_1$, k_1 and k_2: arbitrary.

A general solution for this case can be fixed from (127) as

$$x(t) = (I_1 + t)e^{-(k_2/2)t}\left(I_2 + q\hat{k}_1 \int e^{-(qk_2/2)t}(I_1 + t)^q \mathrm{d}t \right)^{-1/q}. \tag{128}$$

On the other hand the general solution for the parametric choice k_2, $\lambda_1=0$ turns out to be

$$x(t) = \left(\frac{(q+1)(I_1+t)^q}{\hat{k}_1 q(I_1+t)^{q+1} + (q+1)I_2} \right)^{1/q}, \tag{129}$$

which exactly coincides with the result (7) obtained by Feix *et al.*[3] for integer $q(=l)$ values.

Case (ii): $k_3=0$, $k_4=\{k_1/[2(q+1)]\}(k_2\pm\sqrt{k_2^2-4\lambda_1})$, k_1, k_2 and λ_1: arbitrary.

The associated equation of motion and the first integral are (see Table III)

TABLE III. Parametric restrictions, null forms (S), integrating factors (R), and time-dependent integrals of motion (I) of $\ddot{x}+(k_1x^q+k_2)\dot{x}+k_3x^{2q+1}+k_4x^{q+1}+\lambda_1x=0$ (identified with the assumed Ansatz form of S and R).

Cases	Parametric restrictions	Null form (S)	Integrating factor (R)	Integrals of motion (I)
(i)	$k_3=\dfrac{k_1^2}{(q+2)^2}$, $\quad k_4=\dfrac{k_1k_2}{(q+2)}$ (k_1, k_2, λ_1: arbitrary)	$\dfrac{\left(\dfrac{qk_1}{(q+2)}x^{q+1}-\dot{x}\right)}{x}$	$\dfrac{xe^{\mp\omega t}}{\left(\dot{x}-\dfrac{(k_2\pm\omega)}{2}x+\dfrac{k_1}{(q+2)}x^{q+1}\right)^2}$	(a) $I=e^{\mp\omega t}\left(\dfrac{\dot{x}-\dfrac{(-k_2\mp\omega)}{2}x+\dfrac{k_1}{q+2}x^{q+1}}{\dot{x}-\dfrac{(-k_2\pm\omega)}{2}x+\dfrac{k_1}{q+2}x^{q+1}}\right)$ $k_2,\lambda_1\neq0$, $\quad\omega=(k_2^2-4\lambda_1)^{1/2}$ (b) $I=-t+\dfrac{x}{\left(\dfrac{k_2}{2}x+\dfrac{k_1x^{q+1}}{q+2}+\dot{x}\right)}$, $\quad k_2^2=4\lambda_1$
(ii)	$k_4=\dfrac{k_1(k_2\pm\omega)}{2(q+1)}$, $\quad k_3=0$, (k_1, k_2, λ_1: arbitrary)	$\dfrac{1}{2}(k_2\mp\omega)+k_1x^q$,	$e^{[(k_2\pm\omega)/2]t}$	$I=\left(\dot{x}+\dfrac{k_2\mp\omega}{2}x+\dfrac{k_1}{(q+1)}x^{q+1}\right)e^{[(k_2\pm\omega)/2]t}$, $\omega=(k_2^2-4\lambda_1)^{1/2}$
(iii)	$k_1,k_3=0$, $\quad\lambda_1=\dfrac{2(q+2)k_2^2}{(q+4)^2}$ (k_2, k_4: arbitrary)	$\dfrac{\dfrac{2k_2\dot{x}}{(q+4)}+\dfrac{4k_2^2x}{(q+4)^2}+k_4x^{q+1}}{\left(\dot{x}+\dfrac{2k_2x}{(q+4)}\right)}$	$\left(\dot{x}+\dfrac{2k_2x}{(q+4)}\right)e^{\{[2(q+2)]/[(q+4)]\}k_2t}$	$I=e^{\{[2(q+2)]/[(q+4)]\}k_2t}\left[\dfrac{\dot{x}^2}{2}+\dfrac{2k_2x\dot{x}}{(q+4)}+\dfrac{2k_2^2x^2}{(q+4)^2}+\dfrac{k_4x^{q+2}}{(q+2)}\right]$

TABLE III. (*Continued.*)

Cases	Parametric restrictions	Null form (S)	Integrating factor (R)	Integrals of motion (I)
(iv)a	$k_3=\dfrac{(r-1)k_1^2}{(q+1)r^2}$, $k_4=\dfrac{k_1k_2}{(q+2)}$, $\lambda_1=\dfrac{(q+1)k_2^2}{(q+2)^2}$, $r\neq 0$ (k_1, k_2, r: arbitrary)	$\dfrac{k_2}{(q+2)}+k_1x^q+\dfrac{k_3x^{2q+1}}{\left(\dot{x}+\dfrac{k_2}{(q+2)}x\right)}$	$\dfrac{(k_2x+(q+2)\dot{x})e^{\{[(q+1)(2-r)]/[(q+2)]\}k_2t}}{\left(\dfrac{k_2}{(q+2)}x+rk_3x^{q+1}+\dot{x}\right)^r}$	$I=\left(\dfrac{k_3x^{2(q+1)}}{(q+1)}+\left(\dot{x}+\dfrac{k_2x}{q+2}\right)\left(\dot{x}+\dfrac{k_2x}{q+2}+\dfrac{k_1x^{q+1}}{q+1}\right)\right)\times\left(\dfrac{k_2}{(q+2)}x+rk_3x^{q+1}+\dot{x}\right)^{-r}e^{\{[(q+1)(2-r)]/[(q+2)]\}k_2t}$, $r\neq 2$ $I=\dfrac{q+1}{q+2}k_2t+\log\left(k_1x^{q+1}+2(q+1)\left(\dot{x}+\dfrac{k_2}{q+2}x\right)\right)-\left(\dfrac{2(q+1)\left(\dot{x}+\dfrac{k_2}{q+2}x\right)}{k_1x^{q+1}+2(q+1)\left(\dot{x}+\dfrac{k_2}{q+2}x\right)}\right)$, $r=2$
(iv)b	$k_1=0$, $k_4=0$, $\lambda_1=\dfrac{(q+1)k_2^2}{(q+2)^2}$, $r=0$ (k_2, k_3: arbitrary)	$\dfrac{k_2}{(q+2)}+\dfrac{k_3x^{2q+1}}{\left(\dot{x}+\dfrac{k_2}{(q+2)}x\right)}$	$e^{\{[(2q+2)k_2]/[(q+2)]\}t}\left(\dot{x}+\dfrac{k_2}{(q+2)}x\right)$	$I=\left(\dfrac{\dot{x}^2}{2}+\dfrac{k_2x\dot{x}}{(q+2)}+\dfrac{k_2^2x^2}{2(q+2)^2}+\dfrac{k_3x^{2q+2}}{(2q+2)}\right)e^{\{[(2q+2)k_2]/(q+2)\}t}$

$$\ddot{x} + ((q+1)\hat{k}_1 x^q + k_2)\dot{x} + \frac{\hat{k}_1}{2}(k_2 \pm \sqrt{k_2^2 - 4\lambda_1})x^{q+1} + \lambda_1 x = 0, \tag{130}$$

and

$$I = \left(\dot{x} + \frac{k_2 \mp \sqrt{k_2^2 - 4\lambda_1}}{2}x + \hat{k}_1 x^{q+1}\right)e^{[(k_2 \pm \sqrt{k_2^2 - 4\lambda_1})/2]t}, \tag{131}$$

where $k_1=(q+1)\hat{k}_1$. As in the earlier cases, that is, $q=1$ and $q=2$, we are able to integrate the first integral (131) explicitly only for a specific parametric restriction, namely, $\lambda_1=(q+1)\hat{k}_2^2$, where $k_2=(q+2)\hat{k}_2$. In this case the equation of motion (130) and the first integral, Eq. (131), can be recast in the form

$$\ddot{x} + (k_1 x^q + (q+2)\hat{k}_2)\dot{x} + k_1\hat{k}_2 x^{q+1} + (q+1)\hat{k}_2^2 x = 0 \text{ [Eq.(12)]},$$

and

$$I = \left(\dot{x} + \hat{k}_2 x + \hat{k}_1 x^{q+1}\right)e^{(q+1)\hat{k}_2 t}, \tag{132}$$

respectively. Now comparing (132) with (50), we get

$$I = e^{q\hat{k}_2 t}\left(\frac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2 t})\right) + \hat{k}_1(xe^{\hat{k}_2 t})^{(q+1)}. \tag{133}$$

Next, identifying the dependent and independent variables from (133) using the relations (51), we obtain the transformation

$$w = xe^{\hat{k}_2 t}, \quad z = -\frac{1}{q\hat{k}_2}e^{-q\hat{k}_2 t}. \tag{134}$$

Using the transformation (134), the first integral (133) can be rewritten in the form

$$I = w' + \hat{k}_1 w^{(q+1)}, \tag{135}$$

which in turn leads to the solution by an integration, that is,

$$z - z_0 = \int \frac{\mathrm{d}w}{I - \hat{k}_1 w^{(q+1)}}, \tag{136}$$

where z_0 is an arbitrary constant. Solving Eq. (136), we get[25]

$$z - z_0 = \frac{1}{Ig^{1/(q+1)}}\begin{cases} -\dfrac{2}{q+1}\displaystyle\sum_{i=0}^{(q-1)/2} P_i \cos\frac{2i}{q+1}\pi + \frac{2}{q+1}\sum_{i=0}^{(q-1)/2} Q_i \sin\frac{2i}{q+1}\pi \\ \qquad + \dfrac{1}{q+1}\ln\dfrac{(1+w)}{(1-w)}, q\text{-a positive odd number}, \\ -\dfrac{2}{q+1}\displaystyle\sum_{i=0}^{(q-2)/2} R_i \cos\frac{2i+1}{q+1}\pi + \frac{2}{q+1}\sum_{i=0}^{\frac{q-2}{2}} T_i \sin\frac{2i+1}{q+1}\pi \\ \qquad + \dfrac{1}{q+1}\ln(1+w), \quad q\text{-a positive even number}, \end{cases} \tag{137}$$

where $g=\hat{k}_1/I$ and

$$P_i = \frac{1}{2}\ln\left(w^2 - 2w\cos\frac{2i}{q+1}\pi + 1\right), \quad Q_i = \arctan\left[\frac{w - \cos\frac{2i}{q+1}\pi}{\sin\frac{2i}{q+1}\pi}\right],$$

$$R_i = \frac{1}{2}\ln\left(w^2 + 2w\cos\frac{2i+1}{q+1}\pi + 1\right), \quad T_i = \arctan\left[\frac{w + \cos\frac{2i+1}{q+1}\pi}{\sin\frac{2i+1}{q+1}\pi}\right].$$

Rewriting w and z in terms of old variables, one can get the explicit solution.

Case (iii): k_1, $k_3=0$, $\lambda_1=[2(q+2)k_2^2]/[(q+4)^2]$, k_2 and k_4: arbitrary.

The parametric choice given above fixes the equation of motion of the form

$$\ddot{x} + (q+4)\hat{k}_2\dot{x} + k_4 x^{(q+1)} + 2(q+2)\hat{k}_2^2 x = 0 \text{ [Eq.(14)]},$$

where $k_2=(q+4)\hat{k}_2$. Rewriting the first integral I given in case (iii) in Table III, in the form (49), we get

$$I = \frac{1}{2}(\dot{x} + 2\hat{k}_2 x)^2 e^{2(q+2)\hat{k}_2 t} + \frac{k_4 x^{(q+2)}}{(q+2)} e^{2(q+2)\hat{k}_2 t}. \tag{138}$$

Now splitting the first term in Eq. (138) further in the form of (50),

$$I = \left[e^{q\hat{k}_2 t}\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{x}{\sqrt{2}}e^{2\hat{k}_2 t}\right)\right]^2 + \frac{2^{((q+2)/2)}k_4}{(q+2)}\left(\frac{x}{\sqrt{2}}e^{2\hat{k}_2 t}\right)^{(q+2)}, \tag{139}$$

and identifying the dependent and independent variables from (139) using the relations (51), we obtain the transformation

$$w = \frac{x}{\sqrt{2}}e^{2\hat{k}_2 t}, \quad z = -\frac{1}{q\hat{k}_2}e^{-q\hat{k}_2 t}. \tag{140}$$

Using the transformation (140), the first integral (138) can be brought to the form

$$I = w'^2 + \frac{2^{((q+2)/2)}k_4}{(q+2)}w^{(q+2)}. \tag{141}$$

Separating the dependent and independent variables and integrating the resultant equation we get

$$z - z_0 = \int \frac{\mathrm{d}w}{\sqrt{I - \hat{k}_4 w^{(q+2)}}}, \tag{142}$$

where $\hat{k}_4=\{[2^{(q+2)/2}]/[(q+2)]\}k_4$ and z_0 is an arbitrary constant.

Case (iv): $k_3=[(r-1)k_1^2]/[(q+1)r^2]$, $k_4=k_1k_2/(q+2)$, $\lambda_1=[(q+1)k_2^2]/[(q+2)^2]$, k_1, k_2, and r: arbitrary.

The equation of motion in this case turns out to be

$$\ddot{x} + ((q+1)\hat{k}_1 x^q + (q+2)\hat{k}_2)\dot{x} + (q+1)\left(\frac{(r-1)}{r^2}\hat{k}_1^2 x^{2q} + \hat{k}_1\hat{k}_2 x^q + \hat{k}_2^2\right)x = 0, \quad r \neq 0 \text{ [Eq. (16)]},$$

where $k_1=(q+1)\hat{k}_1$, $k_2=(q+2)\hat{k}_2$. Rewriting the associated first integral I, given in case (iv) in Table III, in the form (50), we get

$$I=\begin{cases}\left(\dfrac{(r-1)\hat{k}_1^2}{r^2}(xe^{\hat{k}_2t})^{2(q+1)}+\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})\left(\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})e^{q\hat{k}_2t}+\hat{k}_1(xe^{\hat{k}_2t})^{q+1}\right)e^{q\hat{k}_2t}\right), & \\ \qquad\times\left(\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})e^{q\hat{k}_2t}+\dfrac{\hat{k}_1(r-1)}{r}(xe^{\hat{k}_2t})^{q+1}\right)^{-r}, & r\neq 0,2\\ \dfrac{\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})e^{q\hat{k}_2t}}{\dfrac{\hat{k}_1}{2}(xe^{\hat{k}_2t})^{q+1}+\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})e^{q\hat{k}_2t}}-\log\left(\dfrac{\hat{k}_1}{2}(xe^{\hat{k}_2t})^{q+1}+\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})e^{q\hat{k}_2t}\right), & r=2\\ \dfrac{1}{2}\left(\dfrac{\mathrm{d}}{\mathrm{d}t}(xe^{\hat{k}_2t})\right)^2e^{2qk_2t}+\dfrac{k_3}{2(q+1)}(xe^{\hat{k}_2t})^{2(q+1)}, & r=0.\end{cases} \tag{143}$$

Identifying the dependent and independent variables from (143) and the relations (51), we obtain the transformation

$$w=xe^{\hat{k}_2t},\quad z=-\frac{1}{q\hat{k}_2}e^{-q\hat{k}_2t}. \tag{144}$$

Subsituting the transformation (144) into (16), one obtains

$$w''+(q+1)\hat{k}_1w^qw'+(q+1)\frac{(r-1)}{r^2}\hat{k}_1^2w^{2q+1}=0,\quad r\neq 0,\quad {}'=\frac{\mathrm{d}}{\mathrm{d}z}. \tag{145}$$

In terms of the new variables (144), the time-dependent first integral (143) can be transformed into time-independent ones of the form

$$I=\begin{cases}\left(w'+\dfrac{(r-1)}{r}\hat{k}_1w^{q+1}\right)^{-r}\left[w'(w'+\hat{k}_1w^{q+1})+\dfrac{(r-1)}{r^2}\hat{k}_1^2w^{2(q+1)}\right], & r\neq 0,2,\\ \dfrac{w'}{w'+\dfrac{\hat{k}_1}{2}w^{q+1}}-\log\left(w'+\dfrac{\hat{k}_1}{2}w^{q+1}\right), & r=2,\\ \dfrac{w'^2}{2}+\dfrac{k_3}{2(q+1)}w^{2(q+1)}, & r=0.\end{cases} \tag{146}$$

Once again one can deduce the Hamiltonians in the form

$$H=\begin{cases}\left[\dfrac{((r-1)p)^{(r-2)/(r-1)}}{(r-2)}-\dfrac{(r-1)}{r}\hat{k}_1w^{q+1}p\right], & r\neq 0,1,2,\\ \dfrac{1}{2}\hat{k}_1w^{q+1}p+\log\left(\dfrac{2(q+1)}{p}\right), & r=2,\\ e^p+\hat{k}_1w^{q+1}, & r=1,\\ \dfrac{p^2}{2}+\dfrac{k_3}{2(q+1)}w^{2(q+1)}, & r=0,\end{cases} \tag{147}$$

with

$$p = \begin{cases} \dfrac{1}{(r-1)}\left(w' + \dfrac{(r-1)}{r}\hat{k}_1 w^{q+1}\right)^{(1-r)}, & r \neq 0,1 \\ \log(w'), & r = 1 \\ w', & r = 0, \end{cases} \tag{148}$$

thereby ensuring Liouville integrability of Eq. (16).

C. Summary of results in *q=arbitrary* case

To conclude the integrability of Eq. (9), we have established the fact that the following equations are integrable:

(1) $\ddot{x} + (k_1 x^q + (q+2)k_2)\dot{x} + k_1 k_2 x^{q+1} + (q+1)k_2^2 x = 0$ [Eq. (12)],

(2) $\ddot{x} + ((q+2)k_1 x^q + k_2)\dot{x} + k_1^2 x^{2q+1} + k_1 k_2 x^{q+1} + \lambda_1 x = 0$ [Eq. (13)],

(3) $\ddot{x} + (q+4)k_2\dot{x} + k_4 x^{q+1} + 2(q+2)k_2^2 x = 0$ [Eq. (14)],

(4) $\ddot{x} + ((q+1)k_1 x^q + k_2)\dot{x} + \dfrac{(r-1)}{r^2}((q+1)k_1^2 x^{2q} + (q+2)k_1 k_2 x^q + k_2^2)x = 0,$

$r \neq 0$ [Eq. (15)],

(5) $\ddot{x} + ((q+1)k_1 x^q + (q+2)k_2)\dot{x} + (q+1)(k_3 x^{2q} + k_1 k_2 x^q + k_2^2)x = 0$ [Eq. (16)],

where $r^2 k_3 = (r-1)k_1^2$ and k_1, k_2, k_4, λ_1, and r are arbitrary parameters [for simplicity we have removed the hats in the k_i's, $i=1,2$, in Eqs. (12)–(16)]. The significance and newness of Eqs. (12)–(16) were already pointed out in Sec. I B.

VI. DISCUSSION AND CONCLUSIONS

In this paper, we have investigated the integrability properties of Eq. (9) and shown that it admits a large class of integrable nonlinear systems. In fact, many classical integrable nonlinear oscillators can be derived as subcases of our results. One of the important outcomes of our investigation is that the entire class of Eq. (6) can be derived from a conservative Hamiltonian [*vide* Eq. (123)], even though the system deceptively looks like a dissipative equation.

From our detailed analysis we have shown that Eq. (9) admits both conservative Hamiltonian systems and dissipative systems, depending on the choice of parameters. As far as the former is concerned we have deduced the explicit forms of the Hamiltonians for the respective equations. In fact, for the case $q=1$, we have constructed suitable canonical transformations and transformed the equations into conservative nonlinear oscillator equations. However, the canonical transformations for the conservative Hamiltonian systems for the cases $q=2,\ldots$, arbitrary, if they exist at all, still remain to be obtained. Exploring the classical dynamics underlying these conservative Hamiltonian systems is also of considerable interest for further study. As far as dissipative systems are concerned we have not only shown that Eq. (9) contains the well-known force-free Helmholtz, Duffing, and Duffing–van der Pol oscillators but also have several integrable generalizations which are another important outcome of our investigations. The study of chaotic dynamics of these nonlinear oscillators under further perturbations is one of the current topics[23] in the contemporary literature in nonlinear dynamics. In principle one can extend such analysis to the above-generalized equations as well.

In this paper, we also have not touched the question of linearizability of the integrable cases of Eq. (9). In our earlier work, we have shown that Eq. (55) is linearizable to the free particle

equation, $d^2w/dz^2=0$. Of course one can show that this is the only linearizable equation in (9) through invertible point transformation.[9,11,19] However, linearizablity of other integrable cases through more general transformations still remains to be explored.

In addition to the above, we have also carried out the Painlevé singularity structure analysis of Eq. (9) and compared the results obtained through both the methods. The details of this will be published elsewhere.

As we mentioned at the end of Sec. II, the crux of the PS procedure lies in finding the explicit solutions satisfying all three determining equations (22)–(24). In this paper we have considered only certain specific Ansatz forms to determine the null forms S, and integrating factors R. As a consequence only a specific class of integrable equations have been derived. It is not clear whether the Ansatz forms used in this paper exhaust all possible integrable cases of Eq. (9). One needs to consider more generalized Ansatz forms, and if possible to solve Eqs. (22)–(24) for the most general forms of R and S, and try to identify all possible integrable cases underlying Eq. (9). This is being explored further.

(Received 5 October 2005; accepted 27 January 2006; published online 14 March 2006)

We consider a μ-deformation of the Segal-Bargmann transform, which is a unitary map from a μ-deformed quantum configuration space onto a μ-deformed quantum phase space (the μ-deformed Segal-Bargmann space). Both of these Hilbert spaces have canonical orthonormal bases. We obtain explicit formulas for the Shannon entropy of some of the elements of these bases. We also consider two reverse log-Sobolev inequalities in the μ-deformed Segal-Bargmann space, which have been proved in a previous work, and show that a certain known coefficient in them is the best possible. © *2006 American Institute of Physics.*

I. INTRODUCTION

In this paper we will study a certain entropy in the context of a deformation of quantum mechanics called μ-deformed Segal-Bargmann analysis. This latter we will describe further on. So to start we would like to discuss the role of entropy in quantum mechanics in order to place this work in a broader context. (The text by Ohya and Petz[23] is a good general reference for this.) First of all, the concept of entropy comes from thermodynamics as developed in the 19th century. Entropy was later interpreted in terms of the classical statistical mechanics of the constituent entities (molecules) of matter. This led to the idea that entropy measures the uncertainty (meaning a lack of complete knowledge or information) on a microscopic scale of a macroscopic thermodynamic state. After quantum mechanics was formulated as a physical theory by Schrödinger and Heisenberg, the concept of entropy was soon introduced into this new theory in Ref. 37 by von Neumann, who took thermodynamics as a source of intuition.

The point was to define an entropy of a quantum mechanical state which von Neumann had defined as a positive (and so self-adjoint) trace class operator ρ with $\mathrm{Tr}\,\rho=1$. This operator could in turn be expanded by the spectral theorem in terms of an orthonormal basis $\{\phi_k\}$, depending on ρ, of the underlying Hilbert space of the quantum system under consideration as $\rho=\Sigma_k\lambda_k|\phi_k\rangle\langle\phi_k|$, where $\{\lambda_k\}$ is the set of eigenvalues of ρ and $|\phi_k\rangle\langle\phi_k|$ is the Dirac notation for the orthogonal projection whose range in the one-dimensional subspace spanned by the normalized eigenvector ϕ_k of ρ. The hypotheses on ρ imply that $\lambda_k\geqslant 0$ and $\Sigma_k\lambda_k=1$.

The *pure states* in quantum mechanics are usually thought of as the vectors ψ in the Hilbert space with $\|\psi\|=1$, modulo the equivalence relation $\psi_1\sim\psi_2$ provided that $\psi_1=e^{i\alpha}\psi_2$ for some real number α. In the present context, this is the same as taking the pure states to be the orthogonal projections $|\psi\rangle\langle\psi|$ with ψ satisfying $\|\psi\|=1$. Physical intuition says that any two pure states should have the same entropy, and since entropy in thermodynamics is only defined up to an overall additive constant (as is voltage in electrostatics), one can take the entropy of the pure states to be zero. These considerations, among others, led von Neumann to define the entropy of a general

a)Electronic mail: cpita@mx.up.mx
b)Electronic mail: sontz@cimat.mx

state ρ (also called a *density matrix* or a *mixed state*) as $-\Sigma_k \lambda_k \log \lambda_k$, using the above notation. (We set $0 \log 0 = 0$ by convention.)

Some years later while developing a mathematical theory of communication Shannon (in Ref. 31) introduced a similar definition for the entropy of a probability distribution. Specifically, for a discrete probability space S with probability p_k for each $k \in S$ (so that $p_k \geqslant 0$ and $\Sigma_{k \in S} p_k = 1$), the entropy defined by Shannon is $-\Sigma_{k \in S} p_k \log p_k$, the same formula as used by von Neumann but in another context (and with another notation). These two entropies, as well as natural adaptations of them to more general situations, have been used in many applications in physics, mathematics, computer science and so on. Note that our Definition 2.5 is one such adaptation. (We dropped the minus sign in Definition 2.5 to obtain a positive quantity, so that technically speaking what we then have is an "information" rather than an "uncertainty" or "entropy.")

However, there also arise situations in quantum mechanics where one is led to nontrivial entropies of pure states. To our knowledge the first instance of this in the literature occurs in an article (Ref. 14) by Hirschman in 1957, where the interest is in understanding the relation between a function f and its Fourier transform $\mathcal{F}f$ in terms of an "information" content. Under some hypotheses on $f \in L^2(\mathbf{R})$, Hirschman shows that

$$E_{\mathrm{Sh}}(|f|^2) + E_{\mathrm{Sh}}(|\mathcal{F}f|^2) \leqslant 0,$$

where $E_{\mathrm{Sh}}(g) = \int_{\mathbf{R}} \mathrm{d}x\, g(x) \log g(x)$ is the appropriate Shannon entropy of a function $g \geqslant 0$ in this context and $\mathcal{F}f(k) = \int_{\mathbf{R}} \mathrm{d}x\, e^{-2\pi i k x} f(x)$ is the Fourier transform of f. Moreover, Hirschman conjectured (and many years later in 1975 Beckner[5] proved) that

$$E_{\mathrm{Sh}}(|f|^2) + E_{\mathrm{Sh}}(|\mathcal{F}f|^2) \leqslant \log 2 - 1,$$

where the constant on the right-hand side is now optimal. From this second stronger version Hirschman proved the Heisenberg uncertainty principle in the usual form (due actually to Kennard in Ref. 15) that says that the product of the variances of $|f|^2$ and $|\mathcal{F}f|^2$ has a positive lower bound, or explicitly that

$$\mathrm{Var}(|f|^2)\mathrm{Var}(|\mathcal{F}f|^2) \geqslant \frac{1}{16\pi^2}$$

for our definition of the Fourier transform and with $\|f\|_{L^2} = 1$. Consequently, entropy-entropy inequalities of the sort proved by Hirschman and Beckner are often called entropic uncertainty relations. (See Chap. 16 in Ref. 23.)

Later in 1975, Gross[10] studied log-Sobolev inequalities, which are a type of energy-entropy inequality, again involving a Shannon entropy of a pure state as in Definition 2.5. These inequalities arose in the mathematical study of quantum field theory (see Ref. 8) and have found many applications in quantum theory, statistical mechanics, analysis, probability, etc. A recent survey with many references to the literature in statistical mechanics and probability is Ref. 11. It turns out that log-Sobolev inequalities are related to hypercontractivity, with this relation going back to Federbush's work[8] in 1969. For a rather comprehensive review of the literature on hypercontractivity up to the time of its publication in 1992, see Ref. 7.

Using the article[14] of Hirschman in Fourier analysis as an inspiration, but also keeping in mind the ground-breaking article (Ref. 10), Sontz in Ref. 33 began a study of Segal-Bargmann analysis, and in particular the Segal-Bargmann transform, in terms of a Shannon entropy that arises naturally in that context. This led to new Hirschman-type inequalities (that is, entropic uncertainty relations) and log-Sobolev inequalities, but also rather surprisingly to a reverse log-Sobolev inequality, where the Shannon entropy times a positive constant (together with a norm term) dominates the energy. (In a log-Sobolev inequality, the Shannon entropy is bounded above by a positive constant times the energy.) For a review of these results plus a number of open problems and more references, see Ref. 35.

More recently, Sontz and collaborators (in Refs. 2, 3, and 24) have established similar inequalities in μ-deformed Segal-Bargmann analysis, where the entropy is again an adaptation of

Shannon entropy to the theory. The present paper is a continuation of those works. We would like to understand better these inequalities and, in particular, their optimal constants. The results of Sec. VI are one step in that direction. In this paper we propose to study the entropies of the canonical basis elements of the μ-deformed Hilbert spaces. While it remains an open problem whether these functions are those that give us the optimal constants of the various inequalities that we have proved in our previous works, it is an interesting problem in its own right to evaluate these entropies since they are natural quantities in the theory. A minor surprise is that Euler's constant appears, though this constant has a way of "spontaneously" arising in many situations in analysis. This extends earlier work by Sontz in Ref. 34 to the context of another quantization scheme of classical mechanics, which we will call μ-deformed quantum mechanics and which we will explain shortly.

As a final comment about entropy in quantum mechanics, let us note that the Shannon entropy we are using is closely related to the Wehrl entropy, as introduced in Ref. 39. The idea of Wehrl in our terminology is to take first the Segal-Bargmann transform (described below) of a pure state ψ and then to calculate the Shannon entropy of the resulting state ϕ in the Segal-Bargmann space. (However, his formula is different since he uses a related coherent state transform.) This is then called the *classical entropy* of the state ψ. (This can also be done for mixed states.) We prefer however to refer to this as the Shannon entropy of ϕ, since ψ has its own Shannon entropy, which is not in general equal to the Shannon entropy of ϕ. (See Ref. 33.) We note that Lieb in Ref. 18 proves a reasonable conjecture of Wehrl concerning an inequality for the Wehrl entropy (see Ref. 39), and that he also makes a conjecture about a similar sort of inequality for a finite-dimensional situation involving the Bloch coherent states for spin. Also this conjectured inequality involves a Wehrl entropy, so that it should be amenable to our point of view. However, despite some recent partial results (Refs. 6 and 28), this tantalizing conjecture remains unsolved. And this even though Lieb proved in Ref. 18 the supposedly harder conjecture of Wehrl (in an infinite-dimensional context) almost 30 years ago.

We now review some structures in usual quantum mechanics as preparation for discussing a deformation of it. Two of the basic operators in quantum mechanics for a single one-dimensional particle are the position operator Q and the momentum operator P, which can be represented as $Q\psi(x)=x\psi(x)$ and $P\psi(x)=-i(d/dx)\psi(x)$, acting on complex-valued functions ψ belonging to (a dense subspace of) the Hilbert space $L^2(\mathbb{R},\mathrm{d}x)$. (This space is commonly thought of as a quantum configuration space.) It turns out that P and Q are self-adjoint operators in $L^2(\mathbb{R},\mathrm{d}x)$ and that they satisfy the commutation relation $[P,Q]=-iI$, called the *canonical commutation relation* (CCR). In terms of Q and P we can define the operators $a=2^{-1/2}(Q+iP)$ (annihilation) and $a^*=2^{-1/2}(Q-iP)$ (creation), which are each adjoint to the other and satisfy the CCR $[a,a^*]=I$. In 1932 Fock[9] realized that the relation $[a,a^*]=I$ is also satisfied by the operators $a\varphi(z)=(d/dz)\varphi(z)$ and $a^*\varphi(z)=z\varphi(z)$ acting on the space of all holomorphic functions φ. This interesting observation opened a critical mathematical question: does there exist a Hilbert space of holomorphic functions where the operators described above are each adjoint to the other? In 1961 Bargmann[4] answered this question giving the mathematical foundations for Fock's observation. He defined a Gaussian measure $\mathrm{d}\nu_{\mathrm{Gauss}}$ and considered the holomorphic subspace $\mathcal{B}^2$ of the Hilbert space $L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})$, and showed that in $\mathcal{B}^2$ the creation and annihilation operators are adjoints of each other. [It turns out that $\mathcal{B}^2$ is closed in $L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})$, and then is itself a Hilbert space.] Because of this and similar work by Segal,[29,30] the space $\mathcal{B}^2$ is known as the *Segal-Bargmann space*, and this space is commonly thought of as a quantum phase space.

So we have two Hilbert spaces, $L^2(\mathbb{R},\mathrm{d}x)$ and $\mathcal{B}^2$, in both of which are defined two unbounded operators a and a^*, each adjoint to the other and satisfying the CCR $[a,a^*]=I$. One refers to this fact by saying that the spaces $L^2(\mathbb{R},\mathrm{d}x)$ and $\mathcal{B}^2$ carry representations of the Lie group generated by the exponentiated form of the CCR. It turns out that these representations are irreducible. The so-called Bargmann transform $\tilde{B}:L^2(\mathbb{R},\mathrm{d}x)\to\mathcal{B}^2$ (also described in Ref. 4) is an isomorphism, that is a unitary onto map, between these two quantum spaces which also intertwines the actions of a and a^*. It is possible to replace the quantum configuration space $L^2(\mathbb{R},\mathrm{d}x)$ by another unitarily equivalent space, namely $L^2(\mathbb{R},\mathrm{d}g)$, called the *ground state representation*, where $\mathrm{d}g$ is another

Gaussian measure. In this case, the resulting transform B that maps the ground state representation unitarily onto the Segal-Bargmann space is called the *Segal-Bargmann transform*. What we call *Segal-Bargmann analysis* has to do mainly with the study of operators related to B and spaces of holomorphic functions related to $\mathcal{B}^2$. The present work is a part of Segal-Bargmann analysis. For other related works in the theory of white noise see Kuo's book[16] (where the S-transform is essentially the Segal-Bargmann transform), in microlocal analysis see the works of Martinez[22] and of Sjöstrand[32] (where the FBI transform is closely related though not identical to the Segal-Bargmann transform), in heat kernel analysis (since the kernel function of the Segal-Bargmann transform is related to the heat kernel) see the review article of Hall,[13] in coherent state theory see the book by Ali, Antoine, and Gazeau[1] (since the Segal-Bargmann transform is an example of a coherent state transform), and in all the references therein.

It is easy to see that the CCR implies the *equations of motion* $i[P,H]=Q$ and $i[Q,H]=-P$, where $H:=2^{-1}(P^2+Q^2)$ is the Hamiltonian of the harmonic oscillator. In 1950, Wigner[40] proved that the converse implication is false by exhibiting unbounded operators P_μ and Q_μ, labeled by a parameter $\mu>-1/2$, that satisfy the equations of motion, where $H_\mu:=2^{-1}(P_\mu^2+Q_\mu^2)$ replaces H, but do not satisfy the CCR. We consider this μ-deformation of quantum mechanics to be interesting since it gives a mathematically consistent way of effecting a quantization of classical mechanics. It is well known that at a mathematical level quantization is not unique. However in physics we see that nature manifests just one of these possibilities. (Nelson refers to this as "a mystery" in an oft-cited quotation. See Ref. 25, p. 207.) We hope that further mathematical studies will be able to elucidate the mathematical properties characteristic of nature's choice. As a further comment, we should note that experiment can set a limit on the absolute value of the parameter μ, but cannot definitively prove that it is equal to zero.

Later, Rosenblum and Marron (in Refs. 26, 27, and 21) realized these operators P_μ and Q_μ explicitly acting in a μ-quantum configuration space $L^2(\mathbb{R},|x|^{2\mu}\mathrm{d}x)$ and in a μ-Segal-Bargmann space $\mathcal{B}_\mu^2$. They also defined a μ-Bargmann transform $\widetilde{B}_\mu$, which is a unitary onto transformation mapping the former Hilbert space to the latter Hilbert space. This theory can be understood as a μ-deformation of standard Segal-Bargmann analysis with the property that if one sets $\mu=0$ the standard theory is recovered (see Ref. 36). So we will refer to $L^2(\mathbb{R},|x|^{2\mu}\mathrm{d}x)$ and $\mathcal{B}_\mu^2$, as the "μ-deformed quantum configuration space" and the "μ-deformed Segal-Bargmann space," respectively, and to $\widetilde{B}_\mu$ as the "μ-deformed Bargmann transform." It is also straightforward to obtain explicitly the "μ-deformed ground state representation" $L^2(\mathbb{R},\mathrm{d}g_\mu)$ and the "μ-deformed Segal-Bargmann transform" B_μ, which is a unitary map from $L^2(\mathbb{R},\mathrm{d}g_\mu)$ onto $\mathcal{B}_\mu^2$.

In Ref. 34, Sontz obtained explicit formulas for the entropy of relevant elements of the Hilbert spaces $L^2(\mathbb{R},\mathrm{d}g)$ and $\mathcal{B}^2$, namely, elements of the corresponding canonical (orthonormal) basis of these spaces. By denoting by ζ_n, $n=0,1,\ldots$ the functions of the canonical basis $\{\zeta_n\}_{n=0}^\infty$ of the ground state representation $L^2(\mathbb{R},\mathrm{d}g)$, and by ξ_n, $n=0,1,\ldots$ the functions of the canonical basis $\{\xi_n\}_{n=0}^\infty$ of the Segal-Bargmann space $\mathcal{B}^2$, Sontz proved in Ref. 34 that for $n=0,1,\ldots$ one has that

$$S_{L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})}(\xi_n)=n\left(-\gamma+1+\frac{1}{2}+\cdots+\frac{1}{n}\right)-\log n!, \tag{1.1}$$

$$S_{L^2(\mathbb{R},\mathrm{d}g)}(\zeta_1)=2-\log 2-\gamma, \tag{1.2}$$

where γ is Euler's constant.

In this work we will obtain for the μ-deformed theory results similar to (1.1) and (1.2). More precisely, in Theorem 4.3 we will show that for any $\mu>-1/2$, the entropy $S_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}(\xi_n^\mu)$ of the nth μ-deformed element ξ_n^μ, $n=0,1,\ldots$, of the μ-deformed canonical basis $\{\xi_n^\mu\}_{n=0}^\infty$ of the μ-deformed Segal-Bargmann space $\mathcal{B}_\mu^2$ is given by

$$S_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}(\xi_n^\mu)=\frac{n}{2}\left(\psi\left(\mu+\frac{n+\theta(n)+1}{2}\right)+\psi\left(\frac{n+\theta(n+1)+1}{2}\right)\right)-\log\frac{\gamma_\mu(n)}{2^n},\qquad(1.3)$$

where ψ is the logarithmic derivative of the gamma function, θ is the characteristic function of the odd positive integers, and γ_μ is a μ-deformation of the factorial function (defined in Sec. II). We will show that in the case $\mu=0$ this formula reduces to (1.1), so (1.3) is a generalization of (1.1) for the μ-deformed theory. Also, in Sec. IV we will show that the entropy $S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(\zeta_1^\mu)$ of the μ-deformed element ζ_1^μ of the μ-deformed canonical basis $\{\zeta_n^\mu\}_{n=0}^\infty$ of the μ-deformed ground state representation $L^2(\mathbb{R},\mathrm{d}g_\mu)$ is given by

$$S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(\zeta_1^\mu)=\psi\left(\mu+\tfrac{3}{2}\right)-\log\left(\mu+\tfrac{1}{2}\right),\qquad(1.4)$$

and when $\mu=0$ this formula reduces to (1.2), so (1.4) generalizes (1.2).

In this paper we want to emphasize the importance of an idea that has not played a role in our previous research in Segal-Bargmann analysis. This is the idea of an extensive quantity, which meant originally in the context of thermodynamics a quantity proportional to the size of a physical system. In the context of this paper the size is the index n (or *quantum number*) of the states forming the canonical orthonormal bases of the Hilbert spaces under study. So we say that a number depending on the nth basis element is an *extensive quantity* if it is asymptotically proportional to n. For example, the energy levels of the harmonic oscillator are extensive in this sense of the word. So our main results in Sec. IV concerning the entropies of the basis elements ξ_n^μ show these entropies to be extensive quantities. At one and the same time this shows that entropy is a useful concept from a physical point of view as well as that the μ-deformation of quantum mechanics under study here has this desirable property. Even though being an extensive quantity according to our definition is an asymptotic property, we realize this result by an actual explicit computation of the entropies and only later by doing the asymptotic analysis. In Sec. V we do a similar analysis of the entropies of the monomials t^n in $L^2(\mathbb{R},\mathrm{d}g_\mu)$, basically because we have the mathematical tools for doing this. But it turns out that these entropies are not extensive quantities. This is not surprising since these monomials, while mathematically simple, are not the eigenfunctions of a physically interesting self-adjoint operator. In Sec. VI, we study a μ-deformed energy (defined there) and, among other things, show that it is an extensive quantity.

We now outline in detail the content of the work. In Sec. II we give, on the one hand, the definitions and notation of the μ-deformed objects that will be used throughout the work [here we introduce the μ-deformed Hilbert spaces $L^2(\mathbb{R},\mathrm{d}g_\mu)$ and $\mathcal{B}_\mu^2$, and their canonical bases as well]. On the other hand, we give the definition of the Shannon entropy of a function f in a complex Hilbert space $L^2(\Omega,\mathrm{d}\nu)$ where $(\Omega,\mathrm{d}\nu)$ is a finite measure space. All the material in Sec. II is previously known and is included here only for the clarity of the exposition. In Sec. III we prove some results about the behavior of the μ-deformed factorial function γ_μ and of the logarithmic derivative ψ of the gamma function [both involved in formula (1.3)], that will help us to obtain some properties of the sequence of entropies of the functions ξ_n^μ, $n=0,1,\ldots$. In particular, these entropies are extensive quantities. These properties are not explicitly given (in the case $\mu=0$) in Ref. 34, but we give them as a proposition at the end of Sec. III. Lemma 3.1 in Sec. III is new for us, but we can hardly claim originality for a result about the well-studied special function ψ. However, Lemma 3.2 and the rest of the results of this article (except as noted in Sec. VI) are new. In Sec. IV, besides the discussion that led us to formula (1.3) which generalizes (1.1), we also obtain a generalization of the proposition at the end of Sec. III about some properties of the sequence of entropies. Again, these entropies are extensive quantities. In Sec. V we consider the μ-deformed ground state representation and we obtain explicit formulas for the entropies of the monomials $t^n \in L^2(\mathbb{R},\mathrm{d}g_\mu)$, $n=0,1,\ldots$ and these turn out not to be extensive quantities. Unfortunately the technique we use here to obtain these formulas (and those of Sec. IV) does not work to obtain the entropies of the elements ζ_n^μ of the canonical basis of $L^2(\mathbb{R},\mathrm{d}g_\mu)$, for $n\geqslant 2$. It turns out that our method for calculating the entropy of a function f works only in the case of f being a monomial, and the elements ζ_n^μ are monomials only for $n=0,1$. Also, by means of a concrete example, in Sec. V we show that the μ-deformed Segal-Bargmann transform B_μ does not preserve entropy. In Sec.

VI we consider two reverse log-Sobolev inequalities proved in Ref. 3, in which the condition $c>1$ of a certain parameter c appears as a sufficient condition. In this section we show that this condition is also necessary, or in other words, that the condition $c>1$ is the best possible. Finally, in Sec. VII we make some comments about what we left unfinished in this paper and what is possible to do beyond the results presented here.

We would also like to note that our results can be generalized to the case of $\mathbb{R}^n$ and $\mathbb{C}^n$ (in place of $\mathbb{R}$ and $\mathbb{C}$) for any integer $n>1$. This works out because the functions (of n variables) of the canonical bases can be factored as products of functions (of one variable), which are precisely the basis elements considered here in the one-dimensional case. Since all the relevant measures also factorize in terms of the measures used here, we can immediately calculate all the entropies of the basis functions in dimension n in terms of the entropies studied here in the one-dimensional case. (See Lemma 2.1 in Ref. 34.)

II. DEFINITIONS AND NOTATION

In this section we give the definitions and the notation that we will use throughout the work. First, we take $\mu>-\frac{1}{2}$ to be a fixed parameter (unless otherwise stated). The (Coxeter) group $\mathbb{Z}_2$ is the multiplicative group $\{-1,1\}$, and log is the natural logarithm (base e). We use the convention $0\log 0=0$ [which makes the function $\phi:[0,\infty)\to\mathbb{R}$, $\phi(x)=x\log x$ continuous]. We also use the convention that C denotes a constant (a quantity that does not depend on the variables of interest in the context), which may change its value every time it appears. We denote by $\mathcal{H}(\mathbb{C})$ the space of holomorphic functions $f:\mathbb{C}\to\mathbb{C}$ with the topology of uniform convergence on compact sets.

We begin by defining the μ-deformations of the factorial function and of the exponential function. Let $\mathbb{N}$ denote the set of positive integers.

Definition 2.1: The μ-deformed factorial function $\gamma_\mu:\mathbb{N}\cup\{0\}\to\mathbb{R}$ is defined by $\gamma_\mu(0)=1$ and

$$\gamma_\mu(n) := (n+2\mu\theta(n))\gamma_\mu(n-1),$$

where $n\in\mathbb{N}$ and $\theta:\mathbb{N}\to\{0,1\}$ is the characteristic function of the odd positive integers. The μ-deformed exponential function $\mathbf{e}_\mu:\mathbb{C}\to\mathbb{C}$, is defined by the power series

$$\mathbf{e}_\mu(z) := \sum_{n=0}^{\infty}\frac{z^n}{\gamma_\mu(n)}.$$

We note that $\gamma_0(n)=n!$ (the usual factorial function) and so $\mathbf{e}_0(z)=\exp(z)$ (the usual complex exponential function). It is clear that the power series in the definition of $\mathbf{e}_\mu(z)$ is absolutely convergent for all $z\in\mathbb{C}$. So the μ-deformed exponential $\mathbf{e}_\mu$ is an entire function.

We will use the following explicit formulas for $\gamma_\mu(2n)$ and $\gamma_\mu(2n+1)$, $n=0,1,2,\ldots$ (see Ref. 26, p. 371):

$$\gamma_\mu(2n)=\frac{2^{2n}\Gamma(n+1)\Gamma\left(\mu+n+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}=\frac{(2n)!\Gamma\left(\frac{1}{2}\right)\Gamma\left(\mu+n+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)\Gamma\left(n+\frac{1}{2}\right)}, \tag{2.1}$$

$$\gamma_\mu(2n+1)=\frac{2^{2n+1}\Gamma(n+1)\Gamma\left(\mu+n+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}=\frac{(2n+1)!\Gamma\left(\frac{1}{2}\right)\Gamma\left(\mu+n+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)\Gamma\left(n+\frac{3}{2}\right)}. \tag{2.2}$$

The following definition (from Ref. 26) gives us a μ-deformation of the classical Hermite polynomials.

Definition 2.2: For $n=0,1,\ldots$ *we define the* nth μ*-deformed Hermite polynomial* $H_n^\mu(t)$ *by the generating function*

$$\exp(-z^2)\mathbf{e}_\mu(2tz)=\sum_{n=0}^{\infty}H_n^\mu(t)\frac{z^n}{n!}.$$

It is easy to check that $H_n^\mu(t)$ is in fact a polynomial of degree n in the real variable t. For example, we have that $H_0^\mu(t)=1$, $H_1^\mu(t)=[2/(1+2\mu)]t$, $H_2^\mu(t)=[4/(1+2\mu)]t^2-2$, and so on.

The normalized μ-deformed Hermite polynomials $\zeta_n^\mu(t)$, $n=0,1,\ldots$ defined by

$$\zeta_n^\mu(t):=2^{-n/2}(n!)^{-1}(\gamma_\mu(n))^{1/2}H_n^\mu(t), \tag{2.3}$$

form an orthonormal basis of the μ-deformed ground state representation $L^2(\mathbb{R},\mathrm{d}g_\mu)$, where $\mathrm{d}g_\mu$ is the μ*-deformed Gaussian measure* defined by

$$\mathrm{d}g_\mu(t):=\left(\Gamma\left(\mu+\frac{1}{2}\right)\right)^{-1}\exp(-t^2)|t|^{2\mu}\,\mathrm{d}t. \tag{2.4}$$

The basis $\{\zeta_n^\mu\}_{n=0}^\infty$ is called *the canonical basis of* $L^2(\mathbb{R},\mathrm{d}g_\mu)$. (See Refs. 26 and 24.)

The case $\mu=0$ recovers the well-known fact that for $n=0,1,\ldots$, the normalized polynomials $\zeta_n(t)=2^{-n/2}(n!)^{-1/2}H_n(t)$, where $H_n(t)$ denotes the nth Hermite polynomial, form the canonical orthonormal basis of the ground state representation $L^2(\mathbb{R},\mathrm{d}g)$, where $\mathrm{d}g$ is the Gaussian probability measure $\mathrm{d}g(t)=\pi^{-1/2}\exp(-t^2)\mathrm{d}t$. (See Ref. 12.)

Definition 2.3: We define the measure $\mathrm{d}\nu_\mu$ *on the space* $\mathbb{C}\times\mathbb{Z}_2$ *by*

$$\mathrm{d}\nu_\mu(z,1):=\frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)}K_{\mu-1/2}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y, \tag{2.5}$$

$$\mathrm{d}\nu_\mu(z,-1):=\frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)}K_{\mu+1/2}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y, \tag{2.6}$$

where Γ *is the Euler gamma function,* K_α *is the Macdonald function of order* α *(both defined in Ref. 17), and* $\mathrm{d}x\,\mathrm{d}y$ *is Lebesgue measure on* $\mathbb{C}$.

By using that $\mathbb{C}\cong\mathbb{C}\times\{1\}\cong\mathbb{C}\times\{-1\}$, we will identify the restrictions (2.5) and (2.6) as measures on $\mathbb{C}$.

The Macdonald function K_α is the modified Bessel function of the third kind (with purely imaginary argument, as described in Ref. 38, p. 78), which is known to be a holomorphic function on $\mathbb{C}\backslash(-\infty,0]$ and is entire with respect to the parameter α. Nevertheless, our interest will be only in the values and behavior of this function for $x\in\mathbb{R}^+$ and $\alpha\in\mathbb{R}$. For $z\in\mathbb{C}$, $|\arg z|<\pi$ and $\alpha\notin\mathbb{Z}$, the Macdonald function can be defined as

$$K_\alpha(z)=\frac{\pi}{2}\frac{I_{-\alpha}(z)-I_\alpha(z)}{\sin(\alpha\pi)}$$

(see Ref. 17, p. 108), where $I_\alpha(z)$ is the modified Bessel function of the first kind. For $\alpha\in\mathbb{Z}$, we define $K_\alpha(z)=\lim_{\beta\to\alpha}K_\beta(z)$. This expression shows that $K_a(z)$ is an even function of the parameter α. In particular, since $I_{1/2}(z)=(2/\pi z)^{1/2}\sinh z$ and $I_{-1/2}(z)=(2/\pi z)^{1/2}\cosh z$ (see Ref. 17, p. 112), we have that

$$K_{\pm 1/2}(z) = \left(\frac{\pi}{2z}\right)^{1/2} \exp(-z),$$

which shows that for $\mu=0$ the measures defined on $\mathbb{C}$ by (2.5) and (2.6) are the same Gaussian measure,

$$\mathrm{d}\nu_0(z,1) = \mathrm{d}\nu_0(z,-1) = \pi^{-1} \exp(-|z|^2)\mathrm{d}x\,\mathrm{d}y,$$

which is the Gaussian measure $\mathrm{d}\nu_{\mathrm{Gauss}}$ of the Segal-Bargmann space $\mathcal{B}^2=\mathcal{H}(\mathbb{C})\cap L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})$.

By using the formula

$$\int_0^\infty K_\alpha(s)s^{\beta-1}\,\mathrm{d}s = 2^{\beta-2}\Gamma\left(\frac{\beta-\alpha}{2}\right)\Gamma\left(\frac{\beta+\alpha}{2}\right), \tag{2.7}$$

which holds if $\mathrm{Re}\,\beta>|\mathrm{Re}\,\alpha|$ (see Ref. 38, p. 388), we can see that (2.5) and (2.6) are finite measures on $\mathbb{C}$, and moreover that the former is a probability measure. (See Ref. 24.)

The integral representation

$$K_\alpha(z) = \int_0^\infty \exp(-z\cosh u)\cosh(\alpha u)\mathrm{d}u, \quad \mathrm{Re}\,z>0 \tag{2.8}$$

(see Ref. 17, p. 119) gives us at once two important properties of the Macdonald function. The first is that $K_\alpha(x)>0$ for all $x\in\mathbb{R}^+$, and the second is that K_α is a monotone decreasing function for $x\in\mathbb{R}^+$.

We will work with the Hilbert space $L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)$. The norm of a vector $f\in$ will be denoted by $\|f\|_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}$. Let us consider the space

$$\mathfrak{H}_{2,\mu} = \{f:\mathbb{C}\to\mathbb{C} | f_e \in L^2(\mathbb{C},\,\mathrm{d}\nu_\mu|_{\mathbb{C}\times\{1\}}) \text{ and } f_o \in L^2(\mathbb{C},\,\mathrm{d}\nu_\mu|_{\mathbb{C}\times\{-1\}})\},$$

where $f=f_e+f_o$ is the decomposition of f into its even and odd parts. (We will use this decomposition and its notation without further comment.) Observe that when $\mu=0$ we have $\mathfrak{H}_{2,0}=L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})$.

For $f\in\mathfrak{H}_{2,\mu}$ we define

$$\|f\|^2_{\mathfrak{H}_{2,\mu}} := \|f_e\|^2_{L^2(\mathbb{C},\,\mathrm{d}\nu_\mu|_{\mathbb{C}\times\{1\}})} + \|f_o\|^2_{L^2(\mathbb{C},\,\mathrm{d}\nu_\mu|_{\mathbb{C}\times\{-1\}})}.$$

The linear map $\Phi:\mathfrak{H}_{2,\mu}\to L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)$ defined as $(\Phi f)(z,1)=f_e(z)$ and $(\Phi f)(z,-1)=f_o(z)$ is injective and has the property that

$$\|f\|_{\mathfrak{H}_{2,\mu}} = \|\Phi f\|_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)} \tag{2.9}$$

for all $f\in\mathfrak{H}_{2,\mu}$. Therefore $\|\cdot\|_{\mathfrak{H}_{2,\mu}}$ is a norm on $\mathfrak{H}_{2,\mu}$. It is not hard to show that the range of Φ is a closed subspace of $L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)$. Therefore $\mathfrak{H}_{2,\mu}$ is a Hilbert space, since we have identified it with a closed subspace of the Hilbert space $L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)$. For a function $f\in\mathfrak{H}_{2,\mu}$ we will sometimes write its norm as $\|f\|_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}$, meaning that we are using (2.9) and identifying f with Φf.

We will use the notations $\mathrm{d}\nu_{e,\mu}$ and $\mathrm{d}\nu_{o,\mu}$ for the restrictions $\mathrm{d}\nu_\mu|_{\mathbb{C}\times\{1\}}$ and $d\nu_\mu|_{\mathbb{C}\times\{-1\}}$, respectively. So for $f\in\mathfrak{H}_{2,\mu}$ we have

$$\|f\|^2_{\mathfrak{H}_{2,\mu}} = \|f_e\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})} + \|f_o\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})} = \|f_e\|^2_{\mathfrak{H}_{2,\mu}} + \|f_o\|^2_{\mathfrak{H}_{2,\mu}}.$$

Definition 2.4: The μ-deformed Segal-Bargmann space, denoted by $\mathcal{B}^2_\mu$, is defined as

$$\mathcal{B}^2_\mu := \mathcal{H}(\mathbb{C}) \cap \mathfrak{H}_{2,\mu}. \tag{2.10}$$

That is, $\mathcal{B}^2_\mu$ is the holomorphic subspace of $\mathfrak{H}_{2,\mu}$. It turns out that $\mathcal{B}^2_\mu$ is closed in $\mathfrak{H}_{2,\mu}$, and then it is also closed in $L^2(\mathbb{C}\times\mathbb{Z}_2, d\nu_\mu)$, so $\mathcal{B}^2_\mu$ is itself a Hilbert space. (The proof of this fact does not depend on μ; see Theorem 2.2 in Ref. 12 for the case $\mu=0$.) Observe that when $\mu=0$ we have $\mathcal{B}^2_0=\mathcal{H}(\mathbb{C})\cap\mathfrak{H}_{2,0}=\mathcal{H}(\mathbb{C})\cap L^2(\mathbb{C}, d\nu_{\text{Gauss}})=\mathcal{B}^2$.

If we decompose the space $\mathcal{H}(\mathbb{C})$ of holomorphic functions $f:\mathbb{C}\to\mathbb{C}$ as $\mathcal{H}(\mathbb{C})=\mathcal{H}_e(\mathbb{C})\oplus\mathcal{H}_o(\mathbb{C})$, where

$$\mathcal{H}_e(\mathbb{C}) := \{f \in \mathcal{H}(\mathbb{C}): f = f_e\}$$

and

$$\mathcal{H}_o(\mathbb{C}) := \{f \in \mathcal{H}(\mathbb{C}): f = f_o\}$$

are the subspaces of the even and odd functions of $\mathcal{H}(\mathbb{C})$, respectively, then by writing $\mathcal{H}(\mathbb{C}) \ni f=f_e+f_o$, the space $\mathcal{B}^2_\mu$ is just the space of holomorphic functions $f:\mathbb{C}\to\mathbb{C}$ such that the even part f_e (the odd part f_o) of f is square integrable with respect to the measure $d\nu_{e,\mu}$ (with respect to the measure $d\nu_{o,\mu}$, respectively). That is,

$$\mathcal{B}^2_\mu = \{f \in \mathcal{H}(\mathbb{C}): f_e \in L^2(\mathbb{C}, d\nu_{e,\mu}) \text{ and } f_o \in L^2(\mathbb{C}, d\nu_{o,\mu})\}.$$

Yet another way to think of $\mathcal{B}^2_\mu$ is as

$$\mathcal{B}^2_\mu = \mathcal{B}^2_{e,\mu} \oplus \mathcal{B}^2_{o,\mu}, \tag{2.11}$$

where

$$\mathcal{B}^2_{e,\mu} = \mathcal{H}_e(\mathbb{C}) \cap \mathfrak{H}_{2,\mu}$$

and

$$\mathcal{B}^2_{o,\mu} = \mathcal{H}_o(\mathbb{C}) \cap \mathfrak{H}_{2,\mu}$$

are the even and odd subspaces of $\mathcal{B}^2_\mu$.

Observe that the inner product of the Hilbert space $\mathcal{B}^2_\mu$ (from which the norm on $\mathcal{B}^2_\mu$ defined above comes) is

$$\langle f, g\rangle_{\mathcal{B}^2_\mu} = \langle f_e, g_e\rangle_{L^2(\mathbb{C}, d\nu_{e,\mu})} + \langle f_o, g_o\rangle_{L^2(\mathbb{C}, d\nu_{o,\mu})}. \tag{2.12}$$

We then have that $\mathcal{B}^2_{e,\mu}$ and $\mathcal{B}^2_{o,\mu}$ are orthogonal subspaces of $\mathcal{B}^2_\mu$, and that (2.11) holds as Hilbert spaces.

The monomials $\xi^\mu_n(z)$, $n=0,1,\ldots$ defined for $z\in\mathbb{C}$ by

$$\xi^\mu_n(z) := (\gamma_\mu(n))^{-1/2} z^n, \tag{2.13}$$

form an orthonormal basis of the μ-deformed Segal-Bargmann space $\mathcal{B}^2_\mu$. The basis $\{\xi^\mu_n\}_{n=0}^\infty$ is called the *canonical basis of* $\mathcal{B}^2_\mu$. When $\mu=0$ we obtain the monomials $\xi_n(z)=(n!)^{-1/2}z^n$, $n=0,1,\ldots$ which are known to form the canonical basis of the Segal-Bargmann space $\mathcal{B}^2$. (See Ref. 12.)

The μ-deformed Segal-Bargmann transform $B_\mu: L^2(\mathbb{R}, dg_\mu)\to\mathcal{B}^2_\mu$ can be defined as $B_\mu(\zeta^\mu_n)=\xi^\mu_n$, $n=0,1,\ldots$. It is clear that B_μ so defined is a unitary map. An explicit formula for B_μ is

$$(B_\mu f)(z) = \int_{\mathbb{R}} \exp\left(-\frac{z^2}{2}\right) \mathbf{e}_\mu(2^{1/2}tz) f(t) \mathrm{d}g_\mu(t). \tag{2.14}$$

(See Ref. 24.) When $\mu=0$ this formula becomes

$$(B_0 f)(z) = \int_{\mathbb{R}} \exp\left(-\frac{z^2}{2} + 2^{1/2}tz\right) f(t) \mathrm{d}g(t),$$

which is the undeformed Segal-Bargmann transform studied, for example, in Ref. 12, where it is shown that it is a unitary map from the quantum configuration space $L^2(\mathbb{R}, \mathrm{d}g)$ onto the quantum phase space $\mathcal{B}^2$.

Definition 2.5: Let $(\Omega, \mathrm{d}\nu)$ *be a finite measure space, that is,* $0 < \nu(\Omega) < \infty$. *For* $f \in L^2(\Omega, \mathrm{d}\nu)$, *the Shannon entropy* $S_{L^2(\Omega,\mathrm{d}\nu)}(f)$ *is defined by*

$$S_{L^2(\Omega,\mathrm{d}\nu)}(f) := \int_\Omega |f(\omega)|^2 \log |f(\omega)|^2 \, \mathrm{d}\nu(\omega) - \|f\|^2_{L^2(\Omega,\mathrm{d}\nu)} \log \|f\|^2_{L^2(\Omega,\mathrm{d}\nu)}. \tag{2.15}$$

By considering the convex function $\phi:[0,\infty) \to \mathbb{R}$, $\phi(x) = x \log x$, and the probability measure space $(\Omega, \mathrm{d}\nu')$, where $\mathrm{d}\nu' = W^{-1}\mathrm{d}\nu$, $W = \nu(\Omega)$, we have by Jensen's inequality (see Ref. 19, p. 38) that

$$\left(\int_\Omega |f(\omega)|^2 \, \mathrm{d}\nu(\omega)\right) \log\left(\frac{1}{W}\int_\Omega |f(\omega)|^2 \, \mathrm{d}\nu(\omega)\right) \leqslant \int_\Omega |f(\omega)|^2 \log |f(\omega)|^2 \, \mathrm{d}\nu(\omega)$$

or

$$(-\log W)\|f\|^2_{L^2(\Omega,\mathrm{d}\nu)} \leqslant S_{L^2(\Omega,\mathrm{d}\nu)}(f),$$

which shows that $S_{L^2(\Omega,\mathrm{d}\nu)}(f) \neq -\infty$, though $S_{L^2(\Omega,\mathrm{d}\nu)}(f) = +\infty$ can happen. In particular, this entropy is well defined for every element of $L^2(\Omega, \mathrm{d}\nu)$ since $\nu(\Omega)$ is finite. This is not so if $\nu(\Omega) = \infty$. For example, see Ref. 14 for the case of Lebesgue measure. Also observe that $S_{L^2(\Omega,\mathrm{d}\nu')}(f) \geqslant 0$, though $S_{L^2(\Omega,\mathrm{d}\nu)}(f)$ can be negative. Finally, note that $S_{L^2(\Omega,\mathrm{d}\nu)}(f)$ is homogeneous of degree 2.

Observe that for $f \in \mathcal{B}^2_\mu$, $f \neq 0$, the entropy $S_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}(f)$ is *not in general* equal to $S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(f_e) + S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(f_o)$. What we really have is

$$S_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}(f) = S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(f_e) + S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(f_o) + \|f_e\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})} \log \frac{\|f_e\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}}{\|f\|^2_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}}$$

$$+ \|f_o\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})} \log \frac{\|f_o\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}}{\|f\|^2_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}}. \tag{2.16}$$

Nevertheless, observe that if f is an even (odd) function, its entropy is given by $S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(f)$ [$S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(f)$, respectively]. Then, for the functions ξ^μ_n of the canonical basis of $\mathcal{B}^2_\mu$ we have $S^\mu_n = S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(\xi^\mu_n)$ when n is even, and $S^\mu_n = S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(\xi^\mu_n)$ when n is odd, where $S^\mu_n := S_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}(\xi^\mu_n)$, $n = 0, 1, 2, \ldots$.

III. PRELIMINARY RESULTS

In the calculations we will do in the Secs. IV and V, the derivative of the gamma function will arise naturally. Recall that the *logarithmic derivative* of $z \mapsto \Gamma(z)$, also called the *digamma function* and denoted by $\psi(z)$, is defined by

$$\psi(z) := \frac{\Gamma'(z)}{\Gamma(z)}$$

for all $z \neq 0, -1, -2, \ldots$. (See Ref. 17, p. 5.) We will be interested only in the values and behavior of $\psi(x)$ with $x \in \mathbb{R}^+$.

From the basic property of the gamma function $\Gamma(x+1)=x\Gamma(x)$ one obtains the formula

$$\psi(x+1) = \frac{1}{x} + \psi(x),$$

from which one gets by induction that

$$\psi(x+n) = \sum_{k=0}^{n-1} \frac{1}{x+k} + \psi(x)$$

for $n \in \mathbb{N}$. Using the identities $\psi(1)=-\gamma$ and $\psi(\frac{1}{2})=-\gamma-2\log 2$ (see Ref. 17, p. 6), the previous formula implies (by taking $x=1$ and $x=\frac{1}{2}$) that

$$\psi(n+1) = -\gamma + \sum_{k=1}^{n} \frac{1}{k}$$

and

$$\psi\left(n+\frac{1}{2}\right) = -\gamma - 2\log 2 + 2\sum_{k=1}^{n} \frac{1}{2k-1}.$$

When necessary we will use these formulas without further comment.

In this section we will state and prove two lemmas that we will be using in Secs. IV and V.

Lemma 3.1: (a) The inequality $0 < \psi(x+m) - \log x < (2m-1)(2x)^{-1}$ *holds for all* $x \in \mathbb{R}^+$ *and* $m \in \mathbb{N}$. *In particular, we have that for any* $m \in \mathbb{N}$

$$\lim_{x\to+\infty} (\psi(x+m) - \log x) = 0.$$

(b) For $y > 0$ *fixed we have that*

$$\lim_{x\to+\infty} (\psi(x+y) - \log x) = 0.$$

(c) The inequality $-x^{-1} < \psi(x) - \log x < -(2x)^{-1}$ *holds for all* $x \in \mathbb{R}^+$. *In particular, we have that*

$$\lim_{x\to+\infty} (\psi(x) - \log x) = 0.$$

Proof: From the integral representation of $\psi(z)$,

$$\psi(z) = \int_0^\infty \left(\frac{e^{-t}}{t} - \frac{e^{-tz}}{1-e^{-t}}\right) \mathrm{d}t,$$

and the integral representation of $\log(z)$,

$$\log(z) = \int_0^\infty \frac{e^{-t} - e^{-tz}}{t} \mathrm{d}t,$$

both valid for $\mathrm{Re}\, z > 0$ (see Ref. 17, pp. 6 and 7), one obtains for all $x > 0$ and $m > 0$ that

$$\psi(x+m)-\log x=\int_0^\infty\left(\frac{1}{t}-\frac{e^{-tm}}{1-e^{-t}}\right)e^{-tx}\,dt. \tag{3.1}$$

For $m\in\mathbb{N}$, let us consider the function $h_m:\mathbb{R}\to\mathbb{R}$,

$$h_m(t)=\frac{1}{t}-\frac{e^{-tm}}{1-e^{-t}},$$

where we define $h_m(0)=\lim_{t\to 0}h_m(t)=(2m-1)/2>0$. So h_m is continuous. For all $t>0$ we will prove by induction that $0<h_m(t)<(2m-1)/2$ holds for all $m\in\mathbb{N}$. Observe that $e^t>1+t$ for $t>0$ implies $h_1(t)>0$ for $t>0$. Also observe that $\beta(t)=\tanh(t/2)-(t/2)$ is a decreasing function in $\mathbb{R}^+$, so that $\tanh(t/2)<(t/2)$ for $t>0$, which implies that $h_1(t)<\frac{1}{2}$ for $t>0$. This proves the inequality $0<h_m(t)<(2m-1)/2$ for $m=1$. Suppose now that the inequality holds for a given $m\in\mathbb{N}$. The hypothesis $h_m(t)>0$ gives us

$$h_{m+1}(t)=\frac{1}{t}-\frac{e^{-tm}}{1-e^{-t}}e^{-t}=\left(\frac{1}{t}-\frac{e^{-tm}}{1-e^{-t}}\right)e^{-t}+\frac{1-e^{-t}}{t}>0$$

for $t>0$. Also, the case $m=1$ gives us that $(1/t)<\frac{1}{2}+[e^{-t}/(1-e^{-t})]$, which together with the hypothesis $h_m(t)<(2m-1)/2$ gives us (for $t>0$) that

$$\begin{aligned}h_{m+1}(t)&=\left(\frac{1}{t}-\frac{e^{-tm}}{1-e^{-t}}\right)e^{-t}+\frac{1-e^{-t}}{t}<\frac{2m-1}{2}e^{-t}+(1-e^{-t})\left(\frac{1}{2}+\frac{e^{-t}}{1-e^{-t}}\right)=\frac{2m-1}{2}e^{-t}+\frac{1+e^{-t}}{2}\\&=me^{-t}+\frac{1}{2}<\frac{2m+1}{2},\end{aligned}$$

as wanted. Then (3.1) and the inequality $0<h_m(t)<(2m-1)/2$ we just proved above gives us that

$$0<\psi(x+m)-\log x<\frac{2m-1}{2}\int_0^\infty e^{-tx}\,dt=(2m-1)(2x)^{-1},$$

which proves (a).

For $x\in\mathbb{R}^+$ we have that

$$\psi(x)-\log(x)=\psi(x+1)-\log(x)-x^{-1}.$$

So, by using (a) with $m=1$ we have that

$$-x^{-1}<\psi(x)-\log(x)<(2x)^{-1}-x^{-1}=-(2x)^{-1},$$

which proves (c).

Now we prove (b). (We need to prove the result for $y\notin\mathbb{N}$.) Observe that it is sufficient to demonstrate the result for $y\in(0,1)$, since given that for any fixed noninteger $Y>0$ we can write $Y=\lfloor Y\rfloor+y$, where $\lfloor Y\rfloor$ is the floor function of Y and $y\in(0,1)$. Then, by defining $X:=x+\lfloor Y\rfloor$ we have that

$$\begin{aligned}\lim_{x\to+\infty}(\psi(x+Y)-\log x)&=\lim_{X\to+\infty}(\psi(X+y)-\log(X-\lfloor Y\rfloor))=\lim_{X\to+\infty}\left(\psi(X+y)-\log X-\log\frac{X-\lfloor Y\rfloor}{X}\right)\\&=\lim_{X\to+\infty}(\psi(X+y)-\log X)=0.\end{aligned}$$

We consider the continuous function $h_y:\mathbb{R}\to\mathbb{R}$, $h_y(t)=(1/t)-[e^{-ty}/(1-e^{-t})]$, where $h_y(0)=\lim_{t\to 0}h_y(t)=(2y-1)/2$, and $0<y<1$ is fixed. According to (3.1), with $m=y\in(0,1)$, it is sufficient to prove that h_y is bounded in $[0,\infty)$, since if $|h_y(t)|\leqslant C$ for all $t\geqslant 0$, then

$$|\psi(x+y)-\log x| = \left|\int_0^\infty h_y(t)e^{-tx}\,dt\right| \leqslant C\int_0^\infty e^{-tx}\,dt = \frac{C}{x},$$

and thus $\psi(x+y)-\log x \to 0$ as $x \to +\infty$. But observe that $\lim_{t\to+\infty} h_y(t)=0$ and that h_y is continuous, which shows that h_y is bounded on $[0,\infty)$. Q.E.D.

Lemma 3.2: Let $\mu > -\frac{1}{2}$ be fixed. Then

$$\lim_{n\to\infty} \frac{(\gamma_\mu(n))^{1/n}}{n} = e^{-1}.$$

(Note that this limit does not depend on μ.)

Proof: It is sufficient to prove that

$$\lim_{n\to\infty} \frac{(\gamma_\mu(2n))^{1/2n}}{2n} = \lim_{n\to\infty} \frac{(\gamma_\mu(2n+1))^{1/(2n+1)}}{2n+1} = e^{-1}.$$

Let us consider the even case. We can write by using formula (2.1) that

$$\frac{(\gamma_\mu(2n))^{1/2n}}{2n} = \frac{((2n)!)^{1/2n}}{2n}\left(\frac{\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\right)^{1/2n}\left(\frac{\Gamma\left(\mu+n+\frac{1}{2}\right)}{\Gamma\left(n+\frac{1}{2}\right)}\right)^{1/2n}.$$

We have that $\lim_{n\to\infty}[((2n)!)^{1/2n}/2n]=e^{-1}$ and $\lim_{n\to\infty}(\Gamma(\frac{1}{2})/\Gamma(\mu+\frac{1}{2}))^{1/2n}=1$. So it remains to prove that the limit of the third factor in the left-hand side is 1. By using Stirling's formula we have that

$$\lim_{n\to\infty}\left(\frac{\Gamma\left(\mu+n+\frac{1}{2}\right)}{\Gamma\left(n+\frac{1}{2}\right)}\right)^{1/2n} = \lim_{n\to\infty}\left(\frac{\sqrt{2\pi}\left(\mu+n+\frac{1}{2}\right)^{\mu+n}e^{-(\mu+n+1/2)}}{\sqrt{2\pi}\left(n+\frac{1}{2}\right)^{n}e^{-(n+1/2)}}\right)^{1/2n}$$

$$= \lim_{n\to\infty}\left(\left(\mu+n+\frac{1}{2}\right)^{\mu/2n}e^{-\mu/2n}\left(\frac{\mu+n+\frac{1}{2}}{n+\frac{1}{2}}\right)^{1/2}\right) = 1.$$

For the odd case, by using (2.2) we have that

$$\frac{(\gamma_\mu(2n+1))^{1/(2n+1)}}{2n+1} = \frac{((2n+1)!)^{1/(2n+1)}}{2n+1}\left(\frac{\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\right)^{1/(2n+1)}\left(\frac{\Gamma\left(\mu+n+\frac{3}{2}\right)}{\Gamma\left(n+\frac{3}{2}\right)}\right)^{1/(2n+1)}.$$

We have that

$$\lim_{n\to\infty}\frac{((2n+1)!)^{1/(2n+1)}}{2n+1} = e^{-1} \text{ and } \lim_{n\to\infty}\left(\frac{\Gamma\left(\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\right)^{1/(2n+1)} = 1.$$

So the proof ends by showing that the limit of the third factor in the left-hand side is 1. By using Stirling's formula we have that

$$\lim_{n\to\infty}\left(\frac{\Gamma\left(\mu+n+\frac{3}{2}\right)}{\Gamma\left(n+\frac{3}{2}\right)}\right)^{1/(2n+1)} = \lim_{n\to\infty}\left(\frac{\sqrt{2\pi}\left(\mu+n+\frac{3}{2}\right)^{\mu+n+1}e^{-(\mu+n+3/2)}}{\sqrt{2\pi}\left(n+\frac{3}{2}\right)^{n+1}e^{-(n+3/2)}}\right)^{1/(2n+1)}$$

$$= \lim_{n\to\infty}\left(\left(\mu+n+\frac{3}{2}\right)^{\mu/(2n+1)}e^{-\mu/(2n+1)}\left(\frac{\mu+n+\frac{3}{2}}{n+\frac{3}{2}}\right)^{(n+1)/(2n+1)}\right)=1.$$

Q.E.D.

Observe that formula (1.1), which gives us the entropy of the elements of the canonical basis $\{\xi_n\}$ of $\mathcal{B}^2$, can be written as

$$S_{L^2(\mathbb{C},d\nu_{\text{Gauss}})}(\xi_n) = n\psi(n+1) - \log n!. \tag{3.2}$$

In the case $n=0$ we have $\xi_0(z)=1$ and then from (2.15) we have that $S_{L^2(\mathbb{C},d\nu_{\text{Gauss}})}(1)=0$. [Note that this case is also included in (3.2).]

We can use Lemmas 3.1 and 3.2 to prove some properties of the sequence of entropies $\{S_n\}_{n=0}^{\infty}$, where $S_n := S_{L^2(\mathbb{C},d\nu_{\text{Gauss}})}(\xi_n)$. First, we note that

$$S_{n+1} = (n+1)\psi(n+2) - \log(n+1)! = (n+1)\left(\frac{1}{n+1}+\psi(n+1)\right) - \log n! - \log(n+1)$$

$$= S_n + 1 + \psi(n+1) - \log(n+1) > S_n + 1 - \frac{1}{n+1},$$

where we used Lemma (3.1) (c). Thus, for $n=0$ we have that $S_1>0$, and for $n\in\mathbb{N}$ we have $S_{n+1}>S_n$. That is, the sequence $\{S_n\}_{n=0}^{\infty}$ is increasing. Moreover, $\{S_n\}_{n=0}^{\infty}$ is a sequence of nonnegative terms. [This conclusion also comes from the fact that $(\mathbb{C},d\nu_{\text{Gauss}})$ is a probability measure space.]

Next, by using the equality $S_{n+1}-S_n=1+\psi(n+1)-\log(n+1)$ of the previous argument and Lemma 3.1 (c) we have that

$$\lim_{n\to\infty}(S_{n+1}-S_n)=1,$$

which proves that the sequence $\{S_n\}_{n=1}^{\infty}$ is unbounded and, moreover, implies that

$$\lim_{n\to\infty}\frac{S_n}{n}=1.$$

Proof: $\lim_{n\to\infty}(S_{n+1}-S_n)=1 \Rightarrow \lim_{n\to\infty}(1/n)\sum_{k=0}^{n-1}(S_{k+1}-S_k)=1 \Rightarrow$

$$\lim_{n\to\infty}[(S_n-S_0)/n]=1 \Rightarrow \lim_{n\to\infty}(S_n/n)=1.$$

This limit can also be proved directly by noting that

$$\frac{S_n}{n} = \psi(n+1) - \frac{1}{n}\log n! = \psi(n+1) - \log n - \log\frac{(n!)^{1/n}}{n},$$

and thus, by using that $\psi(n+1)-\log n\to 0$ as $n\to\infty$ [Lemma 3.1 (a)] and that $\log[(n!)^{1/n}/n] \to e^{-1}$ as $n\to\infty$, we obtain the desired result $\lim_{n\to\infty}(S_n/n)=1$.

In conclusion, we have proved the following.

Proposition 3.1 The sequence $\{S_n\}_{n=0}^{\infty}$, *where* $S_n = S_{L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})}(\xi_n)$ *is the entropy of the n*th *canonical basis element in* $L^2(\mathbb{C},\mathrm{d}\nu_{\mathrm{Gauss}})$ *is an unbounded increasing sequence of non-negative terms, with the property* $\lim_{n\to\infty}(S_{n+1}-S_n)=1$. *In particular,* S_n *is an extensive quantity.*

IV. ENTROPIES IN $\mathcal{B}_\mu^2$

As noted in Sec. II, for calculating the entropies $S_n^\mu = S_{L^2(\mathbb{C}\times\mathbb{Z}_2,\mathrm{d}\nu_\mu)}(\xi_n^\mu)$ of the elements of the canonical basis $\{\xi_n^\mu\}_{n=0}^{\infty}$ of the μ-deformed Segal-Bargmann space $\mathcal{B}_\mu^2$, we need to consider the cases when n is even [in which case we have that $S_n^\mu = S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(\xi_n)$] and when n is odd [in which case we have that $S_n^\mu = S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(\xi_n)$]. We begin by considering the even case. For $n=0$ we have $\xi_0^\mu(z)=1$ and then $S_0^\mu=0$. So we are interested in calculating S_{2n}^μ for $n\geqslant 1$. Formula (2.15) tells us that

$$S_{2n}^\mu = \int_{\mathbb{C}} |\xi_{2n}(z)|^2 \log|\xi_{2n}(z)|^2 \,\mathrm{d}\nu_{e,\mu}(z) - \|\xi_{2n}\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})} \log\|\xi_{2n}\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}$$
$$= \frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)} \int_{\mathbb{C}} \left|\frac{z^{2n}}{(\gamma_\mu(2n))^{1/2}}\right|^2 \log\left|\frac{z^{2n}}{(\gamma_\mu(2n))^{1/2}}\right|^2 K_{\mu-1/2}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y.$$

Since the log term in the integral of the right-hand side is $\log|z^{2n}|^2 - \log\gamma_\mu(2n)$, we can write S_{2n}^μ as a difference of two integrals, $I_1 - I_2$ say, in which $I_2 = \log\gamma_\mu(2n)\|\xi_{2n}\|^2_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})} = \log\gamma_\mu(2n)$. In I_1 we change (x,y) to polar coordinates (r,θ), and then let $s=r^2$ to obtain

$$S_{2n}^\mu = \frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)} \int_{\mathbb{C}} \left|\frac{z^{2n}}{(\gamma_\mu(2n))^{1/2}}\right|^2 \log|z^{2n}|^2 K_{\mu-1/2}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y - \log\gamma_\mu(2n)$$
$$= \frac{2^{1/2-\mu}2}{\gamma_\mu(2n)\Gamma\left(\mu+\frac{1}{2}\right)} \int_0^\infty r^{4n}(\log r^{4n}) K_{\mu-1/2}(r^2) r^{2\mu+2}\,\mathrm{d}r - \log\gamma_\mu(2n)$$
$$= \frac{2^{1/2-\mu}}{\gamma_\mu(2n)\Gamma\left(\mu+\frac{1}{2}\right)} \int_0^\infty s^{2n}(\log s^{2n}) K_{\mu-1/2}(s) s^{\mu+1/2}\,\mathrm{d}s - \log\gamma_\mu(2n).$$

For calculating the integral $\int_0^\infty (\log s^{2n}) K_{\mu-1/2}(s) s^{\mu+2n+1/2}\,\mathrm{d}s$, we define the function φ in a neighborhood of $\alpha=1$ as

$$\varphi(\alpha) = \int_0^\infty s^{2n\alpha} K_{\mu-1/2}(s) s^{\mu+1/2}\,\mathrm{d}s.$$

Observe that for $\mu > -\frac{1}{2}$, $n\in\mathbb{N}$ and α in a neighborhood of 1, one has that $2n\alpha+\mu+\frac{3}{2} > |\mu-\frac{1}{2}|$, so we can use formula (2.7) to write

$$\varphi(\alpha) = 2^{2n\alpha+\mu-1/2}\Gamma(n\alpha+1)\Gamma\left(\mu+n\alpha+\tfrac{1}{2}\right).$$

The derivative φ' is on the one hand

$$\varphi'(\alpha) = \int_0^\infty s^{2n\alpha}(\log s^{2n}) K_{\mu-1/2}(s) s^{\mu+1/2}\,\mathrm{d}s,$$

and on the other hand,

$$\varphi'(\alpha) = 2^{2n\alpha+\mu-1/2}\Gamma(n\alpha+1)n\Gamma'\left(\mu+n\alpha+\frac{1}{2}\right) + 2^{2n\alpha+\mu-1/2}n\Gamma'(n\alpha+1)\Gamma\left(\mu+n\alpha+\frac{1}{2}\right)$$
$$+ 2^{2n\alpha+\mu-1/2}2n(\log 2)\Gamma(n\alpha+1)\Gamma\left(\mu+n\alpha+\frac{1}{2}\right)$$
$$= 2^{2n\alpha+\mu-1/2}\Gamma(n\alpha+1)\Gamma\left(\mu+n\alpha+\frac{1}{2}\right)\left(n\psi\left(\mu+n\alpha+\frac{1}{2}\right)+n\psi(n\alpha+1)+2n\log 2\right).$$

Then

$$\varphi'(1) = \int_0^\infty s^{2n}(\log s^{2n})K_{\mu-1/2}(s)s^{\mu+1/2}\,\mathrm{d}s = 2^{2n+\mu-1/2}\Gamma(n+1)\Gamma\left(\mu+n+\frac{1}{2}\right)\begin{pmatrix} n\psi\left(\mu+n+\frac{1}{2}\right) \\ +n\psi(n+1) \\ +2n\log 2 \end{pmatrix}.$$

Thus we have that

$$S_{2n}^{\mu} = \frac{\Gamma(n+1)\Gamma\left(\mu+n+\frac{1}{2}\right)2^{2n}}{\gamma_\mu(2n)\Gamma\left(\mu+\frac{1}{2}\right)}\left(n\psi\left(\mu+n+\frac{1}{2}\right)+n\psi(n+1)+\log 2^{2n}\right)-\log\,\gamma_\mu(2n).$$

By using formula (2.1) for $\gamma_\mu(2n)$ we have that the entropy of the even elements ξ_{2n} is

$$S_{2n}^{\mu} = n\left(\psi\left(\mu+n+\frac{1}{2}\right)+\psi(n+1)\right)-\log\frac{\gamma_\mu(2n)}{2^{2n}}. \tag{4.1}$$

Note that this formula makes sense for $n=0$, obtaining the known result $S_0^\mu=0$.
In the case $\mu=0$, formula (4.1) becomes

$$S_{2n}^{0} = n\left(\psi\left(n+\frac{1}{2}\right)+\psi(n+1)\right)-\log\frac{(2n)!}{2^{2n}}$$
$$= n\left(-\gamma-2\log 2+2\sum_{k=1}^{n}\frac{1}{2k-1}-\gamma+\sum_{k=1}^{n}\frac{1}{k}\right)-\log(2n)!+2n\log 2$$
$$= 2n\left(-\gamma+\sum_{k=1}^{n}\frac{1}{2k-1}+\frac{1}{2}\sum_{k=1}^{n}\frac{1}{k}\right)-\log(2n)! = 2n\left(-\gamma+\sum_{k=1}^{2n}\frac{1}{k}\right)-\log(2n)!,$$

which is (1.1) for even positive integers, as expected.

Since $(\mathbb{C},\mathrm{d}\nu_{e,\mu})$ is a probability measure space, we have that $S_{2n}^{\mu}\geqslant 0$ for all $n=0,1,2,\ldots$. But we can arrive at this conclusion directly from the formula obtained for S_{2n}^{μ} as follows. Observe that for $n\in\mathbb{N}$ we can write formula (2.1) as

$$\frac{\gamma_\mu(2n)}{2^{2n}} = n!\prod_{k=1}^{n}\left(\mu+k-\frac{1}{2}\right). \tag{4.2}$$

Then

$$S_{2n}^{\mu} = n\psi\left(\mu+n+\frac{1}{2}\right) + n\psi(n+1) - \log\left(n!\prod_{k=1}^{n}\left(\mu+k-\frac{1}{2}\right)\right)$$

$$= \sum_{k=1}^{n}\left(\psi\left(\mu+n+\frac{1}{2}\right) - \log\left(\mu+k-\frac{1}{2}\right) + \psi(n+1) - \log(k)\right).$$

Lemma 3.1(a) gives us that $\psi\left(\mu+n+\frac{1}{2}\right)-\log\left(\mu+k-\frac{1}{2}\right)>0$ and that $\psi(n+1)-\log(k)>0$ for all $k=1,\ldots,n$. So we conclude that $S_{2n}^{\mu}>0$, as wanted. Moreover, observe that for fixed $n\in\mathbb{N}$, we have that [again by Lemma 3.1(a)] $\psi\left(\mu+n+\frac{1}{2}\right)-\log\left(\mu+k-\frac{1}{2}\right)\to 0$ as $\mu\to+\infty$, and so

$$\lim_{\mu\to+\infty} S_{2n}^{\mu} = \sum_{k=1}^{n}(\psi(n+1)-\log(k)) = n\psi(n+1) - \log n!\ .$$

That is, for $n\in\mathbb{N}$ fixed we have that

$$\lim_{\mu\to+\infty} S_{2n}^{\mu} = S_n.$$

Let us consider the particular case when $\mu=\frac{1}{2}+m$, $m=0,1,2,\ldots$. Formula (4.2) becomes in this case

$$\frac{\gamma_{1/2+m}(2n)}{2^{2n}} = n!\prod_{k=1}^{n}(k+m) = \frac{n!(m+n)!}{m!},$$

and then formula (4.1) gives us

$$S_{2n}^{1/2+m} = n(\psi(n+m+1)+\psi(n+1)) - \log\frac{n!(m+n)!}{m!}$$

$$= (n+m)\psi(n+m+1) - \log(m+n)! + n\psi(n+1) - \log n! - m\psi(n+m+1) + \log m!$$

$$= S_{n+m} + S_n - m\left(\sum_{k=0}^{n-1}\frac{1}{m+k+1} + \psi(m+1)\right) + \log m! = S_{n+m} + S_n - S_m - \sum_{k=1}^{n}\frac{m}{m+k}.$$

That is, for $n,m=0,1,2,\ldots$, we have the formula

$$S_{n+m} + S_n - S_m = S_{2n}^{1/2+m} + \sum_{k=1}^{n}\frac{m}{m+k},$$

which shows that the values of the entropies S_{n+m}, S_n, and S_m (of the undeformed case) are related by means of the entropy $S_{2n}^{1/2+m}$ corresponding to the $\left(m+\frac{1}{2}\right)$-deformed case.

We claim that $\{S_{2n}^{\mu}\}_{n=0}^{\infty}$ is an increasing sequence for fixed $\mu>-\frac{1}{2}$. In fact, we have that

$$S_{2n+2}^{\mu} = (n+1)\psi\left(\mu+n+\frac{3}{2}\right) + (n+1)\psi(n+2) - \log\frac{\gamma_{\mu}(2n+2)}{2^{2n+2}}$$

$$= n\left(\frac{1}{\mu+n+\frac{1}{2}} + \psi\left(\mu+n+\frac{1}{2}\right)\right) + \psi\left(\mu+n+\frac{3}{2}\right) + n\left(\frac{1}{n+1}+\psi(n+1)\right) + \psi(n+2)$$

$$- \log\frac{(2n+2)(2n+1+2\mu)\gamma_{\mu}(2n)}{2^2 2^{2n}}$$

$$= S_{2n}^{\mu} + \psi\left(\mu + n + \frac{3}{2}\right) - \log\left(\mu + n + \frac{1}{2}\right) + \psi(n+2) - \log(n+1) + \frac{n}{\mu + n + \frac{1}{2}} + \frac{n}{n+1}.$$

Lemma 3.1(a) gives us $\psi(\mu+n+\frac{3}{2})-\log(\mu+n+\frac{1}{2})>0$ and $\psi(n+2)-\log(n+1)>0$. Thus we have that $S_{2n+2}^{\mu}-S_{2n}^{\mu}>0$, as wanted. Lemma 3.1(a) also tells us that $\psi(\mu+n+\frac{3}{2})-\log(\mu+n+\frac{1}{2}) \to 0$ and $\psi(n+2)-\log(n+1)\to 0$ as $n\to\infty$. Thus, for fixed $\mu>-\frac{1}{2}$, we have by the expression above that $\lim_{n\to\infty}(S_{2n+2}^{\mu}-S_{2n}^{\mu})=2$. In particular we see that the sequence $\{S_{2n}^{\mu}\}_{n=0}^{\infty}$ is unbounded. This limit implies that $\lim_{n\to\infty}(S_{2n}/2n)=1$, but we can give a direct proof of this last result by noting that

$$\begin{aligned}\frac{S_{2n}^{\mu}}{2n} &= \frac{1}{2}\left(\psi\left(\mu + n + \frac{1}{2}\right) + \psi(n+1)\right) - \frac{1}{2n}\log\frac{\gamma_{\mu}(2n)}{2^{2n}} \\ &= \frac{1}{2}\left(\psi\left(\mu + n + \frac{1}{2}\right) + \psi(n+1)\right) - \log\frac{(\gamma_{\mu}(2n))^{1/2n}}{2n} - \log n \\ &= \frac{1}{2}\left(\psi\left(\mu + n + \frac{1}{2}\right) - \log n + \psi(n+1) - \log n\right) - \log\frac{(\gamma_{\mu}(2n))^{1/2n}}{2n}.\end{aligned}$$

Lemma 3.1(b) tells us that $\psi(\mu+n+\frac{1}{2})-\log n\to 0$ and $\psi(n+1)-\log n\to 0$ as $n\to\infty$. Lemma 3.2 tells us that $\log[(\gamma_{\mu}(2n))^{1/2n}/2n]\to -1$ as $n\to\infty$. Then we have that $\lim_{n\to\infty}(S_{2n}/2n)\to 1$, as wanted.

In conclusion, we have proved the following theorem.

Theorem 4.1: *The entropy of ξ_{2n}^{μ} is given by*

$$S_{2n}^{\mu} = n\left(\psi\left(\mu + n + \frac{1}{2}\right) + \psi(n+1)\right) - \log\frac{\gamma_{\mu}(2n)}{2^{2n}},$$

where $\mu>-\frac{1}{2}$ and $n=0,1,\ldots$. For fixed $\mu>-\frac{1}{2}$, the sequence $\{S_{2n}^{\mu}\}_{n=1}^{\infty}$ is an unbounded increasing sequence of positive terms such that

$$\lim_{n\to\infty}(S_{2n+2}^{\mu} - S_{2n}^{\mu}) = 2,$$

which implies that

$$\lim_{n\to\infty}\frac{S_{2n}^{\mu}}{2n} = 1.$$

For fixed $n\in\mathbb{N}$, we have that

$$\lim_{\mu\to+\infty} S_{2n}^{\mu} = S_n,$$

where $S_n=S_n^0$.

For $n,m=0,1,2,\ldots$, we have that

$$S_{n+m} + S_n - S_m = S_{2n}^{1/2+m} + \sum_{k=0}^{n-1}\frac{m}{m+k+1}.$$

We now calculate the entropies of the odd functions ξ_{2n+1}, $n=0,1,2,\ldots$. The steps we will follow in the calculations are analogues of the even case. Since $S_{2n+1}^{\mu}=S_{L^2(\mathbb{C},d\nu_{o,\mu})}(\xi_{2n+1})$ we have that

$$S^{\mu}_{2n+1} = \frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)}\int_{\mathbb{C}}\left|\frac{z^{2n+1}}{(\gamma_\mu(2n+1))^{1/2}}\right|^2\log\left|\frac{z^{2n+1}}{(\gamma_\mu(2n+1))^{1/2}}\right|^2 K_{\mu+1/2}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y$$

$$= \frac{2^{1/2-\mu}2}{\gamma_\mu(2n+1)\Gamma\left(\mu+\frac{1}{2}\right)}\int_0^\infty r^{4n+2}(\log r^{4n+2})K_{\mu+1/2}(r^2)r^{2\mu+2}\,\mathrm{d}r - \log\,\gamma_\mu(2n+1)$$

$$= \frac{2^{1/2-\mu}}{\gamma_\mu(2n+1)\Gamma\left(\mu+\frac{1}{2}\right)}\int_0^\infty s^{2n+1}(\log s^{2n+1})K_{\mu+1/2}(s)s^{\mu+1/2}\,\mathrm{d}s - \log\,\gamma_\mu(2n+1).$$

We define

$$\phi(\alpha) = \int_0^\infty s^{(2n+1)\alpha}K_{\mu+1/2}(s)s^{\mu+1/2}\,\mathrm{d}s.$$

Since for $\mu > -\frac{1}{2}$, $n \in \mathbb{N}\cup\{0\}$ and α in a neighborhood of 1, one has that $(2n+1)\alpha+\mu+\frac{3}{2} > |\mu+\frac{1}{2}|$, we can use formula (2.7) to write

$$\phi(\alpha) = 2^{(2n+1)\alpha+\mu-1/2}\Gamma\left(\left(n+\tfrac{1}{2}\right)\alpha+\tfrac{1}{2}\right)\Gamma\left(\left(n+\tfrac{1}{2}\right)\alpha+\mu+1\right).$$

By calculating the derivative $\phi'(1)$ in two different ways as we did in the even case, we get

$$\phi'(1) = \int_0^\infty s^{2n+1}\log s^{2n+1}K_{\mu+1/2}(s)s^{\mu+1/2}\,\mathrm{d}s$$

$$= 2^{2n+\mu+1/2}\Gamma(n+1)\Gamma\left(\mu+n+\frac{3}{2}\right)\left(\begin{array}{c}\frac{2n+1}{2}\psi\left(\mu+n+\frac{3}{2}\right)\\ +\frac{2n+1}{2}\psi(n+1)\\ +(2n+1)\log 2\end{array}\right).$$

Thus, by using formula (2.2) for $\gamma_\mu(2n+1)$ we find that the entropy of ξ_{2n+1} is

$$S^{\mu}_{2n+1} = \left(n+\frac{1}{2}\right)\left(\psi\left(\mu+n+\frac{3}{2}\right)+\psi(n+1)\right) - \log\frac{\gamma_\mu(2n+1)}{2^{2n+1}}. \tag{4.3}$$

In the case $\mu=0$ this formula becomes

$$S^{0}_{2n+1} = \left(n+\frac{1}{2}\right)\left(\psi\left(n+\frac{3}{2}\right)+\psi(n+1)\right) - \log\frac{(2n+1)!}{2^{2n+1}}$$

$$= \left(n+\frac{1}{2}\right)\left(\frac{1}{n+\frac{1}{2}}+\psi\left(n+\frac{1}{2}\right)+\psi(n+1)\right) - \log(2n+1)! + (2n+1)\log 2$$

$$= (2n+1)\left(-\gamma+\frac{1}{2n+1}+\sum_{k=1}^{n}\frac{1}{2k-1}+\frac{1}{2}\sum_{k=1}^{n}\frac{1}{k}\right) - \log(2n+1)!$$

$$= (2n+1)\left(-\gamma+\sum_{k=1}^{2n+1}\frac{1}{k}\right) - \log(2n+1)!\,,$$

which is (1.1) for odd positive integers.

Observe that for $n \in N$ we can write formula (2.2) as

$$\frac{\gamma_\mu(2n+1)}{2^{2n+1}} = n! \prod_{k=1}^{n+1} \left(\mu + k - \frac{1}{2} \right).$$

Thus (4.3) can be written as

$$S^\mu_{2n+1} = \sum_{k=1}^{n} \left(\psi\left(\mu + n + \frac{3}{2} \right) - \log\left(\mu + k - \frac{1}{2} \right) \right) + \frac{1}{2}\left(\psi\left(\mu + n + \frac{3}{2} \right) - \log\left(\mu + n + \frac{1}{2} \right) \right)$$
$$+ \left(n + \frac{1}{2} \right) \psi(n+1) - \log n! - \frac{1}{2} \log\left(\mu + n + \frac{1}{2} \right). \tag{4.4}$$

For fixed $n=0,1,2,\ldots$, we have by Lemma 3.1(a) that $\psi\left(\mu+n+\frac{3}{2}\right)-\log\left(\mu+k-\frac{1}{2}\right)\to 0$ and $\psi\left(\mu+n+\frac{3}{2}\right)-\log\left(\mu+n+\frac{1}{2}\right)\to 0$ as $\mu\to+\infty$. Thus, because of the last term of the right-hand side in (4.4), we have that $\lim_{\mu\to+\infty} S^\mu_{2n+1}=-\infty$. That is, negative entropies do occur in the odd case. [Recall that $(\mathbb{C}, \mathrm{d}\nu_{o,\mu})$ *is not* a probability measure space for $\mu \neq 0$.] Nevertheless we will see now that for fixed $\mu > -\frac{1}{2}$ the sequence $\{S^\mu_{2n+1}\}_{n=0}^\infty$ is increasing and unbounded, and so it is eventually positive. We have that

$$S^\mu_{2n+3} = \left(n + \frac{1}{2} \right)\left(\psi\left(\mu + n + \frac{3}{2} \right) + \psi(n+1) \right) - \log \frac{\gamma_\mu(2n+1)}{2^{2n+1}} + \left(n + \frac{3}{2} \right)\left(\frac{1}{\mu + n + \frac{3}{2}} + \frac{1}{n+1} \right)$$
$$+ \psi\left(\mu + n + \frac{3}{2} \right) + \psi(n+1) - \log\left((n+1)\left(\mu + n + \frac{3}{2} \right) \right)$$
$$= S^\mu_{2n+1} + \left(n + \frac{3}{2} \right)\left(\frac{1}{\mu + n + \frac{3}{2}} + \frac{1}{n+1} \right) + \psi\left(\mu + n + \frac{3}{2} \right) - \log\left(\mu + n + \frac{3}{2} \right) + \psi(n+1)$$
$$- \log(n+1) > S^\mu_{2n+1} + \left(n + \frac{3}{2} \right)\left(\frac{1}{\mu + n + \frac{3}{2}} + \frac{1}{n+1} \right) - \frac{1}{\mu + n + \frac{3}{2}} - \frac{1}{n+1}$$
$$= S^\mu_{2n+1} + \left(n + \frac{1}{2} \right)\left(\frac{1}{\mu + n + \frac{3}{2}} + \frac{1}{n+1} \right) > S^\mu_{2n+1},$$

where we used Lemma 3.1(c). This proves that the sequence $\{S^\mu_{2n+1}\}_{n=0}^\infty$ is increasing. Moreover, since

$$S^\mu_{2n+3} - S^\mu_{2n+1} = \left(n + \frac{3}{2} \right)\left(\frac{1}{\mu + n + \frac{3}{2}} + \frac{1}{n+1} \right) + \psi\left(\mu + n + \frac{3}{2} \right) - \log\left(\mu + n + \frac{3}{2} \right) + \psi(n+1)$$
$$- \log(n+1)$$

and by Lemma 3.1(c) we have that $\psi\left(\mu+n+\frac{3}{2}\right)-\log\left(\mu+n+\frac{3}{2}\right)\to 0$ and also that $\psi(n+1)-\log(n+1)\to 0$ as $n\to\infty$, then we conclude that $\lim_{n\to\infty}(S^\mu_{2n+3}-S^\mu_{2n+1})=2$, which implies the unboundedness of the sequence $\{S^\mu_{2n+1}\}_{n=0}^\infty$. This limit implies that $\lim_{n\to\infty}[S^\mu_{2n+1}/(2n+1)]=1$, but a direct proof of this is as follows. Note that

$$\frac{S^{\mu}_{2n+1}}{2n+1} = \frac{1}{2}\left(\psi\left(\mu+n+\frac{3}{2}\right)+\psi(n+1)\right) - \log\frac{(\gamma_{\mu}(2n+1))^{1/(2n+1)}}{2n+1} - \log\left(n+\frac{1}{2}\right)$$
$$= \frac{1}{2}\left(\psi\left(\mu+n+\frac{3}{2}\right) - \log\left(n+\frac{1}{2}\right) + \psi(n+1) - \log\left(n+\frac{1}{2}\right)\right) - \log\frac{(\gamma_{\mu}(2n+1))^{1/(2n+1)}}{2n+1}.$$

Note that Lemmas 3.1(b) and 3.2 give us that $\psi\left(\mu+n+\frac{3}{2}\right)-\log\left(n+\frac{1}{2}\right)\to 0$, $\psi(n+1)-\log\left(n+\frac{1}{2}\right)\to 0$ and $\log[(\gamma_{\mu}(2n+1))^{1/(2n+1)}/(2n+1)]\to -1$ as $n\to\infty$. Then we have that $[S^{\mu}_{2n+1}/(2n+1)]\to 1$ as $n\to\infty$.

Thus, we have proved the following theorem.

Theorem 4.2: *The entropy of ξ^{μ}_{2n+1} is given by*

$$S^{\mu}_{2n+1} = \left(n+\frac{1}{2}\right)\left(\psi\left(\mu+n+\frac{3}{2}\right)+\psi(n+1)\right) - \log\frac{\gamma_{\mu}(2n+1)}{2^{2n+1}},$$

where $\mu>-\frac{1}{2}$ and $n=0,1,2,\ldots$. For fixed $\mu>-\frac{1}{2}$, the sequence $\{S^{\mu}_{2n+1}\}_{n=0}^{\infty}$ is an unbounded increasing sequence such that

$$\lim_{n\to\infty}(S^{\mu}_{2n+3} - S^{\mu}_{2n+1}) = 2,$$

which implies that

$$\lim_{n\to\infty}\frac{S^{\mu}_{2n+1}}{2n+1} = 1.$$

For fixed $n=0,1,2,\ldots$, we have that

$$\lim_{\mu\to+\infty} S^{\mu}_{2n+1} = -\infty.$$

We can relate the entropies S^{μ}_{2n+1} with the entropies S^{μ}_{2n} as follows. We note that

$$S^{\mu}_{2n+1} = \frac{2n+1}{2}\left(\psi\left(\mu+n+\frac{3}{2}\right)+\psi(n+1)\right) - \log\frac{\gamma_{\mu}(2n+1)}{2^{2n+1}}$$
$$= \left(n+\frac{1}{2}\right)\left(\frac{1}{\mu+n+\frac{1}{2}} + \psi\left(\mu+n+\frac{1}{2}\right)+\psi(n+1)\right) - \log\frac{\gamma_{\mu}(2n+1)}{2^{2n+1}}$$
$$= \left(1+\frac{1}{2n}\right)\left(S^{\mu}_{2n} + \log\frac{\gamma_{\mu}(2n)}{2^{2n}}\right) + \frac{n+\frac{1}{2}}{\mu+n+\frac{1}{2}} - \log\frac{\gamma_{\mu}(2n+1)}{2^{2n+1}}$$
$$= \left(1+\frac{1}{2n}\right)S^{\mu}_{2n} + \frac{n+\frac{1}{2}}{\mu+n+\frac{1}{2}} + \log\frac{(\gamma_{\mu}(2n))^{1/2n}}{2\left(\mu+n+\frac{1}{2}\right)}.$$

So we have that

$$S^{\mu}_{2n+1} - S^{\mu}_{2n} = \frac{S^{\mu}_{2n}}{2n} + \frac{n+\frac{1}{2}}{\mu+n+\frac{1}{2}} + \log\frac{(\gamma_{\mu}(2n))^{1/2n}}{2\left(\mu+n+\frac{1}{2}\right)}.$$

By using Lemma 3.2 and Theorem 4.1 we obtain

$$\lim_{n\to\infty}(S^{\mu}_{2n+1}-S^{\mu}_{2n})=1.$$

Similarly one has that

$$S^{\mu}_{2n}-S^{\mu}_{2n-1}=\frac{S^{\mu}_{2n-1}}{2n-1}+1+\log\frac{\gamma_{\mu}(2n-1)^{1/(2n-1)}}{2n}.$$

Lemma 3.2 and Theorem 4.2 allow us to conclude

$$\lim_{n\to\infty}(S^{\mu}_{2n}-S^{\mu}_{2n-1})=1.$$

Finally, observe that we can express the formulas (4.1) and (4.3) in terms of the characteristic function θ of the odd positive integers as

$$S^{\mu}_{n}=\frac{n}{2}\left(\psi\left(\mu+\frac{n+\theta(n)+1}{2}\right)+\psi\left(\frac{n+\theta(n+1)+1}{2}\right)\right)-\log\frac{\gamma_{\mu}(n)}{2^{n}}.$$

From this formula one can obtain at once the case $\mu=0$ [formula (1.1)] by using the identity

$$\psi\left(\frac{n+1}{2}\right)+\psi\left(\frac{n+2}{2}\right)=2\psi(n+1)-2\log 2,$$

whose proof is an easy exercise by induction.

Combining Theorems 4.1 and 4.2 with the previous results, we have the following.

Theorem 4.3: *Let $\mu>-\frac{1}{2}$ be fixed. The entropy S^{μ}_{n} is given by*

$$S^{\mu}_{n}=\frac{n}{2}\left(\psi\left(\mu+\frac{n+\theta(n)+1}{2}\right)+\psi\left(\frac{n+\theta(n+1)+1}{2}\right)\right)-\log\frac{\gamma_{\mu}(n)}{2^{n}}.$$

The sequence $\{S^{\mu}_{n}\}_{n=0}^{\infty}$ of entropies is such that the subsequences of even terms $\{S^{\mu}_{2n}\}_{n=1}^{\infty}$ and of odd terms $\{S^{\mu}_{2n+1}\}_{n=0}^{\infty}$ are increasing, the former being positive and the latter being eventually positive. Moreover, we have that

$$\lim_{n\to\infty}(S^{\mu}_{n+1}-S^{\mu}_{n})=1,$$

which shows that the sequence $\{S^{\mu}_{n}\}_{n=0}^{\infty}$ is unbounded and implies that

$$\lim_{n\to\infty}\frac{S^{\mu}_{n}}{n}=1.$$

So we have that S^{μ}_{n} is an extensive quantity in n. Note that this assertion is independent of μ.

V. ENTROPIES IN $L^2(\mathbb{R},\mathrm{d}g_{\mu})$

Following the same sort of ideas we used in the preceding section, we will calculate in this section the entropies of the monomials $t^n\in L^2(\mathbb{R},\mathrm{d}g_{\mu})$, $n=1,2,\ldots$. [In the case $n=0$ we obtain from the definition that $S_{L^2(\mathbb{R},\mathrm{d}g_{\mu})}(1)=0$.] That is, for $n=1,2,\ldots$ we will calculate explicitly

$$S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t^n) = \frac{1}{\Gamma\left(\mu+\frac{1}{2}\right)}\int_{\mathbb{R}} |t^n|^2 \log|t^n|^2 \exp(-t^2)|t|^{2\mu}\,\mathrm{d}t - \|t^n\|^2_{L^2(\mathbb{R},\mathrm{d}g_\mu)} \log\|t^n\|^2_{L^2(\mathbb{R},\mathrm{d}g_\mu)}$$

$$= \frac{1}{\Gamma\left(\mu+\frac{1}{2}\right)}\int_0^\infty u^n(\log u^n)\exp(-u)u^{\mu-1/2}\,\mathrm{d}u - \|t^n\|^2_{L^2(\mathbb{R},\mathrm{d}g_\mu)} \log\|t^n\|^2_{L^2(\mathbb{R},\mathrm{d}g_\mu)}.$$

A direct calculation gives us

$$\|t^n\|^2_{L^2(\mathbb{R},\mathrm{d}g_\mu)} = \frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}.$$

Next, define the function

$$\eta(\alpha) = \int_0^\infty u^{n\alpha}\exp(-u)u^{\mu-1/2}\,\mathrm{d}s = \Gamma\left(n\alpha+\mu+\frac{1}{2}\right)$$

in a neighborhood of $\alpha=1$. By calculating the derivative $\eta'(1)$ in two different ways (using the technique from the preceding section) we find that

$$\int_0^\infty u^n(\log u^n)\exp(-u)u^{\mu-1/2}\,\mathrm{d}u = n\psi\left(n+\mu+\frac{1}{2}\right)\Gamma\left(n+\mu+\frac{1}{2}\right).$$

Then the entropy $S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t^n)$ is

$$S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t^n) = \frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\left(n\psi\left(n+\mu+\frac{1}{2}\right) - \log\frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\right). \tag{5.1}$$

When $n=1$ formula (5.1) becomes

$$S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t) = \frac{\Gamma\left(\mu+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\left(\psi\left(\mu+\frac{3}{2}\right) - \log\frac{\Gamma\left(\mu+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\right) = \left(\mu+\frac{1}{2}\right)\left(\psi\left(\mu+\frac{3}{2}\right) - \log\left(\mu+\frac{1}{2}\right)\right).$$

By using that $S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t)$ is homogeneous of degree 2 we can calculate the entropy of the monomial $\zeta_1^\mu(t)=(2/(1+2\mu))^{1/2}t$, which is the second element of the canonical basis $\{\zeta_n^\mu\}_{n=0}^\infty$ of $L^2(\mathbb{R},\mathrm{d}g_\mu)$. In fact, we have that $S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(\zeta_1^\mu)=[2/(1+2\mu)]S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t)$, and then

$$S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(\zeta_1^\mu) = \psi\left(\mu+\tfrac{3}{2}\right) - \log\left(\mu+\tfrac{1}{2}\right). \tag{5.2}$$

When $\mu=0$ this formula becomes

$$S_{L^2(\mathbb{R},\mathrm{d}g)}(\zeta_1^0) = \psi\left(\frac{3}{2}\right) - \log\left(\frac{1}{2}\right) = 2 - \log 2 - \gamma,$$

using $\psi\left(\frac{3}{2}\right)=2-2\log 2-\gamma$, which is (1.2) as expected.

Unfortunately we cannot continue the previous procedure in order to obtain explicit formulas for the entropies of $\zeta_n^\mu \in L^2(\mathbb{R},\mathrm{d}g_\mu)$ with $n\geqslant 2$, since for those values of n the polynomials ζ_n^μ are

no longer monomials, and then (5.1) is not useful. Nevertheless we will study some properties of the sequence $\{s_n^\mu\}_{n=0}^\infty$, where $s_n^\mu := S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(t^n)$, and compare them with the results obtained in Sec. IV.

Before that, recall that the μ-deformed Segal-Bargmann transform $B_\mu: L^2(\mathbb{R},\mathrm{d}g_\mu) \to \mathcal{B}_\mu^2$ is such that $B_\mu(\zeta_n^\mu) = \xi_n^\mu$, $n=0,1,\ldots$. When $n=0$ we have $\zeta_0^\mu(t)=1$, $\xi_0^\mu(z)=1$, and $S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(1) = S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(1)=0$. So in this case we see that B_μ preserves entropy. Let us consider the case $n=1$. Formula (4.3) gives us

$$S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(B_\mu(\zeta_1^\mu)) = \tfrac{1}{2}\left(\psi\left(\mu+\tfrac{3}{2}\right)+\psi(1)\right) - \log\left(\mu+\tfrac{1}{2}\right).$$

This formula, $\psi(1)=-\gamma$, and (5.2) give us that

$$S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(B_\mu(\zeta_1^\mu)) - S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(\zeta_1^\mu) = -\tfrac{1}{2}\left(\psi\left(\mu+\tfrac{3}{2}\right)+\gamma\right). \tag{5.3}$$

Observe that $\lim_{\mu\to-\frac{1}{2}+}\left(\psi\left(\mu+\frac{3}{2}\right)+\gamma\right) = \psi(1)+\gamma = 0$, and that $\mu \mapsto \psi\left(\mu+\frac{3}{2}\right)+\gamma$ is an increasing function since we have that $\psi'(x)>0$ for $x>0$ (see Ref. 20, p. 14). Then $\psi\left(\mu+\frac{3}{2}\right)+\gamma>0$ for $\mu>-\frac{1}{2}$, and thus formula (5.3) tells us that $S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(B_\mu(\zeta_1^\mu)) < S_{L^2(\mathbb{R},\mathrm{d}g_\mu)}(\zeta_1^\mu)$. That is, the μ-deformed Segal-Bargmann transform B_μ decreases the entropy of ζ_1^μ. We have already noted that B_μ preserves the entropy of ζ_0^μ. It seems reasonable to conjecture that B_μ increases the entropy of other functions in $L^2(\mathbb{R},\mathrm{d}g_\mu)$. (This is known to be true in the case $\mu=0$. See Ref. 33.)

As happens in the case of the sequence of entropies $\{S_n^\mu\}_{n=0}^\infty$ in the preceding section, the sequence of entropies $\{s_n^\mu\}_{n=0}^\infty$ is unbounded as we will prove now. By using the asymptotics

$$\psi(z) = \log z + O(z^{-1}), \tag{5.4}$$

valid for $|\arg z|<\pi$ and $z\to\infty$ (see Ref. 20, p. 18), and Stirling's formula

$$\log\Gamma(z) = \left(z-\tfrac{1}{2}\right)\log z - z + O(1), \tag{5.5}$$

also valid for $|\arg z|<\pi$ and $z\to\infty$ (see Ref. 20, p. 12), we see that for large n the term in parentheses on the right-hand side of (5.1) behaves like

$$\begin{aligned} &n\left(\log\left(n+\mu+\tfrac{1}{2}\right)+O(n^{-1})\right) - (n+\mu)\log\left(n+\mu+\tfrac{1}{2}\right) + \left(n+\mu+\tfrac{1}{2}\right) + O(1) \\ &\quad = n - \mu\log\left(n+\mu+\tfrac{1}{2}\right) + O(1), \end{aligned}$$

which is unbounded. In turn this implies that the sequence of entropies $\{s_n^\mu\}_{n=0}^\infty$ is unbounded, as wanted.

Now let us see that the sequence $\{s_n^\mu\}_{n=0}^\infty$ is increasing (as the sequence $\{S_n^\mu\}_{n=0}^\infty$ is). First note that Lemma (3.1) (a) gives us

$$s_1^\mu = \left(\mu+\tfrac{1}{2}\right)\left(\psi\left(\mu+\tfrac{3}{2}\right) - \log\left(\mu+\tfrac{1}{2}\right)\right) > 0 = s_0^\mu,$$

so let us prove that $s_{n+1}^\mu > s_n^\mu$ for $n \geqslant 1$. Observe that

$$\frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)} = \prod_{k=1}^{n}\left(k+\mu-\frac{1}{2}\right).$$

So we can write (5.1) as

$$s_n^\mu = \frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\left(n\psi\left(n+\mu+\frac{1}{2}\right) - \log\prod_{k=1}^{n}\left(k+\mu-\frac{1}{2}\right)\right)$$

$$= \frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\sum_{k=1}^{n}\left(\psi\left(n+\mu+\frac{1}{2}\right) - \log\left(k+\mu-\frac{1}{2}\right)\right).$$

Then, by using Lemma (3.1) (a) we get

$$s_{n+1}^\mu = \frac{\Gamma\left(n+\mu+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\sum_{k=1}^{n+1}\left(\psi\left(n+\mu+\frac{3}{2}\right) - \log\left(k+\mu-\frac{1}{2}\right)\right)$$

$$= \frac{\Gamma\left(n+\mu+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\sum_{k=1}^{n}\left(\frac{1}{n+\mu+\frac{1}{2}} + \psi\left(n+\mu+\frac{1}{2}\right) - \log\left(k+\mu-\frac{1}{2}\right)\right)$$

$$+ \frac{\Gamma\left(n+\mu+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\left(\psi\left(n+\mu+\frac{3}{2}\right) - \log\left(n+\mu+\frac{1}{2}\right)\right)$$

$$= \frac{n\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)} + \left(n+\mu+\frac{1}{2}\right)s_n^\mu + \frac{\Gamma\left(n+\mu+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\left(\psi\left(n+\mu+\frac{3}{2}\right) - \log\left(n+\mu+\frac{1}{2}\right)\right) > s_n^\mu,$$

which proves that $\{s_n^\mu\}_{n=0}^\infty$ is increasing, as wanted. In particular we have that the sequence $\{s_n^\mu\}_{n=1}^\infty$ is positive. [Recall that since $L^2(\mathbb{R}, \mathrm{d}g_\mu)$ is a probability measure space, we have that $s_n^\mu \geqslant 0$ for all $n=0,1,\ldots$.]

Finally, observe that from formulas (2.1), (3.2), and (4.1) we see that (5.1) can be written as

$$s_n^\mu = \frac{\Gamma\left(n+\mu+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}(S_{2n}^\mu - S_n).$$

We know that $\lim_{n\to\infty}(S_{2n}^\mu/2n)=1$ (Theorem 4.1) and $\lim_{n\to\infty}(S_n/n)=1$ (Proposition 3.1). Then we have that

$$\lim_{n\to+\infty}\frac{s_n^\mu}{n\Gamma\left(n+\mu+\frac{1}{2}\right)} = \left(\Gamma\left(\mu+\frac{1}{2}\right)\right)^{-1}.$$

So the sequence $\{s_n^\mu\}_{n=0}^\infty$ diverges to infinity much faster than the sequence $\{S_n^\mu\}_{n=0}^\infty$ does. In particular, s_n^μ is not asymptotic to n, namely it is not extensive in n. Using the log-Sobolev

inequalities proved in Ref. 24, one can show that the entropies of the basis elements ζ_n^μ are comparable, modulo terms linear in n, with the entropies S_n^μ studied in the preceding section. This implies that the entropies of the ζ_n^μ are extensive quantities in n.

VI. μ-DEFORMED ENERGIES

In this section we study two entropy-energy inequalities, known as *reverse log-Sobolev inequalities* (in the μ-deformed Segal-Bargmann space $\mathcal{B}_\mu^2$) that are proved in Ref. 2. We first quote the appropriate definition of energy from Ref. 2 and then calculate it for the functions in the canonical basis of $\mathcal{B}_\mu^2$. Since we already have calculated the entropies for these functions, we can then proceed to the analysis of the two reverse log-Sobolev inequalities.

Definition 6.1: For $f \in \mathcal{B}_{e,\mu}^2$ we define its μ-deformed energy $E_{e,\mu}(f)$ as

$$E_{e,\mu}(f) = \int_{\mathbb{C}} |f(z)|^2 |z|^2 \, \mathrm{d}\nu_{e,\mu}(z).$$

For $f \in \mathcal{B}_{o,\mu}^2$ we define its μ-deformed energy $E_{o,\mu}(f)$ as

$$E_{o,\mu}(f) = \int_{\mathbb{C}} |f(z)|^2 |z|^2 \, \mathrm{d}\nu_{o,\mu}(z).$$

In general, for $f \in \mathcal{B}_\mu^2$ we define its μ-deformed energy $E_\mu(f)$ as $E_\mu(f) = E_{e,\mu}(f_e) + E_{o,\mu}(f_o)$.

We will denote by E_n^μ to the μ-deformed energy $E_\mu(\xi_n^\mu)$, so we have $E_{2n}^\mu = E_{e,\mu}(\xi_{2n}^\mu)$ and $E_{2n+1}^\mu = E_{o,\mu}(\xi_{2n+1}^\mu)$. We have that

$$E_{2n}^\mu = \frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)} \int_{\mathbb{C}} \left| \frac{z^{2n}}{(\gamma_\mu(2n))^{1/2}} \right|^2 |z|^2 K_{\mu-1/2}(|z|^2) |z|^{2\mu+1} \, \mathrm{d}x \, \mathrm{d}y$$

$$= \frac{2^{1/2-\mu} 2}{\Gamma\left(\mu+\frac{1}{2}\right)\gamma_\mu(2n)} \int_0^\infty K_{\mu-1/2}(r^2) r^{2(2n+\mu+2)} \, \mathrm{d}r = \frac{2^{1/2-\mu}}{\Gamma\left(\mu+\frac{1}{2}\right)\gamma_\mu(2n)} \int_0^\infty K_{\mu-1/2}(s) s^{2n+\mu+3/2} \, \mathrm{d}s.$$

Since $2n+\mu+\frac{5}{2} > |\mu-\frac{1}{2}|$ we can use formula (2.7) to write

$$E_{2n}^\mu = \frac{2^{1/2-\mu}}{\Gamma\left(\mu+\frac{1}{2}\right)\gamma_\mu(2n)} 2^{2n+\mu+1/2} \Gamma\left(n+\frac{3}{2}\right)\Gamma(n+\mu+1),$$

which simplifies [by using (2.1)] to

$$E_{2n}^\mu = \frac{2\Gamma\left(n+\frac{3}{2}\right)\Gamma(n+\mu+1)}{\Gamma(n+1)\Gamma\left(n+\mu+\frac{1}{2}\right)}. \tag{6.1}$$

Similarly we have that

$$E_{2n+1}^{\mu} = \frac{2^{1/2-\mu}}{\pi\Gamma\left(\mu+\frac{1}{2}\right)}\int_{\mathbb{C}}\left|\frac{z^{2n+1}}{(\gamma_\mu(2n+1))^{1/2}}\right|^2 |z|^2 K_{\mu+1/2}(|z|^2)|z|^{2\mu+1}\,\mathrm{d}x\,\mathrm{d}y$$

$$= \frac{2^{1/2-\mu}2}{\Gamma\left(\mu+\frac{1}{2}\right)\gamma_\mu(2n+1)}\int_0^\infty K_{\mu+1/2}(r^2)r^{2(2n+\mu+3)}\,\mathrm{d}r$$

$$= \frac{2^{1/2-\mu}}{\Gamma\left(\mu+\frac{1}{2}\right)\gamma_\mu(2n+1)}\int_0^\infty K_{\mu+1/2}(s)s^{2n+\mu+5/2}\,\mathrm{d}s.$$

Since $2n+\mu+\frac{7}{2} > |\mu+\frac{1}{2}|$ we can use formula (2.7) to write

$$E_{2n+1}^{\mu} = \frac{2^{1/2-\mu}}{\Gamma\left(\mu+\frac{1}{2}\right)\gamma_\mu(2n+1)}2^{2n+\mu+3/2}\Gamma\left(n+\frac{3}{2}\right)\Gamma(n+\mu+2),$$

which simplifies [by using (2.2)] to

$$E_{2n+1}^{\mu} = \frac{2\Gamma\left(n+\frac{3}{2}\right)\Gamma(n+\mu+2)}{\Gamma(n+1)\Gamma\left(n+\mu+\frac{3}{2}\right)}. \tag{6.2}$$

When $\mu=0$ formulas (6.1) and (6.2) become

$$E_{2n}^{0} = 2n+1 \quad \text{and } E_{2n+1}^{0} = 2n+2,$$

which agrees with the known result that the (undeformed) energy E_n of the function ξ_n is $n+1$ (see Ref. 33).

In Ref. 2 the following two reverse log-Sobolev inequalities are proved in the context of μ-deformed Segal-Bargmann analysis (Theorems 5.1 and 5.2).

Theorem 6.1: *For all $c>1$ there exists a real number $P_e(c,\mu)$ such that for $f \in \mathcal{B}_{e,\mu}^2$ we have*

$$E_{e,\mu}(f) \leqslant cS_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(f) + P_e(c,\mu)\|f\|_{\mathcal{B}_{e,\mu}^2}.$$

Theorem 6.2: *For all $c>1$ there exists a real number $P_o(c,\mu)$ such that for $f \in \mathcal{B}_{o,\mu}^2$ we have*

$$E_{o,\mu}(f) \leqslant cS_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(f) + P_o(c,\mu)\|f\|_{\mathcal{B}_{o,\mu}^2}.$$

A direct consequence of these results is the following reverse log-Sobolev inequality in the μ-deformed Segal-Bargmann space $\mathcal{B}_\mu^2$ (Theorem 5.3 in Ref. 2).

Theorem 6.3: *For all $c>1$ there exists a real number $P(c,\mu)$ such that for $f \in \mathcal{B}_\mu^2$ we have*

$$E_\mu(f) \leqslant c(S_{L^2(\mathbb{C},\mathrm{d}\nu_{e,\mu})}(f_e) + S_{L^2(\mathbb{C},\mathrm{d}\nu_{o,\mu})}(f_o)) + P(c,\mu)\|f\|_{\mathcal{B}_\mu^2}.$$

In particular, if we consider the elements ξ_n^μ, $n=0,1,\ldots$ of the canonical basis of $\mathcal{B}_\mu^2$, Theorem 6.1 tells us that for all $c>1$ there exists a constant $P_e(c,\mu)$ such that for all $n=0,1,\ldots$ we have that

$$E_{2n}^{\mu} \leqslant cS_{2n}^{\mu} + P_e(c,\mu), \tag{6.3}$$

and Theorem 6.2 tells us that for all $c>1$ there exists a constant $P_o(c,\mu)$ such that for all $n=0,1,\ldots$. we have that

$$E_{2n+1}^{\mu} \leqslant cS_{2n+1}^{\mu} + P_o(c,\mu). \tag{6.4}$$

Remark: By using Stirling's formula it is easy to see from (6.1) and (6.2) that for fixed $n=0,1,\ldots$, we have that $E_n^{\mu} \to +\infty$ as $\mu \to +\infty$. We already know that $S_{2n+1}^{\mu} \to -\infty$ as $\mu \to +\infty$ (see Theorem 4.2). Then (6.4) tells us that for any $c>1$ and any $n=0,1,\ldots$ we have that $P_o(c,\mu) \geqslant E_{2n+1}^{\mu} - cS_{2n+1}^{\mu} \to +\infty$ as $\mu \to +\infty$. That is, the values of the constant $P_o(c,\mu)$ in Theorem 6.2 will be as large as we want, by taking $\mu>0$ large enough.

So Theorem 6.1 tells us that $c>1$ is a sufficient condition to conclude the existence of the constant $P_e(c,\mu)$ such that the inequality (6.3) holds for all $n=0,1,\ldots$. We will prove now that this condition is also necessary, by showing that for fixed $\mu > -\frac{1}{2}$, the sequence $\{E_{2n}^{\mu} - cS_{2n}^{\mu}\}_{n=0}^{\infty}$ is bounded above if and only if $c>1$.

By using the formula

$$\frac{\Gamma(z+\alpha)}{\Gamma(z+\beta)} = z^{\alpha-\beta}(1+O(z^{-1})), \tag{6.5}$$

valid for $|\arg z| < \pi$ and $z \to \infty$ (see Ref. 20, p. 12) we can write the following asymptotics for E_{2n}^{μ}:

$$E_{2n}^{\mu} = 2\frac{\Gamma\left(n+\frac{3}{2}\right)}{\Gamma(n+1)}\frac{\Gamma(n+\mu+1)}{\Gamma\left(n+\mu+\frac{1}{2}\right)} = 2n^{1/2}(1+O(n^{-1}))n^{1/2}(1+O(n^{-1})) = 2n+O(1).$$

Also, by using (2.1), (5.4), and (5.5) and formula (4.1) for S_{2n}^{μ}, we can write

$$\begin{aligned} S_{2n}^{\mu} &= n\left(\psi\left(\mu+n+\frac{1}{2}\right)+\psi(n+1)\right) - \log\frac{\Gamma(n+1)\Gamma\left(\mu+n+\frac{1}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)} \\ &= n\left(\log\left(\mu+n+\frac{1}{2}\right)+\log(n+1)+O(n^{-1})\right) \\ &\quad -\left(n+\frac{1}{2}\right)\log(n+1)+n+1-(\mu+n)\log\left(\mu+n+\frac{1}{2}\right)+\mu+n+\frac{1}{2}+O(1) \\ &= -\frac{1}{2}\log(n+1)-\mu\log\left(\mu+n+\frac{1}{2}\right)+2n+O(1). \end{aligned}$$

Then we have that

$$\begin{aligned} E_{2n}^{\mu} - cS_{2n}^{\mu} &= 2n+O(1)-c\left(-\tfrac{1}{2}\log(n+1)-\mu\log\left(\mu+n+\tfrac{1}{2}\right)+2n+O(1)\right) \\ &= (1-c)2n+\frac{c}{2}\log(n+1)+c\mu\log\left(\mu+n+\frac{1}{2}\right)+O(1) \\ &= (1-c)2n+\frac{c}{2}\log\frac{n+1}{\mu+n+\frac{1}{2}}+c\left(\mu+\frac{1}{2}\right)\log\left(\mu+n+\frac{1}{2}\right)+O(1) \\ &= (1-c)2n+c\left(\mu+\frac{1}{2}\right)\log\left(\mu+n+\frac{1}{2}\right)+O(1). \end{aligned}$$

Clearly, the sequence $\{E_{2n}^{\mu} - cS_{2n}^{\mu}\}_{n=0}^{\infty}$ is bounded above if and only if $c>1$. This shows that the condition $c>1$ is the best possible in the reverse log-Sobolev inequality in Theorem 6.1, namely that this inequality does not hold for $c \leqslant 1$.

Now let us consider Theorem 6.2. We know that $c>1$ is a sufficient condition to conclude the existence of the constant $P_o(c,\mu)$ such that the inequality (6.4) holds for all $n=0,1,\ldots$. We will see now that this condition is also necessary, by showing that for fixed $\mu>-\frac{1}{2}$, the sequence $\{E^{\mu}_{2n+1}-cS^{\mu}_{2n+1}\}_{n=0}^{\infty}$ is bounded above if and only if $c>1$.

By using (6.5) we can write the following asymptotics for E^{μ}_{2n+1}:

$$E^{\mu}_{2n+1}=\frac{2\Gamma\left(n+\frac{3}{2}\right)\Gamma(n+\mu+2)}{\Gamma(n+1)\Gamma\left(n+\mu+\frac{3}{2}\right)}=2n^{1/2}(1+O(n^{-1}))n^{1/2}(1+O(n^{-1}))=2n+O(1).$$

By using (2.2), (5.4), and (5.5) and formula (4.3) for S^{μ}_{2n+1}, we can write

$$\begin{aligned}S^{\mu}_{2n+1}&=\left(n+\frac{1}{2}\right)\left(\psi\left(\mu+n+\frac{3}{2}\right)+\psi(n+1)\right)-\log\frac{\Gamma(n+1)\Gamma\left(\mu+n+\frac{3}{2}\right)}{\Gamma\left(\mu+\frac{1}{2}\right)}\\&=\left(n+\frac{1}{2}\right)\left(\log\left(\mu+n+\frac{3}{2}\right)+\log(n+1)+O(n^{-1})\right)\\&\quad-\left(n+\frac{1}{2}\right)\log(n+1)+n+1-(\mu+n+1)\log\left(\mu+n+\frac{3}{2}\right)+\mu+n+\frac{3}{2}+O(1)\\&=-\left(\mu+\frac{1}{2}\right)\log\left(\mu+n+\frac{3}{2}\right)+2n+O(1).\end{aligned}$$

Then we have that

$$\begin{aligned}E^{\mu}_{2n+1}-cS^{\mu}_{2n+1}&=2n+O(1)-c\left(-\left(\mu+\frac{1}{2}\right)\log\left(\mu+n+\frac{3}{2}\right)+2n+O(1)\right)\\&=(1-c)2n+c\left(\mu+\frac{1}{2}\right)\log\left(\mu+n+\frac{3}{2}\right)+O(1).\end{aligned}$$

As in the case of Theorem 6.1 considered above, we see now that the sequence $\{E^{\mu}_{2n+1}-cS^{\mu}_{2n+1}\}_{n=0}^{\infty}$ is bounded above if and only if $c>1$, which shows that the condition $c>1$ is the best possible in the reverse log-Sobolev inequality in Theorem 6.2.

Either one of the two cases considered in this section shows that the condition $c>1$ in Theorem 6.3 is also the best possible. Note that the asymptotics that we have proved for E^{μ}_{n} show that it is extensive in n.

VII. FINAL REMARKS

In conclusion, we have just a few comments.

First, it would be interesting to evaluate in closed form the entropies of the elements ζ^{μ}_{n} for $n\geqslant 2$ of the canonical basis of $L^2(\mathbb{R},\mathrm{d}g_{\mu})$. This has not even been done yet in the case $\mu=0$.

Second, we would like to repeat the conjecture that the μ-deformed Segal-Bargmann transform increases the entropy of some functions. And again, this is plausible since it is known to be true when $\mu=0$. (See Ref. 33.)

(Received 18 February 2005; accepted 26 January 2006; published online 17 March 2006)

In this paper we perform an exact study of "quantum fidelity" (also called Loschmidt echo) for the time-periodic quantum harmonic oscillator of the following Hamiltonian: $\hat{H}_g(t) := (P^2/2) + f(t)(Q^2/2) + (g^2/Q^2)$, when compared with the quantum evolution induced by $\hat{H}_0(t)$ $(g=0)$, in the case where f is a T-periodic function and g a real constant. The reference (initial) state is taken to be an arbitrary "generalized coherent state" in the sense of Perelomov. We show that, starting with a quadratic decrease in time in the neighborhood of $t=0$, this quantum fidelity may recur to its initial value 1 at an infinite sequence of times t_k. We discuss the result when the classical motion induced by Hamiltonian $\hat{H}_0(t)$ is assumed to be stable versus unstable. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2178153]

I. INTRODUCTION

A growing interest has been devoted recently on the study of the so-called "quantum fidelity"

$$F_g(t) := \langle U_0(t,0)\psi, U_g(t,0)\psi \rangle \tag{1}$$

for some reference state ψ that we take as initial wave packet, $U_0(t,0)$ being the quantum unitary evolution operator induced by some Hamiltonian, and $U_g(t,0)$ the quantum evolution for a perturbation of it, g being the size of the perturbation. The long-time behavior of $F_g(t)$ is of particular interest, and it has been studied for a large class of (time independent) Hamiltonians in a more or less heuristic way, and this long-time behavior has been suggested to depend sensitively on the regular versus chaotic motion of the underlying classical motion (see the reference section).

The first occurrence of this notion in the literature is due to Peres.[22] Recently a large amount of work has been presented on this topic (see Refs. 1–6, 9–19, and 23–44). In most of these works, it is claimed that the quantum fidelity decays very fast to zero as time grows, when the underlying classical (unperturbed) dynamics is generically chaotic.

Although the short time decay of the fidelity is rather well understood,[42] some of the arguments put forward in the above cited works are not entirely convincing, since they are either purely numerical, or extrapolate the "short time" behavior to guess the (Gaussian or exponential) decay at infinity. However there are few (semiclassical and/or perturbative) approaches which explain quantitatively behaviors in different time regimes. In particular there is a semiclassical dephasing approximation put forward by Vanicek,[32] and perturbative semiclassical calculations of Prosen and Znidaric[27] which are valid in the regime of integrable, chaotic, and mixed dynamics regimes. Finally let us mention exact perturbative calculations of fidelity decay via random-matrix description by Gorin *et al.*,[16] and an exact nonperturbative supersymmetric random-matrix de-

[a)]Electronic mail: monique.combescure@ipnl.in2p3.fr

scription by Stoeckmann *et al.*[31] Thus it is a field of very rich and promising insight for the study of stability under perturbations of the quantum dynamics when the underlying classical motion displays chaotic behavior.

In other approaches,[18,41] the case of integrable or regular systems is considered as well, and seems to indicate the occurrence of an anomalous power law decay. Moreover, in a case of nearly integrable system a recurrence of fidelity has been exhibited;[28] in this case the quantum fidelity manifests recurrences very close to the initial value 1 as time evolves.

Thus it is a very intriguing subject of high interest to know more about the complete time behavior of the quantum fidelity when the underlying dynamics is chaotic versus regular. To our knowledge, no completely rigorous approach of this topic has been attempted yet. It would be highly desirable to have a mathematically explicit description of the long-time behavior of the quantum fidelity, although it is a very difficult task.

This paper is a first attempt towards this rigorous understanding. It relies on a rather simplistic class of Hamiltonians for which the perturbed as well as unperturbed quantum dynamics can be explicitly solved in terms of the classical dynamics. Moreover the reference quantum states are taken in a suitable large class of quantum states known as "generalized coherent states" in the sense of Perelomov. The results are rather surprising:

(i) for a large class of reference states, the quantum fidelity never decreases to 0, but instead remains bounded from below by some constant;
(ii) in the unstable case, the quantum fidelity either decays exponentially fast to some nonzero constant, as $t \to \infty$, or manifests strong recurrences to 1;
(iii) in the stable case the quantum fidelity always manifests strong recurrences to 1 as time evolves.

These facts are strongly related to the underlying SU (1, 1) structure underlying the corresponding Hamiltonians, as can be seen from the work of Perelomov.[21]

We also are able to show a strong relationship between "quantum and classical fidelity" for this specific situation.[8]

To complete this Introduction, let us notice that a notion of classical fidelity that "mimics" the quantum fidelity has been proposed in the literature,[27,12,2,36] where decay properties similar to those of the quantum fidelity appear. Thus it would be desirable to understand more deeply the relationships between the classical and quantum fidelity on a firm mathematical basis. We shall pursue this investigation in future presentations, notably in the semiclassical limit (see Refs. 8 and 7).

II. CALCULUS OF THE QUANTUM FIDELITY

Let us consider the following operators in $\mathcal{H}=L^2(\mathbb{R})$ with suitable domains (see Ref. 21):

$$K_0 = \frac{Q^2+P^2}{4} + \frac{g^2}{2Q^2}, \tag{2}$$

$$K_\pm = \frac{Q^2-P^2}{4} \mp i\frac{QP+PQ}{4} - \frac{g^2}{2Q^2}, \tag{3}$$

where Q is the usual multiplication operator by x and

$$P := -i\frac{d}{dx},$$

K_0 and $K_\pm$ satisfy the usual commutation rules of SU (1, 1) algebra, namely

$$[K_0, K_\pm] = \pm K_\pm, \tag{4}$$

$$[K_-, K_+] = 2K_0. \tag{5}$$

We define the "generalized coherent states" (squeezed states) as follows: given any $\beta \in \mathbb{C}$,

$$S_\beta = \exp(\beta K_+ - \bar{\beta} K_-), \tag{6}$$

$$\psi_\beta = S(\beta)\psi, \tag{7}$$

ψ being a normalized state in $\mathcal{H}$ such that

$$K_-\psi = 0, \tag{8}$$

$$2K_0\psi = \left(\alpha + \tfrac{1}{2}\right)\psi, \tag{9}$$

with

$$\alpha := \tfrac{1}{2} + \sqrt{\tfrac{1}{4} + 2g^2}. \tag{10}$$

We shall focus on the following cases $g=1$, $g=\sqrt{3}$, where ψ has the following form:

$$\varphi(x) = c_1 x^2 e^{-x^2/2}, \tag{11}$$

$$\chi(x) = c_2 x^3 e^{-x^2/2} \tag{12}$$

with

$$c_1 = \sqrt{\tfrac{4}{3}}, \tag{13}$$

$$c_2 = \sqrt{\tfrac{8}{15}} \tag{14}$$

(omitting the factors in π).

This makes φ and χ to be (normalized to 1) finite linear combinations of Hermite functions. It has been shown (see Ref. 21) that for $\psi=\varphi$, ψ_β has the following form:

$$\psi_\beta = c_1 x^2 e^{-2(u-\epsilon)} \exp\left(-\frac{5i\theta}{2} + i\frac{\dot{u}x^2}{2} - \frac{1}{2}(u-\epsilon) - \frac{1}{2}(xe^{-(u-\epsilon)})^2\right), \tag{15}$$

where the constants $u, \dot{u}, \theta, \epsilon$ are suitably determined from $\beta \in \mathbb{C}$, whereas for $\psi=\chi$, ψ_β is

$$\psi_\beta = c_2 x^3 e^{-3(u-\epsilon)} \exp\left(-\frac{7i\theta}{2} + i\frac{\dot{u}x^2}{2} - \frac{1}{2}(u-\epsilon) - \frac{1}{2}(xe^{-(u-\epsilon)})^2\right). \tag{16}$$

Now the evolutions of ψ_β with respect to $U_1(t,0)$ and $U_{\sqrt{3}}(t,0)$, respectively, together with $U_0(t,0)$ are completely explicit.

Consider a complex solution of the classical equations of motion induced by Hamiltonian $\hat{H}_0(t)$,

$$\ddot{x} + fx = 0 \tag{17}$$

and look for it in the form

$$x = e^{u+i\theta}, \tag{18}$$

where the functions $t \mapsto u$ and $t \mapsto \theta$ are real.

We assume for $u(t)$ and $\theta(t)$ the following initial data:

$$u(0) = u_0,$$

$$\dot{u}(0) = \dot{u}_0,$$

$$\theta(0) = \theta_0,$$

$$\dot{\theta}(0) = e^{-2(u_0-\epsilon)}.$$

Since f is real, the Wronskian of x and $\bar{x}$ is constant and equals

$$2ie^{2\epsilon} = 2i\dot{\theta}(t)e^{2u(t)}. \tag{19}$$

This yields

$$\ddot{x} = [\ddot{u} + i\ddot{\theta} + (\dot{u} + i\dot{\theta})^2]x = [\ddot{u} + \dot{u}^2 - e^{-4(u-\epsilon)}]x = -fx \tag{20}$$

and therefore u obeys the following differential equation:

$$\ddot{u} + \dot{u}^2 - e^{-4(u-\epsilon)} + f = 0. \tag{21}$$

We have the following result.

Lemma 2.1: Let $\hat{H}_g = (P^2+Q^2)/2 + g^2/Q^2$. *Then the quantum propagator for* $\hat{H}_g(t)$ *is of the following form:*

$$U_g(t,0) = e^{i\dot{u}Q^2/2}e^{-i(u-\epsilon)(QP+PQ)/2}e^{-i(\theta-\theta_0)\hat{H}_g}e^{i(u_0-\epsilon)(QP+PQ)/2}e^{-i\dot{u}_0Q^2/2}. \tag{22}$$

The same formula holds for the propagator $U_0(t,0)$ *of* $\hat{H}_0(t)$ *with* $\hat{H}_g$ *replaced by* $\hat{H}_0$.

Proof: Let us denote

$$V(t) := e^{i\dot{u}Q^2/2}e^{-i(u-\epsilon)(QP+PQ)/2}e^{-i\theta\hat{H}_g}. \tag{23}$$

We have

$$i\frac{d}{dt}V(t) = \left(-\ddot{u}\frac{Q^2}{2} + \frac{\dot{u}}{2}e^{i\dot{u}Q^2/2}(QP+PQ)e^{-i\dot{u}Q^2/2}\right)V(t)$$
$$+ (\dot{\theta}e^{i\dot{u}Q^2/2}e^{i(u-\epsilon)(QP+PQ)/2}\hat{H}_g e^{-i(u-\epsilon)(QP+PQ)/2}e^{-i\dot{u}Q^2/2})V(t) \tag{24}$$

and since

$$e^{i\dot{u}Q^2/2}Pe^{-i\dot{u}Q^2/2} = P - \dot{u}Q \tag{25}$$

we have

$$e^{i\dot{u}Q^2/2}(PQ+QP)e^{-i\dot{u}Q^2/2} = PQ + QP - 2i\dot{u}Q^2. \tag{26}$$

Therefore the first line on the right-hand side (RHS) of (24) is

$$\left(\left(-\frac{\ddot{u}}{2} - \dot{u}^2\right)Q^2 + \frac{\dot{u}}{2}(QP+PQ)\right)V(t). \tag{27}$$

Furthermore

$$e^{-i(u-\epsilon)(QP+PQ)/2}\hat{H}_g e^{-i(u-\epsilon)(PQ+QP)/2} = \left(\frac{P^2}{2} + \frac{g^2}{Q^2}\right)e^{2(u-\epsilon)} + \frac{Q^2}{2}e^{-2(u-\epsilon)} \tag{28}$$

which implies that the second line on the RHS of (24) is

$$\left(\frac{1}{2}(P-\dot{u}Q)^2+\frac{g^2}{Q^2}+\frac{Q^2}{2}e^{-4(u-\epsilon)}\right)V(t), \tag{29}$$

where we have used that

$$\dot{\theta}=e^{-2(u-\epsilon)}.$$

Collecting the different terms, we get

$$i\frac{d}{dt}V(t)=\left(\frac{P^2}{2}+\frac{g^2}{Q^2}+\frac{Q^2}{2}(-\ddot{u}-\dot{u}^2+e^{-4(u-\epsilon)})\right)V(t)=\left(\frac{P^2}{2}+\frac{g^2}{Q^2}+f(t)\frac{Q^2}{2}\right)V(t) \tag{30}$$

using (21). □

We shall now consider the "quantum fidelity" in two particular cases $g=1$ and $g=\sqrt{3}$, starting, respectively, with the initial states $\psi_{\beta,1}=S(\beta)\varphi$, and $\psi_{\beta,2}=S(\beta)\chi$,

$$F_1(t)=\langle U_0(t,0)\psi_{\beta,1},U_g(t,0)\psi_{\beta,1}\rangle, \tag{31}$$

and similarly for $F_2(t)$ with $\psi_{\beta,1}$ replaced by $\psi_{\beta,2}$.

Theorem 2.2: *(i) Let $g=1$ and $\psi_{\beta,1}=S(\beta)\varphi$. Then we have*

$$F_1(t)=\tfrac{2}{3}+\tfrac{1}{3}e^{-2i(\theta(t)-\theta(0))}. \tag{32}$$

(ii) Let $g=\sqrt{3}$ and $\psi_{\beta,2}=S(\beta)\chi$. Then we have

$$F_2(t)=\tfrac{2}{5}+\tfrac{3}{5}e^{-3i(\theta(t)-\theta(0))}. \tag{33}$$

Proof: Since x^2 is expanded as

$$x^2=\tfrac{1}{4}H_2(x)+\tfrac{1}{2}H_0(x)$$

it is clear that

$$U_0(t,0)\psi_{\beta,1}=c_1\exp\left(\frac{i}{2}\dot{u}(t)x^2-\frac{1}{2}(u(t)-\epsilon)\right)\left\{\frac{1}{4}e^{-5i\theta(t)/2}H_2(xe^{-(u(t)-\epsilon)})+\frac{1}{2}e^{-i\theta(t)/2-2i\theta(0)}\right\}$$
$$\times\exp\left(-\frac{1}{2}x^2e^{-2(u(t)-\epsilon)}\right) \tag{34}$$

and

$$U_g(t)\psi_{\beta,1}=V(t)\varphi=c_1\exp\left(-\frac{5}{2}i\theta(t)+\frac{i}{2}\dot{u}(t)x^2-\frac{1}{2}(xe^{-(u(t)-\epsilon)})^2\right) \tag{35}$$

from which we deduce that

$$F_1(t)=c_1^2\int\left[x^2\left(x^2-\frac{1}{2}\right)+\frac{e^{-2i(\theta(t)-\theta(0))}}{2}x^2\right]e^{-x^2}\,dx=\frac{4}{3}\left(\frac{1}{2}+\frac{1}{4}e^{-2i(\theta(t)-\theta(0))}\right)=\frac{2}{3}+\frac{1}{3}e^{-2i(\theta(t)-\theta(0))}, \tag{36}$$

(ii) follows from a very similar calculation using that

$$H_3(x)=8x^3-12x.$$

□

Let us now assume that g has an arbitrary real value [not specifically of the form $g=\sqrt{k(k+1)/2}$ for $k\in\mathbb{N}$ which gives rise to integer values of $\alpha=\frac{1}{2}+\sqrt{\frac{1}{4}+2g^2}$]. Then the state $\psi:=cx^{\alpha}e^{-x^2/2}$ is no longer a finite linear combination of Hermite functions. It has nevertheless an infinite expansion on the basis of Hermite functions φ_n,

$$\psi=\sum_{n=0}^{\infty}\lambda_n\varphi_n$$

and one can establish the following general result about the corresponding "quantum fidelity."

Theorem 2.3:

$$F_g(t)=\exp(-i\alpha(\theta(t)-\theta(0)))\sum_{n=0}^{\infty}|\lambda_n|^2\exp(in(\theta(t)-\theta(0)))$$

which, since $\Sigma_{n=0}^{\infty}|\lambda_n|^2=1$, *returns in absolute value to 1 as long as* $\theta(t)-\theta(0)=0(mod\,2\pi)$. *If* $\alpha=p/q$ *is rational, then the quantum fidelity recurs exactly to 1 (not only in absolute value) provided that* $\theta(t)-\theta(0)=0(mod\,2q\pi)$.

Proof: Again according to Ref. 21, we have

$$\psi_\beta:=S(\beta)\psi=e^{-i(\alpha+1/2)\theta_0}D(u_0)\psi,$$

where by $D(u)$ we denote the following unitary operator:

$$D(u):=e^{iuQ^2/2}e^{-i(u-\epsilon)(QP+PQ)/2}.$$

Then

$$U_0(t,0)\psi_\beta=D(u_t)e^{-i(\theta_t-\theta_0)\hat{H}_0}\sum_{n=0}^{\infty}\lambda_n e^{-i\theta_0(\alpha+1/2)}\varphi_n=D(u_t)\sum_{n=0}^{\infty}\lambda_n e^{-i\theta_t(n+1/2)+i\theta_0(n-\alpha)}\varphi_n,$$

whereas

$$U_g(t,0)\psi_\beta=e^{-i\theta_t(\alpha+1/2)}D(u_t)\psi,$$

so that

$$\langle U_0(t,0)\psi_\beta,U_g(t,0)\psi_\beta\psi_\beta\rangle=\sum_{n,m}\bar{\lambda}_n\lambda_m e^{i\theta_t(n+1/2)-i\theta_0(n-\alpha)-i\theta_t(\alpha+1/2)}\langle\varphi_n,\varphi_m\rangle=\sum_{n=0}^{\infty}|\lambda_n|^2e^{i(\theta_t-\theta_0)(n-\alpha)}.$$

□

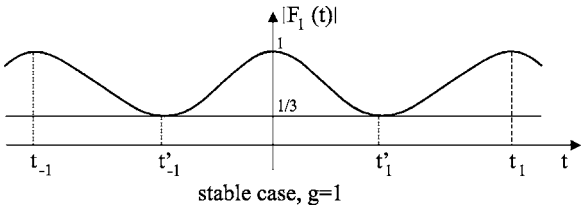
III. DISCUSSION OF THE RESULT

Since f is a T-periodic function, Floquet analysis applies to Eq. (17) which is nothing but the well-known Hill's equation. Depending to the parameters characterizing the function f [as, for example, γ and δ in the case of Mathieu equation where $f(t)=\gamma+\delta\cos\omega t$], the solutions can be either stable or unstable. In all cases the quantum fidelity $F_1(t)$ and $F_2(t)$ are bounded from below by some positive constant in absolute value, and therefore never decrease to zero.

The phase $\theta(t)$ is determined by

$$\theta(t)-\theta(0)=e^{2\epsilon}\int_0^t e^{-2u(s)}\,ds. \tag{37}$$

In the stable case, the function $t \mapsto u(t)$ is T-periodic. Therefore $\theta(t)$ grows from $-\infty$ to $+\infty$ as time evolves from $-\infty$ to $+\infty$. It follows that there exists an infinite sequence of times $\{t_k\}$ where $F_1(t)$ recurs to its initial value 1, and an infinite squence $\{t'_k\}$ where $|F_1(t)|$ attains its minimum $1/3$. The same statement holds for $F_2(t)$ where $1/3$ is replaced by $1/5$.



In the unstable case there is some positive Lyapunov exponent λ and some real solution of Hill's equation such that

$$x(T) = e^{\lambda T} x(0),$$

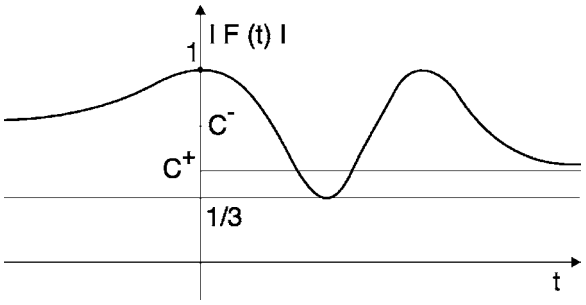
$$\dot{x}(T) = e^{\lambda T} \dot{x}(0).$$

Here, since we deal with complex solutions $x(t)$ such that the Wronskian of x and $\bar{x}$ is nonzero, we deduce that $|x(t)| > 0$. Moreover, depending on the instability zone, $|x(t)|^{-2} = e^{-2u(t)}$ can be integrable near $\pm\infty$, or diverge at $\pm\infty$. These topics are clearly detailed in Ref. 20. In the first case the conclusion is that there exists two constants $\theta_{\pm}$ such that

$$\theta(t) \to \theta_{\pm} \quad \text{as } t \to \pm\infty. \tag{38}$$

This is the case for the inverted harmonic oscillator $(f=-1)$ that we describe in the preceding section.

Therefore the quantum fidelity in this case behaves generically as described in the following picture:



If the instability zone in which the solution $x(t)$ lies is such that $|x(t)|^{-2}$ is not integrable near $\pm\infty$, then the diagram is typically similar to that of the stable case, which shows infinite recurrences to 1 of the quantum fidelity.

IV. LINK WITH THE "CLASSICAL INFIDELITY"

We can call "classical infidelity" the discrepancy between two classical trajectories, along their evolution, when they merge from the same initial phase-space point at $t=0$. The possible crossing of the two trajectories governed by $H_0(t)$ and $H_g(t)$, in phase space, as time evolves, could then be a signature of the "classical fidelity" as defined in the literature.

From now on we assume that ϵ of Sec. II is determined by $(g>0)$,

$$e^{2\epsilon} = g\sqrt{2}. \tag{39}$$

Proposition 1: Let $x(t)$ *be a* real *trajectory for the time-periodic Hamiltonian* $H_0(t)$, *and* $y(t)$

a real *trajectory for Hamiltonian* $H_g(t)$. *Assume in addition that they satisfy* $x(0)=y(0)\in\mathbb{R}$, $\dot{x}(0)=\dot{y}(0)\in\mathbb{R}$. *Then we have*

$$|x(t)-y(t)| = |y(t)|(1-\cos\tilde{\theta}(t)), \tag{40}$$

where $\tilde{\theta}(t)$ *is defined as follows:*

$$\tilde{\theta}(t) := g\sqrt{2}\int_0^t y(s)^{-2}\,\mathrm{d}s \equiv \theta(t)-\theta(0). \tag{41}$$

Proof: Let $z(t)$ be a complex solution of the equation

$$\ddot{z}+fz=0. \tag{42}$$

It can be written as $z(t)=e^{u+i\tilde{\theta}}$ as above, where $t\mapsto u$ and $t\mapsto\tilde{\theta}$ are real functions. Assume that $x(t)$ is such that $x(0)>0$. Then it is easy to see that $x(t)=\Re z(t)=e^{u(t)}\cos\tilde{\theta}(t)$ is a solution of Eq. (42), and that the positive function $y(t):=e^{u(t)}$ is a solution of

$$\ddot{y}+fy-\frac{2g^2}{y^3}=0 \tag{43}$$

which means that it defines a classical trajectory for $H_g(t)$.

Namely we get from Eq. (41) that

$$\frac{d}{\mathrm{d}t}\tilde{\theta}(t)=g\sqrt{2}e^{-2u(t)} \tag{44}$$

and therefore

$$\ddot{x}=(\ddot{u}+\dot{u}^2-2g^2e^{-4u})x=-fx, \tag{45}$$

so that

$$(\ddot{u}+\dot{u}^2-2g^2e^{-4u}+f)e^u=0 \tag{46}$$

which is nothing but Eq. (43) noting that

$$\ddot{y}=(\ddot{u}+\dot{u}^2)y. \tag{47}$$

Moreover, they satisfy $x(0)=y(0)$, $\dot{x}(0)=\dot{y}(0)$, and

$$|x(t)-y(t)| = y(t)(1-\cos\tilde{\theta}(t)).$$

In the case where $x(0)<0$, we just take $x(t)=-\Re z(t)$ and $y(t)=-e^{u(t)}$, which completes the result. □

Conclusion: The classical infidelity vanishes for $\tilde{\theta}(t)=2k\pi$ ($k\in\mathbb{Z}$), which precisely gives rise to recurrences to 1 of the "quantum fidelity" (Theorem 2.3). We expect this remarkable property to be true in more general situations, in particular in the semiclassical regime (see Ref. 8).

By "vanishing of the classical infidelity" we mean that given any solution of the unperturbed dynamics, there exists a solution of the perturbed one that coincides with it at the origin, and at any values of time solving the equation

$$g\sqrt{2}\int_0^t \mathrm{d}s\; y(s)^{-2}=0 \pmod{2\pi}.$$

One may ask whether this holds true for general solution $x(t)$, $y(t)$ of Eqs. (42) and (43). This is answered in the following particular cases below.

(i) *Particular case* $f=1$ (the case $f=\omega^2$ could be treated as well): When we apply the result above, we find that solutions $x(t)=A\cos t$ and $y=A$ coincide for $t=2k\pi$, $k\in\mathbb{Z}$, and that y obeys Eq. (43) provided $A=(2g^2)^{1/4}$. One shows that a more general result holds, involving general solutions of the equations under consideration.

The general solution of Eq. (43) is of the form (apart from the sign before the square root)

$$y(t)=\sqrt{\alpha+\beta\cos 2t+\gamma\sin 2t} \tag{48}$$

with α,β,γ related to each other by the relation

$$\alpha^2-(\beta^2+\gamma^2)=2g^2. \tag{49}$$

It obeys the initial data

$$y(0)=\sqrt{\alpha+\beta},$$

$$\dot{y}(0)=\frac{\gamma}{\sqrt{\alpha+\beta}},$$

and the conserved energy is simply α.

We take as real solution of Eq. (43) (harmonic oscillator),

$$x(t)=\sqrt{\alpha+\beta}\cos t+\frac{\gamma}{\sqrt{\alpha+\beta}}\sin t, \tag{50}$$

which has the same initial data as $y(t)$. Both functions being 2π-periodic, the generic "classical infidelity" vanishes when $t=2k\pi$, $k\in\mathbb{Z}$.

(ii) Particular case $f=-1$ (the case $f=-\omega^2$ could be treated as well): Any complex solution of the differential equation (inverted harmonic oscillator)

$$\ddot{z}-z=0 \tag{51}$$

can be written in the form

$$z(t)=(a+ib)e^t+(c+id)e^{-t}, \tag{52}$$

where a,b,c,d are real constants. We define

$$Z(t):=|z(t)|^2.$$

One can prove that $y(t)=\sqrt{Z(t)}$ obeys the differential equation

$$\ddot{y}-y-\frac{2g^2}{y^3}=0 \tag{53}$$

with

$$g^2=2(ad-bc)^2>0 \tag{54}$$

It is important to note that this implies $Z(t)>0$, $\forall t$.

Define $x(t):=y(t)\cos\theta(t)$, with $\theta(0)=0$. Then, clearly

$$x(0)=y(0),$$

$$\dot{x}(0)=\dot{y}(0).$$

We want $x(t)$ to be a real solution of Eq. (53). Since

$$\ddot{x} - x = \frac{1}{\sqrt{Z}}\left(\frac{\ddot{Z}}{2} - \frac{\dot{Z}^2}{4Z} - Z - \dot{\theta}^2 Z\right)\cos\,\theta - \left(\frac{\dot{\theta}\dot{Z}}{\sqrt{Z}} + \ddot{\theta}\sqrt{Z}\right)\sin\,\theta \tag{55}$$

and since Z obeys

$$\frac{\ddot{Z}}{2} - \frac{\dot{Z}^2}{4Z} - Z - \frac{2g^2}{Z} = 0 \tag{56}$$

the RHS of Eq. (55) vanishes provided

$$\dot{\theta}^2 = 2g^2 Z^{-2}. \tag{57}$$

Then $x(t)$ and $y(t)$ are two trajectories for Hamiltonians $(P^2-Q^2)/2$ and $(P^2-Q^2)/2 + (g^2/Q^2)$ respectively, with the same initial data, and we have

$$|x(t) - y(t)| = y(t)(1 - \cos\,\theta(t)). \tag{58}$$

Using the particular solution of Eq. (51)

$$z(t) = \frac{1+i}{2}e^{t} + \frac{1-i}{2}e^{-t}$$

that can be rewritten as

$$z(t) = \sqrt{\cosh 2t}\,\exp\left(\frac{i}{2}\,\text{arcsin tanh}\,2t\right),$$

i.e., with $u(t)=\frac{1}{2}\ln\cosh 2t$ [which satisfies $u(0)=\dot{u}(0)=0$], the formula (22) can be rewritten in the simple form

$$U_g(t,0) = \exp\left(\frac{i}{2}Q^2\tanh 2t\right)\exp\left(\frac{i}{4}(QP+PQ)\ln\cosh 2t\right)\exp\left(-\frac{i}{2}\hat{H}_g\,\text{arcsin tanh}\,2t\right) \tag{59}$$

which holds true for $g=0$, and $g=1/\sqrt{2}$. For $g=0$, this is nothing but the well-known Mehler's formula.

(iii) Study of $\theta(t)$: Recall that the fidelity $F_g(t)$ strongly depends on the reference state via the constants a,b,c,d,

$$\theta(t) = g\sqrt{2}\int_0^t \frac{\mathrm{d}s}{(a^2+b^2)e^{2s} + (c^2+d^2)e^{-2s} + 2(ac+bd)} = \left(\arctan\left(\frac{ac+bd+(a^2+b^2)e^{2t}}{|ad-bc|}\right)\right.$$
$$\left. - \arctan\left(\frac{ac+bd+(a^2+b^2)}{|ad-bc|}\right)\right). \tag{60}$$

This implies that $\theta(t)\to\theta_{\pm}$ as $t\to\pm\infty$ exponentially fast in the future and in the past. The calculus is especially simple in the particular case where we choose $a=d=g/\sqrt{2}$, $c=b=0$,

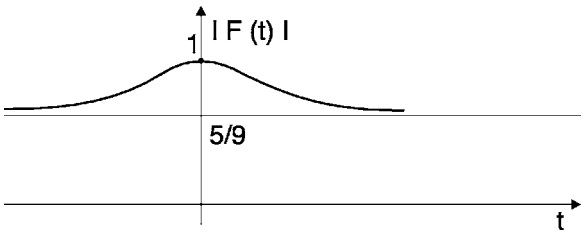
$$\theta(t) = \arctan(e^{2t}) - \frac{\pi}{4}. \tag{61}$$

No crossing of the classical trajectories happens in this case between the perturbed and unperturbed dynamics, and the square of the quantum fidelity in the case $g=1$ is nothing but

$$|F_1(t)|^2 = \frac{5}{9} + \frac{8}{9(e^{2t}+e^{-2t})} \sim \frac{5}{9} + \frac{4}{9}e^{-2|t|} \tag{62}$$

as $t\to\pm\infty$.

Here the symmetry is perfect between the future and the past, and the quantum fidelity has no recurrences to 1, but instead decays exponentially fast to 5/9.



V. CONCLUSION

It has been suggested in many recent works that the type of decay of the quantum fidelity may help to discriminate between chaotic or regular underlying classical motion; in other words the hypersensitivity of quantum dynamics under small perturbations, as measured by the type of decrease of the quantum fidelity, could be a signature of what is often called (rather improperly) "quantum chaos."

Thus it is highly desirable to have a better understanding of how this function of time [represented by Eq. (1) for suitable class of reference quantum states ψ] behaves at infinity in general as well in particular systems. In this paper we have been able to describe the full time behavior of the quantum fidelity for a rather specific class of systems, and for reference states in a suitable class of "generalized coherent states". The underlying SU(1,1) structure possessed by these systems allows us to perform an exact calculus of the quantum fidelity, and to compare it with the "classical infidelity" of the corresponding classical motion. This classical motion can be either stable, or unstable with positive Lyapunov exponent. The quantum fidelity has the following remarkable properties:

(i) either it decays to a (generally nonzero) limit in the past and in the future,
(ii) or it manifests an infinite sequence of recurrences to 1 as time evolves.

This sheds a new light on this question which has been addressed in a great variety of cases in the physics literature, and where the quantum fidelity is generally claimed to decay very rapidly to zero. Thus the first mathematical study presented here on the long-time behavior of the quantum fidelity could allow in the future a better understanding of these features in more general situations on a rigorous level.

ACKNOWLEDGMENTS

The author thanks F. Gieres and M. Kibler for interesting discussions about this topic. She is also very indebted to Boris Mityagin for important information about solutions of Hill's equation (see Ref. 20).

(Received 3 October 2005; accepted 25 January 2006; published online 28 March 2006)

We propose three effective Hamiltonians which approximate atoms in very strong homogeneous magnetic fields B modelled by the Pauli Hamiltonian, with fixed total angular momentum with respect to magnetic field axis. All three Hamiltonians describe N electrons and a fixed nucleus where the Coulomb interaction has been replaced by B-dependent one-dimensional effective (vector valued) potentials but without magnetic field. Two of them are solvable in at least the one electron case. We briefly sketch how these Hamiltonians can be used to analyze the bottom of the spectrum of such atoms. © *2006 American Institute of Physics.*

I. INTRODUCTION

The Pauli Hamiltonian of a nonrelativistic atom with an infinitely heavy nucleus and electrons with spin in a constant magnetic field $\mathbb{B}$ of strength B is given by

$$H^B(Z,N)=\sum_{j=1}^{N}\left(\frac{1}{2}\left(\frac{1}{i}\nabla_j-\frac{1}{2}\mathbb{B}\wedge r_j\right)^2+\vec{\sigma}_j\cdot\mathbb{B}-\frac{Z}{|r_j|}\right)+\sum_{1\leqslant j<k\leqslant N}\frac{1}{|r_j-r_k|},\tag{1}$$

where $r_j=(x_j,y_j,z_j)\in\mathbb{R}^3$ are the coordinates of the jth electron, $\vec{\sigma}_j$ is its spin, and ∇_j is the gradient with respect to r_j. Note that we have made the choice of $\frac{1}{2}\mathbb{B}\wedge r$ for the vector potential of $\mathbb{B}$, and that we are working in atomic units.

We fix the direction of $\mathbb{B}$ to be the z direction: $\mathbb{B}=B(0,0,1)$ with $B\geqslant 0$ without loss of generality. Recall that the z-component of $\vec{\sigma}_j$ is given, in the Pauli representation, by

$$I\otimes\cdots\sigma_{z_j}\cdots\otimes I,\quad \sigma_{z_j}=\frac{1}{2}\begin{pmatrix}-1 & 0\\ 0 & 1\end{pmatrix},$$

acting on the N-fold tensor product $\mathbb{C}^2\otimes\cdots\otimes\mathbb{C}^2$. It is known (see Ref. 13) that $H^B:=H^B(Z,N)$ defines an essentially self-adjoint operator on

$$\mathcal{H} = \bigotimes_{j=1}^{N} L^2(\mathbb{R}^2) \otimes \mathbb{C}^2, \tag{2}$$

the Hilbert space of distinguishable electrons or "boltzons" (meaning particles satisfying the Boltzman statistics: we thank Beth Ruskai for introducing us to this expression). Physical atoms are of course modeled by H^B restricted to the fermionic subspace

$$\mathcal{H}_{\mathrm{f}} = \bigwedge_{j=1}^{N} L^2(\mathbb{R}^3) \otimes \mathbb{C}^2, \tag{3}$$

of totally antisymmetric wave functions in $\mathcal{H}$, where $\wedge$ stands for exterior product. A useful alternative description of $\mathcal{H}$, used in atomic physics, is given by the unitary map

$$\mathcal{H} \to L^2((\mathbb{R}^3 \times \{\pm 1\})^N), \quad \psi \to U(\psi)(r_1, s_1; \ldots; r_N, s_N),$$

the isometry being defined by taking the components of $\psi(r_1, \ldots, r_N)$ with respect to the natural basis of $\mathbb{C}^2 \otimes \cdots \otimes \mathbb{C}^2$ consisting of the products $\otimes_j e_{s_j}$ of the normalized eigenvectors $e_\pm$ of σ_{z_j}, e_- corresponding to "spin down" and e_+ to "spin up." In this new representation, σ_{z_j} acts as the multiplication operator by $s_j/2$, and the fermionic subspace $\mathcal{H}_f$ of (2) is simply obtained by antisymmetrizing with respect to the 4-tuples of variables $(r_1, s_1), \ldots, (r_N, s_N)$.

The main results of this paper can be summarized in the following five theorems below. It is worthwhile to observe that H^B commutes with each individual spin operator σ_{z_j} and therefore decomposes in a direct sum which is unitarily equivalent to

$$\bigoplus_{s_{z_j} \in \{\pm 1\}} H^{B, \mathbb{S}_z = -(NB/2)} + \sum_{j=1}^{N} (1 + s_{z_j}) \frac{B}{2},$$

where $\mathbb{S}_z := \sum_{j=1}^{N} \sigma_{z_j}$ denotes the z component of the total spin operator. So from now on we will consider only $H^{B, S_z = -(NB/2)}$ and denote it again by H^B. Notice that this operator simply acts in $\otimes_{j=1}^{N} L^2(\mathbb{R}^3)$. Since the Hamiltonian H^B also commutes with the total angular momentum operator in the field direction, which we will call $\mathbb{L}_z$, we can fix a value $\mathbb{M} \geqslant 0$ of the latter. Our results will imply that the bottom of the spectrum of H^B will necessarily occur for a non-negative value of $\mathbb{M}$, and we will therefore restrict ourselves to $\mathbb{M} \geqslant 0$. Let $H^{B,\mathbb{M}}$ be the restriction of H^B to the $\mathbb{M}$th angular momentum channel (in the field direction), and let $\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$ be the orthogonal projection onto the lowest Landau states with z-angular momentum $\mathbb{M}$ [cf. (31) for the precise definition]. We define the *effective* Hamiltonian $h_{\mathrm{eff}} = h_{\mathrm{eff}}^{B,\mathbb{M}}$ by

$$h_{\mathrm{eff}}^{B,\mathbb{M}} = \Pi_{\mathrm{eff}}^{B,\mathbb{M}} H^{B,\mathbb{M}} \Pi_{\mathrm{eff}}^{B,\mathbb{M}}, \tag{4}$$

and let

$$\Pi_{\perp}^{B,\mathbb{M}} = I - \Pi_{\mathrm{eff}}^{B,\mathbb{M}}$$

be the projection onto the orthogonal complement (always restricting ourselves to the $\mathbb{M}$th z-angular momentum channel). The operator $h_{\mathrm{eff}}^{B,\mathbb{M}}$ is the first, and most encompassing, of three "effective Hamiltonians" we will consider in this paper. The two other ones, called $h_C^{B,\mathbb{M}}$ and h_δ^B, will be defined below. It will be convenient to complete $h_{\mathrm{eff}}^{B,\mathbb{M}}$ as follows:

$$H_{\mathrm{eff}}^{B,\mathbb{M}} := h_{\mathrm{eff}}^{B,\mathbb{M}} \oplus H_{\perp}^{B,\mathbb{M}}, \quad \text{with } H_{\perp}^{B,\mathbb{M}} := \Pi_{\perp}^{B,\mathbb{M}} H^{B,\mathbb{M}} \Pi_{\perp}^{B,\mathbb{M}}. \tag{5}$$

For any self-adjoint operator A, we let $\sigma(A)$ denote the spectrum of A and $\rho(A)$ its resolvent set. Our first main result is the following.

Theorem 1.1: Let $\alpha = \alpha(B)$ be the unique positive solution of the equation

$$\alpha + \log \alpha = \tfrac{1}{2} \log B, \tag{6}$$

and let $d_{\mathrm{eff}}(\xi)=\mathrm{dist}(\xi,\sigma(h_{\mathrm{eff}}^{B,\mathbb{M}}))$. *There exist positive constants* B_{eff}, c_{eff}, *and* C_{eff}, *which only depend on* Z, N, *and* $\mathbb{M}$, *such that for all* $B\geqslant B_{\mathrm{eff}}$, *and all real* ξ *satisfying*

$$c_{\mathrm{eff}}\frac{\alpha}{\sqrt{B}}\leqslant d_{\mathrm{eff}}(\xi)\leqslant\frac{1}{2}\alpha^2$$

we have that $\xi\in\rho(H^{B,\mathbb{M}})$, *and*

$$\|(H^{B,\mathbb{M}}-\xi)^{-1}-(H_{\mathrm{eff}}^{B,\mathbb{M}}-\xi)^{-1}\|\leqslant C_{\mathrm{eff}}\frac{\alpha(B)^2}{d_{\mathrm{eff}}(\xi)^2\sqrt{B}}. \tag{7}$$

Remarks 1.2: (i) We shall see in Theorem 3.1 that $\sigma(H_{\perp}^{B,\mathbb{M}})\subset\mathbb{R}_+$ for $B\geqslant B_{(36)}$, where the latter is defined by formula (36) (see our convention on constants at the end of this introduction). Since $B_{\mathrm{eff}}\geqslant B_{(36)}$ by (106), and since one can see from (9) and (10) below that $\mathbb{R}_+\subset\sigma(h_{\mathrm{eff}}^{B,\mathbb{M}})$, it follows that $\sigma(h_{\mathrm{eff}}^{B,\mathbb{M}})=\sigma(H_{\mathrm{eff}}^{B,\mathbb{M}})$ when $B\geqslant B_{\mathrm{eff}}$.

(ii) The equation for $\alpha(B)$ is equivalent to $\alpha e^{\alpha}=\sqrt{B}$, and can therefore be written as

$$\alpha(B)=W(\sqrt{B}),$$

where W is the principal branch of the Lambert W function, see, e.g., Ref. 8. Using known properties of the Lambert W function, or by elementary arguments, one shows that

$$\alpha(B)=\frac{1}{2}\log B-\log^{(2)}B+\log 2+O\left(\frac{\log^{(2)}B}{\log B}\right),\quad B\to\infty, \tag{8}$$

where $\log^{(2)}(x):=\log(\log x)$, for $x>1$. In particular, $\alpha(B)\simeq\log(\sqrt{B})$, as $B\to\infty$.

(iii) Our proof yields explicit constants B_{eff}, c_{eff}, and C_{eff}, for given N, $\mathbb{M}$, and Z. This is also true for the constants in Theorems 1.3 and 1.5 below.

(iv) The upper bound $\alpha^2/2$ on $d_{\mathrm{eff}}(\xi)$ is only there to allow a simple expression for the upper bound in (7), and is by no means essential. The same remark applies to Theorems 1.3, 1.5, and 1.6 below.

Some applications of Theorem 1.1, as well as of Theorems 1.3, 1.5, 1.6, and 1.8 below, to the study of spectral properties of $H^{B,\mathbb{M}}$ are given in the concluding remarks section.

The operator $h_{\mathrm{eff}}^{B,\mathbb{M}}$ has the structure of a multiparticle Schrödinger operator on the real line, $\mathbb{R}$,

$$h_{\mathrm{eff}}^{B,\mathbb{M}}=-\frac{1}{2}\Delta-Z\sum_j V_j^{B,\mathbb{M}}(z_j)+\sum_{j<k}V_{jk}^{B,\mathbb{M}}(z_j-z_k), \tag{9}$$

with operator-valued potentials acting pointwise on a certain finite-dimensional Hilbert space $F_{\mathbb{M}}^B$, defined in (32) below. Essentially, $F_{\mathbb{M}}^B$ is the vector space spanned by the lowest Landau states with angular momentum $\mathbb{L}_z=\mathbb{M}$. As we will see, $\mathrm{Ran}\,\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$ is canonically isomorphic to the space $L^2(\mathbb{R}^N,F_{\mathbb{M}}^B)$ of vector-valued L^2-functions, and the potentials in (9) are simply obtained by projecting the respective Coulomb terms in (1) along $\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$,

$$V_j^{B,\mathbb{M}}(z_j):=\Pi_{\mathrm{eff}}^{B,\mathbb{M}}\frac{1}{|r_j|}\Pi_{\mathrm{eff}}^{B,\mathbb{M}},\quad V_{jk}^{B,\mathbb{M}}(z_j-z_k):=\Pi_{\mathrm{eff}}^{B,\mathbb{M}}\frac{1}{|r_j-r_k|}\Pi_{\mathrm{eff}}^{B,\mathbb{M}}. \tag{10}$$

We will show that the potentials (10) can be approximated by certain simpler ones, which will give rise to our two other effective Hamiltonians. Define the tempered distribution q^B on $\mathbb{R}$ by

$$q^B(z)=\log B\,\delta(z)+\mathrm{Pf}\left(\frac{1}{|z|}\right), \tag{11}$$

where

$$\mathrm{Pf}\left(\frac{1}{|z|}\right) := \frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{sgn}(z)\log|z|),$$

(with distributional derivative) is the finite part (in the sense of Hadamard) of the singular function $1/|z|$; $\mathrm{Pf}(|z|^{-1})$ should be interpreted as a regularization of the (three-dimensional) Coulomb potential restricted to the line. Also introduce (constant) finite-dimensional operators $C_j^{n,B,\mathbb{M}}$ and $C_{jk}^{e,B,\mathbb{M}}$, acting on the vector space $F_{\mathbb{M}}^B$ introduced above, defined by

$$C_j^{n,B,\mathbb{M}} := -\Pi_{\mathrm{eff}}^{B,\mathbb{M}} \log\left(\frac{B}{4}(x_j^2+y_j^2)\right)\Pi_{\mathrm{eff}}^{B,\mathbb{M}} \tag{12}$$

and

$$C_{jk}^{e,B,\mathbb{M}} := -\Pi_{\mathrm{eff}}^{B,\mathbb{M}} \log\left(\frac{B}{4}((x_j-x_k)^2+(y_j-y_k)^2)\right)\Pi_{\mathrm{eff}}^{B,\mathbb{M}}. \tag{13}$$

The superscripts "n" and "e" stand for "nucleus" and "electron," respectively, as a reminder that (12) is a vestige of the interaction between the jth electron and the nucleus, while (13) originates in the electron-electron interaction between electrons j and k. Finally, define an operator $h_C^{B,\mathbb{M}}$ on $L^2(\mathbb{R},F_{\mathbb{M}}^B)$ (the C standing for Coulomb) by

$$h_C^{B,\mathbb{M}} = -\frac{1}{2}\Delta - Z\sum_j (q^B(z_j)+C_j^{n,B,\mathbb{M}}\delta(z_j)) + \sum_{j<k}(q^B(z_j-z_k)+C_{jk}^{e,B,\mathbb{M}}\delta(z_j-z_k)). \tag{14}$$

As we will see in Sec. IV, the right-hand side of (14) defines a self-adjoint operator $h_C^{B,\mathbb{M}}$ on $L^2(\mathbb{R}^N)$, despite the distributional potentials. This will be a consequence of the Kato-Lax-Lions-Milgram-Nelson theorem. The form domain of $h_C^{B,\mathbb{M}}$ is simply the vector-valued first Sobolev space $H^1(\mathbb{R}^N;F_{\mathbb{M}})$, while its operator domain will be characterized in the Appendix. As in (5) we introduce

$$H_C^{B,\mathbb{M}} := h_C^{B,\mathbb{M}} \oplus H_\perp^{B,\mathbb{M}}.$$

Our second main theorem then is the following.

Theorem 1.3: *Let $\alpha=\alpha(B)$ be as in Theorem 1.1, and set $d_C(\xi) := \mathrm{dist}(\xi,\sigma(h_C^{B,\mathbb{M}}))$. There exists positive constants B_C, c_C, and C_C which depend only on Z, N, and $\mathbb{M}$, such that for all $B \geqslant B_C$ and all real ξ satisfying*

$$c_C\frac{\alpha^{3/2}}{B^{1/4}} \leqslant d_C(\xi) \leqslant \frac{1}{4}\alpha^2$$

we have that $\xi \in \rho(H^{B,\mathbb{M}})$, and

$$\|(H^{B,\mathbb{M}}-\xi)^{-1}-(H_C^{B,\mathbb{M}}-\xi)^{-1}\| \leqslant \frac{C_C\alpha^{3/2}}{B^{1/4}d_C(\xi)^2}. \tag{15}$$

Remark 1.4: In top order in B, all that remains of the electrostatic potentials in $H^{B,\mathbb{M}}$ are the extremely short-range δ-potentials. In next order, the long-range character of the original Coulomb potentials reasserts itself in two ways: in the magnetic field direction, through the $\mathrm{Pf}(|\cdot|^{-1})$-terms in $h_C^{B,\mathbb{M}}$, and in the transversal directions, through the $C_j^{n,B,\mathbb{M}}$ and $C_{jk}^{e,B,\mathbb{M}}$ terms. The latter are in fact simply the quantum mechanical mean, with respect to the projection onto the lowest Landau band states of total angular momentum $\mathbb{M}$ (in the field direction), of a two-dimensional logarithmic potential, minus a B-dependent constant. This logarithmic potential is the natural electrostatic potential for the plane. Physically, this can be understood as follows: under the influence of the strong magnetic field the electrons will spiral closely around the field lines, along circles of radius $O(B^{-1/2})$ in the plane transversal to the field, while occupying an interval of size $O((\log B)^{-1})$ in the field direction itself, as a consequence of the nuclear attraction. For big B, and at different

locations in the (x,y)-plane, they will see each other and the nucleus as so many infinitely long charged wires, and, as is known from classical electrostatics, such wires interact via a logarithmic potential.

A simpler effective Hamiltonian, our third and last one, and historically the first to be proposed (cf. Refs. 14, 4, and 6), is roughly speaking obtained by only keeping the leading term in the potential of $h_C^{B,\mathbb{M}}$. More precisely, we set

$$h_\delta^B = -\tfrac{1}{2}\Delta_z + 2\alpha(B)v_\delta, \tag{16}$$

where

$$v_\delta(z) = -Z\sum_{j=1}^{N}\delta(z_j) + \sum_{j<k}\delta(z_j - z_k). \tag{17}$$

Looking back at (11) it would seem natural to take as potential $\log B v_\delta$, but it turns out that $2\alpha(B)v_\delta$ leads to smaller error estimates; notice that in view of (8), $2\alpha v_\delta$ is also a $O(\log B)$ part of the potential in h_C^B. Furthermore, with this choice the coupling constant $2\alpha(B)$ is positive for all $B>0$ which is not the case for $\log B$. Contrary to our previous two effective Hamiltonians, h_δ^B does not explicitly depend on $\mathbb{M}$ anymore, but it will operate on an $\mathbb{M}$ and B-dependent Hilbert space, namely $L^2(\mathbb{R}^N, F_{\mathbb{M}}^B) \simeq L^2(\mathbb{R}^N)\otimes F_{\mathbb{M}}^B$ (which in fact are canonically isomorphic for different B). Considering (16) as acting on scalar $L^2(\mathbb{R}^N)$, we define the δ-model as being the operator

$$h_\delta^{B,\mathbb{M}} := h_\delta^B \otimes I_{F_{\mathbb{M}}^B}, \quad I_{F_{\mathbb{M}}^B} \text{ being the identity operator.} \tag{18}$$

We will often simply write h_δ^B, except when we want to stress the vector-valued nature of the L^2-functions in the domain. Again as in (5) we introduce

$$H_\delta^{B,\mathbb{M}} := h_\delta^{B,\mathbb{M}} \oplus H_\perp^{B,\mathbb{M}}.$$

Our third approximation theorem is the following.

Theorem 1.5: *Let $\alpha := \alpha(B)$ be as in Theorem 1.1, and set $d_\delta(\xi) := \operatorname{dist}(\xi, \sigma(h_\delta^{B,\mathbb{M}}))$. There exist positive constants B_δ, c_δ, and C_δ, depending on N, Z, and $\mathbb{M}$, such that for all $B \geqslant B_\delta$ and real ξ satisfying*

$$c_\delta\alpha \leqslant d_\delta(\xi) \leqslant \tfrac{1}{4}\alpha^2, \tag{19}$$

we have that $\xi \in \rho(H^{B,\mathbb{M}})$, and

$$\left\|(H^{B,\mathbb{M}} - \xi)^{-1} - (H_\delta^{B,\mathbb{M}} - \xi)^{-1}\right\| \leqslant \frac{C_\delta\alpha}{d_\delta(\xi)^2}. \tag{20}$$

See Ref. 6 for weaker versions of this theorem. We also mention Ref. 4, which established the convergence of the ground state energy of fermionic H^B (see below) to that of bosonic (scalar) h_δ^B on $L^2(\mathbb{R}^N)$, using variational arguments: these authors did not fix $\mathbb{M}$, but they only proved convergence of the ground state energy, while we can conclude much more from the norm resolvent convergence to the effective Hamiltonians; see Sec. IX for a list of applications of the results of the present paper. (Reference 4, following Ref. 14, first did a rescaling of H^B's ground state energy which allowed them to compare with h_δ^B for a fixed B [e.g., fixing $2\alpha(B)=1$]. Since this homogeneity property is not valid anymore for our other two effective Hamiltonians, we prefer not to do this here (contrary to our earlier papers[6]), in order to have a coherent presentation.) Earlier, Ref. 14 had shown that the ground state of the Hartree mean-field model associated to (16) approximates the quantum mechanical ground state energy in the so-called hyperstrong limit Z, $B/Z^3 \to \infty$, assuming N/Z uniformly bounded. The idea that a model such as the δ-model could be relevant in the context of strong magnetic fields is not new in the physics literature, see, e.g., Ref. 19.

We next turn to the effects of particle symmetry. Electrons in physical atoms are fermions, and we now consider the analogues of Theorems 1.1, 1.3, and 1.5 for H^B restricted to the fermionic subspace $\mathcal{H}_\mathrm{f}=P^{AS}(\mathcal{H})$, where P^{AS} is the orthogonal projection onto the subspace of antisymmetric symmetric wave functions defined by

$$P^{\mathrm{AS}}\psi(r_1,s_1;\ldots;r_N,s_N) := \frac{1}{N!}\sum_{\sigma\in S_N}(-1)^\sigma\psi(r_{\sigma(1)},s_{\sigma(1)};\ldots;r_{\sigma(N)},s_{\sigma(N)}),$$

with $(-1)^\sigma := (-1)^{\mathrm{sgn}(\sigma)}$. The projection P^{AS} commutes with H^B, $\mathbb{L}_z$, $\mathbb{S}_z$ and with the N-particle Landau Hamiltonian H_0^B defined in (24) below, and therefore also with $\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$ (see Sec. II). Recalling that we have fixed our spins to $\mathbb{S}_z=-NB/2$, P^{AS} for us will only act in the spatial variables $(r_1,\ldots,r_N)$. Let $H_\mathrm{f}^{B,\mathbb{M}} := P^{\mathrm{AS}}H^{B,\mathbb{M}}P^{\mathrm{AS}}=H^{B,\mathbb{M}}P^{\mathrm{AS}}$ the fermionic Pauli operator with z-angular momentum $\mathbb{M}$. Similarly, introduce fermionized versions of the other operators: $\Pi_{\mathrm{eff,f}}^{B,\mathbb{M}} := P^{\mathrm{AS}}\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$, $\Pi_{\perp,\mathrm{f}}^{B,\mathbb{M}} := P^{\mathrm{AS}}\Pi_{\perp}^{B,\mathbb{M}}$, $H_{\mathrm{eff,f}}^{B,\mathbb{M}} := P^{AS}H_{\mathrm{eff}}^{B,\mathbb{M}}=P^{AS}h_{\mathrm{eff}}^{B,\mathbb{M}}\oplus H_{\perp,\mathrm{f}}^{B,\mathbb{M}} := h_{\mathrm{eff,f}}^{B,\mathbb{M}}\oplus H_{\perp,\mathrm{f}}^{B,\mathbb{M}}$, $h_{C,\mathrm{f}}^{B,\mathbb{M}}=P^{AS}h_C^{B,\mathbb{M}}$, $h_{\delta,\mathrm{f}}^{B} := P^{AS}h_\delta^B$, $H_{C,\mathrm{f}}^{B,\mathbb{M}}=P^{AS}H_C^{B,\mathbb{M}}$ and finally $H_{\delta,\mathrm{f}}^{B,\mathbb{M}} := P^{AS}H_\delta^{B,\mathbb{M}}$. A careful examination of the proofs of Theorems 1.1, 1.3, and 1.5 will show the following.

Theorem 1.6: *Theorems 1.1, 1.3, and 1.5 also hold true for the fermionized operators. For example, if ξ satisfies the conditions of Theorem 1.1 with $d_{\mathrm{eff}}(\xi)$ replaced by $d_{\mathrm{eff,f}}(\xi) := \mathrm{dist}(\xi,\sigma(h_{\mathrm{eff,f}}^{B,\mathbb{M}}))$, then*

$$\|(H_\mathrm{f}^{B,\mathbb{M}}-\xi)^{-1}-(H_{\mathrm{eff,f}}^{B,\mathbb{M}}-\xi)^{-1}\| \leqslant C_{\mathrm{eff}}\frac{\alpha(B)^2}{d_{\mathrm{eff,f}}(\xi)^2\sqrt{B}}, \tag{21}$$

with the same constants as before. Similarly for $H_{C,\mathrm{f}}^{B,\mathbb{M}}$, $H_{\delta,\mathrm{f}}^{B,\mathbb{M}}$.

Remark 1.7: Theorem 1.6 is not simply obtained by "sandwiching" Theorems 1.1, 1.3, and 1.5 between P^{AS}, since the statements thus obtained would not involve the distances to the spectra of the fermionized operators. Also, we established the fermionic versions with the same constants as for the boltzonic ones, but it is conceivable that one could have smaller constants in the fermionic case.

The operators $h_{\mathrm{eff,f}}^{B,\mathbb{M}}$ and $h_{C,\mathrm{f}}^{B,\mathbb{M}}$ are easily described

$$h_{\mathrm{eff,f}}^{B,\mathbb{M}} = -\frac{1}{2}\Delta - Z\sum_{j=1}^{N}V_{\mathrm{av};1}^{B,\mathbb{M}}(z_j)+\sum_{j<k}V_{\mathrm{av}:2}^{B,\mathbb{M}}(z_j-z_k), \tag{22}$$

where, using the notation of (10),

$$V_{\mathrm{av}:1}^{B,\mathbb{M}}(z) := \frac{1}{N}\sum_j V_j^{B,\mathbb{M}}(z),$$

and

$$V_{\mathrm{av}:2}^{B,\mathbb{M}}(z) := \binom{N}{2}^{-1}\sum_{j<k}V_{jk}^{B,\mathbb{M}}(z),$$

the average one-, respectively, two-particle potentials. Similarly, $h_{C,\mathrm{f}}^{B,\mathbb{M}}$ equals

$$h_{C,\mathrm{f}}^{B,\mathbb{M}} = -\frac{1}{2}\Delta - Z\sum_{j=1}^{N}(q^B(z_j)+C_{\mathrm{av}:1}^{b,B,\mathbb{M}}\delta(z_j))+\sum_{j<k}(q^B(z_j-z_k)+C_{\mathrm{av}:2}^{e,B,\mathbb{M}}\delta(z_j-z_k)), \tag{23}$$

with

$$C^{n,B,\mathbb{M}}_{\mathrm{av:1}} := \frac{1}{N}\sum_{j=1}^{N} C^{n,B,\mathbb{M}}_{j}$$

and

$$C^{e,B,\mathbb{M}}_{\mathrm{av:2}} := \binom{N}{2}^{-1} \sum_{j<k} C^{e,B,\mathbb{M}}_{jk},$$

while $h^{B,\mathbb{M}}_{\delta,\mathrm{f}}$ is given by the same expression as h^{B}_{δ}, except of course that its domain changes.

To complete the picture, we finish with an explicit description of $\mathrm{Ran}(\Pi^{B,\mathbb{M}}_{\mathrm{eff,f}})$, which is equal to $P^{\mathrm{AS}}(\mathrm{Ran}\,\Pi^{B,\mathbb{M}}_{\mathrm{eff}}) = P^{AS}(L^2(\mathbb{R}^N)\otimes F^{B}_{\mathbb{M}})$. Fix $\mathbb{M}\geqslant 0$, and let

$$\Sigma(\mathbb{M}) = \{m \in \mathbb{N}^N : |m| = \mathbb{M}\},$$

the set of partitions of $\mathbb{M}$, where, as usual, $|m| = m_1 + \ldots + m_N$ if $m = (m_1, \ldots, m_N)$. The vector space $F^{B}_{\mathbb{M}}$ is spanned by the lowest Landau (generalized) eigenstates indexed by $m \in \Sigma(\mathbb{M})$, cf. Sec. II below. The symmetric group S_N acts on $\Sigma(\mathbb{M})$ in the natural way, by permuting the indices of an element $m = (m_1, \ldots, m_N)$ of $\Sigma(\mathbb{M})$. Under this action, $\Sigma(\mathbb{M})$ will decompose as a finite union of disjoint orbits,

$$\Sigma(\mathbb{M}) = \bigcup_{\bar{m}\in\mathcal{M}} S_N \cdot \bar{m},$$

$\mathcal{M}$ being a set of representatives of the orbits. If $G_{\bar{m}}$ denotes the stabilizer of $\bar{m} \in \mathcal{M}$, then we write $\mathcal{M}$ as a disjoint union $\mathcal{M} = \mathcal{M}_1 \cup \mathcal{M}_2$, with $\mathcal{M}_1$ the subset of those $\bar{m} \in \mathcal{M}$ such that $G_{\bar{m}} = \{e\}$, and $\mathcal{M}_2 = \mathcal{M}\setminus\mathcal{M}_1$, its complement. In other words, $\bar{m} \in \mathcal{M}_1$ iff no two components of $\bar{m}$ are the same, and $\bar{m} \in \mathcal{M}_2$ iff at least two of its components are identical. Let $L^2_{\mathrm{AS}}(\mathbb{R}^N)$ be the space of anitsymmetrical wave functions in $L^2(\mathbb{R}^N)$. We then will prove, in Sec. VIII, the following.

Theorem 1.8: *There is a natural unitary isomorphism*

$$U^{B}_{\mathbb{M}} : \mathrm{Ran}(\Pi^{B,\mathbb{M}}_{\mathrm{eff,f}}) \to \overset{\oplus}{\sum_{\bar{m}\in\mathcal{M}_1}} L^2(\mathbb{R}^N) \oplus \overset{\oplus}{\sum_{\bar{m}\in\mathcal{M}_2}} L^2_{AS}(\mathbb{R}^N)$$

and

$$U^{B}_{\mathbb{M}} h^{B,\mathbb{M}}_{\delta,\mathrm{f}} U^{B*}_{\mathbb{M}} = \overset{\oplus}{\sum_{\bar{m}\in\mathcal{M}_1}} h^{B}_{\delta}|_{L^2(\mathbb{R}^N)} \oplus \overset{\oplus}{\sum_{\bar{m}\in\mathcal{M}_2}} h^{B}_{\delta}|_{L^2_{AS}(\mathbb{R}^N)}.$$

Remark 1.9: The operators $U^{B}_{\mathbb{M}} h^{B,\mathbb{M}}_{C,\mathrm{f}} U^{B*}_{\mathbb{M}}$ and $U^{B}_{\mathbb{M}} h^{B,\mathbb{M}}_{\mathrm{eff,f}} U^{B*}_{\mathbb{M}}$ can mix different components of $\mathrm{Ran}(U^{B}_{\mathbb{M}})$, as we will see at the end of Sec. VIII, and will therefore have a more complicated structure.

The paper is organized as follows. Section II contains the precise definition of our effective projector $\Pi^{B,\mathbb{M}}_{\mathrm{eff}}$. In Sec. III we establish, with the help of the Feshbach decomposition, a first approximation theorem, comparing $H^{B,\mathbb{M}}$'s resolvent at ξ with that of $H^{B,\mathbb{M}}_{\mathrm{eff}} + \mathcal{W}^{B,\mathbb{M}}(\xi)$, where the last term is an auxiliary potential which itself depends on the spectral parameters ξ. Section IV analyzes the large-B behavior of the potential of $H^{B,\mathbb{M}}_{\mathrm{eff}}$, as well as that of $\mathcal{W}^{B,\mathbb{M}}$. Sections V–VII are devoted to the proofs of, respectively, Theorems 1.1, 1.3, and 1.5. In Sec. VIII we prove Theorems 1.6 and 1.8. Section IX, finally, concludes with some applications to the spectral theory of $H^{B,\mathbb{M}}$, and some general observations.

Convention on constants: In the course of this work, we have had to introduce a large number of constants. To keep track of them, we will use the convention that whenever the subscript of a constant is a number, the number refers to the formula where the constant in question was first introduced. That is, $C_{(x)} :=$ constant defined in formula (x).

II. NONINTERACTING ELECTRONS AND THE LOWEST LANDAU BAND

We begin by reviewing the spectral decomposition of

$$H_0^B := H_0^B(N) := \sum_{j=1}^{N} \frac{1}{2}\left(\left(\frac{1}{i}\nabla_{r_j} - \frac{1}{2}\mathbb{B}\wedge r_j\right)^2 - NB\right), \tag{24}$$

the "free" Hamiltonian of N independent electrons interacting only with the field $\mathbb{B}$. Recall that we have fixed all electron spins in their $s_{z_j}=-1$ state. The operator H_0^B is just a direct sum of N one-particle operators $\frac{1}{2}\left((i^{-1}\nabla_r - \frac{1}{2}\mathbb{B}\wedge r)^2 - B\right)$, whose spectral decomposition is explicitly known,

$$\oplus_{m\in\mathbb{Z},n\in\mathbb{N}}\left(\frac{1}{2}p_z^2 + \frac{B}{2}(2n+|m|-m)\right)\Pi_{m,n}^B.$$

Here, p_z is the momentum in the field direction, and $\Pi_{m,n}^B$ is the projection, in the x,y variables, onto the normalized eigenfunctions $\chi_{m,n}^B=\chi_{m,n}^B(x,y)\in L^2(\mathbb{R}^2)$ of the operator

$$-\frac{1}{2}\Delta_{x,y} + \frac{B^2}{8}(x^2+y^2) - \frac{B}{2},$$

restricted to the m-eigenspace of $L_z=xp_y-yp_x$, the angular momentum in the field direction. These eigenfunctions are explicitly known in terms of Laguerre functions, see, e.g., Ref. 10, but for our purposes we will only need those with $n=0$, $m\geqslant 0$. These have a particularly simple expression: if (ρ,φ) are polar coordinates in the x,y plane, then

$$\chi_m^B := \chi_{m,0}^B:(x,y) \to \left(\frac{B^{m+1}}{2\pi 2^m m!}\right)^{1/2}\rho^m e^{+im\varphi}e^{-B\rho^2/4}. \tag{25}$$

The spectral decomposition of H_0^B is simply the sum of the one-particle decompositions, and the projections onto its eigenstates will be indexed by N-tuples $m=(m_1,\ldots,m_N)\in\mathbb{Z}^N$, $n=(n_1,\ldots n_N)\in\mathbb{N}^N$. If we let

$$\Pi_{m,n}^B := \Pi_{m_1,n_1}^B \otimes \cdots \otimes \Pi_{m_N,n_N},$$

then

$$H_0^B = \oplus_{m,n}\left(\sum_{j=1}^{N}\frac{1}{2}p_{z_j}^2 + \frac{B}{2}(2n_j+|m_j|-m_j)\right)\Pi_{m,n}^B. \tag{26}$$

The lowest Landau band of H_0^B is defined as

$$\mathcal{L}_0^B = \oplus_{m\in\mathbb{Z}_+^N}\mathrm{Ran}\,\Pi_{m,0}^B, \tag{27}$$

where $\mathbf{0}:=(0,\ldots,0)$, and if we set

$$X_m^B(x,y) := \prod_{j=1}^{N}\chi_{m_j}^B(x_j,y_j), \quad m_1,\ldots,m_N\geqslant 0, \tag{28}$$

then $\mathcal{L}_0$ will be spanned by the tensor products $X_m^B\otimes u$, with $u=u(z)\in L^2(\mathbb{R}^N)$. We will call the X_m^B the lowest Landau band states (these are not eigenvectors of H_0^B, but $X_m^B\otimes 1$ would be generalized eigenvectors with eigenvalue 0). The operator H_0^B restricted to $\mathcal{L}_0^B$ simply is the free Laplacian in the field direction,

$$\frac{1}{2}\sum_j p_{z_j}^2 = -\frac{1}{2}\Delta_z,$$

where $z=(z_1,\ldots,z_N)$.

We next reduce the Hamiltonian H^B and H_0^B to their angular momentum sectors with respect to the field direction. The total orbital angular momentum in the direction of $\mathbb{B}=(0,0,B)$,

$$\mathbb{L}_z = \sum_j (x_j p_{y_j} - y_j p_{x_j}), \quad (p_x,p_y,p_z) = \frac{1}{i}\nabla_r,$$

commutes with H^B and H_0^B, and is therefore a constant of motion for both Hamiltonians. If $P^{\mathbb{M}}$ is the orthogonal projection onto the $\mathbb{M}$th eigenspace of $\mathbb{L}_z$, then we let

$$H^{B,\mathbb{M}} := H^B P^{\mathbb{M}}, \quad H_0^{B,\mathbb{M}} := H_0^B P^{\mathbb{M}} \tag{29}$$

acting on $\mathcal{H} := L^2(\mathbb{R}^{3N}) \otimes \mathbb{C}^{2N}$. Since we are primarily interested in the spectral behavior of H^B near the bottom of its spectrum, we will restrict $\mathbb{M}$ to $\mathbb{Z}_+$, for $\mathcal{L}_0^B \cap \mathrm{Ran}\, P^{\mathbb{M}} \neq \{0\} \Leftrightarrow \mathbb{M} \geqslant 0$. Indeed, notice that since $H^{B,-\mathbb{M}}$ is unitarily equivalent to $H^{B,\mathbb{M}} + \mathbb{M}B$, one has $\inf \sigma(H^B|_{\mathbb{M}\geqslant 0}) < \inf \sigma(H^B|_{\mathbb{M}<0})$ as soon as $B>0$.

We next let

$$\Sigma(\mathbb{M}) = \{m=(m_1,\ldots,m_N) \in \mathbb{Z}^N : m_j \geqslant 0,\ m_1+\cdots+m_N = \mathbb{M}\}, \tag{30}$$

the set of partitions of $\mathbb{M}$, and define the *effective projection* $\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$ by

$$\Pi_{\mathrm{eff}}^{B,\mathbb{M}} := \sum_{m\in\Sigma(\mathbb{M})} \Pi_{m,0}^B. \tag{31}$$

This is simply the orthogonal projection onto $\mathcal{L}_0 \cap (\mathbb{L}_z = \mathbb{M}\}$. We also let $\Pi_\perp^{B,\mathbb{M}}$ be the orthogonal projection onto the orthogonal complement of $\mathrm{Ran}(\Pi_{\mathrm{eff}}^{B,\mathbb{M}})$ in $\mathrm{Ran}(P^{\mathbb{M}})$. Observe that

$$\Pi_\perp^{B,\mathbb{M}} = \bigoplus_{\substack{m_1+\cdots+m_N=\mathbb{M},\\ \Sigma_j 2n_j+|m_j|-m_j\geqslant 2}} \Pi_{m,n}.$$

If we let $F_{\mathbb{M}}^B$ be the finite-dimensional vector space spanned by the lowest Landau states with total angular momentum $\mathbb{M}$,

$$F_{\mathbb{M}}^B := \mathrm{Span}\{X_m^B : m \in \Sigma(\mathbb{M})\}, \tag{32}$$

then we can identify the range of $\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$ with the space $L^2(\mathbb{R}^N, F_{\mathbb{M}}^B)$ of $F_{\mathbb{M}}^B$-valued L^2-functions, as we will do without further comment.

To lighten the notations, we will often suppress one or both upper indices B or $\mathbb{M}$, unless where this would cause confusion. This will always be clearly indicated, usually at the beginning of a section.

III. ESTIMATES FOR FESHBACH DECOMPOSITIONS

We fix a non-negative integer $\mathbb{M} \geqslant 0$. In this section we will drop all upper-indices B, $\mathbb{M}$, and simply write H for $H^{B,\mathbb{M}}$, H_0 for $H_0^{B,\mathbb{M}}$ and Π_{eff}, respectively, $\Pi_\perp$ for $\Pi_{\mathrm{eff}}^{B,\mathbb{M}}$ and $\Pi_\perp^{B,\mathbb{M}}$. We write our atomic Hamiltonian $H^{B,\mathbb{M}}$ as

$$H = H_0 + \mathcal{V},$$

where

$$\mathcal{V} := -\sum_j \frac{Z}{|r_j|} + \sum_{j<k} \frac{1}{|r_j - r_k|}, \tag{33}$$

is the electrostatic potential, and introduce the operators

$$\mathcal{V}_{\text{eff}} := \Pi_{\text{eff}} \mathcal{V} \Pi_{\text{eff}}, \quad \mathcal{V}_\perp := \Pi_\perp \mathcal{V} \Pi_\perp, \quad \mathcal{V}_{\perp,\text{eff}} := \Pi_\perp \mathcal{V} \Pi_{\text{eff}},$$

and its adjoint, $\mathcal{V}_{\text{eff},\perp} = \Pi_{\text{eff}} \mathcal{V} \Pi_\perp$. These are to be considered as operators on Ran Π_{eff}, Ran $\Pi_\perp$, and between these two Hilbert spaces, respectively. We furthermore set

$$h_{\text{eff}} := \Pi_{\text{eff}} H \Pi_{\text{eff}}, \quad H_\perp := \Pi_\perp H \Pi_\perp, \quad H_{\perp,\text{eff}} := \Pi_\perp H \Pi_{\text{eff}} = H^*_{\text{eff},\perp},$$

and for $\xi \in \mathbb{C}$ introduce the resolvents (wherever defined)

$$R := R(\xi) := (H_\perp - \xi)^{-1}, \quad R^{\mathcal{W}}_{\text{eff}} := R^{\mathcal{W}}_{\text{eff}}(\xi) := (h_{\text{eff}} + \mathcal{W}(\xi) - \xi)^{-1},$$

where

$$\mathcal{W} := \mathcal{W}(\xi) = -\mathcal{V}_{\text{eff},\perp} R(\xi) \mathcal{V}_{\perp,\text{eff}}.$$

Strictly speaking $R^{\mathcal{W}}_{\text{eff}}$ is not a resolvent since the potential $\mathcal{W}(\xi)$ depends on the spectral parameter ξ. The operators R and $R^{\mathcal{W}}_{\text{eff}}$ act on, respectively, the ranges of $\Pi_\perp$ and of Π_{eff}. Finally, let

$$T := H_0 P^{\mathbb{M}}, \quad T_{\text{eff}} := \Pi_{\text{eff}} T \Pi_{\text{eff}}, \quad T_\perp := \Pi_\perp T \Pi_\perp;$$

T commutes with Π_{eff} and $\Pi_\perp$, and $\Pi_\perp T \Pi_{\text{eff}} = 0$. Note that

$$T_\perp \geqslant B \Pi_\perp,$$

on the range of $P^{\mathbb{M}}$.

Using matrix notation associated to the decomposition $P^{\mathbb{M}}\mathcal{H} = \text{Ran}\, \Pi_{\text{eff}} \oplus \text{Ran}\, \Pi_\perp$, we decompose H as

$$H = \begin{pmatrix} h_{\text{eff}} & H_{\text{eff},\perp} \\ H_{\perp,\text{eff}} & H_\perp \end{pmatrix} = \begin{pmatrix} T_{\text{eff}} + \mathcal{V}_{\text{eff}} & \mathcal{V}_{\text{eff},\perp} \\ \mathcal{V}_{\perp,\text{eff}} & T^{\mathcal{B}}_\perp + \mathcal{V}_\perp \end{pmatrix}. \tag{34}$$

By the classical Feshbach formula, we then have

$$(H - \xi)^{-1} = \begin{pmatrix} R^{\mathcal{W}}_{\text{eff}} & -R^{\mathcal{W}}_{\text{eff}} \mathcal{V}_{\text{eff},\perp} R \\ -R \mathcal{V}_{\perp,\text{eff}} R^{\mathcal{W}}_{\text{eff}} & R + R \mathcal{V}_{\perp,\text{eff}} R^{\mathcal{W}}_{\text{eff}} \mathcal{V}_{\text{eff},\perp} R \end{pmatrix}, \tag{35}$$

for those $\xi \in \mathbb{C}$ for which the right-hand side makes sense. The following theorem is the main result of this section: recall that $\rho(A)$ denotes the resolvent set of an operator A, and $\sigma(A)$ its spectrum.

Theorem 3.1: *Let*

$$B_{(36)} := 16 Z^2 N (\mathbb{M} + N + 2) \tag{36}$$

and

$$C_{(37)} := c_0 + \frac{c_0^2}{\sqrt{B_{(36)}}}, \quad c_0^2 = (32 Z^2 N + 8 N (N-1)^2)(\mathbb{M} + N + 2). \tag{37}$$

If $\xi \leqslant 0$ *and if the field strength* $B \geqslant B_{(36)}$, *then* $\xi \in \rho(H_\perp)$. *If, moreover,* $\xi \notin \sigma(H_{\text{eff}} + \mathcal{W})$, *then* $\xi \in \rho(H)$, *and*

$$\left\| (H - \xi)^{-1} - (h_{\text{eff}} + \mathcal{W} - \xi)^{-1} \oplus R(\xi) \right\| \leqslant \frac{C_{(37)}}{d^{\mathcal{W}}_{\text{eff}}(\xi) \sqrt{B}}, \tag{38}$$

where $d_{\mathrm{eff}}^{\mathcal{W}}(\xi)$ *is the distance of* ξ *to* $\sigma(h_{\mathrm{eff}}+\mathcal{W})$.

Proof of Theorem 3.1: The proof consists of estimating the relevant matrix elements in the Feshbach formula. This will be done in several steps. Let

$$R_0 = (T_\perp - \xi)^{-1},$$

the resolvent of $T_\perp$ on $\mathrm{Ran}\,\Pi_\perp$.

Bound on R_0: Since $T_\perp \geqslant B$ on $\mathrm{Ran}\,\Pi_\perp$ and since $\xi \leqslant 0$, it immediately follows that $\|R_0\| \leqslant B^{-1}$. Write $\mathcal{V}$ as

$$\mathcal{V} = \mathcal{V}_n + \mathcal{V}_e, \quad \text{where } \mathcal{V}_n := -\sum_j \frac{Z}{|r_j|}, \quad \text{and } \mathcal{V}_e := \sum_{j<k} \frac{1}{|r_j - r_k|}, \tag{39}$$

the sum of electron-nucleus and the electron-electron interactions.

A remark on notation: we will often leave the projection $\Pi_\perp$ understood when multiplying operators on the left and/or right by R_0 or R, and for example, simply write $R_0^{1/2}\mathcal{V}_n R_0^{1/2}$ instead of the more explicit $R_0^{1/2}\Pi_\perp \mathcal{V}_n \Pi_\perp R_0^{1/2}$.

Bound on $R_0^{1/2}\mathcal{V}_n R_0^{1/2}$. First, since $R_0 \leqslant B^{-1}$ on the range of $\Pi_\perp$,

$$0 \leqslant (\sqrt{R_0}\mathcal{V}_n\sqrt{R_0})^2 \leqslant B^{-1}\sqrt{R_0}\mathcal{V}_n^2\sqrt{R_0}.$$

By Cauchy-Schwarz,

$$\sqrt{R_0}\mathcal{V}_n^2\sqrt{R_0} \leqslant Z^2 N \sqrt{R_0}\sum_j |r_j|^{-2}\sqrt{R_0}.$$

Next, using Hardy's inequality on $\mathbb{R}^3$: $|r_j|^{-2} \leqslant -4\Delta_j$, and the fact that

$$H_0^B = \sum_j -\frac{1}{2}\Delta_j + \frac{1}{8}|\mathbb{B}\wedge r_j|^2 - \frac{B}{2}(\mathbb{L}_z + N),$$

we find that

$$\sqrt{R_0}\left(\sum_j |r_j|^{-2}\right)\sqrt{R_0} \leqslant 8\sqrt{R_0}\sum_j\left(-\frac{\Delta_j}{2} + \frac{|\mathbb{B}\wedge r_j|^2}{8}\right)\sqrt{R_0} = 8\sqrt{R_0}\left(T_\perp + \frac{B}{2}(\mathbb{M}+N)\right)\sqrt{R_0} = 8\Pi_\perp + 8\xi R_0$$
$$+ 4(\mathbb{M}+N)BR_0 \leqslant (8 + 4(\mathbb{M}+N))\Pi_\perp,$$

since $\xi \leqslant 0$. It follows from these estimates that

$$\|R_0^{1/2}\mathcal{V}_n R_0^{1/2}\| \leqslant 2ZB^{-1/2}\sqrt{N(\mathbb{M}+N+2)}.$$

We note, as a consequence, that if $b_0 = 4Z^2N(\mathbb{M}+N+2)$, then $\|R_0^{1/2}\mathcal{V}_n R_0^{1/2}\| \leqslant (b_0 B^{-1})^{1/2} < 1$ if $B > b_0$. For later reference we also note the following.

Bound on $R_0^{1/2}\mathcal{V}_n^2 R_0^{1/2}$: the estimates above immediately imply that this positive operator is bounded from above by $4Z^2N(\mathbb{M}+N+2)$.

Existence of and bound on R: Since the electron-electron repulsion $\mathcal{V}_e \geqslant 0$, it follows that $R \leqslant R_{\mathrm{NI}}$, where $R_{\mathrm{NI}} = (T_\perp + \mathcal{V}_{n,\perp} - \xi)^{-1}$, the resolvent of an atom with noninteracting electrons. Using the symmetrized resolvent formula,

$$R_{\mathrm{NI}} = \sqrt{R_0}(1 + \sqrt{R_0}\mathcal{V}_n\sqrt{R_0})^{-1}\sqrt{R_0}, \tag{40}$$

we see that R_{NI} exists and is positive if $B > b_0$ and $\xi \leqslant 0$. Hence $T_\perp + \mathcal{V}_{n,\perp} - \xi \geqslant 0$ and therefore also $H_\perp - \xi$ and R. Moreover, if $B > 4b_0 = 16Z^2N(\mathbb{M}+N+2) = B_{(36)}$, then every $\xi \leqslant 0$ belongs to $\rho(H_\perp)$ and

$$0 \leqslant R \leqslant \frac{\|R_0\|}{1-\|R_0^{1/2}\mathcal{V}_n R_0^{1/2}\|} \leqslant B^{-1}\left(\frac{1}{1-(b_0 B^{-1})^{1/2}}\right) \leqslant 2B^{-1}.$$

Bound on $R_0^{1/2}\mathcal{V}_e^2 R_0^{1/2}$: The following elementary operator inequality is very useful to estimate the electron-electron interactions.

Lemma 3.2:

$$\frac{1}{|r_j - r_k|^2} \leqslant 2(-\Delta_j - \Delta_k). \tag{41}$$

Proof: The unitary transformation induced by the following orthogonal transformation of $\mathbb{R}^3 \times \mathbb{R}^3$:

$$s := \frac{r_1 - r_2}{\sqrt{2}}, \quad t := \frac{r_1 + r_2}{\sqrt{2}} \tag{42}$$

commutes with the Laplacian, and transforms $|r_j - r_k|^{-2}$ into $2^{-1}|s|^{-2}$. By Hardy's inequality,

$$\frac{1}{2|s|^2} \leqslant -2\Delta_s \leqslant -2(\Delta_s + \Delta_t),$$

and transforming back to the (r_j, r_k)-coordinates yields (41). Q.E.D.

We can then estimate

$$\mathcal{V}_e^2 = \left(\sum_{i<j}\frac{1}{|r_i - r_j|}\right)^2 \leqslant \frac{N(N-1)}{2}\sum_{i<j}\frac{1}{|r_i - r_j|^2} \leqslant N(N-1)\sum_{i<j}(-\Delta_i - \Delta_j) = N(N-1)^2\sum_i(-\Delta_i)$$
$$\leqslant 2N(N-1)^2\sum_i\left(-\frac{\Delta_i}{2} + \frac{|\mathbb{B}\wedge r_j|^2}{8}\right),$$

and therefore, by similar arguments as before,

$$\sqrt{R_0}\mathcal{V}_e^2\sqrt{R_0} \leqslant 2N(N-1)^2\sqrt{R_0}\left(T_\perp + \frac{B}{2}(\mathbb{M}+N)\right)\sqrt{R_0} \leqslant N(N-1)^2(\mathbb{M}+N+2),$$

on $\mathrm{Ran}(\Pi_\perp)$.

Bound on $\mathcal{V}R_0^{1/2}$: By the general identity $\|AA^*\| = \|A\|^2$, we have

$$\|\mathcal{V}R_0^{1/2}\|^2 = \|R_0^{1/2}\mathcal{V}^2 R_0^{1/2}\| \leqslant 2(\|R_0^{1/2}\mathcal{V}_n^2 R_0^{1/2}\| + \|R_0^{1/2}\mathcal{V}_e^2 R_0^{1/2}\|) \leqslant (8Z^2N + 2N(N-1)^2)(\mathbb{M}+N+2).$$

Bound on $\mathcal{V}_{\mathrm{eff},\perp}R^{1/2}$: (Remember that we have shown that $R \geqslant 0$, so its square root is well-defined.) We first estimate $\|\mathcal{V}R\mathcal{V}\|$, as follows. Recalling the noninteracting resolvent R_{NI} introduced above, we have that

$$0 \leqslant \mathcal{V}R\mathcal{V} \leqslant \mathcal{V}R_{\mathrm{NI}}\mathcal{V} = \mathcal{V}R_0^{1/2}(1 + R_0^{1/2}\mathcal{V}_n R_0^{1/2})^{-1}R_0^{1/2}\mathcal{V}.$$

Hence its norm can be estimated by

$$\|\mathcal{V}R\mathcal{V}\| \leqslant \frac{\|\mathcal{V}R_0^{1/2}\|^2}{1-\|R_0^{1/2}\mathcal{V}_n R_0^{1/2}\|},$$

from which we obtain an estimate for $\|\mathcal{V}R^{1/2}\|$ by taking square roots. Therefore, if $B \geqslant B_{(36)} = 4b_0$ as above,

$$\|\mathcal{V}_{\mathrm{eff},\perp}R^{1/2}\| \leqslant \|\mathcal{V}R^{1/2}\| \leqslant \sqrt{(16Z^2N + 4N(N-1)^2)(\mathbb{M}+N+2)}.$$

We now come to the proof of (38). By Feshbach's formula, we have

$$\|(H-\xi)^{-1}-R_{\mathrm{eff}}^{\mathcal{W}}\oplus R(\xi)\| = \left\| \begin{pmatrix} 0 & -R_{\mathrm{eff}}^{\mathcal{W}}\mathcal{V}_{\mathrm{eff},\perp}R \\ -R\mathcal{V}_{\perp,\mathrm{eff}}R_{\mathrm{eff}}^{\mathcal{W}} & R\mathcal{V}_{\perp,\mathrm{eff}}R_{\mathrm{eff}}^{\mathcal{W}}\mathcal{V}_{\mathrm{eff},\perp}R \end{pmatrix} \right\| \leqslant \|R_{\mathrm{eff}}^{\mathcal{W}}\mathcal{V}_{\mathrm{eff},\perp}R\| + \|R\mathcal{V}_{\perp,\mathrm{eff}}R_{\mathrm{eff}}^{\mathcal{W}}\mathcal{V}_{\mathrm{eff},\perp}R\| \leqslant \|R_{\mathrm{eff}}^{\mathcal{W}}\|\|\mathcal{V}_{\mathrm{eff},\perp}R^{1/2}\|\|R^{1/2}\| + \|R_{\mathrm{eff}}^{\mathcal{W}}\| \times \|\mathcal{V}_{\mathrm{eff},\perp}R^{1/2}\|^2\|R^{1/2}\|^2, \tag{43}$$

where we have used the following elementary estimate for the norm of matrices of operators:

$$\left\| \begin{pmatrix} 0 & A \\ A^* & B \end{pmatrix} \right\| \leqslant \|A\| + \|B\|.$$

Hence if $B > B_{(36)}$ and if $\xi \notin \sigma(R_{\mathrm{eff}}^{\mathcal{W}})$, we obtain

$$\|(H-\xi)^{-1}-R_{\mathrm{eff}}^{\mathcal{W}}\oplus R(\xi)\| \leqslant \frac{1}{d_{\mathrm{eff}}^{\mathcal{W}}(\xi)}\left(\frac{\sqrt{2}\|\mathcal{V}R^{1/2}\|}{\sqrt{B}} + \frac{2\|\mathcal{V}R^{1/2}\|^2}{B}\right) \leqslant \frac{1}{d_{\mathrm{eff}}^{\mathcal{W}}(\xi)B^{1/2}}\left(c_0 + \frac{c_0^2}{\sqrt{B_{(36)}}}\right),$$

with $c_0^2=(32Z^2N+8N(N-1)^2)(\mathbb{M}+N+2)$. Q.E.D.

Corollary 3.3 (of the proof): Theorem 3.1 also holds, if we replace H and $h_{\mathrm{eff}}+\mathcal{W}$ *by their fermionized versions* H_f, $h_{\mathrm{eff},f}+\mathcal{W}_f$, *and* $d_{\mathrm{eff}}^{\mathcal{W}}(\xi)$ *by the distance of* ξ *to the spectrum of* $h_{\mathrm{eff},f}+\mathcal{W}_f$.

Proof: Simply write down the Feshbach's formula (35) for H_f with respect to the decomposition $I=\Pi_{\mathrm{eff},f}+\Pi_{\perp,f}$ of $\mathcal{H}_f$, and estimate as in (43), where all operators will now have a subindex f. Next use that P^{AS} commutes with everything, and trivially estimate $\|A_f\|=\|P^{AS}A\|\leqslant\|A\|$, for $A=R$, $R^{1/2}$ and $\mathcal{V}_{\mathrm{eff},\perp}R^{1/2}$, except for $\|R_{\mathrm{eff},f}^{\mathcal{W}}\|$, which will be estimated by 1 over the distance of ξ to the spectrum of $H_{\mathrm{eff},f}+\mathcal{W}_f$. Q.E.D.

The proof shows that in the fermionic case, Theorem 3.1 will at least be true with the same constants as for the boltzonic case. The optimal constants for fermions might be smaller, though.

Remark 3.4: In the proof of Theorem 3.1 we systematically used Hardy's inequality. Alternatively, one can use, at least when $N=1$, the bounds on the matrix elements of the Coulomb potential with respect to the Landau levels which were derived in Ref. 10.

IV. EFFECTIVE POTENTIALS FOR LARGE FIELDS

The operator $h_{\mathrm{eff}}+\mathcal{W}=h_{\mathrm{eff}}^{B,\mathbb{M}}+\mathcal{W}^{B,\mathbb{M}}$ of Theorem 3.1 acts on $\mathrm{Ran}(\Pi_{\mathrm{eff}}^{B,\mathbb{M}})=\Pi_{\mathrm{eff}}^{B,\mathbb{M}}(\mathcal{H})$, a Hilbert space which depends on both B and $\mathbb{M}$, and which is canonically isomorphic to the space of $F_{\mathbb{M}}^B$-valued L^2-functions on $\mathbb{R}^N$,

$$\mathrm{Ran}(\Pi_{\mathrm{eff}}^{B,\mathbb{M}}) = L^2(\mathbb{R}^N, F_{\mathbb{M}}^B). \tag{44}$$

(Recall that $F_{\mathbb{M}}^B=\mathrm{Span}\ \{X_m^B : m\in\Sigma(\mathbb{M})\}$.) We will mostly suppress the $\mathbb{M}$-dependence from our notations, $\mathbb{M}$ being fixed in our analysis. The potential term of h_{eff}^B,

$$\mathcal{V}_{\mathrm{eff}}^B = \Pi_{\mathrm{eff}}^B\mathcal{V}\Pi_{\mathrm{eff}}^B, \tag{45}$$

can be interpreted as an operator valued function of $z=(z_1,\ldots,z_N)\in\mathbb{R}^N$, with values in the space of linear operators on $F_{\mathbb{M}}^B$ and acting in the natural way on $L^2(\mathbb{R}_z^N;F_{\mathbb{M}}^B)$. To get rid of the B-dependence of our Hilbert spaces we do a unitary rescaling. Let us pose $x=(x_1,\ldots,x_N)\in\mathbb{R}^N$ and similarly for y and z. Define a unitary operator U_{xy}^B on $\mathcal{H}$ by

$$U_{xy}^B\psi(x,y,z) = B^{N/2}\psi(\sqrt{B}x,\sqrt{B}y,z). \tag{46}$$

Since $X_m^B(x,y)=B^{N/2}X_m^1(\sqrt{B}x,\sqrt{B}y)$, it follows that

$$U_{xy}^{B*}\Pi_{\mathrm{eff}}^B U_{xy}^B = \Pi_{\mathrm{eff}}^1.$$

Let us write $\mathcal{V}_{\mathrm{eff}}^B$ in multiparticle form,

$$\mathcal{V}^B_{\text{eff}} = -\sum_j ZV^B_j + \sum_{j<k} V^B_{jk}, \tag{47}$$

with V^B_j and V^B_{jk} defined by (10). Then $U^{B*}_{xy}V^B_j U^B_{xy} = \Pi^1_{\text{eff}} U^{B*}_{xy} |r_j|^{-1} U^B_{xy} \Pi^1_{\text{eff}} = \sqrt{B} V^1_j(\sqrt{B}z_j)$, with

$$V^1_j(z) = \Pi^1_{\text{eff}} \frac{1}{\sqrt{x_j^2 + y_j^2 + z^2}} \Pi^1_{\text{eff}}, \tag{48}$$

and likewise for V^B_{jk}: $U^{B*}_{xy}V^B_{jk}U^B_{xy}(z) = \sqrt{B}V^1_{jk}(\sqrt{B}(z_j - z_k))$, with

$$V^1_{jk}(z) = \Pi^1_{\text{eff}} \frac{1}{\sqrt{(x_j - x_k)^2 + (y_j - y_k)^2 + z^2}} \Pi^1_{\text{eff}}. \tag{49}$$

The operator

$$\hat{h}^B_{\text{eff}} := U^{B*}_{xy} H^{\text{B}}_{\text{eff}} U^B_{xy}, \tag{50}$$

will now act on the fixed, B-independent, Hilbert space, $L^2(\mathbb{R}^N, F^1_{\mathbb{M}})$, and

$$\hat{h}^B_{\text{eff}} = -\frac{1}{2}\Delta_z - \sum_j Z\sqrt{B}V^1_j(\sqrt{B}z_j) + \sum_{j<k} \sqrt{B}V^1_{jk}(\sqrt{B}(z_j - z_k)) = -\frac{1}{2}\Delta_z + \sqrt{B}\mathcal{V}^1_{\text{eff}}(\sqrt{B}z).$$

The next step will be to examine the asymptotic behavior of $\sqrt{B}\mathcal{V}^1_{\text{eff}}(\sqrt{B}z)$ as $B \to \infty$. The main idea is contained in Lemma 4.1 below. We introduce the free Laplacian on $\mathbb{R}^N$,

$$h_{00} = -\tfrac{1}{2}\Delta_z, \tag{51}$$

and its resolvent

$$R_{00}(-\alpha^2) = (h_{00} + \alpha^2)^{-1}. \tag{52}$$

We will need this resolvent both in dimension N and dimension 1. To distinguish between these two cases we will, in the one-dimensional case, systematically use β^2 as spectral parameter instead of α^2, reserving the latter for the multidimensional case.

If u is a function or tempered distribution on $\mathbb{R}^N$, with values in some auxiliary Hilbert space F, then $\|R_{00}(-\alpha^2)^{-s/2}u\|_{L^2(\mathbb{R}^N;F)}$ is a norm on the sth Sobolev space $H^s(\mathbb{R}^N;F)$. A linear operator A sends $H^s(\mathbb{R}^N;F)$ continuously into $H^{-s}(\mathbb{R}^N;F)$ iff the L^2-operator norm $\|R_{00}(-\alpha^2)^{s/2}AR_{00}(-\alpha^2)^{s/2}\|$ is finite. The case of interest for us will be $s=1$. We will also need the Fourier transform $\mathcal{F}$, but only in dimension 1, for which we normalize as follows:

$$\mathcal{F}(u)(\zeta) = \int_{\mathbb{R}} u(z)e^{-iz\zeta}\,\mathrm{d}z.$$

There will consequently be a factor of $(2\pi)^{-1}$ in the inversion formula.

Recall that

$$\text{Pf}\left(\frac{1}{|x|}\right) = \frac{\mathrm{d}}{\mathrm{d}x}(\text{sgn}(x)\log|x|),$$

with the derivative in distribution sense. Let F be a finite-dimensional complex Hilbert space, and $L(F)$ the space of linear operators on F.

Lemma 4.1: Let $\mathfrak{v}$ *be an* $L(F)$*-valued tempered distribution on* $\mathbb{R}$*, such that its Fourier transform can be identified with a locally integrable function* $\mathcal{F}\mathfrak{v} = \mathcal{F}\mathfrak{v}(\zeta)$*. Assume also the following:*

(i) *There exist* C_0, $C_1 \in L(F)$ *and* $a > 1/2$*, such that*

$$\mathcal{F}\mathfrak{v}(\zeta) = -C_0 \log|\zeta| + C_1 + O(|\zeta|^a), \quad \zeta \to 0. \tag{53}$$

(ii) *If*

$$\mathfrak{e}(\zeta) := \mathcal{F}\mathfrak{v}(\zeta) + C_0 \log|\zeta| - C_1,$$

denotes the error in the approximation (53), then

$$C_{\mathfrak{v}}^2 := \int_{\mathbb{R}} \frac{\|\mathfrak{e}(\zeta)\|^2}{|\zeta|^2} \mathrm{d}\zeta < \infty. \tag{54}$$

For each $\lambda > 0$ *let*

$$\mathfrak{v}_{\infty,\lambda} := C_0 \log \lambda \cdot \delta + \frac{1}{2} C_0 \cdot \mathrm{Pf}\left(\frac{1}{|x|}\right) + (\gamma C_0 + C_1) \cdot \delta, \tag{55}$$

where δ *is Dirac's delta distribution in 0, and* $\gamma = \Gamma'(1)$ *is the Euler constant. If* $R_{00}(-\beta^2)$ *denotes the free resolvent in dimension 1 and* $\beta > 0$, *then*

$$\|R_{00}(-\beta^2)^{1/2}(\lambda \mathfrak{v}(\lambda \cdot) - \mathfrak{v}_{\infty,\lambda})R_{00}(-\beta^2)^{1/2}\| \leqslant \frac{2^{1/4} C_{\mathfrak{v}}}{\sqrt{\beta \lambda \pi}}. \tag{56}$$

Remark: Observe that the integral (54) converges in 0, since we assumed that $a > 1/2$ in (53).
Proof: It is known that

$$\mathcal{F}^{-1}(\log|\zeta|) = -\frac{1}{2}\mathrm{Pf}\left(\frac{1}{|x|}\right) - \gamma\delta_0, \tag{57}$$

where γ is Euler's constant, cf., e.g., Ref. 17. [Equation (57) can also easily be shown directly, using the observation that $\mathrm{Pf}(1/|x|)$ and $-2\mathcal{F}^{-1}(\log|\zeta|)$ are both solutions of the distributional equation $x\Lambda = -\operatorname{sgn} x$ and therefore only differ by a multiple of δ, which can then be computed to be -2γ.] Therefore

$$\mathfrak{v}_{\infty,\lambda} = C_0(\log\lambda)\delta - C_0\mathcal{F}^{-1}(\log|\zeta|) + C_1\delta = \mathcal{F}^{-1}(-C_0 \log(|\zeta|/\lambda) + C_1),$$

and

$$\mathcal{F}(R_{00}(-\beta^2)^{1/2}(\lambda \mathfrak{v}(\lambda \cdot) - \mathfrak{v}_{\infty,\lambda})R_{00}(-\beta^2)^{1/2})\mathcal{F}^{-1}$$

is an integral operator with kernel

$$\frac{1}{2\pi}\frac{1}{(\zeta^2/2 + \beta^2)^{1/2}}\mathfrak{e}\left(\frac{\zeta - \zeta'}{\lambda}\right)\frac{1}{(\zeta'^2/2 + \beta^2)^{1/2}}, \tag{58}$$

since multiplication by a distribution $a(x)$ becomes an integral operator with kernel $(2\pi)^{-1}\mathcal{F}a(\zeta - \zeta')$ after conjugation by $\mathcal{F}$. Since conjugation by the Fourier transform does not change the operator norm, it follows that the norm in (56) can be bounded by the Hilbert-Schmidt norm of (58), whose square equals

$$\frac{1}{\pi^2}\int_{\mathbb{R}}\left(\int_{\mathbb{R}}\frac{1}{((\zeta-\eta)^2 + 2\beta^2)(\zeta^2 + 2\beta^2)}\mathrm{d}\zeta\right)\left|\mathfrak{e}\left(\frac{\eta}{\lambda}\right)\right|^2 \mathrm{d}\eta = \frac{\sqrt{2}}{\pi\beta}\int_{\mathbb{R}}\frac{|\mathfrak{e}(\eta/\lambda)|^2}{\eta^2 + 8\beta^2}\mathrm{d}\eta$$
$$= \frac{\sqrt{2}}{\pi\beta\lambda}\int_{\mathbb{R}}\frac{|\mathfrak{e}(\eta)|^2}{\eta^2 + (\beta^2/8\lambda^2)}\mathrm{d}\eta \leqslant \frac{C_{\mathfrak{v}}^2\sqrt{2}}{\pi\beta\lambda}.$$

Here we have used the elementary integral identity:

$$\int_{\mathbb{R}} \frac{1}{(a\zeta^2+b)(a(\zeta-\eta)^2+b)}\mathrm{d}\zeta = \frac{2\pi}{\sqrt{ab}}\frac{1}{a\eta^2+4b}, \tag{59}$$

where $a,b>0$. This finishes the proof of Lemma 4.1. Q.E.D.

We will apply the previous lemma to our potentials (10), but before doing so we first state and prove a weaker variant, which will be used to prove Theorem 1.1. Let us introduce the (numerical) constant,

$$C_{(60)} := \left(\frac{1}{4\pi}\int_{\mathbb{R}} \frac{(|\log|\eta|+2)^2}{\eta^2+4}\mathrm{d}\eta\right)^{1/2}. \tag{60}$$

Numerical evaluation of the integral (using either Mathematica or Maple 8) gives $C_{(60)}^2 \simeq 1.53$.

Lemma 4.2: Let $\mathfrak{v}=\mathfrak{v}(z)$ *be an* $L(F)$*-valued tempered distribution on* $\mathbb{R}$ *such that*

$$C_{\mathfrak{v}} := \sup_{\zeta\in\mathbb{R}} \|(|\log|\zeta|+1)^{-1}\mathcal{F}\mathfrak{v}(\zeta)\| < \infty. \tag{61}$$

Then for all $\lambda \geqslant e$ *and all* $\varepsilon>0$,

$$\left\|(-\varepsilon\Delta+\varepsilon^{-1})^{-1/2}\left(\frac{\lambda}{\log\lambda}\mathfrak{v}(\lambda z)\right)(-\varepsilon\Delta+\varepsilon^{-1})^{-1/2}\right\| \leqslant C_{(60)}C_{\mathfrak{v}}(|\log\varepsilon|+2). \tag{62}$$

Proof: Conjugating as before by the Fourier transform, and estimating the operator norm by the Hilbert-Schmidt one, we find that the left-hand side of (62) is bounded, by the square root of

$$(2\pi)^{-2}\int_{\mathbb{R}}\left(\int_{\mathbb{R}}\frac{1}{(\varepsilon\zeta^2+\varepsilon^{-1})(\varepsilon(\zeta-\eta)^2+\varepsilon^{-1})}\mathrm{d}\zeta\right)\frac{1}{(\log\lambda)^2}\left\|\mathcal{F}\mathfrak{v}\left(\frac{\eta}{\lambda}\right)\right\|^2\mathrm{d}\eta.$$

By (61) we can bound

$$\frac{1}{(\log\lambda)^2}\|\mathcal{F}\mathfrak{v}(\eta/\lambda)\|^2 \leqslant C_{\mathfrak{v}}^2\left(\frac{|\log|\eta||}{\log\lambda}+1+\frac{1}{\log\lambda}\right)^2 \leqslant C_{\mathfrak{v}}^2(|\log|\eta||+2)^2,$$

since we suppose that $\lambda\geqslant e$. Hence, using (59) again, we find that our norm is bounded by the square root of

$$\frac{C_{\mathfrak{v}}^2}{2\pi}\int_{\mathbb{R}}\frac{(|\log|\eta||+2)^2}{\varepsilon\eta^2+4\varepsilon^{-1}}\mathrm{d}\eta \leqslant \frac{C_{\mathfrak{v}}^2}{2\pi}\int_{\mathbb{R}}\frac{(|\log|\eta||+|\log\varepsilon|+2)^2}{\eta^2+4}\mathrm{d}\eta \leqslant \frac{C_{\mathfrak{v}}^2}{\pi}(\log\varepsilon)^2\int_{\mathbb{R}}\frac{\mathrm{d}\eta}{\eta^2+4}$$
$$+\frac{C_{\mathfrak{v}}^2}{\pi}\int_{\mathbb{R}}\frac{(|\log|\eta||+2)^2}{\eta^2+4}\mathrm{d}\eta = C_{\mathfrak{v}}^2\left(\frac{(\log\varepsilon)^2}{2}+4C_{(60)}^2\right),$$

by (60). Since $C_{(60)}^2\geqslant 1/2$, we see that (62) will be bounded by $C_{(60)}C_{\mathfrak{v}}(|\log\varepsilon|+2)$, as claimed. Q.E.D.

The next step will be to apply Lemma 4.1 to the potentials V_j^1 and V_{jk}^1, with $\lambda=\sqrt{B}$. We introduce the B-dependent tempered distribution $q=q^B$, and linear operators C_j^n, $C_{jk}^e \in L(F_{\mathbb{M}}^1)$ by

$$q^B(z) = \log B\,\delta(z) + \mathrm{Pf}\left(\frac{1}{|z|}\right), \tag{63}$$

$$C_j^n := C_j^{n,\mathbb{M}} := -\Pi^1_{\text{eff}} \log\left(\tfrac{1}{4}(x_j^2+y_j^2)\right)\Pi^1_{\text{eff}}, \tag{64}$$

$$C_{jk}^e := C_{jk}^{e,\mathbb{M}} := -\Pi^1_{\text{eff}} \log\left(\tfrac{1}{4}((x_j-x_k)^2+(y_j-y_k)^2)\right)\Pi^1_{\text{eff}}. \tag{65}$$

Observe that (64) and (65) are related to (12) and (13) by conjugation by U^B_{xy}. See also Remark 1.4 for a physical interpretation of these three terms.

Lemma 4.3: Let $R_{00}(-\beta^2)=\left(-\frac{1}{2}\Delta_z+\beta^2\right)^{-1}$, $\beta>0$ *be the free resolvent in dimension 1. There exists a positive constant* $C_{(66)}:=C_{(66)}(\mathbb{M})>0$ *only depending on* $\mathbb{M}$, *such that for all* $B,\beta>0$,

$$\|R_{00}(-\beta^2)^{1/2}(\sqrt{B}V_j^1(\sqrt{B}z)-(q^B(z)+C_j^n\delta(z)))R_{00}(-\beta^2)^{1/2}\| \leqslant \frac{C_{(66)}}{\sqrt{\beta}B^{1/4}} \tag{66}$$

and

$$\|R_{00}(-\beta^2)^{1/2}(\sqrt{B}V_{jk}^1(\sqrt{B}z)-(q^B(z)+C_{jk}^e\delta(z)))R_{00}(-\beta^2)^{1/2}\| \leqslant \frac{C_{(66)}}{\sqrt{\beta}B^{1/4}}, \tag{67}$$

the norm being the operator norm on $L^2(\mathbb{R},F^1_{\mathbb{M}})$.

To simplify future estimates, we have taken the same constant in both inequalities.

Proof: Recall the formulas (48) and (49) for $V_j^1(z)$ and $V_{jk}^1(z)$. We need the asymptotics of their Fourier transforms at 0. By Ref. 1, 9.6.21, the Fourier transform of $(1+z^2)^{-1/2}$ equals

$$\mathcal{F}((1+z^2)^{-1/2})(\zeta)=2K_0(|\zeta|),$$

where K_0 is the Macdonald function. Since the projector Π^1_{eff} effectively only acts in the x and y variables, it follows that

$$\mathcal{F}V_j^1(\zeta)=\Pi^1_{\text{eff}}\mathcal{F}_{z\to\zeta}((x_j^2+y_j^2)^{-1/2}(1+((x_j^2+y_j^2)^{-1/2}z)^2)^{-1/2})\Pi^1_{\text{eff}}=2\Pi^1_{\text{eff}}K_0(\sqrt{x_j^2+y_j^2}\cdot\zeta)\Pi^1_{\text{eff}},$$

with a similar formula for $\mathcal{F}V_{jk}^1$.

Now it is known that

$$K_0(|\zeta|)=-\log|\zeta|+\log 2-\gamma+O(||\zeta^2\log|\zeta||), \quad |\zeta|\to 0,$$

and that $K_0(|\zeta|)$ is bounded on $|\zeta|\geqslant 1$ (even exponentially decreasing there): see, e.g., [Ref. 1 9.6.13]. It then easily follows that, as $\zeta\to 0$ and as operators on $\operatorname{Ran}\Pi^1_{\text{eff}}$,

$$\mathcal{F}V_j^1(\zeta)\simeq -2\log|\zeta|-2\gamma+C_j^n,$$

$$\mathcal{F}V_{jk}^1(\zeta)\simeq -2\log|\zeta|-2\gamma+C_{jk}^e, \tag{68}$$

with an error of $O(|\zeta^2\log|\zeta||)$. An appeal to Lemma 4.1, with $\lambda=\sqrt{B}$ and with $C_0=2$ and $C_1=-2\gamma+C_j^n$, respectively, $C_1=-2\gamma+C_{jk}^e$, then finishes the proof. Q.E.D.

Remark 4.4: An explicit computation of the matrices of C_j^n and C_{jk}^e with respect to the natural basis $X_m^1, m\in\Sigma(\mathbb{M})$ shows that C_j^n and C_{jk}^e do depend on their indices j and j, k, respectively.

We will likewise need Lemma 4.2 for $\mathfrak{v}=V_j^1$. We can without loss of generality assume that $j=1$, by permutational symmetry of $\Sigma(\mathbb{M})$. As we have seen above, $\mathcal{F}V_1^1(\zeta)=2\Pi^1_{\text{eff}}K_0(|\zeta|\sqrt{x_1^2+y_1^2})\Pi^1_{\text{eff}}$. It can easily be verified that $\|(|\log'|\zeta||+1)^{-1}K_0(\zeta)\|_\infty=1$, so that, for example,

$$C_{V_1^1}\leqslant C_{(69)}:=2+2\|\Pi^1_{\text{eff}}|\log\sqrt{x_1^2+y_1^2}|\Pi^1_{\text{eff}}\|. \tag{69}$$

The operator norm on the right-hand side can be evaluated explicitly, and behaves asymptotically for large positive $\mathbb{M}$ as $2\log(\mathbb{M})$.

We next extend Lemma 4.3 to multiparticle potentials. Let us define the multiparticle potential v_C by

$$v_C(z) = v_C^B(z) = -Z\sum_j (q^B(z_j) + C_j^n \delta(z_j)) + \sum_{j<k} (q^B(z_j - z_k) + C_{jk}^e \delta(z_j - z_k)). \tag{70}$$

Lemma 4.5: Let $R_{00}(-\alpha^2) = \left(-\frac{1}{2}\Delta_z + \alpha^2\right)^{-1}$, $\alpha > 0$, *be the resolvent of the free Hamiltonian in* $\mathbb{R}^N$. *Then*

$$\|R_{00}(-\alpha^2)^{1/2}(\sqrt{B}\mathcal{V}_{\text{eff}}^1(\sqrt{B}z) - v_C(z))R_{00}(-\alpha^2)^{1/2}\| \leqslant \frac{C_{(72)}}{\sqrt{\alpha}B^{1/4}}, \tag{71}$$

where

$$C_{(72)} := C_{(72)}(N,Z,\mathbb{M}) := C_{(66)}N^{1/4}\left(Z + \tfrac{1}{2}(N-1)\right). \tag{72}$$

Proof: We split both potentials into their electron-nucleus and electron-electron parts,

$$\mathcal{V}_{\text{eff}}^1 = \mathcal{V}_{\text{eff},n}^1 + \mathcal{V}_{\text{eff},e}^1,$$

and similarly for v_C: $v_C = v_{C,n} + v_{C,e} = v_{C,n}^B + v_{C,e}^B$. Writing $\mathcal{V}_{s,\nu}^B(z)$ for $\sqrt{B}\mathcal{V}_{s,\nu}^1(\sqrt{B}z)$ (with a mild abuse of notation), where $\nu = n$ or e, we bound the left-hand side of (71) by

$$\|R_{00}(-\alpha^2)^{1/2}(\mathcal{V}_{\text{eff},n}^B - v_{C,n})R_{00}(-\alpha^2)^{1/2}\| + \|R_{00}(-\alpha^2)^{1/2}(\mathcal{V}_{\text{eff},e}^B - v_{C,e})R_{00}(-\alpha^2)^{1/2}\|, \tag{73}$$

and estimate the two terms separately. Let $R_{00,j}(-\beta^2)$ be the one-dimensional resolvent in the variable z_j, with a β which will be picked below. We will simply write R_{00} for $R_{00}(-\alpha^2)$ and $R_{00,j}$ for $R_{00,j}(-\beta^2)$. If we set

$$\Delta V_j := V_j^B(z_j) - q^B(z_j) - C_j^n \delta(z_j)$$

and

$$\Delta\mathcal{V}_n := Z\sum_j \Delta V_j = \mathcal{V}_{\text{eff},n}^B - v_{C,n},$$

then, by (66),

$$\begin{aligned} R_{00}^{1/2}\Delta\mathcal{V}_n R_{00}^{1/2} &= Z\sum_j (R_{00}^{1/2}R_{00,j}^{-1/2})(R_{00,j}^{1/2}\Delta V_j R_{00,j}^{1/2})(R_{00,j}^{-1/2}R_{00}^{1/2}) \leqslant \frac{C_{(66)}Z}{\sqrt{\beta}B^{1/4}}\sum_j R_{00}^{1/2}R_{00,j}^{-1}R_{00}^{1/2} \\ &= \frac{C_{(66)}Z}{\sqrt{\beta}B^{1/4}}R_{00}(-\alpha)^2\left(-\frac{1}{2}\Delta_z + N\beta^2\right) \leqslant \frac{C_{(66)}Z}{\sqrt{\beta}B^{1/4}}\max_{\xi\in\mathbb{R}^N}\frac{|\xi|^2/2 + N\beta^2}{|\xi|^2/2 + \alpha^2} \\ &= \frac{C_{(66)}Z\max(1, N\beta^2/\alpha^2)}{\sqrt{\beta}B^{1/4}} = \frac{C_{(66)}ZN^{1/4}}{\sqrt{\alpha}B^{1/4}} \end{aligned}$$

if we pick $\beta = \alpha/\sqrt{N}$; this choice actually minimizes $\beta^{-1/2}\max(1, N\beta^2/\alpha^2)$ as a function of $\beta \geqslant 0$, as is easily checked. Similar estimates show that $-R_{00}^{1/2}\Delta\mathcal{V}_n R_{00}^{1/2}$ is bounded from above, in operator sense, by the same number, and we therefore conclude that the first norm in (73) is bounded by $C_{(66)}ZN^{1/4}/\sqrt{\alpha}B^{1/4}$.

To estimate the second term of (73), we will use the following lemma, which is analogous to Lemma 3.2 from Sec. II. Let $\Delta_j = -d^2/\mathrm{d}z_j^2$, $\Delta_k = -d^2/\mathrm{d}z_k^2$.

Lemma 4.6: Let $\mathfrak{v} = \mathfrak{v}(z)$ *be an* $L(F)$*-valued distribution on* $\mathbb{R}$ *(F a finite-dimensional Hilbert space), such that* $R_{00}(-\beta^2)^{1/2}\mathfrak{v}R_{00}(-\beta^2)^{1/2}$ *is self-adjoint, for* $\beta > 0$. *Then for all* $\mu > 0$,

$$\left\| \left(-\frac{1}{2}\Delta_j - \frac{1}{2}\Delta_k + \mu^2 \right)^{-1/2} \mathfrak{v}(z_j - z_k) \left(-\frac{1}{2}\Delta_j - \frac{1}{2}\Delta_k + \mu^2 \right)^{-1/2} \right\|$$
$$\leqslant \frac{1}{2} \left\| \left(-\frac{1}{2}\Delta_s + \frac{\mu^2}{2} \right)^{-1/2} \mathfrak{v}(s) \left(-\frac{1}{2}\Delta_s + \frac{\mu^2}{2} \right)^{-1/2} \right\|. \tag{74}$$

Proof: We use a similar change of variables as in the proof of Lemma 3.2: $s=(z_j-z_k)/\sqrt{2}$, $t=(z_j+z_k)/\sqrt{2}$. Then, with $\simeq$ denoting unitary equivalence,

$$\left(-\frac{1}{2}\Delta_j - \frac{1}{2}\Delta_k + \mu^2 \right)^{1/2} \mathfrak{v}(z_j - z_k) \left(-\frac{1}{2}\Delta_j - \frac{1}{2}\Delta_k + \mu^2 \right)^{-1/2}$$
$$\simeq \left(-\frac{1}{2}\Delta_s - \frac{1}{2}\Delta_t + \mu^2 \right)^{-1/2} \mathfrak{v}(\sqrt{2}s) \left(-\frac{1}{2}\Delta_s - \frac{1}{2}\Delta_t + \mu^2 \right)^{-1/2}$$
$$\simeq \frac{1}{2} \left(-\frac{1}{2}\Delta_s - \frac{1}{2}\Delta_t + \frac{\mu^2}{2} \right)^{-1/2} \mathfrak{v}(s) \left(-\frac{1}{2}\Delta_s - \frac{1}{2}\Delta_t + \frac{\mu^2}{2} \right)^{-1/2}.$$

Observing that

$$\left\| \left(-\frac{1}{2}\Delta_s + \frac{\mu^2}{2} \right)^{1/2} \left(-\frac{1}{2}\Delta_s - \frac{1}{2}\Delta_t + \frac{\mu^2}{2} \right)^{-1/2} \right\| \leqslant 1$$

on $L^2(\mathbb{R}^2)$, the lemma follows. Q.E.D.

Let us write

$$R_{00,jk} = R_{00,jk}(-\mu^2) = \left(-\tfrac{1}{2}(\Delta_j + \Delta_k) + \mu^2 \right)^{-1/2}, \tag{75}$$

the two-dimensional free resolvent, where μ will be optimized at the end of the proof. Recall that $R_{00}=R_{00}(-\alpha^2)$, and set

$$\Delta V_{jk} = V^B_{jk}(z_j - z_k) - q^B(z_j - z_k) - C^e_{jk}\delta(z_j - z_k).$$

Then, using Lemmas 4.6 and 4.3, $R_{00}^{1/2}(\mathcal{V}^B_{\mathrm{eff},e} - v^B_{C,e})R_{00}^{1/2}$ can be estimated from above as follows:

$$R_{00}^{1/2} \sum_{j<k} \Delta V_{jk} R_{00}^{1/2} = \sum_{j<k} (R_{00}^{1/2} R_{00,jk}^{-1/2})(R_{00,jk}^{-1} \Delta V_{jk} R_{00,jk}^{1/2})(R_{00,jk}^{-1/2} R_{00}^{1/2}) \leqslant \frac{C_{(66)}}{2^{3/4}\sqrt{\mu} B^{1/4}} \sum_{j<k} R_{00}^{1/2} R_{00,jk}^{-1} R_{00}^{1/2}$$
$$= \frac{C_{(66)}}{2^{3/4}\sqrt{\mu} B^{1/4}} R_{00}(-\alpha^2) \left(\sum_{j<k} \left(-\frac{1}{2}(\Delta_j + \Delta_k) + \mu^2 \right) \right)$$
$$= \frac{C_{(66)}(N-1)}{2^{3/4}\sqrt{\mu} B^{1/4}} R_{00}(-\alpha^2) \left(-\frac{1}{2}\Delta_z + \frac{N\mu^2}{2} \right)$$
$$\leqslant \frac{C_{(66)}(N-1)}{2^{3/4} B^{1/4}} \frac{1}{\sqrt{\mu}} \max\left(1, \frac{N\mu^2}{2\alpha^2} \right) \leqslant \frac{C_{(66)}(N-1)N^{1/4}}{2\sqrt{\alpha} B^{1/4}},$$

where we minimized the right-hand side over μ by choosing $\mu=\alpha\sqrt{2/N}$. The similar upper bound for $-R^{1/2}(\mathcal{V}_e - v^B_{C,e})R_{00}^{1/2}$ gives the desired estimate for the second norm in (73), and combining the two estimates, we have proved Lemma 4.5. Q.E.D.

We now derive a similar estimate for $\mathcal{W}^B$ as $B\to\infty$.

Lemma 4.7: Let $R_{00}(-\alpha^2)$ be the free resolvent in dimension N, and let $U=U^B_{xy}$ be the unitary transformation defined by (46). Then, if, $\xi\leqslant 0$,

$$\| R_{00}(-\alpha^2)^{1/2} U^* \mathcal{W}^B U R_{00}(-\alpha^2)^{1/2} \| \leqslant \frac{C_{(77)}}{\alpha\sqrt{B}}, \tag{76}$$

with

$$C_{(77)} := C_{(77)}(N,Z) := 2\pi^{3/2}N^{3/2}\left(Z^2 + \frac{(N-1)^2}{4}\right). \tag{77}$$

Proof: Recall that $\mathcal{W}^B = -\mathcal{V}_{\mathrm{eff},\perp} R \mathcal{V}_{\perp,\mathrm{eff}}$, where $R = R(\xi) = (H_\perp - \xi)^{-1}$ on $\mathrm{Ran}\,\Pi_\perp^B$. Hence

$$U^* \mathcal{W}^B U = -B\mathcal{V}^1_{\mathrm{eff},\perp}(\sqrt{B}z) U^* R U \mathcal{V}^1_{\perp,\mathrm{eff}}(\sqrt{B}z),$$

where $\mathcal{V}^1_{\mathrm{eff},\perp} = \Pi^1_{\mathrm{eff}} \mathcal{V} \Pi^1_\perp$, and similarly for $\mathcal{V}^1_{\perp,\mathrm{eff}}$. Since for $\xi \leqslant 0$, $0 \leqslant R \leqslant 2/B$ (see Sec. III), we have that, letting $\mathcal{V}(\cdot,z)$ be the function $(x,y) \to \mathcal{V}(x,y,z)$,

$$\begin{aligned} 0 \leqslant -U^* \mathcal{W}^B U &\leqslant 2\Pi^1_{\mathrm{eff}} \mathcal{V}(\cdot,\sqrt{B}z) \Pi_\perp \mathcal{V}(\cdot,\sqrt{B}z) \Pi^1_{\mathrm{eff}} \leqslant 2\Pi^1_{\mathrm{eff}} \mathcal{V}(\cdot,\sqrt{B}z)^2 \Pi^1_{\mathrm{eff}} \leqslant 4(\Pi^1_{\mathrm{eff}} \mathcal{V}_n(\cdot,\sqrt{B}z)^2 \Pi^1_{\mathrm{eff}} \\ &+ \Pi^1_{\mathrm{eff}} \mathcal{V}_e(\cdot,\sqrt{B}z)^2 \Pi^1_{\mathrm{eff}}). \end{aligned} \tag{78}$$

As in the previous lemma, we treat the two terms separately. By Cauchy-Schwarz,

$$\mathcal{V}_n(x,y,\sqrt{B}z)^2 \leqslant Z^2 N \sum_{j=1}^N \frac{1}{\rho_j^2 + Bz_j^2},$$

where $\rho_j^2 = x_j^2 + y_j^2$. As before, let $R_{00,j}(-\beta^2)$ be the resolvent of $h_{00,j} = -(1/2)d^2/\mathrm{d}z_j^2$ on $\mathbb{R}$. We first estimate the L^2-norm of each

$$R_{00,j}(-\beta^2)^{1/2} \Pi^1_{\mathrm{eff}} (\rho_j^2 + Bz_j^2)^{-1} \Pi^1_{\mathrm{eff}} R_{00,j}(-\beta^2)^{1/2}, \tag{79}$$

by conjugating with the Fourier transform $\mathcal{F}$. Since $\mathcal{F}((1+z^2)^{-1})(\zeta) = \pi e^{-|\zeta|}$, (79) then becomes an integral operator with kernel

$$\frac{1}{2} B^{-1/2} \left(\frac{\zeta_j^2}{2} + \beta^2\right)^{-1/2} (\Pi^1_{\mathrm{eff}} \rho_j^{-1} e^{-\rho_j B^{-1/2} |\zeta_j - \eta_j|} \Pi^1_{\mathrm{eff}}) \left(\frac{\eta_j^2}{2} + \beta^2\right)^{-1/2}. \tag{80}$$

The norm of (80) can be estimated by its Hilbert-Schmidt norm, whose square can be bounded by

$$\frac{1}{4B} \left\| \Pi^1_{\mathrm{eff}} \frac{1}{\rho_j} \Pi^1_{\mathrm{eff}} \right\|^2 \left(\int_{\mathbb{R}} \left(\frac{\xi^2}{2} + \beta^2 \right)^{-1} \mathrm{d}\xi \right)^2 = \frac{\pi^2 C_{(81)}^2}{2\beta^2 B},$$

where we have set

$$C_{(81)} := \| \Pi^1_{\mathrm{eff}} \rho_j^{-1} \Pi^1_{\mathrm{eff}} \|. \tag{81}$$

Note that $C_{(81)}$ is independent of j, because of the permutational symmetry of $\Sigma(\mathbb{M})$. It follows that

$$R_{00,j}(-\beta^2)^{1/2} \Pi^1_{\mathrm{eff}} (\rho_j^2 + Bz_j^2)^{-1} \Pi^1_{\mathrm{eff}} R_{00,j}(-\beta^2)^{1/2} \leqslant \frac{\pi C_{(81)}}{\sqrt{2}\beta\sqrt{B}}, \tag{82}$$

and therefore

$$\begin{aligned} 0 &\leqslant R_{00}(-\alpha^2)^{1/2} \Pi^1_{\mathrm{eff}} \mathcal{V}_n(\cdot,\sqrt{B})^2 \Pi^1_{\mathrm{eff}} R_{00}(-\alpha^2)^{1/2} \leqslant \frac{\pi C_{(81)} Z^2 N}{\sqrt{2}\beta B^{1/2}} R_{00}(-\alpha^2) \sum_j (h_{00,j} + \beta^2) \\ &= \frac{\pi C_{(81)} Z^2 N}{\sqrt{2}\beta B^{1/2}} R_{00}(-\alpha^2)(h_{00} + N\beta^2) \leqslant \frac{\pi C_{(81)} Z^2 N^{3/2}}{\sqrt{2}\alpha B^{1/2}}, \end{aligned}$$

if we choose $\beta = \alpha/\sqrt{N}$. The same inequality then holds for the norm, since the operator we estimate is positive.

We next treat the interaction term $R_{00}(\alpha^2)^{1/2}\mathcal{V}_e(\cdot,\sqrt{B}z)^2R_{00}(\alpha^2)^{1/2}$ in a similar way as in the proof of Lemma 4.5. First, by Cauchy-Schwarz again,

$$\mathcal{V}_e(\cdot,\sqrt{B}z)^2 \leqslant \frac{N(N-1)}{2}\sum_{j<k}\frac{1}{\rho_{jk}^2+B(z_j-z_k)^2},$$

where we have set $\rho_{jk}^2=(x_j-x_k)^2+(y_j-y_k)^2$. Since the rotation $(r_j,r_k)\to(2^{-1/2}(r_j-r_k),2^{-1/2}(r_j+r_k))$ commutes with Π_{eff}^1 (since it commutes with H_0^1 and with $\mathbb{L}_z$), we find, after a unitary transformation, that

$$\begin{aligned}&\|R_{00,jk}(-\mu^2)^{1/2}\Pi_{\mathrm{eff}}^1(\rho_{jk}^2+B(z_j-z_k)^2)^{-1}\Pi_{\mathrm{eff}}^1R_{00,jk}(-\mu^2)^{1/2}\|\\&\quad\leqslant\left\|\frac{1}{2}R_{00,j}\left(-\frac{\mu^2}{2}\right)^{1/2}\Pi_{\mathrm{eff}}^1(\rho_j^2+Bz_j^2)^{-1}\Pi_{\mathrm{eff}}^1R_{00,j}\left(-\frac{\mu^2}{2}\right)^{1/2}\right\|\leqslant\frac{\pi C_{(81)}}{2\mu\sqrt{B}};\end{aligned}$$

compare the proof of Lemma 4.6. Hence, using similar arguments as before,

$$\begin{aligned}R_{00}(-\alpha^2)^{1/2}\Pi_{\mathrm{eff}}^1\mathcal{V}_e(\cdot,\sqrt{B})^2\Pi_{\mathrm{eff}}^1R_{00}(-\alpha^2)^{1/2}&\leqslant\frac{\pi C_{(81)}N(N-1)}{4\mu\sqrt{B}}R_{00}(-\alpha^2)\sum_{j<k}(h_{00,jk}+\mu^2)\\&\leqslant\frac{\pi C_{(81)}N(N-1)^2}{4\mu\sqrt{B}}R_{00}(-\alpha^2)\left(h_{00}+\frac{N\mu^2}{2}\right)\\&\leqslant\frac{\pi C_{(81)}N^{3/2}(N-1)^2}{4\sqrt{2}\alpha\sqrt{B}},\end{aligned}$$

if we choose $\mu=\alpha\sqrt{2/N}$. Adding this estimate to the one for $\mathcal{V}_n^2$, and remembering the factor 4 from (78), we have proved (76) with the constant $C_{(77)}=2^{3/2}\pi C_{(81)}N^{3/2}(Z^2+[(N-1)^2/4])$. *A priori*, $C_{(81)}$ might still depend on $\mathbb{M}$, but it in fact does not, as we will finally show. We compute $C_{(81)}$ in the Landau basis (28) of $F_{\mathbb{M}}^1$, with respect to which $\Pi_{\mathrm{eff}}^1\rho_1^{-1}\Pi_{\mathrm{eff}}^1$ diagonalizes,

$$C_{(81)}=\max_{0\leqslant m\leqslant\mathbb{M}}\frac{1}{2^m m!}\int_0^\infty\rho_1^{2m}e^{-\rho_1^2/2}\,\mathrm{d}\rho_1=\max_{0\leqslant m\leqslant\mathbb{M}}\frac{1}{m!\sqrt{2}}\int_0^\infty s^{m-1/2}e^{-s}\,\mathrm{d}s=\max_{0\leqslant m\leqslant\mathbb{M}}\frac{\Gamma\left(m+\frac{1}{2}\right)}{\sqrt{2}\Gamma(m+1)}.$$

It is known that

$$\Gamma\left(m+\frac{1}{2}\right)=\frac{1\times3\times5\times\cdots\times(2m-1)}{2^m}\Gamma\left(\frac{1}{2}\right),$$

cf. e.g., Ref. 1, formula 6.1.12, p. 255. Using this, one easily finds that

$$C_{(81)}=\frac{1}{\sqrt{2}}\Gamma\left(\frac{1}{2}\right)=\sqrt{\frac{\pi}{2}},$$

which completes the proof of the lemma. Q.E.D.

To prove Theorem 1.5 we will need to control the Sobolev norm of $V_1^B-v_\delta^B$. This is done in the following lemma, which we formulate in slightly greater generality than needed, with an eye to future applications.

Lemma 4.8: Let $V_1^B:=V_1^{B,\mathbb{M}}$ be defined as in (10), $c>0$ and let $\alpha_c=\alpha_c(B)$ be the unique positive solution of

$$\alpha_c=\frac{2}{c}\log\left(\frac{\sqrt{B}}{\alpha_c}\right). \tag{83}$$

Then the constant

$$C_{(84)} := \left(\pi^2 + 9\log^2(2) + \frac{64\sqrt{2}}{\pi} + \sup_{|\zeta|\leqslant 1} |\mathcal{F}V_1^1(\zeta) + 2\log(|\zeta|)|^2 + \frac{8\sqrt{2}}{\pi} \sup_{|\zeta|\geqslant 1} |\mathcal{F}V_1^1(\zeta)|^2 \right)^{1/2} \tag{84}$$

is finite and depends only on $\mathbb{M}$. *Moreover for all* $c>0$ *and all* $B>0$

$$\|R_{00}(-\alpha_c^2)^{1/2}(V_1^B - c\alpha_c(B)\delta)R_{00}(-\alpha_c^2)^{1/2}\| \leqslant \frac{C_{(84)}}{\alpha_c(B)}. \tag{85}$$

Observe that if $c=2$, then $\alpha_c(B)$ is the $\alpha(B)$ from Theorem 1.1: cf. (6). Also note that the constant $C_{(84)}$ is independent of $c>0$.

Proof: The first statement follows at once using the explicit knowledge of $\mathcal{F}V_1^1$ obtained in the proof of Lemma 4.3. To prove the estimate (85) we introduce the auxiliary function X by

$$\mathcal{F}V_1^B(\zeta) - c\alpha_c\mathcal{F}\delta(\zeta) = \mathcal{F}V_1^1\left(\frac{\zeta}{\sqrt{B}}\right) + 2\log\frac{|\zeta|}{\sqrt{B}} - 2\log\frac{|\zeta|}{\alpha_c} =: X\left(\frac{\zeta}{\sqrt{B}}\right) - 2\log\frac{|\zeta|}{\alpha_c},$$

where in the first line we used Eq. (83). The Fourier transform of $V_1^B - c\alpha_c(B)\delta$ acts as convolution by a function, and we estimate the norm of $Y := R_{00}(-\alpha_c^2)^{1/2}(V_1^B - c\alpha_c\delta)R_{00}(-\alpha_c^2)^{1/2}$ by its Hilbert-Schmidt norm, as in the proofs of Lemmas 4.1 and 4.2. It follows that

$$\|Y\|^2 \leqslant \frac{\sqrt{2}}{\pi\alpha_c}\int_{\mathbb{R}} \frac{|\mathcal{F}V_1^B(\zeta) - c\alpha_c\mathcal{F}\delta(\zeta)|^2}{8\alpha_c^2+\zeta^2}\mathrm{d}\zeta \leqslant \frac{2\sqrt{2}}{\pi\alpha_c}\int_{\mathbb{R}} \frac{\left|X\left(\frac{\zeta}{\sqrt{B}}\right)\right|^2 + \left|2\log\frac{|\zeta|}{\alpha_c}\right|^2}{8\alpha_c^2+\zeta^2}\mathrm{d}\zeta.$$

First,

$$\frac{1}{\alpha_c}\int_{\mathbb{R}} \frac{4}{8\alpha_c^2+\zeta^2}\left|\log\frac{|\zeta|}{\alpha_c}\right|^2 \mathrm{d}\zeta = \frac{\pi}{2\sqrt{2}\alpha_c^2}(\pi^2 + 9\log^2(2)).$$

We next look at the contribution of X, which we split in two parts,

$$\int_{\sqrt{B}}^{\infty} \frac{\left|X\left(\frac{\zeta}{\sqrt{B}}\right)\right|^2 \mathrm{d}\zeta}{8\alpha_c^2+\zeta^2} = \frac{1}{\sqrt{B}}\int_1^{\infty} \frac{|X(\zeta)|^2\,\mathrm{d}\zeta}{8B^{-1}\alpha_c^2+\zeta^2} \leqslant \frac{2}{\sqrt{B}}\int_1^{\infty} \frac{|\mathcal{F}V(\zeta)|^2 + 4(\log|\zeta|)^2}{\zeta^2}\mathrm{d}\zeta$$

$$\leqslant \frac{2}{\sqrt{B}}\left(\sup_{|\zeta|\geqslant 1}|\mathcal{F}V(\zeta)|^2 + 8\right),$$

since

$$\int_1^{\infty} \frac{(\log|\zeta|)^2}{|\zeta|^2}\mathrm{d}\zeta = 2$$

and

$$\int_0^{\sqrt{B}} \frac{\left|X\left(\frac{\zeta}{\sqrt{B}}\right)\right|^2 \mathrm{d}\zeta}{8\alpha_c^2+\zeta^2} \leqslant \sup_{|\zeta|\leqslant 1}|X(\zeta)|^2 \int_0^{\sqrt{B}} \frac{\mathrm{d}\zeta}{8\alpha_c^2+\zeta^2} \leqslant \frac{\pi}{4\sqrt{2}\alpha_c}\sup_{|\zeta|\leqslant 1}|X(\zeta)|^2.$$

The rest is now elementary. Notice in particular that $\sup_{B>0}\alpha_c(B)/\sqrt{B}=1$. Q.E.D.

The limit potential (70) suggests defining an effective Hamiltonian $h_C = h_C^B$ by

$$h_C := h_{00} + v_C. \tag{86}$$

As it stands, this is just a formal expression, and our first task is to give a meaning to h_C as a self-adjoint operator on $L^2(\mathbb{R}^N; F^1_{\mathbb{M}})$. We do this by showing that v_C is form-bounded with respect h_{00}, with zero relative form-bound. Let $\langle \cdot, \cdot \rangle$ denote the duality between distributions and test functions.

Lemma 4.9: The quadratic forms $u \to \langle \delta, |u|^2 \rangle = |u(0)|^2$ *and* $u \to \langle \mathrm{Pf}(1/|z|), |u|^2 \rangle$ *are well defined on* $H^1(\mathbb{R})$, *and form-bounded with respect to* h_{00}, *with relative bound zero. More precisely, we have for all* $\varepsilon > 0$ *that*

$$\delta \leqslant \tfrac{1}{2}(-\varepsilon\Delta_z + \varepsilon^{-1}), \tag{87}$$

and

$$\mathrm{Pf}(|z|^{-1}) \leqslant C_{(89)}(|\log \varepsilon| + 1)(-\varepsilon\Delta_z + \varepsilon^{-1}), \tag{88}$$

where

$$C_{(89)} := \sqrt{\frac{\pi^2}{2} + 2(\log 2)^2} + \gamma. \tag{89}$$

Proof: This is well known for δ. For $\mathrm{Pf}(|z|^{-1})$ we first note that, since $\mathrm{Pf}(|z|^{-1}) = -2\mathcal{F}^{-1}(\log|\zeta|) - 2\gamma\delta_0$, it suffices to prove the form-boundedness of $\mathcal{F}^{-1}(\log|\zeta|)$. The latter will follow from

$$\|(-\varepsilon\Delta + \varepsilon^{-1})^{-1/2}\mathcal{F}^{-1}(\log|\zeta|)(-\varepsilon\Delta + \varepsilon^{-1})^{-1/2}\|^2 \leqslant \frac{1}{2}(\log \varepsilon)^2 + \frac{\pi^2 + 4(\log 2)^2}{8}, \tag{90}$$

for all $\varepsilon > 0$. To prove (90), observe that after conjugation by the Fourier transform $\mathcal{F}$, and estimating the operator norm by the Hilbert-Schmidt norm, the square of (90) can be bounded by

$$\frac{1}{(2\pi)^2}\int_{\mathbb{R}}\int_{\mathbb{R}} \frac{(\log|\zeta - \eta|)^2}{(\varepsilon\zeta^2 + \varepsilon^{-1})(\varepsilon\eta^2 + \varepsilon^{-1})} \mathrm{d}\zeta\, \mathrm{d}\eta. \tag{91}$$

Changing variables and using (59), we find that (91) can be bounded by

$$\frac{1}{2\pi}\int_{\mathbb{R}} \frac{(\log|\zeta|)^2}{\varepsilon\zeta^2 + 4\varepsilon^{-1}} d\zeta = \frac{1}{2\pi}\int_{\mathbb{R}} \frac{(\log|\zeta/\varepsilon|)^2}{\zeta^2 + 4} \mathrm{d}\zeta \leqslant \frac{1}{\pi}(\log \varepsilon)^2 \int_{\mathbb{R}} \frac{\mathrm{d}\zeta}{\zeta^2 + 4} + \frac{1}{\pi}\int_{\mathbb{R}} \frac{(\log \zeta)^2}{\zeta^2 + 4} \mathrm{d}\zeta$$
$$= \frac{1}{2}(\log \varepsilon)^2 + \frac{\pi^2 + 4(\log 2)^2}{8}.$$

Hence, using (87),

$$|\langle \mathrm{Pf}(|x|^{-1}), |u|^2 \rangle| = 2 \cdot |\langle \mathcal{F}^{-1}(\log|\xi|), |u|^2 \rangle + \gamma \langle \delta, |u|^2 \rangle| \leqslant \left\{ \left(2(\log \varepsilon)^2 + \frac{\pi^2}{2} + 2(\log 2)^2 \right)^{1/2} + \gamma \right\}$$
$$\times \{-\varepsilon(\Delta u, u) + \varepsilon^{-1}\|u\|^2\} = (\sqrt{2}|\log \varepsilon| + C_{(89)})\{-\varepsilon(\Delta u, u) + \varepsilon^{-1}\|u\|^2\},$$

which implies (88) since $\sqrt{2}/C_{(89)} < 1$. Q.E.D.

Because of the terms $C^n_j \delta(z_j)$ and $C^e_{jk}\delta(z_j - z_k)$ we must extend the first part of Lemma 4.9 to the vector-valued case, but this is immediate: we just note that if C a linear operator on $F^1_{\mathbb{M}}$ (or any finite-dimensional vector space, for that matter), then the right interpretation of $C\delta$ as quadratic form on $H^1(\mathbb{R}, F^1_{\mathbb{M}})$ is given by $\langle \delta(z), (Cu(z), u(z)) \rangle$, where $(\cdot, \cdot)$ is the inner product on $F^1_{\mathbb{M}}$.

Finally, we lift Lemma 4.9 to $\mathbb{R}^N$. Recall that if $L: \mathbb{R}^N \to \mathbb{R}$ is a linear map, then the pull-back $L^*\Lambda$ of a distribution Λ on $\mathbb{R}$ is well defined, and can be computed by going to linear coordinates

z' with respect to which $L(z')=z'_1$. It then immediately follows from Lemma 4.9 that $L^*\delta$ and L^*q^B will be form-bounded with respect to h_{00} on $\mathbb{R}^N$, with relative bound 0. Taking $L(z)=L_j(z)=z_j$ and $L(z)=L_{jk}(z)=z_j-z_k$, we see that the sequilinear form $t_C^B(u)$ given by

$$t_C^B(u)=\frac{1}{2}\|\nabla u\|^2-Z\sum_j\langle L_j^*q^B,|u|^2\rangle+\langle(L_j^*\delta,(C_j^nu,u)\ \rangle+\sum_{j<k}\langle L_{jk}^*q^B,|u|^2\rangle+\langle L_{jk}^*\delta,(C_{jk}^eu,u)\rangle, \tag{92}$$

is well defined on $H^1(\mathbb{R}^N,F_{\mathbb{M}}^1)$, and bounded from below by $-C\|u\|^2$, for some constant C, depending on B, Z, N, and $\mathbb{M}$. By the Kato-Lax-Lions-Milgram-Nelson theorem (cf., e.g., Ref. 15, Theorem X.17), t_C^B defines a unique self-adjoint operator, which we will call $h_C=h_C^{B,\mathbb{M}}$, and informally write as (86). In the Appendix we will give a characterization of the operator domain of h_C^B. Similar arguments will define h_δ^B as a self-adjoint operator, cf. Ref. 6.

V. PROOF OF THEOREM 1.1

We will first compare the resolvents of $h_{\text{eff}}:=h_{\text{eff}}^{B,\mathbb{M}}$ and of $h_{\text{eff}}+\mathcal{W}$, where $\mathcal{W}:=\mathcal{W}^{B,\mathbb{M}}(\xi)$ was defined at the beginning of Sec. III. Set

$$r_{\text{eff}}:=r_{\text{eff}}(\xi):=(h_{\text{eff}}-\xi)^{-1},\quad R_{\text{eff}}^{\mathcal{W}}:=R_{\text{eff}}^{\mathcal{W}}(\xi):=(h_{\text{eff}}+\mathcal{W}-\xi)^{-1},$$

and let

$$B_{(93)}:=\frac{4C_{(77)}^2}{\alpha(C_{(77)})^2}, \tag{93}$$

where $\alpha=\alpha(B)$ is the function defined by (6), and

$$c_{\text{eff}}:=2\left(\frac{N}{2\varepsilon_{\text{eff}}^2}+1\right)C_{(77)}, \tag{94}$$

with $\varepsilon_{\text{eff}}=\varepsilon_{\text{eff}}(Z,\mathbb{M})$ the unique positive solution of

$$ZC_{(60)}C_{V_1^1}\varepsilon(|\log\varepsilon|+2)=\tfrac{1}{4}, \tag{95}$$

where $C_{V_1^1}$ is defined by (61) with $\mathfrak{v}=V_1^1$ [see (69) for an upper bound]. Note that both constants only depend on N, Z, and $\mathbb{M}$, and this in a controlled way.

We then have the following.

Theorem 5.1: *If* $B\geqslant B_{(93)}$, $\xi\leqslant 0$ *and*

$$c_{\text{eff}}\frac{\alpha}{\sqrt{B}}\leqslant d_{\text{eff}}(\xi)\leqslant\frac{1}{2}\alpha^2, \tag{96}$$

with $\alpha=\alpha(B)$ *is as in Theorem 1.1, then* $\xi\in\rho(h_{\text{eff}}+\mathcal{W})$, *and* $\|R_{\text{eff}}^{\mathcal{W}}(\xi)\|\leqslant 2\|r_{\text{eff}}(\xi)\|$. *Furthermore*,

$$\|R_{\text{eff}}^{\mathcal{W}}(\xi)-r_{\text{eff}}(\xi)\|\leqslant c_{\text{eff}}\frac{\alpha}{d_{\text{eff}}(\xi)^2\sqrt{B}}. \tag{97}$$

Proof of Theorem 5.1: It clearly suffices to establish Theorem 5.1 after conjugation by U_{xy}^B, defined by (46). To simplify notations, we will simply denote the conjugated operators by the same letters as the original ones. Using the symmetrized resolvent formula we estimate

$$\|R_{\text{eff}}^{\mathcal{W}}(\xi)-r_{\text{eff}}(\xi)\|\leqslant\frac{1}{d_{\text{eff}}(\xi)}\left(\frac{\|K_{\text{eff}}(\xi)\|}{1-\|K_{\text{eff}}(\xi)\|}\right), \tag{98}$$

where

$$K_{\mathrm{eff}}(\xi) := |r_{\mathrm{eff}}(\xi)|^{1/2}\mathcal{W}(\xi)r_{\mathrm{eff}}(\xi)^{1/2}, \tag{99}$$

with the convention that $A^{1/2} := \mathrm{sgn}(A)|A|^{1/2}$, if A is a self-adjoint operator. [Note that since ξ is not necessarily below the infimum of the spectrum, $r_{\mathrm{eff}}(\xi)$ is not necessarily positive, and we use the symmetrized resolvent formula in the following form: $R^{\mathcal{W}}_{\mathrm{eff}} = r^{1/2}_{\mathrm{eff}}(1+|r_{\mathrm{eff}}|^{1/2}\mathcal{W}r^{1/2}_{\mathrm{eff}})^{-1}|r_{\mathrm{eff}}|^{1/2}$.] Now let $\mu < \inf\sigma(h_{\mathrm{eff}})$, to be specified later. The following elementary lemma will allow us to replace ξ by μ in (99).

Lemma 5.2: If $\mu < \inf\sigma(h_{\mathrm{eff}})$, then for all real ξ in the resolvent set $\rho(h_{\mathrm{eff}})$,

$$\|r_{\mathrm{eff}}(\xi)(h_{\mathrm{eff}}-\mu)\| \leqslant \max\left(\frac{|\mu|}{d_{\mathrm{eff}}(\xi)}, 1\right). \tag{100}$$

Proof: We distinguish two cases: $\inf\sigma(h_{\mathrm{eff}}) < \xi < 0$ and $\xi < \inf\sigma(h_{\mathrm{eff}})$. [Observe that $\inf\sigma(h_{\mathrm{eff}}) < 0$, by the HVZ theorem, since this is already the case for $N=1$.] In the first case, let (ξ_-, ξ_+) be the largest open interval in $\rho(h_{\mathrm{eff}})$ which contains ξ. Since $[0,\infty)$ is in the spectrum (it is already in the essential spectrum), $\xi_+ \leqslant 0$. It is easy to see that the function $x \to |x-\mu|/|x-\xi|$ is increasing on $(-\infty, \xi_-) \cap \sigma(h_{\mathrm{eff}})$ and decreasing on $(\xi_+, \infty) \cap \sigma(h_{\mathrm{eff}})$. It follows that

$$\|r_{\mathrm{eff}}(\xi)(h_{\mathrm{eff}}-\mu)\| \sup_{x\in\sigma(h_{\mathrm{eff}})} \frac{|x-\mu|}{|x-\xi|} = \max\left(\frac{|\xi_- - \mu|}{|\xi_- - \xi|}, \frac{|\xi_+ - \mu|}{|\xi_+ - \xi|}\right) \leqslant \frac{|\mu|}{d_{\mathrm{eff}}(\xi)},$$

as was to be shown. One shows in a similarly way that (100) equals $[\inf\sigma(h_{\mathrm{eff}}) - \mu]/(\inf\sigma(h_{\mathrm{eff}}) - \xi) \leqslant |\mu|/d_{\mathrm{eff}}(\xi)$, if $\mu < \xi < \inf\sigma(h_{\mathrm{eff}})$, and is equal to 1 if $\xi < \mu$. Q.E.D.

Substituting $\mathrm{Id} = r_{\mathrm{eff}}(\mu)^{1/2}(h_{\mathrm{eff}}-\mu)^{1/2} = (h_{\mathrm{eff}}-\mu)^{1/2}r_{\mathrm{eff}}(\mu)^{1/2}$ at the appropriate places in formula (99), we see that if $\xi \leqslant 0$,

$$\|K_{\mathrm{eff}}(\xi)\| \leqslant \max\left(\frac{|\mu|}{d_{\mathrm{eff}}(\xi)}, 1\right)\|K_{\mathrm{eff}}(\mu;\xi)\|, \tag{101}$$

with

$$K_{\mathrm{eff}}(\mu;\xi) := r_{\mathrm{eff}}(\mu)^{1/2}\mathcal{W}(\xi)r_{\mathrm{eff}}(\mu)^{1/2}.$$

Repeating the same argument for $K_{\mathrm{eff}}(\mu;\xi)$ using $\mathrm{Id} = (h_{00}+\alpha^2)^{1/2}R_{00}(-\alpha^2)^{1/2}$, we obtain from Lemma 4.7 that

$$\|K_{\mathrm{eff}}(\mu;\xi)\| \leqslant \frac{C_{(77)}}{\alpha\sqrt{B}}\|r_{\mathrm{eff}}(\mu)^{1/2}(h_{00}+\alpha^2)^{1/2}\|^2. \tag{102}$$

We will now estimate the norm on the right-hand side, for suitably chosen μ.

Lemma 5.3: Assume $B \geqslant e^2$. Define

$$\mu_{\mathrm{eff}} = \mu_{\mathrm{eff}}(N,Z,\mathbb{M}) := -\frac{\alpha^2}{2}\left(\frac{N}{2\varepsilon^2_{\mathrm{eff}}} + 1\right), \tag{103}$$

where α is as in Theorem 1.1, and where $\varepsilon = \varepsilon_{\mathrm{eff}}$ is the unique positive solution to the equation (95). Then $\mu_{\mathrm{eff}} < \inf\sigma(h_{\mathrm{eff}})$, and

$$\|r_{\mathrm{eff}}(\mu_{\mathrm{eff}})^{1/2}(h_{00}+\alpha^2)^{1/2}\| \leqslant \sqrt{2}. \tag{104}$$

Assuming the lemma for the moment, we continue with the proof of Theorem 5.1: we have, by (101), (102), and (104), that if $d_{\mathrm{eff}}(\xi) \geqslant c_{\#}\alpha/\sqrt{B}$, then

$$\|K_{\mathrm{eff}}(\xi)\| \leqslant 2\max\left\{\frac{\alpha^2}{2}\left(\frac{N}{2\varepsilon^2_{\mathrm{eff}}}+1\right)\frac{1}{d_{\mathrm{eff}}(\xi)}, 1\right\}\frac{C_{(77)}}{\alpha\sqrt{B}} \leqslant \frac{1}{2},$$

provided that $c_{\#}$ satisfies

$$c_{\#} \geqslant 2\left(\frac{N}{2\varepsilon_{\text{eff}}^2}+1\right)C_{(77)} \quad \text{and} \quad \frac{C_{(77)}}{\alpha\sqrt{B}} \leqslant \frac{1}{4}.$$

Since $\alpha(B)\sqrt{B}$ is increasing, and since $\alpha(B)\sqrt{B}=x$ iff $B=x^2/(4\alpha(x/4)^2)$, the last inequality is implied by $B \geqslant B_{(93)}$. Choosing $c_{\#}=c_{\text{eff}}$ defined by (94), we conclude that if ξ is such that $d_{\text{eff}}(\xi) \geqslant c_{\text{eff}}\alpha/\sqrt{B}$, then by (98), (101) and (102) and our choice of $\mu=\mu_{\text{eff}}$,

$$\|R_{\text{eff}}^{\mathcal{W}} - r_{\text{eff}}(\xi)\| \leqslant \frac{4}{d_{\text{eff}}(\xi)} \max\left\{\frac{\alpha^2}{2}\left(\frac{N^2}{2\varepsilon_{\text{eff}}}+1\right)\frac{1}{d_{\text{eff}}(\xi)}, 1\right\}\frac{C_{(77)}}{\alpha\sqrt{B}} \leqslant 2C_{(77)}\left(\frac{N}{2\varepsilon_{\text{eff}}^2}+1\right)\frac{\alpha}{d_{\text{eff}}(\xi)^2\sqrt{B}},$$

provided that $d_{\text{eff}}(\xi) \leqslant \alpha^2/2$. This proves Theorem 5.1, modulo that of Lemma 5.3. Q.E.D.

Proof of Lemma 5.3: We will use a scaling argument. If we let $\simeq$ denote the unitary equivalence induced by the change of variables $z \to z/\alpha$, where $\alpha>0$ is for the moment a free parameter, and if we write $\mathcal{V}_{\text{eff}}^{B}$ for $\sqrt{B}\mathcal{V}_{\text{eff}}^{1}(\sqrt{B}\cdot)$, then if $\mu < \inf\sigma(h_{\text{eff}})$,

$$\begin{aligned} 0 &\leqslant (h_{00}+\alpha^2)^{1/2} r_{\text{eff}}(\mu)(h_{00}+\alpha^2)^{1/2} \simeq (h_{00}+1)^{1/2}\left(-\frac{1}{2}\Delta_z + \alpha^{-2}\mathcal{V}_{\text{eff}}^{B}\left(\frac{\cdot}{\alpha}\right) - \alpha^{-2}\mu\right)^{-1}(h_{00}+1)^{1/2} \\ &\leqslant (h_{00}+1)^{1/2}\left(-\frac{1}{2}\Delta_z + \alpha^{-2}\mathcal{V}_{\text{eff},n}^{B}\left(\frac{\cdot}{\alpha}\right) - \alpha^{-2}\mu\right)^{-1}(h_{00}+1)^{1/2}, \end{aligned} \tag{105}$$

$\mathcal{V}_{\text{eff},n}^{1}$ being the attractive part of $\mathcal{V}_{\text{eff}}$. We now choose $\alpha=\log(\sqrt{B}/\alpha)$, as in (6), and set $\lambda := \sqrt{B}/\alpha$. Notice that $B \geqslant e^2$ implies that $\lambda \geqslant e$. Then, by Lemma 4.2,

$$\begin{aligned} \frac{\sqrt{B}}{\alpha^2}\mathcal{V}_{\text{eff},n}^{1}\left(\frac{\sqrt{B}}{\alpha}z\right) &= -Z\sum_{j=1}^{N}\frac{\lambda}{\log\lambda}V_j^1(\lambda z_j) \geqslant -2C_{(60)}ZC_{V_1^1}\varepsilon(|\log\varepsilon|+2)\left(-\frac{1}{2}\Delta_z + \frac{N}{2\varepsilon^2}\right), \quad \varepsilon>0 \\ &= -\frac{1}{2}h_{00} - \frac{N}{4\varepsilon_{\text{eff}}^2}, \end{aligned}$$

uniformly in λ, if we choose $\varepsilon := \varepsilon_{\text{eff}} = \varepsilon_{\text{eff}}(Z,\mathbb{M})$ such that (95) holds. We now take

$$\mu = \mu_{\text{eff}} = -\frac{\alpha^2}{2}\left(\frac{N}{2\varepsilon_{\text{eff}}^2}+1\right).$$

Then it follows that $\mu_{\text{eff}} < \inf\sigma(h_{\text{eff}})$, since $h_{\text{eff}} - \mu_{\text{eff}} \geqslant \frac{1}{2}(h_{00}+1) \geqslant \frac{1}{2}$. Furthermore, (105) can be estimated by

$$(h_{00}+1)^{1/2}\left(\frac{1}{2}h_{00} - \left(\frac{N}{4\varepsilon_{\text{eff}}^2} + \frac{\mu_{\text{eff}}}{\alpha^2}\right)\right)^{-1}(h_{00}+1)^{1/2} = 2,$$

which implies (104).

Proof of Theorem 1.1: It now suffices to combine Theorem 3.1 and Theorem 5.1, while carefully keeping track of the constants. First of all, (96), implies that $\|R_{\text{eff}}^{\mathcal{W}}\| \leqslant 2\|r_{\text{eff}}(\xi)\|$, and therefore $d_{\text{eff}}^{\mathcal{W}}(\xi) \geqslant d_{\text{eff}}(\xi)/2$. Furthermore, $\xi<0$ if $d_{\text{eff}}(\xi)>0$, and if

$$B \geqslant B_{\text{eff}} := \max\{B_{(36)}, B_{(93)}, e^2\}, \tag{106}$$

then

$$\begin{aligned}\|(H-\xi)^{-1}-(h_{\mathrm{eff}}-\xi)^{-1}\oplus(H_\perp-\xi)^{-1}\| &\leqslant \|(H-\xi)^{-1}-R^{\mathcal{W}}_{\mathrm{eff}}(\xi)\oplus(H_\perp-\xi)^{-1}\|+\|R^{\mathcal{W}}_{\mathrm{eff}}(\xi)-r_{\mathrm{eff}}(\xi)\| \\ &\leqslant \frac{C_{(37)}}{\sqrt{B}}\frac{1}{d^{\mathcal{W}}_{\mathrm{eff}}(\xi)}+c_{\mathrm{eff}}\frac{\alpha}{d_{\mathrm{eff}}(\xi)^2\sqrt{B}}\leqslant\left(2C_{(37)}+c_{\mathrm{eff}}\frac{\alpha}{d_{\mathrm{eff}}(\xi)}\right) \\ &\quad\times\frac{1}{d_{\mathrm{eff}}(\xi)\sqrt{B}}\ [\text{using } d_{\mathrm{eff}}(\xi)/2\leqslant d^{\mathcal{W}}_{\mathrm{eff}}(\xi)] \\ &\leqslant\left(C_{(37)}+\frac{c_{\mathrm{eff}}}{\alpha}\right)\frac{\alpha^2}{d_{\mathrm{eff}}(\xi)^2\sqrt{B}}\ [\text{using } d_{\mathrm{eff}}(\xi)\leqslant\alpha^2/2 \text{ again}] \\ &\leqslant\left(C_{(37)}+\frac{c_{\mathrm{eff}}}{\alpha(B_{\mathrm{eff}})}\right)\frac{\alpha^2}{d_{\mathrm{eff}}(\xi)^2\sqrt{B}},\end{aligned}$$

since $\alpha(B)^{-1}$ is a decreasing function of B. This proves Theorem 1.1 with a constant C_{eff} which is equal to

$$C_{\mathrm{eff}}:=C_{(37)}+\frac{c_{\mathrm{eff}}}{\alpha(B_{\mathrm{eff}})}.$$

Q.E.D.

VI. PROOF OF THEOREM 1.3

As a first step, we will compare the resolvents $r_{\mathrm{eff}}(\xi)$ of h_{eff} and $r_C(\xi):=(h_C-\xi)^{-1}$ of $h_C:=h_C^B$. Recall, that $d_C(\xi):=\mathrm{dist}(\xi,\sigma(h_C))$.

Theorem 6.1: *Let $\alpha=\alpha(B)$ be defined by (6). There exist (computable) constants $B'_C, C'_C\geqslant 0$, only depending on Z, N, and $\mathbb{M}$, such that for all $B\geqslant B'_C$ and all real $\xi\leqslant 0$ satisfying*

$$d_C(\xi)\geqslant C'_C\alpha^{3/2}B^{-1/4}, \tag{107}$$

then $\xi\in\rho(H_{\mathrm{eff}})$, with $\|r_{\mathrm{eff}}(\xi)\|\leqslant 2\|r_C(\xi)\|$. In addition, letting [with $\varepsilon_{\mathrm{eff}}$ defined in (95)]

$$C''_C=\max\left\{C'_C,4C_{(72)}\left(\frac{N}{2\varepsilon^2_{\mathrm{eff}}}+1\right)\right\}\geqslant C'_C,$$

then if

$$d_C(\xi)\geqslant C''_C\alpha^{3/2}B^{-1/4}, \tag{108}$$

we also have that $\|r_C(\xi)\|\leqslant 2\|r_{\mathrm{eff}}(\xi)\|$.

Finally, if

$$C'_C\alpha^{3/2}B^{-1/4}\leqslant d_C(\xi)\leqslant\tfrac{1}{2}\alpha^2, \tag{109}$$

then

$$\|r_{\mathrm{eff}}(\xi)-r_C(\xi)\|\leqslant C'_C\frac{\alpha^{3/2}}{d_C(\xi)^2B^{1/4}}. \tag{110}$$

Proof: The proof is similar to the proof of Theorem 5.1, with however some technical changes, due to the fact that v_C is not homogeneous of degree -1, and that its electron-electron part is not positive anymore. As before, we conjugate all operators by U^B_{xy}, keeping the same letters for the conjugated operators.

Arguing as in the proof of Theorem 5.1, one shows that

$$\|r_{\text{eff}}(\xi) - r_C(\xi)\| \leqslant \frac{1}{d_C(\xi)} \frac{\|K_C(\xi)\|}{1 - \|K_C(\xi)\|},$$

where $K_C := |r_C(\xi)|^{1/2}(h_{\text{eff}} - h_C) r_C(\xi)^{1/2}$. Using Lemma 4.5, we find that, for any $\mu < \inf \sigma(h_C)$,

$$\|K_C(\xi)\| \leqslant \frac{C_{(72)}}{B^{1/4}\sqrt{\alpha}} \max\left\{ \frac{|\mu|}{d_C(\xi)}, 1 \right\} \|r_C(\mu)^{1/2}(h_{00} + \alpha^2)^{1/2}\|^2. \tag{111}$$

We then use the following analogue of Lemma 5.3, of which we only state a qualitative version.

Lemma 6.2: There exists a constant $\nu_C = \nu_C(Z,N,\mathbb{M}) \geqslant 1/2$ *such that if* $B \geqslant e$, *and if* $\mu_C := -\nu_C \alpha^2$, α *defined by (6), then* $\mu_C < \inf \sigma(h_C)$, *and*

$$\|r_C(\mu_C)^{1/2}(h_{00} + \alpha^2)^{1/2}\|^2 \leqslant 2. \tag{112}$$

Proof: As before, we will use scaling. However, contrary to $\delta(z)$, the distribution $\text{Pf}(1/|z|)$ is not homogeneous of degree -1 on $\mathbb{R}$. In fact, if ρ_α is the dilation $\rho_\alpha(z) = \alpha^{-1} z$ on $\mathbb{R}$, $\alpha > 0$ arbitrary, then the pullback of $\text{Pf}\,(1/|\cdot|)$ by ρ_α equals

$$\rho_\alpha^* \text{Pf}\left(\frac{1}{|\cdot|}\right) = \alpha \text{Pf}\left(\frac{1}{|\cdot|}\right) - 2\alpha \log \alpha \delta. \tag{113}$$

Let us split the potential $v_C := v_C^B$ of h_C as

$$v_C = \log B v_\delta + v_Q,$$

where v_δ is defined in (17) and

$$v_Q = -Z \sum_j \left(\text{Pf} \frac{1}{|z_j|} + C_j^n \delta(z_j) \right) + \sum_{j<k} \left(\text{Pf} \frac{1}{|z_j - z_k|} + C_{jk}^e \delta(z_j - z_k) \right),$$

the (pseudo-) Coulombic part. If $\simeq$ denotes unitary equivalence with respect to the dilation ρ_α (on $\mathbb{R}^N$), then in view of our choice of α

$$\begin{aligned} h_C - \mu &\simeq \alpha^2 \left(h_{00} + \frac{\log B - 2 \log \alpha}{\alpha} v_\delta + \frac{1}{\alpha} v_Q - \alpha^{-2} \mu \right) = \alpha^2 \left(h_{00} + 2 v_\delta + \frac{1}{\alpha} v_Q - \alpha^{-2} \mu \right) \\ &\geqslant \alpha^2 \left(\frac{1}{2} h_{00} - b - \alpha^{-2} \mu \right) \end{aligned}$$

form some $b > 0$ depending only on Z, N, and $\mathbb{M}$, since by Lemma 4.9 we know that $2v_\delta + (1/\alpha) v_Q$ is h_{00} form bounded with relative bound 0. Recall that $B \geqslant e$ implies $\alpha \geqslant 1$. Choosing $\mu = \mu_C := -\alpha^2(\frac{1}{2} + b) =: -\alpha^2 \nu_c$ will insure that $(h_{00} + \alpha^2) r_C(\mu)(h_{00} + \alpha^2)^{1/2} \leqslant 2$ which is what we want to prove. A more careful argument, which we will skip, will yield an explicit b. Q.E.D.

We continue with the proof of Theorem 6.1. By (112) and (111) with $\mu = \mu_C$, we find that

$$\|K_C(\xi)\| \leqslant \frac{2C_{(72)}}{B^{1/4}\sqrt{\alpha}} \max\left\{ \frac{\nu_C \alpha^2}{d_C(\xi)}, 1 \right\} \leqslant \frac{1}{2},$$

if both

$$d_C(\xi) \geqslant 4 C_{(72)} \nu_C \frac{\alpha^{3/2}}{B^{1/4}} =: C'_C \frac{\alpha^{3/2}}{B^{1/4}},$$

and $\alpha^{1/2} B^{1/4} \geqslant 4 C_{(72)}$ which, since $B \mapsto \alpha(B)^2 B$ is increasing, is equivalent to $B \geqslant 4^3 C_{(72)}^4 \alpha (4 C_{(72)}^2)^{-2}$. Since we also need $B \geqslant e$ we set

$$B'_C := \max\left\{\frac{4^3 C_{(72)}^4}{4\alpha(C_{(72)}^2)^2}, e\right\}.$$

This fixes our constants C'_C and B'_C, and also implies that $\|r_{\text{eff}}(\xi)\| \leqslant 2\|r_C(\xi)\|$, by the resolvent formula.

To show that (108) implies that $\|r_C(\xi)\| \leqslant 2\|r_{\text{eff}}(\xi)\|$, we repeat the argument with r_C and r_{eff} interchanged: by the resolvent formula,

$$r_C(\xi) = r_{\text{eff}}(\xi)^{1/2}(1 + \widetilde{K}_C(\xi))^{-1}|r_{\text{eff}}(\xi)|^{1/2},$$

with

$$\widetilde{K}_C(\xi) := |r_{\text{eff}}(\xi)|^{1/2}(h_C - h_{\text{eff}})r_{\text{eff}}(\xi)^{1/2},$$

so that, using Lemmas 4.5, 5.2, and 5.3, we arrive at

$$\|\widetilde{K}_C(\xi)\| \leqslant \frac{2C_{(72)}}{B^{1/4}\sqrt{\alpha}} \max\left\{\frac{|\mu_{\text{eff}}|}{d_{\text{eff}}(\xi)}, 1\right\} \leqslant \frac{2C_{(72)}}{B^{1/4}\sqrt{\alpha}} \max\left\{\frac{2|\mu_{\text{eff}}|}{d_C(\xi)}, 1\right\},$$

if $d_C(\xi) \geqslant C'_C\alpha^{3/2}B^{-1/4}$, by the first part. We therefore conclude that $\|\widetilde{K}_C(\xi)\| \leqslant 1/2$, and hence $\|r_C(\xi)\| \leqslant 2\|r_{\text{eff}}(\xi)\|$, if both $\sqrt{\alpha}B^{1/4} \geqslant 4C_{(72)}$, which will be satisfied if $B \geqslant B'_C$ defined above, and if

$$\frac{4|\mu_{\text{eff}}|C_{(72)}}{\sqrt{\alpha}B^{1/4}d_C(\xi)} \leqslant \frac{1}{2}.$$

The latter inequality is equivalent to

$$d_C(\xi) \geqslant 4\left(\frac{N}{2\varepsilon_{\text{eff}}^2} + 1\right)C_{(72)}\frac{\alpha^{3/2}}{B^{1/4}},$$

which yields condition (108).

Finally, if ξ satisfies (109), then

$$\|r_{\text{eff}}(\xi) - r_C(\xi)\| \leqslant \frac{4C_{(72)}}{\alpha^{1/2}B^{1/4}d_C(\xi)} \max\left\{\frac{\nu_C\alpha^2}{d_C(\xi)}, 1\right\} \leqslant 4\nu_C C_{(72)}\frac{\alpha^{3/2}}{d_C(\xi)^2B^{1/4}} = C'_C\frac{\alpha^{3/2}}{d_C(\xi)^2B^{1/4}},$$

where we used that $d_C(\xi) \leqslant \alpha^2/2 \leqslant \nu_C\alpha^2$. This finishes the proof of Theorem 6.1. Q.E.D.

Proof of Theorem 1.3: We define

$$B_C := \max\{B_{\text{eff}}, B'_C\} \tag{114}$$

and

$$c_C := \max\{C''_c, 2c_{\text{eff}}\alpha(B_C)^{-1/2}B_C^{-1/4}\}. \tag{115}$$

Suppose that $B \geqslant B_C$, and that

$$c_C\alpha^{3/2}B^{-1/4} \leqslant d_C(\xi) \leqslant \tfrac{1}{4}\alpha^2.$$

By Theorem 6.1, $d_{\text{eff}}(\xi) \leqslant 2d_C(\xi) \leqslant \alpha^2/2$. By the same theorem, and by (115),

$$d_{\text{eff}}(\xi) \geqslant \tfrac{1}{2}d_C(\xi) \geqslant c_{\text{eff}}\alpha(B_C)^{-1/2}B_C^{-1/4}\alpha^{3/2}B^{-1/4} \geqslant c_{\text{eff}}\alpha(B)B^{-1/2},$$

since $\alpha(B)/\sqrt{B}$ is a decreasing function of $B > 0$. The conditions of Theorem 1.1 are therefore met. Since the condition (109) of Theorem 6.1 is clearly also satisfied, we conclude that the difference of the resolvents (15) can be estimated by

$$C_{\text{eff}}\frac{\alpha^2}{d_{\text{eff}}(\xi)^2\sqrt{B}}+C'_C\frac{\alpha^{3/2}}{d_C(\xi)^2B^{1/4}}\leqslant C_c\frac{\alpha^{3/2}}{d_C(\xi)^2B^{1/4}},$$

for $B\geqslant B_C$, with

$$C_C:=4C_{\text{eff}}\frac{\sqrt{\alpha(B_C)}}{B_C^{1/4}}+C'_C, \tag{116}$$

where we used that $\alpha(B)/\sqrt{B}$ is decreasing. Q.E.D.

VII. PROOF OF THEOREM 1.5

This will be done by closely following the strategy of Sec. VI. First, we compare the resolvents $r_{\text{eff}}(\xi)$ of h_{eff} and $r_\delta(\xi):=(h_\delta-\xi)^{-1}$ of $h_\delta:=h_\delta^{B,\mathbb{M}}$. Recall, that $d_\delta(\xi):=\text{dist}(\xi,\sigma(h_\delta))$.

Theorem 7.1: *Let $\alpha=\alpha(B)$ be defined by (6). There exist (computable) constants B'_δ, $C'_\delta\geqslant 0$, only depending on Z, N, and $\mathbb{M}$, such that for all $B\geqslant B'_\delta$ and all real ξ satisfying*

$$d_\delta(\xi)\geqslant C'_\delta\alpha, \tag{117}$$

we have that $\xi\in\rho(h_{\text{eff}})$, with $\|r_{\text{eff}}(\xi)\|\leqslant 2\|r_\delta(\xi)\|$. In addition, letting

$$C''_\delta=\max\left\{C'_\delta,4C_{(118)}\left(\frac{N}{2\varepsilon_{\text{eff}}^2}+1\right)\right\}\quad\text{with } C_{(118)}:=\left(NZ+\frac{N(N-1)}{2}\right)C_{(84)}, \tag{118}$$

and ε_{eff} given by (95), then if

$$d_\delta(\xi)\geqslant C''_\delta\alpha, \tag{119}$$

we also have that $\|r_\delta(\xi)\|\leqslant 2\|r_{\text{eff}}(\xi)\|$. Finally, if

$$C'_\delta\alpha\leqslant d_\delta(\xi)\leqslant\tfrac{1}{2}\alpha^2, \tag{120}$$

then

$$\|r_{\text{eff}}(\xi)-r_\delta(\xi)\|\leqslant C'_\delta\frac{\alpha}{d_\delta(\xi)^2}. \tag{121}$$

Proof: As in the proof of Theorem 5.1, Theorem 6.1 shows that

$$\|r_{\text{eff}}(\xi)-r_\delta(\xi)\|\leqslant\frac{1}{d_\delta(\xi)}\frac{\|K_\delta(\xi)\|}{1-\|K_\delta(\xi)\|},$$

where $K_\delta:=|r_\delta(\xi)|^{1/2}(h_{\text{eff}}-h_\delta)r_\delta(\xi)^{1/2}$. Using Lemma 4.8 with $c=2$, Lemma 4.6, the triangle inequality, and similar comparison arguments as in the proofs of Theorems 5.1 and 6.1, we easily find that, for any $\mu<\inf\sigma(h_\delta)$,

$$\|K_\delta(\xi)\|\leqslant\frac{C_{(118)}}{\alpha}\max\left\{\frac{|\mu|}{d_\delta(\xi)},1\right\}\|r_\delta(\mu)^{1/2}(h_{00}+\alpha^2)^{1/2}\|^2, \tag{122}$$

where $C_{(118)}$ was defined above. We then use the following analogue of Lemmas 5.3 and 6.2.

Lemma 7.2: Let $\nu_\delta=1/2+4NZ^2$, $\mu_\delta:=-\nu_\delta\alpha^2$ and let α be defined by (6). Then $\mu_\delta<\inf\sigma(h_\delta)$, and

$$\|r_\delta(\mu_\delta)^{1/2}(h_{00}+\alpha^2)^{1/2}\|^2\leqslant 2. \tag{123}$$

Proof: We will use, as before, the scaling $z\mapsto z/\alpha$. We get, with the help of Lemma 4.9,

$$h_\delta - \mu \simeq \alpha^2(h_{00} + 2v_\delta - \alpha^{-2}\mu) \geqslant \alpha^2\left(h_{00} - 2Z\sum_{j=1}^{N}\delta(z_j) - \alpha^{-2}\mu\right)$$

$$\geqslant \alpha^2(h_{00}(1-2Z\varepsilon) - N\varepsilon^{-1}Z - \alpha^{-2}\mu) \quad (\varepsilon > 0) = \frac{1}{2}\alpha^2(h_{00}+1),$$

if we choose $\varepsilon = \varepsilon_\delta := 1/(4Z)$ and $\mu = \mu_\delta := -\alpha^2(\frac{1}{2} + 4NZ^2)$. Q.E.D.

We continue with the proof of Theorem 7.1. By (122) and (123) with $\mu = \mu_\delta$, we find that

$$\|K_\delta(\xi)\| \leqslant \frac{2C_{(118)}}{\alpha}\max\left\{\frac{\nu_\delta\alpha^2}{d_\delta(\xi)}, 1\right\} \leqslant \frac{1}{2},$$

if both

$$d_\delta(\xi) \geqslant 4C_{(118)}\nu_\delta\alpha =: C'_\delta\alpha,$$

and $\alpha \geqslant 4C_{(118)}$ which, since $B \mapsto \alpha(B)$ is increasing, is equivalent to

$$B \geqslant B'_\delta := 16C^2_{(118)}e^{8C_{(118)}}.$$

This fixes our constants C'_δ and B'_δ, and also implies that $\|r_{\text{eff}}(\xi)\| \leqslant 2\|r_\delta(\xi)\|$, by the resolvent formula. To show that (119) implies that $\|r_\delta(\xi)\| \leqslant 2\|r_{\text{eff}}(\xi)\|$, we repeat the argument with r_δ and r_{eff} interchanged: by the resolvent formula,

$$r_\delta(\xi) = r_{\text{eff}}(\xi)^{1/2}(1 + \widetilde{K}_\delta(\xi))^{-1}|r_{\text{eff}}(\xi)|^{1/2},$$

with

$$\widetilde{K}_\delta(\xi) := |r_{\text{eff}}(\xi)|^{1/2}(h_\delta - h_{\text{eff}})r_{\text{eff}}(\xi)^{1/2},$$

so that, using Lemmas 4.8, 5.2, and 5.3, we arrive at

$$\|\widetilde{K}_\delta(\xi)\| \leqslant 2\max\left\{\frac{|\mu_{\text{eff}}|}{d_{\text{eff}}(\xi)}, 1\right\}\frac{C_{(118)}}{\alpha} \leqslant 2\max\left\{\frac{2|\mu_{\text{eff}}|}{d_\delta(\xi)}, 1\right\}\frac{C_{(118)}}{\alpha},$$

if $d_\delta(\xi) \geqslant C'_\delta\alpha$, by the first part. We therefore conclude that $\|\widetilde{K}_\delta(\xi)\| \leqslant 1/2$ if both $\alpha \geqslant 4C_{(118)}$, which is satisfied since $B \geqslant B'_\delta$ defined above, and if

$$\frac{4|\mu_{\text{eff}}|C_{(118)}}{\alpha d_\delta(\xi)} \leqslant \frac{1}{2}.$$

The latter inequality is equivalent to

$$d_\delta(\xi) \geqslant 4\left(\frac{N}{2\varepsilon^2_{\text{eff}}} + 1\right)C_{(118)}\alpha,$$

which yields condition (119). Finally, if ξ satisfies (120), then

$$\|r_{\text{eff}}(\xi) - r_\delta(\xi)\| \leqslant \frac{4C_{(118)}}{\alpha d_\delta(\xi)}\max\left\{\frac{\nu_\delta\alpha^2}{d_\delta(\xi)}, 1\right\} = 4\nu_\delta C_{(118)}\frac{\alpha}{d_\delta(\xi)^2} = C'_\delta\frac{\alpha}{d_\delta(\xi)^2},$$

where we used that $d_\delta(\xi) \leqslant \alpha^2/2 \leqslant \nu_\delta\alpha^2$. This finishes the proof of Theorem 7.1. Q.E.D.

Proof of Theorem 1.5: We want to realize the assumptions of Theorems 1.1 and 7.1 with conditions on B and d_δ. We define

$$B_\delta := \max\{B_{\text{eff}}, B'_\delta\}$$

and

$$c_\delta =: \max\{C''_\delta, 2c_{\text{eff}}B_\delta^{-1/2}\}. \tag{124}$$

Clearly $B \geqslant B_\delta$ and $c_\delta \alpha \leqslant d_\delta(\xi) \leqslant \alpha^2/4$ will do, for under these conditions, using Theorems 1.1 and 7.1, the left-hand side of (20) can be estimated by

$$\frac{C_{\text{eff}}\alpha^2}{d_{\text{eff}}^2(\xi)\sqrt{B}} + \frac{C'_\delta \alpha}{d_\delta^2(\xi)} \leqslant \left(\frac{4C_{\text{eff}}\alpha(B_\delta)}{\sqrt{B_\delta}} + C'_\delta\right)\frac{\alpha}{d_\delta(\xi)^2} =: C_\delta \frac{\alpha}{d_\delta(\xi)^2}$$

since we know that both $2d_{\text{eff}}(\xi) \geqslant d_\delta(\xi)$ and $2d_\delta(\xi) \geqslant d_{\text{eff}}(\xi)$, by Theorem 7.1, and since $\alpha(B)/\sqrt{B}$ is a decreasing function of $B > 0$. Q.E.D.

VIII. THE FERMIONIC CASE

We first prove Theorem 1.6. This is simply done by repeating the proofs of Theorems 1.1, 1.3, and 1.5 for the fermionized operators, that is, for the operators sandwiched between P^{AS}. We must check that the main ingredients of these proofs remain valid. First of all, Corollary 3.3 is used to compare the resolvents of $H_f^{B,\mathbb{M}}$ and $H_{\text{eff},f}^{B,\mathbb{M}} + \mathcal{W}_f$. Next, Lemma 4.7 remains valid for $\mathcal{W}_f := P^{AS}\mathcal{W}P^{AS}$, with the operator norm being the one on $P^{AS}(\text{Ran}\,\Pi_{\text{eff}}^{B,\mathbb{M}})$, since P^{AS} commutes with h_{00} on $\text{Ran}\,\Pi_{\text{eff}}^{B,\mathbb{M}} = L^2(\mathbb{R}^N, F_{\mathbb{M}}^B)$ (as we will explicitly see below, P^{AS} not only mixes the coordinates of $\mathbb{R}^N$, but also the different components with respect to the natural basis of $F_{\mathbb{M}}^B$; however, h_{00} acts in a scalar way). We then repeat the proof of Theorem 1.1 in Sec. V, replacing d_{eff} everywhere by $d_{\text{eff},f}$. Similar remarks apply to the proofs of Theorems 1.3 and 1.5. Q.E.D.

We next turn to Theorem 1.8. The parameter B here plays a nonessential role, and we will simply drop it, writing X_m, χ_m, $F_{\mathbb{M}}$ for X_m^B, χ_m^B, $F_{\mathbb{M}}^B$, etc. We start by analyzing the subspace of antisymmetric wave functions in the range of $\Pi_{\text{eff}} := \Pi_{\text{eff}}^B$. Recall that

$$\Sigma(\mathbb{M}) = \{m = (m_1, \ldots, m_N) : m_j \geqslant 0, m_1 + \cdots + m_N = \mathbb{M}\}.$$

The permutation group S_N acts on $\Sigma(\mathbb{M})$ by $\sigma \cdot (m_1, \ldots, m_N) = (m_{\sigma(1)}, \ldots, m_{\sigma(N)})$ and $\Sigma(\mathbb{M})$ can therefore be written as a disjoint union of orbits of S_N,

$$\Sigma(\mathbb{M}) = \bigcup_{\bar{m} \in \mathcal{M}} S_N \cdot \bar{m},$$

$\mathcal{M} \subset \Sigma(\mathbb{M})$ being a set of representatives of $S_N \backslash \Sigma(\mathbb{M})$. If we let

$$V_{\bar{m}} = \text{Span}\{X_{\sigma \cdot \bar{m}} : \sigma \in S_N\}, \tag{125}$$

then, recalling that $F_{\mathbb{M}} = \text{Span}\,\{X_m : m \in \Sigma(\mathbb{M})\}$, we have the orthogonal decomposition

$$F_{\mathbb{M}} = \bigoplus_{\bar{m} \in \mathcal{M}} F_{\bar{m}}.$$

From this it follows that

$$\Pi_{\text{eff}}^{1,\mathbb{M}}(L^2(\mathbb{R}^{3N}) \otimes \mathbb{C}^{2N}) = L^2(\mathbb{R}^N) \otimes F_{\mathbb{M}} = \bigoplus_{\bar{m} \in \mathcal{M}} L^2(\mathbb{R}^N) \otimes F_{\bar{m}}.$$

Since P^{AS} leaves each $L^2(\mathbb{R}^N) \otimes F_{\bar{m}}$ invariant, it suffices to analyze the subspace of antisymmetric wave functions in each of the latter. We therefore fix an $\bar{m} \in \mathcal{M}$ and let

$$G_{\bar{m}} = \{\sigma \in S_N : \sigma \cdot \bar{m} = \bar{m}\}, \tag{126}$$

the stabilizer of $\bar{m}$. Choose representatives $\sigma_1, \ldots, \sigma_K$, $K = K(\bar{m})$, for the right equivalence classes of $G_{\bar{m}}$ in S_N: $S_N / G_{\bar{m}} = \{\sigma_1 G_{\bar{m}}, \ldots, \sigma_K G_{\bar{m}}\}$ with $\sigma_i G_{\bar{m}} \cap \sigma_j G_{\bar{m}} = \emptyset$ if $i \neq j$. Then $X_{\sigma_1 \cdot \bar{m}}, \ldots, X_{\sigma_K \cdot \bar{m}}$ con-

stitutes an orthonormal basis for $F_{\bar{m}}$, and each element $\psi=\psi(x,y,z)$ of $L^2(\mathbb{R}^N)\otimes F_{\bar{m}}$ can be uniquely written as

$$\psi=\sum_{j=1}^{K} a_j X_{\sigma_j\cdot\bar{m}}=\sum_{j=1}^{K} a_j(z)X_{\sigma_j\cdot\bar{m}}(x,y), \tag{127}$$

for suitable $a_j=a_j(z)\in L^2(\mathbb{R}^N)$. For any such ψ and $r=(x,y,z)\in\mathbb{R}^{3N}=(\mathbb{R}^N)^3$,

$$\psi(\tau\cdot r)=\sum_j a_j(\tau\cdot z)X_{\sigma_j\cdot\bar{m}}(\tau\cdot x,\tau\cdot y)=\sum_j a_j(\tau\cdot z)X_{(\tau^{-1}\cdot\sigma_j)\cdot\bar{m}}(x,y),$$

where $\tau\cdot r=(r_{\tau(1)},\ldots,r_{\tau(N)})$, and similarly for $\tau\cdot x$, $\tau\cdot y$, and $\tau\cdot z$, and where we used that

$$X_m(\tau\cdot x,\tau\cdot y)=\prod_j \chi_{m_j}(x_{\tau(j)},y_{\tau(j)})=X_{\tau^{-1}\cdot m}(x,y).$$

It follows that $\psi\in L^2(\mathbb{R}^N)\otimes F_{\bar{m}}$ is antisymmetric iff, for any $\tau\in S_N$,

$$\sum_j a_j(\tau\cdot z)X_{(\tau^{-1}\sigma_j)\cdot\bar{m}}=(-1)^\tau\sum_j a_j(z)X_{\sigma_j\cdot\bar{m}}.$$

This is equivalent to the statement that ψ is antisymmetric iff,

$$\sum_j a_j(\tau\cdot z)X_{(\tau\sigma_j)\cdot\bar{m}}=(-1)^\tau\sum_j a_j(z)X_{\sigma_j\cdot\bar{m}}, \tag{128}$$

since the two statements are equivalent when τ is a transposition, and these generate S_N. The version (128), with no τ^{-1}, will be more convenient to work with. We next observe that the map $\sigma_j\to\tau\sigma_j$ gives rise to a permutation $\rho(\tau)$ of S_K.

Lemma 8.1: For any $\bar{m}\in\mathcal{M}$ the map $\rho=\rho_{\bar{m}}:S_N\to S_K$, $K=K(\bar{m})$, such that

$$\rho(\tau)(i)=j\Leftrightarrow\tau\sigma_i\in\sigma_j G_{\bar{m}}$$

is a well-defined homomorphism. Q.E.D.

In other words, $\rho(\tau)$ is characterized by

$$\tau\sigma_i\in\sigma_{\rho(\tau)(i)}G_{\bar{m}}.$$

One easily verifies that $\rho(\tau)$ is indeed a permutation of $\{1,\ldots,K\}$, and that ρ is an homomorphism of S_N into S_K.

With this notation, the left-hand side of (128) reads

$$\sum_j a_j(\tau\cdot z)X_{\sigma_{\rho(\tau)(j)}\cdot\bar{m}},$$

and on replacing j by $\rho(\tau)^{-1}(j)$ and using the fact that the $X_{\sigma_j\cdot\bar{m}}$ form a basis of $F_{\bar{m}}$, we find that ψ is antisymmetric iff, for all j and all $\tau\in S_N$,

$$a_j(z)=(-1)^\tau a_{\rho(\tau^{-1})(j)}(\tau\cdot z). \tag{129}$$

If we successively replace τ by τ^{-1} and z by $\tau\cdot z$, this becomes

$$a_j(\tau\cdot z)=(-1)^\tau a_{\rho(\tau)(j)}(z), \tag{130}$$

which implies that all a_j are uniquely determined by any one of them, a_1, say, which we let, by definition, correspond to $\sigma_1=e$, the unity element of S_N. More explicitly, since $\rho(\sigma_j)(1)=j$ (for $\sigma_j\sigma_1=\sigma_j\in\sigma_j G_{\bar{m}}=G_{\rho(\sigma_j)(1)\cdot\bar{m}}$, by definition of ρ), Eq. (129) with $\tau=\sigma_j$ implies the important relation

$$a_j(z) = (-1)^{\sigma_j} a_1(\sigma_j \cdot z). \tag{131}$$

In particular, $P^{AS}(L^2(\mathbb{R}^N) \otimes F_{\bar{m}})$ can be identified with a subspace of $L^2(\mathbb{R}^N)$, by sending ψ to a_1 [see (132)]. We now analyze the symmetry properties of a_1 imposed by the antisymmetry of ψ.

Lemma 8.2: Let H be the subgroup of S_N generated by the set $\{\tau\sigma_{\rho(\tau)(1)}^{-1}: \tau \in S_N\}$. Then, for all $\sigma \in H$, $a_1(\sigma\cdot z)=(-1)^{\sigma}a_1(z)$, and these are the only symmetry-conditions which the anti-symmetry of ψ imposes on a_1.

Proof: Let $\tau \in S_N$ be arbitrary. Then by (130), $a_1(\tau\cdot z)=(-1)^{\tau}a_{\rho(\tau)(1)}(z)$ which, by (131), equals $(-1)^{\tau}(-1)^{\sigma_{\rho(\tau)(1)}}a_1(\sigma_{\rho(\tau)(1)}\cdot z)$. Therefore

$$a_1(\tau\sigma_{\rho(\tau)(1)}^{-1} \cdot z) = (-1)^{\tau\sigma_{\rho(\tau)(1)}^{-1}} a_1(z),$$

whence the lemma. Q.E.D.

Lemma 8.3: The group H of Lemma 8.2 is generated by the union of all stabilizers $G_{\sigma_j\cdot\bar{m}}$ of $\sigma_j\cdot\bar{m}$, $1 \leqslant j \leqslant K$.

Proof: Let $\tau \in S_N$. Then $\tau \in \sigma_j G_{\bar{m}}$, for some j. Since $\tau\sigma_1 = \tau e \in \sigma_j G_{\bar{m}}$, we have that $\rho(\tau)(1) = j$, and therefore $\tau\sigma_{\rho(\tau)(1)}^{-1} \in \sigma_j G_{\bar{m}}\sigma_j^{-1} = G_{\sigma_j\cdot\bar{m}}$.

Conversely, if $\sigma \in G_{\sigma_j\cdot\bar{m}}$, then $\sigma = \sigma_j\sigma'\sigma_j^{-1}$, for some $\sigma' \in G_{\bar{m}}$. Set $\tau = \sigma_j\sigma'$. Then $\rho(\tau)(1)=j$, since $\sigma_j\sigma'\sigma_1 \in \sigma_j G_{\bar{m}}$, and therefore $\sigma = \tau\sigma_j^{-1} = \tau\sigma_{\rho(\tau)(1)}^{-1}$ is a generator of H. We conclude that the set of generators of H equals $\cup_j G_{\sigma_j\cdot\bar{m}}$, which proves the lemma. Q.E.D.

Lemma 8.4: Let H be the subgroup from Lemma 8.2. If $G_{\bar{m}}=\{e\}$, then $H=\{e\}$, while if $G_{\bar{m}} \neq \{e\}$, then $H=S_N$.

Proof: It is obvious, from Lemma 8.3, that if $G_{\bar{m}}=\{e\}$, then $H=\{e\}$, and a_1 does not have to satisfy any symmetry conditions with respect to the action of S_N, by Lemma 8.2.

Now suppose that $G_{\bar{m}}$ is nontrivial. Then there exist two indices i and j such that $\bar{m}_i = \bar{m}_j$. We can suppose, without loss of generality, that $i=1$ and $j=2$. In that case, the transposition (12) is in $G_{\bar{m}}$, and therefore $(\sigma(1),\sigma(2)) = \sigma(12)\sigma^{-1} \in H$, for all $\sigma \in S_N$, by Lemma 8.3 again. But then all transpositions will be in H, which clearly implies that $H=S_N$. Q.E.D.

Define a linear mapping

$$U_{\bar{m}}: P^{AS}(L^2(\mathbb{R}^N) \otimes F_{\bar{m}}) \to L^2(\mathbb{R}^N), \tag{132}$$

by

$$U_{\bar{m}}(\psi)(z) = \sqrt{K}(\psi(\cdot,z), X_{\bar{m}})_{L^2(\mathbb{R}^{2N})},$$

where we recall that $K=K(\bar{m})=\#(S_N/G_{\bar{m}})$. If ψ is given by (127), then $U_{\bar{m}}(\psi)(z)=\sqrt{K}a_1(z)$. By (130), $\|U_{\bar{m}}\psi\|^2 = \|\psi\|^2$, so that $U_{\bar{m}}$ is unitary and therefore injective. If $G_{\bar{m}}$ is nontrivial, then $H = S_N$, and the image of $U_{\bar{m}}$ is contained in the space $L^2_{AS}(\mathbb{R}^N)$ of antisymmetric wave functions on $\mathbb{R}^N$, by Lemmas 8.2 and 8.4. Since the only symmetries of a_1 are those imposed by H, it follows that $U_{\bar{m}}$ is surjective onto $L^2_{AS}(\mathbb{R}^N)$. Similarly, if $G_{\bar{m}}=\{e\}$, then $H=\{e\}$, and the image of $U_{\bar{m}}$ is $L^2(\mathbb{R}^N)$: indeed, if $a_1 = a_1(z)$ is arbitrary, then

$$\psi_{a_1} := \sum_{\sigma \in S_N} a_1(\sigma \cdot z) X_{\sigma\cdot\bar{m}}(y,z)$$

is an antisymmetric element of $L^2(\mathbb{R}^N) \otimes F_{\mathbb{M}}$ such that $U_{\bar{m}}(\psi_{a_1}) = a_1$.

Proof of Theorem 1.8: Recall that

$$\mathcal{M}_1 = \{\bar{m} \in \mathcal{M}: G_{\bar{m}} = \{e\}\}, \quad \mathcal{M}_2 = \{\bar{m} \in \mathcal{M}: G_{\bar{m}} \neq \{e\}\},$$

and define

$$U_{\mathbb{M}} =: U_{\mathbb{M}}^{B}:P^{AS}(L^2(\mathbb{R}^N \otimes F_{\mathbb{M}})) \to \overset{\oplus}{\sum_{\bar{m}\in\mathcal{M}_1}} L^2(\mathbb{R}^N) \oplus \overset{\oplus}{\sum_{\bar{m}\in\mathcal{M}_2}} L^2_{AS}(\mathbb{R}^N), \tag{133}$$

by $U_{\mathbb{M}} := \oplus_{\bar{m}\in\mathcal{M}} U_{\bar{m}}$. Then we have shown that $U_{\mathbb{M}}$ is a surjective isometry. The intertwining formula of $h^{\mathbb{M}}_{\delta,f}$ with $U_{\mathbb{M}}$ being obvious, this proves Theorem 1.8. Q.E.D.

Contrary to $h^{\mathbb{M}}_{\delta,f}$, the operator $U_{\mathbb{M}} h^{\mathbb{M}}_{C,f} U^*_{\mathbb{M}}$ will in general not act diagonally anymore on the range of $U_{\mathbb{M}}$, but will contain terms which couple antisymmetric and boltzonic components in (133), that is, components in $L^2_{AS}(\mathbb{R}^N)$ and $L^2(\mathbb{R}^N)$. The potentially problematic terms in $h^{\mathbb{M}}_{C,f}$ are $U_{\mathbb{M}} C^{n,\mathbb{M}}_{\mathrm{av}:1} U^*_{\mathbb{M}}$ and $U_{\mathbb{M}} C^{e,\mathbb{M}}_{\mathrm{av}:2} U^*_{\mathbb{M}}$ (still dropping the B from our notations). The first one is easily seen to act diagonally on the right-hand side of (133): recall that

$$C^{n,\mathbb{M}}_{\mathrm{av}:1} = -\Pi^1_{\mathrm{eff}} \left(\frac{1}{N} \sum_{j=1}^{N} \log\left(\frac{1}{4}\rho_j^2 \right) \right) \Pi^1_{\mathrm{eff}},$$

and identify this with a Hermitian operator on $F_{\mathbb{M}} = \mathrm{Span}\,\{X_m : m \in \Sigma(\mathbb{M})\}$ [it acts as a multiplication operator on $L^2(\mathbb{R}^N, F_{\mathbb{M}})$]. The matrix of $C^{n,\mathbb{M}}_{\mathrm{av}:1}$ in the basis X_m, $m \in \Sigma(\mathbb{M})$, is easily seen to be diagonal. Moreover,

$$\langle X_{\sigma\cdot m} | C^{n,\mathbb{M}}_{\mathrm{av}:1} | X_{\sigma\cdot m} \rangle = -\int_{\mathbb{R}^{2N}} |X_m(\sigma^{-1}\cdot(x,y))|^2 \log \frac{1}{4} (\Pi_{j=1}^N \rho_j^2)^{1/N} \, \mathrm{d}x \, \mathrm{d}y = \langle X_m | C^{n,\mathbb{M}}_{\mathrm{av}:1} | X_m \rangle.$$

Hence, taking $B=1$, for simplicity, $C^{n,\mathbb{M}}_{\mathrm{av}:1}$ will act on $F_{\bar{m}}$ as scalar multiplication by

$$\begin{aligned}\langle X_{\bar{m}} C^{n,\mathbb{M}}_{\mathrm{av}:1} | X_{\bar{m}} \rangle &= -\frac{1}{N}\sum_{j=1}^{N} \int_{\mathbb{R}^{2N}} \left(\log \frac{\rho_j^2}{4} \right) \Pi_{\nu=1}^N |\chi^1_{\bar{m}_\nu}|^2(\rho_\nu) \mathrm{d}x_\nu \, \mathrm{d}y_\nu = -\frac{1}{N}\sum_{j=1}^{N} \int_{\mathbb{R}^2} \left(\log \frac{\rho^2}{4} \right) |\chi^1_{\bar{m}_j}|^2(\rho) \mathrm{d}x \, \mathrm{d}y \\ &= -\frac{1}{N}\sum_{j=1}^{N} (2^{\bar{m}_j} \bar{m}_j!)^{-1} \int_0^\infty \rho^{2\bar{m}_j+1} \log \frac{\rho^2}{4} e^{-\rho^2/2} \, \mathrm{d}\rho = \log 2 - \frac{1}{N}\left(\sum_{j=1}^{N} \psi(\bar{m}_j + 1) \right),\end{aligned}$$

where $\psi(z) = \Gamma'(z)/\Gamma(z)$, the logarithmic derivative of the Γ-function. Hence $U_{\mathbb{M}} C^{n,\mathbb{M}}_{\mathrm{av}:1} U^*_{\mathbb{M}}$ simply acts diagonally on the right-hand side of (133), and more precisely, by scalar multiplication in each component.

The operator $U_{\mathbb{M}} C^{e,\mathbb{M}}_{\mathrm{av}:2} U^*_{\mathbb{M}}$ is more complicated: it is not going to be diagonal in the natural basis and it will in general mix the different components Ran $U_{\mathbb{M}}$, even those with index in $\mathcal{M}_1$ and $\mathcal{M}_2$. This is already the case in the simplest case in which both $\mathcal{M}_1$ and $\mathcal{M}_2$ are nonempty, namely that of two electrons, $N=2$, and a total angular momentum of $\mathbb{M}=2$. In that case $\Sigma(\mathbb{M})$ is the union of two orbits under S_2, namely $\{(0,2), (2,0)\}$, and $\{(1,1)\}$ the first having as stabilizer the identity, and the second having as stabilizer the full group S_2. We can therefore take $\mathcal{M}_1 = \{(0,2)\}$ and $\mathcal{M}_1 = \{(1,1)\}$. We will now compute the matrix element

$$\langle X^1_{(0,2)} | C^{e,2}_{\mathrm{av}:2} | X^1_{(1,1)} \rangle, \tag{134}$$

and simply observe that the result is nonzero. For this computation it is convenient to use complex notation for the lowest Landau functions (25): if we let $\zeta = x + iy$, then (taking $B=1$ again)

$$\chi^1_m = c_m \zeta^m e^{-|\zeta|^2/4},$$

where $c_m = (2\pi 2^m m!)^{-1/2}$. We then find that (134) equals

$$-c_0 c_2 c_1^2 \int_{\mathbb{C}} \int_{\mathbb{C}} \zeta_1 \zeta_2 \bar{\zeta}_2^2 \log\left(\frac{|\zeta_1 - \zeta_2|^2}{4} \right) e^{-(|\zeta_1|^2 + |\zeta_2|^2)/2} \, \mathrm{d}\zeta_1 \, \mathrm{d}\zeta_2.$$

Making the (by now familiar) change of variables $u = (\zeta_1 + \zeta_2)/\sqrt{2}$, $v = (\zeta_1 - \zeta_2)/\sqrt{2}$, this integral becomes

$$-\frac{c_0c_2c_1^2}{4}\int_{\mathbb{C}}\int_{\mathbb{C}}(u^2-v^2)(\bar{u}-\bar{v})^2\log(|v|^2/8)e^{-(|u|^2+|v|^2)/2}\,\mathrm{d}u\,\mathrm{d}v.$$

Since $(u^2-v^2)(\bar{u}^2-2\overline{uv}+\bar{v}^2)=|u|^4-|v|^4+2i\,\mathrm{Im}\,u^2\bar{v}^2+2\overline{uv}(v^2-u^2)$, and since, in general,

$$\int_{\mathbb{C}}\int_{\mathbb{C}}u^\sigma\bar{u}^\beta v^\nu\bar{v}^\kappa g(|u|^2,|v|^2)\mathrm{d}u\,\mathrm{d}v=0,$$

unless $\alpha=\beta$ and $\nu=\kappa$, we obtain that (134) equals

$$\begin{aligned}&-\frac{c_0c_2c_1^2}{4}\int_{\mathbb{C}}\int_{\mathbb{C}}(|u|^4-|v|^4)\log(|v|^2/8)e^{(|u|^2+|v|^2)/4}\,\mathrm{d}u\,\mathrm{d}v\\&=-\frac{c_0c_2c_1^2}{4}\left\{\int_{\mathbb{C}}|u|^4e^{-|u|^2/2}\,\mathrm{d}u\int_{\mathbb{C}}\log(|v|^2/8)e^{-|v|^2/2}\,\mathrm{d}v\right.\\&\left.-\int_{\mathbb{C}}e^{-|u|^2/2}\,\mathrm{d}u\int_{\mathbb{C}}|v|^4\log(|v|^2/8)e^{-|v|^2/2}\,\mathrm{d}v\right\}=\frac{3}{16\sqrt{2}},\end{aligned}$$

as can be shown using the Γ-function and its derivative. So (134) is nonzero, and $U_{\mathbb{M}}h^{\mathbb{M}}_{C,f}U^*_{\mathbb{M}}$ mixes the two sectors.

IX. CONCLUDING REMARKS

We finally want to give an idea what these effective Hamiltonians might be good for. Our original motivation for introducing them was for studying the structure of the bottom of spectrum of $H^{B,\mathbb{M}}$, in connection with the maximum ionization problem for atoms in strong magnetic fields; see below. To illustrate how this works, we first consider the comparison with $H^{B,\mathbb{M}}_\delta=h^{B,\mathbb{M}}_\delta\oplus H^{B,\mathbb{M}}_\perp$; cf. Theorem 1.5. Since, by construction, $B_\delta>B_{(36)}$, we know from Theorem 3.1 that $\sigma(H^{B,\mathbb{M}}_\perp)\subset(0,\infty)$ if $B>B_\delta$. Let $E_\delta:=\inf h^B_\delta$, then clearly $E_\delta<0$.

Since h^B_δ is unitarily equivalent to $\alpha^2\left(-\frac{1}{2}\Delta_z+2v_\delta\right)$ we conclude that whenever E_δ is an isolated eigenvalue, its position as well as its isolation distance is proportional to α^2. That E_δ is an eigenvalue is true for Z large enough when N is fixed; to determine how big Z must be exactly, relative to N, for this to happen is an open problem (see below). Let us assume henceforth that E_δ is an eigenvalue, which then necessarily is simple. Consequently E_δ is an eigenvalue of $H^{B,\mathbb{M}}_\delta$ with multiplicity $\dim F^B_{\mathbb{M}}$, see (18). Choose two points $\xi_\pm:=E_\delta\pm C\alpha^2$ in $\rho(H^{B,\mathbb{M}}_\delta)\cap\rho(H^{B,\mathbb{M}})$, which satisfy (19). This is possible when $B>B_\delta$, see Theorem 1.5. Let Γ be the circle in the complex plane centered at E_δ with radius $C\alpha^2$ and define P and P_δ as the eigenprojections associated to $H^{B,\mathbb{M}}$ and $h^{B,\mathbb{M}}_\delta$, respectively, onto their spectrum inside Γ. To estimate $P-P_\delta$ we need a bound on $R(\xi)-R_\delta(\xi):=(H^{B,\mathbb{M}}-\xi)^{-1}-(H^{B,\mathbb{M}}_\delta-\xi)^{-1}$ for all $\xi\in\Gamma$. We know already that $\|R(\xi_\pm)-R_\delta(\xi_\pm)\|\leqslant C_\delta\alpha/d_\delta(\xi_\pm)^2=C_\delta C^{-2}\alpha^{-3}$ by Theorem 1.5. To propagate this estimate on all of Γ we use the convenient formula [see Ref. 12, Sec. IV, (3.10)]

$$\|R(\xi)-R_\delta(\xi)\|\leqslant\frac{\left\|\frac{H^{B,M}_\delta-\xi_\pm}{H^{B,M}_\delta-\xi}\right\|^2\|R(\xi_\pm)-R_\delta(\xi_\pm)\|}{1-|\xi-\xi_\pm|\left\|\frac{H^{B,M}_\delta-\xi_\pm}{H^{B,M}_\delta-\xi}\right\|\|R(\xi_\pm)-R_\delta(\xi_\pm)\|}\leqslant\frac{C_\delta C^{-2}\alpha^{-3}}{1-\sqrt{2}C_\delta C^{-1}\alpha^{-1}}.$$

Then integrating over the contour Γ finally gives $\|P-P_\delta\|=\mathcal{O}(\alpha^{-1})$ as B tends to infinity. This shows that for B large enough these two projections have the same dimension and since they are continuous with respect to B we finally get that for all $B>B_\delta$, $\dim P=\dim P_\delta=\dim F^B_{\mathbb{M}}$.

Our conclusion is therefore that, for sufficiently large B, $H^{B,\mathbb{M}}$ will have a cluster of eigenvalues in the interval $(E_\delta - c_\delta\alpha^2, E_\delta + c_\delta\alpha^2)$ with total multiplicity of $\dim F^B_{\mathbb{M}}$, and apart from this no eigenvalues at a distance $C\alpha^2$ from E_δ (the allowed B's will depend on C), so that the cluster is separated from the rest of the spectrum by a distance proportional to α^2. In the particular case when $\dim F^B_{\mathbb{M}}=1$, i.e., $\mathbb{M}=0$ or $N=1$, we get an estimate on the difference of the eigenvectors $\Phi - \Phi_\delta = \mathcal{O}(\alpha^{-1})$ as $B\to\infty$ (in the L^2 norm). Here Φ denotes the eigenvector of $H^{B,\mathbb{M}}$ and $\Phi_\delta(x,y,z) := \varphi^B_\delta(z)X^B_{m=0}(x,y)$ if $\mathbb{M}=0$, where φ^B_δ is the ground state of h^B_δ. In the case $N=1$ one has $\varphi^B_\delta(z) = \sqrt{2\alpha Z}e^{-2\alpha Z|z|}$.

Consider now the comparison with $h^{B,\mathbb{M}}_C$. The difficulty here is to find the necessary *a priori* information on the structure of $\sigma(h^{B,\mathbb{M}}_C)$. In the case of $N=1$, using the invariance of $\sigma(h^{B,\mathbb{M}}_C)$ under the reflection $z\mapsto -z$, and the characterization of the domain of $\sigma(h^{B,\mathbb{M}}_C)$ in the Appendix, one sees that the odd spectrum (that is, the spectrum of h_C restricted to the odd wave functions) is B-independent and coincides with the spectrum of the hydrogen in the s sector of symmetry. Since the even spectrum intertwines with the odd spectrum and since it is monotonically decreasing with respect to B, cf. (11), it is easy to realize that $\sigma(h^{B,\mathbb{M}}_C)\cap\mathbb{R}_-$, apart from the ground state energy, is made up of clusters of two eigenvalues, the clusters being separated by a distance of order 1 as $B\to\infty$. Thus by using Theorem 1.3 and following a similar strategy as above one can conclude that for $N=1$, and arbitrarily small ε, $\sigma(H^{B,\mathbb{M}})\cap(-\infty,-\varepsilon]$ has the same cluster structure for $B > B_\varepsilon$ sufficiently large. Moreover this spectrum deviates from the one of the Coulomb model by at most $c_C\alpha(B)^{3/2}B^{-1/4}$ as $B\to\infty$.

The model operator $h^{B,\mathbb{M}}_{\text{eff}}$ is for the moment of mainly theoretical interest since it does not seem to be solvable even in the one electron case. Notice however that one could solve $h^{B,\mathbb{M}}_{\text{eff}}$ numerically, at least for few electrons and small $\mathbb{M}$, and subsequently use Theorem 1.1 to approximate the true spectrum of $H^{B,\mathbb{M}}$ for large B. Given the nontrivial dimension reduction achieved by Theorem 1.1 (from wave functions of $3N$ variables to ones of N variables, albeit vector-valued) such a procedure would, from a numerical point of view, seem preferable to attacking $H^{B,\mathbb{M}}$ directly.

Whether the simpler models, i.e., the delta and the Coulomb model, are solvable in the N-electron case, $N\geqslant 2$, is a challenging question in view of applications. We are thinking in particular of the problem of *determining the maximum number N_c of electrons which a clamped nucleus with charge Z can bind when an intense homogeneous magnetic field is applied*. Reference 14 has shown that $\liminf N_c/Z \geqslant 2$ as Z, $B/Z^3\to\infty$. Very little precise is known for fixed Z and high B. It is conjectured that there should be a B-independent absolute (that is, nonasymptotic) upper bound of the form $N_c \leqslant aZ+b$, similar to Lieb's bound $N_c \leqslant 2Z+1$ valid when $B=0$, but this is as yet unproved. Some weaker results are known, of which the best to date is the one of Ref. 18; see also Ref. 7 for work on heuristic models related to our $h^{B,\mathbb{M}}_{\text{eff}}$. It is natural to first try to solve the maximal binding question for h^B_δ, or any of our other effective Hamiltonian, and use the approximation theorems of this paper to draw conclusions for $H^{B,\mathbb{M}}$ itself. Some modest progress is possible in this way. It is, for example, known that the delta model with two electrons is at least numerically solvable, see Ref. 16, and that this model possesses a unique bound state at the bottom of its spectrum as long as $Z>0.375$. Therefore using Theorem 1.5 we see that for all $Z>0.375$ there exists $B_Z\geqslant 0$ such that for all $B\geqslant B_Z$ one nucleus with such a charge can bind two electrons. As a consequence, Lieb's bound of $N_c\leqslant 2Z+1$ is no longer valid in strong magnetic fields. For general Z, no maximum ionization bound for the δ-model is known as yet.

Let us now briefly turn to the effect of particle symmetry. It follows from Theorems 1.6 and 1.8 that $H^{B,\mathbb{M}}_f$ can be approximated by a direct sum of copies of h^B_δ acting on antisymmetric $L^2(\mathbb{R}^N)$ plus a direct sum of copies of h^B_δ acting on $L^2(\mathbb{R}^N)$ *without any symmetry condition*. The latter will occur iff $\mathcal{M}_1\neq\emptyset$, which is the case iff $\mathbb{M}\geqslant 0+1+\cdots+(N-1)=\frac{1}{2}N(N-1)$. For such $\mathbb{M}$, the ground state energy will be approximately that of boltzonic h^B_δ, which is also the ground state energy of the bosonic h^B_δ, and the same can be shown to be the case for the ground state wave function (assuming there is one), by standard permutation arguments. In fact, Theorem 1.6 plus Theorem 1.8 predict the existence of a cluster of $\#\mathcal{M}_1$ eigenvalues at the bottom of the spectrum of $H^{B,\mathbb{M}}_f$, at a distance of order $\alpha(B)^2$ from the origin as $B\to\infty$.

A further interesting corollary to Theorem 1.8 can be obtained by considering $\mathbb{M}$ as a free parameter. If h_δ^B possesses a ground state, whose energy is isolated in its spectrum, then for sufficiently large B, $H_f^B := P^{\mathrm{AS}} H^B$ will assume its ground state for an $\mathbb{M} \geqslant \frac{1}{2}N(N-1)$. Stated otherwise, assuming there is a mechanism for transfer of the angular momentum (e.g., emission and absorption of photons), atoms in strong magnetic fields will have an orbital angular momentum in the field direction of at least $\frac{1}{2}N(N-1)$. A natural conjecture is that we have equality here. Notice that this conjecture was shown to be true in the case of $N=1$ in Ref. 2, see also Ref. 3.

We mention one further application of these effective Hamiltonians. After the location of the spectrum to leading order one can now use regular perturbation theory to compute lower order corrections. We have shown how this can be done in Ref. 5. This seems definitely more convenient than variational techniques and more familiar than the Birman-Schwinger method used in Ref. 2 for the one electron case. Continuing, for example, the above comparison of $H^{B,\mathbb{M}}$ with $h_\delta^{B,\mathbb{M}}$, it is immediate to realize that adding the first order perturbative correction will give an error of order 1. In case $N=1$ we get that the ground state energy of $H^{B,\mathbb{M}}$ is equal to $\langle h_{\mathrm{eff}}^{B,\mathbb{M}} \Phi_\delta, \Phi_\delta \rangle + \mathcal{O}(1)$ with $\Phi_\delta(x,y,z) = \sqrt{2\alpha Z} e^{-2\alpha Z|z|} \chi_{\mathbb{M}}^B(x,y)$. This should be compared to Theorem 2.5 of Ref. 2. In fact, one can write the ground state energy as a convergent power series, each term of which being of order α^{-k} for k running from -2 to infinity. However, as pointed out in Ref. 2, in view of the $\log(B)$ behavior of α this series is of limited value. The situation will be much better with the Coulomb model $h_C^{B,\mathbb{M}}$ since the perturbation series will converge much faster because of the $\alpha^{3/2}B^{-1/4}$ behavior of the rhs of (15). We hope to tackle this program soon.

The above remarks concentrated on applications of our effective Hamiltonians to the ground state energy of $H^{B,\mathbb{M}}$, but their potential interest is not limited to that. As the example of h_C shows, other parts of the discrete spectrum of $H^{B,\mathbb{M}}$ will also become amenable to analysis, if this is the case for the effective operator. On a conceptual level, Theorem 1.1 gives a precise mathematical sense to, and justification of, the physicist's attractive heuristic picture of an atom in a strong homogeneous magnetic field as consisting of electrons in their lowest Landau band states interacting through a kind of "residual" electrostatic interaction. Finally let us note that the techniques developed in this paper are expected to work in other contexts. An interesting example is that of two-dimensional electronic systems on a cylinder which describe excitons in carbon nanotubes; cf. Ref. 9.

ACKNOWLEDGMENTS

The authors first of all would like to thank Beth Ruskai for having introduced us to the fascinating world of atoms in strong magnetic fields. The authors would also like to thank the organizers of the Clausthal PDE Conference, Summer 1999, and of the Critical Stability Workshop at les Houches, October 2001, for having given us the opportunity to report on preliminary written versions of this work.[6]

APPENDIX: A CHARACTERIZATION OF THE OPERATOR DOMAIN OF h_C

In this appendix we will characterize the operator domain of $h_C = h_C^B$. It will in fact be convenient to consider a slightly more general situation. Let $\mathcal{L} = \{L_\nu, 1 \leqslant \nu \leqslant K\}$, be a finite collection of hyperplanes in $\mathbb{R}^N$ (we might more generally consider nonsingular C^1 hypersurfaces). Let F be a finite-dimensional complex vector space, with Hermitian inner product $(\cdot,\cdot)$ and let A_ν, B_ν be Hermitian operators on F. Let $H^k(\mathbb{R}^N, F)$ be the kth Sobolev space on $\mathbb{R}^N$, with values in F. Then the following sesquilinear form is well defined on $H^1(\mathbb{R}^N, F)$ and bounded from below:

$$t_{\mathcal{L}}(u,v) = \frac{1}{2}(\nabla u, \nabla v) + \sum_\nu \langle L_\nu^* \mathrm{Pf}(|\cdot|^{-1}), (A_\nu u, v) \rangle + \langle L_\nu^* \delta, (B_\nu u, v) \rangle, \tag{A1}$$

$\langle \cdot,\cdot \rangle$ denoting the duality between distributions and test functions. We let

$$h_{\mathcal{L}} = -\frac{1}{2}\Delta_z + \sum_\nu A_\nu \mathrm{Pf}\left(\frac{1}{L(z)}\right) + B_\nu \delta(L_\nu(z)).$$

be the associated self-adjoint operator, whose existence is guaranteed by the KL^{2}MN-theorem. Let $\mathcal{R}$ be the set of connected components of $\mathbb{R}^N \backslash \cup_\nu \mathrm{Ker}\, L_\nu$, so that $\mathbb{R}^N \backslash \cup_\nu \mathrm{Ker}\, L_\nu = \cup_{R\in\mathcal{R}} R$ and $R \cap R' = \emptyset$, if R, $R' \in \mathcal{R}$, $R \neq R'$. Note that, on any of these components R, $L_j^* \mathrm{Pf}(1/|\cdot|)$ simply equals the function $1/|L_j(z)|$. We will identify L_j with an element of $\mathbb{R}^N$, using the Euclidean inner product on $\mathbb{R}^N$; the latter will be denoted by a dot: $z \cdot w$, to distinguish it from the Hermitian inner product (v,w) on F. If we let $H^2(R,F)$ be the F-valued Sobolev space of order 2 on the open subset $R \subset \mathbb{R}^N$, then the domain of $h_{\mathcal{L}}$ can be characterized as follows.

Theorem A.1: *Let $u \in L^2(\mathbb{R}^N, F)$. Then $u \in \mathrm{Dom}(h_{\mathcal{L}})$ iff the following three conditions hold*:

(i) $u \in H^1(\mathbb{R}^N, F)$.

(ii) *For each $R \in \mathcal{R}$,*

$$-\frac{1}{2}\Delta u + \sum_\nu \frac{1}{|L_\nu(z)|} A_\nu u \in H^2(R,F).$$

(iii) *For each j and for each $x \in \{L_j = 0\} \backslash \cup_{k\neq j}\{L_k = 0\}$:*

$$L_j \cdot \nabla u\left(x + \varepsilon \frac{L_j}{\|L_j\|}\right) - L_j \cdot \nabla u\left(x - \varepsilon \frac{L_j}{\|L_j\|}\right) \simeq 4 \log \varepsilon A_j u(x) + 2B_j u(x) + o(1),$$

as $\varepsilon \to 0$.

Proof: We will use the following characterization (see Ref. 12) of $\mathrm{Dom}(h_{\mathcal{L}})$:

$$u \in \mathrm{Dom}(h_{\mathcal{L}}) \Leftrightarrow \begin{cases} u \in \mathrm{Dom}(t_{\mathcal{L}}) = H^1(\mathbb{R}^N, F), \\ \text{and} \\ |t_{\mathcal{L}}(u,v)| \leq C_u \|v\|^2, \qquad \forall v \in \mathrm{Dom}(t_{\mathcal{L}}) = H^1(\mathbb{R}^N, F), \end{cases} \tag{A2}$$

the norm on the right-hand side being the L^2-norm. Here we may, and will, suppose without loss of generality that $v \in C_c^1(\mathbb{R}^N, F)$, the space of compactly supported F-valued C^1-functions.

To analyze (A2), we will first establish a convenient integral expression for the pull-backs of δ and of Pf $(1/|\cdot|)$ under a linear map $L: \mathbb{R}^N \to \mathbb{R}$. Using the Euclidean inner product, we can identify L with an element of $\mathbb{R}^N$, which we also denote by L. Using the definition of pull-back (cf. Hörmander,[11] Chap. 6), one easily shows that if $\mathrm{d}\sigma_L$ denotes the Euclidean surface measure on $\mathrm{Ker}(L)$, and $\|L\|$ is the Euclidean norm of L, then

$$\langle L^* \delta, \varphi \rangle = \int_{\{L=0\}} \frac{\varphi}{\|L\|} \mathrm{d}\sigma_L, \tag{A3}$$

and

$$\langle L^* \mathrm{Pf}(1/|\cdot|), \varphi \rangle = -\int_{\mathbb{R}^N} \frac{\mathrm{sgn}(L(z)) \log |L(z)|}{\|L\|^2} L \cdot \nabla u(z) \mathrm{d}z. \tag{A4}$$

In fact, since taking pull-backs is coordinate invariant, it suffices to verify these formulas in an orthogonal coordinate system in which $L = (\|L\|, 0, \ldots, 0)$.

We next observe that, for each $R \in \mathcal{R}$, there exists a (unique) function $s_R: \{1, \ldots, K\} \to \{0,1\}$, such that

$$R = \{z \in \mathbb{R}^N : (-1)^{s_R(j)} L_j(z) \geqslant 0, j = 1, \ldots, K\},$$

and if $\varepsilon > 0$, we define R_ε by

$$R_\varepsilon = \{z \in \mathbb{R}^N : (-1)^{s_R(j)} L_j(z) \geqslant \varepsilon, j = 1, \ldots, K\}.$$

Observe that the boundary of R_ε, as well as that of R, are polyhedrae, each of whose faces are contained in one of the hypersurfaces $\{(-1)^{s_R(j)} L_j = \varepsilon\}$ and $\{L_j = 0\}$, respectively. On such face, the outward-pointing normal $n_{R,\varepsilon}$ can be identified with the vector $-(-1)^{s_R(j)} L_j / \|L_j\|$ (translated to the relevant base point on the face, to be precise). Note, that $n_{R,\varepsilon}$ is only defined almost everywhere on the boundary (with respect to the surface measure). This will not cause difficulties, though.

Suppose now that $u \in \mathrm{Dom}(h_{\mathcal{L}})$ and in particular satisfies the conditions (A2). We then have, for any $v \in C_c^1(\mathbb{R}^N, F)$,

$$t_{\mathcal{L}}(u,v) = \lim_{\varepsilon \to 0} \left\{ \frac{1}{2} \sum_{R \in \mathcal{R}} \int_{R_\varepsilon} (\nabla u, \nabla v) \mathrm{d}z - \sum_\nu \sum_R \int_{R_\varepsilon} \frac{\mathrm{sgn}(L_\nu) \log |L_\nu|}{\|L_\nu\|^2} (L_\nu \cdot \nabla)(A_\nu u, v) \mathrm{d}z \right.$$
$$\left. + \sum_\nu \int_{\{L_\nu = 0\}} \frac{(B_\nu u, v)}{\|L_\nu\|} \mathrm{d}\sigma_{L_\nu} \right\}. \tag{A5}$$

We want to apply Gauss' divergence theorem to each of the integrals over R_ε: this is allowed since if $u \in H^1(\mathbb{R}^N, F)$ satisfies (A2), then by choosing v compactly supported in R, we see that

$$-\frac{1}{2} \Delta_z u + \sum_\nu A_\nu \left(\frac{1}{L(z)} \right) u \in L^2_{\mathrm{loc}}(R, F),$$

which obviously implies that $\Delta u \in L^2_{\mathrm{loc}}(R, F)$ (since we are staying away from the singularities on the hyperplanes), and hence $u \in H^2_{\mathrm{loc}}(R, F)$. Now

$$\int_{R_\varepsilon} (\nabla u, \nabla v) \mathrm{d}z = \int_{R_\varepsilon} (-\Delta u, v) \mathrm{d}z + \int_{\partial R_\varepsilon} (n_{R,\varepsilon} \cdot \nabla u, v) \mathrm{d}\sigma_{R,\varepsilon}, \tag{A6}$$

$\mathrm{d}\sigma_{R,\varepsilon}$ being the Euclidean surface measure on the boundary. Furthermore,

$$-\|L_\nu\|^{-2} \int_{R_\varepsilon} \mathrm{sgn}(L_\nu) \log |L_\nu| (L_\nu \cdot \nabla)[(A_\nu u, v)] \mathrm{d}z = \int_{R_\varepsilon} \frac{(A_\nu u, v)}{|L_\nu(z)|} \mathrm{d}z - \|L_\nu\|^{-2} \int_{\partial R_\varepsilon} \mathrm{sgn}(L_\nu) \log |L_\nu|$$
$$\times (A_\nu u, v)(L_\nu \cdot n_{R,\varepsilon}) \mathrm{d}\sigma_{R,\varepsilon}.$$

Using this, the second term in (A5) can, after rearranging, be written as

$$\sum_{R \in \mathcal{R}} \int_{R_\epsilon} \left(\sum_j \frac{(A_j u, v)}{|L_j(z)|} \right) \mathrm{d}z + \sum_j \sum_{\pm} \pm \|L_j\|^{-1} \int_{\substack{L_j = \pm\varepsilon, \\ |L_\nu| > \varepsilon \text{ if } \nu \neq j}} \mathrm{sgn}(L_j(z)) \log |L_j(z)| (A_j u, v)$$
$$+ \sum_{j,k: j \neq k} \sum_{\pm} \pm \|L_k\|^{-1} \|L_j\|^{-2} L_k \cdot L_j \int_{\substack{L_k = \pm\varepsilon, \\ |L_\nu| > \varepsilon \text{ if } \nu \neq k}} \mathrm{sgn}(L_j(z)) \log |L_j(z)| (A_j u, v),$$

the surface integrals being with respect to the natural surface measures. Since v is compactly supported, the third sum will vanish, in the limit of $\varepsilon \to 0$. This follows from the local integrability of $u \cdot \log |L_j|$ on $\{L_k = 0\}$ (if $j \neq k$), which can be seen as follows. Since $u \in H^1$, its restriction $u|_{\{L_k = 0\}}$ is in (vector-valued) L^2. On the other hand, $\log |L_j|$, restricted to $\{L_k = 0\}$ is in $L^2_{\mathrm{loc}}(\mathbb{R}^{N-1})$, and therefore $u \log |L_j|$, restricted to $\{L_k = 0\}$ is locally integrable. Rearranging also the sum over $\mathcal{R}$ of the boundary terms in (A6) as a sum of integrals over the various hypersurfaces $\{L_j = \pm\varepsilon\}$, we conclude that for $v \in C_c^1(\mathbb{R}^N, F)$,

$$t_{\mathcal{L}(u,v)} = \lim_{\varepsilon\to 0} \int_{R_\varepsilon} \left(-\frac{1}{2}\Delta u + \sum_\nu \frac{A_\nu u}{|L_\nu(z)|}, v \right) \mathrm{d}z + \sum_j \sum_\pm \mp \frac{1}{2} \int_{L_j=\pm\varepsilon, |L_\nu|>\varepsilon(\nu\neq j)} \frac{(L_j\cdot\nabla u, v)}{\|L_j\|} \mathrm{d}\sigma_{\{L_j=\pm\varepsilon\}}$$
$$+ \sum_j 2\log\varepsilon \sum_\pm \int_{L_j=\pm\varepsilon, |L_\nu|>\varepsilon(\nu\neq j)} \frac{(A_j u, v)}{\|L_j\|} \mathrm{d}\sigma_{\{L_j=\pm\varepsilon\}} + \int_{\{L_j=0\}} \frac{(B_j u, v)}{\|L_j\|} \mathrm{d}\sigma_{\{L_j=0\}}.$$

Since $u \in H^1$ implies that $\|u(\cdot+\varepsilon L_j/\|L_j\|) - u(\cdot)\|_{L^2(\{L_j=0\})} = O(\sqrt{\varepsilon})$, and since $(u,v) \in L^1(\{L_j=0\})$, we can replace the next to last term by

$$2\log\varepsilon \|L_j\|^{-1} \int_{\{L_j=0\}} (A_j u, v) \mathrm{d}\sigma_{\{L_j=0\}} + o(1), \quad \varepsilon \to 0.$$

We can, for the same reason, replace v in the second integral by its restriction to $\{L_j=0\}$. Letting $\varepsilon \to 0$, it follows that if u satisfies (A2), then it satisfies (i), (ii), and (iii).

Conversely, suppose that u satisfies conditions (i), (ii), and (iii) of the theorem. Then running the argument backwards shows that $|t_{\mathcal{L}}(u,v)| \leqslant C_u \|v\|^2$, first for all compactly supported v and thence for all $v \in H^1(\mathbb{R}^N, F)$. Hence $u \in \mathrm{Dom}(\mathrm{h}_{\mathcal{L}})$, by (A2).

Reflection symmetries for multiqubit density operators

(Received 11 July 2005; accepted 1 February 2006; published online 31 March 2006)

For multiqubit density operators in a suitable tensorial basis, we show that a number of nonunitary operations used in the detection and synthesis of entanglement are classifiable as reflection symmetries, i.e., orientation changing rotations. While one-qubit reflections correspond to antiunitary symmetries, as is known, for example, from the partial transposition criterion, reflections on the joint density of two or more qubits are not accounted for by the Wigner theorem and are well-posed only for sufficiently mixed states. One example of such nonlocal reflections is the unconditional NOT operation on a multiparty density, i.e., an operation yeilding another density and such that the sum of the two is the identity operator. This nonphysical operation is admissible only for sufficiently mixed states. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2181827]

I. INTRODUCTION

The Wigner theorem asserts that unitary and antiunitary operations exhaust all possible symmetric transformations applicable to the wave function of a quantum mechanical system. The unitary transformations are physically associated with forward-in-time evolution, and antiunitary with backward-in-time evolution (see, for example, Ref. 1). The characteristic feature of this last class is the presence of a conjugation operation on a wave function or a transposition operation on a density operator. It is known[2] that the geometric interpretation of the time reversing operation for a density operator in a two-dimensional Hilbert space (also known as "qubit") is a *reflection*, i.e., an orientation-changing rotation in $\mathrm{O}^{-}(3)=\mathrm{O}(3)\backslash\mathrm{SO}(3)$ of the corresponding Bloch vector.

A closely related operation, variously known as a spin flip,[3] (unconditional) NOT operation, or universal inverter,[4] changes the sign of the entire Bloch vector. In this sense it corresponds geometrically to inversion in the origin, which is widely known as the parity operation.[5] For a single isolated qubit these operations are indistinguishable from equivalent orientation preserving operations, since O(3) and SO(3) both act transitively on the Bloch sphere, but for multiqubit systems they correspond to partially antiunitary transformations such as the "partial transposition," which can be used to detect bipartite entanglement.[6] This highlights the intrinsically "discrete" nature of such tests and their invariance under LOCC (local operations and classical communication).

In this paper we introduce a more general class of involutory "symmetry" operations, and argue that these are likewise useful in studying the multiparty nonseparability of density operators. These operations are most easily described in terms of the Stokes tensor[7–9] and its "unfolding" to the so-called real density matrix,[10] both of which are equivalent, as carrier spaces, to the coherence vector.[11,12] All these representations parametrize the real linear space of multiqubit density operators by the expectation values of all possible tensor products of the Pauli operators, differing only in their notations and indexing systems. The Stokes tensor indexing has the advantage of making the "affine" structure of the set of n-qubit density operators $\mathcal{D}_n$ explicit, whereas the real density

matrix has the advantages that both the matrix itself, as well as any operations on it which are diagonal with respect to the Stokes tensor, can be displayed as a compact two-dimensional (2D) table on a printed page (see below for examples).

As is well known, unitary operations on the usual Hermitian density operator induces orientation-preserving rotations of the coherence vector, and thereby also norm-preserving linear group actions on the Stokes tensor and/or real density matrix [*loc. cit.*]. In the following, we shall frequently use the term "density," without further qualification, to indicate an equivalence class of probability distributions over an ensemble of multiqubit systems which all give rise to the same density operator, irrespective of how this is represented (as a Hermitian matrix, or a Stokes tensor, etc.).

We now distinguish the following two types of nonunitary but norm-preserving operations on a multiqubit Stokes tensor:

(i) local reflections applied simultaneously to two or more qubits;
(ii) "nonlocal" reflections, i.e., reflections applied to the *joint* density of two or more qubits.

The two cases are *qualitatively different*: while (i) is equivalent, up to local unitary operations, to multiqubit partial transposition, (ii) is a genuinely new operation and does not correspond to any local operation on two or more qubits. In particular, the total reflection of all components of the Stokes tensor other than the expectation value of the identity does *not* correspond to time-reversal (i.e., to the total transpose of the density matrix) but rather to a multiparty NOT operation.

Reflections on more than one qubit are nonunitary operations that do not necessarily yield valid (positive semidefinite) density operators. However, it can be shown that any mixed state with eigenvalues "small enough" is still a density operator when it is totally reflected. In other words, total reflection is a nonunitary involution which preserves such sufficiently mixed sets of density operators. On this set, total reflection behaves like a antiunitary operation in the sense that it preserves the Hermitian structure, the trace and the (Hilbert-Schmidt) inner product. This tells us that for general mixed states there are more symmetries to be exploited than those of Wigner theorem.

For three qubits, the set of density operators admitting a total reflection includes, for example, the unextendible product basis (UPB) states used in Ref. 13 to generate a bound entangled density operator with all positive partial transpositions (PPT). The "complement" operation that turns a separable density into the bound entangled UPB state is in fact a total reflection of the type (ii) above. The various entanglement measures (the concurrence, the negativity and the tangle among them) that rely on the use of spin-flip operations are also examples of application of multiple one-qubit reflections of the type (i). In between local and total reflections lies a class of "nonlocal yet partial" reflections which also belong to the class (ii) above. These maps resemble very closely those used in the so-called reduction criterion.[14,15]

Besides their unifying mathematical (group theoretic) character, we see reflections as a new tool to "probe" the structure of the set of multiparticle density operators, in particular its nonseparable regions, by means of operations analogous, but inequivalent, to partial transposition. Hopefully this will eventually lead to a better understanding of bound entanglement in multipartite systems.

II. ONE QUBIT: TRANSPOSITION AND TIME-REVERSAL

For a single qubit with density operator $\rho \in \mathcal{D}_1 \subset \mathbb{C}^{2\times 2}$, the Stokes tensor is the affine 3-vector $[\varrho^0\ \vec{\varrho}^T]^T$, where $\varrho^0=\mathrm{tr}(\rho)/\sqrt{2}=1/\sqrt{2}$ and $\vec{\varrho}=[\varrho^1\ \varrho^2\ \varrho^3]^T$ is the Bloch vector of the qubit times $\sqrt{2}$. Thus (summing over repeated indices) we have $\rho=\varrho^j\lambda_j$ where $\lambda_j=\sigma_j/\sqrt{2}$ are the rescaled Pauli matrices ($j=1,2,3$), $\lambda_0=\mathbb{1}_2/\sqrt{2}$, and $\varrho^j=\mathrm{tr}(\rho\lambda_j)$. In this notation, the real density matrix is given by

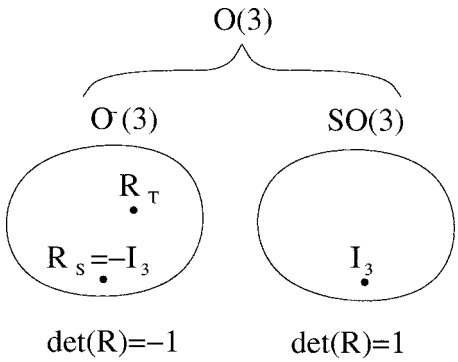

FIG. 1. Topological structure of the rotation group O(3).

$$\sigma = \sigma(\rho) \equiv \sqrt{2}\begin{bmatrix} \varrho^0 & \varrho^2 \\ \varrho^1 & \varrho^3 \end{bmatrix}. \tag{1}$$

The Stokes tensor is readily recovered from this by applying the "col"[16] (or reshaping[17]) operator to it and dividing by $\sqrt{2}$. As is well known, unitary transformations of ρ by $U \in \mathrm{SU}(2)$, namely $U\rho U^\dagger$, induce rotations of the corresponding Bloch vector. This geometric interpretation will now be extended to antiunitary transformations.[18,19]

Any antiunitary operation can be written as the product of a unitary operation and complex conjugation K. Given a pure state with wave vector $|\psi\rangle = c_0|0\rangle + c_1|1\rangle$ $(c_0, c_1 \in \mathbb{C})$, let $|\tilde{\psi}\rangle$ be the wave vector obtained by means of K alone: $|\tilde{\psi}\rangle = K|\psi\rangle = c_0^*|0\rangle + c_1^*|1\rangle$. The corresponding density matrix is $\rho = |\psi\rangle\langle\psi| = \Sigma_{j,k=0}^{1,1} c_j c_k^* |j\rangle\langle k|$, so that $|\tilde{\psi}\rangle\langle\tilde{\psi}| = \Sigma_{j,k=0}^{1,1} c_j^* c_k |j\rangle\langle k| = (|\psi\rangle\langle\psi|)^T$. Since any density matrix is a convex combination of pure state density matrices, the effect of K on a general ρ is to transpose it, i.e., $\rho^T = K\rho K^\dagger = \varrho^0\lambda_0 + \varrho^1\lambda_1 - \varrho^2\lambda_2 + \varrho^3\lambda_3$. As indicated, this is simply a change in the sign of the λ_2 component of the Bloch vector, i.e., $[\varrho^1 \ -\varrho^2 \ \varrho^3]^T$.

The rotation group O(3), of course, has two connected components, one of which preserves the orientation of a frame [namely SO(3), which contains the identity operator $\mathbb{1}_3$], and one of which changes its orientation [denoted here by $\mathrm{O}^-(3)$, to which $-\mathbb{1}_3$ belongs]. This topological structure is illustrated in Fig. 1. A *reflection* is a rotation which does not preserve orientation. The canonical example is *spatial inversion*, which is defined as multiplication by $R_S \equiv -\mathbb{1}_3$. Any reflection $R \in \mathrm{O}^-(3)$ is obtained by multiplying R_S with a rotation in SO(3). For example, the reflection used in the transpose, $R_T = \mathrm{diag}(1, -1, 1)$, can be written as the product of a spatial inversion with a rotation by π about the y axis.

For any vector $\vec{\varrho}$, spatial inversion maps $\vec{\varrho}$ to its antipode $-\vec{\varrho} = R_S(\vec{\varrho})$ on a sphere of radius $\|\vec{\varrho}\| = \sqrt{(\varrho^1)^2 + (\varrho^2)^2 + (\varrho^3)^2}$. It follows from this together with the above that, for density matrices, $\rho^S \equiv UK\rho K^\dagger U^\dagger = \varrho^0\lambda_0 - \varrho^1\lambda_1 - \varrho^2\lambda_2 - \varrho^3\lambda_3$ where $U = i\lambda_2 \in \mathrm{SU}(2)$ rotates the Bloch vector by π about the y axis. In addition, it is easily shown that the eigenvalues of ρ are given by

$$\mathrm{eig}(\rho) = \left\{ \frac{1}{\sqrt{2}}\left(\frac{1}{\sqrt{2}} \pm \|\vec{\varrho}\| \right) \right\}. \tag{2}$$

Since reflections, like rotations in SO(3), are length preserving actions on the Bloch sphere, we see that the eigenvalues are preserved under reflections: $\mathrm{eig}(\rho^S) = \mathrm{eig}(\rho^T) = \mathrm{eig}(\rho)$. For pure states, an important difference between R_S and R_T is that R_S maps any ket $|\psi\rangle$ to an orthogonal one, whereas R_T does not. In other words, spatial inversion corresponds exactly to the spin-flip operation.[3,20]

Both the transposition and the spin-flip can also be defined in terms of the real density matrix, using the componentwise (also known as Hadamard, or sometimes Schur) matrix product "$\odot$." In the case of the transpose, this is simply

$$\sigma(\rho^T) = \sqrt{2}\begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \odot \begin{bmatrix} \varrho^0 & \varrho^2 \\ \varrho^1 & \varrho^3 \end{bmatrix}. \tag{3}$$

As shown in Ref. 16, an operator sum representation is obtained from the singular value decomposition of the sign matrix (left-hand factor), leading to

$$\sigma(\rho^T) = \sigma(\rho)|0\rangle\langle 0| - \sqrt{2}\lambda_3\sigma(\rho)|1\rangle\langle 1|. \tag{4}$$

For the spin-flip, on the other hand, it is easily seen that

$$\sigma(\rho^S) = \sqrt{2}\begin{bmatrix} 1 & -1 \\ -1 & -1 \end{bmatrix} \odot \begin{bmatrix} \varrho^0 & \varrho^2 \\ \varrho^1 & \varrho^3 \end{bmatrix} = 2|0\rangle\langle 0| - \sigma(\rho). \tag{5}$$

These alternative representations of transposition and spin-flip will be useful in studying multiqubit reflections below.

For a single qubit the notion of reflection admits a further interpretation in terms of "co-completely positive" (co-CP) maps. From the Størmer-Woronowicz theorem, any positive 2×2 map Φ is decomposable as

$$\Phi = c\Phi_1 + (1-c)\Phi_2 \circ T \quad (0 \leqslant c \leqslant 1), \tag{6}$$

where Φ_1, Φ_2 are completely positive (CP) maps and T is transposition. The composition $\Phi_2 \circ T$ is called a *co-CP map*. For the Bloch vector, the CP maps form a semigroup in the group of orientation-preserving affine maps $\mathrm{GL}^+(3,\mathbb{R})\textcircled{S}\mathbb{R}^3$, where $\mathrm{GL}^+(3,\mathbb{R}) = \{g \in \mathrm{GL}(3,\mathbb{R}^3) \,|\, \det(g) > 0\}$ and "Ⓢ" denotes its semidirect product with the translation group $\mathbb{R}^3$.[17,21,22] Unital CP maps live in the $\mathrm{GL}^+(3,\mathbb{R})$ component, while unital co-CP maps live in the other component, $\mathrm{GL}^-(3,\mathbb{R}) \equiv \{g \in \mathrm{GL}(3,\mathbb{R}^3) \,|\, \det(g) < 0\}$. Restricting further to symmetries (i.e., trace- and norm-preserving maps), one gets rotations and reflections as above.

III. TWO QUBITS: PARTIAL TRANSPOSITION, PARTIAL TIME REVERSAL, MULTIPLE LOCAL REFLECTIONS AND TOTAL REFLECTIONS

For two qubits, a complete basis for the space of density matrices $\mathcal{D}_2 \subset \mathbb{C}^{4\times 4}$ is given by $\Lambda_{jk} = \lambda_j \otimes \lambda_k$ $(j,k \in \{0,1,2,3\})$. This basis is also orthonormal relative to the Hilbert-Schmidt inner product, i.e., $\mathrm{tr}(\Lambda_{jk}\Lambda_{lm}) = \delta_{jl}\delta_{km}$ for all $j,k,l,m \in \{0,1,2,3\}$. For a given density matrix ρ, the Λ-basis defines a real, rank 2 tensor ϱ^{jk} which gives a contravariant representation of the same density, $\rho = \varrho^{jk}\Lambda_{jk}$. Viewed as a 16-vector, ϱ^{jk} is affine, i.e., $\varrho^{00} = \mathrm{tr}(\rho\Lambda_{00}) = 1/2$, and it is bounded by the 15-dimensional sphere in $\mathbb{R}^{16}$ of radius 1,

$$\mathrm{tr}(\rho^2) = \mathrm{tr}((\varrho^{jk}\Lambda_{jk})^2) = \sum_{j,k=0}^{3,3} (\varrho^{jk})^2 \leqslant 1, \tag{7}$$

with equality if and only if the state is pure.

A two-qubit density matrix ρ is said to be *separable* if it can be written as a convex combination $\rho = \sum_{r=1}^{s} w^r \rho_{A,r} \otimes \rho_{B,r}$ for some set of real numbers $w^r \geqslant 0$ such that $\sum_{r=0}^{s} w^r = 1$, where $\rho_{A,r}$, $\rho_{B,r}$ are all single-qubit density matrices. A necessary and sufficient condition for the separability of a two-qubit density is provided by the positive partial transpose (PPT) criterion of Peres[6] and Horodecki.[23] The partial transpose of a two-qubit density matrix ρ with respect to the first (left) subsystem A is defined as $\rho^{T_A} \equiv (K \otimes \mathbb{1}_2)\rho(K \otimes \mathbb{1}_2)^\dagger$, and similarly $\rho^{T_B} \equiv (\mathbb{1}_2 \otimes K)\rho(\mathbb{1}_2 \otimes K)^\dagger$. Each partial transpose is still a well-defined (i.e., positive semidefinite) density operator if and only if ρ is separable. The PPT criterion may be viewed as a check on the feasibility of the "partial time reverse" operation:[18,19] changing the time arrow of one of the subsystems alone.

In terms of the Stokes tensor ϱ^{jk}, the description of partial transposition is very intuitive and relies on the observation that $\lambda_2 = -\lambda_2^T$ is the only Pauli matrix with imaginary elements.

Proposition 1: *For two qubits, the partial transpose operations on the density matrix* ρ^{T_A} *and*

ρ^{T_B} act on the Stokes tensor ϱ^{jk} by changing the sign of all elements bearing the index "2" *in the corresponding subsystem*:

$$\rho^{T_A} = \varrho^{0k}\Lambda_{0k} + \varrho^{1k}\Lambda_{1k} - \varrho^{2k}\Lambda_{2k} + \varrho^{3k}\Lambda_{3k}, \tag{8a}$$

$$\rho^{T_B} = \varrho^{j0}\Lambda_{j0} + \varrho^{j1}\Lambda_{j1} - \varrho^{j2}\Lambda_{j2} + \varrho^{j3}\Lambda_{j3}. \tag{8b}$$

The verification is just a straightforward calculation, which may be found in Table I. Note also that for the "total" transpose ρ^T $(=(\rho^{T_A})^{T_B})$ we have instead

$$\Lambda_{jk}^T = \Lambda_{jk} \quad \text{if } j,k \neq 2 \quad \text{or } j=k=2, \tag{9a}$$

$$\Lambda_{jk}^T = -\Lambda_{jk} \quad \text{if } j=2 \quad \text{or } k=2, \quad j \neq k, \tag{9b}$$

showing that Λ_{22} behaves differently under partial or total transposition.

The PPT separability test of Peres-Horodecki relies essentially on the decomposability property (6): any 1-qubit positive but not CP map, when applied to a 2-qubit density, returns a density if and only if the original density is separable. Restricting from positive maps to symmetry operations is the same as restricting to local reflections. In fact, the map (8a) can be thought of as the linear transformation $\bar{R}_T\otimes\mathbb{1}_4$, where $\bar{R}_T$ is the following affine orientation-changing three-dimensional rotation: $\bar{R}_T=\mathrm{diag}(1,R_T)=\mathrm{diag}(1,1,-1,1)$. Since all single qubit reflections are unitarily equivalent, any matrix $R\in\mathrm{O}^-(3)$ can be used in place of R_T. Indeed, if $\bar{R}=\mathrm{diag}(1,R)$, then local operations from the same connected component of O(3) satisfy

$$\mathrm{eig}((\bar{R}\otimes\mathbb{1}_4)(\rho)) = \mathrm{eig}((\bar{R}_T\otimes\mathbb{1}_4)(\rho)), \tag{10}$$

where the notation must be interpreted as follows: the matrix $\bar{R}\otimes\mathbb{1}_4$ acts on the 16-vector ϱ^{jk} and the resulting 16-vector provides the coefficients in the sum over the basis elements Λ_{jk}, i.e., $(\bar{R}\otimes\mathbb{1}_4)(\rho)=((\bar{R}\otimes\mathbb{1}_4)^{lm}_{jk}\varrho^{jk})\Lambda_{lm}$.

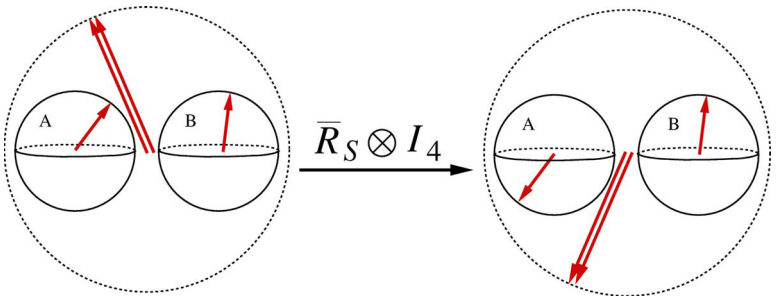

FIG. 2. (Color online) Reflections on a 2-qubit density matrix: the single qubit reflection $\bar{R}_S \otimes \mathbb{1}_4$ (PPT test).

Equation (10) shows that all reflections are positive but not completely positive. Thus we can reformulate the PPT criterion for the separability of two qubits as follows:

Theorem 1: *A two-qubit density matrix ρ is separable if and only if $(\bar{R} \otimes \mathbb{1}_4)(\rho)$ is a density matrix for any $R \in \mathrm{O}^-(3)$.*

A particularly simple such map is $\bar{R}_S = \mathrm{diag}(1, R_S)$, where R_S is the spin-flip operation from the preceding section. It is easily seen that $(\bar{R}_S \otimes \mathbb{1}_4)(\rho) = 2\varrho^{0k}\Lambda_{0k} - \rho$, so that the sign is changed in all elements ϱ^{jk} except those appearing in the reduced density matrix of the second qubit (i.e., the ϱ^{0k}).

The (total) transpose ρ^T of ρ corresponds to the matrix $\bar{R}_{T,16} = \bar{R}_T \otimes \bar{R}_T = \mathrm{diag}(1, R_{T,15})$ with $R_{T,15} = \mathrm{diag}(1,-1,1,1,1,-1,1,-1,-1,1,-1,1,1,-1,1) \in \mathrm{SO}(15)$, where the minus signs correspond to the six basis elements obeying (9b). Since the determinant of this matrix is positive, for two qubits the transpose is an orientation-preserving operation. Up to local operations $\bar{R}_T \otimes \bar{R}_T$ is equivalent to the "double local reflection" (or double spin-flip) map $\bar{R}_S \otimes \bar{R}_S$. The difference between $\bar{R}_S \otimes \mathbb{1}_4$ and $\bar{R}_S \otimes \bar{R}_S$ is easily understood by looking at Figs. 2 and 3. [In Figs. 2–4, the two vectors contained in the smaller spheres correspond to the Bloch vectors ϱ^{j0} and ϱ^{0k} of the two reduced density matrices, the third vector (double arrow) to the two-body correlation part of the Stokes tensor ϱ^{jk}, $j,k \neq 0$.] While $\bar{R}_S \otimes \mathbb{1}_4$ leaves the reduced density of the second qubit unchanged (Fig. 2), the correlation part remains unchanged under the action of $\bar{R}_S \otimes \bar{R}_S$ because its sign is flipped twice (Fig. 3). It may be shown, however, that both are positive but not-completely-positive maps.

All the "local" maps in O(3) mentioned so far are orientation-preserving when acting on two qubits, even though they all have at least one factor that is orientation-changing when acting on a single, isolated qubit: $\det(\bar{R}_T \otimes \mathbb{1}_4) = \det(\bar{R}_T \otimes \bar{R}_T) = \det(\bar{R}_S \otimes \mathbb{1}_4) = \det(\bar{R}_S \otimes \bar{R}_S) = 1$. The recovery of "parity" whenever an orientation-changing map is applied to two or more qubits is due to the

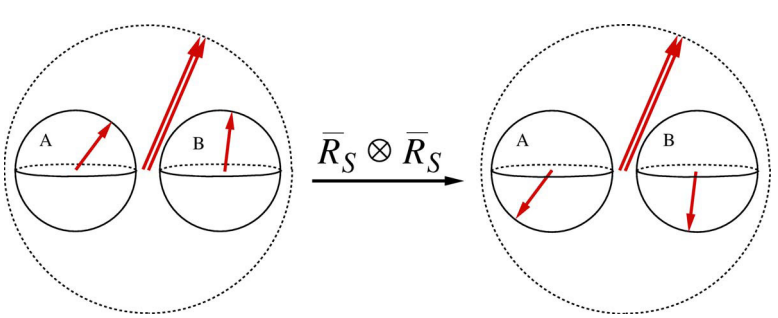

FIG. 3. (Color online) Reflections on a 2-qubit density matrix: the double local reflection $\bar{R}_S \otimes \bar{R}_S$ (which is equivalent to the total transpose under LOCC).

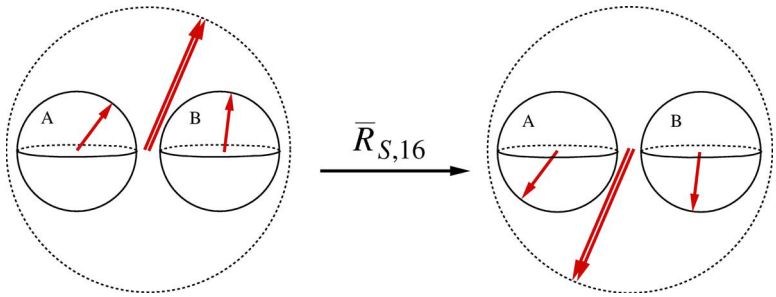

FIG. 4. (Color online) Reflections on a 2-qubit density matrix: the total reflection $\bar{R}_{S,16}$ (a nonlocal operation).

affine structure of the Hilbert space of a qubit (resulting in a *affine Bloch vector*), itself a consequence of the trace-preserving condition,

$$\begin{bmatrix} 1 & \\ & \mathrm{O}(3) \end{bmatrix} \otimes \begin{bmatrix} 1 & \\ & \mathrm{O}(3) \end{bmatrix} \subset \begin{bmatrix} 1 & \\ & \mathrm{SO}(15) \end{bmatrix}.$$

Hence the question arises: do there exist any orientation-changing symmetric operations on two qubits? One such map is the 2-qubit total reflection $\bar{R}_{S,16}=\mathrm{diag}(1,-\mathbb{1}_{15})$, $-\mathbb{1}_{15}\in O(15)\backslash\mathrm{SO}(15)=\mathrm{O}^{-}(15)$. Its action (see Fig. 4) corresponds to changing the sign of the entire tensor ϱ^{jk} except for affine component $\varrho^{00}=1/2$, thus the name *total reflection*. This nonlocal operation is genuinely new and inequivalent to any composition of local symmetric operations.

The most significant difference between total transpose and total reflection is that whereas the former map preserves the eigenvalues of the density matrix, the latter does not. Indeed, the total reflection is not even a positive map, since it converts the density matrix of any pure state to one with eigenvalues $[1,1,1,-1]/2$. This fact is readily established by writing the total reflection directly in terms of the Hermitian density matrix as

$$\bar{R}_{S,16}(\rho)=\tfrac{1}{2}\mathbb{1}_4-\rho, \tag{11}$$

which makes it clear that it holds for the density matrices of the basis states $|00\rangle\langle 00|$, $|01\rangle\langle 01|$, $|10\rangle\langle 10|$, and $|11\rangle\langle 11|$, and that the total reflection commutes with arbitrary two-sided unitary transformations of ρ.

The changes in the signs of the elements of the Stokes tensor are summarized in Table I for all the discrete symmetric operations mentioned in this section. It may be observed that $\bar{R}_S\otimes\bar{R}_S$ and $\bar{R}_{T,16}=\bar{R}_T\otimes\bar{R}_T$ both have an even number of "–" signs (6), whereas $\bar{R}_{S,16}$ has an odd number (namely 15), thus confirming that a total reflection on a two-qubit joint density is inequivalent to such operations.

In terms of density matrices, the positive-but-not-completely-positive operation $\bar{R}_S\otimes\bar{R}_S$ corresponds to

$$\bar{R}_S\otimes\bar{R}_S(\rho)=(\sigma_2\otimes\sigma_2)\rho^*(\sigma_2\otimes\sigma_2)=4\Lambda_{22}\rho^*\Lambda_{22}. \tag{12}$$

The transformed density matrix $\rho'\equiv\bar{R}_S\otimes\bar{R}_S(\rho)$ is frequently found in entanglement measures, including the concurrence $C(\rho)=\max\{0,\nu_1-\nu_2-\nu_3-\nu_4\}$ [where $\nu_j\in\mathrm{eig}(\rho\rho')$ (Ref. 24)] and the Lorentzian metric $\mathrm{tr}(\rho\rho')=(\varrho^{00})^2-\Sigma_{j=1}^3((\varrho^{0j})^2+(\varrho^{j0})^2)+\Sigma_{j,k=1}^3(\varrho^{jk})^2$.[9]

IV. TWO QUBITS: MATRIX STRUCTURES AND THE COMPUTABLE CROSS-NORM

In this section, we show how the foregoing nonunitary symmetry operations on a two-qubit density matrix can be expressed compactly using the Hadamard product of matrices[25] together with either the Stokes tensor or the real density matrix. We will also show that a non-separability

criterion called the computable cross-norm[26] (or the matrix realignment method[27]), which is inequivalent to the PPT criterion, can be computed directly from the Stokes tensor without having to convert back to the traditional Hermitian representation. For two qubits, the Stokes tensor can also be viewed as a square array of real numbers, which is related to the real density matrix as follows:

$$2\begin{bmatrix} \varrho^{00} & \varrho^{01} & \varrho^{02} & \varrho^{03} \\ \varrho^{10} & \varrho^{11} & \varrho^{12} & \varrho^{13} \\ \varrho^{20} & \varrho^{21} & \varrho^{22} & \varrho^{23} \\ \varrho^{30} & \varrho^{31} & \varrho^{32} & \varrho^{33} \end{bmatrix} \leftrightarrow \begin{bmatrix} \varrho^{00} & \varrho^{20} & \varrho^{02} & \varrho^{22} \\ \varrho^{10} & \varrho^{30} & \varrho^{12} & \varrho^{32} \\ \varrho^{01} & \varrho^{21} & \varrho^{03} & \varrho^{23} \\ \varrho^{11} & \varrho^{31} & \varrho^{13} & \varrho^{33} \end{bmatrix}. \tag{13}$$

The rearrangement of the elements seen here corresponds to the Choi[16] (also known as reshuffling[17]) map for $n=2$ qubits, but for $n>2$ the Stokes tensor-to-real density matrix map is not the same as the Choi map; indeed, then the order of the Stokes tensor is greater than 2, so it can no longer be identified so simply with a matrix.

The real density matrix has the useful feature of preserving the tensor product structure of the corresponding Hermitian density matrix, i.e., for two qubits: $\sigma(\rho\otimes\rho')=\sigma(\rho)\otimes\sigma(\rho')\equiv\sigma\otimes\sigma'$. It follows immediately that a 2-qubit real density matrix can be written as a convex combination of 1-qubit real density matrices if and only if the 2-qubit density is separable. A 2×2 real matrix, on the other hand, is a real density matrix if and only if its upper-left element is unity and the length of the Bloch vector determined by the remaining elements does not exceed unity [cf. Eq. (2)]. It should also be noted that, with either the real density matrix or the Stokes tensor, the partial trace operation involves only discarding elements involving the qubit traced over: no additional operations are needed as in the Hermitian representation.

As shown previously for the 1-qubit case, we can express involutory symmetry operations by means of Hadamard products of the real density matrix with matrices the elements of which are all ± 1. Moreover, these matrices will be tensor products if and only if the operations that define them are. This may be seen in the following list of sign matrices for all the operations given in Table I:

$$\bar{R}_T\otimes \mathbb{1}_4 \leftrightarrow \begin{bmatrix} +1 & -1 \\ +1 & +1 \end{bmatrix} \otimes \begin{bmatrix} +1 & +1 \\ +1 & +1 \end{bmatrix}, \tag{14a}$$

$$\mathbb{1}_4\otimes \bar{R}_T \leftrightarrow \begin{bmatrix} +1 & +1 \\ +1 & +1 \end{bmatrix} \otimes \begin{bmatrix} +1 & -1 \\ +1 & +1 \end{bmatrix}, \tag{14b}$$

$$\bar{R}_T\otimes \bar{R}_T \leftrightarrow \begin{bmatrix} +1 & -1 \\ +1 & +1 \end{bmatrix} \otimes \begin{bmatrix} +1 & -1 \\ +1 & +1 \end{bmatrix}, \tag{14c}$$

$$\bar{R}_S\otimes \mathbb{1}_4 \leftrightarrow \begin{bmatrix} +1 & -1 \\ -1 & -1 \end{bmatrix} \otimes \begin{bmatrix} +1 & +1 \\ +1 & +1 \end{bmatrix}, \tag{14d}$$

$$\mathbb{1}_4\otimes \bar{R}_S \leftrightarrow \begin{bmatrix} +1 & +1 \\ +1 & +1 \end{bmatrix} \otimes \begin{bmatrix} +1 & -1 \\ -1 & -1 \end{bmatrix}, \tag{14e}$$

$$\bar{R}_S\otimes \bar{R}_S \leftrightarrow \begin{bmatrix} +1 & -1 \\ -1 & -1 \end{bmatrix} \otimes \begin{bmatrix} +1 & -1 \\ -1 & -1 \end{bmatrix}, \tag{14f}$$

$$\bar{R}_{S,16} \leftrightarrow \begin{bmatrix} +1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix}. \tag{14g}$$

Note that $\bar{R}_{S,16}$ is distinguished from the other operations not only by the fact that it is not orientation-preserving, but also by the fact that it is nonlocal and hence does not preserve the tensor product structure in the space of (real or Hermitian) density matrices. It is easily seen that the involutory mapping induced by any tensor product of sign matrices as above must preserve orientation, but there are many orientation-preserving mappings that are not tensor products, including the pair given below:

$$\begin{bmatrix} +1 & +1 & +1 & +1 \\ +1 & -1 & -1 & +1 \\ +1 & -1 & -1 & +1 \\ +1 & +1 & +1 & +1 \end{bmatrix} \leftrightarrow \begin{bmatrix} +1 & +1 & +1 & -1 \\ +1 & +1 & -1 & +1 \\ +1 & -1 & +1 & +1 \\ -1 & +1 & +1 & +1 \end{bmatrix}. \tag{15}$$

As indicated by the double arrow, these two are related by the Choi map, i.e., taking the Hadamard product of one with the real density matrix is the same as taking the Hadamard product of the other with the Stokes tensor [cf. Eq. (13)]. Tests with randomly generated pure states quickly show that neither of these maps is positive, let alone completely positive.

Similarly, one can easily construct many other discrete reflection symmetries which are neither locally nor unitarily equivalent to the total reflection, simply by composing the latter with any other nonlocal and nonunitary rotation symmetry. One interesting example is obtained by composing the local reflections $\bar{R}_S \otimes \bar{R}_S$ with the total reflection $\bar{R}_{S,16}$ on two qubits, obtaining

$$(\bar{R}_S \otimes \bar{R}_S)\bar{R}_{S,16} \leftrightarrow C \equiv \begin{bmatrix} +1 & +1 & +1 & -1 \\ +1 & +1 & -1 & -1 \\ +1 & -1 & +1 & -1 \\ -1 & -1 & -1 & -1 \end{bmatrix}. \tag{16}$$

The Hadamard product with C changes the sign of the bilinear (two-body) part of the Stokes tensor. It is, of course, a nonpositive map which takes the Hermitian density matrix of any pure state to one with eigenvalues $[1,1,1,-1]/2$. This map may also be written quite simply as an operator sum, as follows:

$$\sigma^{-1}(C \odot \sigma(\rho)) = \sum_{k=1}^{3} (\Lambda^{k0}\rho\Lambda^{k0} + \Lambda^{0k}\rho\Lambda^{0k}) - \frac{1}{2}\mathbb{1}_4. \tag{17}$$

Finally, we show how a separability test based on the so-called computable cross-norm (CCN), denoted in what follows by "ξ," can be performed directly using the Stokes tensor. The CCN is a lower bound on the cross-norm entanglement measure in a bipartite system, denoted by "Ξ," which satisfies $\Xi(\rho)=1$ if ρ is separable and $\Xi(\rho)>1$ if it is not.[26] Consequently, $\xi(\rho)>1$ implies ρ is nonseparable, though not vice versa; this condition is neither weaker nor stronger than the PPT criterion, but inequivalent to it. The CCN ξ is not itself an entanglement measure, since it may increase under the partial trace operation, but it has the advantage that it is readily computed as the sum of the singular values (also known as trace class norm) of the reshuffled density matrix Choi(ρ). For two qubits it can also be computed directly from the Stokes tensor, as shown by the following:

Proposition 2: *For two qubits, the singular values of the Stokes tensor* $\varrho^{k\ell}$, *regarded as a matrix as in Eq.* (13), *are twice those of the reshuffled density matrix* Choi(ρ).

Proof: The reshuffling operation is defined to satisfy $\mathrm{Choi}(\rho_1^T \otimes \rho_2) = |\rho_2\rangle\langle\rho_1^T|$, where $|\rho_2\rangle$ denotes the result of applying the reshaping operator to ρ_2, and $\langle\rho_1^T| = |\rho_1\rangle^T$. The one nonzero singular value of this matrix is simply the product of the Hilbert-Schmidt norms of its factors $\|\rho_1\|\|\rho_2\|$. Recall now that ρ is factorizable if and only if the corresponding real density matrix $\sigma(\rho)$ is and that the linear mapping $\sigma/2^{n/2}$ preserves the Hilbert-Schmidt norm (where n is the number of qubits). Hence $|\sigma(\rho_2)\rangle\langle\sigma(\rho_1^T)|/2$ is the singular value decomposition of the corresponding reshuffled real density matrix $\mathrm{Choi}(\sigma(\rho_1^T \otimes \rho_2))/2$, and its nonzero singular value is $\|\sigma(\rho_1)\|\|\sigma(\rho_2)\|/2 = \|\rho_1\|\|\rho_2\|$. Together with the fact that for two qubits the Stokes tensor and the real density matrix are related by the Choi map, this establishes the result for factorizable states.

To prove the general case, we recall that the reshaping map Choi is self-inverse. Thus the singular value decomposition of a general matrix $\mathrm{Choi}(\rho) = \Sigma_k \xi_k r_k s_k^T$ provides a canonical decomposition of ρ into a sum of tensor products $\Sigma_k p_k \rho_{1k}^T \otimes \rho_{2k}$, where $p_k = \xi_k r_k^T|\mathbb{1}_2\rangle s_k^T|\mathbb{1}_2\rangle$. Although p_k may be negative and the factors ρ_{1k}^T, ρ_{2k} of each term in this sum are not necessarily states (i.e., non-negative definite), we are free to apply the composition $\mathrm{Choi} \circ \sigma$ to each term $\rho_{1k}^T \otimes \rho_{2k}$ thereby obtained. Then noting that σ also preserves orthogonality and invoking the uniqueness of singular value decompositions completes the proof. □

The claim that ρ is separable implies $\xi(\rho) \leqslant 1$ can now be established directly, since $\xi(\rho_1 \otimes \rho_2) = \|\rho_1\|\|\rho_2\| \leqslant 1$ and ξ satisfies the triangle inequality just like any norm, so that for any $p_k \geqslant 0$ summing to unity we have $\xi(\Sigma_k p_k \rho_{1k} \otimes \rho_{2k}) \leqslant \Sigma_k p_k = 1$. The singular value decomposition of these matrices can be regarded as an extension of the Schmidt composition for pure states to mixed states. Indeed it can be shown that for pure states $\mathrm{Choi}(\rho)$ has a degenerate pair of singular values which are equal to twice the product of the corresponding Schmidt coefficients.

V. REFLECTIONS ON THREE OR MORE QUBITS

The situation is similar for three (or more) qubits, since the adjoint action (conjugation) still corresponds to a real "one-sided" rotation of the Stokes tensor, and the rotation group in all dimensions splits into orientation preserving and changing connected components. The main difference is that the number of inequivalent kinds of rotations and reflections goes us rapidly with the number of qubits. It is possible, however, to identify some particularly significant involutions. In the case of three qubits $\rho = \varrho^{jkl}\Lambda_{jkl}$, the following are some of the new possibilities:

(ia) the two-qubit partial transposition $\bar{R}_{T,16} \otimes \mathbb{1}_4$ (and the two others obtained by qubit permutation);

(ib) the total transposition $\bar{R}_{T,64} = \mathrm{diag}(1, R_{T,63})$ [where $R_{T,63} \in \mathrm{SO}(63)$ is diagonal with 28 −1's and 35 +1's in it], which changes the sign of just those elements ϱ^{jkl} with an odd number of indices equal "2";

(iia) the two-qubit "reflection" $\bar{R}_{S,16} \otimes \mathbb{1}_4$ (and the two others obtained by qubit permutation)—which is however an orientation-preserving rotation on three qubits;

(iib) the total (three-qubit) reflection $\bar{R}_{S,64} = \mathrm{diag}(1, -\mathbb{1}_{63})$.

The effect of $\bar{R}_{S,64}$ on ϱ^{jkl} is to change the sign of the entire tensor except for its constant component $\varrho^{000} = 1/(2\sqrt{2})$, showing that it may be expressed as

$$\bar{R}_{S,64}(\rho) = 2\varrho^{000}\Lambda_{000} - \rho = \tfrac{1}{4}\mathbb{1}_8 - \rho. \tag{18}$$

This is again a nonlocal operation which admits no factorization into independent one-qubit operations. Similarly, the action of $\bar{R}_{S,16} \otimes \mathbb{1}_4$ on $\varrho^{jk\ell}$ is to change the sign of the entire tensor except for the Bloch vector of the 1-qubit reduced density $\varrho^{00\ell}$. Items (ia) and (ib) above are fundamentally different from (iia) and (iib). The first two produce a Hermitian matrix with negative eigenvalues whenever the density has bipartite entanglement through the cut, whereas the latter two instead may map even separable densities to Hermitian matrices with negative eigenvalues. This can be seen looking at the components of the UPB state. If $\bar{R}_{S,64}$ is applied to the

(separable) density $\rho_{\mathrm{UPB-sep}}=\frac{1}{4}\Sigma_{j=1}^{4}|\psi_j\rangle\langle\psi_j|$ with $|\psi_j\rangle=|01+\rangle,|1+0\rangle,|+01\rangle,|---\rangle$ and $|\pm\rangle=1/\sqrt{2}(|0\rangle\pm|1\rangle)$, one gets the bound entangled state ρ_{UPB} used in Ref. 13. So in this case a separable state is reflected into an entangled state. However, no one of the four components $|\psi_j\rangle\langle\psi_j|$ taken alone (each is obviously separable) is a density when reflected. Obviously (ib) only reverses the time arrow on any 3-qubit density.

In similar fashion, for any number $n>1$ of qubits one can define an *m-qubit* $(1<m\leqslant n)$ *nonlocal* "reflection" $\bar{R}_{S,4^m}\otimes\mathbb{1}_{4^{n-m}}$, which is only a true (i.e., orientation-changing) reflection when the reflection is total $(m=n)$. Assuming the reflection acts on the first m qubits of an n-qubit density operator ρ, this may be written as

$$\bar{R}_{S,4^m}\otimes\mathbb{1}_{4^{n-m}}(\rho)=2\varrho^{0\cdots0j_{m+1}\cdots j_n}\Lambda_{0\cdots0j_{m+1}\cdots j_n}-\rho. \tag{19}$$

These operations leave the norm of the n-qubit tensor $\varrho^{j_1\cdots j_n}$ [i.e., $\mathrm{tr}(\rho^2)$] invariant, but need not preserve the spectrum nor even leave it nonnegative, as we saw above. Hence it is a "generically" ill-defined operation on the set of density operators of composite systems $\mathcal{D}_n$.

These observations are summarized in the following:

Proposition 3: *In* $\mathcal{D}_n$, *the linear map* $\bar{R}_{S,4^n}$ $(1<n)$:

(i) *preserves the trace and Hermiticity*;
(ii) *preserves the Hilbert-Schmidt inner product*;
(iii) *is neither unitary nor antiunitary*;
(iv) *is not* $\mathcal{D}_n$*-invariant*.

Properties (i) and (ii) together say that $\bar{R}_{S,4^n}$ is neither a contraction nor a dilation map, whereas (iv) affirms that $\bar{R}_{S,4^n}$ is not a positive map.

Nevertheless, it is possible to specify a simple spectral condition on the density matrix that guarantees that its total reflection is still non-negative definite.

Theorem 2: *Given* $\rho=\varrho^{0\ldots0}\Lambda_{0\ldots0}+\chi\in\mathcal{D}_n$ (*where* χ *is the associated homogeneous tensor*), *a sufficient condition for* $\tilde{\rho}=\bar{R}_{S,4^n}(\rho)=\varrho^{0\ldots0}\Lambda_{0\ldots0}-\chi\in\mathcal{D}_n$ *is that the set of eigenvalues satisfies* $\mathrm{eig}(\rho)\subset[0,2^{1-n}]$.

Proof: The proof is based on the well-known fact[25] that adding a multiple of the identity $c\mathbb{1}_m$ onto an $m\times m$ Hermitian matrix A shifts its eigenvalues by c, i.e., $\mathrm{eig}(A+c\mathbb{1}_m)=\mathrm{eig}(A)+c$. Since the eigenvalues of the random state's density matrix $\mathrm{eig}(\varrho^{0\ldots0}\Lambda_{0\ldots0})=\{2^{-n}\}$ (with multiplicity 2^n), we see that $\mathrm{eig}(\rho)\in[0,2^{1-n}]$ implies both $\mathrm{eig}(\chi)\in[-2^{-n},2^{-n}]$ and $\mathrm{eig}(-\chi)\in[-2^{-n},2^{-n}]$, so that $\mathrm{eig}(\tilde{\rho})\in[0,2^{1-n}]$, as well. □

Hence the linear map $\bar{R}_{S,4^n}$ is well-defined (positive) in the subset of densities with eigenvalues in the interval $[0,2^{1-n}]$.

Corollary 1: *A necessary but not sufficient condition for Theorem 2 to hold is that* $\mathrm{tr}(\rho^2)\leqslant 2^{1-n}$.

Proof: If $\mu_{\chi_1},\ldots,\mu_{\chi_{2^n}}$ are the eigenvalues of χ, when Theorem 2 holds it must be $r^2=\mu_{\chi_1}^2+\cdots+\mu_{\chi_{2^n}}^2\leqslant 1/2^n$. Hence $r\leqslant 1/2^{n/2}$ and $\mathrm{tr}(\rho^2)=(\varrho^{0\cdots0})^2+r^2\leqslant 1/2^{n-1}$. □

Corollary 2: *A necessary but not sufficient condition for* $\tilde{\rho}$ *to be a density is that* $\mathrm{rank}(\rho)\geqslant 2^{n-1}$.

In fact, only when ρ is a mixture of at least 2^{n-1} pure states one can achieve $\mathrm{eig}(\rho)\in[0,1/2^{n-1}]$.

On a 3-qubit density, the action of $\bar{R}_{S,16}\otimes\mathbb{1}_4$ is depicted in Fig. 5. Essentially the entire Stokes tensor changes sign, except for the reduced density $\mathrm{tr}_{AB}(\rho)$. Its action closely resembles the reduction criterion of Refs. 14 and 15. That criterion also makes implicit use of nonlocal reflections, but it is formulated based on a positive map, hence it is well-posed on all of $\mathcal{D}_n$. For a 3-qubit density it affirms that a necessary condition for separability is $\mathbb{1}_2\otimes\mathbb{1}_2\otimes\mathrm{tr}_{AB}(\rho)-\rho\geqslant 0$ as well as $\mathbb{1}_2\otimes\mathrm{tr}_A(\rho)\geqslant 0$ (and likewise for the other indexes). Since $\mathrm{tr}(\mathbb{1}_2\otimes\mathbb{1}_2\otimes\mathrm{tr}_{AB}(\rho)-\rho)=3$, one difference between our partial reflection and the reduction criterion is that the latter is not a trace preserving

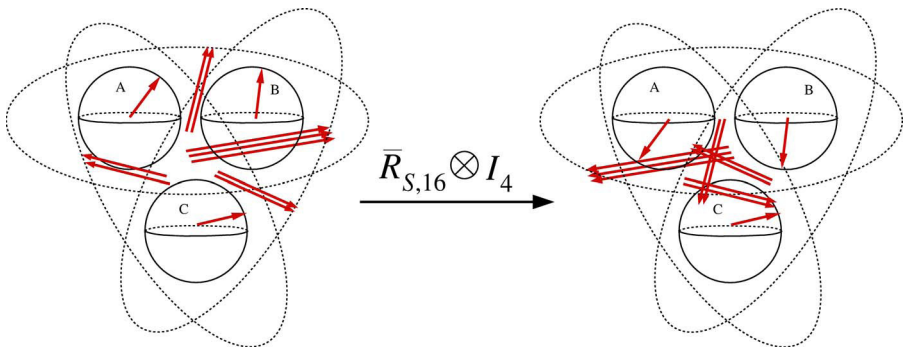

FIG. 5. (Color online) Schematic illustration of the action of a two-qubit reflection $\bar{R}_{S,16}\otimes\mathbb{1}_4(\rho)$ on three qubits. One-body (ϱ^{j00}, ϱ^{0k0} and $\varrho^{00\ell}$), two-body (ϱ^{jk0}, $\varrho^{j0\ell}$ and $\varrho^{0k\ell}$), and three-body ($\varrho^{jk\ell}$) correlation terms are indicated by single, double, and triple arrows. All the signs are changed except for those of $\varrho^{00\ell}$.

map. Thus it is not a symmetry in the sense used in the paper. Nonetheless, the reduction criterion utilizes a positive map which can be used to test separability. In our case $\bar{R}_{S,16}\otimes\mathbb{1}_4$ is not a positive map even when restricted to separable states with eigenvalues in $[0,1/4]$, in which the 3-qubit total reflection $\bar{R}_{S,64}$ is always well-posed.

We can, however, convert our 2-qubit total reflection $\bar{R}_{S,16}$ into a "relaxed" total reflection, namely

$$\bar{R}^{\mathrm{rel}}_{S,16}(\rho)=\tfrac{1}{3}(\mathbb{1}_4-\rho), \tag{20}$$

which is the same as $\bar{R}_{S,16}$ applied to the "remixed" density matrix $(\mathbb{1}_4/2+\rho)/3$. Since the remixed density matrix now has eigenvalues in $[0,1/2]$, the relaxed reflection is a positive map by Theorem 2. It is also easily shown that $\bar{R}^{\mathrm{rel}}_{S,16}$ is not completely positive, and hence provides a necessary condition for the separability of an arbitrary $2^n\times 2^n$, $n>2$, density matrix. It should be possible to relax all the reflections described in this paper to positive maps by a similar strategy.

Concerning a total reflection, all pairs ρ and $\tilde{\rho}=\bar{R}_{S,4^n}(\rho)$ satisfying Theorem 2 are complementary in the sense that their mixture is the random state:

$$\frac{1}{2}(\rho+\tilde{\rho})=\frac{1}{2^n}\mathbb{1}_{2^n}. \tag{21}$$

Equation (21) implies that $\bar{R}_{S,4^n}$ corresponds to a multiparty NOT operation. In fact, also in the single qubit case, the NOT operation corresponds to a change of sign to the homogeneous part (i.e., the Bloch vector) but it is not modifying the sign of the trace part and hence a qubit and its reflection obey to (21). Such operation is used for example to map a density operator belonging to a subset of the Hilbert space $\mathcal{D}_n$ to its complement in $\mathcal{D}_n$, for example in the UPB construction mentioned above.[13,28]

VI. CONCLUDING REMARKS

Reflections are a natural discrete class of transformations relative to the Stokes tensor and/or real density matrix parametrization. Their meaning and relation to LOCC is interesting and calls for natural generalizations to nonlocal operations in the way explained above. The nonlocal reflections, in fact, originate from the nonconnectedness of the group of rotations acting on the Stokes tensor parametrization. In terms of density matrices, this interpretation is not as sharp. As a matter of fact, operations reducible to reflections appear in the PPT test and in the various measures of entanglement relying upon "spin-flip" operations (like concurrence, negativity and tangle) for what concerns (multiple) 1-qubit reflections. Also nonlocal reflections are used: for

example a total reflection corresponds to what is normally referred to as "taking the complement of a density," used for example, in the construction of unextendible product basis states.[13] Likewise, the reduction criterion makes use of a positive map closely related to our nonlocal reflections.

For the purposes of further understanding the structure of composite quantum systems, we find it useful to have a unifying perspective on these nonunitary yet symmetric (in the sense of Wigner theorem) transformations.

It is worth pointing out that reflections can be defined in the same terms also for SLOOC (stochastic LOCC).[9,29,30] For the Stokes tensor, in fact, this class of operations relaxes the group of admissible local transformations from affine rotations to proper orthochronous local Lorentz transformations $\mathrm{SO}(1,3)$. The reflected action in $\mathrm{O}^{-}(3)$ then corresponds to choosing the other connected component of $\mathrm{O}(1,3)$ with the same time direction as $\mathrm{SO}(1,3)$ (i.e., with positive "timelike" metric element). Also nonlocal reflections fit in with the group structure of nonlocal filtering operations. For example, total reflections belong to $\mathrm{O}(1,4^n-1)\backslash\mathrm{SO}(1,4^n-1)$. Note further that the idea of restricting the set of density operators in order to have a larger set of symmetries is "dual" to the idea of using group actions that are contractions.[31,32]

The idea of using reflections does not extend in a straightforward manner to qutrids (nor to higher dimension quantum systems), as in this case the admissible parameters live on a rather complicated subset of the seven-dimensional sphere[33,34] for which the rotation representing transposition is always admissible but spatial inversion may not be. However, the various UPB constructions on 3×3 systems of Ref. 13 correspond to well-defined reflections.

Finally notice that there are many isometries of the Stokes tensor that do not correspond to reflections relative to any basis; those that do are of course involutions, and it would be interesting to show that any Stokes tensor isometry which is an involution (and hence is described by a symmetric orthogonal matrix) is a reflection relative to some basis.

Arbitrarily small changes in the commutation relations suffice to transform the usual singular quantum theories into regular quantum theories. This process is an extension of canonical quantization that we call general quantization. Here we apply general quantization to the time-independent linear harmonic oscillator. The unstable Heisenberg group becomes the stable group SO(3). This freezes out the zero-point energy of very soft or very hard oscillators, like those responsible for the infrared or ultraviolet divergencies of usual field theories, without much changing the medium oscillators. It produces pronounced violations of equipartition and of the usual uncertainty relations for soft or hard oscillators, and interactions between the previously uncoupled excitation quanta of the oscillator, weakly attractive for medium quanta, strongly repulsive for soft or hard quanta. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2070088]

I. MAKE IT SIMPLE

The three main evolutions of physics in the twentieth century have a suggestive family resemblance. Each introduces a new kind of noncommutativity. The new noncommutativity in special relativity was that of boosts, in general relativity and the standard model gauge theories that of infinitesimal translations, and in quantum theory that of filter operations. The seminal work of Segal,[17] which stimulated the present work, pointed out that further changes of this kind are necessary for stability and suggested one. Our main goal is finiteness, not stability, but the stabilizing changes Segal suggested lead ultimately to a finite quantum theory, including one of space-time. Such a theory has been sought by physicists since the formulation of quantum theory.

By gently modifying the commutation relations of an existing quantum theory one produces a simpler theory with the existing quantum theory as a suitable limiting case, and with nearly the same continuous symmetries. A special form of Segal's general concept was applied retroactively to the relation between special relativity and Galileo relativity.[13,12] More proactively, Snyder's space-time quantization[19] was an attempted regularization and moved unwittingly toward simplicity but did not simplify the momentum algebra. Vilela made the first efforts to find a new particle theory on a simple algebra.[21] Something like the regularization of the harmonic oscillator proposed by Segal is now under study by several groups from several points of view.[6,1,14,15,20]

For example, 'tHooft[20] studies the classical particles on a circle and shows that under certain conditions, this system is equivalent to a quantum harmonic oscillator. The work of Vilela Mendes differs from others in presenting the quantum harmonic oscillator as a limit case of a "more quantum" oscillator that has a more stable algebra in the sense of Segal. We follow that line here.[18]

Naturally one discards the unregularized theory in favor of the regularized one. This last step is overlooked in some older studies.

General quantization changes the quantization rules. It replaces the usual quantization prescription by the following one:

Make the commutator algebra of the generators a simple Lie algebra.

Briefly put: If the algebra is simple, keep it simple. If it is not simple, make it simple by the least change possible.

We apply this strategy to all the algebras postulated in a physical theory, on the grounds that they must all depend continuously on experimental data that are subject to error. An algebra that is not stable is not empirical but is at least partly based on ideology. It is not possible to eliminate all such ideology-based hypotheses from physics. But it is possible to reduce their number systematically.

This implies that canonical quantization and special and general relativization are relatively small parts of a vast unifying drift toward simplicity and unity of the groups beneath our physical theories. General quantization is an attempt to take part in that drift.

In the case of the algebra of variables, semisimplicity is as good as simplicity, since it implies a direct sum that we can reduce to a simple term forever by a single measurement of the superselection variable that distinguishes these terms.

Canonical quantization introduced one quantum constant and stabilized the atom. General quantization introduces as many quantum constants as necessary to stabilize the group of the theory.

General quantization has no effect on (say) the rotator quantum algebra with given angular momentum l [$\mathbf{L}\times\mathbf{L}=\mathbf{L}$, $\mathbf{L}\cdot\mathbf{L}=l(l+1)$], whose group is already simple. But it changes the quantum dynamics of a free particle deeply, revising the theories of both space and time.

We test general quantization here on the kinematics of the linear harmonic oscillator, a ubiquitous constituent of all present field theories, and compare the finite quantum oscillators with the usual quantum oscillators, which are singular in several senses. The differences have profound consequences for extreme energy physics: the physics of both very high and very low energies.

Planck's quantum constant h froze out the very stiff oscillators responsible for the infinite heat capacity of cavity radiation in Maxwell's theory, but the zero-point energy of the resulting quantum theory of electromagnetism still diverged, however, unless one arbitrarily replaced the local Lagrangian and Hamiltonian of Maxwell by nonlocal ones tailored to have some finite zero-point energy, usually set to 0 on grounds of Lorentz invariance. Indeed, the quantum theory of the harmonic oscillator carries the germs of all the main divergences of quantum field theory. Its basic operators of position q, momentum p, and Hamiltonian $H\sim\frac{1}{2}(p^2+q^2)$ are undefined on almost every vector ψ in its Hilbert space, $q\psi=p\psi=H\psi=\infty$. Such divergences occur in a quantum theory if and only if its Hilbert space is infinite dimensional.

The usual quantum oscillator theory is also unstable in the Segal sense detailed below. It is not as unstable as the classical theory, which has the operators q and p commute, and we have become accustomed to its foibles, but it is still not operational, in that its basic operations usually cannot be carried out. General quantization makes its Hilbert space finite dimensional. The result is a finite quantum theory whose operations can in principle be carried out, with two Segal quantum constants h',h'' besides the usual Planck constant.

We find that introducing these constants freezes out even the offending zero-point oscillations of extremely hard or soft oscillators without greatly changing the zero-point energies of medium ones. The frozen oscillators have infinitesimal zero-point energies compared to the usual quantum values. They also grossly violate the usual equipartition and uncertainty relations.

This toy model illustrates how a finite quantum theory of the cavity might produce a finite zero-point energy without conflicting with the many finite predictions and symmetries of the usual quantum theory. We propose that the linear harmonic field oscillators considered fundamental in present quantum physics—those of supposedly fundamental fields, not those of elastic solids, say—are actually finite quantum oscillators near the bottoms of their energy spectra. The unobserved oscillators responsible for the infrared and ultraviolet divergencies of present quantum theories are frozen by finite quantum effects described here and contribute negligibly to the zero-point energy.

The change we carry out here is not enough to make quantum field theory finite. For that we must also simplify the Heisenberg algebra of the space-time operators x^μ and ∂_μ. This replaces the manifold theory of space-time, which assumes an infinity of events, by a simple quantum theory, with only a finite number of disjoint events, though the number may be arbitrarily large. Field theory has compound algebra on two levels, that of the underlying space-time and that of the overlying canonical commutation relations. In this paper we change only one level.

II. ALGEBRA FLEXING AND FLATTENING

A *semisimple* group is a Lie group whose Lie algebra has no invariant solvable subalgebras; a Lie algebra A being solvable if for some integer $n \geqslant 0$, $A^n = \{0\}$. Then its Lie algebra has no radical. A group that is not semisimple we call *compound*. General quantization reduces the radical and ultimately eliminates it.

Lie products $\times$ on a given vector space A, also called structure tensors, form a submanifold $\{\times\}$ of the tensor space $A \otimes A\dagger \otimes A\dagger$. A *regular* (stable, robust) algebra is one that is unchanged up to isomorphism by all sufficiently small changes in its structure tensor (Lie product) within the manifold $\{\times\}$. For example, the Lorentz algebra is stable against corrections to the speed of light. By algebra *flexing* we mean a homotopy of the structure tensor of a compound algebra that makes it semisimple. Algebra *flattening* is the inverse process. The well-known contraction process of Inönü and Wigner[13] is a special case of flattening accomplished by a one-parameter group of dilations of a coordinate system of the Lie algebra in a fixed direction. The inverse to group contraction is *group expansion*[11] and is a special case of flexing.

Several regularization processes have been used to remove unwanted infinities from physics. Unphysical regularizations cope with the divergencies of a theory without changing the finite results. They are regarded as giving the theory meaning rather than changing the theory. These include Pauli-Villars regularization,[16] lattice regularization (lattice gauge theory)[22] and dimensional regularization.[4,5,20] They contain regularization parameters that go to singular limits, like the lattice spacing going to 0. Physical regularizations, on the contrary, change the finite predictions as well as making the infinite ones finite, and are intended as distinct physical theories in their own right. Their regularization parameters do not go to a singular limit but must be determined by experiment. The most famous example is Planck's, which ultimately led to quantum theory. This was a simplification in that the associative algebra generated by the position and momentum variables has a Lie algebra with an infinite-dimensional radical for $h=0$ but only a one-dimensional radical for $h>0$.

Physical regularizations are subtler than unphysical ones but their consequences for human thought have been more dramatic. General quantization is proposed as a physical regularization.

Compound algebras are *unstable* with respect to a small change in their structures.[17] Flexing stabilizes them.

Conversely, flattening destabilizes. Approximating a circle by a tangent line or a sphere by a tangent plane are well-known flattenings. The circle and sphere are finite and their flattened form is infinite. Finite dimensional representations of the group of the sphere—such as spherical harmonic polynomials—form a complete set on the sphere, and all the operators of an irreducible representation have finite bounded spectra. On the other hand, the tangent plane is not compact and requires infinite-dimensional representations of the translation group for a complete set, and its algebra generators have unbounded spectra.

III. SIMPLIFYING THE HEISENBERG ALGEBRA

The Heisenberg Lie algebra $\mathbf{H}(1)$ is defined by the commutation relations:

$$[p,x] = -i\hbar,$$

$$[i,x] = 0, \tag{1}$$

$$[x,i] = 0.$$

It is compound and the imaginary unit i generates its radical. Segal proposed to simplify H1 by introducing two more quantum constants, which we designate here by $\hbar'$ and $\hbar''$. His expanded commutation relations are, except for notation,

$$[p,x] = -\hbar i,$$

$$[i,p] = -\hbar' x, \tag{2}$$

$$[x,i] = \hbar'' p.$$

(Refs. 6, 21, and 17). The irreducible unitary representations of this group are infinite dimensional. To avoid possible divergences and other problems, we instead use the SO(3) regularization[3,2,9,10]

$$[p,x] = -i\hbar,$$

$$[i,p] = -x\hbar', \tag{3}$$

$$[x,i] = -p\hbar''.$$

Ultimately we will need an indefinite metric for physical reasons, but not for the time-independent harmonic oscillator.

Regularizing the Heisenberg algebra means changing the role of i in the theory from constant central element to quantum variable operator on the same footing as p and q. We call this i-activation. The new variable that it introduces is called a regulator. A previous exploration in quaternion quantum theory activated an i that served as the electromagnetic axis $\eta(x)$ that resolves the electroweak gauge boson into electromagnetic and weak bosons,[8] and gives mass to the charged partner of the photon through the Stückelberg-Higgs effect. This led to a natural SU(2) that was interpreted as isospin. That theory was dropped because it did not leave room for color SU(3). Here we activate i on more principled grounds, namely the principle of simplicity. There is now plenty of room for internal groups like color SU(3), though they do not arise for the harmonic oscillator.

General quantization leads to the same kind of factor-ordering problems as the special case of canonical quantization. To reduce these we regularize not Hermitian observables directly but skew-Hermition generators

$$\hat{q} = iq, \quad \hat{p} = -ip. \tag{4}$$

The usual quantum commutation relations are then

$$[\hat{q},\hat{p}] = \hbar i,$$

$$[i,\hat{q}] = 0, \tag{5}$$

$$[\hat{p},i] = 0,$$

$$\breve{\imath}^2 = -1.$$

The regularized generators $\breve{q},\breve{p},\breve{\imath}$ obey

$$[\breve{q},\breve{p}] = \hbar\breve{\imath},$$

$$[\breve{\imath},\breve{q}] = \hbar'\breve{p}, \tag{6}$$

$$[\breve{p},\breve{\imath}] = \hbar''\breve{q},$$

We suppose $\hbar,\hbar',\hbar''>0$ so the orthogonal group is SO(3). The quantities with a breve "" are the new expanded quantum operators. In this way the simplification process introduces a new dynamically variable generator $\breve{\imath}$, somewhat as general-relativization introduced the new dynamical variable $g_{\mu\nu}$ the gravitational metric tensor field. The most primitive theory with a dynamical variable like $\breve{\imath}$ is quaternion quantum field theory.[8] There $\breve{\imath}$ generates rotations about the electric (or electromagnetic) axis in isospin space, defining a natural Higgs field. We suppose that the present generator $\breve{\imath}$ is also a Higgs field.

When general quantization introduces new group generators in this way for simplification, we call these regularization operators or "regulators." The physical constants to which regulators reduce in the singular theory we call regularization constants or "regulants." Examples of a regulator in present physics are the Riemann curvature of space-time (as the commutator of covariant transports) and the gravitational field itself (as the anticommutator of unit Clifford vectors). Examples of regulants are $\hbar$ and c.

Except for scale factors the simplified commutation relations are those of an SU(3) quantum skew-angular-momentum operator-valued vector $\breve{\mathbf{L}}=\breve{\mathbf{L}}\times\breve{\mathbf{L}}$ for a dipole rotator in three dimensions. We assume an irreducible representation with

$$\breve{\mathbf{L}}^2 = -l(l+1), \tag{7}$$

where l can have any non-negative half-integer eigenvalue. In the present work it suffices to consider only integer values of l. Then the $\breve{L}_x,\breve{L}_y,\breve{L}_z$ are represented by $(2l+1)\times(2l+1)$ matrices obeying

$$[\breve{L}_1,\breve{L}_2] = \breve{L}_3,$$

$$[\breve{L}_2,\breve{L}_3] = \breve{L}_1, \tag{8}$$

$$[\breve{L}_3,\breve{L}_1] = \breve{L}_2,$$

$$(\breve{L}_1)^2 + (\breve{L}_2)^2 + (\breve{L}_3)^2 = -l(l+1).$$

We fix the scale factors with

$$\breve{q} = Q\breve{L}_1,$$

$$\breve{p} = P\breve{L}_2, \tag{9}$$

$$\breve{\imath} = J\breve{L}_3.$$

By (6),

$$J = \sqrt{\hbar' \hbar''} = 1/l,$$

$$Q = \sqrt{\hbar \hbar'}, \tag{10}$$

$$P = \sqrt{\hbar \hbar''}.$$

The commutation relations (8) and the angular momentum quantum number l determine a simple (associative) enveloping algebra $\mathrm{Alg}(\mathbf{L}, l)$. The spectral spacing of the $\check{L}_3$ is 1, so the finite quantum constants Q, P, J serve as quanta of position, momentum and $\check{\imath}$. Since q, p are supposed to have continuous spectra in quantum theory, the constants Q, P must be very small on the ordinary quantum scale. It follows that $J = QP/\hbar$ is also very small on that scale and $l \gg 1$.

For $l \gg \sqrt{l} \gg 1$, variations $\delta(\check{\imath}^2) \leqslant O(l^{-1/2}) \ll 1$ about $(\check{\imath})^2 = -1$ can be negligible at the same time as the spectral intervals $\delta p \leqslant P\sqrt{l}$ and $\delta q \leqslant Q\sqrt{l}$ for quasicontinuous $p, q \approx 0$. This simulates the usual oscillator.

IV. FINITE LINEAR HARMONIC OSCILLATOR

Now we specialize to the oscillator by fixing a Hamiltonian. For given finite-quantum constants P, Q the finite harmonic oscillator has a Hamiltonian of the form

$$H = \frac{P^2 L_x^2}{2m} + \frac{kQ^2 L_y^2}{2} := \frac{K}{2}(L_x{}^2 + \kappa^2 L_y{}^2), \tag{11}$$

where

$$K = \frac{P^2}{m}, \quad \kappa^2 = \frac{\hbar' mk}{\hbar''}. \tag{12}$$

For fixed $\hbar, \hbar', \hbar''$, all finite oscillators are divided into three kinds with ill-defined boundaries: *medium*, where kinetic and potential terms in H are of comparable size ($\kappa \sim 1$); *soft*, when the potential energy term is dominant ($\kappa \to 0$); and hard, when the kinetic energy term is dominant ($\kappa \to \infty$). Examination of the Hamiltonian of a spin-zero scalar field (Klein-Gordon field) in quantum field theory shows that the possibilities $\kappa \ll 1$ and $\kappa \gg 1$ are also important. The oscillators that give rise to infrared divergencies of the quantum field theory correspond to soft oscillators of the finite quantum theory. Those that feed ultraviolet divergencies correspond to hard oscillators.

V. MEDIUM OSCILLATORS

The case $\kappa = 1$ is symmetric under rotations about the z axis, and so is especially simple.[20] Since

$$(\check{L}_1)^2 + (\check{L}_2)^2 + (\check{L}_3)^2 = (\check{L}^2), \tag{13}$$

$$\check{H} = \frac{K}{2}(l(l+1) + (\check{L}_3)^2). \tag{14}$$

The oscillator quantum number n that labels the energy level is now

$$n = l + m. \tag{15}$$

The expanded energy spectrum is

$$E_n = \frac{K}{2}(l(l+1) - (n-l)^2) = lK\left(n + \frac{1}{2} - \frac{n^2}{2l}\right). \tag{16}$$

For $n \ll \sqrt{l} \ll l$ this reproduces the usual uniformly spaced oscillator energy spectrum as closely as desired, but with multiplicity 2 for each level instead of 1.

The ground-state energy for this oscillator is

$$E_0 = \tfrac{1}{2}Kl = \tfrac{1}{2}1/2\hbar\omega, \tag{17}$$

exactly the usual oscillator ground energy, since $Kl = \hbar\omega$.

The main new feature is that this finite oscillator has an upper energy limit

$$E_{\max} = \tfrac{1}{2}Kl(l+1) \tag{18}$$

as required by a finite quantum theory.

In the general case of $\kappa \sim 1$ we obtain an upper bound for the ground energy by a variational approximation with the trial function $|L_z = \pm l\rangle$. This reproduces our previous result (17), now as an upper bound for the ground energy of a medium FLHO,

$$E_0 \leqslant \tfrac{1}{2}Kl. \tag{19}$$

Medium oscillators have many states with m-value close to its extremum value $m = \pm l$. The usual Heisenberg uncertainty principle

$$(\Delta p)^2(\Delta q)^2 \geqslant \frac{1}{4}\langle i[p,q]\rangle^2 = \frac{\hbar^2}{4} \tag{20}$$

becomes

$$(\Delta L_x)^2(\Delta L_y)^2 \geqslant \frac{\hbar^2}{4}\langle L_z\rangle^2_{|L_z \approx \pm l\rangle} \tag{21}$$

for a low-lying energy level of a medium oscillator. By (9) and (10),

$$(\Delta p)^2(\Delta y)^2 \geqslant \frac{\hbar^2}{4} \tag{22}$$

for large l. So medium oscillator states in low-lying energy levels have uncertainties at or above the lower limit set by the Heisenberg uncertainty principle.

VI. SOFT OSCILLATORS

Recall our finite quantum oscillator Hamiltonian

$$\check{H} = \frac{K}{2}(\check{L}_x^2 + \kappa^2 \check{L}_y^2). \tag{23}$$

When $\kappa \ll 1$ we can estimate the spectrum of $\check{H}$ using perturbation theory. The unperturbed Hamiltonian for our problem is the kinetic energy

$$H_0 = \frac{K}{2}L_x^2 \tag{24}$$

and the unperturbed eigenvectors are $|L_x = m\rangle$ so the unperturbed energy levels are

$$E_m(0) = \frac{K}{2}m^2. \tag{25}$$

The first-order shifts are

$$\delta E_m = \frac{K}{2}\langle L_x = m|L_y^2|L_x = m\rangle. \tag{26}$$

Due to the axial symmetry of $|L_x=m\rangle$,

$$\langle L_x = m|L_y^2|L_x = m\rangle = \langle L_x = m|L_z^2|L_x = m\rangle. \tag{27}$$

Therefore the energy shift is, to lowest order in κ^2,

$$\begin{aligned}\frac{K}{2}\langle L_x = m|\kappa^2 L_y^2|L_x = m\rangle &= \frac{K}{4}\kappa^2\langle m|L_x^2 + L_y^2|m\rangle \\ &= \frac{K}{4}\kappa^2\langle m|L^2 - L_z^2|m\rangle \\ &= \frac{K}{4}\kappa^2 l(l+1) - m^2.\end{aligned} \tag{28}$$

The new energy spectrum is then

$$E_m \approx \frac{K}{2}m^2 + \Delta E_m = \frac{K}{2}m^2 + \frac{1}{4}K\kappa^2[l(l+1) - m^2]. \tag{29}$$

The estimated upper bound for the energy is

$$E_{\max} \approx \frac{1}{2}Kl^2\left(1 + \frac{\kappa^2}{2l}\right). \tag{30}$$

For $\kappa \to 0$ this reproduces the upper bound for the unperturbed Hamiltonian L_z^2, as it should. The zero-point energy E_0 of first-order perturbation theory is

$$E_0 \approx \tfrac{1}{4}\kappa^2 Kl(l+1). \tag{31}$$

For $\kappa \to 0$ this is infinitesimal compared to the usual QLHO.

A soft oscillator shows no resemblance to the usual quantum oscillator. Its energy levels do not have uniform spacing. Its kinetic energy dwarfs its potential energy, so equipartition is grossly violated. The low energy states are near $|L_x=0\rangle$ instead of $|L_z=\pm l\rangle$. Its p degree of freedom is frozen out. It is "too soft to oscillate:" There is not enough energy in the q degree of freedom, even at its maximum excitation, to produce one quantum of p. The uncertainty relation reads

$$(\Delta L_x)^2(\Delta L_y)^2 \geqslant \frac{\hbar^2}{4}\langle L_z\rangle^2_{|L_x\approx 0\rangle} \approx 0. \tag{32}$$

Therefore

$$\Delta p \Delta q \ll \frac{\hbar}{2}, \tag{33}$$

which violates the Heisenberg uncertainty principle grossly.

VII. HARD OSCILLATORS

The story is just reversed for hard oscillators but the gross violations of usual quantum principles remain the same. A hard oscillator has much greater potential than kinetic energy. Its low energy states are now near $|L_y=0\rangle$ instead of $|L_z=\pm l\rangle$ (the medium case) or $|L_x=0\rangle$ (the soft case). Its q degree of freedom is frozen out. It is "too hard to oscillate." There is not enough energy in the p degree of freedom, even at maximum excitation, to arouse one quantum of q.

A hard oscillator can also be treated by perturbation theory. The kinetic energy is the perturbation. We may carry all of the main results in the preceding section for soft FLHO oscillators to the hard ones simply by replacing κ with $1/\kappa$ and K with $K\kappa^2$. A hard FLHO shows no resemblance to the usual QLHO. Its zero-point energy E_0 is now

$$E_0 \approx \frac{K}{4} l(l+1). \tag{34}$$

For $\kappa \to \infty$ this is infinitesimal compared to the usual quantum oscillator zero-point energy. Its energy levels of a hard oscillator are not uniformly spaced. Its uncertainty relation reads

$$(\Delta L_x)^2 (\Delta L_y)^2 \geqslant \frac{\hbar^2}{4} \langle L_z \rangle^2_{|L_y \approx 0\rangle} \approx 0. \tag{35}$$

Therefore

$$\Delta p \Delta q \ll \frac{\hbar}{2}, \tag{36}$$

which seriously violates the Heisenberg uncertainty principle again.

VIII. UNITARY REPRESENTATIONS

Variables p and q do not have finite-dimensional unitary representations in classical and quantum physics. They are continuous variables and generate unbounded translations of each other. But since in the finite quantum theory, all operators become finite and quantized, we expect all translations to become rotations with simple finite-dimensional unitary representations.

The canonical group of a classical oscillator becomes the unitary group of an infinite-dimensional Hilbert space for a quantum oscillator, and the unitary group of a $2l+1$ dimensional Hilbert space for the finite oscillator.

The Lie algebra generated by momentum and position as infinitesimal symmetry generators is $\mathbf{H}(1)$ for the classical and quantum oscillator and the $\mathbf{SO}(3)$ angular momentum algebra for the finite oscillator. The corresponding Lie groups are the Heisenberg group $\mathbf{H}(1)$ and $\mathbf{SO}(3)$.

Unitarily inequivalent unitary representations of the canonical commutation relations are forbidden in quantum mechanics but are present and important in quantum field theory, but general quantization eliminates them. After general quantization the commutation relations become those of a large simple group, and we presently explore the orthogonal groups. Once its invariants are fixed, as by measurement, the finite-dimensional unitary representations of this group are uniquely determined up to unitary equivalence. Yet the general quantized theory approaches the usual singular theory in an appropriate limit, where the dimension of the representations grow without bound and the group becomes compound. The inequivalent representations of quantum field theory must return in that singular limit. More than that we cannot say at this stage in the development.

IX. CONCLUSION

We suggest that algebra flattening causes the infinities of present physics. Since quantum theory began as a regularization procedure of Planck, it is rather widely accepted that further regularization of present quantum physics calls for further quantization, but what to quantize and

how to quantize it remains at least a bit unclear. If we regard quantization as another step in group regularization, the rest of the path becomes clear. It is blazed with radicals ripe for relativization. General quantization of the linear harmonic oscillator results in a finite quantum theory with three quantum constants $\hbar, \hbar', \hbar''$ instead of the usual one. The finite quantum oscillator is isomorphic to a dipole rotator with $N=l(l+1)\sim 1/(\hbar'\hbar'')\gg 1$ states and bounded Hamiltonian $H=A(L_x)^2+B(L_y)^2$. Its position and momentum variables are quantized with uniformly spaced bounded finite spectra and supposedly universal quanta of position and momentum. For fixed quantum constants and large $N\gg 1$ there are three broad classes of finite oscillator, soft, medium, and hard. The field oscillators responsible for infrared and ultraviolet divergences are soft and hard, respectively. Medium oscillators have $\sim\sqrt{N}$ low-lying states having nearly the same zero-point energy and level spacing as the quantum oscillator and nearly obeying the Heisenberg uncertainty principle and the equipartition principle. The corresponding rotators are nearly polarized along the z axis with $L_z \sim \pm l$.

The soft and hard oscillators have infinitesimal 0-point energy, and grossly violate both equipartition and the Heisenberg uncertainty relation. They do not resemble the quantum oscillator at all. Their low-lying energy states correspond to rotators with $L_x\sim 0$ or $L_y\sim 0$ instead of $L_z\sim \pm l$. Soft oscillators have frozen momentum $p\approx 0$ because their maximum potential energy is too small to produce one quantum of momentum. Hard oscillators have frozen position $q\approx 0$ because their maximum kinetic energy is too small to produce one quantum of position.

The zero-point energy of a physical oscillator likely contributes to its gravitational field. It will be interesting to estimate its contribution to astronomical gravitational fields. For a consistent estimate we should regularize the quantum field theory, not just one of its oscillators. This changes not only the structure of the individual oscillators, as considered here, but also the number and distribution of the oscillators. We leave this study for later, but it is already easy to say how it will proceed, and what form it will take.

Field theory has compound algebras on two levels, that of the underlying space-time and that of the overlying canonical commutation relations regularization. In this paper we change only the top level, but to simplify field theory we must also simplify the Heisenberg algebra of the lower-level space-time operators x^μ and ∂_μ. This replaces the manifold theory of space-time, which assumes an infinity of events, by a simple quantum space-time theory, with only a finite number of disjoint events, though that number may be arbitrarily large.

We must then combine two finite-dimensional algebras, that of the local field variables and that of the space-time-energy-momentum variables, to make the finite-dimensional algebra of the field theory. In c discrete theories, the combination process is exponentiation S^T where S is the local field-variable state-set and T is the space-time set. In the q/c theories that work best today, where the numerator q indicates that S is quantum and the denominator c indicates that T is still classical, an exponential still exists and is used. General quantization leads to q/q theories. In that case the usual exponential S^T becomes basis dependent, and the most economical invariant construct that includes all the special cases is the exterior algebra over $S\otimes T$, but this is still finite dimensional. Since general quantization gives time too a beginning and an end, the time development is certainly not unitary. As a result the problem of reconciling unitarity, causality, and Lorentz invariance[7] is eliminated. On the other hand, since the Lorentz group is already simple, Lorentz invariance is unaffected by general quantization.

General quantization modifies low- and high-energy physics. Because the low-lying energy levels of medium oscillators have nearly uniform spacing, the energy of two excitations is but slightly less than the sum of their separate energies. The corresponding quanta nearly do not interact, and the small interaction that they have is attractive. For soft or hard oscillators, the energy level varies quadratically with the energy quantum number. The energy of two quanta of oscillation is twice the sum of their separate energies, for example. The corresponding quanta have a repulsive interaction of great strength; the interaction energy is equal to the total energy of the separate quanta. Thus the simplest regularization leads to interactions between the previously uncoupled excitation quanta of the oscillator, weakly attractive for medium quanta, strongly repulsive for soft or hard quanta.

Like Dirac's theory of the "anomalous" magnetic moment of the relativistic electron, these extreme-energy effects depend on factor ordering. They can be adjusted to fit the data by reordering factors and so are not crucial tests of the theory. A group regularization of a time-dependent free Dirac equation has been carried out[10] and the extension to interactions is under study.

Exact supersymmetry in the relativistic hydrogen atom in general dimensions—supercharge and the generalized Johnson-Lippmann operator

Hosho Katsura[a] and Hideo Aoki
Department of Physics, University of Tokyo, Hongo, Tokyo 113-0033, Japan

(Received 18 July 2005; accepted 17 January 2006; published online 7 March 2006)

A Dirac particle in general dimensions moving in a $1/r$ potential is shown to have an exact supersymmetry, for which the two supercharge operators are obtained in terms of (a D-dimensional generalization of) the Johnson-Lippmann operator, an extension of the Runge-Lenz-Pauli vector that relativistically incorporates spin degrees of freedom. So the extra symmetry (S(2)) in the quantum Kepler problem, which determines the degeneracy of the levels, is so robust as to accommodate the relativistic case in arbitrary dimensions. © *2006 American Institute of Physics.*

INTRODUCTION

There is an increasing amount of fascination with supersymmetry (SUSY) in various fields of physics.[1,2] In a broad context SUSY is a kind of (graded) Lie algebra that closes under a combination of commutation and anticommutation.[3] One of the simplest realizations of such a symmetry may be found in one of the oldest problems in physics—motion of an electron in a hydrogen atom, or, classically, Kepler's problem. It has long been known that there is a hidden symmetry (a dynamical symmetry) in the problem, which is related to an extra conservation (the Runge-Lenz vector). So the symmetry of the problem is higher (SO(4)) than the trivial SO(3), which is the cause of the "accidental" degeneracy (i.e., the energy level independent of l) in the spectrum of the hydrogen in nonrelativistic quantum mechanics. If we move on to the Dirac electron in hydrogen in the relativistic quantum mechanics, the accidental degeneracy is lifted (since the Runge-Lenz vector, which designates the direction of the perihelion, is no longer conserved). However, the degeneracy is lifted only incompletely, and twofold degeneracies [for the Dirac-operator quantum number $\kappa \equiv -(2\mathbf{S}\cdot\mathbf{L}+1) = \pm(j+1/2)$ with j being the total angular momentum] remain, which was puzzling.

In 1985 Sukumar made an interesting suggestion that the strange degeneracy may be explained as a supersymmetry in the problem.[4] Subsequently however, Tangerman and Tjon[5] who have pointed out that there is indeed an exact supersymmetry for the nonrelativistic hydrogen atom, criticized that Sukumar's work has not actually constructed supercharges for the relativistic hydrogen atom. On the other hand, analytic studies for the relativistic hydrogen in general spatial dimensions have been developed, and analytic solutions are now obtained.[6,7]

Given this background, the purpose of the present paper is to show that an exact supersymmetry for the relativistic Dirac particle in a $1/r$ potential in fact exists in general D spatial dimensions. In doing so we have actually constructed the supercharges $Q_{\pm}$ (i.e., mutually anticommuting operators that commute with the Hamiltonian) for the Dirac Hamiltonian in $(D+1)$ dimensions. The symmetry enables us to obtain the lowest eigenenergy and its wave function for each sector of (the D-dimensional generalization of) $|\kappa|$ in a simple and transparent manner, so the problem indeed turns out to be algebraically solvable.

---

[a]Present address: Department of Applied Physics, University of Tokyo, Hongo, Tokyo 113-8656, Japan.

One interesting point is whether the supersymmetry in the hydrogen problem is related to the Runge-Lenz vector that describes the hidden conservation law on the nonrelativistic level. Dahl and Jorgensen[8] have shown, for the relativistic hydrogen in $(3+1)$ dimensions, that the Runge-Lenz-Pauli vector (that necessarily involves spin degrees of freedom for the Dirac particle, and is called Johnson-Lippmann operator[9]) may be indeed used to construct supercharges describing the supersymmetry. So the question we address here amounts to whether this extends to general dimensions. We first construct the Johnson-Lippmann operator generalized to the relativistic hydrogen in $(D+1)$ dimensions, and then show that the generalized operator may actually be used to construct the supercharges. The supercharges are in fact shown to reduce to (the $(D+1)$ dimensional generalization of) Runge-Lenz-Pauli vector in the nonrelativistic limit. While the Runge-Lenz-Pauli vector in general dimensions has been discussed in Refs. 10 and 11 for the nonrelativistic case, the relativistic one is obtained for the first time. So we shall conclude that the supersymmetry is unexpectedly robust enough to be extended to the most general case, i.e., relativistic case in general dimensions. We can summarize the situation as

	$D=3$	General D
Nonrelativistic	SUSY (Ref. 5)	energy levels (Ref. 12)
Relativistic	SUSY (Ref. 8)	SUSY (present work)

DIRAC'S EQUATION

Dirac's equation for the relativistic hydrogen atom in $(D+1)$ dimensions is written, in natural units (where $c=\hbar=1$), as

$$\{\gamma^0(p_0 - eA_0) + \gamma^j p_i - m\}\Psi(x) = 0 \tag{1}$$

in standard notations, where γ's satisfy $\{\gamma^\mu, \gamma^\nu\}=g^{\mu\nu}=\mathrm{diag}(1,-1,-1,\ldots)$, $p_\mu = i\partial_\mu$, $x=(x^0,x^1,\ldots,x^D)$, and summations over repeated indices are implied. We assume a $1/r$ potential, so we have $eA_0=-Z\alpha/r$, where $\alpha=e^2/(\hbar c)$ is the fine-structure constant and Z the atomic number. When the lines of electric force are allowed to spread in the D spatial dimensions the Coulomb potential becomes $1/r^{D-2}$, but we focus on the $1/r$ potential for general dimensions to retain the atomic stability.[13] We come back to this point later. If the time derivative is explicitly written, we have

$$\begin{aligned} i\frac{\partial}{\partial x^0}\Psi(x^0,x^1,\ldots,x^D) &= H\Psi(x^0,x^1,\ldots,x^D), \\ H &= \gamma^0 m + \gamma^0\gamma^j p^i - \frac{Z\alpha}{r}(i=1,2,\ldots,D), \end{aligned} \tag{2}$$

where H is the Hamiltonian and summations are implied for repeated spatial superscripts.

The operators that commute with the Hamiltonian are the total angular momentum (in D spatial dimensions),

$$\begin{aligned} J_{ab} &= L_{ab} + \frac{i}{2}\gamma^a\gamma^b, \\ L_{ab} &= ix_a\partial_b - ix_b\partial_a, \end{aligned} \tag{3}$$

and the Dirac operator (in D dimensions),

$$K \equiv \gamma^0 \left\{ \frac{i}{2} \sum_{a \neq b} \gamma^a \gamma^b L_{ab} + \frac{1}{2}(D-1) \right\} = \gamma^0 \left\{ \mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2 + \frac{1}{2}(D-1) \right\}, \tag{4}$$

that is related to the spin-orbit interaction.

GENERALIZED JOHNSON-LIPPMANN OPERATOR

While $\mathbf{J}$ and K are (usually the only) constants of motion for arbitrary central fields, it is known, for the ordinary $D=3$, that there is an extra operator, a relativistic analogue of the Runge-Lenz-Pauli vector, that commutes with the Hamiltonian, as first constructed by Johnson and Lippmann.[9] We now generalize the Johnson-Lippmann operator to $(D+1)$ dimensions to define a generalized Johnson-Lippmann operator,

$$A \equiv \gamma^{D+1} \gamma^0 \gamma^j \frac{x^i}{r} - \frac{i}{Zm\alpha} K \gamma^{D+1} (H - \gamma^0 m). \tag{5}$$

Here we have defined γ^{D+1}, a pseudoscalar, which is a generalization of γ^5 in $(3+1)$ dimensions, and which satisfies $(\gamma^{D+1})^\dagger = \gamma^{D+1}, (\gamma^{D+1})^2 = 1$, $\{\gamma^{D+1}, \gamma^\mu\} = 0$. γ^{D+1} is constructed from $\{\gamma^0, \gamma^1, \ldots, \gamma^D\}$, but its actual form depends on whether the spatial dimension is even or odd.

From the (anti)commutation relations above, we can show, after a rather tedious manipulation, that we have indeed $[H,A]=0$ with a notable relation between H and A,

$$A^2 = 1 + \left(\frac{K}{Z\alpha} \right)^2 \left(\frac{H^2}{m^2} - 1 \right). \tag{6}$$

The expression reduces to the $D=3$ counterpart obtained in Refs. 8 and 14.

For K and A, on the other hand, we can show that

$$\{A,K\} = 0,$$

i.e., we end up with mutually anticommuting operators, K,A, that commute with H.

CONSTRUCTION OF THE SUPERCHARGE OPERATORS

We are now in position to construct the generators of the supersymmetry, which was left undone in Ref. 8 and stated in Ref. 5 as an operator interesting to find. We can do so by going back to a supersymmetric quantum mechanical model originally conceived by Witten,[3,15] to which the present Hamiltonian is shown to be formally equivalent. Due to the relation (6), we can take $\mathcal{H} \equiv A^2$ as a Hamiltonian of the present problem. We can construct two operators Q_1, Q_2 that commute with $\mathcal{H}$,

$$Q_1 = A, \quad Q_2 = i \frac{AK}{|\kappa|}, \tag{7}$$

where κ is the eigenvalue of K. We have then

$$\begin{aligned} \mathcal{H} &= Q_1^2 = Q_2^2, \\ \{Q_1, Q_2\} &= 0. \end{aligned} \tag{8}$$

If we further define

$$Q_\pm \equiv \frac{1}{2}(Q_1 \pm iQ_2) = \frac{1}{2}\left(1 \pm \frac{K}{|\kappa|}\right)A = \frac{1}{2}A(1 \mp \mathcal{P}_\kappa) \tag{9}$$

with $\mathcal{P}_\kappa \equiv K/|\kappa|$, we have

$$\begin{aligned} Q_+^2 = Q_-^2 = 0, \\ \mathcal{H} = \{Q_+, Q_-\}. \end{aligned} \tag{10}$$

This establishes an equivalence to Witten's model.

So we can take the eigenvectors $|n, \pm\rangle$ that satisfy

$$\begin{aligned} \mathcal{H}|n, \pm\rangle = E_n^{(\pm)}|n, \pm\rangle, \\ \mathcal{P}_\kappa|n, \pm\rangle = \pm|n, \pm\rangle, \end{aligned} \tag{11}$$

since $\mathcal{H}=A^2$ commutes with K, and we can talk about the simultaneous eigenvectors.

$\mathcal{P}_\kappa$ does not commute with $Q_\pm$, for which we have $Q_\pm|n, \pm\rangle = 0$. On the other hand, $[\mathcal{H}, Q_\mp] = 0$ implies that $|n, \pm\rangle$ and $Q_\mp|n, \pm\rangle$ have a degenerate eigenvalue of $\mathcal{H}$ with different eigenvalues of $\mathcal{P}_\kappa$. From the relation (6) a zero eigenstate of $\mathcal{H}=A^2$ is the ground state of the original H (or, more precisely, the lowest-energy state for each value of κ). Since $\langle n, \sigma|\mathcal{H}|n, \sigma\rangle = \langle n, \sigma|\{Q_+, Q_-\}|n, \sigma\rangle = |Q_+|n, \sigma\rangle|^2 + |Q_-|n, \sigma\rangle|^2 \geqslant 0$ (for $\sigma = \pm$), a state is the ground state of H if the equality holds in the above inequality. The equality occurs when $Q_+|0, -\rangle = 0$ or $Q_-|0, +\rangle = 0$. If we go back to the definition of $Q_\pm$ [Eq. (9)], the zero-eigenvalue state $|0\rangle$ should satisfy

$$A|0\rangle = 0,$$

since $(1 \mp \mathcal{P}_\kappa)|n, \mp\rangle \neq 0$.

KERNEL OF *A*

One way to establish the existence of such a state is an analytic method. Following Ref. 6, we write the wave function for odd spatial dimensions $D=2N+1$ as

$$\psi_\kappa(x^1, x^2, \ldots, x^D) = r^{-N}\begin{pmatrix} F(r)\phi_\kappa(\Omega) \\ iG(r)\phi_{-\kappa}(\Omega) \end{pmatrix}, \tag{12}$$

where $F(G)$ is the "large (small)" components, ϕ_κ is the angular part with angular coordinates Ω, and $K\psi_\kappa = \kappa\psi_\kappa$ holds. If we plug this into $A\psi_\kappa = 0$, we have, after some manipulation,

$$\begin{aligned} \left[\left(x\frac{\mathrm{d}}{\mathrm{d}x} + \mathrm{sign}(\kappa)x\right)^2 - s^2\right]\begin{pmatrix} f(x) \\ g(x) \end{pmatrix} = 0, \\ s \equiv \sqrt{\kappa^2 - (Z\alpha)^2}, \end{aligned} \tag{13}$$

where we have defined $F(r) \equiv f(x)$, $G(r) \equiv g(x)$ in terms of a dimensionless $x \equiv (Z\alpha m/|\kappa|)r = (Z/|\kappa|a_0)r$ with a_0 being the Bohr radius.

For this differential equation of second order, there are two independent solutions, $f(x) \propto x^{-s}e^{-\mathrm{sign}(\kappa)x}$ or $x^s e^{-\mathrm{sign}(\kappa)x}$ with

$$\kappa = \pm\left[l + \tfrac{1}{2}(D-1)\right],$$

where $l(=0, 1, \ldots)$ is the orbital angular momentum, but the only normalizable one is the latter with $\kappa > 0$. With a similar argument for $g(x)$, we arrive at the kernel of A,

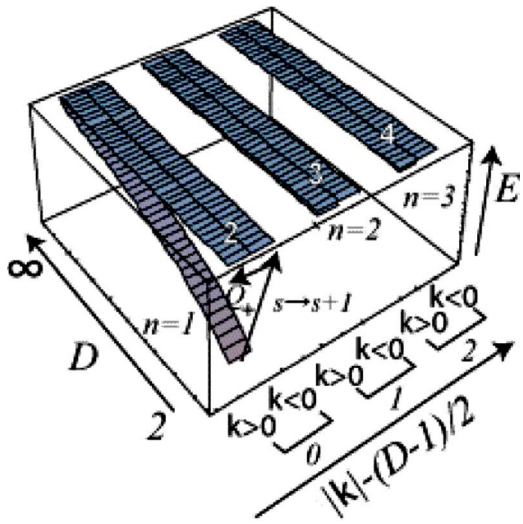

FIG. 1. (Color online) Energy level scheme for the relativistic hydrogen in D spatial dimensions. The lowest few levels are plotted against the Dirac quantum number κ and $\tanh D$, where the energy is plotted on a logarithmic scale to make the level splittings clearer. How the S(2) ladder is obtained with a shift in s and the supercharge operation Q_+ is indicated by arrows with the sign of κ and the principal quantum number n (solid and open numbers) indicated.

$$\psi_\kappa \propto x^{s-N}e^{-x}\begin{pmatrix} \phi_\kappa(\Omega) \\ i\dfrac{\kappa - s}{Z\alpha}\phi_{-\kappa}(\Omega) \end{pmatrix} \tag{14}$$

as the nondegenerate lowest state (the unpaired levels in Fig. 1).

For even $D=2N$ we can perform a similar procedure, again following Ref. 6. This time we can set $\psi_\kappa = r^{-N+1/2}[F(r)\phi_\kappa(\Omega) + iG(r)\phi_{-\kappa}(\Omega)]$, for which the same differential equation results for $F(r), G(r)$, so we have a nondegenerate ground state, $\psi_\kappa \propto x^{s-N+1/2}e^{-x}\{\phi_\kappa(\Omega) + i[(\kappa - s)/Z\alpha]\phi_{-\kappa}(\Omega)\}$.

EIGENENERGIES AND THE GROUP THEORY

Eigenenergies may readily be obtained algebraically: As used above, Eq. (6) dictates that each of the zero eigenstates of the supersymmetric Hamiltonian $\mathcal{H}=A^2$ is the lowest-energy state (for each sector of K) of the original H. This immediately implies that E, the lowest-lying (within each sector of K) eigenvalue of H, is

$$E/m = \sqrt{1 - \left(\frac{Z\alpha}{\kappa}\right)^2} = \left[1 + \left(\frac{Z\alpha}{s}\right)^2\right]^{-1/2}, \tag{15}$$

in agreement with the analytical result in Ref. 6. We can go up the ladder (where the leg corresponds to $\kappa = \pm|\kappa|$ while the rung spanned by a quantum number we call n') by making $s \equiv \sqrt{\kappa^2 - (Z\alpha)^2} \to s+1$.

So we end up with

$$E/m = \left[1 + \frac{(Z\alpha)^2}{\left(n - |\kappa| + \dfrac{D-3}{2} + \sqrt{\kappa^2 - (Z\alpha)^2}\right)^2}\right]^{-1/2},$$

where we assume $Z\alpha < (D-1)/2$ for the atomic stability. Here the principal quantum number is given as

$$n = l + 1 + n'$$

with $n' = 0, 1, \ldots$, where each level is doubly degenerated [corresponding to $\kappa = \pm(l + (D-1)/2)$ and related by Q_+], except at the bottom of each ladder at $n' = 0$ (i.e., $n = l + 1$) for which only $\kappa > 0$ should be taken (Fig. 1). We can also see that the interdimensional degeneracy, which exists between the levels $(l, D) \to (l \pm 1, D \mp 2)$ noted for the nonrelativistic case,[12] persists for the relativistic case, and the supersymmetric ladders live on such a spectrum.

Group theoretically the present result implies the following. The nonrelativistic hydrogen atom in D spatial dimensions has a hidden symmetry (with the Runge-Lenz vector conserved), and the symmetry of the problem is higher (SO($D+1$)) than the symmetry (SO(D)) of the space. If we go to the relativistic case the symmetry is degraded, but only partially degraded into SO(D) $\otimes$ S(2) due to the supersymmetry. So the conjecture, stated in Ref. 5, is established here for general dimensions.

RELATION WITH THE RUNGE-LENZ-PAULI VECTOR

Related to the above, we can note a certain relation between the generalized Johnson-Lippmann operator (A) and the Runge-Lenz-Pauli vector as follows. Since A is Hermitian, we have

$$A = \frac{1}{2}(A + A^\dagger) = -\gamma^{D+1}\gamma^0\gamma^j\left[\frac{1}{2Zm\alpha}\gamma^0(p^j L_{ij} - L_{ji}p^j) - \frac{x^i}{r}\right] + \frac{i}{m}K\gamma^{D+1}\frac{1}{r}. \tag{16}$$

This expression reduces, in the nonrelativistic limit, to

$$A \to -\sigma^i M^i,$$

where

$$M^i = \frac{1}{2mZ\alpha}(p^j L_{ij} - L_{ji}p^j) - \frac{x^i}{r}$$

is the nonrelativistic Runge-Lenz-Pauli vector in D spatial dimensions[10,11] and $\sigma^i = \gamma^{D+1}\gamma^0\gamma^i$ the spin operator in D dimensions. Namely, the operator in this limit is the inner product of the Runge-Lenz-Pauli vector ($\mathbf{M}$) and the spin ($\boldsymbol{\sigma}$) in D dimensions.[16]

SUMMARY AND DISCUSSIONS

So the higher symmetry for the $1/r$ potential in general dimensions is revealed to be surprisingly robust against the relativistic generalization and is retained as a supersymmetry. The supercharge is indeed related to (a D-dimensional generalization of) the Johnson-Lippmann operator.

Given the formula for the general D, we are tempted to ask what happens in the $D \to \infty$ limit. In the nonrelativistic case the kinetic energy ($\sim(1/D) \times$ potential energy) is dominated by the potential energy, so the system reduces to a set of harmonic oscillations around the classical potential minima as stressed in Ref. 12. In the relativistic case, however, we see that we cannot eliminate the small component (G) in the $D \to \infty$ limit, since the coupling between F and G does not vanish in this limit. This implies that we cannot trivially relate the supersymmetry with a set of oscillators even asymptotically.

Another basic question is whether the supersymmetry is just accidental to the $1/r$ potential. As mentioned above, electromagnetically there is a problem of how we can conceive the $1/r$ potential as the Coulomb potential in general dimensions. We should have $1/r^{D-2}$ potential from Gauss's law if the lines of electromagnetic force extend over the D spatial dimensions, but there is a well-known Ehrenfest's 1920 result that the atom becomes unstable for this potential. Some authors argue that we should in fact stick to $1/r$ in general dimensions.[17] Experimentally, a low-dimensional ($D=2$) case may be interesting as an accessible one.

In a broader context, a supercharge is a kind of generalization of the Dirac operator, so it could be that supersymmetry is shared by a wide class of Dirac-type equations. Recently, Leviatan[18] has explicitly constructed the supercharges of the Dirac equation in $(3+1)$ dimensions for more general potentials which include the case of the $1/r$ potential. Furthermore, some authors[19] have discussed generalization of the Runge-Lenz-Pauli vector, such as the case of a particle around a magnetic monopole with a vector potential around it. So the exploration of supersymmetry in wider gauge-field models will be an interesting future problem.

Bose-Einstein condensate and spontaneous breaking of conformal symmetry on Killing horizons II

Valter Moretti[a)]
Dipartimento di Matematica dell'Università di Trento and Istituto Nazionale di Alta Matematica "F. Severi," Unità Locale di Trento and Istituto Nazionale di Fisica Nucleare, Gruppo Collegato di Trento, via Sommarive 14, I-38050 Povo (TN), Italy

(Received 19 July 2005; accepted 16 January 2006; published online 10 March 2006)

In the paper cited in the title [J. Math. Phys. **46**, 062303 (2005)] local scalar QFT (in Weyl algebraic approach) has been constructed on degenerate semi-Riemannian manifolds $\mathbb{S}^1\times\Sigma$ corresponding to the extension of Killing horizons by adding points at infinity to the null geodesic forming the horizon. It has been proved that the theory admits a natural representation of $\mathrm{PSL}(2,\mathbb{R})$ in terms of *-automorphisms and this representation is unitarily implementable if referring to a certain invariant state λ. Among other results it has been proved that the theory admits a class of inequivalent algebraic (coherent) states $\{\lambda_\zeta\}$, with $\zeta\in L^2(\Sigma)$, which break part of the symmetry, in the sense that each of them is not invariant under the full group $\mathrm{PSL}(2,\mathbb{R})$ and so there is no unitary representation of whole group $\mathrm{PSL}(2,\mathbb{R})$ which leaves fixed the cyclic GNS vector. These states, if restricted to suitable portions of $\mathbb{M}$ are invariant and extremal KMS states with respect to a surviving one-parameter group symmetry. In this paper we clarify the nature of symmetry breakdown. We show that, in fact, *spontaneous* symmetry breaking occurs in the natural sense of algebraic quantum field theory: if $\zeta\neq 0$, there is no unitary representation of whole group $\mathrm{PSL}(2,\mathbb{R})$ which implements the *-automorphism representation of $\mathrm{PSL}(2,\mathbb{R})$ itself in the GNS representation of λ_ζ (leaving fixed or not the state). © *2006 American Institute of Physics.*

I. SUMMARY OF SOME ACHIEVED RESULTS

In Ref. 1 local scalar QFT (in Weyl algebraic approach) is constructed on degenerate semi-Riemannian manifolds $\mathbb{M}=\mathbb{S}^1\times\Sigma$ corresponding to the extension of future Killing horizons by adding points at infinity to the null geodesic forming the horizon. Above the transverse manifold Σ has a Riemannian metric inducing the volume form ω_Σ, whereas $\mathbb{S}^1$ is equipped with the null metric. To go on, fix a standard frame (see Sec. II A of Ref. 1) $\theta\in(-\pi,\pi]$ on $\mathbb{S}^1$ of $\mathbb{M}=\mathbb{S}^1\times\Sigma$ – so that $\mathbb{S}^1$ is realized as $(-\pi,\pi]$ with the endpoints identified—and consider the C^*-algebra of Weyl $\mathcal{W}(\mathbb{M})$ generated by nonvanishing elements $V(\omega)$ in Eq. 12 in Sec. II E in Ref. 1, the smooth forms ω of the space $\mathcal{D}(\mathbb{M})$ being the space of forms ϵ_ψ defined in Eq. 1 in Sec. 2.1 in Ref. 1. We shall exploit the group of *-automorphisms α defined in Eq. 19 in Ref. 1 representing the Möbius group $\mathrm{PSL}(2,\mathbb{R})$ viewed as a subgroup of diffeomorphisms of $\mathbb{S}^1$ and thus of $\mathbb{M}$ (see Sec. III A of Ref. 1):

$$\alpha_g(V(\omega))=V(\omega^{(g^{-1})}), \tag{1}$$

$\omega^{(g)}:=g^*\omega$ being the natural pullback action of $g\in\mathrm{PSL}(2,\mathbb{R})$ on forms. In the following $\{\alpha_t^{(\mathcal{X})}\}_{t\in\mathbb{R}}$ indicates the one-parameter subgroup associated with the vector field $\mathcal{X}$ on $\mathbb{M}$ corresponding to an element of the Lie algebra of $\mathrm{PSL}(2,\mathbb{R})$. In particular the vector field on $\mathbb{M}$, $\mathcal{D}$, generating a

a)Electronic mail: moretti@science.unitn.it

one-parameter subgroup of $\mathrm{PSL}(2,\mathbb{R})$, is that defined in Eq. 16 in Ref. 1. If $\zeta \in L^2(\Sigma, \omega_\Sigma)$ and λ_ζ is the coherent state on $\mathcal{W}(\mathbb{M})$ defined by means of 33 of Sec. IV B in Ref. 1, we indicate its GNS triple by $(\mathfrak{H}_\zeta, \Pi_\zeta, \Psi_\zeta)$.States λ_ζ are constructed as follows with respect to $\lambda := \lambda_0$. The map $V(\omega) \mapsto V(\omega) e^{i \int_{\mathbb{M}} \Gamma(\zeta \omega_+ + \overline{\zeta \omega_+})}$, $\omega \in \mathcal{D}(\mathbb{M})$, uniquely extends to a *-automorphism γ_ζ on $\mathcal{W}(\mathbb{M})$ such that $\gamma_\zeta \circ \alpha_t^{(\mathcal{D})} = \alpha_t^{(\mathcal{D})} \circ \gamma_\zeta$ for all $t \in \mathbb{R}$. The function $\Gamma := \ln|\tan(\theta/2)|$ and the $\mathcal{D}$-positive-frequency part of ω, ω_+, are, respectively, defined and discussed in Sec. IV B [Eq. 32] and in Lemma 3.1 of Sec. III B of Ref. 1.

$$\lambda_\zeta(w) := \lambda(\gamma_\zeta w) \quad \text{for all } w \in \mathcal{W}(\mathbb{M}). \tag{2}$$

The state λ was defined in Eq. 13 in Ref. 1 and it is pure in accordance with Lemma A.2 in Ref. 2, because the real linear map $K: \mathcal{S}(\mathbb{M}) \ni \psi \mapsto \psi_+$ has dense range in the one-particle space $\mathcal{H}$ by construction. It is clear that the GNS representation generated by λ_ζ is irreducible if that of λ is irreducible. As a consequence every λ_ζ is pure.

Among other results it has been proved that (Theorems 4.1, 4.2, and 5.1) the pure states λ_ζ are inequivalent states and, the restrictions to the algebra localized at the "half circle times Σ," give rise to different extremal KMS states at rationalized Hawking temperature $T = 1/2\pi$ with respect to $\{\alpha_t^{(\mathcal{D})}\}_{t \in \mathbb{R}}$. If one is dealing with a bifurcate Killing horizon of a black hole the "half circle times Σ" is nothing but $\mathbb{F}_+$, the future right branch of the Killing horizon (see Sec. I and figure in Ref. 1). In this case $-\zeta^{-1}\mathcal{D}$, with $\zeta^{-1} = \kappa$ being the surface gravity of the examined black hole, can be recognized as the restriction to the horizon to the Killing vector field defining Schwarzschild time, kT becomes proper Hawking's temperature and the order parameter associated with the breakdown of symmetry can be related with properties of the black hole.

II. SPONTANEOUS BREAKING OF PSL(2,*R*) SYMMETRY

As illustrated in further details below, a remarkable property of states λ_ζ is that, for $\zeta \neq 0$, they break part of the symmetry, in the sense that each of them is not invariant under the full group $\mathrm{PSL}(2,\mathbb{R})$ and so there is no unitary representation of whole group $\mathrm{PSL}(2,\mathbb{R})$ which leaves fixed the cyclic GNS vector. We want here to clarify the nature of this breakdown of $\mathrm{PSL}(2,\mathbb{R})$ symmetry, proving that, actually there is no unitary representation of $\mathrm{PSL}(2,\mathbb{R})$ which implements the full group action of $\mathrm{PSL}(2,\mathbb{R})$ no matter the issue of the invariance of λ_ζ under $\mathrm{PSL}(2,\mathbb{R})$. This leads to *spontaneous* breaking of $\mathrm{PSL}(2,\mathbb{R})$ symmetry.

Let us focus on this issue from a general point of view. In the physical literature there are several, also strongly inequivalent, definitions of *spontaneous* breaking of symmetry related to different approaches to quantum theories. We adopt the following elementary definition which is quite natural in algebraic QFT and is equivalent to the definition given on p.119 of the recent review[3] on breaking symmetry theory (see the end of the paper for further comments).

Definition 1: Referring to a C^*-algebra $\mathcal{A}$, one says that

(a) *A Lie group $\mathcal{G}$ is a* group of symmetries *for $\mathcal{A}$ if there is a representation β of $\mathcal{G}$ made of *-automorphisms of $\mathcal{A}$. If some notion of time evolution is provided, it is required that it corresponds to a one parameter subgroup of $\mathcal{G}$.* [If this subgroup does not belong to the center of $\mathcal{G}$, *the self-adjoint generators of unitary representations of $\mathcal{G}$ implementing β, if any, give rise to constants of motion which may depend parametrically on time. It happens, for instance, for Poincaré-invariant systems, where the conserved self-adjoint operator $K^i(t)$ associated with boost invariance along the i*th *axis depend parametrically on time. Indeed, on the appropriate domain, $K^i(t) = K^i(0) - tP^i$ and it is conserved under Heisenberg evolution $U_t K^i(t) U_t^\dagger = K^i(0)$.*]

(b) *Assuming that* (a) *is valid*, spontaneous breaking of $\mathcal{G}$ symmetry *occurs with respect to an algebraic state μ on $\mathcal{A}$ and β, if there are elements $g \in \mathcal{G}$ such that β_g are not implementable unitarily in the GNS representation $(\mathfrak{H}_\mu, \Pi_\mu, \Psi_\mu)$ of μ, i.e. for those elements there is no unitary operator U_g on $\mathfrak{H}_\omega$ with $U_g \Pi_\mu(a) U_g^\dagger = \Pi_\mu(\beta_g(a))$ for all $a \in \mathcal{A}$.*

Considering the inequivalent GNS triples $(\mathfrak{H}_\zeta, \Pi_\zeta, \Psi_\zeta)$, Theorems 3.2 and 3.3 in Ref. 1 show that, if $\zeta=0$ the group of automorphisms α representing $\mathrm{PSL}(2,\mathbb{R})$ can be unitarily implemented in the space $\mathfrak{H}=\mathfrak{H}_0$ and the cyclic vector $\Psi:=\Psi_0$ of the GNS representation is invariant under that (strongly continuous) unitary representation of $\mathrm{PSL}(2,\mathbb{R})$. [In the proof theorem 3.2 in all occurrences of the symbol $\widetilde{\mathrm{PSL}(2,\mathbb{R})}$ before the statement "…is in fact a representation of $\mathrm{PSL}(2,\mathbb{R})$." It must be replaced by $\widetilde{\mathrm{PSL}(2,\mathbb{R})}$, it denoting the universal covering of $\mathrm{PSL}(2,\mathbb{R})$.] Conversely, if $\zeta\neq 0$, $\mathrm{PSL}(2,\mathbb{R})$ symmetry turns out to be broken. Indeed, Theorem 4.1 states that each state λ_ζ with $\zeta\neq 0$ is invariant under $\{\alpha_t^{(\mathcal{D})}\}_{t\in\mathbb{R}}$, but it is not under any other one-parameter subgroup of α (barring those associated with $c\mathcal{D}$ for $c\in\mathbb{R}$ constant). In the general case this is not enough to assure occurrence of *spontaneous* breaking of $\mathrm{PSL}(2,\mathbb{R})$ symmetry as defined in Definition 1.

In a different context, it is possible to show that—see Sec. III.3.2 of Ref. 4—if $\mathcal{G}$ is Poincaré group or an internal symmetry group for a special relativistic system and the reference state μ is a primary vacuum state over the net of algebras of observables, then non-$\mathcal{G}$ invariance of the vacuum state implies—and in fact is equivalent to—spontaneous breaking of $\mathcal{G}$ symmetry. Our considered case is far from that extent and thus there is no *a priori* guarantee for the occurrence of spontaneous breaking of $\mathrm{PSL}(2,\mathbb{R})$ symmetry for states λ_ζ with $\zeta\neq 0$ and the issue deserves further investigation. The following theorem gives an answer to the issue.

Theorem 1: *If* $L^2(\Sigma,\omega_\Sigma)\ni\zeta\neq 0$, *spontaneous breaking of* $PSL(2,\mathbb{R})$*-symmetry occurs with respect to* λ_ζ *and the representation* α. [*In particular, there is no unitary implementation of the nontrivial elements of the subgroup of* $PSL(2,\mathbb{R})$ *generated from the vector field* $\partial/\partial\theta$.]

Proof: Referring to the GNS triple of λ_ζ define $\hat{V}_\zeta(\omega):=\Pi_\zeta(V(\omega))$. The existence of a unitary implementation, $L_g:\mathfrak{H}_\zeta\to\mathfrak{H}_\zeta$, of α in the GNS triple $(\mathfrak{H}_\zeta,\Pi_\zeta,\Psi_\zeta)$ implies, in particular, that

$$L_g\hat{V}_\zeta(\omega)L_g^\dagger=\Pi_\zeta(\alpha_g(V_\zeta(\omega))),\quad \text{for all } \omega\in\mathcal{D}(\mathbb{M}) \quad\text{and}\quad \text{every } g\in\mathrm{PSL}(2,\mathbb{R}). \tag{3}$$

By construction, $(\mathfrak{H}_\zeta,\Pi,\Psi_\zeta)$ (notice that we wrote Π instead of Π_ζ) is a GNS triple of λ (notice that we wrote λ instead of λ_ζ) if

$$\Pi:V(\omega)\mapsto\hat{V}(\omega):=\hat{V}_\zeta(\omega)e^{-i\int_{\mathbb{M}}\Gamma(\zeta\omega_+ +\overline{\zeta\omega_+})}. \tag{4}$$

In this realization α can be unitarily implemented (Theorem 3.2 in Ref. 1): There is a (strongly continuous) unitary representation U of $\mathrm{PSL}(2,\mathbb{R})$ such that

$$U_g\hat{V}(\omega)U_g^\dagger=\Pi(\alpha_g(V(\omega))),\quad \text{for all } \omega\in\mathcal{D}(\mathbb{M}) \text{ and every } g\in\mathrm{PSL}(2,\mathbb{R}). \tag{5}$$

Suppose that α can be implemented also in $(\mathfrak{H}_\zeta,\Pi_\zeta,\Psi_\zeta)$, where now $\Pi_\zeta:V(\omega)\mapsto\hat{V}_\zeta(\omega)$, and let L be the corresponding unitary representation of $\mathrm{PSL}(2,\mathbb{R})$ satisfying (3). That equation together with (4) entail that the unitary operator $S_g:=U_g^\dagger L_g$ satisfies

$$\begin{gathered} S_gV(\omega)S_g^\dagger=e^{ic_{g,\omega}}V(\omega),\\ c_{g,\omega}:=\int_{\mathbb{M}}(\zeta(\omega^{(g^{-1})})_+ +\overline{\zeta(\omega^{(g^{-1})})_+}-\zeta\omega_+-\overline{\zeta\omega_+})\Gamma. \end{gathered} \tag{6}$$

Now, dealing with exactly as in the proof of (ii) of (b) of Theorem 4.1 [where the role of our S_g was played by the operator U and the role of $c_{g,\omega}$ was played by the simpler phase $\int_{\mathbb{M}}(\zeta\omega_+ +\overline{\zeta\omega_+})\Gamma$] one finds that (6) entails that $\langle\Psi_\zeta,S_g\Psi_\zeta\rangle\neq 0$ and

$$\|S_g\Psi_\zeta\|^2=|\langle\Psi_\zeta,S_g\Psi_\zeta\rangle|^2e^{\sum_{n,j}^{\infty}|\eta_{n,j}|^2},$$

$$\eta_{n,j} := -2i\int_{\mathbb{M}} \Gamma(\theta)\overline{\zeta(s)}u_j(s)\frac{\partial}{\partial\theta}\frac{e^{i\theta_g}-e^{i\theta}}{\sqrt{4\pi n}}\mathrm{d}\theta\,\mathrm{d}\omega_\Sigma(s). \tag{7}$$

Above the real compactly supported functions u_j defines a Hilbert base in $L^2(\Sigma,\omega_\Sigma)$, and $(\theta_g,s_g):=g(\theta,s)\in\mathbb{M}$ is obtained by the action of $g\in\mathrm{PSL}(2,\mathbb{R})$ on $(\theta,s)\in\mathbb{M}$ [obviously $s_g=s$ since $\mathrm{PSL}(2,\mathbb{R})$ acts on the factor $\mathbb{S}^1$ of $\mathbb{M}=\mathbb{S}^1\times\Sigma$]. Now take $g\in\{\alpha_t^{(\mathcal{K})}\}_{t\in\mathbb{R}}$, the one-parameter subgroup of $\mathrm{PSL}(2,\mathbb{R})$ generated by the vector field $\mathcal{K}:=\partial/\partial\theta$, and realize the factor $\mathbb{S}^1$ of $\mathbb{M}=\mathbb{S}^1\times\Sigma$ as $[-\pi,\pi)$ with the identification of its endpoints. In this case, obviously, $\theta_g=\theta+t$. A direct computation shows that, for some j_0 with $\int_\Sigma u_j(s)\overline{\zeta(s)}\omega_\Sigma(s)=0$ (which does exist otherwise $\zeta=0$ almost everywhere)

$$|\eta_{2n+1,j_0}|^2 = C\left[\frac{1}{2n+1}-\frac{\cos((2n+1)t)}{2n+1}\right]$$

for some constant $C>0$ independent form n. The series of elements $-\cos((2n+1)t)/(2n+1)$ converges for $t\neq 0,\pm\pi$ (it diverges to $+\infty$ for $t=\pm\pi$), whereas that of elements $1/(2n+1)$ diverges to $+\infty$. Thus the exponent in (7) and L_g cannot exist, if $g=\alpha_t^{(\mathcal{K})}$ with $t\neq 0$ □

Remark: The automorphism γ_ζ is a symmetry of the system because it commutes with time evolution α_t. (It is worth noticing that, if restricting to real functions ζ, $\zeta\mapsto\gamma_\zeta$ defines a group of automorphisms.) Since $\lambda_\zeta\restriction_{\mathcal{W}(\mathbb{F}_+)}\neq\lambda_{\zeta'}\restriction_{\mathcal{W}(\mathbb{F}_+)}$ for $\zeta\neq\zeta'$, and all these states are extremal $\alpha^{(\mathcal{D})}$-KMS states at the same temperature, following Haag (Sec. V.I.5 in Ref. 4), we can say that *spontaneous symmetry breaking* with respect to γ_ζ occurs in the context of extremal KMS states theory.

III. FINAL COMMENTS ON INEQUIVALENT APPROACHES CONCERNING SYMMETRY BREAKDOWN

If μ is a state on the C^*-algebra $\mathcal{A}$, its *Gelfand ideal*, $\mathcal{I}_\mu$, consists of the elements $a\in\mathcal{A}$ such that $\mu(a^*a)=0$. $\mathcal{I}_\mu$ plays a central role in GNS reconstruction procedure. Breakdown of symmetry could be investigated from another point of view—relying upon the invariance properties of Gelfand ideal—with some overlap with our approach. It is based on the following proposition.

*Proposition 1: Let β be a faithful *-automorphism representation of the group $\mathcal{G}$ on the C^*-algebra $\mathcal{A}$ with unit $\mathbb{I}$ and let $\mu:\mathcal{A}\to\mathbb{C}$ be a state with GNS triple $(\mathfrak{H}_\mu,\Pi_\mu,\Psi_\mu)$.*

The Gelfand ideal $\mathcal{I}_\mu$ is invariant under β if and only if there is a $\mathcal{G}$-representation made of densely defined operators $U_g:\Pi_\mu(\mathcal{A})\to\Pi_\mu(\mathcal{A})$ which implements β leaving fixed Ψ_μ, i.e.,

$$\text{(i) } U_g\Pi_\mu(a)U_g^{-1}=\Pi_\mu(\beta_g(a)) \text{ for all } a\in\mathcal{A}, g\in\mathcal{G} \quad \text{and (ii) } U_g\Psi_\mu=\Psi_\mu \text{ for all } g\in\mathcal{G}. \tag{8}$$

If a representation $\mathcal{G}\ni g\mapsto U_g$ satisfying (8) *exists the following holds.*

(a) *It is unique and the operators U_g are completely determined by*

$$U_g\Pi_\mu(a)\Psi_\mu=\Pi_\mu(\beta_g a)\Psi_\mu \quad \text{for all} \quad a\in\mathcal{A} \text{ and } g\in\mathcal{G}. \tag{9}$$

(b) *Operators U_g are* [*restrictions to the dense domain $\Pi_\mu(\mathcal{A})$ of uniquely determined*] *unitary operators on $\mathfrak{H}_\mu$, if and only if μ is invariant under β.*

Sketch of proof: From GNS theorem $\mathcal{I}_\mu=\{a\in\mathcal{A}\,|\,\Pi_\mu(a)\Psi_\mu=0\}$. From it one easily proves that if $\mathcal{I}_\mu$ is β-invariant (9) define a well-posed representation of $\mathcal{G}$ satisfying (8) [notice that, $\beta_g(\mathbb{I})=\mathbb{I}$ and $\Pi_\mu(\mathbb{I})=I$ so that (ii) in (8) holds true from (9)]. Since (i) and (ii) in (8) entails (9), $\mathcal{I}_\mu=\{a\in\mathcal{A}\,|\,\Pi_\mu(a)\Psi_\mu=0\}$ proves that the existence of a representation satisfying (8) implies β-invariance of $\mathcal{I}_\mu$and (a) is valid as well. Proofs of (b) are based on the identities (from GNS theorem) $\|U_g\Pi_\mu(a)\Psi_\mu\|^2=\mu(\beta_g(a^*a))$ and $\mu(a^*a)=\|\Pi_\mu(a)\Psi_\mu\|^2$. □

In view of that result, by a pure mathematical point of view, a strategy to distinguish several degrees of $\mathcal{G}$-symmetry breakdowns for a state $\mu:\mathcal{A}\to\mathbb{C}$ when $\mathcal{G}$ is represented, at algebraic level, by the *-automorphism representation β, could be the following.

(1) (*No symmetry breaking*) Gelfand ideal is invariant under β_g—i.e., (i) and (ii) in (8) are valid for an operator representation of $\mathcal{G}$.

(2) Gelfand ideal is invariant under β—so that both (i) and (ii) in (8) hold true—but the induced action of β in the GNS representation of μ is *not* unitarily implementable.

(3) Gelfand ideal is *not* invariant under β_g—so that at least one of (i) and (ii) in (8) is not valid for any operator representation of $\mathcal{G}$ on the relevant domain.

In this paper we, instead, have adopted quite a different point of view (sharing however some overlap with the point of view illustrated above) entirely based on the definition of spontaneous breaking of symmetry defined on p. 119 of Ref. 3. We considered only the problem of *unitary* (non)implementability of $(\mathrm{PSL}(2,\mathbb{R}))$ symmetry. This is in accordance with the well-known general Wigner-Kadison notion of *quantum symmetry* described in terms of appropriate (projective) unitary or antiunitary operators.[5] The three degree of symmetry breakdown one may consider in this context are the following, referring to $\mu,\mathcal{G},\beta$ as before.

(U1) (*No symmetry breaking*) Algebraic symmetry β is implementable for μ by means of unitary operators *and* the state μ is invariant under the action β of the full group $\mathcal{G}$—(i), and (ii) in (8) are valid for a unitary representation of $\mathcal{G}$.

(U2) (*Symmetry breaking due to the cyclic vector*) Algebraic symmetry β is implementable for μ by means of unitary operators *and* the state μ is *not* invariant under the action β of the full group $\mathcal{G}$—(i), but not (ii) in (8), is valid for a unitary representation of $\mathcal{G}$.

(U3) (*Spontaneous symmetry breaking*) Algebraic symmetry β is not implementable for μ by means of unitary operators—(i) in (8) does not hold for any unitary representation of $\mathcal{G}$.

In Ref. 1 we established, for states λ_ζ with $\zeta\neq 0$ the validity of either degree (U2) or (U3) concerning $\mathcal{G}=\mathrm{PSL}(2,\mathbb{R})$ symmetry breaking. This paper shows that, actually, the strongest degree (U3) takes place.

A priori this extent may be compatible with either (2) or (3) of the other scheme. A closed scrutiny would be necessary to examine this issue but it is far from the goal of this paper where only Wigner-Kadison unitary symmetries are considered since they are the only way to preserve quantum probabilities and have direct physical meaning.

To conclude we notice that an example of the intermediate case (U2) is realized in the framework of Ref. 1 with respect to the Weyl algebra $\mathcal{W}(\mathbb{M})$, with $\mathbb{M}=\mathbb{S}^1$, and for the fully $\mathrm{PSL}(2,\mathbb{R})$-symmetric state $\lambda_{\zeta=0}$. Breaking of symmetry at level (U2) occurs when extending the symmetry group from $\mathrm{PSL}(2,\mathbb{R})$ to the infinite dimensional one $\mathcal{G}:=\mathrm{Diff}^+(\mathbb{S}^1)$.

Non-Abelian gauge field theory in scale relativity

(Received 21 November 2005; accepted 18 January 2006; published online 13 March 2006)

Gauge field theory is developed in the framework of scale relativity. In this theory, space-time is described as a nondifferentiable continuum, which implies it is fractal, i.e., explicitly dependent on internal scale variables. Owing to the principle of relativity that has been extended to scales, these scale variables can themselves become functions of the space-time coordinates. Therefore, a coupling is expected between displacements in the fractal space-time and the transformations of these scale variables. In previous works, an Abelian gauge theory (electromagnetism) has been derived as a consequence of this coupling for global dilations and/or contractions. We consider here more general transformations of the scale variables by taking into account separate dilations for each of them, which yield non-Abelian gauge theories. We identify these transformations with the usual gauge transformations. The gauge fields naturally appear as a new geometric contribution to the total variation of the action involving these scale variables, while the gauge charges emerge as the generators of the scale transformation group. A generalized action is identified with the scale-relativistic invariant. The gauge charges are the conservative quantities, conjugates of the scale variables through the action, which find their origin in the symmetries of the "scale-space." We thus found in a geometric way and recover the expression for the covariant derivative of gauge theory. Adding the requirement that under the scale transformations the fermion multiplets and the boson fields transform such that the derived Lagrangian remains invariant, we obtain gauge theories as a consequence of scale symmetries issued from a geometric space-time description. © *2006 American Institute of Physics.*

I. INTRODUCTION

In standard gauge field theory, the nature of the gauge transformations, of the gauge fields and of the conserved charges are postulated and designed from experimental considerations. The group of gauge transformations does not act upon the space-time coordinates, as does, for example, the SU(2) spin rotation group or the Lorentz group, but in an "internal space" whose physical meaning is not understood from first principles. For a general gauge group G, the particle wave functions that are multiplets of Dirac bi-spinors form a n-component vector in the internal space, and the gauge potentials A_μ (more generally W_μ^α) are fields in standard space-time defined only up to a gauge transformation.

There is indeed a fundamental difference between the situation of transformations in the standard gauge theories and of, e.g., Lorentz transformations. Thanks to the fact that space-time coordinates are directly observable, we know from the very beginning what Lorentz transformations are, namely, space-time rotations of the coordinates, $dx' = \Lambda_\beta^\alpha dx^\beta$. They write in the case of an infinitesimal transformation, (i) $dx'^\alpha = (\delta_\beta^\alpha + \omega_\beta^\alpha) dx^\beta$, where the ω^{ij} (i and $j = 1$ to 3) represent the

[c]Electronic mail: thierry.lehner@obspm.fr

infinitesimal angles of rotation in space and the $\omega^{0i}=v^i/c$ ($v^i \ll c$) are the infinitesimal Lorentz boosts. Then, once this basic definition is given, one can consider the effect of these transformations on various physical quantities defined in space-time, e.g., the wave function ψ. This involves representations of the Lorentz group adapted to the nature of the physical object under consideration, i.e., (ii) $\psi' = \left(1+\frac{1}{2}\omega^{\alpha\beta}\sigma_{\alpha\beta}\right)\psi$ (see, e.g., Ref. 1).

In contradistinction with this situation, in standard gauge theories the gauge functions, being arbitrary, are considered to be devoid of physical meaning. As a consequence, there is up to now no equivalent of the basic defining transformation (i). Therefore, in the standard framework, the gauge group is indirectly defined through its action on the various physical objects according to its representations, in similarity with relation (ii), but the physical meaning of the gauge space itself is lacking.

In the present paper, we place ourselves in the framework of the scale relativity theory, in which the description of the space-time geometry is generalized to continuous but nondifferentiable manifolds. In this theory, one attempts to recover the quantum behavior as a manifestation of the nondifferentiability, then the gauge fields themselves as a manifestation of the nondifferentiable and fractal geometry (in analogy with gravitation interpreted as a manifestation of the non-Euclidean curved geometry in general relativity).

In this framework, we give a geometric meaning to the gauge space, then we can rebuild the gauge transformations of the various physical quantities (namely, the various quantum fields) as consequences of the fundamental transformations of the variables which define this gauge space. In other words, it is precisely an equivalent for gauge theories of the defining transformation (i) that can be proposed in scale relativity. The specifically new results given in the present paper consist of extending to non-Abelian gauge theory the results of previous works[2–4] devoted to the understanding of the simpler gauge invariant theory of electromagnetism.

The paper is organized as follows. After a summarized review (Sec. II) of the main steps of the construction of the scale relativity theory, including the exposition of the salient features that have led to the demonstration of the Dirac equation[5,6] from the scale relativistic first principles, we give a brief reminder of the results previously obtained for electromagnetism (Sec. III). Then we give, in Sec. IV, an extension of the concepts and methods thus obtained, and we apply them to a general development of the non-Abelian gauge formalism. Section V is devoted to the conclusion.

II. SCALE RELATIVITY AND QUANTUM MECHANICS: SUMMARY

A. Foundations of scale relativity

The theory of scale relativity is based on the giving up of the hypothesis of manifold differentiability which is a key assumption of Einstein's general relativity. In the new theory, the coordinate transformations are continuous but can be differentiable (and therefore it includes general relativity) or non-differentiable. The giving up of the assumption of differentiability implies several consequences,[7] leading to the successive steps of the construction of the theory:

(1) It has been proved[7,3,8] that a continuous and nondifferentiable curve is fractal in a general meaning, namely, its length is explicitly scale dependent and goes to infinity when the scale interval ε goes to zero, i.e., $\mathcal{L}=\mathcal{L}(\varepsilon)\to\infty$ when $\varepsilon\to 0$. This result can be readily extended to a continuous and nondifferentiable manifold.

(2) The fractality of space-time[9,10] involves the scale dependence of the reference frames. We therefore add to the usual variables defining the reference frames (position, orientation, motion), new variables ε characterizing their state of scale. In particular, the coordinates themselves become functions of these scale variables, i.e., $X=X(\varepsilon)$ (in the simplified case of only one variable). In an experimental situation, these scale variables are identified with the resolution scale of the measurement apparatus. In the case of a theoretical physics description, they are identified with the differential elements themselves, of which the coordinates become explicit functions, i.e., $X=X(\mathrm{d}X)$.

(3) The scale variables ε can never be defined in an absolute way, but only in a relative way. Namely, only their ratio $\rho=\varepsilon'/\varepsilon$ does have a physical meaning. This universal behavior leads to

extend to scales the principle of relativity,[11,12,7] in order to include in the possible changes of reference frames the new ones which are described by the transformations of these scale variables.

(4) Though the nondifferentiability manifests itself at the limit $\varepsilon \to 0$, the use of differential equations is made possible by representing physical quantities f by fractal functions $f[X(\varepsilon),\varepsilon]$.[7] Even if the function $f(X,0)$ is nondifferentiable with respect to the variable X, the fractal function $f(X,\varepsilon)$ is differentiable for any $\varepsilon \neq 0$ with respect to both X and ε. This allows us to complete the differential equations of standard physics by new differential equations of scale, which are constrained by the principle of scale relativity. The study of the scale laws derived from these differential equations has been developed according to various levels of relativistic transformations.[12,3,13] In what follows, we consider only the simplest case, namely Galilean-type scale transformations (i.e., characterized by a constant fractal dimension).

(5) The simplest possible scale differential equation is a first order equation, $\partial X/\partial \ln \varepsilon = \beta(X)$, which can be simplified again by Taylor expanding the unknown function β, so that it reads $\partial X/\partial \ln \varepsilon = a + bX + \cdots$. The solution of this equation is made of two terms, a scale-independent, differentiable, classical part and a power-law, nondifferentiable fractal part, which read

$$X = x + \zeta\left(\frac{\lambda}{\varepsilon}\right)^{-b}, \tag{1}$$

where $x = -a/b$. When the coefficient b is constant, the second term is the standard expression for the length of a fractal curve of dimension $D_F = 1 - b$.[14] Moreover, the transformation law of this power-law term under a scale transformation $\ln(\lambda/\varepsilon) \to \ln(\lambda/\varepsilon')$ takes the mathematical form of the Galileo group, and it therefore comes under the principle of relativity,[12] as initially required.

B. Metric of a fractal space-time

In Eq. (1), the scale variable ε is a space resolution, e.g., $\varepsilon = \delta X$. The next step consists of considering its four-dimensional differential counterpart and to express it in terms of intervals of the invariant length (proper time) $\mathrm{d}s$, by using the standard relation between the resolution interval of projected coordinates and the resolution interval of the invariant length on a fractal, $(\delta X^\mu)^{D_F} \sim \delta s$,

$$\mathrm{d}X^\mu = \mathrm{d}x^\mu + \mathrm{d}\xi^\mu = v^\mu\,\mathrm{d}s + \zeta^\mu \times (\lambda_c)^{1-1/D_F} \times \mathrm{d}s^{1/D_F}, \tag{2}$$

where ζ^μ is dimensionless, λ_c is a length scale which must be introduced for dimensional reasons and D_F is a fractal (covering) dimension. In the case where this description holds for a quantum particle of mass m, λ_c will be identified with its Compton length $\hbar/mc$. The elementary displacement on a fractal space-time is therefore the sum of a classical, standard differentiable element, which is leading at large scales, and of a fractal, nonstandard fluctuation which is leading at small scales.

In what follows, we simplify again the description by considering only the case $D_F = 2$. For this, we base ourselves on Feynman's result[15,16] according to which the typical paths of quantum particles (those which contribute mainly to the path integral) are nondifferentiable and (in modern words) fractal of dimension $D_F = 2$. The case $D_F \neq 2$ has also been studied in detail: it has been shown that $D_F = 2$ is a critical dimension for which the explicit scale dependence disappears in the final equations (see Ref. 3 and references therein).

Let us now show how Eq. (2) can be used to give an explicit form to the metric of a fractal space-time (disregarding at this step of the construction other consequences of nondifferentiability such as the multivaluedness of derivatives, see next sections). The fractal fluctuations (here in four dimensions) write for fractal dimension 2,

$$\mathrm{d}\xi^\mu = \zeta^\mu \sqrt{\lambda_c\,\mathrm{d}s}, \tag{3}$$

where the ζ^μ are dimensionless highly fluctuating functions.

In what follows, we replace them (in a provisional way) by stochastic variables such that $\langle\zeta^\mu\rangle=0$, $\langle(\zeta^0)^2\rangle=-1$, and $\langle(\zeta^k)^2\rangle=1$ ($k=1$ to 3). We recover here a description which is familiar in usual stochastic processes, which can also be separated in a regular part and a stochastic part, but here this is done at the level of the metric. As we shall see, we do not have to be more specific about the probability distribution of these stochastic variables. Their zero mean and unit variance is the only information needed in the subsequent calculations, which are therefore valid whatever this distribution.

Now we can write the fractal fluctuations in terms of the coordinate differentials instead of the invariant length differential,

$$\mathrm{d}\xi^\mu = \zeta^\mu\sqrt{\lambda^\mu\,\mathrm{d}x^\mu}. \tag{4}$$

The identification of Eqs. (3) and (4) leads very simply to the establishment of the expressions for the de Broglie-Einstein length and time scales from the Compton one, i.e., for two variables,

$$\lambda_x = \frac{\lambda_c}{\mathrm{d}x/\mathrm{d}s} = \frac{\hbar}{p_x}, \quad \tau = \frac{\lambda_c}{\mathrm{d}t/\mathrm{d}s} = \frac{\hbar}{E}. \tag{5}$$

The de Broglie scale (and the Compton scale in rest frame) therefore plays an essential role in the properties of the scale variables (identified here with the differential elements). It stands out as a natural reference scale for them, since it plays the role of a fractal to nonfractal transition (that should not be understood as a transition acting in position space but instead in scale space). Indeed we see from the relation $\langle\mathrm{d}\xi_x^2\rangle=\lambda_x\,\mathrm{d}x$ (and similar relations for the other variables) that when $|\mathrm{d}x|\ll\lambda_x$, the fractal fluctuation becomes $|\mathrm{d}\xi_x|\gg|\mathrm{d}x|$ and therefore it dominates the classical (differentiable) contribution. On the contrary, when $|\mathrm{d}x|\gg\lambda_x$, the fractal fluctuation $|\mathrm{d}\xi_x|\ll|\mathrm{d}x|$ becomes negligible and only the classical term remains. The subsequent developments of the theory, which lead to construct a wave function and to derive Schrödinger and Dirac equations (see Sec. II D), finally allow one to identify this transition with a quantum to classical transition.[7]

Let us now assume that the large scale (classical) behavior is given by Riemannian metric potentials $g_{\mu\nu}(x,y,z,t)$. The invariant proper time $\mathrm{d}S$ along a geodesic (which is therefore subjected to curvature at large scale and fractality at small scales) writes in terms of the complete differential elements $\mathrm{d}X^\mu=\mathrm{d}x^\mu+\mathrm{d}\xi^\mu$,

$$\mathrm{d}S^2 = g_{\mu\nu}\,\mathrm{d}X^\mu\,\mathrm{d}X^\nu = g_{\mu\nu}(\mathrm{d}x^\mu+\mathrm{d}\xi^\mu)(\mathrm{d}x^\nu+\mathrm{d}\xi^\nu). \tag{6}$$

Now replacing the $\mathrm{d}\xi$'s by their expression [Eq. (4)], we obtain a fractal metric. Assuming for simplicity (1+1) dimensions, a diagonal classical part of the metric and a fractal dimension $D_F=2$, it reads

$$\mathrm{d}S^2 = g_{00}\left(1+\zeta_0\sqrt{\frac{\tau}{\mathrm{d}t}}\right)^2 c^2\,\mathrm{d}t^2 - g_{11}\left(1+\zeta_1\sqrt{\frac{\lambda_x}{\mathrm{d}x}}\right)^2\mathrm{d}x^2. \tag{7}$$

We therefore obtain generalized fractal metric potentials which are explicitly dependent on the coordinate differential elements, in agreement with the program of Refs. 11 and 7. More generally the metric potentials can be written in their turn as the sum of the standard metric potentials (which describe curvature) and of divergent, highly fluctuating terms (which describe fractality), e.g., for the g_{00} component,

$$\tilde{g}_{00}(x,t;\mathrm{d}t) = g_{00}(x,t) + \gamma_{00}(x,t)\left(\frac{\tau}{\mathrm{d}t}\right), \tag{8}$$

where we have kept only the leading term, owing to the fact that $\langle\zeta^\mu\rangle=0$. The $\gamma_{\mu\nu}(x,t)$ can be described at a first approximation in terms of stochastic variables. We recover here our result[7] according to which, in the limit $(\mathrm{d}x,\mathrm{d}t\to0)$, the metric is divergent (singular) at each of its points and instants, which is the very intrinsic expression of the fractality of space-time. As a consequence, the curvature is also explicitly scale-dependent and divergent when the scale intervals tend

to zero. This property ensures the fundamentally non-Riemannian character of a fractal space-time as well as the ability to characterize it in an intrinsic way.

Note that all the above developments have been made in the framework of Galilean scale relativity, in which the fractal dimension is assumed to be constant (we call it Galilean because its laws of scale transformation are similar to inertial laws of motion). However it is worth briefly recalling here that a special scale relativity theory has been proposed,[7,12] in which the transformation laws of the scale variables $\ln \rho$ take the form of a Lorentz group, so that the fractal dimension becomes itself a variable. In this framework, the differential elements $\mathrm{d}X$ can no longer tend to zero since they are limited at small scales by a minimal length scale, invariant under dilations, that we have identified with the Planck length $\lambda_{\mathrm{P}}=\sqrt{\hbar G/c^3}$. It has a status similar to that of c in motion special relativity, i.e., of an unreachable and impassable horizon rather than of a cutoff or a barrier: namely, it replaces the zero point since an infinite contraction would be needed to obtain it from another scale. Combined with the role of scale transition played by the Compton length (in rest frame), this interpretation of the Planck scale leads to introduce a set of fundamental constants $\mathbb{C}=\ln(\lambda_c/\lambda_{\mathrm{P}})=\ln(m_{\mathrm{P}}/m)$ which are characteristic of elementary particles of mass m and Compton length $\lambda_c=\hbar/mc$. These constants play an essential role in structuring the geometry of the geodesics families of the fractal space-time[3] (to which we identify the particles, see next Sec. II C), in particular when accounting for the coupling between scale and motion that leads to the emergence of gauge fields, which is the main subject of the present paper.

C. Geodesics of a fractal space-time

1. Infinity of geodesics

The next step in such a geometric approach consists of writing the geodesics equation. We make the conjecture that the description of quantum particles can be reduced to that of these geodesics. Then their internal properties are the geometrical properties of the geodesics bundle corresponding to their state, according to the various conservative quantities (prime integrals) that define them.

Any measurement performed on the "particle" is interpreted as a selection of the geodesics bundle linked to the interaction with the measurement apparatus (that depends on its resolution) and/or to the information known about it (for example, the which-way-information in a two-slit experiment[3]).

Generalizing to space-times the definition of fractal functions, we have defined a fractal space-time as the equivalence class of a family of Riemannian manifolds, explicitly depending on the scale variables. In such space-times, the geodesics equations are also scale dependent and the number of geodesics that relate any two events (or starts from any event) is infinite. We are therefore led to adopt a generalized statistical fluidlike description where the deterministic velocity $V^\mu(s)$ is replaced by a scale-dependent, fractal velocity field $V^\mu[X^\mu(s,\mathrm{d}s),s,\mathrm{d}s]$.

2. Discrete symmetry breaking

Another consequence of nondifferentiability is the breaking of the invariance by reflexion of the differential element $\mathrm{d}s$. Indeed, for fractal functions $f(s,\mathrm{d}s)$, two generalized derivatives are defined instead of one,

$$f'_+(s,\mathrm{d}s)=\frac{f(s+\mathrm{d}s,\mathrm{d}s)-f(s,\mathrm{d}s)}{\mathrm{d}s},\quad f'_-(s,\mathrm{d}s)=\frac{f(s,\mathrm{d}s)-f(s-\mathrm{d}s,\mathrm{d}s)}{\mathrm{d}s},\tag{9}$$

that are transformed one into the other by the reflexion $\mathrm{d}s\leftrightarrow-\mathrm{d}s$. Applied to the space-time coordinates, these two derivatives give two divergent velocity fields, $V^\mu_+[x(s,\mathrm{d}s),s,\mathrm{d}s]$ and $V^\mu_-[x(s,\mathrm{d}s),s,\mathrm{d}s]$. Each of them can be in turn decomposed in terms of classical parts v_+ and v_-, and of fractal parts w_+ and w_-.

Then we define two "classical" derivatives $d_+/\mathrm{d}s$ and $d_-/\mathrm{d}s$, which, when they are applied to x^μ, yield the "classical" velocity fields

$$\frac{d_+}{ds}x^\mu(s) = v_+^\mu, \quad \frac{d_-}{ds}x^\mu(s) = v_-^\mu. \tag{10}$$

Since there is no reason to privilegize one process rather than the other, we consider both (+) and (−) processes on the same footing, and we combine them in a unique twin process in terms of which the microscopic reversibility is recovered.[7] A simple and natural way to account for this doubling is to use complex numbers and the complex product.[6] In the scale relativity framework, this fundamental two-valuedness implied by nondifferentiability can be shown to be the origin of the complex nature of the wave function of quantum mechanics.

3. Quantum-covariant derivative

The next step of the scale-relativity program amounts to include in the construction of a complex derivative operator the various effects (described above) of nondifferentiability and fractality,[7]

$$\frac{\bar{d}}{ds} = \frac{1}{2}\left(\frac{d_+}{ds} + \frac{d_-}{ds}\right) - \frac{i}{2}\left(\frac{d_+}{ds} - \frac{d_-}{ds}\right). \tag{11}$$

Such an operator will play the role of a covariant derivative (in Einstein's general meaning given to this word, i.e., as a tool of implementation of the principle of covariance, according to which the fundamental equations of physics should keep their form under transformations of the reference system). It can be used to define a complex four-velocity field,

$$\mathcal{V}^\mu = \frac{\bar{d}}{ds}x^\mu = V^\mu - iU^\mu = \frac{v_+^\mu + v_-^\mu}{2} - i\frac{v_+^\mu - v_-^\mu}{2}. \tag{12}$$

The total derivative of a fractal function contains finite terms up to highest orders. For a constant fractal dimension $D_F=2$, a finite contribution only proceeds from terms up to second order. Since only stationary functions which do not depend explicitly on s are considered, one can show that the complex covariant derivative operator reads in the relativistic case[2,6]

$$\frac{\bar{d}}{ds} = \left(\mathcal{V}^\mu + i\frac{\lambda_c}{2}\partial^\mu\right)\partial_\mu. \tag{13}$$

Finally, using the strong covariance principle (extended to scales), we are led to write a geodesics equation by using this covariant derivative in terms of a freelike equation of motion,

$$\frac{\bar{d}}{ds}\mathcal{V}^\mu = 0. \tag{14}$$

At this stage, the wave function $\psi = e^{iS/m\lambda_c}$ is defined as a mere re-expression of the complex action S. By introducing it in the above geodesics equation thanks to its relation to the velocity field $\mathcal{V}_\mu = i\lambda\partial_\mu \ln\psi$, it gives after integration the complex (standard) free Klein-Gordon equation, $\lambda_c^2\partial^\mu\partial_\mu\psi + \psi = 0$.[2,3]

Note that we consider in this paper only the full relativistic case in which both space and time are fractal (which corresponds to energies larger than mc^2, i.e., to scales smaller than the Compton scale). However it is worth briefly recalling that nonrelativistic quantum mechanics (which usually applies at intermediate scales) is recovered in our framework in terms of a three-dimensional fractal space, with no fractal time. In this case a generalized Schrödinger equation for a complex wave function is derived.[7,3,6,17–19] The reason for such an asymmetry between space and time in the scale-relativity description (and in quantum mechanics) is to be found in the quantum-classical transition, identified with the fractal-nonfractal transition (see Sec. II B). Indeed, for a free particle it is given by the Einstein-de Broglie scale $\lambda_\mu = \hbar/p^\mu$, whose time scale $\tau = \hbar/E$ is always smaller than its corresponding space-scales $\lambda = \hbar/p$, because of the relation $E^2 = p^2 + m^2$ (and therefore

finally because of the existence of mass). This implies a first transition from standard space-time to fractal space, then at smaller scales a second transition to fractal space-time.[7] These three regimes manisfest themselves successively as classical, quantum nonrelativistic then quantum relativistic mechanics.

D. The Dirac equation as a geodesics equation in a fractal space-time

As recalled hereabove, the Klein-Gordon equation is obtained as a result of the $\mathrm{d}s \leftrightarrow -\mathrm{d}s$ symmetry breaking. The consideration of a more general case where we add the breaking of the symmetries $dx^\mu \leftrightarrow -dx^\mu$ and $x^\mu \leftrightarrow -x^\mu$ leads to the appearance of bispinors which are solutions of the Dirac equation.[6]

Following the method described in Sec. II C 3, these additional discrete symmetry breakings lead to two new doublings of the velocity field and of the classical derivative. The four-velocity field has now eight components, which are used to construct a biquaternionic (complex-quaternionic) velocity field. Then a biquaternionic covariant derivative operator may be built, which keeps once again the same form [Eq. (13)] as in the complex case,[6] even though the velocity field is now a biquaternion instead of a complex number.

The biquaternionic geodesics equation reads

$$\frac{\bar{d}}{\mathrm{d}s}\mathcal{V}_\alpha = \left(\mathcal{V}^\mu + i\frac{\lambda_c}{2}\partial^\mu\right)\partial_\mu \mathcal{V}_\alpha = 0. \tag{15}$$

A biquaternionic action is defined according to

$$\delta\mathcal{S} = \partial_\mu \mathcal{S}\,\mathrm{d}x^\mu = -mc\mathcal{V}_\mu \delta x^\mu. \tag{16}$$

The biquaternionic four-momentum can therefore be written $\mathcal{P}_\mu = mc\mathcal{V}_\mu = -\partial_\mu \mathcal{S}$. Then we introduce a biquaternionic wave function, which is once again a mere reexpression of the action, as

$$\psi^{-1}\partial_\mu \psi = \frac{i}{cS_0}\partial_\mu \mathcal{S}, \tag{17}$$

which yields for the biquaternionic four-velocity the expression

$$\mathcal{V}_\mu = i\lambda_c \psi^{-1}\partial_\mu \psi. \tag{18}$$

This relation is destined to play an essential role in the subsequent construction of the non-Abelian gauge theory. Indeed, its specific form $(\psi^{-1}\partial_\mu\psi)$, which is linked to the noncommutativity of biquaternions, will allow a proper generalization to multiplets which permits in its turn a geometric construction of the non-Abelian charges in accordance with the standard Yang-Mills theory (Sec. IV).

Then we replace in Eq. (15) the velocity field $\mathcal{V}_\alpha$ by its expression [Eq. (18)]. We obtain the motion equation as a third-order differential equation, which becomes after some calculations $\partial_\mu[(\partial^\nu\partial_\nu\psi)\psi^{-1}]=0$ and may therefore be integrated. This yields the Klein-Gordon equation for a free particle, $\lambda_c^2\partial^\mu\partial_\mu\psi+\psi=0$, but now generalized to complex quaternions.[5,6]

Long-known properties of the quaternionic formalism (see, e.g., Refs. 20 and 21) can finally be used to readily obtain the Dirac equation for a free particle, namely,

$$\frac{1}{c}\frac{\partial\psi}{\partial t} = -\alpha^k\frac{\partial\psi}{\partial x^k} - i\frac{mc}{\hbar}\beta\psi, \tag{19}$$

as a mere square root of the Klein-Gordon operator,[5,6] which was itself derived from the geodesics equation (15). Then the isomorphism which can be established between the quaternionic and spinorial algebrae[22] allows us to identify the wave-function ψ to a Dirac spinor. In a Lagrangian formalism, the Dirac equation proceeds from the Lagrangian density,

$$\mathcal{L} = \bar{\psi}(i\gamma^{\mu}\partial_{\mu} - m)\psi, \tag{20}$$

which therefore becomes a direct consequence of the scale relativity principles.[6] It is also easy to derive the Pauli equation, since it is known that it can be obtained as a non-(motion)-relativistic approximation of the Dirac equation, while, in this approximation, Dirac bi-spinors become Pauli spinors.

Let us conclude this section by a final remark: one of the consequences of this theory is that it provides a physical picture of the nature of spin. In the scale-relativistic framework, the complex nature of the wave function and the existence of spin have both a common origin, namely, the fundamental two valuedness of the derivative (in its generalized definition) coming from nondifferentiability. These two successive doublings are naturally accounted for in terms of algebra doublings (see Appendix of Ref. 6), i.e., of a description tool that jumps from real numbers $\mathbb{R}$ to complex numbers $\mathbb{C}=\mathbb{R}^2$, then to quaternions $\mathbb{H}=\mathbb{C}^2$. However, while the origin of the complex nature of the wave function is linked to the total derivative (and therefore to proper time) through the doubling $d/\mathrm{d}s \rightarrow (d_+/\mathrm{d}s, d_-/\mathrm{d}s)$, the origin of spin is linked to the partial derivative with respect to the coordinates through the doubling $\partial/\partial x^{\mu} \rightarrow (\partial_+/\partial x^{\mu}, \partial_-/\partial x^{\mu})$, which finally leads to the two valuedness of the wave function itself $\psi \rightarrow (\psi_1, \psi_2)$, characterizing a (Pauli) spinor.

Such a physical effect has naturally a consequence on the angular momentum $(x^{\mu}\partial/\partial x^{\nu} - x^{\nu}\partial/\partial x^{\mu})$, leading to the two directions in which spin can become locked. Moreover, numerical simulations of the fractal geodesical curves (work in preparation) which are solutions of Eq. (15) allow us to obtain a more specific picture of the spin as an internal angular momentum of these geodesics. Indeed, these solutions are characterized by spiral structures at all scales, in agreement with Ord's reformulation of the Feynman relativistic chessboard model in terms of spiral paths.[23] They also support our early models of emergence of a spinlike internal angular momentum in fractal spiral curves of fractal dimension 2.[7,11] We here recall briefly the argument: the angular momentum $L_z = mr^2\dot{\varphi}$ should classically vanish for $r \rightarrow 0$. But in the fractal spiral model, $\dot{\varphi} \rightarrow \infty$ when $r \rightarrow 0$ in such a way that $r^2\dot{\varphi}$ remains finite when $D_F = 2$ (while it is vanishing for $D_F < 2$ and divergent for $D_F > 2$). This result solves the problem of the apparent impossibility to define a spin in a classical way both for an extended object and for a pointlike object, and provides another proof of the critical character of the value $D_F = 2$ for the fractal dimension of quantum particle paths (which can be derived from the Heisenberg relations).

III. SCALE-RELATIVISTIC THEORY OF ELECTROMAGNETISM: SUMMARY

A. Electromagnetic field and electric charges

Let us now briefly recall the results previously obtained in the case of a U(1) field.[2–4]

We consider here a special situation in which the set of the scale variables comes down to only one element, $\varrho = \varepsilon/\lambda$. This amounts to limit ourselves to the study of global scale transformations (contractions/dilations) in "scale-space."

Because, according to the principle of scale relativity, this "scale-space" is fundamentally nonabsolute, the scale of a structure (internal to the fractal geodesics which are identified with a "particle") is expected to change during a displacement in space-time. In other words, we now consider scale variables which become explicit functions of the coordinates, i.e., $\varrho = \varrho(x, y, z, t)$.

This is analogous to the situation encountered in general relativity (GR) for a curved space-time: namely, in a parallel displacement, a vector V^{μ} is subjected to an increase $\delta V^{\mu} = -\Gamma^{\mu}_{\nu\rho} V^{\nu}\,\mathrm{d}x^{\rho}$ (where the $\Gamma^{\mu}_{\nu\rho}$ are the Christoffel symbols, i.e., the gravitational field), due to the geometric effects of curvature. Then, if one subtracts this geometric increase from its total variation $\mathrm{d}V^{\mu}$, one recovers the inertial part of the variation (see, e.g., Ref. 24). This allows one to define the GR covariant derivative D as $DV^{\mu} = \mathrm{d}V^{\mu} - \delta V^{\mu} = \mathrm{d}V^{\mu} + \Gamma^{\mu}_{\nu\rho} V^{\nu}\,\mathrm{d}x^{\rho}$.

The same kind of behavior is true in the scale relativity framework, but with an essential difference: while the effects of curvature affect vectors, tensors, etc., but not scalars, the effects of fractality begin already at the level of scalars, among which the "invariant" of length $\mathrm{d}s^2$ itself.

Therefore, we expect in a displacement the appearance of a resolution change due to the fractal geometry, that reads

$$\delta\varepsilon = -\frac{1}{q}A_\mu \varepsilon \, \mathrm{d}x^\mu, \tag{21}$$

i.e., in terms of the scale ratio,

$$\delta \ln \varrho = \frac{1}{q}A_\mu \, \mathrm{d}x^\mu. \tag{22}$$

The introduction of the $(1/q)$ term in this definition is an important point for the electromagnetic case and also for its non-Abelian generalizations. Indeed, as we shall see in what follows, the "field" A_μ will be identified with an electromagnetic potential. Since $\ln \varrho$ is dimensionless, we are led to divide the potential term by the "active" electric charge q, leaving a charge-independent purely geometric contribution.

This leads to the appearance of a dilation field, according to the construction of a scale-covariant derivative,

$$D\chi = \mathrm{d}\chi - \delta\chi = \mathrm{d}\chi - A_\mu \, \mathrm{d}x^\mu, \tag{23}$$

where we have set $\chi = q \ln \varrho$. We finally obtain the partial derivative as the sum of the inertial and of the geometric terms as

$$\partial_\mu \chi = D_\mu \chi + A_\mu. \tag{24}$$

Let us now consider the action S for, e.g., an electron. In the framework of a space-time theory based on a relativity principle, which is here the case, its variation should be given directly by the space-time invariant $\mathrm{d}s$, i.e., $\delta \int \mathrm{d}S = 0$ becomes identical with a geodesics (Fermat) principle $\delta \int \mathrm{d}s = 0$. But now the fractality of the geodesical curves to which the electron wave field is identified means that their proper length becomes a function of the scale variable, so that $S = S(\chi)$.

Therefore the differential of the action reads

$$\mathrm{d}S = \frac{\partial S}{\partial \chi}\mathrm{d}\chi = \frac{\partial S}{\partial \chi}(D\chi + A_\mu \, \mathrm{d}x^\mu), \tag{25}$$

so that we obtain

$$\partial_\mu S = D_\mu S + \frac{\partial S}{\partial \chi}A_\mu. \tag{26}$$

This result provides us with a definition for the "passive" charge (on which the electromagnetic field acts) as[2,3]

$$\frac{e}{c} = -\frac{\partial S}{\partial \chi}. \tag{27}$$

This is a second important point worth to be emphasized, since it will play an important role for the generalization to non-Abelian gauge theories. In the standard theory, the charge is set from experiment, then it is shown to be related to gauge transformations, while the gauge functions are considered to be arbitrary and devoid of physical meaning. In the scale relativity approach, the charges are built from the symmetries of the "scale-space." One indeed recognizes in Eq. (27) the standard expression that relates a conservative quantity to the symmetry of a fundamental variable (here, the relative resolution), according to Noether's theorem.

Note that, at this level of the construction of the theory, the charge is defined as a large scale prime integral (conservative quantity). But, once this result is obtained, a second step consists of

studying in detail the internal structures of the fractal geodesics (that are identified with the charged particle).[3,7] These internal structures can afterwards be interpreted (at time scales smaller than $\tau=\hbar/E$), in terms of virtual particle-antiparticle pairs, then of radiative corrections and of the scale variation of the charge toward small scales, as described by the renormalization group equations.

It is also remarkable that, in such a relativistic foundation of electromagnetism, we are led to introduce in a separate way an active and a passive charge. This is also analogous to the introduction in GR of an active gravitational mass and of a passive mass which are equal according to the GR strong principle of equivalence. As a consequence, a scale-relativistic principle of equivalence of these charges can be set (in order to account for the action-reaction principle in Coulomb's law). Under this principle, $e=q$ and Eq. (27) becomes $e^2/c=-\partial S/\partial \ln \varrho$.

We have therefore established from first principles the form of the action in the classical electromagnetic theory, in particular the form of the particle-field coupling term (which was postulated in the standard theory), as (see, e.g., Ref. 24)

$$\mathrm{d}S=-mc\,\mathrm{d}s-\frac{e}{c}A_\mu\,\mathrm{d}x^\mu. \tag{28}$$

But this form has also a new geometrical interpretation. It means that, in this framework, an increase of the length can come from two contributions: the first is the usual variation due to the motion of the particle, while the second new contribution, which is of geometric nature, is a length dilation of the internal fractal structures.

We are now able to write a geodesics equation minimizing the length invariant (i.e., the proper time), which coincides with the least-action principle $\delta\int \mathrm{d}S=0$ (see Ref. 24). The variation of the above action yields the Lorentz equation of electrodynamics,

$$mc\frac{\mathrm{d}u_\alpha}{\mathrm{d}s}=\frac{e}{c}F_{\alpha\mu}u^\mu, \tag{29}$$

where $F_{\alpha\mu}=\partial_\alpha A_\mu-\partial_\mu A_\alpha$ is the electromagnetic tensor field. We also recover the standard form for the differential of the action as a function of the coordinates, namely,

$$\mathrm{d}S=-\left(mcu_\mu+\frac{e}{c}A_\mu\right)\mathrm{d}x^\mu. \tag{30}$$

B. Quantum electrodynamics

Let us proceed with a brief account of the generalization of this approach to quantum electrodynamics. As recalled in Sec. II, in the scale relativistic approach to the quantum theory,[3,7] the four-velocity $\mathcal{V}^\mu$ that describes a scalar particle is complex, so that its action is also a complex number and it now writes $S=S(x^\mu,\mathcal{V}^\mu,\chi)$. The wave function is defined from this action as $\psi=\exp(iS/\hbar)$.

Therefore Eq. (30) now takes the form

$$\mathrm{d}S=-mc\mathcal{V}_\mu\,\mathrm{d}x^\mu-\frac{e}{c}A_\mu\,\mathrm{d}x^\mu. \tag{31}$$

The new relation between the wave function and the velocity reads

$$mc\mathcal{V}_\mu=i\hbar\,D_\mu\ln\psi=i\hbar\,\partial_\mu\ln\psi-\frac{e}{c}A_\mu, \tag{32}$$

so that we recover the standard QED covariant derivative as being nothing but the scale-covariant derivative previously introduced, but now acting on the wave function,

$$D_\mu = \partial_\mu + i\frac{e}{\hbar c}A_\mu. \tag{33}$$

C. Gauge invariance

Let us now consider a second internal structure of the fractal geodesics, that lies at a relative scale $\varepsilon' = \rho'\lambda$. Equation (22) becomes

$$\delta \ln \rho' = \frac{1}{q}A'_\mu \, \mathrm{d}x^\mu. \tag{34}$$

Let φ be the ratio between the scales ε' and ε. In the framework of Galilean scale relativity (where the product of two successive dilations ρ and ρ' is $\rho'' = \rho \times \rho'$), this ratio is simply $\varphi = \rho'/\rho$. One therefore finds

$$A'_\mu = A_\mu + q\partial_\mu \ln \varphi, \tag{35}$$

which is the standard gauge invariance relation for the potential. But here a gauge transformation, instead of being arbitrary, is identified with a scale transformation of the resolution variable in scale space. Under such a transformation, the wave function of the particle becomes

$$\psi' = \psi \exp\left(-i\frac{eq}{\hbar c}\ln \varphi\right). \tag{36}$$

As a consequence, the Lagrangian given by Eq. (31), that includes the particle and field-particle coupling terms, remains globally invariant under a gauge transformation.

When $q = e$ (the electron charge), we have $e^2 = 4\pi\alpha\hbar c$, where α is the "fine structure constant," i.e., the electromagnetic coupling constant. The previous expression becomes in this case $\psi' = \psi \exp(-i4\pi\alpha \ln \varphi)$. In the framework of the special scale-relativity theory[12] in which possible scale ratios become limited $[\ln \varphi < \ln(m_\mathrm{P}/m_e)]$ because of the identification of the Planck length scale with a lowest (invariant under dilations) scale, this expression has been used to suggest the existence of a relation between the mass and the charge of the electron.[2–4]

Let us conclude this review part by stressing that the scale-relativity theory of electromagnetism shares some features with the Weyl-Dirac theory,[25,26] but that it has new and essential differences. Namely, the Weyl theory considers scale transformations of the line element, $\mathrm{d}s \rightarrow \mathrm{d}s' = \rho\, \mathrm{d}s$, but without specifying any fundamental cause for this dilation. The variation of $\mathrm{d}s$ should therefore exist at all scales, in contradiction with the observed invariance of the Compton length of the electron (i.e., of its mass).

In the scale-relativity proposal, the change of the line element comes from the fractal geometry of space-time, and it is therefore a consequence of the dilation of the scale variables ("resolutions"). Moreover, the explicit effects of the dependence on resolutions is observable only below the transition between scale dependence and scale independence, which is identified with the Compton scale of the particle in its rest frame. This ensures the invariance, in this theory, of the observed electron mass.

IV. NON-ABELIAN GAUGE FIELDS

A. Scale-relativistic description

1. Introduction

We now generalize the electromagnetic description to a geometric foundation of non-Abelian gauge theories, based upon the scale-relativity first principles. We consider that the internal fractal structures of the "particle" (i.e., of the family of geodesics of a nondifferentiable space-time) are now described in terms of several scale variables $\eta_{\alpha\beta\ldots}(x,y,z,t)$, that generalize the single reso-

lution variable ε. We write them for simplicity in units of λ, and we assume that the various indices can be gathered into one common index: we therefore write the scale variables under the simplified form η_α ($\alpha=0$ to N).

In the simplest case, $\eta_\alpha=\varepsilon_\alpha$, where ε_α correspond to the resolutions of the space-time coordinates X_α ($\alpha=1-4$). However, other situations can be considered, since their true nature is tensorial rather than vectorial, and since, in analogy with GR, general transformations can be applied to these variables, for example, the transformation $\varepsilon_\alpha \to \ln \varepsilon_\alpha$ may be particularly relevant for such scale variables. In this paper, we shall not be more specific about the choice of the scale variables, in order to keep generality. Moreover, our aim here is mainly to relate in a general way the scale-relativistic tools to the standard description of current gauge theories, so that we shall present only a general description of the scale transformations obtained, leaving to future works a more specific establishment of the final gauge group. However, even at this preliminary stage of the analysis, we can show that in any case it contains at least an SU(2) subgroup, e.g., the three-dimensional rotations in scale-space which can be identified with the isospin transformation group (see Sec. IV A 4 below).

2. General scale transformations

Let us consider infinitesimal scale transformations. The transformation law on the η_α can be written in a linear way as

$$\eta'_\alpha = \eta_\alpha + \delta\eta_\alpha = (\delta_{\alpha\beta} + \delta\theta_{\alpha\beta})\eta^\beta, \tag{37}$$

where $\delta_{\alpha\beta}$ is the Kronecker symbol, or equivalently,

$$\delta\eta_\alpha = \delta\theta_{\alpha\beta}\eta^\beta. \tag{38}$$

Let us now assume that the η_α's are functions of the standard space-time coordinates. This leads us to generalize the scale-covariant derivative previously defined in the electromagnetic case as follows: the total variation of the resolution variables becomes the sum of the inertial one, described by the covariant derivative, and of the new geometric contribution, namely,

$$\mathrm{d}\eta_\alpha = D\eta_\alpha - \eta^\beta\delta\theta_{\alpha\beta} = D\eta_\alpha - \eta^\beta W^\mu_{\alpha\beta}\,\mathrm{d}x_\mu. \tag{39}$$

Note that, here, this covariant derivative is similar to that of GR, i.e., it amounts to subtract the new geometric part in order to keep only the inertial part (for which the motion equation will therefore take a geodesical, freelike form). This is different from the case of the quantum-covariant derivative [Eq. (13)], which includes the effects of nondifferentiability by adding new terms in the total derivative.

Recall that in the Abelian case, which corresponds to a unique global dilation, this expression can be simplified since $\mathrm{d}\eta/\eta=\mathrm{d}\ln\eta=\mathrm{d}\chi$. We want also to note here that we have chosen to write the new geometric contribution $-\eta^\beta\delta\theta_{\alpha\beta}$, i.e., with a minus sign, in order to recover the covariant derivative of gauge theories in its standard form (this is actually an inessential sign ambiguity).

In this new situation we are led to introduce "gauge field potentials" $W^\mu_{\alpha\beta}$ that enter naturally in the geometrical frame of Eq. (39). These potentials are linked to the scale transformations as follows:

$$\delta\theta_{\alpha\beta} = W^\mu_{\alpha\beta}\,\mathrm{d}x_\mu. \tag{40}$$

One should remain cautious about this expression and keep in mind that these potentials find their origin in a covariant derivative process and are therefore not gradients (this is expressed by the use of a difference sign $\delta\theta_{\alpha\beta}$ instead of $\mathrm{d}\theta_{\alpha\beta}$). They formalize the coupling between displacements in space-time and transformations of the scale variables and play in Eq. (39) a role analogous to the one played in general relativity by the Christoffel symbols. It is also important to notice that the $W^\mu_{\alpha\beta}$ introduced at this level of the analysis do not include charges. They are functions of the space and time coordinates only. This is a necessary choice because our method generates, as we shall

see, not only the fields but also the charges from, respectively, the scale transformations and the scale symmetries of the dynamical fractal space-time.

3. Multiplets

After having written the transformation law of the basic variables (the η_α's), we are now led to describe how various physical quantities transform under these η_α transformations. These new transformation laws are expected to depend on the nature of the objects to transform (e.g., vectors, tensors, spinors, etc.), which implies to jump to group representations.

In the case where the particle is a spin-1/2 fermion, it has been recalled in Eq. (18) that the relation between the velocity and the spinor fields reads

$$\mathcal{V}_\mu = i\lambda\psi^{-1}\partial_\mu\psi, \tag{41}$$

where $\mathcal{V}_\mu$ and ψ are complex quaternions and the constant $\lambda = \hbar/mc$ is the Compton length of the particle.

However, bispinors are not a general enough description for fermions subjected to a general gauge field. Indeed, we consider here a generalized group of transformations which therefore involves generalized charges. As a consequence of these new charges (whose existence will be fully justified below and their form specified), the very nature of the fermions is expected to become more complicated. Experiments have indeed shown that new degrees of freedom must be added in order to represent the weak isospin, hypercharge and color. In order to account in a general way for this more complicated description, we shall simply introduce multiplets ψ_k, where each component is a Dirac bispinor. Therefore, as already remarked in previous presentations,[3] when the scale variables become multiplets, the same is true of the charges. As we shall see in what follows, in the present approach it is at the level of the construction of the charges that the set generators enter.

In this case the multivalued velocity becomes a biquaternionic matrix,

$$\mathcal{V}^\mu_{jk} = i\lambda\psi_j^{-1}\partial^\mu\psi_k. \tag{42}$$

The biquaternionic (therefore noncommutative) nature of the wave function (which is equivalent to Dirac bispinors) plays here an essential role, as previously announced. Indeed, it leads to write the velocity field as $\psi^{-1}\partial^\mu\psi$ instead of $\partial^\mu \ln\psi$ in the complex case, so that its generalization to multiplets involves two indices instead of one. As we shall see in what follows, the general structure of Yang-Mills theories and the correct construction of non-Abelian charges will be obtained thanks to this result.

Therefore the action becomes also a tensorial two-index quantity,

$$\mathrm{d}S_{jk} = \mathrm{d}S_{jk}(x^\mu, \mathcal{V}^\mu_{jk}, \eta_\alpha). \tag{43}$$

In the absence of a field, it is linked to the generalized velocity (and therefore to the spinor multiplet) by the relation

$$\partial^\mu S_{jk} = -mc\mathcal{V}^\mu_{jk} = -i\hbar\,\psi_j^{-1}\partial^\mu\psi_k. \tag{44}$$

Now, in the presence of a field [i.e., when the second-order effects of the fractal geometry appearing in the right-hand side of Eq. (39) are included], using the complete expression for $\partial^\mu\eta_\alpha$,

$$\partial^\mu\eta_\alpha = D^\mu\eta_\alpha - W^\mu_{\alpha\beta}\eta^\beta, \tag{45}$$

we are led to write a relation that generalizes Eq. (25) to the non-Abelian case,

$$\partial^\mu S_{jk} = \frac{\partial S_{jk}}{\partial\eta_\alpha}\partial^\mu\eta_\alpha = \frac{\partial S_{jk}}{\partial\eta_\alpha}(D^\mu\eta_\alpha - W^\mu_{\alpha\beta}\eta^\beta). \tag{46}$$

Thus we obtain

$$\partial^{\mu} S_{jk} = D^{\mu} S_{jk} - \eta^{\beta} \frac{\partial S_{jk}}{\partial \eta_{\alpha}} W^{\mu}_{\alpha\beta}. \tag{47}$$

We are finally led to define a general group of scale transformations whose generators are

$$T^{\alpha\beta} = \eta^{\beta} \partial^{\alpha} \tag{48}$$

(where we use the compact notation $\partial^{\alpha} = \partial / \partial \eta_{\alpha}$), yielding the generalized charges,

$$\frac{\tilde{g}}{c} t^{\alpha\beta}_{jk} = \eta^{\beta} \frac{\partial S_{jk}}{\partial \eta_{\alpha}}. \tag{49}$$

This group is submitted to a unitarity condition, since, when it is applied to the wave functions, $\psi\psi^{\dagger}$ must be conserved.

4. Rotations in "scale-space"

In order to enlight the meaning of the new definition we have obtained for the charges, we consider in the present section a subsample of the possible scale transformations on intrinsic scale variables: namely, those which are built from the antisymmetric part of the gauge set (that can therefore be identified as rotations in the scale space). In this case the infinitesimal transformation is such that

$$\delta\theta_{\alpha\beta} = -\delta\theta_{\beta\alpha} \Rightarrow W^{\mu}_{\alpha\beta} = -W^{\mu}_{\beta\alpha}. \tag{50}$$

Therefore, reversing the indices in Eq. (47), we may write

$$\partial_{\mu} S_{jk} = D_{\mu} S_{jk} - \eta^{\alpha} \frac{\partial S_{jk}}{\partial \eta_{\beta}} W^{\mu}_{\beta\alpha}. \tag{51}$$

Taking the half-sum of Eqs. (47) and (51) we finally obtain

$$\partial_{\mu} S_{jk} = D_{\mu} S_{jk} - \frac{1}{2} \left(\eta^{\beta} \frac{\partial S_{jk}}{\partial \eta_{\alpha}} - \eta^{\alpha} \frac{\partial S_{jk}}{\partial \eta_{\beta}} \right) W^{\mu}_{\alpha\beta}. \tag{52}$$

This leads to define the new charges,

$$\frac{\tilde{g}}{c} t^{\alpha\beta}_{jk} = \frac{\partial S_{jk}}{\partial \theta_{\alpha\beta}} = \frac{1}{2} \left(\eta^{\beta} \frac{\partial S_{jk}}{\partial \eta_{\alpha}} - \eta^{\alpha} \frac{\partial S_{jk}}{\partial \eta_{\beta}} \right). \tag{53}$$

We recognize here a definition similar to that of the angular momentum, i.e., of the conservative quantity that finds its origin in the isotropy of space; but the space under consideration is here the "scale-space," i.e., the space of the scale variables that must be added for a proper description of a fractal geometry of space-time. Therefore the charges of the gauge fields are identified, in this interpretation, with "scale-angular momenta."

The subgroup of transformations corresponding to these generalized charges is, in three dimensions, a SO(3) group related to a SU(2) group by the homomorphism which associates to two distinct 2×2 unitary matrices of opposite sign the same rotation. We are therefore naturally led to define a "scale-spin," which we propose to identify to the simplest non-Abelian charge in the current standard model: the weak isospin.

Coupling this SU(2) representation of the rotations in a three-dimensional sub-"scale-space" to the U(1) representation of the global scale dilations (that describes the electromagnetism process) analyzed in Sec. III, we are therefore able to give a physical geometric meaning to the transformation group corresponding to the $U(1) \times SU(2)$ representation of the standard electroweak theory.[27,28]

It is worth stressing here that the group of three-dimensional rotations in "scale-space" is only a subgroup of an at least four-dimensional rotation group (one scale variable for each space-time coordinate), and therefore at least SO(4), and, more precisely, its universal covering group $\mathrm{SU}(2)\times\mathrm{SU}(2)$.

B. Yang-Mills theory with the scale-relativity tools

1. Simplified notation

For the subsequent developments, we shall simplify the notations and use only one index $a=(\alpha,\beta)$ for the scale transformations: this index runs on the gauge group parameters, now written θ_a. For example, in three dimensions, this means that we replace the three rotations $\theta_{23},\theta_{31},\theta_{12}$, respectively, by $\theta_1,\theta_2,\theta_3$. We obtain the following more compact form for the complete action:

$$\mathrm{d}S_{jk}=\left(D_\mu S_{jk}-\frac{\widetilde{g}}{c}t^a_{jk}W_{a\mu}\right)\mathrm{d}x^\mu, \tag{54}$$

and therefore

$$D^\mu S_{jk}=-i\hbar\,\psi_j^{-1}D^\mu\psi_k=-i\hbar\,\psi_j^{-1}\partial^\mu\psi_k+\frac{\widetilde{g}}{c}t^a_{jk}W^\mu_a. \tag{55}$$

2. Scale relativistic tools for Yang-Mills theory

The previous equations have used new concepts that are specific of the scale-relativity approach, namely (i) the scale variables η_α, (ii) the biquaternionic velocity matrix $\mathcal{V}^\mu_{jk}$, and (iii) its associated action S_{jk}. The standard concepts of quantum field theories, namely the fermionic field ψ, the bosonic field W^μ_a, the charges g, the gauge group generators t^a_{jk} and the gauge-covariant derivative D_μ are here all of them derived from these new tools.

Let us show that we are thus able to recover the basic relations of standard non-Abelian gauge theories (see, e.g., Ref. 29). From Eq. (55), we first obtain the standard form for the covariant partial derivative, now acting on the wave-function multiplets,

$$D^\mu\psi_k=\partial^\mu\psi_k+i\frac{\widetilde{g}}{\hbar c}t^{ja}_k W^\mu_a\psi_j. \tag{56}$$

The ψ_k's do not commute together since they are biquaternionic quantities, but this is the case neither of t^{ja}_k nor of W^μ_a, so that ψ_j can be set to the right as in the standard way of writing; from the multiplet point of view (index j), we simply exchange the lines and columns.

Now introducing a dimensionless coupling constant α_g and a dimensionless charge g, such that

$$g^2=4\pi\alpha_g=\frac{\widetilde{g}^2}{\hbar c}, \tag{57}$$

and redefining the dimensionality of the gauge field (namely, we replace $W^\mu_a/\sqrt{\hbar c}$ by W^μ_a), the covariant derivative may be more simply written under its standard form,

$$D^\mu\psi_k=\partial^\mu\psi_k+igt^{ja}_k W^\mu_a\psi_j, \tag{58}$$

where all of the three new contributions, g, t^{ja}_k, and W^μ_a have been constructed from the origin by the theory and given a geometric meaning.

In the simplified case of a fermion singlet, it reads

$$D^{\mu} = \partial^{\mu} + igt^{a}W_{a}^{\mu}. \tag{59}$$

Let us now derive the laws of gauge transformation for the fermion field. Consider a transformation θ_a of the scale variables. As we shall now see, the θ_a can be identified with the standard parameters of a non-Abelian gauge transformation. Indeed, using the above remark about the exchange of lines and columns, Eq. (44) becomes

$$-i\hbar\,\partial^{\mu}\psi_{k} = \partial^{\mu}S_{k}^{j}\psi_{j} \tag{60}$$

and allows us to recover by a different way Eq. (58), from which we obtain the standard form for the transformed fermion multiplet in the case of an infinitesimal gauge transformation $\delta\theta_a$,

$$\psi_{k}' = (\delta_{k}^{j} - igt_{k}^{ja}\delta\theta_{a})\psi_{j}. \tag{61}$$

3. Yang-Mills theory

We have now at our disposal all the tools of quantum gauge theories. The subsequent developments are standard ones in terms of these tools. Namely, one introduces the commutator of the matrices t_a (which have *a priori* no reason to commute), under the form

$$t_{a}t_{b} - t_{b}t_{a} = if_{ab}^{c}t_{c}. \tag{62}$$

Therefore the t_a's are identified with the generators of the gauge group and the if_{ab}^{c}'s with the structure constants of its associated Lie algebra. The noncommutativity of the generators and the requirement of the full Lagrangian invariance under the scale transformations finally imply the appearance of an additional term in the gauge transformation law of the boson fields. We obtain this additional term by the standard method recalled below.

We replace into the Lagrangian of the fermionic field given by Eq. (20) the partial derivative ∂_μ by its covariant counterpart D_μ of Eq. (59). The development of the covariant derivative leads to the appearance of two terms, a free particle one and a fermion-boson coupling term,

$$\mathcal{L} = \bar{\psi}(i\gamma^{\mu}\partial_{\mu} - m)\psi - g\bar{\psi}\gamma^{\mu}t_{a}W_{\mu}^{a}\psi. \tag{63}$$

Let us now consider an infinitesimal scale transformation of the fermion field,

$$\psi \to \psi e^{-ig\,\delta\theta^{b}t_{b}}. \tag{64}$$

The requirement of the full Lagrangian invariance under this transformation involves also the coupling term. Let us consider the transformation of this term, except for the W_μ contribution,

$$\bar{\psi}\gamma^{\mu}t_{a}\psi \to \bar{\psi}e^{ig\,\delta\theta^{b}t_{b}}\gamma^{\mu}t_{a}\psi e^{-ig\,\delta\theta^{b}t_{b}}. \tag{65}$$

Accounting for the fact that this is an infinitesimal transformation, it becomes

$$\bar{\psi}(1 + ig\,\delta\theta^{b}t_{b})\gamma^{\mu}t_{a}\psi(1 - ig\,\delta\theta^{b}t_{b}) = \bar{\psi}\gamma^{\mu}t_{a}\psi + ig\bar{\psi}\gamma^{\mu}\delta\theta^{b}(t_{b}t_{a} - t_{a}t_{b})\psi. \tag{66}$$

We replace the commutator $t_bt_a - t_at_b$ by its expression in Eq. (62), and we obtain

$$\bar{\psi}\gamma^{\mu}t_{a}\psi \to \bar{\psi}\gamma^{\mu}t_{a}\psi - g\bar{\psi}\gamma^{\mu}\delta\theta^{b}f_{ba}^{c}t_{c}\psi. \tag{67}$$

Then the requirement of invariance could be fulfilled only provided the transformation of the field W_μ^a itself involves a new term (in addition to the Abelian term $\partial_\mu\delta\theta^a$), i.e.,

$$W_{\mu}^{a} \to W_{\mu}^{a} + \delta W_{\mu}^{a}. \tag{68}$$

The transformation of the full coupling term now reads

$$\bar{\psi}\gamma^{\mu}t_a W_{\mu}^{a}\psi \to [(\bar{\psi}\gamma^{\mu}t_a\psi) - g f_{ba}^{c}\delta\theta^{b}(\bar{\psi}\gamma^{\mu}t_c\psi)][W_{\mu}^{a} + \delta W_{\mu}^{a}]. \tag{69}$$

Neglecting the second order term in the elementary variations and using the fact that we can interchange the running indices, we see that this expression is invariant provided

$$\bar{\psi}\gamma^{\mu}\{t_a[\delta W_{\mu}^{a} - g f_{bc}^{a}\delta\theta^{b}W_{\mu}^{c}]\}\psi = 0. \tag{70}$$

One general solution, independent of the t_a's, to the requirement of the Lagrangian invariance in the non-Abelian case is therefore

$$\delta W_{\mu}^{a} = g f_{bc}^{a}\delta\theta^{b}W_{\mu}^{c}. \tag{71}$$

Finally, under an infinitesimal scale transformation $\delta\theta^{b}$, the non-Abelian gauge boson field W_{μ}^{a} transforms as

$$W_{\mu}^{a} \to W'^{a}_{\mu} = W_{\mu}^{a} + \partial_{\mu}\delta\theta^{a} + g f_{bc}^{a}\delta\theta^{b}W_{\mu}^{c}. \tag{72}$$

We recognize here once again a standard transformation of non-Abelian gauge theories, which is now derived from the basic transformations on the η_a's of Eq. (39).

We can finish as usual the development of standard Yang-Mills theory. The gauge field self-coupling term, $-\frac{1}{4}F_{\mu\nu}F^{\mu\nu}$, is retained as the simplest invariant scalar that can be added to the Lagrangian. It is defined as follows.

First, one defines the Yang-Mills field,

$$A_{\mu} \equiv t_a W_{\mu}^{a}, \tag{73}$$

which yields the covariant derivative of Eq. (59) under the standard form,

$$D_{\mu} = \partial_{\mu} + igA_{\mu}. \tag{74}$$

Then, one establishes the analogue of the Faraday tensor of electromagnetism, by defining

$$F_{\mu\nu}^{a} \equiv \partial_{\mu}W_{\nu}^{a} - \partial_{\nu}W_{\mu}^{a} - g f_{bc}^{a}W_{\mu}^{b}W_{\nu}^{c} \tag{75}$$

and

$$F_{\mu\nu} \equiv t_a F_{\mu\nu}^{a}, \tag{76}$$

which gives

$$F_{\mu\nu} = \partial_{\mu}A_{\nu} - \partial_{\nu}A_{\mu} + ig[A_{\mu},A_{\nu}]. \tag{77}$$

One adds to the Lagrangian density $\mathcal{L}$ a kinetic term for the free Yang-Mills gauge field,

$$\mathcal{L}_A = -\tfrac{1}{4}F_{\mu\nu}F^{\mu\nu}. \tag{78}$$

This form is justified by the same reasons as in the standard theory (namely, it must be a scalar and constructed from the fields and not from the potentials, which are gauge dependent). The Euler-Lagrange equations therefore read

$$\partial_{\mu}F^{\mu\nu} + ig[A_{\mu},F^{\mu\nu}] = 0. \tag{79}$$

Introducing the Yang-Mills derivative operator,

$$\nabla_{\mu} = \partial_{\mu} + ig[A_{\mu}, \ ], \tag{80}$$

one finally obtains the standard Yang-Mills equations which generalize to the non-Abelian case the source-free Maxwell equation,

$$\nabla_\mu F^{\mu\nu} = 0. \tag{81}$$

We are therefore provided with a fully consistent gauge theory obtained as a consequence of scale symmetries issued from a geometric space-time description.

V. CONCLUSION

In the present paper our purpose has been to give a physical meaning to the various items entering the gauge field theories in the framework of scale relativity, extending to the non-Abelian case the results of previous works devoted to the understanding of the Abelian gauge-invariant theory of electromagnetism.

We have so far reached an understanding of the nature of gauge transformations, in terms of a geometric space-time description. We decompose, for simplification purpose, the dynamics emerging from displacements in the fractal space-time of scale relativity into (i) transformations occuring on the scale variables in the framework of a nondirectly observable local "scale-space" coupled to (ii) displacements in space-time. The scale variables become thus functions of the space-time coordinates.

The gauge charges appear as the generators of the set of scale transformations applied to a generalized action, therefore emerging from the scale symmetries of the dynamical fractal space-time. Considering the transformation laws verified by the scale variables, we are able to establish how the various physical quantities transform under these laws and to recover the standard gauge theory form of these transformations.

We are now provided with a theory where the gauge group is no more defined through its only action on the physical objects, as in the standard framework, but as the transformation group of the scale variables, and where the boson fields and the charges are given a physical meaning. We have established the following correspondences between the standard gauge theory items and the scale-relativistic tools:

(i) gauge transformations $\leftrightarrow$ scale transformations in scale-space,
(ii) internal gauge space $\leftrightarrow$ local "scale-space,"
(iii) gauge fields $\leftrightarrow$ manifestations of the fractal and scale-relativistic geometry of space-time (analogues of the Christoffel symbols issuing from the curvature of space-time in general relativity),
(iv) gauge charges $\leftrightarrow$ conservative quantities, conjugate to the scale variables, originating from the symmetries of the "scale space" and generators of the scale transformation group.

Since, in the present study, our aim was to recover the standard description of current gauge theory, we have, in the main part of the work, retained a general form for the scale variables. However we have shown that, whatever will be their more specific form, the gauge set will contain in any case the $U(1) \times SU(2)$ electroweak theory group as subset.

In future works, we shall study other sets of transformations that can be derived from the present study, where the scale variables will be given new precise definitions and which hopefully could yield hypercharge, color and maybe new developments in gauge field theory. We shall also consider in more details the issues of the fermion sectors, of the mass and charge renormalization and of the Higgs field.

(Received 22 November 2005; accepted 27 January 2006; published online 15 March 2006)

We consider three-dimensional (3D) flow equations inspired by the renormalization group (RG) equations of string theory with a three-dimensional target space. By modifying the flow equations to include a U(1) gauge field, and adding carefully chosen De Turck terms, we are able to extend recent two-dimensional results of Bakas to the case of a 3D Riemannian metric with one Killing vector. In particular, we show that the RG flow with De Turck terms can be reduced to two equations: the continual Toda flow solved by Bakas, plus its linearizaton. We find exact solutions which flow to homogeneous but not always isotropic geometries. © *2006 American Institute of Physics.* [DOI: 10.1063/1.2178585]

I. INTRODUCTION

The Ricci flow of d-dimensional manifolds is interesting because of its relationship to the renormalization group (RG) equations of generalized two-dimensional (2D) sigma models with d-dimensional target space. In two space-time dimensions, Ricci flow also provides a proof[1] of the uniformization theorem,[2] which states that every closed orientable two-dimensional manifold with handle number 0,1, or >1 admits *uniquely* the constant curvature geometry with positive, zero, or negative curvatures, respectively. Bakas[3] has shown that the 2D Ricci flow equations in conformal gauge provide a continual analogue of the Toda field equations. Using this algebraic approach he was able to write down the general solution.

The potential importance of a three-dimensional (3D) uniformization theorem is evident particularly in the context of (super) membrane physics and three-dimensional quantum gravity where one should be able to perform path-integral quantization via a similar procedure to that in two dimensions. Unfortunately, there is no uniformization theorem in three dimensions, only a conjecture due to Thurston[4,5].

Recently there has been speculation that Perelman[6] has overcome some roadblocks in Hamilton's program to prove the conjecture using the Ricci flow.[7,8] It is therefore important to understand in detail the properties of this flow.

In the following, we follow up on a suggestion by Bakas to use his 2D results in order to analyze the flow equations for 3D manifolds with a single Killing vector. This provides a tractable midisuperspace approach which can be systematically studied in the context of the stringy flow first considered in Ref. 9. We will show that this flow reduces to the infinite dimensional generalization of the Toda equation for the conformal factor of the invariant 2D submanifold plus a linear equation for the scale factor of the extra dimension. Note that since the latter scale factor depends on the coordinates of the invariant subspace, our manifolds are not simple direct products. In addition, we will analyze two exact analytic solutions in detail and show that they have the expected behavior.

The paper is organized as follows. Section II reviews 2D flow equations and Bakas' results, Sec. III reviews the stringy flow of Ref. 9, but with the De Turck modification.[10] The De Turck

modification contains a vector field ξ_i, and we show that if we choose this vector field as a linear combination of two vector fields, one of which is proportional to the gradient of the dilaton field, then the dilaton can be decoupled from the flow of the remaining fields. In Sec. IV we discuss the flow for a metric ansatz where one of the coordinates is in the direction of a Killing vector field, and the remaining part of the metric is in the form of a conformal 2D metric. We use the second part of the De Turck vector field to preserve this form of the metric throughout the flow. In order that the flow is self-consistent, the U(1) vector field in the stringy flow must be fixed in terms of the functions that occur in the metric tensor. The flow then reduces to two equations for the two metric degrees of freedom. One of these is the continual Toda equation[3] for the conformal factor of the 2D geometry orthogonal to the Killing vector field, and the other, for the component of the metric in the direction of the Killing vector field, is the linearization of the continual Toda equation. Section V presents specific solutions and Sec. VI ends with conclusions and prospects for future work.

II. THE 2D CASE

We now summarize the methodology and results of Bakas[3] since they play a crucial role in the following. The Ricci flow equations, for arbirary 2-metric g_{AB} are

$$\frac{\partial g_{ij}}{\partial t} = -R_{ij} + \nabla_i \xi_j + \nabla_j \xi_i. \tag{1}$$

The last two terms (the so-called "De Turck" terms) incorporate the effects of all possible diffeomorphisms and can be chosen arbitrarily in order to simplify the equations and/or optimize convergence. The original reason for the inclusion of these terms was to show that the bare Ricci flow—without the Lie derivative term—satisfied short term existence. To do this, one had to break the diffeomorphism invariance and this was accomplished by introducing a background symmetric connection $\bar{\Gamma}^i_{jk}$, and the vector field $\xi^i := g^{jk}(\Gamma^i_{jk} - \bar{\Gamma}^i_{jk})$, where the last term is the Christoffel connection with respect to the metric g_{ij}. It was shown[10] that the resulting flow was strongly parabolic and short time existence could be proved. It was also shown that any solution of the bare Ricci flow was also a solution of the De Turck modified flow.

Bakas chose to work in the conformal gauge,

$$ds^2 = g_{ij}\, dx^i\, dx^j = \tfrac{1}{2} \exp(\Phi)(dx^2 + dy^2). \tag{2}$$

In this gauge there is no need to add De Turck terms and the flow takes the form of a nonlinear "heat equation:"

$$\frac{\partial}{\partial t} e^{\Phi} = \nabla^2 \Phi. \tag{3}$$

The Toda equations describe the integrable interactions of a collection of two-dimensional fields $\Phi_i(x,y)$ coupled via the Cartan matrix K_{ij},

$$\sum_j K_{ij} e^{\Phi_j(x,y)} = \nabla^2 \Phi_i(x,y). \tag{4}$$

Bakas argues that Eq. (3) is a continual analogue of the above, with the Cartan matrix replaced by the kernel,

$$K_{ij} \to K(t,t') = \frac{\partial}{\partial t} \delta(t,t'). \tag{5}$$

This leads to a general solution to (3) in terms of a power series around the free field expanded in path ordered exponentials. Each term in the perturbation series is itself a solution of the Ricci flow. Although the resulting expression is difficult to work with explicitly, it does provide a formal

complete solution to the 2D flow equations. Bakas showed that several solutions of the flow found by other means can be written as continual Toda flows, and this provides some confidence in the convergence of the latter. One of these solutions is the so-called sausage model, and this 2D flow will appear in the 3D case discussed below. Furthermore, Bakas indicates that the continual Toda flow, though formally a solution of the RG flow in 2D only to lowest order in the coupling constant, may be lifted at least in some cases to a solution of the flow with higher order terms.[3] Finally, it is clear that the solution will provide some insight into how uniformization works that cannot be easily seen via the more conventional discussion of the heat equation.

In the next sections we will show that a similar formal solution can also be found for three-dimensional metrics with at least one Killing field.

III. 3D FLOW EQUATIONS

We consider here a generalization of the Ricci flow, in which, besides the metric g_{ij}, there are additional fields which flow, consisting of a dilaton ϕ, a gauge two-form potential B_{ij} with field strength H_{ijk} and finally, a U(1) gauge field with potential 1-form A_i and corrresponding field strength F_{ij} which couples as a Maxwell-Chern-Simons theory. Including De Turck terms plus gauge terms for the flow of the nonmetric fields, the flow is

$$\dot{g}_{ij} = -2\left(R_{ij} + 2\phi_{|ij} - \left(\epsilon_F F_i{}^k F_{jk} + \frac{\epsilon_H}{4} H_{ikl} H_j{}^{kl}\right)\right) + L_\xi g_{ij}, \tag{6}$$

$$\dot{A}_i = -\left(e^{2\phi}\nabla_j(e^{-2\phi}F_i{}^j) + \frac{e\epsilon_F}{2}\eta_i{}^{jk}F_{jk}\right) + L_\xi A_i + \partial_i\Lambda, \tag{7}$$

$$\dot{B}_{ij} = e^{2\phi}\nabla_k(e^{-2\phi}H^k{}_{ij}) + L_\xi B_{ij} + \partial_i\Lambda_j - \partial_j\Lambda_i, \tag{8}$$

$$\dot{\phi} = -\chi + \Delta\phi - |\nabla\phi|^2 + \frac{\epsilon_F}{2}F^2 + \frac{\epsilon_H}{12}H^2 + L_\xi\phi. \tag{9}$$

In the above, the terms in the Lie derivatives L_ξ are the De Turck terms. The terms containing Λ and Λ_i appear for similar reasons to the De Turck terms: that is, they correspond to arbitrary gauge transformations on the gauge fields with potentials A_i and B_{ij}. By choosing the gauge and coordinate transformation terms judiciously, we are able to simplify the equations considerably.

This flow is motivated by two considerations. First, as shown in Ref. 9, all of the Thurston geometries are solutions of the equations of motion of this theory for various values of the parameters χ, ϵ_H, ϵ_F, e, as well as the other fields. In particular, the addition of the Maxwell term alone ($e=0$) yields $S^2\times E^1$, $H^2\times E^1$ and Sol as solutions. Moreover, there exists a generalized Birkhoff theorem which guarantees that these are the only solutions when $\phi=$constant and $A\neq 0$. With $e\neq 0$, one finds that the remaining Thurston geometries Nil and $\mathrm{SL}(2,R)$ are also solutions. As argued in Ref. 9 it seems plausible that these are the only solutions, but to date no rigorous proof exists.

The second motivation comes from string theory. In particular, the RG flow for a nonlinear sigma model with a four-dimensional (4D) Kaluza-Klein target space resembles the flow above, with the A_i potential originating as the twist potential of the 4D Kaluza-Klein metric. That is, the idea is to introduce an extra fourth dimension y, with the g_{yi} components of the metric and the B_{iy} components of the antisymmetric tensor field proportional to each other. The g_{yy} component of the metric is a constant, and all the remaining components of the various fields are independent of the y coordinate. The Chern-Simons term arises from the presence of such a term in the definition of the field strength H_{ijk} in terms of the B_{ij} and B_{yj} potentials. The details of this are being investigated elsewhere.[11]
