Variansly substituted 1,4,5,6-tetrahydra-as-triazines were prepared via the condensation of β -aminoalkylbydrazines with inninesters and orthoesters. The scope of these reactions and the pharmacological activity of the compounds is discussed.

Previously, we reported¹ the results of an investigation of the synthesis of substituted 1,4,5,6-tetrahydroas-triazines via condensation of nitriles with hydrazino alcohols catalyzed by concentrated sulfuric acid. During this investigation we found that the condensation could be effected only if the hydrazino alcohol possessed a hydroxyl group which yielded a relatively stable carbonium ion. This stringent requirement as to the types of hydrazino alcohols that could be condensed with nitriles to give triagenes limited the scope of this synthetic method. Therefore, in order to synthesize other structurally diverse types of triazines. we studied the condensation of β -aminoalkylhydrazines with a variety of iminoesters and orthoesters. This paper describes our study of these reactions which led to the synthesis of new substituted 1,4,5,6-tetrahydroas-triazines, and it also reports the pharmaeological activity of these compounds.

The required β -aminoalkylhydrazines were prepared by treating either aziridine, N-ethylaziridine, or 2methylaziridine with a 10-mole excess of either hydrazine or methylhydrazine in the presence of a catalytic amount of ammonium chloride. The large excess of the hydrazine reactant was necessary to minimize the formation of polymeric products. Also, slow, dropwise addition of the aziridine to the rapidly stirred, heated hydrazine reactant containing the ammonium chloride gave a higher yield of the β -aminoethylhydrazine.

The four β -aminoethylhydrazines (Ia-d) were allowed to react with either an iminoester hydrochloride or an orthoester to give the desired substituted 1,4,5,6tetrahydro-*as*-triazines (II).

(1) D. L. Uropanier, E. R. Wagner, G. Harris, and A. D. Rudzik, J. Med. Chem. 9, 881 (1966). The iminoester hydrochlorides were prepared using the Pinner synthesis² which consists of condensing the nitrile and the alcohol under anhydrous conditions in the presence of HCl at $0-5^{\circ}$. Ethanol was used in all cases. However, both methyl and ethyl benzimidate hydrochloride were prepared. The iminoester hydrochlorides were not purified and characterized. They were used as crude products that were washed thoroughly with anhydrous ether and dried *in cacuo* at ambient temperature.

The iminoester hydrochlorides were condensed with the β -aminoalkylhydrazines by slowly adding the β aminoalkylhydrazine to a stirred solution or suspension of the iminoester hydrochloride in absolute ethanol (method A), chloroform (method B), or methanol (method G) at ambient temperature and then heating the stirred mixture so that it refluxed for 6 hr. Method F is the same as method B except that methyl iminoester hydrochloride was used instead of the ethyl iminoester hydrochloride. A survey of Table I which lists the results obtained using these four methods with a variety of iminoester hydrochlorides and the aminoalkylhydrazines la-d indicates that (1) the yield of triazine varied considerably, (2) generally higher yields were obtained with aminoalkylhydrazine Ib and lower yields were obtained with aminoalkylhydrazine Ia. (3) iminoester hydrochlorides of lower alkyhitriles (aceto- or propionitrile) or evanopyridines gave low yields of triazines, and (4) the reaction proceeded equally well in either ethanol, methanol, or chloroform. The fact that the condensation proceeds as well in chloroform as it does in ethanol or methanol indicates that alcoholysis of the immoester hydrochloride to the orthoester is not a necessary intermediate step.

Three commercially available orthoesters (triethyl orthoformate, -acetate, and -propionate) were allowed to react with the various aminoalkylhydrazines. Just as with the ininoester hydrochlorides, yields varied considerably. The condensation was effected by heating at reflux for 20 hr either neat or in the presence of a solvent, such as ethanol, chloroform, or ethyl acetate. Condensation of β -aminoethylhydrazine and triethyl orthoformate gave the unsubstituted 1,4,5,6-tetrahydro-*as*-triazine.

We previously reported¹ the preferred position of the double bond in this heterocyclic system to be between N_2 - C_3 rather than between C_3 - N_4 . To further substantiate this assignment we compared the nurr spectra

^{*a*} See Experimental Section. ^{*b*} See Pharmacology. ^{*c*} Writhing was induced by intraperitoneal injection of 10 ml/kg of 0.1% HCl. The results are expressed as a ratio of the number of animals not writhing over the number of animals tested. ^{*d*} The results are expressed as a ratio of the number of animals protected from the tonic hind himb extensor phase of the seizure over the number of animals tested. ^{*e*} Chlorine.

II

March 1967

of 15 and 18. The position of the double bond in 18 is unambiguous. It must be between N₂-C₃ because N₄ bears an ethyl substituent. The unit spectrum of 18 showed the two ring CH₂ groups at -2.79 (sharp) and -3.33 ppm (sharp) and the spectrum of 15 showed these groups at -2.64 (sharp) and -3.36 ppm (broadened by NH). The lack of significant shift change of these ring CH₂ protons in the NH (15) and the NC₂H₅ compound (18) can be taken as good support for assigning the same double bond position to both compounds.

Results.—Table I shows the results of the pharmacological evaluation of the 22 *as*-triazines in this series. Five (2, 17–19, 21) of the 22 compounds tested were found to be potentiators of hexobarbital-induced sleep (greater than threefold increase). Compound 5 produced a significant shortening of hexobarbital-induced sleep.

Eight of the compounds (4-6, 17, 19-22) tested were found to inhibit the writhing response induced by HCl in mice. These eight compounds were subsequently tested for antiinflanmatory activity using the carrageen-induced rat paw edema test.³ None of these compounds exhibited significant antiinflammatory activity in this test (not shown). One of them (4) was also tested for analgetic activity in a modified hot plate procedure and was found to be inactive (Table II). However, when administered simultaneously with 2 mg/kg of morphine sulfate it was found to enhance the analgetic activity of morphine.

^a See Pharmacology section. ^b Compound **4** of Table 1 is 3-(2,6-dichlorobenzyl)-1-methyl-1,4,5,6-tetrahydro-*as*-triazine.

In the maximal electroshock test only two compounds (2, 19) showed significant activity. Both of these compounds were also potentiators of hexobarbital sleep time.

Three compounds (12, 14, 15) decreased the toxicity of *d*-amphetamine in the aggregated situation. It is of interest that these compounds did not show significant activity in any of the other screening procedures employed. In control experiments with *d*-amphetamine itself only 1/30 of the animals survived the aggregation procedure.

Experimental Section

Pharmacology. Analgetic Tests. Adult male mice (Cox) weighing 18–22 g were used in these tests. In the hydrochloric acid writhing tests, the method of Eckhardt, *et al.*,⁴ was used, and the modified hot plate method of Marshall, *et al.*,⁵ was used. Maximal electroshock seizures were produced by the method of Swinyard, *et al.*,⁶

For the hexobarbital sleep time test, adult male mice were injected intraperitoneally with the test compound 30 min prior to injection of 100 mg/kg of hexobarbital. The time in minutes between injection of the hexobarbital and the regain of the righting reflex was taken as the duration of sleeping time. The results are expressed as a ratio of the treated group over the control group.

In the *d*-amphetamine aggregation toxicity test, female albino mice (19-25 g) of the Swiss-Webster strain (laboratory Supply Co.) were used in all experiments. The test compounds were administered 30 min prior to the injection of 20 mg/kg of *d*-amphetamine. Immediately after the administration of *d*-amphetamine the mice were aggregated in groups of four for initial screening or in groups of ten. In the retests (groups of ten) the wire mesh cages for aggregation measured 15 cm on each side. The number of animals that died during 24 hr of aggregation was recorded. The results are expressed as the number of animals sortiving over the number of animals tested.

Chemistry. Melting points were determined in open capillary tubes using the Thomas-Hoover Uni-Melt and are uncorrected. The elemental analyses were done by Midwest Microlab., Indianapolis, Ind.

General Preparation of Aminoalkylhydrazines (Ia-d).—To a rapidly stirred, refluxing mixture of 10 moles of the hydrazine and 1 g of NII₄Cl was added, dropwise, over a period of 4 hr, 1 mole of the aziridine compound. After the addition was completed, the mixtore was stirred and heated at reflux for 16 hr. Most of the excess hydrazine compound was removed by distillation at atmospheric pressure using a 40-cm Vigrent column.

2-Aminoethylhydrazine (Ia) was obtained in 71% yield; bp 73-80° (8 mm); $\lambda_{\text{max}}^{100}$ 3.05, 3.15, and 6.20 μ ; pnr (50% in CDCl₅), -2.65 (5 H) and -2.78 ppn (4 H).

1-(2-Aminoethyl)-1-methylhydrazone (**Ib**) was obtained in 75% yield, bp 155–161°. Anal. Caled for $C_3H_{11}N_3$; C, 40.42; II, 12.44; N, 47.14. Found: C, 39.73; H, 12.53; N, 46.88.

1-(2-Aminopropyl)-1-methylhydrazine (Ic), was obtained in 52% yield, bp $51-54^{\circ}$ (10 mm). Anal. Calcd for C₄H₁₃N₃: C, 46.56; H, 12.70; N, 40.73. Found: C, 45.97; H, 12.67; N, 39.48.

1-(2-Ethylaminoethyl)-1-methylhydrazine (Id), was obtained in 53% yield, bp $103-105^{\circ}$ (75 mm). Anal. Caled for $C_5H_{15}N_3$: C₅ 51,24; H, 12.90; N, 35.86. Found: C₅ 50.29; H, 12.58; N, 35.56.

General Procedure for the Preparation of Methyl and Ethyl Iminoester Hydrochlorides.—A stirred, cooled (5°) mixture of 0.20 mole of the nitrile, 0.26 mole of either methanol or ethanol, and 100 ml of anhydrons ether was saturated with dry HCl. After standing for an additional 3 br at 5°, the mixture was concentrated to about one-half the original volume under a stream of dry nitrogen. The precipitated iminoester hydrochloride was removed by suction filtration, washed with anhydrons ether, and allowed to dry in a vacuum desiccator. When the infineeter hydrochloride separated as an oil, anlydrons ether was added and the evaporation was repeated. This usually cansed the oil to crystallize. When this failed crystallization was induced by scratching with a glass rod or allowing the oil to stand overnight at ambient temperature in a vacuum desiccator.

Methods Used to Prepare the Compounds Listed in Table I. Method A.—To a stirred mixture of 0.10 mole of ethyl iminoester hydrochloride and 250 ml of absolute ethanol was added, dropwise, over a period of 0.5 hr, a solution of the β -aminoethylhydrazine in 50 ml of absolute ethanol. The mixture was stirred and refluxed for 6 hr, concentrated *in varuo*, cooled, dibited with 150 ml of ice water, acidified to approximately pH 2 with HCL and washed twice with 150-ml portions of CH₂Cl₂. The

washed acidic, aqueous solution was made strongly basic with cold aqueous NaOH and extracted CHCl₃. The washed (water) and dried (MgSO₄) chloroform solution was evaporated *in vacuo*, and the residue was purified either by distillation or crystallization.

Method B is identical with method A except that chloroform is used as the reaction solvent instead of absolute ethanol.

Method C.—A mixture of 0.10 mole of orthoester, 0.10 mole of β -aminoethylhydrazine, and 50 ml of ethyl acetate was refluxed for 20 hr and then distilled *in vacuo*.

Method D is identical with method C except that $CHCl_3$ is used as the reaction solvent instead of ethyl acetate.

Method E is the same as method C except that absolute ethanol is used as the reaction solvent instead of ethyl acetate.

Method F is the same as method B except that the methyl iminoester hydrochloride is used instead of the ethyl iminoester hydrochloride.

Method G is the same as method F except that methanol is used as the reaction solvent instead of CHCl_3 .

1,4,5,6-Tetrahydro-*as*-triazine.—A mixture of 30 g (0.40 mole) of β -aminoethylhydrazine and 80 g (0.54 mole) of ethyl orthoformate was heated at reflux temperature for 24 hr and then distilled, bp 98-100° (0.3 mm), yield 20%. Anal. Calcd for C₃H₇N₃: C, 42.34; H, 8.29; N, 47.37. Found: C, 41.82; H, 8.57; N, 47.27.

1,4,5,6-Tetrahydro-as-triazine monopicrate was prepared in ethanol and after recrystallization from water; mp 136–138°. Anal. Calcd for $C_9H_{10}N_6O_7$: C, 34.40; H, 3.21; N, 26.75. Found: C, 34.61; H, 3.47; N, 26.95.

Acknowledgment.—The authors are grateful to Dr. J. Heeschen of the Chemical Physics Laboratory for recording and interpreting the nmr spectra.

The Synthesis and Pharmacology of ¹³¹I-Labeled 1,10-Bis(trimethylammonium)-5-chloro-6-iodo-5-decene Dihalide and Related Neuromuscular Blocking Agents¹

OVE A. NEDERGAARD² AND DERMOT B. TAYLOR

Department of Pharmacology, School of Medicine, and Brain Research Institute, University of California, Los Angeles, California 90024

Received March 26, 1966 Revised Manuscript Received November 14, 1966

Synthesis of ¹³¹I-labeled 1,10-bis(trimethylammonium)-5-chloro-6-iodo-5-decene dihalide has been accomplished by several different methods. It is a stable depolarizing neuromuscular blocking agent. Some related unsaturated diquaternary amines of interest in structure–activity relationships were also prepared.

Stable depolarizing neuromuscular blocking agents such as 1,10-bis(trimethylammonium)decane dihalide [decamethonium (I)] characteristically produce a dual block on isolated nerve-muscle preparations.³ It has been suggested⁴ that the second phase of this biphasic block is related to the penetration of the drug into the skeletal muscle fiber. This hypothesis can be studied most conveniently by using labeled depolarizing drugs.

Decamethonium (I) labeled with N-methyl-¹⁴C has been prepared.⁵ However, labeling with ¹³¹I

$$({}^{14}\mathrm{CH_3})_3\mathrm{N}^+(\mathrm{CH_3})_{10}\mathrm{N}^+({}^{14}\mathrm{CH_3})_3$$
 I

would be advantageous, since γ -emitting isotopes permit easier and more accurate counting than is possible with β emitters. Furthermore, the counting is simplified since no disintegration of the tissue or extraction

$$\begin{array}{ccc} {}^{1_{31}}\mathrm{ICH}_{2}\mathrm{CH}_{2} & \mathrm{CH}_{2}\mathrm{CH}_{2}{}^{1_{31}}\mathrm{I} \\ & | & | \\ \mathrm{(CH}_{3})_{2}\mathrm{N}^{+}(\mathrm{CH}_{2})_{10}\mathrm{N}^{+}(\mathrm{CH}_{3})_{2} \\ & \mathrm{II} \end{array}$$

it is difficult to obtain pure iodocholinium by the method employed; the product appears to be unstable and a biphasic block is not observed consistently. These difficulties have been overcome largely by the synthesis of 1,10-bis(trimethylammonium)-5-chloro-6-iodo-5-decene dihalide [TID-5^{1d} (III)].

Some unsaturated diquaternaries related to I, which are of interest in structure-activity studies, have been prepared also. These compounds and some of the intermediaries can serve as a convenient starting material for specific tritium labeling of neuromuscular blocking agents.

Partial hydrogenation of 1,10-dichloro-5-decyne (IV)⁷ gave 1,10-dichloro-5-decene (V), which, when heated with anhydrous trimethylamine, gave 1,10-bis(trimethylammonium)-5-decene dichloride (VI). Addition of iodine monochloride to VI in glacial acetic acid or methanol-dimethylformamide failed to give the expected 1,10-bis(trimethylammonium)-5-chloro-6-io-
