## Irreversible Enzyme Inhibitors. 197.†,‡ Water-Soluble Reversible Inhibitors of Dihydrofolate Reductase with Potent Antitumor Activity Derived from 4,6-Diamino-1,2-dihydro-2,2-dimethyl-1-phenyl-s-triazine

B. R. Baker § and Wallace T. Ashton\*

Department of Chemistry, University of California at Santa Barbara, Santa Barbara, California 93106. Received September 26, 1972

A series of 39 derivatives of the title compound was prepared with the object of optimizing reversible inhibition of dihydrofolate reductase and cell membrane transport while achieving sufficient water solubility for effective intravenous administration. Four compounds which met all the criteria were selected for antitumor testing *in vivo*. Of these, three showed excellent activity against Walker 256 ascites, intramuscular Walker 256, and Dunning leukemia ascites in the rat. Overall, the most active comcompound *in vivo* was 1-[3-chloro-4-(*m*-dimethylcarbamoylbenzyloxy)]phenyl-4,6-diamino-1,2-dihydro-2,2-dimethyl-s-triazine ethanesulfonate (36).

An earlier report from this laboratory demonstrated that several potent reversible as well as irreversible inhibitors of dihydrofolate reductase are highly effective in promoting cures# of the Walker carcinosarcoma 256 and Dunning leukemia tumor systems in the rat when given by intraperitoneal injection.<sup>2</sup> From a clinical standpoint it would be desirable to administer such a compound by intravenous infusion, so that administration could be discontinued at once should toxicity develop. Unfortunately, the inhibitors which have shown the greatest effectiveness in vivo2 lack sufficient aqueous solubility. Solubilities of representative compounds 1-4 are given in Table I. Even the most soluble of these (3), a potent agent against Walker 256 ascites when administered intraperitoneally, was not soluble enough to achieve a toxic dose intravenously.3 It was proposed that insufficient solubility in body fluids hindered the distribution of 3, thus accounting for its substantially lower activity against intramuscular Walker 256 when given intraperitoneally.3

Consequently, a study was undertaken to prepare a series of reversible inhibitors of dihydrofolate reductase with the

charged substituents, were avoided because sufficient lipophilicity must be maintained for membrane transport. It was theorized that introduction of semipolar groupings could increase solubility without necessary loss in transport. Another factor to consider is that transport of inhibitors of this type is very sensitive to steric and conformational effects; compounds of comparable polarity can differ dramatically in their relative abilities to penetrate the cell membrane

Among the structural modifications tested were variation of the acyl and amino moieties of the amide side chain, presence or absence of the 3-chloro substituent, and placement of the amide moiety meta to the triazine ring. The biological results of this study are discussed below.

In Vitro Evaluation. Thirty-nine candidate reversible inhibitors of dihydrofolate reductase were prepared as ethanesulfonate salts and evaluated for inhibition of the Walker 256 enzyme, inhibition of growth of L1210 mouse leukemia cell culture, and solubility in H<sub>2</sub>O (Table II).

Compounds of the first series 5-10 were analogs of 2 in which substituents on the amide nitrogen were varied. All of these compounds were good reversible inhibitors. The N-methylated analog 5 of 2 had good solubility but showed

very poor activity against the L1210 cell culture. Of the dialkylamides tested, 7 and 10 had ED<sub>50</sub> values substantially better than that of 2 (0.6  $\mu$ M);<sup>2</sup> 8 and 9 were comparable to 2. The diethylamide 7, which had the lowest ED<sub>50</sub> in this series, was also the least soluble.

The next series 11-17 was similar to the first, except that the 3-chloro substituent was absent. This modification led to increased solubility but also to poorer cell culture potency and, in most cases, somewhat poorer enzyme inhibition. The highly soluble morpholino derivative 15 was surprising, in that its  $ED_{50}$  was comparable to that of 2 and the corresponding 3-chloro analog 8.

Inhibitors 18-21 had the oxyacetamide side chain meta to the triazine ring. Compounds 18 and 19 were only fair reversible inhibitors; 20 and 21 were exceptionally poor. Each of these compounds demonstrated only weak activity against the L1210 cell culture. Of some interest is the extraordinarily low solubility of 18.

Compounds 22-26, containing a 4-acetamide grouping, were fair to good reversible inhibitors and in general quite soluble. However, none of these inhibitors had a sufficiently low  $ED_{50}$ . The related acetonitrile derivative 27 had properties very similar to those of the dimethylcarboxamide 23.

Several triazines containing a propionamide side chain (28-33) were also prepared. These showed good reversible binding, and several had excellent solubility. With the exception of 33, these compounds had poor  $\mathrm{ED}_{50}$ 's. The ineffective transport of 28 could be attributed to the rigid, planar bulk of the N-methylanilide moiety. It was hypothesized that the N-benzyl-N-methylamide 33 might show better transport as a result of its greater conformational flexibility. This was borne out by the fact that the  $\mathrm{ED}_{50}/\mathrm{I}_{50}$  ratio of 33 was 300-fold better than that of 28. (Surprisingly, a similar modification in the acetamide series led to no improvement; cf. 26 and 22.) Unfortunately, the solubility of 33 was too low to be useful.

$$NH_{2}$$

$$NN_{N}$$

$$NMe_{2}$$

$$OCH_{2}$$

$$CONH$$

$$SO_{2}F$$

The exceptionally potent in vitro activity of 44 (ED<sub>50</sub> =  $0.0007 \,\mu M$ , ED<sub>50</sub>/I<sub>50</sub> =  $0.01)^8$  raised the question of whether a reversible analog of this compound could be sufficiently soluble while retaining good transport. A series of related

amides 34-40 was thus prepared. The unsubstituted anilide 34, besides being an excellent reversible inhibitor, was found to be quite potent against the L1210 cell culture. Although its solubility of 15 mg/ml was not high enough, the prospects for developing more soluble analogs were encouraging. N-Methylation, which in several other instances increased solubility, in this case (35) resulted in a dramatic decrease in solubility; transport was unchanged. The dimethylamide 36, as hoped, was very soluble, and although transport was impaired, the ED<sub>50</sub> was still comparable to that of 2. The diethylamide 37 was near the minimum acceptable solubility, but it was 1000-fold more inhibitory against the L1210 cell culture than 36. The morpholine amide 38 also demonstrated excellent cell culture potency and good solubility. Whereas the pyrrolidine and piperidine amides 39 and 40 were comparable in activity to 38, they were poorly soluble.

The unsubstituted 3-chloro-4-benzyloxy compound 41 was evaluated for comparison purposes. As expected, it was very insoluble and was actually less effective against the L1210 cell culture than several of the amide derivatives. It is of interest that the corresponding 4-benzyloxy compound without the 3-chloro substituent is reported to have antimalarial, anthelmintic, antibacterial, and antiviral activity. Substitution of a dimethylsulfonamide group in the para position of 41 to give 42 had little effect. The excellent

solubility of 27 suggested that the introduction of cyano groups as solubilizing substituents should be investigated further; with this in mind, the *m*-cyano derivative 43 of 41 was synthesized. Although the solubility of 43 was disappointing, its potency against the L1210 cell culture  $(ED_{50} = 6 \times 10^{-6} \mu M, \text{ confirmed})$  is noteworthy.

Arbitrary criteria were set in order to evaluate the inhibitors. According to these guidelines, to be worthy of in vivo testing the compound should have  $I_{50} < 0.1 \ \mu M$ ,  $ED_{50} < 2 \ \mu M$ , and solubility  $> 50 \ \text{mg/ml}$  of  $H_2O$ . Of the 39 triazines studied, 28 met the  $I_{50}$  requirement, 17 met the  $ED_{50}$  requirement, and 23 met the solubility criterion. Five inhibitors (8-10, 15, 36) met all three conditions. Four representative compounds were ultimately chosen for in vivo investigation. Inhibitors 8 and 15 provided a comparison for assessing the effect of the 3-chloro substituent. The other compounds submitted for in vivo testing were 36 and its analog 37. Although the solubility of 37 was somewhat less than desired, its selection was warranted on the basis of its outstanding in vitro activity.

In Vivo Evaluation. The four selected triazines (8, 15, 36, 37) were administered intraperitoneally on days 1-9 to rats bearing the Walker 256 ascites tumor (Table IIIA). All

of the compounds were effective in promoting cures over a range of dose levels, the order of activity being  $36 \ge 37 > 8 \ge 15$ . A comparison of 8 and 15 indicates that whereas these two inhibitors were virtually indistinguishable in vitro, the 3-chloro substituent of 8 is markedly activity-enhancing in vivo. It is also of interest that 36 and 37 are active over approximately the same range of dosages, even though 37 was 1000-fold more potent than 36 in the L1210 cell culture assay.

In delayed treatment studies on Walker 256 ascites, compounds 36 and 37 given intraperitoneally on days 5-13 produced, respectively,  $\frac{4}{6}$ - $\frac{6}{6}$  and  $\frac{3}{6}$ - $\frac{6}{6}$  45-day survivors over a range of 0.8-12.5 mg/kg/day.\*\*

As could be predicted, the inhibitors were less effective when administered intravenously against Walker 256 ascites than when given by the localized intraperitoneal route (Table IIIB). Still, compounds 8, 36, and 37 were capable of producing some cures under these conditions, although the curative dose range was narrow and, at least in the case of 36 and 37, bordered on being toxic.

The ability of the compounds to reach a tumor target in

<sup>\*\*</sup>Median survival time of untreated rats was 9.0 days.

and triazinyl junction = 1. bYield of analytically pure material except where indicated. cAnal. C, H, N. d2-Methoxyethanol used as hydrogenation solvent. Recrystallized from i-PrOH-H<sub>2</sub>O. MeOH used as hydrogenation solvent. Recrystallized from i-PrOH-H<sub>2</sub>O. MeOH used as hydrogenation solvent. Recrystallized from i-PrOH-petroleum ether (bp 65-110°). Recrystallized from i-PrOH. MeOH added to condensation reaction mixture as cosolvent. p-Nitrocinnam-amides reduced in presence of EtSO<sub>3</sub>H. MDMF was added to the condensation reaction mixture as cosolvent and removed by evaporation in vacuo when reaction was complete; after addition of fresh Me<sub>2</sub>CO, the mixture was stirred at reflux until product precipitated. THF used as hydrogenation solvent. Analytical sample had mp 214-215° dec. PAnalytical sample had mp 199-201° dec.

sufficient concentration via the blood stream was also an important factor when tested by the intraperitoneal route against intramuscular Walker 256 in the leg of the rat (Table IIIC). Inhibitors 8, 36, and 37 were effective in producing complete or nearly complete inhibition of tumor growth, with 36 and 37 showing the greatest activity.

The pattern of activity against Dunning leukemia ascites in the rat closely paralleled that against Walker 256 ascites when the inhibitors were administered intraperitoneally. The order of activity was  $36 > 37 > 8 \gg 15$ , with 36 producing a substantial fraction of 40- or 45-day survivors at doses of 0.2-6.25 mg/kg/day. ††

In contrast to the high order of activity shown against the Walker 256 and Dunning leukemia tumor systems, the inhibitors were inactive against L1210 mouse leukemia. Compound 36 also proved ineffective when screened against a variety of other mouse tumors, including P388 leukemia, Lewis lung carcinoma, and B16 melanocarcinoma. The

††Administered on days 1-9; median survival time of controls was 6.0 days.

reasons for the lack of activity in these mouse tumor systems are not understood.

It is presumed that "nonclassical" antifolates such as 36 enter cells by passive diffusion rather than active transport. The exceptional activity of 36 and related compounds against Walker carcinosarcoma 256 gives support to this assumption. Walker 256 apparently has a poor active transport system for folic acid and is thus resistant to the "classical" folate antagonist, amethopterin, which is dependent on active transport for cellular uptake. 10,11 The poor response to amethopterin of certain leukemias in mice 12,13 and in man 14,15 has also been correlated, at least in part, with impaired transport of the drug. The potential therapeutic value of a potent nonclassical antifolate in such cases has been discussed elsewhere. 3

## **Experimental Section**

All analytical samples gave combustion values for C, H, and N within 0.4% of theoretical values. These microanalyses were performed by Galbraith Laboratories, Knoxville, Tenn. Each compound

had ir and uv spectra in agreement with its assigned structure; purity was confirmed by tlc using Brinkmann silica gel GF. Melting points are uncorrected and were taken in capillary tubes on a Mel-Temp block.

 $\alpha$ -(2-Chloro-4-nitrophenoxy)-m-toluic acid, a precursor for the synthesis of inhibitors 34-40, has already been described. The base-catalyzed ester hydrolysis was modified by using aqueous DMSO in place of aqueous MeOH. In this medium the reaction was essentially complete in 1 hr at  $80-85^{\circ}$ , with yields of up to 79% being obtained.

N-Arylamides (Method A). Conversion of the nitro-substituted acid to the acid chloride and condensation with the arylamine in toluene at reflux was performed as previously described. Compounds prepared in this manner are listed in Table IV.

N,N-Dialkylamides (Method B). N,N-Diethyl-p-nitrophenoxyacetamide (54). A mixture of 983 mg (5.0 mmol) of p-nitrophenoxyacetic acid, 4 ml of SOCl<sub>2</sub>, and 8 ml of C<sub>6</sub>H<sub>6</sub> was stirred under reflux for 4.5 hr, then cooled, and spin evaporated in vacuo. The residual oil was dissolved in 8 ml of CH<sub>2</sub>Cl<sub>2</sub> and cooled in an ice bath. The cold solution of acid chloride was added slowly with stirring to a chilled solution of 802 mg (11 mmol) of Et<sub>2</sub>NH in 10 ml of CH<sub>2</sub>Cl<sub>2</sub>. Stirring was continued under protection from moisture for 10 min, while maintaining the temperature below 10°. Next, the mixture was diluted with 35 ml of CH<sub>2</sub>Cl<sub>2</sub> and shaken with 50 ml of H<sub>2</sub>O. The organic layer was washed with 1% HCl (1 × 50 ml) and 5% Na<sub>2</sub>CO<sub>3</sub> (3 × 50 ml), then dried (MgSO<sub>4</sub>), and evaporated to dryness. Upon trituration with petroleum ether (bp 30-60°) and scratching, the residual oil solidified. Recrystallization from EtOAcpetroleum ether (bp 65-110°) afforded 1.01 g (80%) of very pale yellow crystals, mp 64-65° (tlc in 1:1 EtOAc-petroleum ether). Anal. (C<sub>12</sub>H<sub>16</sub>N<sub>2</sub>O<sub>4</sub>) C, H, N. For additional compounds prepared by this method, see Table IV

2-Chloro-4-nitrophenyl Benzyl Ethers (80-82) (Method C). The  $\alpha$ -bromination of substituted toluenes and subsequent reaction with 2-chloro-4-nitrophenol were carried out in the usual manner. Physical properties of the ethers are given in Table IV.

The reaction of N,N-dimethyl-p-toluenesulfonamide with NBS was complicated by side reactions, resulting in a low overall yield of 81. A possible alternative route to compound 76, involving  $\alpha$ -bromination of N,N-diethyl-m-toluamide followed by reaction with 2-chloro-4-nitrophenol, was unsuccessful on account of the mixture of products formed when the diethyltoluamide was treated with NBS.

4,6-Diamino-1,2-dihydro-2,2-dimethyl-s-triazine Ethanesulfonates (5-43) (Methods D-F). The nitro intermediates 45-82 were hydro-

genated over PtO<sub>2</sub> (Method D), Raney Ni (Method E), or 5% Pd/C (Method F); the resulting crude amines were condensed with cyanoguanidine and Me<sub>2</sub>CO<sup>16</sup> in the presence of EtSO<sub>2</sub>H as previously described.<sup>8</sup> Compounds obtained by this procedure are shown in Table V.

Acknowledgments. We wish to thank Dr. Florence White of Drug Research and Development, National Cancer Institute, for supplying the cell culture and in vivo testing data. In addition, we wish to acknowledge the assistance of Mrs. Julie Beardslee and Mrs. Janet Wood in performing the enzyme assays.

## Studies on Psychotropic Drugs. 18. Synthesis and Structure-Activity Relationships of 5-Phenyl-1,3-dihydro-2*H*-thieno[2,3-*e*][1,4]diazepin-2-ones

Michio Nakanishi,\* Tetsuya Tahara, Kazuhiko Araki, Masami Shiroki, Tatsumi Tsumagari, and Yukio Takigawa Research Laboratories, Yoshitomi Pharmaceutical Industries, Ltd., Yoshitomi-cho, Chikujo-gun, Fukuoka-ken, Japan. Received July 3, 1972

A series of 5-phenyl-1,3-dihydro-2*H*-thieno [2,3-*e*][1,4]diazepin-2-ones was synthesized and evaluated for CNS depressant activity. Structure-activity relationships were discussed.

It is well known that a number of 1,4-benzodiazepine derivatives show potent antianxiety activity.<sup>2</sup> From the standpoint of bioisosterism, we synthesized a series of thienodiazepine derivatives, which have a thieno moiety in place of the benzo moiety of the benzodiazepine ring system, starting from readily obtainable 2-amino-3-benzoylthio phenes according to Gewald, et al.<sup>3</sup> 5-Phenyl-1,3-dihydro-2H-thieno [2,3-e] [1,4] diazepin-2-ones thus synthesized were pharmacologically screened and, as was expected, several compounds in this series (84, 109, and 110) were found to show higher CNS depressant activity than CDP and not less than DZP. These compounds were observed to have similar low toxicity to CDP and DZP.

Chemistry. The synthetic route to thienodiazepine derivatives is shown in Scheme I.

Starting materials, 2-amino-3-benzoylthiophenes (I), were

prepared by the reaction of  $\omega$ -cyanoacetophenone with aldehyde or ketone and sulfur in the presence of catalytic amine (Table I). Compounds of type I were converted into corresponding aminoacetamide derivatives IV via methods A and B, respectively.

Method A. Benzyloxycarbonylaminoacetamide intermediates II were synthesized by condensation of I with benzyloxycarbonylaminoacetyl chloride in CHCl<sub>3</sub> at low
