Synthesis of Analogs of 6-Arylthio-, 6-Arylsulfinyl-, and 6-Arylsulfonyl-2,4-diaminoquinazolines as Potential Antimalarial Agents†

John B. Hynes,* Wallace T. Ashton, Hugh G. Merriman, III, and Flornoy C. Walker, III

Department of Pharmaceutical Chemistry, College of Pharmacy, Medical University of South Carolina, Charleston, South Carolina 29401. Received February 11, 1974

Numerous 6-arylthio-, 6-arylsulfinyl-, and 6-arylsulfonyl-2,4-diaminoquinazolines have been synthesized, many of which possess potent activity against both sensitive as well as drug-resistance strains of plasmodia. The present study describes the preparation of 23 analogs involving modifications of the substituents in the 2 and/or 4 positions of the quinazoline nucleus. Only one of the new compounds, 2-amino-4-hydroxy-6-(2-naphthylsulfonyl)quinazoline (16a), displayed curative activity against *Plasmodium berghei* in mice and was substantially less potent than its 4-amino counterpart 2a.

The discovery of the antiprotozoan activity of 2,4-diaminoquinazolines as exemplified by **1a,b**^{1,2*} has led to the synthesis of a wide variety of compounds of this class.³⁻⁵

Of these, the most promising potential antimalarial agents are certain 6-arylthio-2,4-diaminoquinazolines and their sulfinyl and sulfonyl analogs. For example, **2a,b** are currently undergoing clinical trials since they have shown efficacy against drug-resistant strains of plasmodia.⁶ Al-

though the mechanism of action of these compounds has not been fully elucidated, it is noteworthy that a variety of compounds of this type are effective inhibitors of dihydrofolate reductase isolated from either rat liver or *Streptococcus faecium* (in vitro).[‡]

In a recent communication, we described the preparation of a series of isomers and analogs of **2a,b** in which the aromatic moiety was attached to the 5 position of the quinazoline nucleus by a suitable spacer.⁷ None of these displayed any significant activity against *Plasmodium berghei* in mice. However, several were found to be moderately potent inhibitors of rat liver dihydrofolate reductase.⁷ The present study was initiated in order to determine the effect of altering the groups attached to the 2

and 4 positions of the quinazoline ring upon antimalarial activity. It was hoped that configurations such as 2-amino-4-hydroxy or 2-amino-4-mercapto would confer greater inhibitory action upon tetrahydrofolate-dependent enzymes such as thymidylate synthetase. Inhibitors of this type could prove to be of value when used in conjunction with 2,4-diaminoquinazolines such as **2a,b**. Physical data for the new compounds synthesized are summarized in Table I.

Chemistry. The 2-amino-4-hydroxyquinazolines **14a,b**, **15**, and **16a,b** were prepared by the standard acid-catalyzed hydrolysis of the corresponding 2,4-diamino compounds.^{7,§} Two of the products **14a** and **16a** were subsequently reacted with P₂S₅ in pyridine to afford the corresponding 2-amino-4-mercapto analogs **7** and **8**. Acylation of **16a** with acetic anhydride or trichloroacetic anhydride in pyridine yielded the 2-acetamido derivatives **17** and **18**, respectively.

Synthetic routes to the remaining analogs of 6-arylthio-2,4-diaminoquinazolines are summarized in Scheme I. Standard cyclization procedures employing urea, thiourea, potassium ethyl xanthate, or formamide were employed to prepare compounds **13a,b**, **5**, **9**, and **19a,b**, respectively. The key 5-arylthioanthranilonitriles **3a,b** were prepared according to methods developed by Elslager and coworkers.^{§,=} Similarly, the reaction of ethyl 2-amino-5-(2-naphthylthio)benzoate (4)^{§,**} with thiourea and urea yielded **11** and **12**. Oxidation of the 4-aminoquinazolines **19a,b** with 30% H₂O₂ or triethylenediamine dibromide yielded the sulfoxides **20a,b**, while the corresponding sulfones **21a,b** were obtained with excess permanganate in aqueous AcOH.⁷

Alkylation of 4-amino-2-mercapto-6-(2-naphthylthio)quinazoline (**5**) with MeI in the presence of base afforded the 2-methylmercapto derivative **6**. The reaction of the 4-amino-2-hydroxyquinazoline **13a** with P₂S₅ was attempted as an alternate route to compound **5**. However, in this case the 4-amino group was preferentially displaced yielding **10**. Proof of this configuration was provid-

ed by the synthesis of its isomer 11 which had different physical and spectroscopic properties.

Biological Results. Each of the compounds presented in Table I was tested against *P. berghei* in mice.^{8,††} Data for compounds showing significant activity are summarized in Table II. 2-Amino-4-hydroxy-6-(2-naphthylsulfanyl)quinazolin-5(1H)-thione (16a) was curative at dose levels of 160 mg/kg and above and is, therefore, significantly less potent than its 4-NH₂ counterpart 2a.⁶ The modest activity of the 2-trichloroacetyl derivative 18 may be due to slow *in vivo* hydrolysis to 16a since the corresponding acetyl

††Testing of all compounds was carried out by Dr. L. Rane of the University of Miami.

compound 17 was not active. Two other 2-amino-4-hydroxyquinazolines 14a and 15 showed slight activity, while the 3,4-dichlorophenylthio 14b and 3,4-dichlorophenylsulfonyl 16b analogs were not effective. It is apparent from this work that as in the case of pyrimidines such as pyrimethamine, the 2,4-diamino configuration affords optimal antimalarial action for quinazolines bearing a large hydrophobic group in position 6.

Experimental Section

All analytical compounds gave combustion values for C, H, and N (and S, where noted) within $\pm 0.4\%$ of the theoretical values. Melting points were determined with a Fisher-Johns or a Mel-Temp apparatus and are uncorrected. All compounds had ir spec-

tra (Beckman IR-8) in agreement with their assigned structures and appeared free of significant impurities by tlc (Gelman SAF). Examples for each of the synthetic procedures designated in Table I are presented below with the exception of F, H, J, and K which have been described in detail in a recent paper.⁷

Method A. 5 and 11. A mixture of 5.53 g (0.02 mol) of 2-amino-5-(2-naphthylthio)benzoxazole (3a), 4.57 g (0.06 mol) of thiourea, and 11 ml of tetramethylene sulfone was heated at ca. 200° for 1.5 hr. Precipitation of the product was effected by scratching and allowing the solution to stand at room temperature for 48 hr. The mixture was filtered after the addition of 5 ml of tetramethylene sulfone and the resulting solid was washed carefully with MeOH. Recrystallization from pyridine, washing the solid with MeOH, and vacuum drying at 100° afforded 1.0 g (15%) of 5 as a yellow solid, mp 298–299° dec (tlc in 1:4 DMF-MeCN).

Method B. 4-Amino-2-methylmercapto-6-(2-naphthylthio)quinazoline (6). To a stirred mixture of 1.7 g (0.005 mol) of 5 and 0.57 g (0.01 mol) of KOH in 11 ml of H₂O was added 1.44 g (0.01 mol) of MeI. An immediate reaction ensued and after 1 hr the product was separated by filtration, washed with H₂O and MeOH, and then vacuum dried over P₂O₅. There was obtained 1.5 g (86%) of a white amorphous solid, mp 226–228° (tlc in 1:9 DMF-MeCN).

Method C. 7, 8, and 10. Each of these compounds was prepared by the reaction of excess P₂S₅ (purified by Soxhlet extraction with CS₂) with the appropriate quinazoline (14a, 16a, and 13a, respectively) in pyridine at 75–80°. In the case of 10, however, a 19-hr reflux was employed while crude 7 was initially purified by formation of a phosphate salt with 85% H₃PO₄ in 2-methoxyethanol.

A mixture of 5.0 g (0.0143 mol) of 16a, 7.5 g of P₂S₅, and 125 ml of pyridine was stirred at 75–80° under protection from moisture and a continuous N₂ purge for 23 hr. The tlc indicated incomplete reaction so 3.75 g of P₂S₅ was added and the heating continued for an additional 3 hr. The two-phase mixture was added gradually to 1250 ml of stirred, boiling H₂O. After boiling for 2 hr, the mixture was filtered while hot and the filter cake washed with H₂O. Two recrystallizations (cf. Table I) afforded 2.93 g (56%) of 8 as yellow crystals after vacuum drying at 100°, mp 320° dec (tlc in 1:12 DMF-EtOAc).

The hydrochloride salt was prepared by suspending 1.68 g (0.0046 mol) of 8 in 150 ml of 2-methoxyethanol and admitting HCl gas until complete dissolution had occurred. After cooling to 0°, the solution was saturated with HCl and the product precipitated by gradual addition of ice. The solid was collected on a filter, washed successively with H₂O, MeOH, and Me₂CO, and then vacuum dried over P₂O₅. There was obtained 1.25 g (68%) of orange solid, mp >275° dec (tlc in 1:12 DMF-MeCN).

Method D. 2,4-Dimercapto-6-(2-naphthylthio)quinazoline (9). The following is a modification of the general procedure of Kabbe.⁹ A solution of 2.21 g (0.008 mol) of 2-amino-5-(2-naphthylthio)benzoxazole (3a) and 2.56 g (0.016 mol) of potassium

ethyl xanthate in 12 ml of DMF was stirred at reflux for 1 hr. Next, the mixture was diluted with ca. 30 ml of DMF, cooled, and acidified with glacial AcOH. The product was precipitated by gradual addition of H₂O and then isolated by filtration and washed with H₂O, MeOH, and Et₂O. Recrystallization gave 2.37 g (84%) of fine yellow crystals, mp 305–307° dec. with slight preliminary softening (tlc in EtOAc).

Method E. 12 and 13a,b. The fusion of ethyl 2-amino-5-(2-naphthylthio)benzoate** (4) with excess urea was conducted in tetramethylene sulfone at ca. 195° for 1.75 hr to yield 12. Compounds 13a,b were prepared similarly as exemplified below.

A mixture of 4.23 g (0.0143 mol) of 2-amino-5-(3,4-dichlorophenyl)thio]benzoxazole (3b) and 4.50 g (0.075 mol) of urea was heated at ca. 180° for 5 hr. The resulting solid was extracted twice with boiling H₂O, isolated by filtration, and vacuum dried over P₂O₅. Recrystallization produced 1.3 g (27%) of 13b as a yellow crystalline solid, mp 396–398° dec, after vacuum drying at 100°.

Method F. 14a,b, 15, and 16a,b. This method involved refluxing the requisite 2,4-diaminoquinazoline in a 2:1 mixture of diglyme and 2N HCl for 4–6 hr.⁷

Method G. 17 and 18. Compound 17 was prepared by heating 16a with a large excess of Ac₂O in pyridine at reflux for 1 hr. Compound 18 was prepared at ambient temperature as follows. To a stirred suspension of 3.86 g (0.011 mol) of 16a in 50 ml of acetone were added 2.08 g (0.0264 mol) of pyridine and 7.48 g (0.0242 mol) of (CCl₃CO)₂O. The resulting solution was stirred for 3.75 hr and then diluted with 150 ml of MeOH. The solid which separated was isolated by filtration and washed with MeOH and then Et₂O yielding 4.2 g (77%) of a white solid, mp 282–283°, with preliminary softening (tlc in EtOAc).

Method H. 19a,b. This procedure involves heating the requisite anthranilonitrile with excess formamide.⁷

Method I. 4-Amino-6-(2-naphthylsulfinyl)quinazoline (20a). To a stirred solution of 2.8 g (0.009 mol) of 19a in 44 ml of glacial AcOH was added 29.4 ml (0.294 mol) of 30% H₂O₂. After 3.5 hr the reaction mixture was poured into 44 ml of 50% NaOH containing an equal amount of ice which resulted in precipitation of the product. The solid was separated by filtration, washed with H₂O, and then recrystallized from 2-methoxyethanol. After vacuum drying there was produced 1.3 g (44%) of yellow crystals, mp 294–297° (tlc in 1:1 DMF-MeCN).

Method J. 4-Amino-6-[(3,4-dichlorophenyl)thio]quinazoline (20b). This oxidation was conducted using N(CH₂CH₂)₃N·2Br₂¹⁰ in 70% AcOH.⁷

Method K. 21a,b. Compounds 19a,b were oxidized by the recently described procedure using KMnO₄.⁷
