Anthraquinones substituted at the 2 position with a basic side chain were prepared, and their binding to DNA was evaluated. All compounds showed an intercalative mode of binding to DNA; 1,4-dihydroxy derivatives bound more strongly than 1-hydroxy or nonhydroxylated compounds. Greatest DNA-binding activity was found where there were five atoms between the anthraquinone ring and the basic nitrogen.

Doxorubicin (1) has a wide spectrum of antitumor ac-

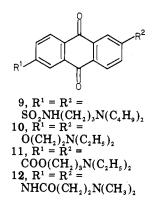

### doxorubicin (1)

tivity<sup>1</sup> but is cardiotoxic and causes bone marrow depression.<sup>2</sup> Although alternative natural and semisynthetic derivatives have been sought<sup>3-6</sup> and synthetic routes developed,<sup>7</sup> less attention has been directed toward totally synthetic analogues. Doxorubicin could act either by direct<sup>8</sup> or indirect<sup>9</sup> action on DNA; in either case the anthraquinone unit is central to the action. Hence, anthraquinones with amino-substituted side chains have been synthesized,<sup>10-13</sup> and one compound, 2, is in clinical trial.<sup>14</sup>

Generally these compounds have peri substituents, whereas doxorubicin can be regarded as having substituents at the 2 and 3 positions. Although 2-substituted anthraquinones are a closer analogy, few have been evaluated to date: 3-5are stated to bind to DNA,<sup>15</sup> and 6 and 7 have been shown to inhibit cellular nucleic acid synthesis.<sup>16</sup> However, compounds with an aromatic ring in the side chain are inactive,<sup>16,17</sup> and 8 is inactive against P-388 lekemia "in vivo".<sup>18</sup> Biologically active, nonhydroxylated, 2-substituted anthraquinones are also known, for example, 9-11

are interferon inducers<sup>19,20</sup> and compounds such as 12 have antiprotozoal activity,<sup>21</sup> and 2-methylanthraquinone de-

rivatives substituted with a good leaving group have been prepared, such that "in vivo" reduction will generate the reactive anthraquinone methide moiety.<sup>22</sup> Here the acetamide and carboxamide derivatives 13–24 (Table I) have been prepared and evaluated.

Syntheses. 1,4-Dihydroxy-9,10-dioxoanthracene-2acetamide Hydrochlorides 13-17. 1,4-Dihydroxy-9,10dioxoanthracene-2-acetic acid (25) was prepared by Mar-

schalk reaction<sup>23</sup> of sodium oxoethanoate with the leuco derivative of 1,4-dihydroxyanthracene-9,10-dione. The intramolecular lactone 26 was prepared using DCCI and

reacted with the appropriate amines to give the free bases (yields between 30 and 70%), which were converted to their hydrochloride salts 13-17.

1-Hydroxy-9,10-dioxoanthracene-2-carboxamide Hydrochlorides 18-21. 2-Methyl-1-nitroanthracene-9,10-dione (from 2-methylanthracene-9,10-dione<sup>24</sup>) was oxidized to 1-nitro-9,10-dioxoanthracene-2-carboxylic acid.<sup>25</sup> Borohydride reduction,<sup>26</sup> followed by diazotization and hydrolysis, gave 27. The free bases of 18-21 were then prepared in 25-80% yields from the appropriate amines using DCCI and N-hydroxysuccinimide in dry THF and converted to their hydrochloride salts.

9,10-Dioxoanthracene-2-carboxamide Hydrochlorides 22-24. Chromic acid oxidation of 2-methylanthracene-9,10-dione gave the parent acid. This was then converted to the acid chloride and reacted with the appropriate amines to give the free bases, which were converted to the salts 22-24.

**DNA-Binding Studies.** All compounds showed bathochromic and hypsochromic shifts on binding to DNA with a clear isosbestic point, in the visible region of the spectrum (studies on 13–17 and 22–24 were carried out at pH 7.0, whereas those on 18–21 were carried out at pH 5.8 since the phenolic group of the latter compounds has a  $pK_a$ of 7.2). For 13–17 the shifts in  $\lambda_{max}$  were between 21 and 29 nm (with decreases in extinction of between 25 and 35%), for 18–21 the shifts were between 4 and 6 nm (with decreases of 14–30%), and for 22–24 the shifts were between 2 and 3.5 nm (with a 15–21% decrease in extinction). The bathochromic shift expected on basification of phenols

- (26) J. O. Morley, Synthesis, 528 (1976).

is not seen with 13-21 in the presence of DNA (Table I). All these changes, particularly for 13-17, are suggestive of an intercalative mode of binding.<sup>27,28</sup> Only 13–17 showed sufficient fluorescence for evaluation of the effects of DNA binding on their fluorescence properties. All showed between 78 and 90% reduction in fluorescence intensity (compared to 92% for doxorubicin) on binding to DNA. When maximally bound, the degrees of polarization of fluorescence for 13-17 (when irradiated with polarized light) were 0.33, 0.31, 0.28, 0.27, and 0.21, respectively, compared to 0.04-0.06 for free drug. The reduction in fluorescence and increase in polarization are consistent with intercalation into DNA. With all compounds, the  $T_{\rm m}$ of DNA was increased in the presence of drug (Table I). Doxorubicin under the same conditions gives a  $\Delta T_{\rm m}$  of 14.75 °C: hence, the affinity of binding is as follows: doxorubicin >>> dihydroxy compounds >>> monohydroxy compounds > anthraquinones with no hydroxy group. Data from spectrophotometric titration of drug with DNA were analyzed by a nonlinear regression program for their fit to a one-site or two-site binding model.<sup>28</sup> The dihydroxy compounds had the highest affinity for DNA (Table I), but the values were, at best, only half that for doxorubicin, with n values consistent with an intercalative mode of binding.

Antitumor Testing. The compounds prepared were evaluated, as their hydrochloride salts, for activity against P-388 leukemia in mice, and the results to date are given in Table II. One compound, 17, shows moderate activity (T/C = 125%).

#### Conclusions

The changes in the spectral properties of compounds 13-24 on interaction with DNA and the effects of these compounds on the thermal denaturation of DNA are consistent with an intercalative mode of interaction. The 1,4-dihydroxyanthraquinones 13–17 have a greater affinity for DNA than do the 1-hydroxy and nonhydroxylated compounds 18-24, and there is greatest activity where there are five atoms between the ring system and the basic nitrogen. The nature of the alkyl substituents on the nitrogen does not appear to be important. All the compounds prepared have a lower affinity for DNA than does doxorubicin. The retention of DNA-binding properties in the 1.4-dihydroxy-2-substituted-anthraquinones provides a further lead for the development of totally synthetic anthraquinones based on the DNA-binding properties of doxorubicin, since the group is amenable to synthetic manipulation. Enhancement of the binding to DNA is necessary; this might be achieved by multiple substitution (e.g., at the 2 and 3 or the 2 and 6 positions of hydroxyanthraquinones) or, more likely, by preparation of bis-intercalating analogues.

#### **Experimental Section**

Melting points were recorded on a Kofler hot-stage apparatus and are uncorrected. All hydrochloride salts were hygroscopic and were stored over  $P_2O_5$ .

1,4-Dihydroxy-9,10-dioxoanthracene-2-acetic Acid (25). Oxygen-free nitrogen was bubbled through 10%, w/v, sodium carbonate in freshly boiled distilled water (800 mL) containing a small amount of sodium dithionite. Leuco-1,4-dihydroxyanthracene-9,10-dione (20 g, 0.082 mol) was added and dissolved by heating to 90 °C. A solution of oxoethanoic acid (glyoxylic acid) dihydrate (6.6 g, 0.052 mol) in freshly boiled and cooled water (50 mL) was made just alkaline and added to the reaction mixture

over 30 min. After a further 2 h at 90 °C, the mixture was cooled and oxygenated for 1 h and then acidified. The precipitate was filtered, washed extensively with cold water, and then exhaustively extracted with successive portions  $(3 \times 600 \text{ mL})$  of hot 2%, w/v, sodium bicarbonate solution. The sodium salt was salted out using solid sodium chloride, filtered, and dissolved in water, and the solution was acidified. The product was removed by filtration, washed with water, and dried at 50 °C. The filtrate was also acidified and treated in a similar manner to yield a second cruder product. The product was crystallized from methanol as orange-brown crystals: yield 19.2 g (78%); mp 200 °C; IR (KBr) 3000 (OH), 1710 (acid CO), 1620 (quinone CO), 1585 and 1430 cm<sup>-1</sup> (aromatic); UV (C<sub>2</sub>H<sub>5</sub>OH)  $\lambda_{max}$  206 nm ( $\epsilon$  21 980), 252 (36 137), 463 (8598), 486 (9553); <sup>1</sup>H NMR (Me<sub>2</sub>SO-d<sub>6</sub>) δ 13.4 (1 H, s, replaceable with  $D_2O$ ,  $C_1OH$ ), 12.9 (1 H, s, replaceable with  $D_2O$ , C<sub>4</sub>OH), 8.3–8.1 (2 H, m, 5-CH and 8-CH), 7.9–7.7 (2 H, m, 6-CH and 7-CH), 7.2 (1 H, s, 3-CH), 3.6 (2 H, s, benzyl CH<sub>2</sub>); EIMS, m/e 298 (M<sup>+</sup>). Intramolecular Lactone of 1,4-Dihydroxy-9,10-dioxoanthracene-2-acetic Acid (26). 1,4-Dihydroxy-9,10-dioxoanthracene-2-acetic acid (25; 2.0 g, 0.068 mol) was dissolved in dry tetrahydrofuran (150 mL). N,N'-Dicyclohexylcarbodiimide (2.0 g, 0.01 mol) in dry tetrahydrofuran (50 mL) was added, and the mixture was stirred at room temperature for 3.5 h. After the mixture was filtered, the filtrate was evaporated to dryness in vacuo, and the product was washed with 2%, w/v, sodium bicarbonate  $(3 \times 300 \text{ mL})$  and then with water, dried at 60 °C, and crystallized from glacial acetic acid: yield 2.2 g (75%); mp 245-248 °C; IR (KBr) 3320 (OH), 3080 (aromatic), 2930 (intramolecular H-bonded OH), 2850 (CH), 1815 (y-lactone), 1660 and 1630 (quinone CO), 1585 (aromatic) cm<sup>-1</sup>; UV ( $C_2H_5OH$ )  $\lambda_{max}$  208 nm ( $\epsilon$  30661), 250 (34612), 282 (16887), 384 (5330); <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  13.1 (1 H, s, replaceable with D<sub>2</sub>O), 8.25-8.05 (2 H, m, 5-CH and 8-CH), 7.85-7.65 (2 H, m, 6-CH and 7-CH), 7.2 (1 H, s, 3-CH), 4.1 (2 H, s, benzyl CH<sub>2</sub>); high-resolution MS, m/e 280.2390 (M<sup>+</sup>) (C<sub>16</sub>H<sub>8</sub>O<sub>5</sub> requires 280.2392, 2 ppm error).

N-[2-(Dimethylamino)ethyl]-1,4-dihydroxy-9,10-dioxoanthracene-2-acetamide Hydrochloride (13). A mixture of 2-(dimethylamino)ethylamine (1.056 g, 0.012 mol) and the intramolecular lactone 26 (1.12 g, 0.004 mol) in sodium-dried toluene (100 mL) was heated under reflux for 1 h. The reaction mixture was cooled and evaporated to dryness in vacuo, and the excess amine was removed by steam distillation in vacuo. The residue was shaken with concentrated hydrochloric acid (2 mL), and the hydrochloride salt was dissolved in hot water (100 mL). The solution was filtered, and the filtrate was just basified and then extracted with ethyl acetate  $(3 \times 100 \text{ mL})$ . The organic layers were combined, backwashed with water, dried over anhydrous sodium sulfate, and evaporated to dryness in vacuo. After crystallization from chloroform, the free base was dissolved in the minimum quantity of dry ethyl acetate, dry hydrogen chloride was passed through the solution, and the hydrochloride salt was quickly removed by filtration: yield 50 mg (40%); mp 100 °C; IR (KBr) 3290 (H-bonded OH), 3090 (aromatic), 2950 (intramolecular H-bonded OH), 2905 (CH), 2790 (NCH<sub>3</sub>), 1650 (>NCO); UV (H<sub>2</sub>O) λ<sub>max</sub> 463 nm (ε 7331), 482 (7140); <sup>1</sup>H NMR (CDCl<sub>3</sub>) δ 12.95 (1 H, s, replaceable with  $D_2O$ ,  $C_1OH$ ), 12.4 (1 H, s, replaceable with  $D_2O$ ,  $C_4OH$ ), 8.4–8.2 (2 H, m, 5-CH and 8-CH), 7.82–7.7 (2 H, m, 6-CH and 7-CH), 7.2 (1 H, s, 3-CH), 6.55–6.4 (1 H, br s, replaceable with  $D_2O$ , NH), 3.62 (1 H, s, benzyl CH<sub>2</sub>), 3.4–3.2 (2 H, q, CH<sub>2</sub>), 2.45–2.3 (2 H, t, CH<sub>2</sub>), 2.2 (6 H, s, CH<sub>3</sub>); CIMS (ammonia), m/e 371 (M<sup>+</sup> +3), 370 (M<sup>+</sup> +2), 369 (M<sup>+</sup> +1). Anal. ( $C_{20}H_{20}N_2O_5$ -HCl) C, H, N, Cl.

Compounds 14-17 were prepared in an analogues manner in yields of 70, 56, 52, and 32%, respectively.

1-Nitro-9,10-dioxoanthracene-2-carboxylic Acid. 2-Methyl-1-nitroanthracene-9,10-dione<sup>24</sup> (3 g, 0.0112 mol) and 80%, w/w, sulfuric acid (25.7 g) were heated to 55 °C and chromium trioxide (3.89 g, 0.039 mol) was added with stirring over 0.5 h. The temperature was raised to 65 °C, and 96%, w/w, sulfuric acid (17.7 g) was added over 7 h. The mixture was heated at 70–75 °C for 4 h, diluted with water (4.5 mL), and filtered while still hot. The residue was washed with water and then digested in 5% aqueous sodium hydroxide solution (9 mL) at 90 °C for 1 h. After the mixture was filtered, the product was precipitated from the filtrate by acidification with 75%, w/w, sulfuric acid. The product was filtered, washed free of acid with warm water, dried at 60 °C, and crystallized from glacial acetic acid: yield 1.73 g (52%); mp 286–288 °C (lit.<sup>25</sup> 284–288 °C); IR (KBr) 1710 (acid CO), 1675 (quinone CO), 1590 (aromatic), and 1320 (NO<sub>2</sub>) cm<sup>-1</sup>; <sup>1</sup>H NMR (Me<sub>2</sub>SO-d<sub>6</sub>)  $\delta$  8.4–7.9 (m, aromatic CH); EIMS, m/e 297 (M<sup>+</sup>). Anal. (C<sub>15</sub>H<sub>7</sub>NO<sub>6</sub>) C, H, N.

1-Amino-9,10-dioxoanthracene-2-carboxylic Acid. An aqueous solution (10 mL) of NaBH<sub>4</sub> (0.70 g, 0.0185 mol) was added to 1-nitro-9,10-dioxoanthracene-2-carboxylic acid (6.0 g, 0.0202 mol) in aqueous 1%, w/w, ammonia (400 mL) at 25 °C. The

mixture was stirred for 4 h, diluted with water (100 mL), and carefully acidified, and the product was collected by filtration: yield 5.29 g (98%); mp 292 °C after recrystallization from DMF (lit.<sup>26</sup> 291 °C); IR (KBr) 3410 (H-bonded OH), 1750 (acid CO), 1660 (quinone CO), 1585 (aromatic) cm<sup>-1</sup>; EIMS, m/e 267 (M<sup>+</sup>).

1-Hydroxy-9,10-dioxoanthracene-2-carboxylic Acid (27). 1-Amino-9,10-dioxoanthracene-2-carboxylic acid (12 g, 0.045 mol) was added quickly to a solution of sodium nitrite (3.36 g, 0.049 mol) in 90%  $H_2SO_4$  (72 mL), and the mixture was heated at 50–60 °C for 0.5 h until the water-soluble diazo intermediate was formed. Water (4 mL) was added, and the mixture was heated at 95–100 °C for 2 h to effect N<sub>2</sub> evolution. The mixture was cooled and added to excess ice/water, and the precipitate was removed by filtration, washed with water, dried at 60 °C, and crystallized from glacial acetic acid: yield 10.5 g (87%); IR (KBr) 1700 (acid CO), 1665 and 1630 (quinone CO), 1590 (aromatic) cm<sup>-1</sup>; EIMS, m/e 268 (M<sup>+</sup>). Anal. (C<sub>15</sub>H<sub>8</sub>O<sub>5</sub>) C, H.

N-[2-(Diethylamino)ethyl]-1-hydroxy-9,10-dioxoanthracene-2-carboxamide Hydrochloride (18). A solution of 1-hydroxy-9,10-dioxoanthracene-2-carboxylic acid (1.072 g, 0.004 mol) in dry THF (150 mL) was stirred at 0 °C with exclusion of light, and N-hydroxysuccinimide (0.912 g, 0.008 mol) and N,-N'-dicyclohexylcarbodiimide (0.9 g, 0.004 mol), dissolved in the minimum quantity of dry THF, were added. After 20 min, it was allowed to warm to room temperature; after an additional 0.5 h, 2-(diethylamino)ethylamine (1.4 g, 0.012 mol) in dry THF (5 mL) was added, and the mixture was stirred for 62 h. After the mixture was filtered, the filtrate was evaporated to dryness in vacuo, and the free base was extracted as with 13 earlier and crystallized from methanol, and the hydrochloride salt was prepared: yield 700 mg (48%); mp 180 °C; IR (KBr) 3400 (OH), 3060 (aromatic), 2955 (CN), 1650 and 1630 (quinone CO), 1600 (aromatic), 1540 (CON<) cm<sup>-1</sup>; UV (pH 5.8 buffer)  $\lambda_{max}$  406 nm ( $\epsilon$  6000); <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  12.9 (1 H, s, replaceable with D<sub>2</sub>O, C<sub>1</sub>OH), 8.75–8.58 (1 H, d, 3-CH), 8.4–8.25 (2 H, p, 5-CH and 8-CH), 7.95–7.78 (3 H, m, 4-CH, 6-CH, 7-CH), 3.7-3.5 (2 H, m, CH<sub>2</sub>), 3.2-3.0 (1 H, br s, replaceable, slowly with D<sub>2</sub>O, NH), 2.8-2.5 (6 H, m, NCH<sub>2</sub>), 1.15-0.9 (6 H, t,  $CH_3$ ; CIMS (ammonia), m/e 368 (M<sup>+</sup> +2), 367 (M<sup>+</sup> +1). Anal.  $(C_{21}H_{22}N_2O_4 \cdot HCl) C, H, N, Cl.$ 

Compounds 19-21 were prepared in an analogous manner in yields of 52, 25, and 82%, respectively.

19: mp 85–90 °C; IR (KBr) 3400 (OH), 3055 (aromatic) 2940 (CH), 1660 and 1635 (quinone CO), 1595 (aromatic), 1540 (CON<) cm<sup>-1</sup>; UV (pH 5.8 buffer) 404 nm ( $\epsilon$  5340); <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  12.85 (1 H, s, replaceable with D<sub>2</sub>O, C<sub>1</sub>OH), 8.65–8.57 (1 H, d, 3-CH), 8.4–8.25 (2 H, m, 5-CH and 8-CH), 7.95–7.77 (3 H, m, 4-CH, 6-CH, and 7-CH), 3.2–3.05 (1 H, br s, replaceable slowly with D<sub>2</sub>O, NH), 3.70–3.45 (2 H, m, CH<sub>2</sub>), 2.5–2.28 (8 p, NCH<sub>2</sub> and CH<sub>3</sub>), 1.9–1.75 (2 H, t, CH<sub>2</sub>); CIMS (ammonia), m/e 354 (M<sup>+</sup> +2), 353 (M<sup>+</sup> +1).  $\hat{N}$ -[2-(Diethylamino)ethyl]-9,10-dioxoanthracene-2carboxamide Hydrochloride (22). 9,10-Dioxoanthracene-2carboxylic acid, prepared by chromic acid oxidation of 2methylanthraquinone, was converted to its acid chloride with redistilled thionyl chloride in THF. This acid chloride (1.08 g, 0.005 mol) was heated under reflux (2 h) with 2-(diethylamino)ethylamine (0.58 g, 0.005 mol) in dry THF (150 mL). The mixture was cooled and evaporated to dryness in vacuo, and the free base was isolated as for 13. The product was crystallized from acetone, and the hydrochloride was prepared: yield 0.98 g (70%); mp 105 °C; UV (H<sub>2</sub>O)  $\lambda_{max}$  331 nm ( $\epsilon$  5720); <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  8.56 (1 H, s, 1-CH), 8.4–8.2 (4 H, m, 3-CH, 4-CH, 5-CH, 8-CH), 7.85–7.7 (2 H, m, 6-CH, 7-CH), 3.62–3.45 (2 H, q, CH<sub>2</sub>), 2.76–2.5 (6 H, m, NCH<sub>2</sub>), 1.15–1.10 (6 H, t, CH<sub>3</sub>); CIMS (ammonia), m/e 352 (M<sup>+</sup> +2), 351 (M<sup>+</sup> +1). Anal. (C<sub>21</sub>H<sub>22</sub>N<sub>2</sub>O<sub>3</sub>) C, H, N, Cl.

Compounds 23 and 24 were prepared in an analogous manner in yields of 69 and 73%, respectively.

**23**: mp 100–102 °C; UV (H<sub>2</sub>O) 331 nm ( $\epsilon$  5293); <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  8.7 (1 H, s, 1-CH), 8.5–8.38 (4 H, m, 3-CH, 5-CH, 8-CH), 7.96–7.85 (2 H, m, 6-CH, 7-CH), 3.8–3.6 (2 H, q, CH<sub>2</sub>), 2.75–2.62 (2 H, t, CH<sub>2</sub>), 2.5 (6 H, s, CH<sub>3</sub>), 2.45–2.25 (1 H, br s, replaceable with D<sub>2</sub>O, NH), 1.95–1.8 (2 H, t, CH<sub>2</sub>); MS, m/e 336 (M<sup>+</sup>). Anal. (C<sub>20</sub>H<sub>20</sub>N<sub>2</sub>O<sub>3</sub>·HCl) C, H, N, Cl.

**24:** mp 90–93 °C; UV (H<sub>2</sub>O)  $\lambda_{max}$  330 nm ( $\epsilon$  5687); <sup>1</sup>H NMR (CDCl<sub>3</sub>)  $\delta$  8.55 (1 H, s, 1-CH) 8.4–8.2 (4 H, m, 3-CH, 4-CH, 5-CH, 8-CH), 7.88–7.74 (2 H, m, 6-CH, 7-CH), 4.32–4.1 (1 H br s, replaceable with D<sub>2</sub>O, NH), 2.68–2.4 (7 H, NCH<sub>2</sub> and methine), 1.75–1.6 (4 H, m, CH<sub>2</sub>), 1.36–1.28 (3 H, d, CH<sub>3</sub>), 1.1–0.92 (6 H, t, CH<sub>3</sub>); CIMS (ammonia), m/e 394 (M<sup>+</sup>+2), 393 (M<sup>+</sup>+1). Anal. (C<sub>24</sub>H<sub>28</sub>N<sub>2</sub>O<sub>3</sub>·HCl) C, H, N, Cl.

**DNA Binding.** Solutions were prepared in pH 7.0, 0.05 M NaCl, 0.008 M Tris-Cl buffer and for compounds 18–21 also in pH 5.8, Sorensen's citrate II buffer. Calf thymus DNA (Sigma Type I) in buffer (1 mg mL<sup>-1</sup>) was assayed using the figure  $\epsilon(P)_{280}$  = 6600. All compounds obeyed Beer–Lambert's law over the concentration range used. All glassware was silanized before use.

(a) Determination of Spectral Shifts. Six solutions of drug  $(2.5 \times 10^{-5} \text{ M})$  and DNA were prepared with DNA/drug ratios of 0, 1, 2, 5, 10, and 15. The spectra for each drug were recorded superimposed.

(b) Effect of pH on the Drug  $\lambda_{max}$  in the Presence and Absence of DNA. Solutions were prepared containing just drug  $(2.5 \times 10^{-5} \text{ M})$  and drug and DNA  $(2.5 \times 10^{-5} \text{ and } 3.75 \times 10^{-4} \text{ M})$ , respectively) in pH 7.0 and in pH 9.3 buffer (pH 5.8 and 7.8 for 18–21). The spectra for each compound were recorded superimposed. (c) Spectrophotometric Titration. Aliquots  $(4 \times 40, 12 \times 20, \text{ and } 7 \times 100 \,\mu\text{L})$  of DNA solution  $(2.5 \times 10^{-3} \text{ M})$  were added sequentially to three samples of drug solution  $(5 \times 10^{-5} \text{ M})$  in pH 7.0 buffer (3.0 mL) at 25 °C (pH 5.8 buffer for compounds 18–21), and the absorbance at the  $\lambda_{\text{max}}$  of the unbound drug was determined after a 5-min equilibration against a blank of buffer treated in an identical manner. The binding parameters  $K_1$  and  $n_1$  were then determined for a one-site binding model and, if necessary, for a two-site binding model by nonlinear regression of absorbance (as the dependent variable) against cumulative volume of DNA added (as independent variable) by the method previously reported.<sup>28</sup>

(d) Spectrofluorimetric Studies. For compounds 13-17, aliquots of DNA solution were added sequentially to three samples of drug solution  $(2.5 \times 10^{-6} \text{ M in pH 7.0 buffer})$  at 25 °C, and the fluorescence polarization was determined at the  $\lambda_{max}$  of emission for the unbound drug when irradiated with polarized light at the  $\lambda_{max}$  of excitation for the unbound drug. The usual correction was applied to account for spurious polarization due to the instrument. The fluorescence polarization titrations were continued until ratios of DNA to drug were reached at which the drug is fully bound. The change (percent) in fluorescence was also calculated at these DNA/drug ratios. Additionally, polarization values at DNA/drug ratios of 50, 100, and 150 were determined.

(e) Thermal Denaturation. Two solutions with an identical concentration of DNA (about  $15 \times 10^{-5}$  M) were prepared in 0.018 M NaCl, 0.003 M Tris-chloride buffer at pH 7.0, one just containing DNA and the other also containing drug (about  $1.5 \times 10^{-5}$  M) such that the ratio of drug to DNA was precisely 1:10. The absorbance of each solution was measured at 260 nm, as the temperature was raised from 55 to 105 °C (0.25 °C min<sup>-1</sup>), against a blank containing GMP, the absorbance of which was exactly matched to the starting absorbance of the sample.

Several series of N<sup>6</sup>- or 8-substituted derivatives of adenosine 5'-triphosphate (ATP) were synthesized. N<sup>6</sup>-( $\omega$ -Aminoalkyl) derivatives of adenosine 5'-monophosphate (AMP) were converted into their  $\omega$ -N-carbobenzyloxy derivatives, and these were converted, via the 2',3'-O-carbonyl derivatives of their 5'-phosphorimidazolidates, into the corresponding ATP derivatives. Hydrogenolytic removal of the carbobenzyloxy groups, followed by iodoacetylation of the  $\omega$ -amino groups with N-(iodoacetoxy)succinimide, gave N<sup>6</sup>-R-ATP, where R = (CH<sub>2</sub>)<sub>n</sub>NHCOCH<sub>2</sub>I (n = 2-8) or (CH<sub>2</sub>)<sub>n</sub>CON(CH<sub>3</sub>)(CH<sub>2</sub>)<sub>m</sub>N(CH<sub>3</sub>)CO(CH<sub>2</sub>)<sub>n</sub>NHCOCH<sub>2</sub>I (n = m = 3; n = 3, m = 4; n = 4, m = 3; n = m = 4). Condensation of N<sup>6</sup>-( $\omega$ -aminoalkyl) derivatives of AMP with N-hydroxysuccinimide esters of  $\omega$ -[N-(carbobenzyloxy)amino] carboxylic acids gave N<sup>6</sup>-(CH<sub>2</sub>)<sub>n</sub>NHCO(CH<sub>2</sub>)<sub>m</sub>NH-Cbz derivatives of AMP which, upon conversion to the corresponding derivatives of ATP, followed by removal of the carbobenzyloxy group and iodoacetylation, as described above, gave N<sup>6</sup>-(CH<sub>2</sub>)<sub>n</sub>NHCO(CH<sub>2</sub>)<sub>m</sub>NHCOCH<sub>2</sub>I-ATP derivatives (n = 3, m = 5 or 6; n = 4, m = 5; n = 6, m = 1-6). The same sequence of reactions starting with N<sup>6</sup>-[ $\omega$ -(methylamino)alkyl] derivatives of N<sup>6</sup>-CH<sub>3</sub>-AMP gave N<sup>6</sup>-(CH<sub>2</sub>)<sub>n</sub>N(CH<sub>3</sub>)CO(CH<sub>2</sub>)<sub>m</sub>NHCOCH<sub>2</sub>I derivatives of ATP (n = 4, m = 3, 5 or 6; n = 6, m = 5 or 6). Reaction of  $\alpha$ , $\omega$ -diaminoalkanes with 8-Br-ATP gave 8-NH(CH<sub>2</sub>)<sub>n</sub>NH<sub>2</sub> derivatives of ATP, which upon iodoacetylation gave 8-NH(CH<sub>2</sub>)<sub>n</sub>NHCOCH<sub>2</sub>I derivatives of ATP (n = 2, 4, 6, or 8). Substrate and inhibitor properties indicated that the ATP derivatives are potential exo-ATP-site-directed inactivators of hexokinases, adenylate kinases, and pyruvate kinases.

It is now recognized that enzymes which catalyze the same transformation, whether they be derived from different species or are isozymes characteristic of different tissues of the same species, exhibit structural dissimilarities
