#### Abstract

Prompted by pharmacophore and docking based models, we have synthesized and tested a number of N -alkyl and N -acyl-(7-substituted-2-phenylimidazo[1,2-a][1,3,5]triazin-4-yl)amines (ITAs, 7) designed as a new class of $\mathrm{A}_{1}$ adenosine receptor ( $\mathrm{A}_{1} \mathrm{AR}$ ) antagonists. Binding affinities at the $A_{1} A R, A_{2 A} A R$, and $A_{3} A R$ were determined using bovine cerebral membranes. Most of the compounds displayed $K_{i}$ values at the $A_{1} A R$ in the submicromolar or even in the low nanomolar range, thus confirming the rationale leading to their synthesis. All or most of the ligands turned out to be selective for the $A_{1} A R$ over the $A_{2 A} A R$ and $A_{3} A R$ subtypes, respectively. Structure-affinity relationships at the $\mathrm{A}_{1}$ AR were rationalized by docking simulations in terms of putative ligand/receptor interactions. Among the ITAs investigated, 1-[(7-methyl-2-phenyl-imidazo[1,2-a][1,3,5]triazin-4-yl)amino]acetone (7j) exhibited the best combination of affinity at the $A_{1} A R\left(K_{i}=12 \mathrm{nM}\right)$ and selectivity over the $A_{2 A} A R$ and $A_{3} A R$ subtypes $\left(K_{i} s>10000\right.$ $\mathrm{nM})$.

## Introduction

The activation of cell surface adenosine receptors (ARs) is predominantly responsible for the wide variety of effects produced by adenosine throughout several organ systems. The combination of pharmacological studies and molecular cloning have led to the discovery of the existence of at least four distinct adenosine receptors which have been identified and classified as $A_{1}, A_{2 A}, A_{2 B}$, and $A_{3}$. The responses of these four ARs are mediated by receptor-coupled G-proteins which activate several effector systems including adenylate cydase, potassium and calcium channels, phospholipase A2 or C, and guanylate cyclase. ${ }^{1-3}$

On the basis of the widespread effects attributed to the accumulation of endogenously released adenosine, it has long been considered that regulation of ARs has substantial therapeutic potential.

The $A_{1}$ adenosine receptor ( $A_{1} A R$ ) is the best known and the most comprehensively studied AR subtype, and during the last 20 years a large number of $A_{1} A R$ agonists ${ }^{4}$ and antagonists ${ }^{5-7}$ have been developed. With regards to possible therapeutic application of $A_{1} A R$ antagonist, effects on the cardiovascular system, kidney,

[^0]and CNS have been studied. Currently, $\mathrm{A}_{1}$ AR selective antagonists are developed as potassium-saving diuretics with kidney-protective properties, as general cognition enhancers for geriatric therapy, and for the treatment of acute renal failure and of CNS disorders such as Alzheimer desease. ${ }^{5-7}$
We have recently described 3-aryl [1,2,4]triazino[4,3a]benzi midazol-4(10H)-one (ATBI) derivatives as a new dass of selective $\mathrm{A}_{1}$ AR antagonists. ${ }^{8}$ The most potent ATBI, compound $\mathbf{1}$, displayed a $K_{i}$ value of 18 nM on bovine cortical preparations. Pharmacophore and dock-ing-based modeling of $\mathbf{1}$ and other well-known $\mathrm{A}_{1}$ AR antagonists (2-6) (see Chart 1) suggested that these ligands could interact with three H -bond sites (HB1, HB2, and HB3) and three lipophilic pockets (L1, L2, and L3) within the receptor binding site. The Asn254 (helix VI ) side chain CO and $\mathrm{NH}_{2}$ moieties (HB1 and HB2, respectively) and the Ser277 (helix VII) hydroxyl (HB3 as a H -bond donor) group correspond to the H -bond centers. The above interactions are highlighted in Figure 1.
In pursuing our researches in this field we have investigated N -al kyl and N -acyl 7 -substituted-2-phenyl-imidazo[1,2-a][1,3,5]triazin-4-amines (ITAs, 7a-r), which fulfill the pharmacophore requirements for $A_{1} A R$ antagonism (Figure 2). These compounds were prepared

Figure 1. Pharmacophoric overlay of compounds 1-6. HB1, HB2 and HB3 are H -bond sites of $\mathrm{A}_{1} A R$ corresponding to Asn254 (helix VI) and Ser277 (helix VII) side chains. L1, L2 and L 3 map hydrophobic interactions. 1-6 are described in the following references: $\mathbf{1},{ }^{8} \mathbf{2},{ }^{9} \mathbf{3},{ }^{10} \mathbf{4},{ }^{11} \mathbf{5},{ }^{12} \mathbf{6} .{ }^{13}$

Figure 2. Pharmacophoric scheme of $I T A s / A_{1} A R$ interaction.
following a versatile procedure similar to that described by us for isosteric imidazo[1,2-a]pyrimidines showing antiinflammatory activity. ${ }^{14}$

Selection of substituents $\mathrm{R}^{\prime}$ and R at the N-4 and 7-position of the imidazotriazine nucleus was guided by
the results of docking simulations into our model of bovine $A_{1} A R$ (details are given in the Experimental Section). Inspection of the L 1 lipophilic pocket suggested that R' has to be hydrophobic and not exceedingly large. However, a less lipophilic R', such as $\mathrm{CH}_{2} \mathrm{COCH}_{3}$ would enable the carbonyl oxygen to accept one or two H-bonds from Ser277 and Thr91 (helix III) hydroxyls. Figure 3 shows the docking model of $7 \mathrm{j}\left(\mathrm{R}^{\prime}=\mathrm{CH}_{2} \mathrm{COCH}_{3}, \mathrm{R}=\right.$ $\mathrm{CH}_{3}$ ) featuring the two putative H -bonds described above.

A phenyl ring in position 2, supposed to fill the L2 site (Figure 2), was maintained fixed all through the ITA series. This substituent gave, in fact, the most potent ATBI (compound 1) by interacting with the L2 lipophilic pocket.

Lead optimization efforts focused initially on the nature of $\mathrm{R}^{\prime}$ by keeping fixed $\mathrm{R}=\mathrm{CH}_{3}$. Replacements of the $7-\mathrm{CH}_{3}$ with a $7-\mathrm{C}_{2} \mathrm{H}_{5}$, a 7 -isoC ${ }_{3} \mathrm{H}_{7}$, or a 7 -Ph, to optimize the hydrophobic and steric interactions between R and the L3 site, were accomplished on a few selected structures.

The present paper describes the design, the synthesis, the biological evaluation, and the structure-activity relationships (SARs) of compounds with a general formula 7.

## Chemistry

The imidazo[1,2-a][1,3,5]triazine derivatives 7a-r were prepared in two steps. First, the imidazo[1,2-a][1,3,5]triazines were synthesized using a synthetic method in which the starting 2,4-diamino-6-phenyl[1,3,5]triazine 8 was warmed in refluxing ethanol with 2-chloroacetone 9, 1-chlorobutan-2-one 10, 1-bromo-3-methylbutan-2-one 11, or 2-bromoacetophenone 12, to obtain the corresponding 7-methyl-2-phenylimidazo[1,2-a][1,3,5]triazin-4-ylamine 7a, 7-ethyl-2-phenylimidazo-[1,2-a][1,3,5]triazin-4-ylamine 13, 7-isopropyl-2-phenyl-imidazo[1,2-a][1,3,5]triazin-4-ylamine 14, and 2,7-di-phenylimidazo[1,2-a][1,3,5]triazin-4-ylamine 15, respectively (Scheme 1).

The correct structural assignments for these products were performed with ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy. In

Figure 3. Model of the $A_{1} A R$ binding site complexed with compound 7j. Only amino acids located within $5 \AA$ from any atom of the bound ligand are displayed. Dotted lines highlight ligand/receptor H-bonds.

## Scheme 1

13
particular, the starting compound $\mathbf{8}$ is differently substituted in the 4 and 6 positions, so it was possible, in theory, to obtain a pair of isomeric products from the cyclocondensation reaction of this amine with the $\alpha$ hal oketo derivatives 9, 10, 11, and 12. The correct structural assignment for products $\mathbf{7 a}, \mathbf{1 3}, \mathbf{1 4}$, and $\mathbf{1 5}$, was obtained by a HMBC experiment. The carbon atom in the triazine ring that showed a correlation pathway with the phenyl hydrogen atoms ( $\delta 162.9$ ) was not correl ated to the hydrogen atom into the imi dazole ring (H-6, $\delta 7.35$ ). This hydrogen, however, showed a correlation with the two carbon atoms ( $\delta 152.4$ and 152.3) in the triazine ring.
The amino group of compounds $\mathbf{7 a}, \mathbf{1 3}, \mathbf{1 4}$, and $\mathbf{1 5}$ was subsequently allowed to react with haloal kyl or acyl derivatives according to the condition described in the Experimental Section, and summarized in Scheme 2, to give the derivatives $\mathbf{7 b} \mathbf{i}, \mathbf{k}-\mathbf{r}$. The compound $\mathbf{7 j}$ was obtained together 7a by reaction of triazine $\mathbf{8}$ with 2-chloroacetone. The presence of carbonyl function in compounds $\mathbf{7 j}, \mathbf{7 k}, \mathbf{7 0}, \mathbf{7 p}$, and $\mathbf{7 q}$ has been unequivocally ascertained on the basis of the IR spectra.

## Results and Discussion

The binding affinity of each ITA derivative at the $A_{1}$ and $A_{2 A} A R s$ were determined in competition assays

## Scheme $\mathbf{2 a}^{\text {a }}$

a (a) $\mathrm{R}^{\prime} \mathrm{Cl}$ or $\mathrm{R}^{\prime} \mathrm{Br}, \mathrm{CH}_{3} \mathrm{CN}, \mathrm{K}_{2} \mathrm{CO}_{3}, \mathrm{KI}$; (b) (MeCO) $)_{2} \mathrm{O}, 4$-DMAP, THF.
of [ $\left.{ }^{3} \mathrm{H}\right]-\mathrm{N}^{6}-$ cyclohexyladenosine ( $\left[{ }^{3} \mathrm{H}\right] \mathrm{CHA}$ ) and $\left[{ }^{3} \mathrm{H}\right]-2-$ \{[4-(2-carboxyethyl)phenethyl]amino\}-5'-(N-ethylcarbamoyl)adenosine ( $\left.{ }^{3} \mathrm{H}\right] C G S$ 21680) to bovine cortical $\left(\mathrm{A}_{1}\right)$ and striatal $\left(\mathrm{A}_{2 \mathrm{~A}}\right)$ membranes, respectively. Affinity at the $A_{3} A R$ was determined in competition assays of [ ${ }^{125}$ I ]-N ${ }^{6}$-(3-iodo-4-aminobenzyl)-5'-N-methyl carboxamidoadenosine ( $\left.{ }^{125}\right]$ ]AB-MECA) to bovine cortical membranes in the presence of the $A_{1} A R$ selective antagonist DPCPX ( 20 nM ). ${ }^{8}$

The results of the binding experiments are summarized in Table 1. Most of the compounds display $\mathrm{K}_{\mathrm{i}}$ values at the $A_{1} A R$ in the sub-micromolar or even in the low nanomolar range, thus confirming the rationale leading to their synthesis. Most of the ligands turned out selective for the $A_{1} A R$ over the $A_{2 A} A R$ and $A_{3} A R$ subtypes. Those binding to the $A_{1} A R$ with a high potency and selectivity are $\mathbf{7 g}, \mathbf{7 j}$, and $\mathbf{7 n}$. Moreover, compounds $\mathbf{7 g}, \mathbf{7 I}$, and $\mathbf{7 m}$ are characterized by $\mathrm{K}_{\mathrm{i}}$ values which represent a 3-5.5-fold gain in affinity with respect to that of the previously described most active ATBI derivative 1 ( $\mathrm{K}_{\mathrm{i}} 18 \mathrm{nM}$ ).

As stated in the Introduction, our research started with the 7-methyl derivatives $\mathbf{7 a}-\mathbf{k}$ seeking the optimal $R^{\prime}$ substituent. In the 7-methyl series $\mathbf{7 a}-\mathbf{k}$, the parent compound 7a showed a fair affinity at the $A_{1} A R$ with a low selectivity toward $A_{2 A}$ (2-fold) and $A_{3}$ (6-fold) ARs. The affinity, as expected, is improved by a hydrophobic character of R' (hypothesized to fill the L1 lipophilic pocket as schematized in Figure 2). Indeed, introduction of an alkyl (cyclopentyl) substituent at N-4 (7b) determined an 8 -fold enhancement in $A_{1} A R$ potency and a parallel gain in selectivity vs $A_{2 A}$ and $A_{3} A R s$ (100-fold and 55 -fold, respectively). Bulkier alkyl and arylalkyl substituents at this position ( $\mathbf{7 c} \mathbf{-} \mathbf{e}$ ) dramatically decreased $A_{1}$ and $A_{2 A} A R s$ affinity, while varying results were obtained at the $A_{3} A R$ with respect to $7 \mathbf{a}$ : an

enhancement in affinity for 7c, equipotency for 7d, and a complete loss of affinity in the case of $7 \mathbf{e}$.

Also the introduction of an acetyl moiety at the N-4 (7f) reduced $A_{1}$ and $A_{2 A} A R$ affinity, while a 8.5-fold gain in potency was observed for the $A_{3} A R$. N otwithstanding, 7g ( $R^{\prime}=$ CO-cyclopentyl), 7h ( $R^{\prime}=$ CO-cyclohexyl), and 7 i ( $\mathrm{R}^{\prime}=\mathrm{COPh}$ ) showed an enhancement in $\mathrm{A}_{1} A R$ affinity vs 7 a by 75.5 -fold, 3 -fold and 12 -fold, respectively, with a good selectivity toward $A_{2 A} A R$ but not $A_{3} A R$. Moreover, a comparison between 7h ( $R^{\prime}=C O-$ cyclohexyl) and the 2-fold less potent 7d ( $\mathrm{R}^{\prime}=\mathrm{CH}_{2^{-}}$ cyclohexyl) suggests that the amidic CO in $\mathrm{R}^{\prime}$ is indeed beneficial, provided that a sufficiently hydrophobic moiety occupies the L1 pocket. The favorable effect of the CO linker with respect to $\mathrm{CH}_{2}$ might be ascribed to either an improved H -bond donor ability of the NH group and/or to a more precise orientation of R'into L1.

However, prompted by docking simulations, we al so prepared 7j featuring $\mathrm{R}^{\prime}=\mathrm{CH}_{2} \mathrm{COCH}_{3}$. This substituent is rather hydrophilic but nevertheless makes two H bonds with the Ser277 and Thr91 side chains (see Figure 3). The significant gain in $\mathrm{A}_{1}$ AR potency (71-fold) and selectivity achieved by inserting a methylene spacer between the acetyl group and the N-4 (compare $7 \mathbf{j}$ vs 7f) confirmed our prevision. Finally, we observed a complete loss of affinity at all the three ARs when the acetyl moiety of $7 \mathbf{j}$ was substituted with a propionyl one in 7k.

In the $7-\mathrm{CH}_{3}$ series of ITAs, $\mathbf{7 g}$ ( $\mathrm{R}^{\prime}=\mathrm{CO}$-cycl opentyl, $\mathrm{K}_{\mathrm{i}}=4 \mathrm{nM}$ ) achieves the highest potency. Replacement of the cyclopentyl of $\mathbf{7 g}$ with a cyclohexyl to yield $\mathbf{7 h}$ produces a 25 -fold drop of affinity probably because the
latter ring is exceedingly large. Unfavorable steric effects of $\mathrm{R}^{\prime}$ can be likewise observed on comparing $\mathbf{7 b}$ vs 7c, 7d vs 7e and $\mathbf{7 j}$ vs $\mathbf{7 k}$. Regarding 7d and 7e, the steric differences between the $\mathrm{CH}_{2}$-cyd ohexyl and $\mathrm{CH}_{2}{ }^{-}$ phenyl groups seem to us essentially related to the different valence geometry about the endocyclic C1 atom ( $s p^{3}$ or $s p^{2}$ hybridized, respectively).

The two most potent $7-\mathrm{CH}_{3}$ derivatives, $\mathbf{7 g}$ and $\mathbf{7 j}$, were then selected as leads for structural modifications aimed at optimizing the nature of the substituent R hypothesized to dock into the L3 lipophilic site (Figure 2). Accordingly, the $7-\mathrm{CH}_{3}$ in $\mathbf{7 g}$ and $7 \mathbf{j}$ was replaced with a $7-\mathrm{C}_{2} \mathrm{H}_{5}$, a 7 -isoC $\mathrm{SH}_{3}$ or a 7 -Ph by synthesizing compounds $\mathbf{7 I}-\mathbf{n}$ and, respectively, 70-q.

In the CO-cyclopentyl series (71-n) potency remained almost similar ( $71 \mathrm{~K}_{\mathrm{i}}=3.3 \mathrm{nM}$ ) to that of the parent compound $7 \mathbf{g}\left(K_{i}=4.4 \mathrm{nM}\right)$, while selectivity, especially toward $A_{3} A R$, was lost. The $\mathrm{CH}_{2} \mathrm{COCH}_{3}$ series ( $70-\mathbf{q}$ ) gave even worst results, both in affinity and selectivity.

The above results suggest that the $A_{1} A R L 3$ cavity is filled with optimal shape complementarity by the $\mathrm{C}_{2} \mathrm{H}_{5}$ or $\mathrm{CH}_{3}$ of $\mathbf{7 I}$ and $\mathbf{7 j}$, respectively, so that bulkier substituents $R$ cannot fit properly in this cavity. It is interesting to note that in the $\mathbf{7 g}, \mathbf{7 I}-\mathbf{n}$ and $\mathbf{7 j}, \mathbf{7 0}-\mathbf{q}$ series the R groups larger than the optimal ones reduce affinity to quite different extents (up to 4-fold or more than 200-fold, respectively). The moderate or dramatic impact of nonoptimal $R$ substituents on affinity strictly depends on the nature of R'. In other words, the effects of $R$ and $R^{\prime}$ are not additive but interdependent.

In light of the docking model of 7j (Figure 3), we speculate that the strong H -bonds accepted by the
carbonyl oxygen of $\mathrm{CH}_{2} \mathrm{COCH}_{3}$ from Ser277 and Thr91 hydroxyls somehow "freeze" the mobility of the complexed ligand. This implies that the steric hindrance arising from insertion of a relatively large substituent $R$ cannot be counterbalanced through rotations and translations of the ligand to adapt $R$ into the $L 3$ pocket. Alternatively, accommodation of R into the L3 cavity would disrupt the putative H -bonds described above. If $\mathrm{R}^{\prime}$ is not engaged in H -bonds with L 1 (i.e., CO-cyclopentyl), the ligand can more freely move within the binding site, thus minimizing the steric repulsion between R and the L3 pocket.

Totest our "dynamic" model of ITA/A ${ }_{1} A R$ interaction, we synthesized and assayed $7 \mathbf{r}$ which combines a substituent $\mathrm{R}^{\prime}$ smaller than CO -cyclopentyl $\left(\mathrm{COCH}_{3}\right)$ with a large R (Ph). In this case the replacement of the 7-CH3 with a 7-Ph leads to a 37-fold improvement of affinity (compare $7 r$ vs $7 f$ ) reaching a $K_{i}$ value of 23 nM . The remarkable beneficial effect of 7-Ph in $7 \mathbf{r}$ might be related to an "easier" positioning of the small $\mathrm{COCH}_{3}$ into the L1 cavity, which in turn facilitates the anchoring of 7-Ph into the L3 site. Unfortunately, this enhancement in the affinity for $A_{1} A R$ was paralleled by $A_{3} A R$ potency ( $\mathrm{K}_{\mathrm{i}}=40 \mathrm{nM}$ ), with a consequent decrease in $A_{1} / A_{3}$ selectivity.

## Conclusions

Prompted by pharmacophore- and docking-based models, we have synthesized and tested a series of N -alkyl and N-acyl-(7-substituted-2-phenylimidazo[1,2-a][1,3,5]-triazin-4-yl)amines (ITAs, 7) designed as a new class of $\mathrm{A}_{1}$ AR antagonists. Nonadditive, but interdependent, effects of $R$ and $R^{\prime}$ substituents on $A_{1} A R$ affinity could be rationalized by our docking model. The most interesting compound within this series is $7 \mathbf{j}\left(\mathrm{R}^{\prime}=\mathrm{CH}_{2} \mathrm{COCH}_{3}\right.$ and $\mathrm{R}=\mathrm{CH}_{3}$ ) which exhibits the best combination of affinity at he $A_{1} A R\left(K_{i}=12 \mathrm{nM}\right)$ and selectivity over the $A_{2 A} A R$ and $A_{3} A R$ subtypes ( $K_{i} s>10000 n M$ ).

## Experimental Section

Chemistry. The course of reactions and purity of products were controlled by TLC, using precoated silica gel plates (Merck 60 F254) and chloroform/methanol 95:5 as eluant. Preparative separation was performed in columns containing Merck 60 silica gel (70-230 mesh ASTM) and with a Flash 40i chromatography module using prepacked cartridge system (Biotage). Melting points were determined with a Kofler hot stage microscope and are uncorrected.

Elemental analysis was within $\pm 0.4 \%$ of the theoretical values. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ NMR, and HMBC experiments were recorded using a Bruker WM-250 or AMX-500 spectrometer, equipped with a Bruker X-32 computer. Chemical shift values are reported in $\delta$ units (ppm) relative to TMS used as the internal standard. Infrared spectra were recorded with a PYE/ UNICAM Infracord model PU 9516 spectrophotometer in Nujol mulls. Molecular sieves UOP Type 4A (Fluka 69834) and UOP Type 13X (Fluka 69853), reagent grade chemi cals, and solvents were used. Compound $\mathbf{1 1}^{15}$ was prepared according to published procedure.

General Procedure for the Synthesis of Compounds 7a, 7j, 13-15. A solution of 2,4-diamino-6-phenyl[1,3,5]triazine $8(20 \mathrm{mmol})$ and the appropriate $\alpha$-haloketo derivative 9, 10, 11, $12(30 \mathrm{mmol})$ in absolute ethanol ( 100 mL ) was stirred under reflux for $30-40 \mathrm{~h}$ with small amounts of molecular sieves UOP Type 4A and, when suitable, UOP 13X. After being cool ed, the solvent was removed under reduced pressure and the residue was treated with $\mathrm{NaHCO}_{3}$ saturated aqueous
solution. This alkaline mixture was extracted with ethyl acetate ( $3 \times 20 \mathrm{~mL}$ ). The combined extracts were dried ( $\mathrm{Na}_{2} \mathrm{SO}_{4}$ ), reduced to a small volume, and purified by flash chromatography.

7-Methyl-2-phenylimidazo[1,2-a][1,3,5]triazin-4-ylamine (7a) and 1-[(7-Methyl-2-phenylimidazo[1,2-a][1,3,5]-triazin-4-yl)amino]acetone (7j). Eluant: n-hexane/ethyl acetate ( $3: 2 \mathrm{v} / \mathrm{v}$ ). The faster running band gave pure $7 \mathrm{j}(36 \%$, $\mathrm{mp} 290^{\circ} \mathrm{C}$ dec), the slower one gave pure $7 \mathrm{a}\left(43 \%, \mathrm{mp} 293^{\circ} \mathrm{C}\right.$ dec). Spectroscopic data for 7a: ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CD}_{3} \mathrm{OD}$ ) $\delta 8.40$ (d, J $=6.9 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{H}-\mathrm{Ar}), 7.51-7.41(\mathrm{~m}, 3 \mathrm{H}, \mathrm{H}-\mathrm{Ar})$, 7.35 (s, 1H, H-6), 2.34 (s, 3H, 7-Me); ${ }^{13} \mathrm{C}$ NMR ( $125 \mathrm{MHz}, \mathrm{CD}_{3}{ }^{-}$ OD) $\delta 162.9$ (C-2), 152.4, 152.3 (C-4 and C-8a), 143.9 (C-7), 138.1 (C-1'), 131.9, 129.4, 129.2, 104.1 (C-6), 14.1 (Me). Anal. $\left(\mathrm{C}_{12} \mathrm{H}_{11} \mathrm{~N}_{5}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$. Spectroscopic data for 7j: ${ }^{1} \mathrm{H}$ NMR ( 500 $\left.\mathrm{MHz}, \mathrm{CDCl}_{3}\right) \delta 8.46(\mathrm{~d}, \mathrm{~J}=7.7 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{H}-\mathrm{Ar}), 7.51-7.43(3 \mathrm{H}$, H -Ar), 7.32 (s, 1H, H-6), 4.99 (s, 2H, NCH 2 ), 2.39 (s, 3H, 7-Me), 2.24 (s, 3H, COMe). Eluant: n-hexane/ethyl acetate (7:3 $\mathrm{v} / \mathrm{v}) .24 \%, \mathrm{mp} 269^{\circ} \mathrm{C}$ dec; ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.46$ (d, J = $7.7 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{H}-\mathrm{Ar}$ ), 7.46 (m, 1H, H-Ar), 7.45 (m, 2H, H-Ar), 7.35 (s, 1H, H-6), $5.00\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{NCH}_{2}\right.$ ), 2.75 (septuplet, $\mathrm{J}=6.9 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{CH}), 2.39(\mathrm{~s}, 3 \mathrm{H}, \mathrm{COMe}), 1.33(\mathrm{~d}, \mathrm{~J}=6.9 \mathrm{~Hz}$, $6 \mathrm{H}, 2 \mathrm{MMe}$ ). IR (Nujol) $1686 \mathrm{~cm}^{-1}$. Anal. ( $\mathrm{C}_{17} \mathrm{H}_{19} \mathrm{~N}_{5} \mathrm{O}$ ) C, H, N.

1-[(2,7-Diphenylimidazo[1,2-a][1,3,5]triazin-4-yl)amino]acetone (7q). Eluant: n-hexane/ethyl acetate ( $7: 3 \mathrm{v} / \mathrm{v}$ ). $20 \%$, mp $353{ }^{\circ} \mathrm{C}$ dec; ${ }^{1} \mathrm{H}$ NMR ( $500 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 8.49(\mathrm{~d}, \mathrm{~J}$ $=7.4 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{H}-\mathrm{Ar}), 7.57(\mathrm{~s}, 1 \mathrm{H}, \mathrm{H}-6), 7.55-7.52(\mathrm{~m}, 4 \mathrm{H}$, $\mathrm{H}-\mathrm{Ar}), 7.50-7.48$ (m, 2H, H-Ar), 7.43-7.37 (m, 2H, H -Ar ), 4.97 (s, 2H, NCH 2 ), 2.29 (s, 3H, COMe). IR (Nujol) $1687 \mathrm{~cm}^{-1}$. Anal. $\left(\mathrm{C}_{20} \mathrm{H}_{17} \mathrm{~N}_{5} \mathrm{O}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

Receptor Binding Assays. $A_{1}, A_{2 A}$, and $A_{3}$ Receptor Binding. Displacement of $\left[{ }^{3} \mathrm{H}\right] \mathrm{CHA}(31 \mathrm{Ci} / \mathrm{mmol})$ from $\mathrm{A}_{1} \mathrm{AR}$ in bovine cortical membranes, $\left[{ }^{3} \mathrm{H}\right] \mathrm{CGS} 21680$ ( $42.1 \mathrm{Ci} / \mathrm{mmol}$ ) from $A_{2 A} A R$ in bovine striatal membranes and [125] ]AB-MECA ( $2000 \mathrm{Ci} / \mathrm{mmol}$ ) from $\mathrm{A}_{3} A R$ in bovine cortical membranes were performed as described elsewhere. ${ }^{8}$

Compounds were dissol ved in DMSO and added to the assay mixture (DMSO concentration maximum 2\%). Blank experiments were carried out to determine the effect of solvent on binding. Protein estimation was based on a reported method, ${ }^{16}$ after solubilization with 0.75 N sodium hydroxide, using bovine serum albumin as standard. At least six different concentrations of each compound were used. The experiments ( $n=4$ ), carried out in triplicate, were analyzed by an iterative curvefitting procedure (GraphPad, Prism program, San Diego, CA), which provided $\mathrm{IC}_{50}, \mathrm{~K}_{\mathrm{i}}$, and SEM values for tested compounds.

The dissociation constant $\left(\mathrm{K}_{\mathrm{d}}\right)$ of $\left[{ }^{3} \mathrm{H}\right] \mathrm{CH}$, $\left.{ }^{3} \mathrm{H}\right] \mathrm{CGS} 21680$ and [ ${ }^{125 I}$ ]AB-MECA was $1.2,14$, and 1.02 nM , respectively.

Computational Chemistry. All molecular modeling was performed using the software package SYBYL ${ }^{17}$ running on a Silicon Graphics R10000 workstation. Molecular models of imidazotriazine derivatives were built according to SYBYL
standard bond lengths and valence angles. Geometry optimizations were realized with the SYBYL/MAXIMIN2 minimizer by applying the BFGS algorithm ${ }^{18}$ and setting a root-meansquare gradient of the forces acting on each atom at $0.05 \mathrm{kcal} /$ mol $\AA$ as a convergence criterion. Molecular graphics, root-mean-squares (rms) fit, and calculations of ring centroids of substructures were also carried out using SYBYL.

Docking simulations were carried out starting from the previously published bovine $A_{1}$ AR model, ${ }^{8}$ which was built using as template the frog rhodopsin, ${ }^{19,20}$ a membrane protein belonging to the G-protein coupled receptors (GPCRs) superfamily. Additional details regarding the receptor structure, site-directed mutagenesis data and methods applied in developing the $A_{1} A R$ model are reported in ref 8 . The model has also been compared with the rhodopsin template recently published by Palczewski and co-workers. ${ }^{21}$ Although slight differences in the orientation of the helices in the transmembrane domain are apparent; the juxtaposition of the residues within the putative adenosine binding pocket is well-conserved between the two models.

The position of the docked ligand 5 (Chart 1) in the receptor model ${ }^{8}$ was taken as a starting point. Selected ITAs ( $7 \mathbf{g}$ and 7j) were docked into the receptor model by means of the following steps: (i) superposition on the docked compound 5 about the NH atoms plus the centroid of the pendant phenyl ring; (ii) removal of 5 from the receptor; (iii) energy-minimization of the resulting ligand/binding site complexes based on the molecular mechanics Tripos force field. ${ }^{22}$

Molecular dynamics simulations of the $\mathbf{7 j} / \mathrm{A}_{1} A R$ complex were performed with the SYBYL/DYNAMICS module under default settings. These simulations, in which the protein backbone was treated as a rigid aggregate, were run at 300 K for 50 ps after reaching equilibration. Five structures extracted at 10, 20, 30, 40, and 50 ps were selected and energyminimized. Figure 3, displaying the interaction between $7 \mathbf{j}$ and the side chains of residues within a distance of $5 \AA \AA$ from any atom of the bound ligand, refers to the last MD snapshot.
