Received February 10, 2005

Compounds presenting an additional fused ring on the xanthine nucleus have been reported to exhibit antagonistic activity with various levels of affinity and selectivity toward the four adenosine receptors subtypes A_1, A_{2A}, A_{2B}, and A_3. This paper reports synthesis and biological evaluation of new 1-benzyl-3-propyl-1*H*,6*H*-pyrrolo[2,1-*f*]purine-2,4-diones and 1-benzyl-3-propyl-1*H*,8*H*-imidazo[2,1-*f*]purine-2,4-diones, among which we identified potent and selective A_3 adenosine receptors antagonists. In particular, 1-benzyl-7-methyl-3-propyl-1*H*,8*H*-imidazo-[2,1-*f*]purine-2,4-dione (**11e**) shows a K_i (hA_3) value from binding assay of 0.8 nM.

Introduction

Adenosine exerts a number of physiological functions through the activation of cell membrane G-protein coupled receptors classified into four different subtypes named A_1, A_{2A}, A_{2B}, and A_3.[1] The A_3 adenosine receptor is able to cause inhibition of forskolin-induced cAMP accumulation, to increase phosphatidylinositol-specific phospholipase C and D activity, and to elevate IP_3 levels and intracellular Ca^{2+} pools.[2] As a therapeutic target, it is the subject of intensive pharmacological characterization due to its significant involvement in several pathophysiological processes, such as inflammation, neurodegeneration,[3,4] cardiac and brain ischaemic damage,[5,6] asthma,[7] and cancer.[8]

A_3 receptor agonists appear to exert dual and opposite effects, either cytoprotective or cytotoxic, depending on the cell type and on the level of receptor activation.[9,10] A_3 receptors and their ability to regulate cell survival represent a promising therapeutic target in diseases in which excessive cell death is either undesirable, such as neurodegeneration, or desirable, such as cancer and inflammation.[11,12] Adenosine acts as a potent regulator of both normal and tumor cell growth.[13,14] Evidence of high levels of expression of A_3 adenosine receptor subtype has been provided in Jurkat cells,[15] a human leukemia cell line originating from the immune system, in the human melanoma A375 cell line,[16] and in human pancreatic, breast, prostate, colon, lung, and ovarian carcinoma cells.[17] A_3 antagonists seem to synergistically enhance cytotoxic treatment and counter P-glycoprotein efflux in multidrug resistance.[17] Furthermore, A_3 receptor antagonists may be useful in the treatment of glaucoma.[18]

In the past few years, different classes of compounds with nonxanthine structures have been reported to be A_3 adenosine receptor antagonists.[19−21] In a recent work, the approach based on the annelation of xanthine derivatives for the development of adenosine receptors antagonists has been extensively considered.[22] In particular, 1*H*,3*H*-pyrido[2,1-*f*]purine-2,4-diones[23] and imidazo[2,1-*i*]purin-5-ones[24] have been claimed as potent A_3 adenosine receptor antagonists. Recently, we reported a series of 1,3-dipropyl-7-aryl/heteroaryl-1*H*,6*H*-pyrrolo[2,1-*f*]purine-2,4-dione derivatives which were conceived as rigid analogues of KF17837, a known A_{2A} adenosine receptor antagonist belonging to the class of styryl xanthines.[25] Unfortunately, the synthesized compounds did not show significant affinity for the investigated targets.

The report by Priego et al.[23] about the mentioned 1*H*,3*H*-pyrido[2,1-*f*]purine-2,4-diones highlighted the importance of a benzyl and a propyl moieties at the 1 and 3 positions, respectively. In light of this we thought that the lack of activity of our reported 1,3-dipropyl-pyrrolo[2,1-*f*]purine-2,4-dione derivatives might be partially due to the presence of a propyl chain, instead of the benzyl moiety at the 1 position. We therefore evaluated the effect of the introduction of a benzyl and a propyl at the 1 and 3 position, respectively, in our previous series and in a new series of fused xanthine derivatives. In particular, we performed the synthesis of 1-benzyl-3-propyl-7-aryl/alkyl-1*H*,6*H*-pyrrolo[2,1-*f*]purine-2,4-dione (**7a**−**d**, Table 1) and 1-benzyl-3-propyl-7-aryl/alkyl-1*H*,8*H*-imidazo[2,1-*f*]purine-2,4-dione (**11a**−**n**, Table 1). We report the synthesis of these new tricyclic structures and the evaluation of their affinity and activity for the human adenosine A_1, A_{2A}, A_{2B}, and

A_3 receptors through radioligand binding assays and cAMP assays.

Results and Discussion

Chemistry. 1-Benzyl-3-propyl-1*H*,6*H*-pyrrolo[2,1-*f*]-purine-2,4-dione derivatives (**7a**−**d**) and 1-benzyl-3-propyl-imidazo[2,1-*f*]purine-2,4-dione derivatives (**11a**−**n**) were prepared following the general synthetic strategy depicted in Scheme 1. The 6-amino-1-benzyl-3-propyl-uracil **1** was synthesized starting from 1-benzyl-6-aminouracil according to a known procedure for the alkylation at the N^3 position via protection of the amino group at the 6-position as *N*-[(dimethylamino)methylene] derivative.[26] Subsequent nitrosation at the 5-position in acetic acid with $NaNO_2$ furnished compound **2**, and then the reduction of the nitroso group with sodium dithionite[27] gave 5,6-diamino-1-benzyl-3-propyl-uracil **3** in good yield.

The synthesis of the final 1-benzyl-3-propyl-1*H*,6*H*-pyrrolo[2,1-*f*]purine-2,4-dione derivatives **7a**−**d** required the conversion of intermediate **3** into the 3-benzyl-8-hydroxymethyl-1-propyl-3,7-dihydro-purine-2,6-dione **4** by a two-step reaction. Refluxing derivative **3** with glycolic acid, followed by cyclization of the resulting amide intermediate by heating in a solution of aqueous NaOH, afforded the desired product **4**.[25] Alkylation at the N^7-position with the appropriate α-halo-ketone using K_2CO_3 in DMF as solvent provided the 3-benzyl-8-hydroxymethyl-7-(2-oxo-alkyl)-1-propyl-3,7-dihydro-purine-2,6-dione derivatives **5a**−**d** in good yield. The obtained 7-(2-oxo-alkyl)-8-hydroxymethyl derivatives were converted into the corresponding 8-bromomethyl-purine-2,6-dione intermediates **6a**−**d** via treatment with PBr_3 in anhydrous benzene.

To obtain the cyclization which furnished the pyrrole ring condensed at the N^7−C^8 link of the purinone nucleus, we employed a strategy involving an intramo-

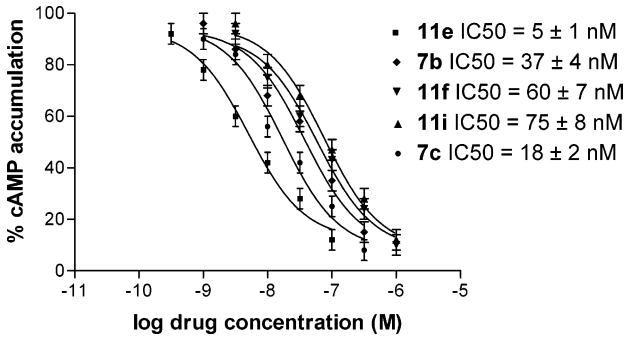

Figure 1. Inhibitory curves of cAMP accumulation in human A_3 adenosine receptors by adenosine antagonists blocking the effect of 100 nM Cl-IB-MECA.

lecular Wittig reaction between the carbonyl moiety of the introduced N^7-chain and the bromomethyl function at the 8-position. Thus, we treated the 8-bromomethyl derivatives **6a**−**d** with triphenylphosphine in benzene, heating the mixture at reflux for 5 h to allow the formation of the intermediate phosphonium salts. The crude material was easily cyclized into the corresponding pyrrolo[2,1-*f*]purine-2,4-diones **7a**−**d** by treatment with sodium methoxide.[25]

The 3-benzyl-1-propyl-3,7-dihydro-purine-2,6-dione **8** was obtained by reacting the diamino derivative **3** with formic acid[28] according to the same procedure followed for preparation of compound **4**. Bromination at the 8-position with Br_2 and sodium acetate in acetic acid at 60 °C for about 1 h led to formation of the key 8-bromo-intermediate **9** in excellent yield. Alkylation at the N^7-position with different α-halo-ketones under the same conditions employed for the synthesis of **5a**−**d** supplied 7-(2-oxo-alkyl)-1-propyl-3,7-dihydro-purine-2,6-dione derivatives **10a**−**n**. Treatment of these intermediates with liquid ammonia in a sealed tube at 120 °C overnight in ethanol effected, at first, the substitution of the bromine at the 8-position followed by the in situ cyclization of the amino group with the N^7 carbonyl function to give the desired 1-benzyl-3-propyl-1*H*,8*H*-imidazo[2,1-*f*]purine-2,4-dione derivatives **11a**−**n**.

Biological Evaluation and Structure-Affinity Relationships. All the synthesized compounds were evaluated in radioligand binding assays to determine their affinities for human A_1, A_{2A}, and A_3 adenosine receptors. Potency of the compounds versus hA_{2B} adenosine receptors were studied, evaluating their capability to inhibit (100 nM) NECA-stimulated cAMP production. Basal and NECA stimulation of cAMP levels were 15 ± 2 and 80 ± 9 pmoles cAMP/10^6 cells, respectively. NECA was able to stimulate cAMP levels in hA_{2B}CHO cells with an EC_{50} value of 145 ± 15 nM. Moreover, the compounds showing high affinity to hA_3 receptors were also studied through cAMP experiments performed in hA_3CHO cells evaluating their capability to block, in the presence of forskolin 10 μM, the inhibitory effect mediated by (100 nM)-Cl-IB-MECA (Figure 1). Basal, forskolin stimulation, and Cl-IB-MECA inhibition of cAMP levels were 14 ± 2, 75 ± 8, and 40 ± 5 pmoles cAMP/10^6 cells, respectively. Cl-IB-MECA was able to inhibit forskolin stimulated cAMP levels with an IC_{50} value of 8.7 ± 0.9 nM. Affinity data for A_1, A_{2A} and A_3 receptors, expressed as K_i values, and IC_{50} values derived from the cAMP assay carried out for hA_{2B} subtypes, are listed in Table 2.

In the reported series of compounds we evaluated the effect of different heterocycles fused on the N_7−C_8 positions of the xanthine nucleus. The fundamental feature of these molecules lies in their practically complete selectivity in binding A_3 receptor versus A_1, A_{2A} and A_3 subtypes, as reflected by the notable K_i (hA_1-hA_{2A}/hA_3) and IC_{50} (hA_{2B})/K_i (hA_3) ratios (Table 2). The K_i values related to the interaction with the adenosine A_3 receptor are strictly dependent on the nature of the substituents at the 7-position of the tricyclic structures while the ability to discriminate between the different AR subtypes is not generally affected by such structural modification. The synthesized compounds include both 7-(4-substituted-aryl)-pyrrolo/imidazo[2,1-*f*]purine-2,4-dione and 7-(cyclo)alkyl-pyrrolo/imidazo[2,1-*f*]purine-2,4-dione derivatives.

Among the examined tricycles, the imidazo[2,1-*f*]-purine-2,4-dione derivatives **11a**, **11e**, **11f**, and **11m** were 2- to 10-fold more active than the corresponding substituted-pyrrolo[2,1-*f*]purine-2,4-dione derivatives **7a**−**d** toward the adenosine A_3 receptor subtype. Both series had K_i values in the low nanomolar range (K_i = 0.8−200 nM). This indicates a possible involvement of

the N^8-position in the interaction of the molecules with the receptor, suggesting an opportunity to establish a hydrogen bond.

Among the 7-aryl-substituted series, it was observed that substitution at the 4-position of the phenyl ring with a methoxy function or especially with the small electron-withdrawing fluorine atom, which is also able to form hydrogen bonds, produces an increase in affinity, while the introduction of a *p*-phenyl group leads to the total loss of affinity. This indicates that the presence of a large aromatic and lipophilic moiety, such as the biphenyl, at the 7-position of the corresponding tricyclic derivative establishes repulsive interactions with the receptor.

We then decided to evaluate the effect of replacing the phenyl ring at the 7-position of compounds **7a** and **11a**−**d** with various (cyclo)alkyl chains. Compounds **7b**−**d** and **11e**−**l** contain at the 7-position alkyl chains with different length such as -methyl (**7b** and **11e**), -ethyl (**7c** and **11f**), branched alkyl chains such as -isobutyl (**11g**), -*tert*-butyl (**11h**), and cycloalkyl chains such as -cyclopropyl (**11i**) and -cyclohexyl (**11*l***). The best results were obtained with the introduction of small linear alkyl chains, in particular a methyl group (**11e**, $K_i(hA_3) = 0.8$ nM with a surprising selectivity pattern versus the other AR subtypes). Longer chains or branching led to a loss of activity (**11g** $K_i(hA_3) = 99$ nM and **11*l*** $K_i(hA_3) = 555$ nM), supporting the observation with the 7-biphenyl derivative (**11c**), which indicates that a sterically demanding, lipophilic moiety at the 7-position would be detrimental to binding. The synthesis of compounds **7d** and **11m**,**n** permitted us to estimate the effect of the introduction of an additional methyl group at the 6-position of the tricyclic derivatives. In all the examples, this kind of structural modification decreased the affinity of the molecules for the receptor binding site, inducing a significant increase of the related $K_i(hA_3)$ values (**7d** 10-fold less active than **7b**, **11m** 45-fold less active than **11e**, **11n** 4-fold less active than **11f**). However, modification of this side of the molecule did not seem to affect the selectivity versus A_1, A_{2A}, and A_{2B} receptors.

Conclusions

In conclusion the present study can be considered an innovative contribution to the previously reported[22] approach based on annelation of xanthine derivatives. Some of the newly reported imidazo[2,1-*f*]purine-2,4-dione and pyrrolo[2,1-*f*]purine-2,4-dione derivatives represent, to the best of our knowledge, the most potent and selective hA_3 adenosine receptor antagonists containing a xanthine nucleus. In particular 1-benzyl-7-methyl-3-propyl-1*H*,8*H*-imidazo[2,1-*f*]purine-2,4-dione (**11e**) shows a subnanomolar affinity toward the desired receptor target with a noteworthy selectivity versus the other adenosine receptors subtypes ($K_i(hA_3) = 0.8$ nM, $K_i(hA_1/hA_3) = 3163$, $K_i(hA_{2A}/hA_3) > 6250$, $IC_{50}(hA_{2B})/K_i(hA_3) = 2570$). These data are even more surprising when compared with the binding profile of MRE3008F20,[29] a potent A_3 adenosine receptor antagonists belonging to the family of pyrazolo[4,3-*e*]-1,2,4-triazolo[1,5-*c*]pyrimidines (K_i (hA_3) = 0.85 nM, $K_i(hA_1/hA_3) = 1294$, $K_i(hA_{2A}/hA_3) = 165$, $K_i(hA_{2B}/hA_3) = 2471$). From the selectivity pattern, it is apparent that compound **11e** represents a significant improvement over MRE3008F20, in particular with regard to the significant increase of selectivity toward adenosine A_{2A} subtype.

Interestingly, a notable concordance between binding and functional experiments performed with the hA_3 receptor has been revealed. Among the examined compounds, the molecules showing the best affinities for the hA_3 adenosine receptor have also proved to have very high potency in functional assays (Figure 1). In particular, derivative **11e** can be considered the most potent compound, exhibiting an IC_{50} value of 5 nM.

Experimental Section

General Procedure for Preparation of 1-Benzyl-3-propyl-1*H*,6*H*-pyrrolo[2,1-*f*]purine-2,4-dione Derivatives (7a−d, Intramolecular Wittig Reaction). A solution of the corresponding bromide **6a**−**d** (0.42 mmol) and PPh_3 (0.46 mmol) in anhydrous benzene (5 mL) was refluxed for 5 h. After this time, the resulting mixture was concentrated to half-volume and the precipitates collected by filtration. The intermediate phosphonium salts (0.26 mmol) were then added to an ice-cooled and stirred solution of sodium methoxide (0.29 mmol) in anhydrous methanol (5 mL). The reaction was stirred at 0 °C for 10 min, the solvent was evaporated, and the products were purified by column chromatography on silica gel eluting with the appropriate mixture of light petroleum−EtOAc (6:4 for **7a**, 1:1 for **7b**−**d**).

General Procedure for Preparation of 1-Benzyl-3-propyl-1*H*,8*H*-imidazo[2,1-*f*]purine-2,4-dione Derivatives (11a−n). A solution of the appropriate 7-(2-oxo-alkyl)-3,7-dihydro-purine-2,6-dione derivatives **10a**−**n** (0.4 mmol) in EtOH (4 mL) was cooled at −40 °C. Liquid ammonia (3−4 mL) was then added to the mixture. The mixture was heated in a sealed tube overnight at 100−120 °C. The reaction was finally allowed to cool at room temperature, and then the solvent and the excess of ammonia were evaporated to obtain a residue that was suspended with water and extracted with EtOAc (3 × 25 mL). The organic phase was dried with anhydrous sodium sulfate, and the solvent was evaporated to give a residue, which was purified by column chromatography on silica gel, eluting with the appropriate mixture of light petroleum−EtOAc.
