Received July 27, 2005

Abstract: Ring-constrained adenosine analogues have been designed to act as dual agonists at tissue-protective A₁ and A₃ adenosine receptors (ARs). 9-Ribosides transformed into the ring-constrained (N)-methanocarba-2-chloro-5'-uronamides consistently lost affinity at A₁/A_{2A}ARs and gained at A₃AR. Among 9-ribose derivatives, only N⁶-cyclopentyl and 7-norbornyl moieties were extrapolated for mixed A₁/A₃ selectivity and rat/human A₃AR equipotency. Consequently, **2** was balanced in affinity and potency at A₁/A₃ARs as envisioned and dramatically protected in an intact heart model of global ischemia and reperfusion.

There are four subtypes of adenosine receptors (ARs): A₁, A_{2A}, A_{2B}, and A₃, and their selective agonists are under development as therapeutic agents.^{1–3} Activation of one or more of the ARs and receptor overexpression have been shown to have a cytoprotective role in ischemic models.^{3–8} Specifically, activation of either A₁ or A₃ARs in cardiac myocytes in several species has

been shown to mimic the cardioprotective effect of ischemic preconditioning.^{9–11} The coactivation of A₁ or A₃ARs in the cardiac myocyte has been shown to be protective to a greater degree than activation of either subtype alone. In vivo experiments have also demonstrated the cardioprotective effects of A₁ and A₃ARs in certain species.¹² Activation of A₁ and A₃ARs leads to activation of PLC and PLD (phospholipase C and D), respectively, in cultured cardiac myocytes.⁹ PLC and PLD converge on activation of protein kinase C (PKC), which mediates cardioprotection.^{9,13} In the brain, activation of A₁ or chronic activation of A₃ARs has been shown to protect neurons against ischemia in a variety of models.^{14,15} In a model of global ischemia in gerbils, the A₁ agonists CPA (N⁶-cyclopentyladenosine) and ADAC(N⁶-[4-[[[4-[[[(2-aminoethyl)amino]carbonyl]methyl]anilin]carbonyl]methyl]phenyl]adenosine) and the chronically administered A₃ agonist IB-MECA (1-[6-[[[3-iodophenyl]methyl]amino]-9H-purin-9-yl]-1-deoxy-N-methyl-β-D-ribofuranuronamide) were cytoprotective at very low doses.

The concurrent activation of A₁ and A₃ARs has been carried out either by coadministering selective agonists for each subtype or using novel conjugates of functionalized congeners of A₁ and A₃ agonists.¹⁶ Some agonists of balanced potency have been reported,^{17–19} however, they are often partial agonists and of selectivities limited to a particular species. The careful design and covalent joining of amine-functionalized congeners provide binary conjugates that are balanced in their ability to activate A₁ and A₃ARs. However, due to the high molecular weights (in excess of 1000) and the presence of multiple hydrogen bond donors, these molecules do not satisfy the criteria proposed by Lipinski for prediction of oral bioactivity²⁰ and are of limited application in vivo.

We have taken a new approach, i.e. based on differential effects on ARs of the ring-constrained (N)-methanocarba ring system [(N) = North],²¹ to design dual acting A₁/A₃AR agonists of relatively low molecular weight. The new agonists (**1–3**, Scheme 1) were synthesized after careful SAR analysis of a large number

^a Reagents and conditions: (a) RNH_2 , MeOH, triethylamine; (b) CH_3NH_2 , MeOH; (c) TFA, H_2O , MeOH, 70 °C; (d) 10% Pd/C/ H_2 , MeOH.

of adenosine derivatives at ARs with respect to both binding affinity and relative efficacy.^{22–24} We have incorporated specific molecular features that provide a balance in potency at A_1 and A_3 ARs and that also maintain full efficacy at the A_3 AR.^{21,22} In the present study, several derivatives have been shown in binding and functional assays to be dual-acting at the two receptor subtypes. Furthermore, a potent antiischemic cardioprotective effect in an intact mouse heart model of global ischemia and reperfusion injury was demonstrated.^{6,13} This mammalian heart model has been shown to express both AR subtypes.

The selection of N^6 -, C2-, and 5'-uronamide substituents in the target compounds has been based largely on our recent findings relating to AR affinity, selectivity, and relative efficacy for specific adenine-9-ribose derivatives as well as a series of adenine-(N)-methanocarba-5'-alkyl uronamide derivatives.^{21,22} At the A_3 AR, in contrast to the A_1 AR, relative efficacy is easily diminished by substitution of the N^6 and C2 positions while preserving affinity. This reduction in efficacy is readily overcome by a flexible 5'-methyluronamide moiety.²² The desired analogues would be balanced in high affinity at both human and rat A_1 and A_3 ARs and would display full agonism. According to published SAR findings (correlated in Figure 1) the substitution of adenine-9-ribosides to obtain the corresponding 2-chloro-(N)-methanocarba-5'-alkyl uronamides produced consistent effects on AR affinity. Upon undergoing these modifications for various hydrophobic N^6 -substituents there was roughly 1 order of magnitude loss of binding affinity at the A_1 AR and slightly less loss at the A_{2A} -AR. The effect of this transformation on binding affinity at the A_3 AR resulted in either equal to or greater affinity (up to 14-fold), due to the conformational preference of the A_3 AR binding site.²¹ Thus, we examined a large published series of seventy-four adenosine derivatives,^{23,24} monosubstituted at N^6 , for the ideal candidates predicted to have balanced binding affinity when adapted to the 2-Cl-(N)-methanocarba series. The following criteria were sought: (1) equipotency at rat and human A_3 ARs; (2) roughly 2 orders of magnitude greater affinity at A_1 ARs in comparison to A_3 ARs; and (3) selectivity for A_1 and A_3 ARs in comparison to both A_{2A} and A_{2B} ARs. Few N^6 -substituents satisfied all criteria; for example, although the affinities at the rat and human A_1 ARs were generally similar,²⁴ at the A_3 -ARs the species difference was as high as 1100-fold.²³ The most likely candidates identified were N^6 -cycloalkyl groups of the A_1 -selective agonists 4–6.

Figure 1. Correlation of K_i values at human A_1 (■), A_{2A} (◆), and A_3 (▲) receptors of adenosine derivatives in two structural series were compared. The two series compared are monosubstituted adenosine (9-ribose) derivatives and trisubstituted 2-chloro-(N)-methanocarba derivatives. In each case, pairs of compounds in which both members have the same N^6 -substitution (as indicated) are correlated. The five (N)-methanocarba analogues depicted in this graph contained N^6 -benzyl and phenylethyl-type groups; however, the effects on affinity at each of the three adenosine receptor subtypes were generalized to design new N^6 -cycloalkyl analogues having desired pharmacological properties.

The synthetic route to three adenosine agonists 1–3 that were designed for high affinity at the A_1 and A_3 adenosine receptors and low affinity at the A_2 receptors is shown in Scheme 1. The synthesis of the target cyclopentyl derivative 2 and the 7-norbornyl derivative 3 was according to the general route presented for 5'-uronamido-(N)-methanocarba derivatives.²¹ The synthetic approach of Joshi et al.²⁵ has been followed to incorporate the 5'-uronamido-(N)-methanocarba ring system. The requisite 7-norbornylamine was prepared in three steps from 7-norbornyl bromide using a Curtius rearrangement. Accordingly, the 2,6-dichloro 5'-ester 7²¹ was treated first with a cycloalkylamine, which substituted selectively at the 6-position. Subsequent treatment with a large excess of methylamine converted the ester group to the corresponding amide. The final step was acidic deprotection of the isopropylidene protecting group at the 2',3'-hydroxyl groups. Both 2 and 3 contain the 2-chloro and 5'-uronamido-(N)-methanocarba substituents. The 2-Cl group in 2 was hydrogenolyzed to give 1 in good yield.

Binding and functional assays were carried out at human A_1 , A_{2A} , and A_3 ARs expressed in CHO (Chinese hamster ovary) cells. The results confirmed that 1 and 2 were highly selective for A_1 and A_3 ARs, and that the affinities were nearly balanced. However, 3 was considerably more potent in binding to the A_3 than to the

^a All AR experiments were performed using adherent CHO cells stably transfected with cDNA encoding the human or rat ARs. Percent activation of the human A₃AR was determined at 10 μM. Binding at human A₁ and A_{2A}ARs in this study was carried out as described in Methods using [³H]R-PIA or [³H]CGS 21680 as a radioligand. Values from the present study are expressed as mean ± SEM, *n* = 3–5. ^b Percent activity at 10 μM, relative to 10 μM Cl-IB-MECA (A₃). ^c **1**, MRS3706; **2**, MRS3630; **3**, MRS3638. ^d Data from Gao et al., unless noted.^{22,23} ^e Data from Klotz et al.²⁸ ^f K_i at rat A₁ AR is 17.4 ± 2.7 nM. ND not determined. CP, cyclopentyl; NB, 7-norbornyl.

A₁AR. For all three derivatives, the K_i values at the human A_{2A}AR were at least several 100-fold greater than at the A₁ or the A₃AR. Compound **2** was equipotent in binding to human and rat A₁ARs with K_i values of 18.3 and 17.4 nM, respectively. Also, the affinity of compound **2** was similar at human and rat A₃ARs with K_i values of 3.7 and 5.8 nM, respectively.

In functional assays consisting of measuring inhibition of forskolin-stimulated production of 3',5'-cyclic-adenosine monophosphate (cAMP) in intact transfected CHO cells, single concentration determinations (Table 1) indicated that full A₃AR agonism was maintained in compounds **1–3**. Concentration response curves indicated that compound **2** was a dual acting full agonist with nearly equivalent functional potencies at human A₁ (EC₅₀ = 8.2 nM) and A₃ (EC₅₀ = 2.8 nM) ARs.

Compounds **1–3** were assayed for activation of the human A_{2B}AR stably expressed in CHO cells.¹⁸ Each adenosine derivative was tested at a concentration of 10 μM. As for the ribosides **4–6**, the EC₅₀ values at the human A_{2B}AR of the (N)-methanocarba-5'-uronamide N⁶-substituted nucleosides **1–3** were all >10 μM. Compound **2** also showed negligible effect in stimulation of adenylate cyclase at the murine A_{2A} or A_{2B}ARs endogenously expressed in PC12 (rat) and NIH/3T3 cells (mouse), respectively.

Since **2** was the most potent and still nearly matched in binding affinity and in function at the two AR subtypes known to be cardioprotective, this compound was chosen for further pharmacological studies in an intact mouse heart model of ischemia and reperfusion.^{6,13} In this model, compound **2** at 30 nM exerted a potent antiischemic cardioprotective effect (Table 2). The mixed agonist was perfused until the induction of ischemia. The recovery of left ventricular developed pressure (LVDP), +dP/dt, -dP/dt, and heart rate (HR) all improved significantly following treatment with the mixed agonist **2**. The infarct size determined using computer morphometry²⁶ after staining with triphenyltetrazolium chloride (TTC) was significantly reduced in the group treated with **2** (Figure 2). The percent necrosis in the group treated with **2** was 15 ± 7% compared to 23 ± 8% in the vehicle-treated controls, *n*

Table 2. Recovery of Left Ventricular Function in a Mouse Heart Model of Ischemia/Reperfusion^a

parameter	vehicle ^b	compound 2 ^c	significance
LVDP ^d	8.5 ± 5.3	26.0 ± 4.8	<i>t</i> = 7.1, <i>P</i> < 0.0001
+dP/dt ^d	6.3 ± 3.9	21.1 ± 4.9	<i>t</i> = 7.4, <i>P</i> < 0.0001
-dP/dt ^d	8.2 ± 3.7	24.6 ± 7	<i>t</i> = 7.22, <i>P</i> < 0.0001
HR ^d	37.1 ± 32.6	93.8 ± 19.3	<i>t</i> = 4.1, <i>P</i> < 0.0005
% necrosis	23.4 ± 7.8	15.0 ± 6.9	<i>t</i> = 2.32, <i>P</i> ^e = 0.029

^a Values were obtained after 35 min global ischemia followed by reperfusion. ^b DMSO, *n* = 16. ^c A concentration of 30 nM **2** (initially dissolved in DMSO) was used, *n* = 6. During buffer perfusion of heart via the side port, the spontaneous heart rate dropped by 24 ± 8.2% (SEM) due to a decrease in the perfusion pressure. Perfusion of buffer containing 30 nM **2** was associated with a larger decrease in the heart rate of 57 ± 6.7%, likely because of a negative inotropic effect of **2**. ^d % of baseline prior to ischemia/reperfusion. ^e Two-tailed.

Figure 2. Antiischemic infarct-reducing effects of adenosine receptor agonists. Murine hearts were excised and subjected to normothermic global ischemia and reperfusion with or without (A) adenosine receptor agonists as described in Methods. The adenosine receptor agonists were (B) A₃ agonist Cl-IB-MECA, 30 nM; (C) A₁ agonist **5**, 100 nM; (D) mixed A₁/A₃ agonist **2**, 30 nM. Agonists were infused for 5 min till the induction of ischemia. The heart was stained with TTC after 35 min of ischemia and 120 min of reperfusion, and the infarcted areas were visualized as TTC-negative (pale, white). The infarct was quantified by morphometry and normalized to the whole heart as % necrosis. Data were representative of 6 (adenosine receptor agonist-treated) and 16 (DMSO/vehicle-treated) mice. A vehicle control not subjected to ischemia showed no pale or TTC-negative area.

= 6. In the same model, the classical A₁AR agonist **5** at a higher concentration (100 nM) could also reduce myocardial infarct size. The percent necrosis following infusion of **5** was 15 ± 10%, *n* = 15.

Thus, we have designed novel cardioprotective agents based on mechanistic and structural considerations. The adenosine N^6 -substituents, cyclopentyl and 7-norbornyl, were selected based on predictions made from the binding affinities of the corresponding adenosine derivatives²² and from the consistent effects on AR affinity of replacing the 9-ribose moiety with a 5'-uronamido-(N)-methanocarba-pseudoribose moiety in combination with the 2-Cl substituent. The sum of these effects on affinity at each of the three AR subtypes was generalized to design new N^6 -cycloalkyl analogues having desired pharmacological properties. The results of Tchilibon et al.²¹ for substituted N^6 -benzyl and N^6 -(2-phenylethyl) derivatives suggested that in each case, in comparison to the corresponding adenine-9-ribose, the affinity at the human A_1 AR decreased by at least 1 order of magnitude while the affinity at the human A_3 AR tended to increase by typically 1 order of magnitude. In the case of N^6 -cyclopentyl- and N^6 -(7-norbornyl)adenine 9-ribosides, **4** and **6**, respectively,²² the affinity of each was similar at rat and human A_3 ARs, but the effects of such N^6 -cycloalkyl substitution had not yet been probed in the 5'-uronamido-(N)-methanocarba series. The affinity of both 9-ribosides at the human A_{2A} and A_{2B} ARs was weak; thus, the corresponding 5'-uronamido-(N)-methanocarba derivatives were expected to be highly selective for A_1 and A_3 ARs in comparison to A_{2A} and A_{2B} ARs. We have confirmed the anticipated selectivity for the N^6 -cyclopentyl derivatives **1** and **2**. Also, based on the 9-ribosides, a large species difference at the A_3 AR common among N^6 -substituted adenosine derivatives²⁴ was predicted to be absent in the new analogues, and this prediction was confirmed in binding assays of all three newly synthesized derivatives.

We have examined the mixed A_1/A_3 agonist **2** in an intact mouse heart model of ischemia and reperfusion injury,^{6,13} in which either an A_1 - or A_3 -selective agonist acts as a potent cardioprotective agent. The initial findings validate the model for studying AR-dependent protection and illustrate the highly cardioprotective effect of **2**. The role of cardiac A_3 ARs is complex, with protective effects demonstrated in models of preconditioning, delayed cardioprotection,¹³ and ischemia-reperfusion.^{6,8} The activation of the A_3 AR in the rat coronary circulation has been proposed to mediate vasodilation.²⁷ Also, potential side effects of adenosine agonists, such as hypotension and sedation, must be considered.¹ Therefore, additional pharmacological examination of **2** and similar mixed agonists will be needed.

In conclusion, a series of (N)-methanocarba nucleosides previously characterized as selective A_3 AR agonists has now been adapted to mixed AR selectivity desired for cytoprotection in a variety of tissue systems. These compounds may serve as prototypical examples for more detailed pharmacological studies leading to the development of novel dual acting cardioprotective AR agonists.
