#### Abstract

Twenty novel $\beta$-secretase inhibitors containing biarylpiperazine moieties belonging to naphthyl and coumarinyl series were designed for their potential use in Alzheimer's disease therapy. Enzymatic and cell-based assays have been carried out. The biological results clearly demonstrate that specific substituents located at the $\mathrm{N}_{4}$-position of the piperazine ring result in excellent in vitro inhibitory potency ( $\mathrm{IC}_{50}$ values ranging between 40 and 70 nM ). Variable temperature NMR and modeling studies are consistent with the obtained biological data, since these studies confirmed that introduction at the $\mathrm{N}_{4}$-position of the piperazine ring allows productive interactions within the BACE-1 active site, which appear to be determinative for high BACE-1 inhibitory activity. These results are of particular interest since some of the new analogues belonging to the naphthyl series are almost one log more active than the best inhibitor of the similar family recently reported.

## Introduction

As the number of cases of Alzheimer's disease (AD) rises in developed countries, the unmet medical need for diseasemodifying pharmacotherapy continues to grow. Much of $A D$ research has been focused on the amyloid cascade hypothesis, which states that amyloid- $\beta$-42 ( $\mathrm{A} \beta_{42}$ ), a proteolytic derivative of the large transmembrane protein amyloid precursor protein (APP), plays an early role in any case of AD. Consequently, blocking the production of $\mathrm{A} \beta_{42}$ by specific inhibition of key proteases required for $\mathrm{A} \beta_{42}$ generation is a major focus of research into AD therapy. The identification of secretase inhibitors has triggered a race to develop drug-like inhibitors of these enzymes, which have become major AD targets.

Since it has been established that $\gamma$-secretase cleaves various substrates, some of which might have important physiological roles (Notch cleavage), $\gamma$-secretase inhibitors might have insurmountable mechanism-based toxicity. ${ }^{1}$ Taking into account those observations developing $\beta$-secretase inhibitors appears to be more encouraging.
$\beta$-Secretase is an aspartic protease that generates the N terminus of $\mathrm{A} \beta_{42}{ }^{2}$ whose therapeutic promise is based on the absence of major problems as a result of $\beta$-secretase ablation. Indeed, the phenotype of young BACE knock-out mice was analyzed, and they were found to be healthy and fertile. ${ }^{3}$ Taken together, the absence of $\mathrm{A} \beta$ production and distinct pathology in the BACE knock-out mice led us to search for $\beta$-secretase drug inhibitors, particularly in view of the situation regarding the $\gamma$-secretase target. An overview on the design and development of $\beta$-amyloid cleaving enzyme-1 (BACE-1) has been recently published by Cumming et al. ${ }^{4}$

Several types of BACE-1 inhibitors are reported:

[^0](i) Substrate-Based BACE-1 Inhibitors: The first generation of these inhibitors was predominantly of peptidic nature which precludes their full development as AD drugs. Less peptidic second generation inhibitors are under investigation. ${ }^{5}$
(ii) Statin and Homostatine BACE-1 Inhibitors. These types of inhibitors have been mostly developed by Elan and Pharmacia \& Upjohn. (Note: 18 patents have been published in the (homo)statine field but are not listed in this paper).
(iii) Hydroxyethylamine (HEA) BACE-1 Inhibitors. The HEA dipeptide isostere is a known motif of the aspartyl protease inhibitors, notably from early research on HIV protease and renin inhibitors. Elan, Pharmacia, Bristol Myers Squibb, and Takeda chemical industries have made important contributions with closely related core structures. Several patent applications have been disclosed.
(iv) Other Inhibitors. These include various piperidine derivatives developed by different pharmaceutical companies such as Vertex, Actelion Pharmaceuticals, De Novo Pharmaceuticals, Elan, and Pharmacia. These BACE-1 inhibitors have been recently reviewed. ${ }^{4}$

From this survey, it appears that the ideal properties of a BACE-1 inhibitor for clinical use are (i) ability to potently and effectively lower $\mathrm{A} \beta$ in transgenic mice, (ii) CNS penetration, (iii) oral bioavailability, (iv) good pharmacokinetic profile, and finally (v) selectivity against other aspartyl proteases.

To overcome the historical problems associated with peptide like structures such as low oral bioavailability, poor bloodbarrier permeability, and susceptibility to P-glycoprotein transport, ${ }^{6}$ we chose to focus on the identification of nonpeptide or pseudopeptide inhibitors. In this perspective, starting from already published data on arylpiperazine amide scaffolds as a possible framework for the design of $\beta$-secretase inhibitors, we investigated original and judicious modifications at different positions on the aryl piperazine scaffold. Molecular modeling and the Protein Data Bank revealed that the arylpiperazine scaffold allows the design of a large diversity of BACE-1

Figure 1. Arylpiperazine amide scaffolds.
inhibitors through the substitution possibilities offered at various positions as shown on Figure 1.

Among the numerous substitution possibilities we have deliberately limited our project to two series of analogues: on one hand, the naphthyl series which has been already studied, and, on the other hand, the coumarinyl series (Figure 1). In the original coumarin series, the replacement of the naphthyl moiety by a coumarin nucleus could rigidify the resulting structure through a possible hydrogen bonding between the carbonyl of the lactone and the NH group of the amide functional group. Such hydrogen bonding possibility could favor specific conformations, which could improve or impair the inhibitory activity of the resulting derivatives. Indeed, individual rotamers of certain drugs involving amide bonds could be required for highaffinity receptor binding ${ }^{7}$ or for high-enzymatic active affinity within the $\beta$-secretase active site. The rotational process is largely governed by steric and electronic effects provided by substituents around the $\mathrm{C}-\mathrm{N}$ bond. In the course of our synthetic chemistry program to design these $\beta$-secretase inhibitors, variable temperature NMR studies revealed that some interactions between the amide group and the amino group at the 4-position of the piperazine ring most likely occurred in both naphthyl and coumarin series rather than hydrogen bonding with the carbonyl of the lactone ring. This observation led us to focus our synthetic efforts on the synthesis of a library of derivatives in which the $\mathrm{N}_{4}$-position of the piperazine ring was substituted by a wide diversity of substituents.

## Chemistry

Both series of compounds required common intermediates $\mathbf{2 a - c}$, which were obtained through sequences described in Scheme 1.

Compounds 1a-c were obtained in quite good yields by condensation of commercially available 2,5-dibromonitrobenzene with morpholine, $N$-Boc piperazine, or $N$-benzyl piperazine in refluxed 2-propanol. ${ }^{8}$ Reduction of the nitro group was assayed under different conditions in order to optimize the yields. Indeed, classical catalytic hydrogenation with palladium
on charcoal led to the loss of the bromine atom, while other conditions, such as $\mathrm{NiCl}_{2} / \mathrm{NaBH}_{4}$ in $\mathrm{CH}_{3} \mathrm{OH} / \mathrm{CH}_{2} \mathrm{Cl}_{2}{ }^{9}$ or $\mathrm{Fe} /$ $\mathrm{NH}_{4} \mathrm{Cl}$ in refluxed ethanol, ${ }^{10,11}$ led to low yields of desired compounds. In contrast, the use of Zn powder in $\mathrm{KH}_{2} \mathrm{PO}_{4}$ in refluxed THF ${ }^{12,13}$ led to high yields of the expected aniline derivatives $\mathbf{2 a}-\mathbf{c}$. These anilines were subsequently acylated with 1-naphthoyl chloride affording intermediates $\mathbf{3 a}-\mathbf{c}$. The $N$-benzyl protecting group of compound $\mathbf{3 c}$ was removed by using ammonium formate as hydric source and $\mathrm{Pd} / \mathrm{C}$ as catalyst. ${ }^{14}$ The resulting amino derivative 3d was alkylated ${ }^{15}$ with bromoethanol to give 3e. Phenyl substituents were then introduced on derivatives 3b and 3c through a Suzuki crosscoupling reaction ${ }^{16,17}$ with the commercially available phenyl boronic acid, leading to the corresponding biphenyl piperazine derivatives $\mathbf{4 b}$ and $\mathbf{4 c}$. This reaction represents the limiting step of this synthetic scheme. We observed that the yield of this reaction depends on the nature of the substituent located at the $\mathrm{N}_{4}$-position of the piperazine ring. Compound $\mathbf{4 c}$ bearing an N -benzyl substituent was obtained in high yields while compound $\mathbf{4 b}$ with a $N$-Boc protecting group was isolated in low yield. Compound $4 \mathbf{c}$ was then deprotected with ammonium formate ${ }^{14}$ to afford the corresponding free amino derivative $\mathbf{4 d}$.

This key intermediate $\mathbf{4 d}$ was subsequently functionalized with various halide derivatives or carboxylic acids (Scheme 2). Compound $\mathbf{4 d}$ was N -alkylated ${ }^{15}$ with different bromide or chloride derivatives such as bromoethanol, ethyl bromoacetate, N -(5-bromopentyl)phthalimide, ( S )-( - )-3-chloro-1-phenyl-1propanol, or $(R)-(+)$-3-chloro-1-phenyl-1-propanol, in the presence of potassium carbonate in acetonitrile to give respectively compounds 5a, 5b, 5c, 5e, and 5f. Compound 5d was obtained after removal of the phthalimide protecting group of $\mathbf{5 c}$ by hydrazine monohydrate in ethanol. ${ }^{18} \mathrm{~N}$-Acylation of $\mathbf{4 d}$ by benzoyl chloride led to compound 6a, while $\mathbf{6 b}$ was isolated in good yield by acylation of ( $\pm$ )- $\alpha$-lipoic acid ${ }^{19}$ using 1,3dicyclohexylcarbodiimide (DCC) and 1-hydroxybenzotriazole (HOBt) as coupling system.

Coumarin-3-carboxylic acids $\mathbf{7}$ and $\mathbf{8}$ were obtained in high yields from the corresponding $o$-hydroxybenzaldehydes and Meldrum's acid in refluxed ethanol (Scheme 3). ${ }^{20} \mathrm{~N}$-Acylation of anilines $\mathbf{2 a}-\mathbf{c}$ by the carboxylic acids $\mathbf{7}$ or $\mathbf{8}$ was achieved by using phosphorus oxychloride $\left(\mathrm{POCl}_{3}\right)$ in pyridine as a coupling system at a temperature ranging from $-20^{\circ} \mathrm{C}$ to room temperature. ${ }^{21}$ The corresponding adducts $\mathbf{9 a}-\mathbf{c}$ and $\mathbf{1 0 a}-\mathbf{c}$ were obtained in satisfactory yields. Standard removal of the $N$-Boc protecting group of $\mathbf{9 b}$ and $\mathbf{1 0 b}$ allowed the isolation of the corresponding TFA salts $\mathbf{9 d}$ and $\mathbf{1 0 d}$ which were subsequently N -alkylated with bromoethanol ${ }^{15}$ to give respectively 9 e and

10e. Bromophenyl piperazine 9b and 9c were involved in a Suzuki cross-coupling reaction ${ }^{16,17}$ in order to synthesize the corresponding biphenyl piperazine derivatives 11b and 11c. The $N$-Boc protected biphenylpiperazine analogue was treated by TFA to ensure the removal of the protecting group and to isolate the corresponding TFA salt 11d.

## NMR Studies

The magnetic anisotropy induced by the amide function has been the subject of numerous NMR studies. ${ }^{22}$ This anisotropic effect might be used to predict the preferential conformation around $\mathrm{N}-\mathrm{C} \alpha$ bond. The interconversion of diastereotropic ${ }^{1} \mathrm{H}$ NMR signals can be followed by variable temperature nuclear magnetic resonance (VT NMR) techniques. In some cases, coalescence of peaks arising from $\mathrm{Ar}-\mathrm{CO}$ and/or $\mathrm{C}-\mathrm{N}$ rotations can be observed. Two pairs of analogues belonging to both the naphthyl ( $\mathbf{3 b}$ and $\mathbf{3 d}$ ) and coumarin ( $\mathbf{1 0 b}$ and $\mathbf{1 0 d}$ ) series were selected for this study.

The NMR spectra of compounds dissolved in DMSO- $d_{6}$ were recorded at various temperatures ranging from 30 to $130{ }^{\circ} \mathrm{C}$. Variations in chemical shifts and/or coalescence of signals for
representative piperazine ring protons $\mathrm{Ha}, \mathrm{Hb}$ or for aromatic protons $\mathrm{Hc}, \mathrm{Hd}$, and He of the halogenated phenyl ring were observed (Table 1).

For compounds unsubstituted at the $\mathrm{N}_{4}$-position of the piperazine ring ( $\mathbf{3 d}$ and $\mathbf{1 0 d}$ ), no significant temperature effects on the chemical shifts as well as on the patterns of signal coalescence for the protons $\mathrm{Ha}, \mathrm{Hb}, \mathrm{Hc}$, and Hd were observed. We concluded that the hypothesis that replacing a naphthyl moiety by a coumarin, to favor the formation of a hydrogen bond between the NH of the exocyclic amide and the carbonyl group of the coumarin moiety to hinder the rotation around $\mathrm{N}-\mathrm{C} \alpha$ or $\mathrm{Ar}-\mathrm{CO}$ bonds, was not fulfilled.

In contrast, VT NMR carried out for compounds bearing a Boc substituent at the $\mathrm{N}_{4}$-position of the piperazine ring ( $\mathbf{3 b}$ and 10b) induced chemical shift variations, broadened line shapes, and coalesced signals of some of the specific protons $\mathrm{Ha}, \mathrm{Hb}, \mathrm{Hc}, \mathrm{Hd}$, and He. In Table 1 we report chemical shifts and patterns of signal coalescence of identified protons.

As it can be observed, for compounds ( $\mathbf{3 d}$ and 10d) with a free amino group at the $\mathrm{N}_{4}$-position of the piperazinyl ring, no pattern of coalescence occurred at $130^{\circ} \mathrm{C}$. In contrast, for the

|  |  | 130 | no change |  |  |  |  |

${ }^{a} \mathrm{t}=$ triplet, $\mathrm{bs}=$ broad singlet, $\mathrm{q}=$ quintet, $\mathrm{bd}=$ broad doublet; d $=$ doublet, n.d. $=$ not determined; $\delta=$ chemical shift (ppm).
corresponding $N$-Boc protected analogues ( $\mathbf{3 b}$ and $\mathbf{1 0 b}$ ), between $100^{\circ} \mathrm{C}$ to $130^{\circ} \mathrm{C}$, a pattern of coalescence is observed for some signals of the piperazinyl ring (10b) as well as for the signals of the aromatic ring ( $\mathbf{3 b}$ ).

These results suggest that some substituents at the $\mathrm{N}_{4}$-position of the piperazine ring stabilize the interconversion of the different possible conformations of the piperazine ring, favoring the most energetically stable conformation. It cannot be excluded that the presence of a bulky group at the $\mathrm{N}_{4}$-position of the piperazine ring could also affect the $\mathrm{Ar}-\mathrm{CO}$ and $\mathrm{C}-\mathrm{N}$ bond rotations. The same effects are not observed in the case of free $N_{4}$-amino analogues.

## Molecular Modeling Studies

The development of substrate-based inhibitors has been significantly aided by X-ray crystallographic analysis of BACE-1 complexes with a standard peptide-based inhibitor OM- $2,{ }^{23}$ since the structure of this complex has allowed the identification of critical ligand-active site interactions. The BACE- 1 active site was found more open than that of other aspartic proteases and exhibited conformational flexibility. Since peptide-based or hydroxyethylene inhibitors were relatively large and "undruglike", other X-ray crystallographic studies of BACE-1 complexes with other inhibitors (nonpeptidic) have been performed. The most detailed account of nonpeptidic BACE inhibitors comes from Vertex Pharmaceuticals Inc., ${ }^{24 a}$ which disclosed several hundreds of compounds along with their associated BACE inhibition $K_{\mathrm{i}}$ values. Among the more potent classes reported were the biaryl naphthalenes represented by compound $\mathbf{4 d}$, in which the $\mathrm{N}_{4}$-position of the piperazine ring is free. Vertex proposed the first 3-D pharmacophore map of BACE. ${ }^{24 a}$ Hydrogen interactions within the active site and with other key residues, as well as other hydrophobic interactions with BACE subsites, were determined. Unfortunately, crystallographic data to substantiate this 3-D model was not provided. Simulated molecular dynamics analysis of superimposition of analogue $\mathbf{4 d}$ and its coumarin analogue 9 c in their low energy structures (not shown) reveals only small distortions between both structures, indicating that both structures can make direct contact through amide hydrogen bonding interactions with the catalytic aspartic acids Asp 32 and Asp $228 .{ }^{23}$

Compounds $\mathbf{4 d}$ and $9 \mathbf{c}$ were placed in the most favorable position in the BACE-1 active site, allowing both hydrogen bonding within the active site as well as hydrophobic interactions with enzyme subsites (Figure 2). To make Figure 2 more clear,

Figure 2. Superposition of $\mathbf{4 d}$ and $\mathbf{9 c}$ structures placed in their favored position within the BACE-1 active sites.
enzyme residues were not represented; only the superimposition of the inhibitors $\mathbf{4 d}$ (white) and $9 \mathbf{c}$ (green) placed in their best fitting position is shown.

From this representation, it appears that the $\mathrm{N}_{4}$-position of the piperazine ring could be suitable to accommodate various substituents capable of additional interactions with enzyme subsites. Taking into account that such $\mathrm{N}_{4}$-substituted analogues have never been described in both series, aryl naphthyl or coumarinyl, $N_{4}$-piperazine substitution represented an opportunity to design new optimized $\beta$-secretase inhibitors.

## Biological Results and Discussion

Enzymatic Assay Evaluation. All the compounds were assayed as BACE-1 inhibitors, using a fluorescence resonance energy transfer (FRET) assay, which uses purified baculovirusexpressed (BACE-1) and a specific substrate (Rh-EVNLDAEFKQuencher) based on the Swedish mutation of the amyloid precursor protein (APP). This peptidic substrate becomes highly fluorescent upon enzymatic cleavage. $\mathrm{IC}_{50}$ inhibition values were determined at least six times. The $\mathrm{IC}_{50}$ values obtained for both naphthyl and coumarinyl series of compounds are summarized respectively in Tables 2 and 3.

1-Aryl Naphthyl Series. Identification of nonpeptidomimetic BACE inhibitors, has led to the discovery of biaryl N-substituted piperazine naphthalenes. Among the compounds described by Vertex Pharmaceuticals Inc., ${ }^{24}$ compound $\mathbf{4 d}$ was reported as one of the most potent. We used this compound as the standard inhibitor in this study. From Table 2, it can be seen that monoaryl analogues $\mathbf{3 a}-\mathbf{d}$ are less active inhibitors than their biaryl counterparts, with the exception of compound $\mathbf{3 e}$. These results lead to the finding that the lack of a biphenyl moiety is detrimental for $\beta$-secretase inhibitory activity. In contrast in this series, substitution at the $\mathrm{N}_{4}$-position of the piperazinyl moiety was determinative for inhibitory activity. Specific substituents induced inhibitory activities with $\mathrm{IC}_{50}$ values ranging from 0.07 to $0.1 \mu \mathrm{M}$, as illustrated by the inhibitory potencies found for compounds $5 \mathbf{a}-\mathbf{f}$ and $\mathbf{6 a}$ which are more active than the reference compound $\mathbf{4 d}\left(\mathrm{IC}_{50}=0.3 \mu \mathrm{M}\right)$. The most active compound $\mathbf{5 f}$ shows an $\mathrm{IC}_{50}$ value of $0.046 \mu \mathrm{M}$. These results are of particular interest since to our knowledge; analogues incorporating a wide diversity of substituents at the $\mathrm{N}_{4}$-position of the piperazinyl have not been described. ${ }^{24}$

The observed enhancement of the inhibitory potency of these $\mathrm{N}_{4}$-substituted analogues is supported by modeling conformational analysis as well as by NMR studies. Modeling studies have shown that BACE-1 active site allows quite a large diversity of substituents at the $\mathrm{N}_{4}$-position of the piperazinyl ring. These substituents induce conformational changes at the piperazinyl ring level which could influence the planar position

${ }^{a}$ The BACE-1 fluorescence resonance energy transfer assay kit was purchased from PanVera (Madison, WI; no. P2985). BACE-1 activity assays were carried out according to the manufacturer's instructions. Average value is from three independent experiments. Values show means of at least three independent experiments each performed in triplicates, with standard errors (s.e.m). $p<0.05\left(^{*}\right)$ and $p<0.01\left(^{* *}\right)$.
of the piperazinyl ring relative to the naphthyl planar ring, generating specific favored conformations to the resulting molecule. These later conformations may allow better productive interactions through hydrogen bonding within the active site. The presence of hydrogen bonding donnors (hydroxyl or amino groups introduced at the $N_{4}$-piperazinyl position (compounds $\mathbf{5 d}$ and 5e) may have favored those conformations.

It should also be noted, that introduction of a chiral center in the side chain at the $N_{4}$-piperazinyl position does not significantly influence the observed inhibitory activity of the resulting
derivatives. As illustrated on Table 2, enantiomers $\mathbf{5 e}$ and $\mathbf{5 f}$ have very similar inhibitory activities, with $\mathrm{IC}_{50}$ values of 0.069 $\mu \mathrm{M}$ for the $(S)$ isomer 5 e and $0.046 \mu \mathrm{M}$ for its corresponding $(R)$ isomer $\mathbf{5 f}$. It was also observed that compound $\mathbf{6 b}$ bearing a $N_{4}$-acylalkyldithiolane moiety is two log less active than the most active inhibitor $\mathbf{5 f}$, strengthening the prime importance of the nature of the substitution at the $N_{4}$-piperazine position.

2-Coumarinyl Series. Replacement of the naphthyl moiety by a coumarin nucleus was envisaged in order to possibly restrict the rotation along the amide bond. Indeed, the possibility for the carbonyl group of the lactone function to accept a hydrogen bond with the hydrogen atom of the NH of the exocyclic amide through a possible six-membered ring formation appears to be energetically favorable. Increased hindrance could favor specific constrained conformations which could influence the inhibitory activities (increase or decrease). NMR analysis carried out within the coumarin series of analogues suggests that such a hypothesis is rather unlikely, since VT NMR did not show any effect on the chemical shifts of representative protons mentioned in the NMR studies

As shown on Table 3, generally speaking, the average BACE-1 inhibitory activities for the coumarin analogues ( 9 a , $\mathbf{9 b}$, and $\mathbf{1 0 a}-\mathbf{e}$ ) were lower than that of the corresponding naphthyl analogues. However some compounds, bearing various groups at the $\mathrm{N}_{4}$-position piperazinyl were found almost equipotent ( $\mathbf{9 c} \mathbf{c} \mathbf{e}$ and 11d) or more active (11c), than the reference compound $\mathbf{4 d}$. These results are of interest since it confirms NMR observations obtained in both naphthyl and coumarin series, showing that substitution at the $N_{4}$-piperazinyl position by various groups could stabilize specific favored conformations, which influence BACE-1 inhibitory activity. Introduction of substituents at the $\mathrm{N}_{4}$-position such as hydroxy ethyl (9e) and benzyl (9c and 11c) groups increases the inhibitory activity, while in contrast introduction at this position of other substituents such as Boc ( $\mathbf{9 b}$ and $\mathbf{1 0 b}$ ) or oxygen ( $\mathbf{9 a}$ and 10a) results in a decrease of the inhibitory activity. Besides it could also be observed that in this series, the presence of a biphenyl moiety does not influence noticeably the inhibitory activity of the resulting analogues, as exemplified by the $\mathrm{IC}_{50}$ values found for compound 9 c and its biphenyl analogue 11c which are very similar.

From a pharmacokinetic perspective, most of the reported analogues are sufficiently lipophilic to allow high brain penetration. Indeed, $\log P$ values reported in Tables 2 and 3 were calculated using ACD (Advanced Chemistry Development, Inc; $\log P 1.0$ base calculations) ranged from 2.72 to 7.84 . On average compounds belonging to the coumarin series have log $P$ values lower than their corresponding naphthyl analogues.

Cell-Based Assay Evaluation. Considering the BACE-1 enzymatic assay as a primary screening of two series of analogues, we have selected almost the most active analogues and analyzed the effect on the production of $\mathrm{A} \beta$ peptides from mouse Neuro2a (N2a) cells. $\mathrm{IC}_{50}$ values are reported in Table 4. Unexpectedly, analogue $\mathbf{4 d}$ was unable to diminish $\mathrm{A} \beta$ generation, whereas it showed the tendency for inhibition with significant toxicity over $10 \mu \mathrm{M}$ concentration. Compound $\mathbf{3 e}$ decreased both $\mathrm{A} \beta_{40}$ and $\mathrm{A} \beta_{42}$ secretion $\left(\mathrm{IC}_{50}=2.37\right.$ and 0.9 $\mu \mathrm{M}$, respectively) without obvious toxicity. In contrast, many compounds with strong inhibitory potencies (i.e., 5a, 5d, 5e, 5f) were unable to inhibit $\mathrm{A} \beta$ secretion. Compound $9 \mathbf{e}$ showed moderate inhibitory potency against $\mathrm{A} \beta_{40}$ and $\mathrm{A} \beta_{42}$ generation ( $\mathrm{IC}_{50}=3.9$ and $2.49 \mu \mathrm{M}$, respectively), while it was toxic for cells over $10 \mu \mathrm{M}$. Finally, no compounds were affected the processing of C 100 , the direct $\gamma$-secretase substrate (data not

Table 4. Cell-Based Assay Inhibition Activity ${ }^{a}$

$a *$ Compound used as control ( $\beta$-secretase inhibitor IV from Calbiochem cat. no. 565788). ${ }^{24}$
shown), suggesting that these compounds (i.e., compounds $\mathbf{3 e}$ and $\mathbf{9 e}$ ) are genuine $\beta$-secretase inhibitors.

## Discussion

From these results, several comments can be made: Compound $\mathbf{3 e}$ appears to be the most active compound $\left(\mathrm{IC}_{50}=2.37\right.$ $\mu \mathrm{M})$ in the cell assay. This analogue is more active than the analogue $\mathbf{4 d}$ which was used as reference compound $\left(\mathrm{IC}_{50}>\right.$ $10 \mu \mathrm{M})$. It should be also noted that these results confirm the enzymatic assay, since the $\mathrm{IC}_{50}$ values for these two analogues were respectively: $0.079 \mu \mathrm{M}$ and $0.3 \mu \mathrm{M}$. It should be noted that to our knowledge, no data have been reported to the inhibitory activity of Vertex compound on the $A \beta$-peptides production.

One explanation for these observed differences in inhibitory potency could be support by the differences in lipophilicity of the analogue. It seems that the presence of a supplementary phenyl ring in compound $\mathbf{4 d}$ increased their corresponding log $P$ values (5.73) compared to compound $\mathbf{3 e}$, which lop $P$ value is 4.19 .

Compound 3 e appears to be a genuine BACE-1 inhibitor, since it has no effect on SC100 processing. We verified that the inhibitory activity of $\mathbf{3 e}$ was similar to that of $\beta$-secretase inhibitor IV (Calbiochem cat. no. 565788), ${ }^{24}$ analogue known to be a genuine BACE-1 inhibitor.

It is also interesting to note that compounds $\mathbf{3 e}$ and $\mathbf{5 a}$, which structurally only differ by the presence of a biphenyl piperazine moiety in analogue $\mathbf{5 a}$ instead of a phenyl piperazine in analogue 3e, are almost equipotent in the enzyme assay but differ with respect to $\mathrm{IC}_{50}$ values, $0.11 \mu \mathrm{M}$ and $0.079 \mu \mathrm{M}$. Their inhibitory activities in cell assay are different, respectively $2.37 \mu \mathrm{M}$ for 3e and up to $10 \mu \mathrm{M}$ for $\mathbf{5 a}$. Again it can be observed that log $P$ for the less potent analogue 5a $(\log P=5.59)$ is higher than analogue $3 \mathrm{e}(\log P=4.19)$.

As mentioned before, taking BACE- 1 enzymatic inhibitory activity as a primary screening, we selected one of the most potent coumarinyl analogues $9 \mathrm{e}\left(\mathrm{IC}_{50}=0.63 \mu \mathrm{M}\right)$ as the representative analogue of the coumarin series, to be screened in the cell-based assay.

Moreover, this analogue has a calculated $\log P$ value around 2.85. We found that this new analogue, which differs from the most potent analogue 3 e by the replacement of the naphthyl ring by a coumarinyl heterocycle, shows a moderate inhibitory activity $\left(\mathrm{IC}_{50}=3.86 \mu \mathrm{M}\right)$. This result shows that in this case the $\log P$ value is not the only parameter which influences the inhibitory potency, since the $\log P$ value for 9 e is much lower than the corresponding $\log P$ value for compound $\mathbf{3 e}$.

From the reported results it can seen that compounds which are the most potent in the cell-based assay are also the most active inhibitors of BACE-1 enzyme. This observation could be of interest since BACE-1 assay could be viewed as a primary screening before performing the cell assay. Moreover, these results confirmed the NMR and modeling studies which suggest that substitution at the $N$-piperazinyl position was determinative for $\beta$-secretase activity. This was confirmed by compound $\mathbf{3 e}$ which is substituted by an hydroxyethyl moiety. If lipophilicity of the analogues influences the inhibitory potency in cell assay, it is not the only parameter.

## Conclusions

We have synthesized two series of new aryl-piperazine derivatives, possessing either naphthyl or coumarinyl moieties, and determined their inhibitory activities on BACE-1 enzyme. The structure-activity data for the two series of derivatives bring to light the importance of substituents located at the $\mathrm{N}_{4}{ }^{-}$ position of the piperazinyl ring. Some new analogues bearing at this position a side chain with a hydroxy group were highly potent BACE- 1 inhibitors in both enzymatic and cell assays.

In contrast, substitution of the naphthyl moiety by a coumarin ring led to a significant decrease of their inhibitory properties. Compound 3e, belonging to the naphthyl series, was found more active than the reported analogues by Vertex Pharmaceuticals, Inc. ${ }^{25,26}$ Inhibitory activities of compound $\mathbf{4 d}$ from cell-based assays have not been previously reported, at least to our knowledge. By its inhibitory activity on $\mathrm{A} \beta$-peptide production in a cell-based assay, compound $\mathbf{3 e}$, bearing an $N$-hydroxyethyl substituent, could be considered as a new representative hit in these series. Unfortunately, cytotoxicity of new active analogues could represent a serious obstacle for their future development. It should be also noted that these new nonpeptidic analogues should have good catabolic stabilities compared to recently described inhibitors which are of peptidomimetic nature, such as compound JMV2764. ${ }^{27}$

## Experimental Section

General Procedures. Unless otherwise noted, starting materials and reagents were obtained from commercial suppliers and were used without purification. Methylene dichloride $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right)$ was distilled over $\mathrm{P}_{2} \mathrm{O}_{5}$ just prior to use. Acetonitrile was of anhydrous quality from commercial suppliers (Aldrich, Carlo Erba Reagents). Melting points were determinated on an Electrothermal IA-9100 digital, and all temperatures are given in degrees Celsius and are uncorrected. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at 250 MHz on a Brüker AC-250 spectrometer. Chemical shifts are expressed as $\delta$ units (part per million) downfield from TMS (tetramethylsilane). Electro-spray mass spectra were obtained on a Waters Micromass ZMD spectrometer by direct injection of the sample solubilized in acetonitrile. Elemental analyses were within $\pm 0.4 \%$ of theorical values for all compounds. All reactions were monitored by thinlayer chromatography. Analytical thin layer chromatographies (TLC) were performed using silica gel plates 0.2 mm thick $\left(60 \mathrm{~F}_{254}\right.$ Merck). Preparative flash column chromatographies were carried out on silica gel ( $230-400$ mesh, G60 Merck).

4-(4-Bromo-2-nitro-phenyl)-morpholine (1a). To a mixture of 2,5-dibromonitrobenzene ( $4.0 \mathrm{~g}, 14.2 \mathrm{mmol}$ ), triethylamine ( 1 mL , $7.2 \mathrm{mmol})$ in $i-\mathrm{PrOH}(15 \mathrm{~mL})$ was added morpholine ( $2.5 \mathrm{~mL}, 28.4$ mmol ). The resulting mixture was stirred at $70^{\circ} \mathrm{C}$ for 24 h . The reaction mixture was cooled to room temperature and then concentrated under reduced pressure. The brown residue was purified by chromatography on silica gel. Elution with increasing proportions of $\mathrm{EtOAc}-\mathrm{cHex}$ ( $1: 3$ to 1:1) gave the desired compound 1a ( $3.0 \mathrm{~g}, 73 \%$ ) as an orange oil. $R_{f} 0.18$ (cHex:EtOAc, 3:1). ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 3.02\left(\mathrm{t}, 4 \mathrm{H}, J=4.5 \mathrm{~Hz}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right), 3.82(\mathrm{t}$, $\left.4 \mathrm{H}, J=4.5 \mathrm{~Hz}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right), 7.02(\mathrm{~d}, 1 \mathrm{H}, J=8.8 \mathrm{~Hz}, \mathrm{Ar} H), 7.58$ (dd, 1H, $J=2.3$ and $8.8 \mathrm{~Hz}, \mathrm{Ar} H$ ), $7.91(\mathrm{~d}, 1 \mathrm{H}, J=2.3 \mathrm{~Hz}, \mathrm{Ar} H)$. ESI-MS m/z $[\mathrm{M}+\mathrm{H}]^{+}=287$. Anal. $\left(\mathrm{C}_{10} \mathrm{H}_{11} \mathrm{BrN}_{2} \mathrm{O}_{3}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

4-(4-Bromo-2-nitro-phenyl)-1-tert-butoxycarbonyl-piperazine (1b). Compound 1b was prepared by a method similar to that described for 1a. Yield $72 \%, R_{f} 0.79$ (cHex:EtOAc, 1:1). ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ) $\delta_{\mathrm{H}} 1.46\left(\mathrm{~s}, 9 \mathrm{H}, \mathrm{CH}_{3}, t \mathrm{Bu}\right), 2.98(\mathrm{t}, 4 \mathrm{H}, J=4.7 \mathrm{~Hz}$, $\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NBoc}^{2}$ ), 3.57 ( $\mathrm{t}, 4 \mathrm{H}, J=4.7 \mathrm{~Hz}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NBoc}$ ), 7.01 $(\mathrm{d}, 1 \mathrm{H}, J=8.9 \mathrm{~Hz}, \mathrm{Ar} H), 7.58(\mathrm{dd}, 1 \mathrm{H}, J=2.4$ and $8.9 \mathrm{~Hz}, \mathrm{Ar} H)$, $7.91(\mathrm{~d}, 1 \mathrm{H}, J=2.4 \mathrm{~Hz}, \operatorname{Ar} H)$. ESI-MS $m / z[\mathrm{M}+\mathrm{H}]^{+}=386$. Anal. $\left(\mathrm{C}_{15} \mathrm{H}_{20} \mathrm{BrN}_{3} \mathrm{O}_{4}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

1-Benzyl-4-(4-bromo-2-nitro-phenyl)-piperazine (1c). Compound $\mathbf{1 c}$ was prepared by a method similar to that described for 1a. Yield $85 \%, R_{f} 0.51$ (cHexane:EtOAc, 1:1). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right)$ $\delta_{\mathrm{H}} 2.59\left(\mathrm{t}, J=4.8 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{Ph}\right), 3.06(\mathrm{t}, J=4.8$ $\mathrm{Hz}, 4 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{Ph}$ ), 3.56 ( $\mathrm{s}, 2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{Ph}$ ), 7.01 (d, $J=$ $8.7 \mathrm{~Hz}, \mathrm{Ar} H), 7.28-7.34(\mathrm{~m}, 5 \mathrm{H}, \mathrm{Ar} H), 7.54(\mathrm{dd}, J=8.7$ and 2.4 $\mathrm{Hz}, 1 \mathrm{H}, \mathrm{ArH}), 7.89(\mathrm{~d}, J=2.4 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{Ar} H)$. ESI-MS $m / z[\mathrm{M}+$ $\mathrm{H}]^{+}=376$. Anal. $\left(\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{BrN}_{3} \mathrm{O}_{2}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

4-(2-Amino-4-bromo-phenyl)-morpholine (2a). Zinc dust (3.4 $\mathrm{g}, 52.3 \mathrm{mmol})$ was added to a stirred solution of $1 \mathrm{a}(3.0 \mathrm{~g}, 10.4$ $\mathrm{mmol})$ in THF ( 60 mL ) followed by $\mathrm{KH}_{2} \mathrm{PO}_{4}(20 \mathrm{~mL}, 1 \mathrm{M})$. The resulting mixture was stirred at $80^{\circ} \mathrm{C}$ for 24 h . The reaction mixture was cooled to room temperature, filtered, and evaporated to a small
volume. The mixture was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic layer was dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure. The residue was purified by chromatography on silica gel, with EtOAc-cHex as eluant (1:6), giving aniline 2a (1.7 g, 63\%) as a pale yellow foam. M.p. $123^{\circ} . R_{f} 0.53$ (EtOAc:cHex, 1:1). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 2.59\left(\mathrm{bs}, 4 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right), 2.89(\mathrm{t}, J=4.8 \mathrm{~Hz}, 4 \mathrm{H}$, $\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}$ ), 4.01 (brs, $2 \mathrm{H}, \mathrm{NH}_{2}$ ), 6.78-6.87 (m, 3H). ESI-MS $m / z[\mathrm{M}+\mathrm{H}]^{+}=257$. Anal. $\left(\mathrm{C}_{10} \mathrm{H}_{13} \mathrm{BrN}_{2} \mathrm{O}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

4-(2-Amino-4-bromo-phenyl)-1-tert-butoxycarbonyl-piperazine (2b). Compound 2b was prepared by a method similar to that described for 2a. Yield $63 \%, R_{f} 0.42$ (EtOAc:toluene, 1:6). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 1.48\left(\mathrm{~s}, 9 \mathrm{H}, \mathrm{CH}_{3}, t \mathrm{Bu}\right), 2.81(\mathrm{t}, 4 \mathrm{H}, J=4.7 \mathrm{~Hz}$, $\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NBoc}$ ), 3.56 (br s, $4 \mathrm{H}, \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{NBoc}$ ), 4.08 (br s, 2 H , $\left.\mathrm{N} H_{2}\right), 6.81-6.87(\mathrm{~m}, 3 \mathrm{H}, \mathrm{Ar} H)$. ESI-MS $\mathrm{m} / \mathrm{z}[\mathrm{M}+\mathrm{H}]^{+}=356$. Anal. $\left(\mathrm{C}_{15} \mathrm{H}_{22} \mathrm{BrN}_{3} \mathrm{O}_{2}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

1-Benzyl-4-(2-amino-4-bromo-phenyl)-piperazine (2c). Compound $\mathbf{2 c}$ was prepared by a method similar to that described for 2a. Yield $86 \%$, mp $85^{\circ}$ C. $R_{f} 0.66$ (EtOAc:cHex, 1:1). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 2.62$ (brs, $4 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{Ph}$ ), 2.91 (t, 4H, $J=$ $4.7 \mathrm{~Hz}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{NCH}_{2} \mathrm{Ph}$ ), 3.59 (s, $2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{Ph}$ ), 4.00 (brs, 1 H , $\left.\mathrm{N} H_{2}\right), 6.82-6.85(\mathrm{~m}, 3 \mathrm{H}, \mathrm{Ar} H), 7.29-7.36(\mathrm{~m}, 5 \mathrm{H}, \mathrm{ArH})$. ESIMS $m / z[\mathrm{M}+\mathrm{H}]^{+}=346$. Anal. $\left(\mathrm{C}_{17} \mathrm{H}_{20} \mathrm{BrN}_{3}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.
\{4-Bromo-2-[(naphthalene-1-carbonyl)-amino]-phenyl\}-morpholine (3a). To a solution of $\mathbf{2 a}(210 \mathrm{mg}, 0.81 \mathrm{mmol})$ in methylene chloride ( 10 mL ) with DIEA ( $210 \mu \mathrm{~L}, 1.21 \mathrm{mmol}$ ) was added 1-naphthoyl chloride ( $200 \mathrm{mg}, 1.05 \mathrm{mmol}$ ). The reaction mixture was stirred for 4 h at room temperature. The mixture was extracted with water ( 15 mL ), and the organic layer was dried over $\mathrm{MgSO}_{4}$ and concentrated under reduced pressure. The residue was purified by chromatography on silica gel, with EtOAc-cHex eluant (1:9) giving 3c ( $300 \mathrm{mg}, 90 \%$ ) as a yellow solid. M.p. $172^{\circ}$. $R_{f} 0.61$ (EtOAc:cHex, 1:1). ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta_{\mathrm{H}} 2.86(\mathrm{t}, 4 \mathrm{H}, J=4.4 \mathrm{~Hz}$, $\mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}$ ), $3.70\left(\mathrm{t}, 4 \mathrm{H}, J=4.4 \mathrm{~Hz}, \mathrm{NCH}_{2} \mathrm{CH}_{2} \mathrm{O}\right), 7.08(\mathrm{~d}, 1 \mathrm{H}$, $J=8.4 \mathrm{~Hz}, \mathrm{Ar} H), 7.27(\mathrm{dd}, 1 \mathrm{H}, J=2.2$ and $8.4 \mathrm{~Hz}, \mathrm{Ar} H), 7.51-$ $7.60(\mathrm{~m}, 3 \mathrm{H}, \mathrm{Ar} H), 7.71-7.75(\mathrm{~m}, 1 \mathrm{H}, \mathrm{ArH}), 7.91-7.95(\mathrm{~m}, 1 \mathrm{H}$, $\mathrm{ArH}), 8.01(\mathrm{~d}, 1 \mathrm{H}, J=8.2 \mathrm{~Hz}, \mathrm{ArH}), 8.44-8.48(\mathrm{~m}, 1 \mathrm{H}, \mathrm{ArH})$, $8.93(\mathrm{~d}, 1 \mathrm{H}, J=2.2 \mathrm{~Hz}, \mathrm{Ar} H), 9.15$ (brs, $1 \mathrm{H}, \mathrm{NHC}(\mathrm{O})$ ). Coumarin-3-carboxylic Acid or 2-Oxo-2H-chromene-3-carboxylic Acid (7). A mixture of salicylaldehyde, 2-hydroxybenzaldehyde, ( $1.22 \mathrm{~g}, 10.0 \mathrm{mmol})$, Meldrum's acid $(1.44 \mathrm{~g}, 10.0$ mmol ), piperidinium acetate ( $30 \mathrm{mg}, 0.2 \mathrm{mmol}$ ), and ethanol ( 10 mL ) was stirred at room temperature for 20 min and then refluxed for 2 h . The reaction mixture was allowed to cool to room temperature. The crystallized product was filtered, washed three times with ethanol, and dried in vacuo to give quantitativelly the desired compound 7 as yellow needles ( 1.9 g , quantitative) as yellow needles. M.p. $188^{\circ} . R_{f} 0.12$ (cHex-EtOAc, 2:1). ${ }^{1} \mathrm{H}$ NMR (DMSO$\left.d_{6}\right) \delta_{\mathrm{H}} 7.38(\mathrm{dd}, 1 \mathrm{H}, J=1.0$ and $7.5 \mathrm{~Hz}, \mathrm{Ar} H), 7.41-7.45(\mathrm{~m}, 1 \mathrm{H}$, $\mathrm{Ar} H), 7.69-7.76(\mathrm{~m}, 1 \mathrm{H}, \mathrm{Ar} H), 7.90(\mathrm{dd}, 1 \mathrm{H}, J=1.6$ and 7.7 Hz , $\mathrm{Ar} H$ ), 8.73 (s, $1 \mathrm{H}, H_{4}$ ), 13.12 (brs, $1 \mathrm{H}, \mathrm{COOH}$ ). ESI-MS $m / z[\mathrm{M}$ $+\mathrm{H}]^{+}=191$. Anal. $\left(\mathrm{C}_{10} \mathrm{H}_{6} \mathrm{O}_{4}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

8-Methoxy-coumarin-3-carboxylic Acid or 8-Methoxy-2-oxo$\mathbf{2 H}$-chromene-3-carboxylic Acid (8). Compound 8 was prepared by a method similar to that described for 7 using 2-hydroxy-3-methoxy-benzaldehyde. Yield $99 \%$, mp $182^{\circ} \mathrm{C} . R_{f} 0.09$ (cHexEtOAc, 2:1). ${ }^{1} \mathrm{H}$ NMR (DMSO- $d_{6}$ ) $\delta_{\mathrm{H}} 3.89\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 7.25-$ $7.41(\mathrm{~m}, 3 \mathrm{H}, \mathrm{ArH}), 8.67\left(\mathrm{~s}, 1 \mathrm{H}, H_{4}\right), 13.40$ (brs, $1 \mathrm{H}, \mathrm{COOH}$ ). ESIMS $m / z[\mathrm{M}+\mathrm{H}]^{+}=221$. Anal. $\left(\mathrm{C}_{11} \mathrm{H}_{8} \mathrm{O}_{5}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.
\{4-Bromo-2-[(2-Oxo-2H-chromene-3-carbonyl)-amino]-phen-yl\}-morpholine (9a). Coumarin-3-carboxylic acid 7 ( $350 \mathrm{mg}, 1.90$ mmol ) and the amino moiety 2a ( $400 \mathrm{mg}, 1.56 \mathrm{mmol}$ ) were dissolved in anhydrous pyridine ( 10 mL ). The solution was cooled to $-15{ }^{\circ} \mathrm{C}$, and phosphorus oxychloride ( $160 \mu \mathrm{~L}, 1.72 \mathrm{mmol}$ ) was added dropwise under vigorous stirring. The reaction mixture was stirred at $-15{ }^{\circ} \mathrm{C}$ for at least 30 min . The solution was then stirred 12 h at room temperature. The reaction was quenched by addition of crushed ice/water ( 30 mL ). The desired compound was extracted into $\mathrm{AcOEt}(3 \times 30 \mathrm{~mL})$. The combined organic layers were dried over anhydrous $\mathrm{MgSO}_{4}$, filtered, and concentrated under reduced pressure. The crude material was purified by flash chromatography to lead to the desired compound $9 \mathrm{a}(200 \mathrm{mg}, 30 \%)$ as yellow needles. M.p. $222^{\circ} . ESI-MS $m / z[\mathrm{M}+\mathrm{H}]^{+}=426$. Anal. $\left(\mathrm{C}_{28} \mathrm{H}_{24} \mathrm{~F}_{3} \mathrm{~N}_{3} \mathrm{O}_{5}\right) \mathrm{C}, \mathrm{H}, \mathrm{N}$.

Bace-1 Enzymatic Assay. These experiments have been preformed using BACE1 ( $\beta$-secretase) FRET Kit assay, from PanVera Corporation (Madison, WI), according to the described protocol and using a multiwell spectrofluorometer instrument capable of $530-545 \mathrm{~nm}$ excitation and $570-590 \mathrm{~nm}$ emission wavelengths (Wallac Victor ${ }^{2} 1420$, Perkin-Elmer, Turku, Finland). The procedure is as follows: the substrate and enzyme are diluted according to the described protocol into the provided assay buffer ( 50 mM Tris, $\mathrm{pH} 7.5,10 \%$ glycerol). Each inhibitor is diluted into DMSO at the desired concentration. The substrate (Rh-EVNLDAEFK-Quencher; $10 \mu \mathrm{~L}$ of the main solution) and each inhibitor ( $1 \mu \mathrm{~L}$ of the corresponding solution) are introduced in the 96-well flat bottom black polystyrene plate (Corning, NY). The resulting mixtures are gently mixed and $10 \mu \mathrm{~L}$ of the enzyme solution are then added to each well to start the reaction. The reaction mixtures are incubated at $25^{\circ} \mathrm{C}$ for 90 min and the spectrofluorescence is monitored at $530-545 \mathrm{~nm}$ (excitation wavelength) and $570-590 \mathrm{~nm}$ (emission wavelength). The kinetic assays are performed in duplicate for each inhibitor, using BACE1 inhibitor (H-Lys-Thr-Glu-Glu-Ile-Ser-Glu-Val-Asn-( $3 S, 4 S$ )-Stat-Val-Ala-Glu-Phe-OH, $\mathrm{IC}_{50}=30 \mathrm{nM}$; Calbiochem, Beeston, UK) as reference (negative test, no cleavage), the provided BACE1 Product Standard (Rh-EVNL) as positive test ( $100 \%$ cleavage), and a control test using only the enzyme and the substrate under the same conditions to allow a $15 \%$ cleavage of the substrate after 90 min .
$\mathbf{A} \beta$ Cell-Based Assay $\mathbf{E C}_{\mathbf{5 0}}$. Inhibitory potencies of each compound on $\gamma$-secretase activity were analyzed by cell-based assay. Mouse Neuro2a (N2a) and human embryonic kidney (HEK293) cells were used for $\mathrm{A} \beta$ cell-based assays. ${ }^{28}$ Cells were plated in 24-well plates and were cultured at confluency. HEK293 cells were further transfected with C100 in pcDNA3.1-Hygro and cultured for 12 h . For compound screening and dose-response testing, compounds were diluted from stock solutions in dimethyl sulfoxide (DMSO) to yield a final concentration equal to $0.1 \%$ DMSO in media. After 24 h treatment with compounds, conditioned media were drawn off and analyzed by a sandwich ELISA (BNT77/ BA27 and BNT77/BC05) specific for total $\mathrm{A} \beta .{ }^{28,29}$ Reduction of $\mathrm{A} \beta$ production was measured relative to control cells treated with $0.1 \%$ DMSO and expressed as a percentage inhibition. Compounds toxicities were measured by MTT assay as previously described. ${ }^{30}$

Acknowledgment. Conseil Régional Provence-Alpes-Côte d'Azur and INSERM are greatly acknowledged for C.G.'s financial support. We are grateful to Doctor Philippe Pierre and members of his research team (CIML, Inserm-CNRS, Université de la Méditerranée, France) for their assistance when we performed the spectrofluorimetric measurements for the BACE-1 ( $\beta$-secretase) FRET assays. The authors thank Professor Keith Dudley (INSERM U-623, IBDM, Université de la Méditerranée, France) for manuscript preparation.

Supporting Information Available: Synthetic procedures and table of elemental analyses. This material is available free of charge via the Internet at http://pubs.acs.org.
