ABSTRACT: Dinucleoside polyphosphates, Np_nN', exert their physiological effects via P2 receptors (P2Rs). Np_nN' are attractive drug candidates as they offer better stability and specificity compared to nucleotides, the most common P2R ligands. To further improve the agonist properties of Np_nN', we synthesized novel isosters of dinucleoside polyphosphates where N and N' are A or U and where the P α or P β phosphate groups are replaced by boranophosphate, denoted as Np_n(α -B)N' or Np_n(β -B)N' (n = 3, 4), respectively. The potency of Np_n(α / β -B)N' analogues was evaluated at tP2Y₁, hP2Y₂, hP2Y₄, and rP2Y₆ receptors. The most potent P2Y₁R and P2Y₆R agonists were the Up₄(β -B)A (A isomer, EC₅₀ of 0.5 μ M vs 0.004 μ M for 2-SMe-ADP) and Up₃(α -B)U (B isomer, EC₅₀ of 0.3 μ M vs 0.2 μ M for UDP), respectively. The receptor subtype selectivity is controlled by the position of the borano moiety on the Np_nN' polyphosphate chain and the type of the

nucleobase. In addition, $Np_n(\alpha/\beta-B)N'$ proved ~22-fold more resistant to hydrolysis by e-NPP1, as compared to the corresponding Np_nN' analogues. In summary, $Up_4(\beta-B)A$ and $Up_3(\alpha-B)U$ are potent, stable, and highly selective $P2Y_1$ and $P2Y_6$ receptor agonists, respectively.

INTRODUCTION

Naturally occurring dinucleoside polyphosphates, denoted also as dinucleotides and Np_nN' (N and N' = A, G, U, C; n = 2–6; analogue 1) (Figure 1),^{1–3} comprise two nucleosides linked

by a polyphosphate chain through phosphoester bonds at the 5'-position of the two ribose moieties. Dinucleotides control

various physiological functions.⁴ In recent years, interest in dinucleoside polyphosphates as potent and stable purinergic receptors agonists has been growing.⁵

The biological activities of these extracellular dinucleotides include regulation of vascular tone, platelet aggregation, neuro-transmission, glycogen breakdown, and renal Na^+ excretion and urine flow.^{6–8}

Extracellular effects of dinucleotides involve activation of nucleotide receptors, P2Rs, and possibly dinucleotide receptors.^{9–12} The members of the P2 receptor superfamily are subdivided into ligand-gated ion channels (P2X receptors, P2XRs) and G-protein-coupled receptor subtypes (P2Y receptors, P2YRs). The principal physiological agonists of the P2Rs are adenosine 5'-triphosphate (ATP), adenosine 5'-diphosphate (ADP), uridine 5'-triphosphate (UTP), uridine 5'-diphosphate (UDP), and UDP-glucose.¹³ In addition, several dinucleoside polyphosphates⁹ potently activate various P2YRs.^{14,15}

¹ P2YRs are attractive pharmaceutical targets because they control many physiological functions.^{16,13} Currently, most P2YR agonists proposed as drugs consist of a nucleotide scaffold,^{17,16} the stability of which is still unsatisfactory. One of the approaches to overcome the inherent instability of nucleotide-based drug candidates is the use of dinucleotides that are metabolically more stable than the corresponding nucleotides.¹⁸ This approach is rather promising, and indeed several

Received: October 3, 2011 Published: November 22, 2011 dinucleotides have been tested in preclinical trials. For instance, diadenosine tetraphosphate, Ap₄A, diuridine tetraphosphate, Up₄U, and uridine deoxycytidine tetraphosphate, Up₄dC are effective at lowering blood pressure during anesthesia, and in the treatment of dry eye disease, cystic fibrosis, and retinal detachment.^{18–21} Up₄U and Up₄dC, known as diquafosol and denufosol, respectively, are currently in phase III of clinical development.¹⁶

Although several endogenous dinucleoside polyphosphates have good pharmacological activities, their in vivo half-lives are relatively short.¹⁴ Prolongation of the in vivo half-lives of dinucleotides is a prerequisite to their use as potential drugs. In addition, enhancement of affinities and enhancement of selectivities of endogenous Np_nN' analogues for specific P2 receptor subtypes are other important challenges.

Previously, we demonstrated the improved pharmacological properties of a series of dinucleoside poly(borano)phosphate analogues, Np_n(β/γ -B)N', **2–5** (Figure 2) compared to the

Figure 2. Previously synthesized dinucleoside poly(borano)phosphate analogues.

parent compounds.²² We found that $Ap_{3/5}(\beta/\gamma-B)A$ analogues were potent P2Y₁R agonists. Specifically, $Ap_5(\gamma-B)A$ was equipotent to 2-MeS-ADP, thus making it one of the most potent P2Y₁R agonists currently known. Moreover, $Ap_5(\gamma-B)A$ did not activate the P2Y₂R. In contrast, $Up_{3/5}(\beta/\gamma-B)U$ analogues were extremely poor agonists at both P2Y₁R and P2Y₂R. $Np_n(\beta/\gamma-B)N'$ analogues exhibited remarkable chemical stability under physiological conditions, including at a pH mimicking gastric juice acidity. The rate of hydrolysis of $Ap_3(\beta-B)A$ by human e-NPP1 and e-NPP3 was decreased by 40% and 59%, respectively, compared to Ap_3A . However, $Ap_5(\gamma-B)A$ was hydrolyzed by e-NPP1 at a rate comparable to that of Ap_5A . Apparently, the stabilizing effect of the borano modification is pronounced only when in the vicinity of the cleavage site.

Here, we leveraged the above findings on the beneficial pharmacological properties of the boranophosphate bioisosters for the design of stable, potent, and selective P2Y₁ and P2Y₆R agonists. Specifically, we report on the synthesis and characterization of dinucleoside tetra- or tri(α/β -borano)phosphate analogues, **6**–**13** (Figure 3), their resistance to hydrolysis by e-NPP1, and their activity at P2Y_{1,2,4,6} receptors. In addition we analyze the effect of the position of the boranophosphate moiety, the composition of the nucleobase, and the length of the polyphosphate linker on the pharmacological properties of analogues **6**–**13**. Our findings provide structure–activity relationship (SAR) tools to further design potential drug candidates targeting P2Y₁ and P2Y₆ receptors.

Figure 3. Dinucleoside poly(borano)phosphate analogues synthesized and investigated in this study.

RESULTS

Design of Novel Dinucleoside Poly(borano)phosphate Analogues. Recently we reported the synthesis and P2YR activity of diadenosine and diuridine tri- and penta(β/γ borano)phosphate analogues 2–5.²² The most evident change in receptor affinity was observed for the γ -borano modification of Ap₅A, which greatly increased agonist potency for the rP2Y₁-GFP receptor, compared to Ap₅A. Ap₅(γ -B)A (EC₅₀ = 6.3×10^{-8} M), 4, was found to be slightly more potent at the rP2Y₁-GFP receptor than 2-MeS-ADP (EC₅₀ = 1.0×10^{-7} M).²² We found that the hydrolytic stability of the Np_n(β/γ -B)N' analogues 2–5 at physiological or gastric pH is dependent on the length of the polyphosphate chain. The dinucleoside triphosphate analogues 2 and 3 were more stable than the pentaphosphate analogues 4 and 5 regarding both chemical and e-NPP1-dependent hydrolysis.

The potent P2Y₁R agonist, analogue **4**, is not a good drug candidate, since it is hydrolyzed by e-NPP1 at a similar rate as Ap₅A. This susceptibility to hydrolysis is probably related to the distance of the borano group from the enzymatic cleavage site between P_{α} and P_{β} .

On the basis of these findings and the enhanced stability of an analogue when the borano modification is in the vicinity of the e-NPP1 cleavage site $(P_{\alpha} \cdot P_{\beta})$, we produced here a new series of diadenosine and diuridine tri- and tetra(borano)phosphate analogues in which the borano modification is in either the P_{α} or P_{β} position, with a view toward developing novel drug candidates targeting certain P2YRs.

Since $Ap_5(\gamma$ -B)A is a potent P2Y₁R agonist, whereas $Ap_3(\beta$ -B)A is moderately less potent (EC₅₀ = 6.3 × 10⁻⁸ and 9.0 × 10⁻⁷ M, respectively), we synthesized $Ap_4(\beta$ -B)A, analogue **6**, to evaluate its potency at the P2Y₁R. The high potency of Up₄U as a P2Y₂R agonist (EC₅₀ = 0.06 μ M vs 0.015 μ M for UTP, an endogenous P2Y₂R agonist)¹⁴ led us to synthesize Up₄(β -B)U, analogue 7, whereas the use of Ap₄U as a vasoconstrictive factor²³ prompted us to synthesize Ap₄(β -B)U, analogue **8**, and Up₄(β -B)A, analogue **9**.

Synthesis of Dinucleoside Poly(β -borano)phosphate Analogues 6–9. Previously, we synthesized dinucleoside poly(borano)phosphate analogues using two nucleoside phosphoroimidazolides²⁴ as P-donors and an inorganic boranophosphate salt (BPi)²⁵ as a P-acceptor. MgCl₂ was added as an activator to overcome the low nucleophilicity of BPi as a P-acceptor.²²

Scheme 1^a

"Reaction conditions: (a) CDI (5 equiv), DMF, room temp 3 h; (b) dry MeOH (5 equiv), room temp 8 min; (c) BPi (1 equiv), DMF, MgCl₂ (8 equiv), room temp overnight.

Here, we used the same synthetic method to prepare the Np₄(β -B)N' analogues. Briefly, the synthesis of analogues **6–9** involved the activation of a nucleotide bis- and tristributylammonium salt, compounds **14** and **15**, respectively, with CDI in dry DMF at room temperature for 3 h followed by the addition of BPi and MgCl₂ and stirring at room temperature for ~12 h (Scheme 1) to produce analogues **6–9** at up to 40% yield after LC separation.

This synthesis involves a concerted reaction of three molecules (two P-donors and one P-acceptor) (Figure 4). Np₄(β -B)N' (~40% yield) (Figure 4), Np₃N' (~25% yield) (Figure 5, path a),

Figure 5. Proposed structure for nucleotide-BPi Mg^{2+} complexes leading to possible byproducts.

and Np₄N (~10% yield) analogues were the sole products formed. No Np_n(B) products, Figure 5 path b, were formed under these conditions.

The identity and purity of the products were established by ¹H and ³¹P NMR, ESI or FAB mass spectrometry, and HPLC in two solvent systems. ³¹P NMR spectra showed a typical P_{β} signal as a multiplet at about 80 ppm. ¹H NMR spectra showed borane hydrogen atoms as a very broad signal at about 0.3 ppm.

Because of the chiral center at P_{β} , analogues 6–9 were each obtained as a pair of two diastereoisomers. In both ¹H and

³¹P NMR spectra, there was a slight difference between the chemical shifts for the two diastereoisomers.

These isomers were separated by reverse-phase HPLC, using triethylammonium acetate/MeOH isocratic elution, with about 1 min difference in their retention times. The first eluting isomer was designated as the A isomer, and the other was designated as the B isomer. Surprisingly, the ratio between the diastereoisomers was not always 1:1, as determined by the integration of the respective HPLC peaks. The area under the curve (AUC) for each diastereoisomer was calculated as the average of peak areas from three different HPLC chromatograms. A comparison of the AUC for the Np₄(β -B)N' diastereoisomers showed that the formation of each analogue (6–9) involves a different degree of diastereoselectivity. The diastereoisomer ratio (A/B) was 0.65:0.35 for analogue 6, 0.51:0.49 for analogue 7, 0.52:0.48 for analogue 8, and 0.55:0.45 for analogue 9.

Synthesis of Dinucleoside Poly(α -borano)phosphate Analogues 10–13. The synthesis of Np₄(α -B)N' analogues 12 and 13 is based on the Eckstein procedure for the preparation of triphosphates,²⁶ which was applied by Jones et al.²⁷ to the synthesis of dinucleoside tetra- and pentaphosphates. Specifically, 5'-phosphitylation of 2',3'-methoxymethylidene nucleoside 14 with 2-chloro-4*H*-1,3,2-benzodioxaphosphorin-4-one (salicylchlorophosphite) followed by reaction with inorganic pyrophosphate yielded the cyclic derivative 16 (Scheme 2). Then, borane-dimethyl sulfide complex was added to yield product 17, which was then treated with either AMP or UMP bis-tributylammonium salt in dry DMF, and MgCl₂, to yield the partially protected dinucleotide. ZnCl₂ was found to be less effective than MgCl₂, yet better than no catalyst. Finally, removal of the 2',3'-methoxymethylidene group at pH 2.3 and then at pH 9 produced products 12 and 13 at high yields (up to 85% after LC separation).

This method could not be applied to the synthesis of dinucleoside triphosphates **10** and **11**. These analogues were synthesized via the activation of the 5'-phosphate of NMP **18** with CDI, followed by coupling with the appropriate NDP(α -B)²⁸ analogue to yield dinucleotide **10** or **11** (Scheme 3). In preliminary experiments to synthesize analogues **10** and **11**, we first activated NDP(α -B) with CDI to generate the P-donor and used NMP as the P-acceptor. In a second approach, CDI-activated NMP was the P-donor, and NDP(α -B) was the P-acceptor. The activation of NMP (**18**) and NDP(α -B) with CDI was monitored by TLC, which showed that NMP completely reacted with CDI after 3 h, whereas the activation of NDP(α -B) was incomplete

over this time period, likely because of the lower nucleophilicity of the phosphate in this analogue. Therefore, our subsequent syntheses of analogues **10** and **11** utilized the activation of NMP(Bu₃NH)⁺₂ salt with CDI in dry DMF at room temperature for 3 h, followed by the addition of nonactivated NDP(α -B)-(Bu₃NH)⁺₂ salt, in the presence of MgCl₂ at room temperature for 12 h. Analogue **10** or **11** was formed as the exclusive product at up to 85% after LC separation.

Analogues 10–13 were characterized by ³¹P NMR spectrometry and high resolution mass spectrometry. Because of the chiral center at P α , analogues 10–13 were each obtained as a pair of diastereoisomers (A and B isomers). Unlike analogues 6–9, the ratio between the diastereoisomers for analogues 10–13 was 1:1. Mg²⁺ ion serves as a catalyst, and reactions carried out without Mg²⁺ resulted in yields of <10%.

Activity of Analogues 6–13 at P2Y_{1/2/4/6}-Rs. To study the activity of dinucleotides 6–13 at the P2Y_{1/2/4/6}Rs, we evaluated the magnitude of increase in $[Ca^{2+}]_i$ induced by these analogues. These studies were performed in human 1321N1 astrocytoma cells that are devoid of endogenous P2Y receptors but were stably transfected with turkey (t) P2Y₁, human (h) P2Y₂, human (h) P2Y₄, or rat (r) P2Y₆ receptors. Concentration–response curves were derived for each dinucleotide and compared with data of agonist for these receptor subtypes (i.e., 2-MeS-ADP for tP2Y₁R, UTP for hP2Y_{2/4}Rs, and UDP for rP2Y₆R). The results are summarized in Table 1. In control

experiments we found that untransfected 1321N1 astrocytoma cells did not respond to any of the analogues or endogenous agonists (data not shown).

Analogues 6-13 had no or weak activity at P2Y₂ and P2Y₄ receptors, whereas these compounds were relatively selective for either P2Y₁ or P2Y₆ receptor.

Adenosine containing dinucleotides 6, 10, and 12 were found to be $P2Y_1$ -R selective agonists, with EC_{50} values from 0.5 to

4.3 μ M. Uridine containing dinucleotides 7, 11, and 13 were found to be selective P2Y₆R agonists, with EC₅₀ values from 0.3 to 3.9 μ M. As for the mixed adenosine-uridine compounds, analogue 9 is a selective P2Y₁R agonist (EC₅₀ values of 0.5 and 0.81 μ M for A and B isomers, respectively), whereas analogue 8 is a selective P2Y₆R agonist (EC₅₀ values of 1.29 and 1.92 μ M for A and B isomers, respectively).

Analogue **9A** is the most potent P2Y₁R agonist found here with an EC₅₀ = 0.5 μ M, compared to 0.004 μ M for 2-MeS-ADP, which is the most potent P2Y₁R agonist currently known. Analogue **11B** is the most potent P2Y₆-R agonist with an EC₅₀ = 0.3 μ M, equipotent to UDP (EC₅₀ = 0.2 μ M).

None of the analogues antagonized the effect of equimolar concentrations of 2-MeS-ADP on P2Y₁R activation, UTP on P2Y_{2/4}R activation, or UDP on P2Y₆R activation in 1321N1 cell transfectants (data not shown).

Hydrolysis of Np_n(**B**)**N Analogues by Human NPP1.** Dinucleoside polyphosphates are substrates of certain members of the ectonucleotide pyrophosphatase/phosphodiesterase (e-NPP) family, namely, e-NPP1, e-NPP2, and e-NPP3.²⁹ These enzymes cleave Ap_nAs asymmetrically to generate AMP and Ap_{n-1}. The degradation products could activate P2R subtypes other than the parent compound. Hence, more stable dinucleotides are desirable, since they result in less degradation products and may serve as drugs with limited side effects. We therefore investigated if analogues 6–13 resist hydrolysis by human e-NPP1.

Since members of the e-NPP family have an alkaline pH optimum, e-NPP1 activity was measured at pH 8.5. Hydrolysis of parent dinucleotides and analogues 6-13 by human e-NPP1 was determined after 20 min at 37 °C. The reaction was started by the addition of a dinucleotide analogue and terminated after 20 min by addition of perchloric acid. Dinucleotides and the nucleotides degradation products were separated and quantified by HPLC. The concentrations of reactants and products were determined from the relative areas for their absorbance maxima peaks.

The acid used to terminate the enzymatic reaction can cause partial degradation of the dinucleotide and nucleotide analogues. Therefore, the percentage of degradation for each analogue was assessed in the absence of enzyme, and this value was subtracted from the percentage of analogue degradation in the presence of enzyme.

Human e-NPP1 hydrolyzed Np₄(β -B)N' analogues **6** and 7 to NMP and either NTP(γ -B) (Scheme 4, path a) or NTP(β -B) (Scheme 4, path b). The time-dependent increase in NMP was monitored by HPLC. The identity of the degradation products was determined by comparing their retention times to those of controls. Good precision was obtained for determinations of NMP concentration, since the peaks of Np_n(B)N' analogues have longer retention times than NMP.

The NTP(β -B) degradation product was easily identified, since it appeared as two peaks of the same height in the reversephase HPLC chromatogram, corresponding to the two diastereoisomers of this chiral compound. The HPLC chromatogram indicated that most of the degradation product was NTP(β -B) rather than NTP(γ -B) (the NTP(β -B)/NTP(γ -B) ratio was ~95:5), thus making path b of Scheme 4 the major hydrolytic pathway. We concluded that e-NPP1 cleaves dinucleotides **6**/7 preferentially away from the boranophosphate moiety.

Np₄(β -B)N' analogues 8 and 9 can be hydrolyzed by e-NPP1 to yield both NMP (Scheme 5, path a) and N'MP (Scheme 5,

Scheme 4. Possible Hydrolytic Pathways of Dinucleoside Poly(borano)phosphate Analogues 6 and 7 by hNPP1

Scheme 5. Possible Hydrolytic Pathways of Dinucleoside Poly(borano)phosphate Analogues 8 and 9 by hNPP1

path b), with N' being the nucleotide base further from the borane moiety. HPLC analysis of the samples showed that the main hydrolysis product was N'MP (N'MP/NMP was ~94:6). Thus, path b of Scheme 5 is the main hydrolytic pathway. HPLC analysis of the hydroloysis of analogues 8 and 9 in the absence of enzyme showed that most of the NMP generated is due to the acidic medium. Thus, under acidic conditions, path a (Scheme 5) is the main chemical hydrolytic pathway.

Np_n(α -B)N analogues **10–13** can be hydrolyzed by e-NPP1 to either NMP (Scheme 6, path b) or NMP(α -B) (Scheme 6, path a). HPLC and MS analysis of these samples showed that the major enzymatic cleavage product was NMP. Most of the NMP(α -B) was attributed to acid-induced hydrolysis. Thus, most of the enzymatic degradation of analogues **10–13** is via path b, and most of the acid-induced degradation is via path a.

The above data clearly demonstrate the protective effect of the boranophosphate group against e-NPP1-dependent hydrolysis of dinucleotides, in either P_{α} or P_{β} position.

DISCUSSION

Np₄(β -B)N' Analogues, 6–9, Are Obtained via a Metal-Preorganized Concerted Three-Component Reaction. Dinucleoside poly(borano)phosphate products 6-9 are probably formed as a result of a preorganization of a P-acceptor (BPi) and two P-donors (nucleoside phosphoroimidazolides) coordinated with one Mg²⁺ ion (Figure 4). Although we expected to obtain the Np₄(β -B)N' analogues as exclusive products, Np₃N' (Figure 5, path a) and Np₄N byproducts were also isolated. The formation of Np₃N' byproduct is driven by NDP remaining in the reaction mixture due to incomplete reaction with CDI (and not by NMP, as determined by TLC which indicated that over the same time period NMP reacted completely with CDI, whereas NDP did not). Thus, the activated form, NMP-Im, becomes a P-donor, whereas NDP, instead of the less nucleophilic BPi, functions as a P-acceptor. Furthermore, since a phosphate moiety is a better nucleophile than BPi, the Np_3N' byproduct is obtained and not NTP(γ -B) (Figure 5, path b). Scheme 6. Possible Hydrolytic Pathways of Dinucleoside Poly(borano)phosphate Analogues 12 and 13 by hNPP1

Figure 6. Steric hindrance is the origin of the diastereoselectivity of the reaction leading to products 7A and 7B.

Since NDP was not completely activated by CDI, nonactivated form and the activated form, NDP-Im, reacted to yield the Np_4N byproduct.

The concerted three-component reaction giving rise to analogues **6**–**9** proved to be diastereoselective in certain cases. Thus, the diastereoisomers ratio (A/B) for Ap₄(β -B)A was 65:35 rather than 50:50. Likewise, the ratio for Up₄(β -B)A was 55:45. However, the ratio for Up₄(β -B)U and Ap₄(β -B)U was almost 50:50. It appears that the origin of diastereoselectivity is the nucleobase of the NDP-Im component. When the nucleobase is A rather than U, there is steric hindrance between the borano group and the adenine in the transition state (Figure 6), resulting in the formation of less B-isomer vs A-isomer. Apparently, U does not induce significant steric hindrance, and therefore, analogues 7 and 8 are produced in ~50:50 ratio.

Analogues 6–13 Are Highly Resistant to Hydrolysis by Human e-NPP1. Dinucleoside polyphosphates have considerably longer half-lives in vivo than nucleotides (i.e., NTP, NDP, and NMP), which are rapidly metabolized by members of various enzyme families, including nucleoside triphosphate diphosphohydrolase (NTPDases), ectonucleotide pyrophosphatase/phosphodiesterase (e-NPPs), and alkaline phosphatases.³⁰ Naturally occurring dinucleoside polyphosphates are substrates for only a few e-NPPs.²⁹

Therefore, here, dinucleoside poly(borano)phosphate derivatives 6-13 were tested for their resistance to hydrolysis by human e-NPP1, compared to the corresponding naturally occurring dinucleotides (Figure 7), to evaluate the effect of the

borane moiety on the stability of dinucleotides. Naturally occurring dinucleotides (i.e., Up₃U, Ap₃A, Ap₄A, Up₄U, and Ap₄U) were 17-22% hydrolyzed by human e-NPP1 over 20 min at 37 °C. The identity of the nucleobase (A or U) did not affect stability to enzymatic hydrolysis, since the rate of the hydrolysis was the same for both diadenosine and diuridine analogues with the same length of polyphosphate chain. For example, Ap₃A and Up₃U were 22% and 21% hydrolyzed over 20 min by e-NPP1, respectively. E-NPP1-dependent hydrolysis is not significantly affected by the length of the Np, N' polyphosphate chain for either naturally occurring or synthetic analogues. Thus, dinucleoside tri- and tetraphosphates were hydrolyzed at similar rates (18% and 21% hydrolysis over 20 min for Up₄U and Up₃U, respectively), although dinucleoside triphosphate analogues were found to be slightly less stable, consistent with a previous report.²⁹

Substitution of the nonbridging oxygen atom on either P_{α} or P_{β} with a BH₃⁻ group inhibits the hydrolysis of analogues **6–13** by e-NPP1 (Figure 7). All of the borane containing compounds were hydrolyzed by e-NPP1 at a significantly slower rate over 20 min at 37 °C than the corresponding naturally occurring dinucleotides. The presence of BH₃⁻ near the cleavage site (i.e., at P_{α} or P_{β}) confers stability to the dinucleoside polyphosphates regarding enzymatic hydrolysis by e-NPP1 compared to a BH₃ group at P_{γ}^{-22}

Within the group of borane containing dinucleotides **6–13**, there is a difference in their resistance to hydrolysis by e-NPP1, resulting from a difference in the position of the borane on the polyphosphate chain, i.e., α or β position.

The hydrolysis of dinucleotides is known to be asymmetric and to involve the α,β -pyrophosphate bond.³¹ We found that when borane is in the β -position, both diastereoisomers exhibit similar hydrolysis rates. Yet, when the borane moiety is in the α -position, there is a considerable difference between the hydrolysis rates of the diastereoisomers, with the A-isomer being more stable. Thus, the nucleophilic attack by the ⁻OH group in water occurs at P_{α}, rather than P_{β}.

Analogues in which the borane moiety is in the β -position relative to adenosine are slightly more stable than those in which the borane moiety is in the β -position to uridine (1.5% vs 3% hydrolysis over 20 min). The most stable analogues with respect to hydrolysis by e-NPP1 are the A-isomers of Ap₃(α -B)A, analogue **10**, and of Up₃(α -B)U, analogue **11**, which are completely resistant to hydrolysis by e-NPP1, in contrast to Np₄(α -B)N' (A-isomers), which are ~3% hydrolyzed over 20 min by e-NPP1.

Each dinucleotide has two possible cleavage sites for e-NPP1 in the polyphosphate chain that differ in their proximity to the borane moiety. Analysis of the degradation products showed that the dinucleotides 6-13 were almost exclusively cleaved by e-NPP1 at the site furthest from the borane moiety (Schemes 4-6), probably because the P-BH₃ phosphodiester bond is less recognized by the enzyme as a substrate. On the other hand, analysis of the control (acidinduced degradation of analogues 6-13 in the absence of enzyme) showed that acid-induced hydrolysis (used to stop the enzyme activity) occurred preferentially near the borane moiety. This is likely due to a reduction in electron density of the P-BH₃ coordinate bond, compared to phosphate, making the P-BH₃ more susceptible to nucleophilic attack by a water molecule.

Analogues 6–13 Are Selective P2YR Agonists. The activity of dinucleoside polyphosphates Np_nN' at various

purinergic receptors was previously reported.^{9–11} Adenosine containing dinucleotides have at least minimal activity at P2Y₁R, while uridine containing dinucleotides have at least minimal activity at P2Y₂R and P2Y₆R. The length of the polyphosphate chain determines P2Y subtype specificity, i.e., nucleoside diphosphates have similar specificity to dinucleoside triphosphates, and nucleoside triphosphates are similar to dinucleoside tetraphosphates.¹⁴

In the case of dinucleoside poly(borano)phosphates, the presence and position of the borane group in the polyphosphate chain (i.e., P_{α} , P_{β} , or P_{γ}) also affects P2YR specificity. Although Up₄U is a highly potent P2Y₂R agonist,^{14,15} neither $Up_4(\alpha - B)U$ nor $Up_4(\beta - B)U$ is an agonist of the P2Y₂R subtype (Table 1), implying that the P_{α} and P_{β} oxygen atoms of Up₄U are involved in molecular recognition by the P2Y₂R. Another interesting finding for the mixed dinucleotides, $Ap_4(\beta-B)U$ and $Up_4(\beta$ -B)A, is that when the borane is closer to the uridine, the analogue is 42-fold more selective for the P2Y₁R than the P2Y₆R (and inactive at the $P2Y_{2/4}Rs$). When the borane is closer to the adenosine, the compound is a selective P2Y6R agonist with no activity at P2Y_{1/2/4}Rs. These results led us to define the borane moiety as a "boundary marker", dividing the molecule into two parts. Thus, in Up₄(β -B)A, analogue 9, the boundary marker, divides the molecule into UDP- β -B and ADP. Since ADP is the naturally occurring P2Y₁R agonist, Up₄(β -B)A acts as a better agonist for the P2Y₁R than the P2Y₆R. For Ap₄(β -B)U, analogue 8, the boundary marker divides the molecule into ADP- β -B and UDP, which is the naturally occurring P2Y₆R agonist, and therefore, $Ap_4(\beta - B)U$ is a P2Y₆R agonist and inactive at the $P2Y_1R$.

Previously, we observed similar agonist potencies for ATP, ATP- α -B, and Ap₃(β -B)A at the P2Y₁R, which suggests that these molecules share the same P2Y₁R binding site (and binding mode).²² Ap₃(β -B)A may occupy the same binding site as ATP if the extra adenosine moiety is oriented parallel to the receptor's α -helical domain away from the agonist binding site. Similarly for the Np_n(α / β -B)N' analogues, the borane moiety might define the boundary between the part of the dinucleotide that binds to the receptor and the part that is oriented outside the agonist binding binding domain.

When the borane moiety is situated at either P_{α} or P_{β} , each analogue is obtained as two diastereoisomers. At the P2Y₁R, the A-isomer is equipotent or slightly more active (up to 4-fold) than the B-isomer. At the P2Y₆R, the B-isomer is more potent than the A-isomer (up to 9-fold). These data indicate that the P2Y1 and P2Y6 receptor subtypes have opposite diastereoselectivity. Our previous study on the diastereoselectivity of the P2Y₁R showed that for ATP- α -B analogues, A and B isomers possess the Rp and Sp configuration, respectively. The absolute configuration of the two diastereoisomers was determined based on their NMR spectra.^{22,32} Applying the same considerations to the P2Y1R selective dinucleotides described here resulted in similar conclusions regarding the absolute configuration of the diastereoisomers (i.e., A-isomer is the Rp isomer). Assuming the same elution order of diastereoisomers from the HPLC column, if $P2Y_1$ is a $P\alpha$ -Rp isomer preferring receptor, then P2Y₆ is a P α -Sp preferring receptor.

CONCLUSION

 $Np_{3/4}(\alpha$ -B)N' and $Np_4(\beta$ -B)N' (N and N' = A, U) derivatives are selective P2Y₁ or P2Y₆ receptor agonists, having no activity at the P2Y₂ and P2Y₄ receptors. The potency and receptor subtype selectivity can be controlled by the position of the borane moiety in the polyphosphate chain. This is most evident in dinucleotides $Ap_4(\beta-B)U$ and $Up_4(\beta-B)A$, in which the difference in the position of the borane moiety renders the analogue either a selective P2Y₁R or P2Y₆R agonist, respectively. Furthermore, a boranophosphate bioisoster at either P_{α} or P_{β} significantly improves metabolic stability with respect to hydrolysis by human e-NPP1. Resistance to e-NPP1-dependent hydrolysis increased up to >20-fold compared to the same compound lacking the borane moiety. Analogues with borane at P_{α} were more enzymatically stable than analogues with borane at P_{β} . When the borane is at P_{α} , the A isomer is more stable than the B isomer, indicating that e-NPP1-dependent hydrolysis occurs at P_{α} whereas when the borane is at P_{β} , there is no difference in the rates of hydrolysis for the A and B isomers. The most potent agonists are the P2Y1R-selective A and B isomers of Ap₃(α -B)A, analogues **10A**/**B**, and the P2Y₆R-selective B isomer of Up₃(α -B)U, analogue 11B. Since these analogues are also resistant to e-NPP1-dependent hydrolysis, we propose them as promising scaffolds for the design of future drug candidates targeting P2Y1 and P2Y6 receptors. Improved drug candidates will be reported in due course.

EXPERIMENTAL SECTION

General. All commercial reagents were used without further purification unless otherwise noted. All reactants in moisture-sensitive reactions were dried overnight in a vacuum oven. All air- and moisturesensitive reactions were carried out in flame-dried, argon-flushed, twoneck flasks sealed with rubber septa, and the reagents were introduced with a syringe. Progress of reactions was monitored by TLC on precoated Merck silica gel plates (60F-254). Visualization of reactants and products was accomplished with UV light. Nucleotides and dinucleoside polyphosphates were characterized by ¹H NMR spectrometry at 200 or 300 MHz or by ³¹P NMR spectrometry in D₂O, using 85% H₃PO₄ as an external reference on a Bruker AC-200 or DPX-300 spectrometer. In certain cases some of the signals of ribose protons were hidden by the very large HOD signal. High resolution mass spectra of nucleotides and dinucleoside polyphosphates were recorded on an AutoSpec-E FISION VG mass spectrometer using ESI (electron spray ionization) on a Q-TOF microinstrument (Waters, U.K.). Primary purification of the dinucleoside polyphosphates was achieved on an LC (Isco UA-6) system using a column of Sephadex DEAE-A25 swollen in 1 M NaHCO3 at 4 °C for 1 day. The resin was washed with deionized water before use. The LC separation was monitored by UV detection at 280 nm. Final purification of the dinucleoside polyphosphates and separation of the diastereomeric pairs were achieved by HPLC (Elite Lachrom, Merck-Hitachi) using a semipreperative reverse-phase column. (Gemini 5 µm C18 110A, 250 mm \times 10 mm 5 μ m, Phenomenex, Torrance, CA, U.S.). The purity of the dinucleoside polyphosphates was evaluated by analytical reversephase column chromatoghraphy (Gemini 5 μ m C18 110A, 150 mm \times 4.60 mm, 5 μ m Phenomenex, Torrance, CA, U.S.) with two solvent systems. Solvent system I consisted of (A) MeOH and (B) 100 mM triethylammonium acetate (TEAA), pH 7. Solvent system II consisted of (A) 0.01 M KH₂PO₄, pH 4.5, and (B) MeOH. The details of the eluent gradients used for the separation of each product are given below. In addition, novel dinucleotides were characterized by HRMS-FAB (negative). Np_nN analogues were prepared according to literature procedures.¹⁴ The purity of the dinucleotides was ≥95%. pH measurments were performed with an Orion microcombination pH electrode and a Hanna Instruments pH meter.

2',3'-O-Methoxymethylideneadenosine was prepared as previously described.³³ AMP(Bu₃NH⁺)₂ and UMP(Bu₃NH⁺)₂ salts were prepared from the corresponding nucleotide free acids and Bu₃N (2 equiv) in EtOH. ADP(Bu₃NH⁺)₂ and UDP(Bu₃NH⁺)₂ were prepared from the corresponding disodium salts. The latter salts were passed through a column of activated Dowex 50WX-8 200 mesh, H⁺ form. The column eluate was collected in an ice-cooled flask

containing Bu_3N (2 equiv) and EtOH. The resulting solution was freeze-dried to yield $ADP(Bu_3NH^{\ast})_2$ or $UDP(Bu_3NH^{\ast})_2$ as a white solid.

NDP(α -B)(Bu₃NH⁺)₂ salt was prepared from the corresponding bisammonium salt. The latter salt was passed through a column of Sephadex Na⁺-form washed with tetrabutylammonium bromide (4 equiv) and then with deionized water (10 mL). The column eluate was freeze-dried to yield NDP(α -B) (Bu₃NH⁺)₂ as a white solid.

Reverse-Phase HPLC Purification and Diastereoisomers Separation. The dinucleotide purification and diasteromers separation were achieved with a semipreparative reverse-phase Elite Lachrom 250-10 column and isocratic elution (MeOH [A]/100 mM triethylammonium acetate (TEAA), pH 7 [B]) at a flow rate of 5 mL/ min. Fractions containing the same compound (similar retention time) were freeze-dried. The excess buffer was removed by repeated freezedrying cycles until a constant weight was attained, with the solid residue dissolved each time in deionized water. The triethylammonium counterions were exchanged for Na⁺ by passing the pure dinucleoside poly(borano)phosphate isomer through a Sephadex-CM C-25 (Na⁺ form) column.

Typical Procedure for the Preparation of Dinucleoside *P*-*β*-**Tetraboranophosphates (Analogues 6–9).** NMP (Bu₃NH⁺)₂ (0.22 mmol) and NDP(Bu₃NH⁺)₂ (0.22 mmol) were dissolved in dry DMF (3 mL), followed by addition of CDI (349 mg, 2.15 mmol). The resulting solution was stirred at room temperature for 4 h. Dry MeOH (87 µL, 2.15 mmol) was added. After 8 min BPi(Bu₃NH⁺)₂ (100 mg, 0.22 mmol) and MgCl₂ (4 equiv) in dry DMF (3 mL) were added. The resulting solution was stirred at room temperature overnight. The semisolid obtained after evaporation of the solvent was chromatographed on a Sepadex DEAE-A25 column by applying a buffer gradient of water (500 mL) to 0.5 M NH₄HCO₃ (500 mL). The relevant fractions were pooled and freeze-dried to yield a white solid. Product 6 was obtained at 40% yield (80.8 mg). Product 7 was obtained at 38% yield (75.5 mg). Product 8 was obtained at 35% yield (68.9 mg). Product 9 was obtained at 37% yield (72.8 mg).

Synthesis and Separation of P^2 -Borano- P^1 , P^4 -di(5'adenosine)tetraphosphate (Analogues 6A and 6B). Analogue 6 was synthesized from AMP(Bu₃NH⁺)₂ and ADP(Bu₃NH⁺)₂. The separation of diastereoisomers 6A and 6B was accomplished using a semipreparative reverse-phase column and solvent system I, by isocratic elution with 4:96 A/B at a flow rate of 5 mL/min.

P²-Borano-P¹, P⁴-di(5'-adenosine)tetraphosphate (Analogue 6A). $t_{\rm R} = 22.06$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 75 (m, Pβ, 1P), -10.5 (d, Pα, 2P), -22.5 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 200 MHz): δ 8.6 (s, H-8, 1H), 8.3 (s, H-2, 1H), 6.2 (d, H-1', 1H), 4.5 (m, H-3', 1H), 4.3 (m, H-4', 2H), 0-0.97 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₂₀H₃₀BN₁₀O₁₈P₄ 833.214, found 833.221. Purity data obtained on an analytical column: retention time of 3.76 min (98% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 1.76 min (97% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P²-Borano-P¹, P⁴-di(5'-adenosine)tetraphosphate (Analogue 6B). $t_{\rm R} = 24.03$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 76.0 (m, Pβ, 1P), -11 (d, Pα, 2P), -22.5 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 200 MHz): δ 8.5 (s, H-8, 1H), 8.2 (s, H-2, 1H), 6.1 (d, H-1', 1H), 4.4 (m, H-3', 1H), 4.3 (m, H-4', 2H), 0-0.97 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 4.49 min (99% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 2.46 min (98.5% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Synthesis and Separation of P^2 -Borano- P^1 , P^4 -di(5'-uridine)tetraphosphate (Analogues 7A and 7B). Analogue 7 was synthesized from UMP (Bu₃NH⁺)₂ and UDP(Bu₃NH⁺)₂. The separation of diastereoisomers 7A and 7B was accomplished using a semipreparative reverse-phase column and solvent system I, by isocratic elution with 6:94 A/B at a flow rate of 5 mL/min.

P²-Borano-**P**¹,**P**⁴-di(5'-uridine)tetraphosphate (Analogue **7A**). $t_{\rm R} = 11.06$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 77.0 (m, Pβ, 1P), -10.97 (d, Pα, 2P), -23.5 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 7.98 (d, J = 8.1 Hz H-5, 1H), 5.99 (d, J = 5.1 Hz, H-1', 1H), 5.97 (d, J = 8.1 Hz, H-6, 1H), 4.44 (m, H-4', 1H), 4.27 (m, H-5', 2H), 0.94–0.99 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for $C_{18}H_{28}BN_4O_{22}P_4$ 787.134, found 787.141. Purity data obtained on an analytical column: retention time of 3.5 min (98% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 2.5 min (97.8% purity), using solvent II system and elution with 4:96 A/B at a flow rate of 1 mL/min.

 \dot{P}^2 -Borano- P^1 , P^4 -di(5'-uridine)tetraphosphate (Analogue 7B). $t_{\rm R} = 12.73$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 77.0 (m, P β , IP), -10.81 (d, P α , 2P), -23.0 (dd, P β , 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 7.97 (d, J = 8.1 Hz, H-5, 1H), 5.99 (d, J = 5.2 Hz, H-1', 1H), 5.98 (d, J = 8.1 Hz, H-6, 1H), 4.43 (m, H-4', 1H), 4.26 (m, H-5', 2H), 0.94–0.99 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 3.76 min (98% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 2.69 min (97.5% purity), using solvent system II and elution with 4:96 A/B at a flow rate of 1 mL/min.

Synthesis and Separation of P^3 -Borano- P^1 , P^4 -5'-uridine-5'adenosinetetraphosphate (Analogues 8A and 8B). Analogue 8 was synthesized from AMP (Bu₃NH⁺)₂ and UDP (Bu₃NH⁺)₂. The separation of diastereoisomers 8A and 8B was accomplished using a semipreparative reverse-phase column and using solvent system I, by isocratic elution with 8:92 A/B at a flow rate of 5 mL/min.

P³-Borano-*P*¹,*P*⁴-5'-uridine-5'-adenosinetetraphosphate (Analogue 8A). $t_{\rm R} = 21.47$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 77.7 (m, Pβ, 1P), -10.65 (d, Pα, 2P), -21.78 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.56 (s, H-8, 1H), 8.26 (s, H-2, 1H), 7.87 (d, *J* = 8.2 Hz, H-5, 1H), 6.14 (d, H-1', 1H), 5.95 (d, *J* = 5.1 Hz, H-1', 1H), 5.89 (d, *J* = 8.2 Hz, H-6, 1H), 4.60 (m, H-3', 1H), 4.38 (m, H-4', 2H), 4.28 (m, H-5', 2H), 0-0.97 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₁₉H₂₉BN₇O₂₀P₄ 810.173, found 810.180. Purity data obtained on an analytical column: retention time of 2.40 min (96% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 1.60 min (95.8% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P³-Borano-*P*¹, *P*⁴-5'-uridine-5'-adenosinetetraphosphate (Analogue 8B). $t_{\rm R} = 24.55$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 78.5 (m, Pβ, 1P), -10.55 (d, Pα, 2P), -21.30 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.57 (s, H-8, 1H), 8.25 (s, H-2, 1H), 7.86 (d, *J* = 8.2 Hz, H-5, 1H), 6.14 (d, H-1', 1H), 5.93 (d, *J* = 5.1 Hz, H-1', 1H), 5.89 (d, *J* = 8.2 Hz, H-6, 1H), 4.59 (m, H-3', 1H), 4.42 (m, H-4', 2H), 4.27 (m, H-5', 2H), 0-0.97 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 3.53 min (97.3% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 1.66 min (97% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Synthesis and Separation of P^2 -Borano- P^1 , P^4 -5'-uridine-5'adenosinetetraphosphate (Analogues 9A and 9B). Analogue 9 was synthesized from UMP(Bu₃NH⁺)₂ and ADP(Bu₃NH⁺)₂. The separation of diastereoisomers 9A and 9B, was accomplished using a semipreparative reverse-phase column and solvent system I, by isocratic elution with 7:93 A/B at a flow rate of 5 mL/min.

*P*²-Borano-*P*¹,*P*⁴-5'-uridine-5'-adenosinetetraphosphate (Analogue 9A). $t_{\rm R}$ = 15.12 min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 76.5 (m, Pβ, 1P), −11 (d, Pα, 2P), −22.6 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.51 (s, H-8, 1H), 8.26 (s, H-2, 1H), 7.87 (d, *J* = 8.0 Hz, H-5, 1H), 6.11 (d, *J* = 5.2 Hz, H-1', 1H), 5.99 (d, H-1', 1H), 5.98 (d, *J* = 8.0 Hz, H-6, 1H), 4.57 (m, H-3', 1H), 4.37 (m, H-4', 2H), 4.22 (m, H-5', 2H), 0−0.97 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₁₉H₂₉BN₇O₂₀P₄ 810.173, found 810.179. Purity data obtained on an analytical column: retention time of 3.36 min (98% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 1.93 min (97.3% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P²-Borano-**P**¹,**P**⁴-5'-uridine-5'-adenosinetetraphosphate (Analogue 9B). $t_{\rm R} = 17.74$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 76.0 (m, Pβ, 1P), -11 (d, Pα, 2P), -22.6 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.51 (s, H-8, 1H), 8.26 (s, H-2, 1H), 7.87 (d, J = 8.1 Hz, H-5, 1H), 6.32 (d, J = 5.2 Hz, H-1', 1H), 6.14 (d, H-1', 1H), 5.98 (d, J = 8.1 Hz, H-6, 1H), 4.54 (m, H-3', 1H), 4.36 (m, H-4', 2H), 4.22 (m, H-5', 2H), 0–0.97 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 4.65 min (97% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 2.11 min (96.7% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Typical Procedure for the Preparation of Dinucleoside-*P*- α boranotriphosphate (Analogues 10 and 11). $NMP(Bu_3NH^+)_2$ (0.2 mmol) was dissolved in dry DMF (2 mL), and CDI (163.7 mg, 1 mmol) was added. The resulting solution was stirred at room temperature for 3 h. Dry MeOH (80 µL, 1 mmol) was added. After 8 min NDP(α -B)(Bu₃NH⁺)₂ (0.2 mmol) in dry DMF (2 mL), and MgCl₂ (4 equiv) were added. The resulting solution was stirred at room temperature overnight. The semisolid obtained after evaporation of the solvent was chromatographed on a Sephadex DEAE-A25 column. A buffer gradient of water (700 mL) to 0.5 M NH₄HCO₃ (700 mL) was applied. The relevant fractions were pooled and freezedried to yield a white solid. Final purification was achieved on a semipreparative HPLC column. Finally, purified A and B isomers were passed through a Sephadex-CM C-25 (Na⁺-form) column to exchange triethylammonium counterions for Na⁺ ions. Product 10 was obtained at 84% yield (50 mg). Product 11 was obtained at 85% yield (60.5 mg).

Synthesis and Separation of P^1 -Borano- P^1 , P^3 -5'-diadenosinetriphosphate (Analogues 10A and 10B). Analogue 10 was synthesized from AMP(Bu₃NH⁺)₂ and ADP(α -B)(Bu₃NH⁺)₂. The separation of diastereoisomers 10A and 10B was accomplished using a semipreperative reverse-phase column, using solvent system I, and isocratic elution with 11:89 A/B at a flow rate of 5 mL/min.

P¹-Borano-**P**¹,**P**³-5'-diadenosinetriphosphate (Analogue 10A). $t_{\rm R} = 16.05$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 84(m, Pα, 1P), -11.5 (d, Pα, 1P), -23 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 200 MHz): δ 8.45 (s, H-8, 1H), 8.2 (s, H-2, 1H), 6.1 (d, H-1', 1H), 4.60 (m, H-2', 1H), 4.30 (m, H-4', 1H), 4.25 (m, H-5', 1H), 0.5 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₂₀H₂₈BN₁₀O₁₅P₃ 752.223, found 752.227. Purity data obtained on an analytical column: retention time of 3.13 min (96% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 2.55 min (96.5% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P¹-Borano-P¹,P³-5'-diadenosinetriphosphate (Analogue **10B**). $t_{\rm R} = 24.49$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 84 (m, Pα, 1P), -11 (d, Pα, 1P), -22.5 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 200 MHz): δ 8.50 (s, H-8, 1H), 8.1 (s, H-2, 1H), 6.1 (d, H-1', 1H), 4.60 (m, H-2', 1H), 4.35 (m, H-4', 1H), 4.25 (m, H-5', 1H), 0.7 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 6.68 min (98% purity), using solvent system I and elution with 7:93 A/B at a flow rate of 1 mL/min. Retention time of 3.18 min (98.8% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Synthesis and Separation of P^1 -Borano- P^1 , P^3 -5'-diuridinetriphosphate (Analogues 11A and 11B). Analogue 11 was synthesized from UMP (Bu₃NH⁺)₂ and UDP(α -B)(Bu₃NH⁺)₂. The separation of diastereoisomers 11A and 11B was accomplished using a semipreparative reverse-phase column and solvent system I, by isocratic elution with 8:92 A/B at a flow rate of 5 mL/min.

P¹-Borano-P¹,P³-5'-diuridinetriphosphate (Analogue 11A). $t_{\rm R} = 6.36$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 83 (m, Pα, 1P), -11 (d, Pα, 1P), -22.5 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.00 (d, J = 8.1 Hz, H-5, 1H), 5.80 (d, J = 5.2 Hz, H-1', 1H), 5.75 (d, J = 8.1 Hz, H-6, 1H), 4.40 (m, H-4', 1H), 4.25 (m, H-5', 2H), 0.94–0.99 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₁₈H₂₆BN₄O₁₉P₃ 706.146, found 706.153. Purity data obtained on an analytical column: retention time of 2.12 min (99% purity), using solvent system I and elution with 9:91 A/B at a flow rate of 1 mL/min. Retention time of 2.00 min (98.8% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P¹-Borano-P¹,P³-5'-diuridinetriphosphate (Analogue 11B). $t_{\rm R} =$ 9.25 min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 82.5 (m, Pα, 1P), -11 (d, Pα, 1P), -22.5 (dd, Pβ, 1P) ppm. ¹H NMR (D₂O, 300 MHz): δ 7.95 (d, *J* = 8.1 Hz, H-5, 1H), 5.85 (d, *J* = 5.1 Hz, H-1', 1H),

5.75 (d, J = 8.1 Hz, H-6, 1H), 4.35 (m, H-4', 1H), 4.26 (m, H-5', 2H), 0.94–0.99 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 2.20 min (98% purity), using solvent system I and elution with 9:91 A/B at a flow rate of 1 mL/min. Retention time of 1.81 min (97% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Typical Procedure for the Preparation of Dinucleoside-P- α boranotetraphosphates (analogues 12 and 13). To a solution of 2',3'-O-methoxymethylidene protected nucleoside (0.5 mmol) in anhydrous DMF (2 mL) and pyridine (0.2 mL) was added 2-chloro-4H-1,3,2-benzo-dioxaphosphorin-4-one (111.5 mg, 0.55 mmol) at room temperature. The solution was stirred for 10 min at room temperature. A 0.5 M solution of bis(tri-n-butylammonium)pyrophosphate in anhydrous DMF (1.5 mL, 0.75 mmol) was vortexed with tri-n-butylamine (0.47 mL, 2 mmol) and immediately added to the reaction mixture. After 10 min, a solution of BH₃/SMe₂ complex, 2 M in THF (2.5 mL, 5 mmol), was added. After 15 min, a mixture of nucleoside monophosphate monohydrate (2.5 mmol) and magnesium chloride (5 mmol), which had been dried together before by evaporation of DMF, was added and stirring continued for 16 h. The mixture was freeze-dried overnight and chromatographed on a Sephadex DEAE-A25 column. A buffer gradient of 600 mL of water to 600 mL of 0.5 M NH₄HCO₃ was applied. The relevant fractions were pooled and freeze-dried three times to yield the product as a white solid. Final purification was achieved on a semipreperative C-18 HPLC column. Product 12 was obtained at 82% yield (69.1 mg). Product 13 was obtained at 80% yield (48.3 mg).

Synthesis and Separation of P^1 -Borano- P^1 , P^3 -5'-diadenosinetetraphosphate (Analogues 12A and 12B). Analogue 12 was synthesized from 2',3'-O-methoxymethylidene adenosine. The separation of diastereoisomers 12A and 12B was accomplished using a semipreparative reverse-phase column and solvent system I, by isocratic elution with 8:92 A/B at a flow rate of 5 mL/min.

P¹-Borano-P¹, P³-5'-diadenosinetetraphosphate (Analogue 12A). $t_{\rm R} = 6.62$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 83.5 (m, Pα, 1P), -10.5 (d, Pα, 1P), -22.5 (dd, Pβ, 2P) ppm. ¹H NMR (D₂O, 200 MHz): δ 8.45 (s, H-8, 1H), 8.2 (s, H-2, 1H), 6.25 (d, H-1', 1H), 4.45 (m, H-2', 1H), 4.35 (m, H-4', 1H), 4.25 (m, H-5', 1H), 0.5 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₂₀H₃₀BN₁₀O₁₈P₄ 833.214, found 833.221. Purity data obtained on an analytical column: retention time of 1.94 min (95% purity), using solvent system I and elution with 13:87 A/B at a flow rate of 1 mL/min. Retention time of 2.15 min (95.3% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P¹-Borano-P¹, P³-5'-diadenosinetetraphosphate (Analogue **12B)**. $t_{\rm R} = 8.96$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 83.5 (m, Pα, 1P), -10.5 (d, Pα, 1P), -22.0 (dd, Pβ, 2P) ppm. ¹H NMR (D₂O, 200 MHz): δ 8.45 (s, H-8, 1H), 8.2 (s, H-2, 1H), 6.1 (d, H-1', 1H), 4.60 (m, H-2', 1H), 4.35 (m, H-4', 1H), 4.20 (m, H-5', 1H), 0.5 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 2.36 min (97% purity), using solvent system I and elution with 13:87 A/B at a flow rate of 1 mL/min. Retention time of 3.21 min (96.5% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Synthesis and Separation of P^1 -Borano- P^1 , P^4 -5'-diuridinetetraphosphate (Analogues 13A and 13B). Analogue 13 was synthesized from 2',3'-O-methoxymethylideneuridine. The separation of analogue 13 diastereoisomers 13A and 13B was accomplished using a semipreparative reverse-phase column and solvent system I, by isocratic elution with 10:90 A/B at a flow rate of 5 mL/min.

P¹-Borano-**P**¹,**P**⁴-5'-diuridinetetraphosphate (Analogue 13A). $t_{\rm R} = 5.55$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 83.5 (m, Pα, 1P), -10.8 (d, Pα, 1P), -22.7 (dd, Pβ, 2P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.00 (d, J = 8.1 Hz, H-5, 1H), 5.80 (d, J = 5.1 Hz, H-1', 1H), 5.75 (d, J = 8.1 Hz, H-6, 1H), 4.40 (m, H-4', 1H), 4.25 (m, H-5', 2H), 0.94–0.99 (m, BH₃, 3H) ppm. HR MALDI (negative): calculated for C₁₈H₂₈BN₄O₂₂P₄ 787.134, found 787.139. Purity data obtained on an analytical column: retention time of 2.53 min (96% purity), using solvent system I and elution with 8:92 A/B at a flow rate of 1 mL/min. Retention time of 1.64 min (96.5% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

P¹-Borano-P¹, -P⁴-5'-diuridinetetraphosphate (Analogue 13B). $t_{\rm R} = 7.11$ min. ³¹P NMR (D₂O, 81 MHz, pH 7): δ 84 (m, Pα, 1P), -10.8 (d, Pα, 1P), -22.9 (dd, Pβ, 2P) ppm. ¹H NMR (D₂O, 300 MHz): δ 8.00 (d, J = 8.1 Hz, H-5, 1H), 5.80 (d, J = 5.1 Hz, H-1', 1H), 5.75 (d, J = 8.1 Hz, H-6, 1H), 4.40 (m, H-4', 1H), 4.25 (m, H-5', 2H), 0.94–0.99 (m, BH₃, 3H) ppm. Purity data obtained on an analytical column: retention time of 2.82 min (95% purity), using solvent system I and elution with 8:92 A/B at a flow rate of 1 mL/min. Retention time of 1.69 min (98% purity), using solvent system II and elution with 5:95 A/B at a flow rate of 1 mL/min.

Intracellular Calcium Measurements. Human 1321N1 astrocytoma cells stably expressing the turkey P2Y₁ receptor, the human P2Y₂ receptor, the human P2Y₄ receptor, or the rat P2Y₆ receptor were grown in Dulbecco's modified Eagle's medium containing 5% (v/v) fetal bovine serum, 100 units/mL penicillin, 100 μ g/mL streptomycin, and 500 μ g/mL Geneticin (G-418; Life Technologies, Inc.). Changes in the intracellular free calcium concentration, $[Ca^{2+}]_{i}$ were detected by dual-excitation spectrofluorometric analysis of cell suspensions preloaded with fura-2, as described previously.³⁴ Cells were treated with the indicated nucleotide or analogue at 37 °C in 10 mM Hepes-buffered saline (pH 7.4) containing 1 mM CaCl₂ and 1 mM MgCl₂, and the maximal increase in $[Ca^{2+}]_i$ was determined at various nucleotide or analogue concentrations to calculate the EC₅₀. Concentration–response data were analyzed with the Prism curve fitting program (GraphPAD software, San Diego, CA). Three experiments were conducted on separate days for each P2Y receptor subtype.

Measurement of Enzymatic Hydrolysis of Dinucleoside Poly(borano)phosphate Analogues. e-NPP1 activity was measured at 37 °C in 1 mL of the following incubation medium: (in mM) 1 CaCl₂, 200 NaCl, 10 KCl, and 100 Tris, pH 8.5 (Sigma-Aldrich). Then 0.1 mL of human NPP1 enzyme preparation was added to the reaction mixture and the mixture was preincubated for 3 min at 37 °C. The reaction was initiated by addition of 0.5 mL of 0.2 mM substrate. The reaction mixture to 0.375 mL of ice-cold 1 M perchloric acid. The samples were centrifuged for 5 min at 10000g. Supernatants were neutralized with 1 M KOH at 4 °C and centrifuged for 5 min at 10000g. An aliquot of the supernatant (0.2 mL) was analyzed by HPLC to monitor the increase of NMP. The percentage of substrate (dinucleotide) decomposition in 20 min corresponds to the average of two experiments preformed in triplicate.

Quantification of NMP Hydrolysate by HPLC. e-NPP1dependent degradation products generated from dinucleoside poly-(borano)phosphate analogues 6-13 were isocratically eluted from an analytical reverse-phase Gemini 150-4.60 column with a mobile phase composed of 100 mM triethylammonium acetate (TEAA), pH 7, and 10-18% acetonitrile at a flow rate of 1 mL/min. Nucleotide concentrations were determined from the relative area under the respective HPLC peaks.
