#### Abstract

In a recent paper, we have described the discovery of antimalarial compounds derived from tadalafil, using a drug-to-genome-to-drug approach (J. Med. Chem. 2011, 54 (9), pp 3222-3240). We have shown that these derivatives inhibit the phosphodiesterase activity of Plasmodium falciparum and the parasite growth in culture. In this paper, we describe the optimization of these compounds. A direct consequence of our approach based on gene orthology is the lack of selectivity of the compounds over the original activity on the human target. We demonstrate here that it is  possible to take advantage of subtle differences in SAR between HsPDE5 inhibition and antiplasmodial activity to improve significantly the selectivity. In particular, the replacement of the piperonyl group in compound 2 by a dimethoxyphenyl group was the best way to optimize selectivity. This observation is consistent with the differences between human and plasmodial sequences in the Q2 pocket receiving this group.

## INTRODUCTION

In a recent paper, ${ }^{1}$ we described the drug-to-genome-to-drug approach for the discovery of new potent antiplasmodial compounds. This approach consists of screening compounds inspired from drugs acting on proteins that have orthologues in Plasmodium falciparum. We focused on PDE5 inhibitors inspired from tadalafil and showed that inhibition of Plasmodium phosphodiesterase activity by these compounds was linked to the disruption of the life cycle of the parasite in cell-based assay (Table 1).

Compound 2 and 3 are the most potent antiplasmodial compounds in our series. They were previously described by Maw et al. as potent human PDE5 inhibitor, ${ }^{2}$ and we showed that they inhibit cGMP hydrolysis in a parasite lysate. In the first part of this article we report improved antiplasmodial compounds and structure-activity relationships (SARs). In the second part, we show that it is possible to find structural modifications that reverse the selectivity over human PDE5. The lead compound is further profiled to show that the original PDE selectivity of tadalafil is conserved while switching from HsPDE5 to antiplasmodial activity.

## CHEMISTRY

Compound 2 was selected as a lead compound for variation of the side chain on the pyrrolidine ring in the first instance. The

Table 1. In Vitro Antiplasmodial Activity and Cytotoxicity

piperonyl moiety in the C6 position, the $R$-configuration of the pyrrolidine group, and the cis configuration $(6 R, 12 \mathrm{a} R)$ were kept unchanged in this series. The benzyl group on the pyrrolidine of compound 2 was replaced by diverse aromatic or

## Scheme 1. General Synthetic Route ${ }^{a}$

${ }^{a}$ Conditions: (a) $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}, \mathrm{EtOH}$, reflux, 30 min ; (b) aldehyde, (polystyrylmethyl)trimethylammonium cyanoborohydride $\mathrm{resin}^{2} \mathrm{CH}_{2} \mathrm{Cl} / \mathrm{AcOH}_{2}$, $10 / 1,12-24 \mathrm{~h}$ or (c) R-X, dioxanne, triethylamine, $70^{\circ} \mathrm{C}$; (d) refluxed in methanol under basic conditions.

Scheme 2. General Synthetic Route of Lead 2 Analogues ${ }^{a}$

${ }^{a}$ Conditions: (a) $\mathrm{CF}_{3} \mathrm{COOH}, \mathrm{CH}_{2} \mathrm{Cl}_{2}$, diastereoisomer separation; (b) chloroacetyl chloride, $\mathrm{Et}_{3} \mathrm{~N}, \mathrm{CHCl}_{3} 0^{\circ} \mathrm{C}$ to room temp; (c) $\mathrm{R} 1-\mathrm{NH}, \mathrm{MeOH}$, reflux, or EtOH , microwave $100 \mathrm{~W} / 5 \mathrm{~min}$.
aliphatic derivatives. Compounds 4-16 were obtained following the synthetic route described in Scheme 1. The starting point of the synthesis was compound 2 itself. It was debenzylated in ethanol in the presence of hydrogen and Pd on charcoal to afford compound 4, which was then alkylated using alkyl halides or reductive amination of aldehydes. Some derivatives were obtained by reaction of the corresponding N -substituted aminopyrrolidine with the chloroacetylated ester 18. Intermediates 4 and $\mathbf{1 8}$ have been previously described by Beghyn et al. ${ }^{1}$

The synthesis of analogues where the piperonyl group is replaced by other substituents implies the use of the various aldehydes in the Pictet-Spengler reaction (Scheme 2). Recently, Dunn et al. ${ }^{3}$ described the diastereoselective industrial synthesis of tadalafil in which the precipitation of the product in isopropanol is responsible for diastereoselectivity. Unfortunately, these diastereoselective conditions could not be applied to other substrates. Pictet-Spengler reactions were thus performed in dichloromethane in the presence of trifluoroacetic acid at room temperature, starting from D tryptophan methyl ester hydrochloride (Scheme 2). Diastereoisomers cis $(1 R, 3 R)$ and trans $(1 S, 3 R)$ were separated by column chromatography.

## RESULTS AND DISCUSSION

Structure-Activity Relationships. Compounds were tested in vitro for inhibitory activity against $P$. falciparum
(GHA chloroquine-sensitive strain unless otherwise mentioned) in culture and for cytotoxicity on human fetal lung fibroblast (MRC5) to assess the specificity of action of the compounds (Table 2). A compound is considered as "highly active" when the $\mathrm{IC}_{50}$ is less than $1 \mu \mathrm{M}$ and specific ratio is $>100 .{ }^{4}$

The replacement of the benzyl group on the pyrrolidine by an alkyl chain led to a slightly decreased activity for 5 and 6 . The length of the chain between the aryl ring and the protonable nitrogen is important. Adding a methylene group is deleterious (7), while lengthening the chain by introducing an ether function restored activity (8). Compared to compound 2, activity is retained with a piperonyl moiety but significantly reduced with other aryl groups (10-12) except for methylimidazole (13). Adding substituents at the para position of the benzyl group increased the cytotoxicity of compounds 10 and 11 (respectively methoxy and dimethylamino groups). Introduction of nonaromatic moieties such as a $\mathrm{N}, \mathrm{N}$ dimethylacetamide (14) led to a moderately active compound, whereas compound 15 bearing a $t$-Boc-aminoethyl substituent was very potent. A hydrophobic moiety (aromatic or aliphatic) such as the tert-butyl in compound 15 seems to be favorable for activity, whereas introduction of polar group appeared deleterious. The replacement of the aromatic ring by aliphatic cyclopentyl (16) or cyclohexyl (17) led to potent antiplasmodial compounds, but these compounds exhibit a significant cytotoxicity. The most promising compound (i.e., displaying

the best antiplasmodial activity and the best specificity ratio) is compound 15.

Selectivity Issue. As a likely consequence of our approach, many of our compounds are also potent inhibitors of human PDE5. Activity measured by us confirm the trend published by Maw et al. (Table 3). ${ }^{2}$ It is not surprising to note that $\mathbf{1 5}$, one of the best antiplasmodial compounds in our series, is also a subnanomolar inhibitor of human PDE5.
We believed, however, that we could eventually overcome this selectivity issue. Indeed, a multiple alignment of the sequences of PDEs from human and Plasmodium reveals a few but possibly critical nonconservative differences in the residues of the Q2 pocket between the two species. ${ }^{1}$ Therefore, the replacement of the piperonyl group of tadalafil known to bind to this pocket ${ }^{5}$ could be a way to design compounds devoid of HsPDE5 inhibition while keeping antiplasmodial activity.

The choice of aldehydes for the Pictet reaction was based on SAR described for HsPDE5 inhibition in the tadalafil series. It has been demonstrated that the best interaction within the Q2 pocket of HsPDE5 is obtained with a piperonyl group or a $p$ methoxyphenyl group ${ }^{6}$ and that a hindered group led to a loss of activity. It has also been shown that oxygen atoms in para- or meta-position are important for HsPDE5 inhibition. We selected several analogues of the piperonyl group, such as benzoxadiazole or benzothiadiazole group, fluorinated derivatives, and also vanilloyl, isovanilloyl, dimethoxyphenyl, and ethylenedioxyphenyl groups. Tetrazolo[1,5-a] pyridine-6-carbaldehyde 19 was prepared beforehand, reacting 6 -chloropyridine3 -carbaldehyde with sodium azide in DMF (Scheme 3).? Intermediate 19a was also included in the set of aldehydes.

cytotoxicity on MRC5 cells of the series are presented in Table 4.

We confirmed that the benzothiadiazol group is a suitable bioisoster of the methylendioxyphenyl group (compound 21), as Anzali et al. proposed in 1998, 8,9 better than the benzoxadiazole group (20). Moreover, it makes this compound original, slightly less toxic on MRC5, and expectedly more stable. At first, it seemed that the SAR at that position is identical for antiplasmodial activity and HsPDE5 inhibition. ${ }^{10-12}$ Indeed, replacement of the piperonyl group by 6 chloropyridine and tetrazolo $[1,5-a]$ pyridine $(22,23)$ led to a loss of activity. Also, the presence of 2 oxygens at the meta and para positions $(24,25$, and 26 ) is favorable except when these oxygens are substituted by electron withdrawing groups (27, 29) or when the methylenedioxy group is replaced by a bulkier ethylenedioxy group (28). However, compound 24, which is as potent as the lead compound, retained our attention because the dimethoxyphenyl group is deleterious for the inhibition of HsPDE5. ${ }^{2}$ The most potent derivatives of the series were tested on HsPDE5 (Table 5). This experiment confirmed that introduction of dimethoxyphenyl group in place of piperonyl

| 29 |  | 11.00 | >64.00 | $>6$ |

leads to a 1000 -fold decrease on PDE5 inhibition. In all, these data also confirm that benzothiadiazol is a suitable bioisoster and that the Q2-pocket of human PDE5 does not tolerate a group larger than piperonyl. We thus synthesized a series of derivatives where the piperonyl group is replaced by a dimethoxyphenyl group in the C-6 position and compare the selectivity profile within the two series (Table 6).

We confirmed that the introduction of the dimethoxyphenyl group greatly reduces the activity on human PDE5 in all tested cases. We demonstrated that even slight differences in SAR can be exploited to remove the original undesired activity from the compound's profile. Noteworthy, the human to plasmodial cytotoxicity ratio is not correlated to the selectivity over PDE5. This suggests that another mechanism underlies the variable toxicity observed with our series on MRC5 cells. The phosphodiesterases inhibition profile has also been studied and confirms that the lead compound 24 does not inhibit significantly other phosphodiesterases (Table 7).

## CONCLUSION

Compared to classical random screening on the whole parasite, the focused "drug-to-genome-to-drug" approach proved to be a work-efficient lead discovery process. It produced a novel and promising series of antimalarial compounds. One of the inherent weaknesses of the strategy is the issue of selectivity over HsPDE5, the original target of our series of compounds. A

Table 5. HsPDE5 Inhibition of the Most Potent Antiplasmodial Compounds

detailed analysis of structure-activity relationships published on tadalafil revealed that small modifications of the piperonyl moiety can be made that preserve antiplasmodial activity while almost abolishing the activity on HsPDE5. By use of this information, the selectivity index could be systematically inverted by replacing the piperonyl substituent by a 3,4dimethoxyphenyl group. However, it needs to be further improved by increasing the antiplasmodial activity in the next round of optimization. Even if in vitro culture of the parasite in erythrocytes is known to be predictive of in vivo activity, we still need to formally prove the utility of our series in a rodent model of the disease. Characterization and optimization of ADME properties to achieve in vivo efficacy will be reported in due course.

## EXPERIMENTAL SECTION

Biology. The standard screening methodologies were adopted as have been described by Cos et al. ${ }^{13}$

In Vitro P. falciparum Culture and Drug Assay. The chloroquine-susceptible P. falciparum GHA strain was used. Parasites were cultured in human erythrocytes $\mathrm{A}+$ at $37{ }^{\circ} \mathrm{C}$ under a low oxygen atmosphere $\left(3 \% \mathrm{O}_{2}, 4 \% \mathrm{CO}_{2}\right.$, and $\left.93 \% \mathrm{~N}_{2}\right)$ in a modular incubation chamber. The culture medium was RPMI-1640, supplemented with $10 \%$ human serum. An amount of $200 \mu \mathrm{~L}$ of infected human red blood cells suspension ( $1 \%$ parasitemia, $2 \%$ hematocrit) was added to each well of the plates with test compounds and incubated for 72 h . After incubation, test plates were frozen at $-20^{\circ} \mathrm{C}$. Parasite multiplication was measured by the Malstat method. An amount of $100 \mu \mathrm{~L}$ of Malstat reagent was transferred to a new plate and mixed with $20 \mu \mathrm{~L}$ of the hemolysed parasite suspension for 15 min at room temperature. After addition of $20 \mu \mathrm{~L}$ of NBT/PES solution and 2 h of incubation in the dark, the absorbance was spectrophotometrically read at 655 nm (Biorad 3550 UV microplate reader). Percentage growth inhibition was calculated compared to the negative blanks. $\mathrm{IC}_{50}$ values are calculated from the duplicate determinations with relative difference below $25 \%$.

Cytotoxicity Test upon MRC-5 Cells. MRC-5 SV2 cells, human fetal lung fibroblast, were cultivated in MEM, supplemented with Lglutamine ( 20 mM ), 16.5 mM sodium hydrogen carbonate, and $5 \%$ FCS at $37{ }^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$. For the assay, $104 \mathrm{MRC}-5$ cells/well were seeded onto the test plates containing the prediluted compounds and

| PDE11A $_{4}(\mathrm{~h})$ | 0 |

incubated at $37^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$ for 72 h . After 72 h of incubation, parasite growth was assessed fluorimetrically by adding resazurin ${ }^{8}$ for 24 h at $37^{\circ} \mathrm{C}$. Fluorescence was measured using a GENios Tecan fluorimeter (excitation 530 nm , emission 590 nm ). $\mathrm{IC}_{50}$ values are calculated from duplicate determinations with relative difference below $25 \%$.

HsPDE5 Inhibition Assay: IC $_{50}$ Measurement. Compounds were evaluated with a time-resolved fluorescence resonance energy transfer-based assay (HTRF technology) using the cGMP quantification kit (Cisbio International, No. 62GMPPEB) and bovine cGMPspecific PDE5 (Calbiochem, No. 524715). This quantitation method relies on the competition between free cGMP and a conjugate cGMPfluorophore for the binding to a cGMP-specific antibody labeled with europium cryptate. Fixed amounts of bovine HSPDE5 ( $2 \mu \mathrm{~L}$ ) and cGMP ( 150 nM ) were incubated for 24 h at $37^{\circ} \mathrm{C}$ in the presence of varying inhibitor concentrations. Theses assays were performed in black half-area 96 -well microplates (Corning, No. 3694). Assay volume
was $36 \mu \mathrm{~L}$, and the assay buffer contained 50 mM Tris- $\mathrm{HCl}, \mathrm{pH} 7.4$, and 6 mM MgCl . At the end of the incubation, the detection reagents were added according to the manufacturer's protocol. After 1 h of incubation at room temperature in the dark, the HTRF signals were later read using a Victor3V (Wallac 1420 multilabel counter, PerkinElmer). Each inhibition assay was performed in duplicate and each well read twice. $\mathrm{IC}_{50}$ values were obtained using the curve fitting software XLfit4.2 (IDBS).

PDE Inhibition: \% Inhibition. Compounds were evaluated on human recombinant (Sf9 cells) PDE1B, PDE2A 1, PDE3A, PDE4A $A_{1 A}$, PDE7A, PDE8A ${ }_{1}$, PDE10A ${ }_{1}$, and PDE11A 4 with HTRF technology after 30 min of incubation at room temperature using a cGMP or cAMP quantification kit. ${ }^{14-19}$ Compounds were evaluated on human PDE5 isolated from platelets with scintillation counting of [ $\left.{ }^{3} \mathrm{H}\right] 5^{\prime}$ 'GMP as described by Weishaar et al. in 1986, after 60 min of incubation at room temperature. ${ }^{20}$ Compounds were evaluated on bovin PDE6 isolated from bovine retina with scintillation counting of $\left[{ }^{3} \mathrm{H}\right] 5^{\prime} \mathrm{GMP}$ as described by Ballard et al. in 1998, after 60 min of incubation at room temperature. ${ }^{21}$ The results are expressed as a percent inhibition of control specific activity ( $100-(($ measured specific activity/control specific activity) $\times 100$ ) obtained in the presence of the test compound(s) and are the mean of duplicated experiments.

Chemistry. NMR spectra were recorded on a Bruker Avance 300 or Avance 500 spectrometer. Chemical shifts are in parts per million (ppm). The assignments were made using one-dimensional (1D) ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ spectra (classical or Jmod) and two-dimensional (2D) HSQC, HMBC, ROESY, and COSY spectra. Mass spectra were recorded with a LCMS-MS triple-quadrupole system (Varian 1200ws). HPLC analyses were performed using a C18 TSK-GEL Super ODS $2 \mu \mathrm{~m}$ particle size column ( $50 \mathrm{~mm} \times 4.6 \mathrm{~mm}$ ). HPLC gradient started from $100 \% \mathrm{H}_{2} \mathrm{O} / 0.1 \%$ formic acid, reaching $20 \% \mathrm{H}_{2} \mathrm{O} / 80 \% \mathrm{CH}_{3} \mathrm{CN} / 0.08 \%$ formic acid within 10 min at a flow rate of $1 \mathrm{~mL} / \mathrm{min}$. All derivatives were isolated with purity higher than $95 \%$ (HPLC). Melting points
were determined on a Büchi B-540 apparatus and were not corrected. All commercial reagents and solvents were used without further purification. Organic layers obtained after extraction of aqueous solutions were dried over $\mathrm{MgSO}_{4}$ and filtered before evaporation in vacuo. Purification yields were not optimized. Thick layer chromatography was performed with silica gel 60 (Merck, 40-63 $\mu \mathrm{m}$ ).

The syntheses of compounds 2,3 , and 18 are described in ref 1 .
Protocol "a": Reductive Amination. The intermediate 12 (1 equiv) and the aldehyde ( 1.5 equiv) were dissolved in a mixture of dichloromethane/acetic acid, $10 / 1(0.1 \mathrm{M})$. An amount of 2 equiv of (polystyrylmethyl)trimethylammonium cyanoborohydride resin was suspended, and the reaction mixture was stirred at room temperature for $12-24 \mathrm{~h}$. The precipitate was dissolved with methanol. The resin was filtered, and the solution was evaporated to dryness. The reaction mixture was purified by chromatography (dichloromethane/methanol).
(6R,12aR)-6-Benzo[1,3]dioxol-5-yl-2-((R)-1-butylpyrrolidin-3-yl)-2,3,6,7,12,12a-hexahydropyrazino[ $\left.1^{\prime}, 2^{\prime}: 1,6\right]$ pyrido[3,4-b]-indole-1,4-dione (5). 5 was prepared according to protocol " a ", starting from intermediate $4(45 \mathrm{mg})$ and butyraldehyde ( 1.5 equiv) and obtained after purification by TLC (dichloromethane/methanol) as a white powder $(20 \mathrm{mg}, 39 \%)$. LC: $t_{\mathrm{R}}=4.6 \mathrm{~min}$. ((R)-1-Cyclohexylmethylpyrrolidin-3-yl)carbamic Acid tertButyl Ester (17a). (R)-(+)-3-(Boc-amino)pyrrolidine (300 mg), cyclohexanecarbaldehyde ( 1.1 equiv), and acetic acid ( $5 \mathrm{~mol} \%$ ) were dissolved in DCM ( 10 mL ) . $\mathrm{NaBH}_{3} \mathrm{CN}(1.1$ equiv) was added, and the reaction mixture was stirred at room temperture over a weekend. The reaction mixture was diluted with EtOAc. The product was extracted in aqueous $\mathrm{HCl}(\mathrm{pH} 1)$, then basified to pH 9 to be extracted in dichloromethane. DCM was evaporated to dryness. 17a was obtained as a clear oil ( $365 \mathrm{mg}, 80 \%$ ). LC: $t_{\mathrm{R}}=4.20 \mathrm{~min}$. MS (ESI + ): $m / z=283[\mathrm{M}+\mathrm{H}]^{+}$.
(R)-1-Cyclohexylmethylpyrrolidin-3-ylamine, Trifluoroacetate Salt (17b). 17a ( 457 mg ) was dissolved in dichloromethane $(3 \mathrm{~mL})$. Trifluoroacetic acid $(3 \mathrm{~mL})$ was added, and then the mixture was stirred for 2 h . Solvent was removed by evaporation to give 664 mg of oil (100\%). LC: $t_{\mathrm{R}}=1.75 \mathrm{~min}$. MS (ESI+): $m / z=183[\mathrm{M}+$ $\mathrm{H}]^{+}$.

Tetrazolo[1,5-a]pyridine-6-carbaldehyde (19). To a solution of 19a ( $800 \mathrm{mg}, 5.67 \mathrm{mmol}$ ) in ethanol $(25 \mathrm{~mL})$ was added $\mathrm{NaN}_{3}$ ( $738 \mathrm{mg}, 11.34 \mathrm{mmol}$ ). After the mixture was stirred at reflux overnight, the solvent was removed under reduced pressure. The product was purified by TLC (dichloromethane/methanol, 96:4) to provide 19 as a white solid ( $260 \mathrm{mg}, 31 \%$ ). LC: $t_{\mathrm{R}}=2.58 \mathrm{~min}$. MS (ESI $): m / z=149[\mathrm{M}+\mathrm{H}]^{+} .{ }^{1} \mathrm{H}$ NMR (MeOD): $\delta 9.12(\mathrm{~d}, J=1.2 \mathrm{~Hz}$, 1 H ), 8.07 (dd, $J=9.3 \mathrm{~Hz}$ and $J=0.9 \mathrm{~Hz}, 1 \mathrm{H}$ ), 7.93 (dd, $J=9.3 \mathrm{~Hz}$ and $J=1.5 \mathrm{~Hz}, 1 \mathrm{H})$.

6-Chloropyridine-3-carbaldehyde (19a). To a solution of 2-chloro-5-hydroxymethylpyridine ( $1 \mathrm{~g}, 6.96 \mathrm{mmol}$ ) in chloroform ( 70 mL ) was added manganese dioxide ( $1.8 \mathrm{~g}, 20.9 \mathrm{mmol}$ ). After being stirred at room temperature overnight, the reaction mixture was filtered on Celite and solvent evaporated under reduced pressure. 19a was isolated as a white solid $(870 \mathrm{mg}, 88 \%) . \mathrm{LC}: t_{\mathrm{R}}=3.02 \mathrm{~min}$. MS (ESI+): $m / z=142[\mathrm{M}+\mathrm{H}]^{+}$.

Protocol "c": Pictet-Spengler Reaction. D-Tryptophan$\mathrm{OMe} \cdot \mathrm{HCl}$ or L-tryptophan- $\mathrm{OMe} \cdot \mathrm{HCl}(1$ equiv) and piperonal ( 1 equiv) were dissolved in dry, dichloromethane ( 0.05 M ) containing activated molecular sieves ( $4 \AA$ Á). The solution was cooled to $0^{\circ} \mathrm{C}$. An amount of 3 equiv of trifluoroacetic acid in dichloromethane was added dropwise, and the mixture was allowed to warm to room temperature and stirred for 24 h . The reaction mixture was filtered and partially evaporated. The crude product was diluted with ethyl acetate and washed with aqueous $\mathrm{NaHCO}_{3}$ and water. The organic layer was
dried over $\mathrm{MgSO}_{4}$ and evaporated to dryness. The diastereoisomers were separated by column chromatography.

Protocol "d": Acylation. Intermediates tetrahydro- $\beta$-carboline 18 ( 1 equiv) was suspended in chloroform ( 0.2 M ) with triethylamine. The reaction mixture was cooled at $-10{ }^{\circ} \mathrm{C}$, and an amount of 2.4 equiv of chloroacetyl chloride in chloroform ( 0.5 M ) was added dropwise. The reaction mixture was stirred at $-10^{\circ} \mathrm{C}$ until completion and quenched with water. The organic layer was washed with an aqueous solution of $\mathrm{NaHCO}_{3}$ and brine, dried over $\mathrm{MgSO}_{4}$, and evaporated to dryness.
(6R,12aR)-6-Benzo[1.2.5]oxadiazol-5-yl-2-((R)-1-benzylpyr-rolidin-3-yl)-2.3.6.7.12.12a-hexahydropyrazino[1'.2':1.6]-pyrido[3.4-b]indole-1.4-dione (20). ## ACKNOWLEDGMENTS

We thank An Matheeussen and Sylvain Delaroche who performed biological experiments. We also thank Vanessa Yardley who performed the first experiment of the project. We are grateful to the institutions that support our laboratory (Inserm, Université de Lille2 and Institut Pasteur de Lille). Data management was performed using Pipeline Pilot from

Accelrys. We thank also the following institutions or companies: Waters Corp., Varian Inc., and the Laboratoire d'Application de Résonance Magnétique Nucléaire (LARMN). This project was funded by ANR (Grant No. ANR-07-PEMPB-O32-01).

## ABBREVIATIONS USED

SAR, structure-activity relationship; PDE, phosphodiesterase; EtOH , ethanol; MeOH , methanol; AcOH , acetic acid; $\mathrm{IC}_{50}$, concentration inhibiting $50 \% ; \mathrm{CC}_{50}$ cytotoxic concentration $50 \%$; DMF, dimethylformamide; DCM, dichloromethane; TLC, thick layer chromatography; EtOAc, ethyl acetate; Boc, tert-butyloxycarbonyl; NC, not calculated; TFA, trifluoroacetic acid; DMSO, dimethylsulfoxide; LC, liquid chromatography; $t_{\mathrm{R}}$, retention time; MS, mass spectrometry; ESI, electrospray ionization; Mp , melting point
