#### Abstract

The definition, in a previous paper, of a new type of carbon atom (type 44) in the MM2 force field, i.e. when it is cross-conjugated, implies the reparameterisation of the bonds adjacent to the carbonyl bond. By means of a statistical study based on data issued from the Cambridge Structural Data System, we propose here new $\sigma$ dipole moments and new stretching parameters for the $\mathrm{C}(44)-\mathrm{O}(41)$ and $\mathrm{C}(44)-\mathrm{N}(40)$ bonds included in heterocyclic compounds. These stretching parameters, which are $\pi$-bond-order dependent, are quite satisfactory (mean of unsigned deviations: $0.023 \AA$ ) within limited $\pi$-bond-order ranges: 0.25 to 0.32 for the C - O bond, 0.37 to 0.53 , for the $\mathrm{C}-\mathrm{N}$ bond. As for the $\mathrm{C}(44)=\mathrm{O}(7)$ bond the parameters are generally inappropriate for compounds in which both atoms connected to the type 44 carbon are heteroatoms. The maximum deviation from the experimental bond length, for both bond types can reach $\pm 0.03 \AA$. Here also, part of the dispersion of the results could be attributed to the variation of the effective dielectric constant D from one crystal to another.

## Introduction

The intracyclic oxygen atom of $\alpha$-pyrones or, more generally, of conjugated lactones is part of the delocalised $\pi$ system. In MM2 nomenclature its type is 41. It participates in the $\pi$ system by 2 electrons and is explicitly attributed a lone pair (type 20). In conjugated «lactams» the N atom is in a similar situation with 2 electrons also engaged in the $\pi$

Correspondence to: J. Devillers
system (atom type 40). In both cases the C(3)-O(41) or C(3)$\mathrm{N}(40)$ bonds adjacent to the carbonyl are not parameterised in the classical MM2 force field (Fig. 1).

Similarly, when the carbonyl is cross-conjugated deserving a special carbon type (type number: 44), parameters concerning the $\mathrm{C}(44)-\mathrm{O}(41)$ and $\mathrm{C}(44)-\mathrm{N}(40)$ bonds are missing [1].

In the present paper we propose, in conjunction with the parameterisation of the $\mathrm{C}(44)=\mathrm{O}(7)$ bond, parameters for these adjacent bonds with emphasis on stretching parameters. Molecules cited in this paper are listed in Table 1.

Figure 1 Type numbers of the atoms involved in the $\pi$ system of conjugated lactones and lactams

## Parameterisation of the $\mathbf{C ( 4 4 ) - 0 ( 4 1 ) ~ b o n d ~ a d j a c e n t ~ t o ~ a ~}$ cross-conjugated carbonyl

The $\sigma$ dipole moment of the $\mathrm{C}(44)-\mathrm{O}(41)$ bond being reevaluated [1] and non- $\pi$-dependent parameters evaluated from already existing parameters in similar bonds, our effort was first applied to stretching parameters. Geometries of the molecules were found in the C.S.D.S. [2] in a similar way as in the preceding paper [1].

## First estimation of $\mathbf{I}_{\mathbf{2}}, \mathbf{k}_{\mathbf{2}}$, TSLOPE and SSLOPE

The first estimation of the stretching parameters was performed in the usual way $[1,3]$. The reference molecules were restricted here to $\alpha$-pyrones ( 6 -membered rings) and conjugated $\delta$ lactones ( 5 -membered rings). Coumarin was added, thus giving 52 molecules containing $56 \mathrm{C}(44)-\mathrm{O}(41)$ bonds (compounds $\mathbf{1}$ to $\mathbf{5 2}$ ). The plot of $1_{\text {exp }}$ versus $P_{\text {exp }}$ is reported in Fig 2. The equation of the corresponding best fit straight line is:
$l_{\text {exp }}=1.685-0.977 \times P_{\text {exp }}$
with $r=-0.85386$

Figure 2 Plot of $l_{\text {exp }}$ versus $P_{\text {exp }}$ for the adjacent $C(44)-O(41)$ bond in $\alpha$-pyrones and $\delta$-lactones

Its slope is steep and, around it, the dispersion of the dots rather high $( \pm 0.02 \AA)$. For the variation of the force constant with the $\pi$ bond order, Badger's rule was used together with Allinger's parameters for atoms of the same period [4]:
$k_{\text {exp }} \times\left(l_{\text {exp }}-0.73\right)^{3}=1.865$

Combination of equations (1) and (2) leads to a theoretical expression of $\mathrm{k}_{\text {exp }}$ :
$k_{\text {exp }}^{\text {theor }}=f\left(P_{\exp }\right)$
whose graph is reported in Fig 3 together with the dots corresponding to the couples ( $\mathrm{k}_{\text {exp }}, \mathrm{P}_{\text {exp }}$ ) directly calculated from equation (2). Within the narrow domain of $\mathrm{P}_{\text {exp }}$, a linear appproximation is justified and the equation of the best fit straight line is:
$k_{\text {exp }}=-2.02+28.32 \times P_{\exp }$

## $\mathrm{r}=0.85127$

For the first estimations of the stretching parameters see Table 2.

## Refinement of the stretching parameters for the C(44)-0(41) bond

For the refinement of the estimated parameters, the usual strategy was used [1] but some modifications had to be made. The present bond is part of a ring (as is the $\mathrm{C}(44)-\mathrm{N}(40)$ bond), so, its calculated length is dependent on its own parameters but also on the accuracy of the parameters related to the other parts of the ring. In the process of refinement, during the optimisation step, if we let the heavy atoms move, there would be a risk of over-correction of the $\mathrm{C}(44)-\mathrm{O}(41)$ bond parameters to improve the geometry in other regions of the ring. In other terms, all the parameters involved in the ring are interdependent.

Several attempts were made using the rough values reported above and different types of constraint in the geometry optimisation phases. Most of them failed (poor values of $\alpha, \beta, \mathrm{r}$ and $\delta$ ), but it was possible to draw some lessons from them:

- necessity to look for a value of $1_{2}$ far from the first estimation
- necessity to modify $\mathrm{k}_{2}$ and SSLOPE in relation to the evolution of $1_{2}$
- necessity to modify the bending parameters around the $\mathrm{O}(41)$ atom in conjunction with the refinement of the stretching parameters
- abandon of Badger's rule
- necessity to introduce some geometric constraints during the optimisation phase.

Around the intracyclic $\mathrm{O}(41)$ atom, there are 3 bonds: $\mathrm{C}(44)-\mathrm{O}(41), \mathrm{O}(41)-\mathrm{C}(2)$ and $\mathrm{O}(41)-\mathrm{Lp}(20)$. In MM2, the only way to fix some geometrical parameters (dihedral angles excluded) is to fix the cartesian coordinates of certain atoms. So, it was chosen to freeze, in their crystalline positions, all the heavy atoms but the $\mathrm{O}(41)$ and its lone pair. Thus, three bond lengths and seven bond angles are free to change in the course of optimisation (Fig 4).

Concerning the dihedral angles, care was taken to fix the $\mathrm{O}(7)=\mathrm{C}(44)-\mathrm{O}(41)-\mathrm{C}(2)$ angle at its value in the crystal to prevent the relaxation of the molecule by an out-of-plane movement of $\mathrm{O}(41)$. In this context, the parameters to be refined will be dependent on the stretching parameters of the $\mathrm{O}(41)-\mathrm{C}(2)$ and $\mathrm{O}(41)-\mathrm{Lp}(20)$ bonds (which are known and

Table 4 Values adopted for the torsional parameters involving the C(44) atom along the optimisation process in the determination of the stretching parameters of the C(44)-O(41) bond
resident in the program) and also on the bending parameters which were known or were adopted by analogy, at least at the beginning of the refinement. They are presented in Tables 3 and 4 .

For a preliminary estimation of $\mathrm{k}_{2}\left(\mathrm{k}_{2}=\mathrm{k}_{1}+\right.$ SSLOPE $)$, Badger's rule was rejected and a simulation adapted to force constants performed in the following way. On the whole set of reference molecules, for $1_{2}=0.708$ and TSLOPE $=0.977$ (see above) a series of optimisations was run, with geometries partialy fixed and progressively changing values of $\mathrm{k}_{2}$. Simultaneously, for each value of $k_{2}$, for the whole set of molecules, the sum of the $\left(l_{\text {cal }}-l_{\text {exp }}\right)$ deviations was calculated. Figure 5 represents this sum versus $\mathrm{k}_{2}$. A minimum was found for $k_{2}=19.31 \mathrm{md} . \AA^{-1}$. This was the best starting value, i.e. for starting values of $1_{2}$ and TSLOPE. Any further modification of these last two parameters would, of course,
imply a reestimation of $k_{2}$ and so on. We proceeded in the same way to improve the bending parameters whose first values are collected in Table 3.

At that point, in order to extend the bond length domain, molecules containing a shorter C-O bond adjacent to a crossconjugated carbonyl were looked for. Three vinyl esters were introduced (compounds 53 to 55) containing altogether six $\mathrm{C}-\mathrm{O}$ bonds.

By a process similar that described in a previous paper [1], for the last values of $k_{2}$ and SSLOPE, the best parameters (i.e. the parameters which satisfy the $\alpha, \beta$, r and $\delta$ criteria) were found to be:

$$
1_{2}=0.350 \AA \quad \text { TSLOPE }=1.474 \AA
$$

Figure 6 illustrates this. An attempt to reevaluate $\mathrm{k}_{2}$ to put it in accordance with these new values of $1_{2}$ and TSLOPE showed that $\mathrm{k}_{2}=19.81 \mathrm{md} . \AA^{-1}$ was still suitable (see Fig 7).

Figure 4 [a] Frozen and free atoms in the optimisation process. [b] Angles which consequently are allowed to distort in the optimisation process

(a)

(b)

To test these values of the stretching parameters and possibly improve them once again, 20 molecules were selected whose geometries were fully optimised. It appeared from the results that the main discrepancies involved the bending parameters which, because of the cyclic character of the molecules, entail some errors in the bond lengths.

The "natural" angles involving a carbon atom of type 44 were thus improved. To do so, molecules containing the $\alpha$-pyrone ring or analogues were selected from the C.S.D.S. and, from 558 observations, slightly different new bending parameters were adopted (see Table 5). With these new bending parameters, two approaches were followed:

- The 20 test molecules were optimised using the new bending parameters and the former stretching parameters.
- Using the new bending parameters, an attempt was made to improve the stretching parameters once again.

The second option led to a new set of parameters which, tested on the 20 test molecules, did not improve the results. The first option, on the contrary, showed a systematic error on the $\mathrm{C}(44)-\mathrm{O}(41)$ natural bond length and so $1_{2}$ was increased by $0.012 \AA$ which subtantially improved the results. Finaly, we propose for this bond, the following stretching parameters (see table 6) and for the bending parameters, those gathered in Table 5.

Table 5 New bending parameters (involving the C type 44) proposed for the $\alpha$-pyrone moiety and analogues

Tables 7 and 8 show the final results obtained on the 20 test molecules (among which 12 were reference molecules and 8 extra molecules) for the part of the molecule we are concerned with (see Fig 8). As can be seen, the results are globally satisfactory. The unsigned mean deviation on the $\mathrm{C}(44)-\mathrm{C}(2)$ bond length is rather large and possibly shows that the stretching parameters of the $\mathrm{C}(3)-\mathrm{C}(2)$ bond are not directly transferable to the $\mathrm{C}(44)-\mathrm{C}(2)$ bond.

## Parameterisation of the $\mathrm{C}(44)-\mathrm{N}(40)$ bond adjacent to a cross-conjugated carbonyl

## $\sigma$ bond dipole moment

The $\sigma$ bond dipole moment had, here also, to be estimated for two reasons. The only dipole moment known for a $\mathrm{C}(\mathrm{O})-$ N bond in the MM2 (91) force field is that for amides in which the separation $\mu_{\sigma} / \mu_{\pi}$ is not done (type 9 N atom) and

## (a)Mean of unsigned deviations

so the N atom is not included in the $\pi$ calculation. The second reason is that we have suggested a correction of the $\pi$ bond dipole moment which has consequential effects on the $\sigma$ bond dipole moment. Phthalimide (63) was chosen as model molecule,

for its symetry and the availability of its experimental molecular dipole moment. Four values were found in the literature: 2.12D [5], 2.14D [6], 2.91D [7] and 2.17D [8]. The 2.91 value was rejected because the determination was suspected of having been performed on an impure compound
[8] and thus the mean value ( 2.14 D ) was adopted. A calculation by MM2, based on the crystalline geometry, gave the $\pi$ atomic charges and permitted the calculation of the $\pi$ bond dipole moments and, from the geometry, a vectorial combination led to the molecular $\pi$ dipole moment:

$$
\begin{equation*}
\mu_{\pi}^{\text {total }}=3.17 \mathrm{D} \tag{5}
\end{equation*}
$$

which is known to be overestimated and must be corrected by a factor which we have suggested to be 0.46 [3]:
$\mu_{\pi . c o r}^{\text {total }}=0.46 \times 3.17=1.46 \mathrm{D}$
It follows that:
$\mu_{\sigma . c o r}^{\text {total }}=\mu_{\exp }-\mu_{\pi . c o r}^{\text {total }}=2.14-1.46=0.68 \mathrm{D}$
In accordance with the MM2 philosophy, the $\mathrm{C}(2)-\mathrm{C}(2)$ and $\mathrm{C}(2)-\mathrm{H}(5)$ bonds were attributed a nul bond dipole moment. It thus results that the $\mu_{\sigma . c o r}^{\text {total }}$ is the vectorial sum of the $\mathrm{C}=\mathrm{O}, \mathrm{N}-\mathrm{C}$ and $\mathrm{N}-\mathrm{H} \sigma$ dipole moments. If we keep Allinger's

value for the $\mathrm{N}-\mathrm{H}$ bond moment and assume that the H atom is correctly located in the X-ray structure, from the value of the $\mathrm{C}(44)=\mathrm{O}(7) \sigma$ bond moment already reported (2.10D [1]) and by simple geometrical considerations we find that:
$\mu_{\sigma}^{44-40}=-0.282 \mathrm{D}$
The experimental molecular dipole moments as well as the X-ray structures are also known for three more symetrical
imides: N-Phenyl-phthalimide (64), (2,4,6-trimethylphenyl)phthalimide (65) and Naphtaloimide (66). They were thus used to test the value of this $\sigma$ bond moment as well as other values close to it. (see Table 9).

In the Phthalimide (63) and Naphthaloimide (66) X-ray structures, the H atom is poorly located which can somewhat perturb the N atom location. So we assumed that the value of -0.31 , for which the deviations are lower for the two first molecules, was a better estimation.

Figure 8 Definitions of the angles and bond lengths reported in tables 6, 7, 11 and 12

## First estimation of $\mathbf{I}_{\mathbf{2}}, \mathbf{k}_{\mathbf{2}}$, TSLOPE and SSLOPE stretching parameters

In a first step, we selected in the C.S.D.S., five or six-membered rings for which the exo-bonds on the nitrogen atom were either $\mathrm{N}-\mathrm{H}, \mathrm{N}-\mathrm{C}, \mathrm{N}-\mathrm{N}$ or $\mathrm{N}-\mathrm{OH}$. Examination, for 73 values, of the correlation led to:
$l_{\text {exp }}=1.61-0.525 \times P_{\text {exp }}$
with a poor correlation factor: $\mathrm{r}=-0.7$.
A closer look to the dispersion of the dots led to the rejection of all but one (72) of the N-H compounds. The main reason being the disturbance of the geometries by intermolecular H -bonding in the crystals. We also rejected the $\mathrm{N}-\mathrm{N}$ and $\mathrm{N}-\mathrm{OH}$ derivatives. After rejection, for $28 \mathrm{C}(44)-\mathrm{N}(40)$ bonds ( 25 molecules) the correlation function was:
$l_{\text {exp }}=1.608-0.487 \times P_{\text {exp }}$
with $\mathrm{r}=0.83$ (see Fig 9).
For a first estimation of the variation of the force constant with the $\pi$ bond order, here also, Badger's rule was used together with Allinger's parameters (see eq(2)). Figure 10 presents the graph of the function obtained by the combination of eq 2 and 10 as well as the dots directly issued from eq 2. The best fit straight line which results is:
$k_{2}=-0.28+15.2 \times P_{\exp }$
with $\mathrm{k}_{1}=-0.28$ and SSLOPE $=15.2 \mathrm{md} . \AA^{-1}$
These first estimations are consistent with the values given by Allinger for the $\mathrm{C}(3)-\mathrm{N}(9)$ bond in amides. For the $\mathrm{l}_{0}$ value (MM2(91): $1.385 \AA$ ), eq(10) gives an estimation of « $\mathrm{P}_{\text {exp }}$ " (0.45) which, through eq(11), leads to $\mathrm{k}_{2}=6.69 \mathrm{md} . \mathrm{A}^{-1}$ (MM2(91) value: 6.40).

Figure 9 Plot of $l_{\text {exp }}$ versus $P_{\text {exp }}$ for the adjacent $C(44)-N(40)$ bond in conjugated lactams

## Refinement of the stretching parameters for the C(44)-N(40) bond

Determination of $1_{2}$, TSLOPE and $\mathrm{k}_{2}$, SSLOPE from the first "statistical estimation" was performed in the same way as for the adjacent $\mathrm{C}(44)-\mathrm{O}(41)$ bond (see above) using the programs previously constructed [1].

Simulations were run while fixing the positions of all the heavy atoms (but the N atom) as well as the $\mathrm{O}(7)=\mathrm{C}(44)$ -$\mathrm{N}(40)-\mathrm{C}(2)$ dihedral angle. First, for the above values of $\mathrm{k}_{2}$ and SSLOPE, successive grid searches led to:
$l_{2}=l_{1}-T S L O P E=0.980 \AA$
with TSLOPE $=0.718 \AA$ and satisfy the criteria:
$l_{\text {cal }}=\alpha \times l_{\text {exp }}+\beta$
with $\alpha=1.00222 \quad \mathrm{r}=0.78$
$\beta=0.00242 \quad \delta=0.368$ (for 28 bonds)
Then, with these values and considering a SSLOPE value of $15.2, \mathrm{k}_{2}$ was optimised by trial and error to lower $\delta$. In this way a better estimation of $\mathrm{k}_{2}$ (16.9) was reached. Critical examination of the results nevertheless showed that a rather large dispersion mainly resulted from the fact that, in numer-

Table 10 Bending parameters involving the nitrogen atom (type 40) in conjugated «lactams». Parameters involving the cross-conjugated C atom (type 44) are revised parameters

| Topology | Atom type | $\mathbf{k}_{\mathbf{2}}\left(\mathbf{m d y n} \cdot \AA \cdot \mathbf{r a d}^{-\mathbf{2}}\right)$ | $\Theta_{\mathrm{ijk}}\left({ }^{\circ}\right)$ |
| :--- | :---: | :---: | :---: |
| O-C-N | $7-44-40$ | 0.67 | 120.0 |
| C-O-C | $44-40-2$ | 0.60 | 126.0 |
| C-C-N | $2-44-40$ | 0.45 | 115.0 |
| C-N-C | $44-40-1$ | 0.76 | 117.0 |
| N-C-C | $40-2-2$ | $(M M 2(91))$ |  |
|  | $40-2-1$ | 0.42 | 119.0 |
| C-N-H | $44-40-23$ | values of $(M M 2(91))$ for C(3)-N(9)-H(28) |  |
|  |  | 0.2 | out of plane |
| P-N-C | $0-40-44$ | 0.8 |  |
| P-C-N | $0-44-40$ |  |  |

ous molecules, the N atom was at the hinge of fused rings, thus being itself cross-conjugated. So, in accordance with our philosophy, it deserves a special type number. After rejecting molecules of that type, the remaining eleven led to $\mathrm{k}_{2}$ $=16.3 \mathrm{md} . \AA^{-1}$. With this value, a better correlation was obtained with:

$$
\begin{array}{ll}
1_{2}=1.002 \AA & \text { TSLOPE }=0.688 \AA \\
\alpha=1.00407 & \mathrm{r}=0.953 \\
\beta=0.00252 & \delta=0.1143
\end{array}
$$

Finaly, alternating refinements of $\left(1_{2}\right.$, TSLOPE) and ( $\mathrm{k}_{2}$, SSLOPE) led to:

$$
\begin{array}{ll}
1_{2}=1.002 \AA & \text { TSLOPE }=0.685 \AA \\
\mathrm{k}_{2}=20.5 \mathrm{md} . \AA^{-1} & \text { SSLOPE }=15.2 \mathrm{md} . \AA^{-1}
\end{array}
$$

As for the parameterisation of the $\mathrm{C}(44)-\mathrm{O}(41)$ bond, it was then necessary to improve the bending parameters for the angles containing both the $\mathrm{C}(44)$ and $\mathrm{N}(40)$ atoms. That is to say: $\mathrm{O}(7)-\mathrm{C}(44)-\mathrm{N}(40)$ called $\alpha, \mathrm{C}(2)-\mathrm{C}(44)-\mathrm{N}(40)(\beta)$, $\mathrm{C}(2)-\mathrm{N}(40)-\mathrm{C}(44)(\delta)$ and $\mathrm{C}(1)-\mathrm{N}(40)-\mathrm{C}(44)(\phi)$ angles. The $\mathrm{C}(2)-\mathrm{C}(44)-\mathrm{O}(7)(\gamma)$ and $\mathrm{C}(2)-\mathrm{C}(2)-\mathrm{C}(44)(\varepsilon)$ angles were examined previously(see above).

Because the adjustment of these angles was not severe, the bending force constants were assumed to be identical to those found in MM2(91) replacing C(44) by C(3). Only the "natural" angles were slightly modified to minimise the sum of the unsigned deviations. The $\theta^{\circ}{ }_{i \mathrm{ijk}}$ angles found (giving a mean of unsigned deviations of $0^{\circ} 73$ ) are reported in Table 10. The finaly proposed stretching parameters are given in Table 11 . As it can be see, the agreement of $1_{\text {cal }}$ with $l_{\text {exp }}$ is satisfactory.

Tables 12 and 13 show the final results obtained after complete optimisation of 28 test-molecules. The first 10 were already used as reference molecules, i.e. to set up the param-
eters. Among them 72 is an exception for it contains an $\mathrm{N}-\mathrm{H}$ bond (see above).

The following 11 are extra molecules containing either a nitrogen atom at the hinge of fused rings (one of which can be unconjugated) or an N-Ph exo-bond (81). For these molecules there is a possibility of cross-conjugation of the N atom itself, in which case it should be attributed a special atom type and special parameters. Compound 86 is mentioned here because it is also an exception in that it contains several C atoms which could be cross-conjugated. The last 7 are molecules containing an exo $\mathrm{N}-\mathrm{H}(40-23)$ bond which give rise to cyclic dimers by hydrogen bonding. The last two categories were excluded from the determination of the parameters but it was interesting to see to what extent they could be suitable in these special cases.

The global mean of unsigned deviations for the $\mathrm{C}(44)$ $\mathrm{N}(40)$ bond length $(0.0222 \AA)$ is comparable to the global mean for the $\mathrm{N}(40)-\mathrm{C}(2)$ bond length $(0.0227 \AA)$ for which we used the MM2(91) resident parameters and compares favourably with that obtained for the similarly adjacent $\mathrm{C}(44)-\mathrm{O}(41)$ bond ( $0.0246 \AA$ ).

The results concerning fused ring moieties are not as good. When both rings are conjugated, the poor results were expected for the reasons already presented, but when only one ring is conjugated the reasons for the discrepancy are unclear.

Results for the N-H compounds, on the other hand, are very good although they were not included in the statistical study ( 72 is the sole exception). The discrepancies on the $\mathrm{C}(44)-\mathrm{C}(2)$ adjacent bond confirm - as was suspected - that the $\mathrm{C}(3)-\mathrm{C}(2)$ parameters are not transferable when the C atom is cross-conjugated. The means of unsigned deviations

[b] For the definitions of bond angles, please see Fig 8
[c] The angles marked with an asterisk correspond to the definition of Fig 8, but the C atom is type 1 not type 2
[d] $\gamma$ angle opposite to the $N$ atom. $\varepsilon$ angle in the "lactam" ring
[e] $\gamma$ angle opposite to the $O$ atom. $\varepsilon$ angle in the "lactone" ring
[f] In this compound the exo $\mathrm{N}-\mathrm{C}$ bond is replaced by an $\mathrm{N}-\mathrm{H}$ bond
[g] Mean of unsigned deviations
[h] The global mean is the sum of the means for the 3 categories of compounds divided by 3. $\phi$ is an exception)
on the angles of interest are globally satisfying. They are only especially large for the $\alpha$ and $\gamma$ angles of the $\mathrm{N}-\mathrm{H}$ compounds. Here, the deviations are correlated (same order of magnitude but opposite signs) and concern the orientation of the $\mathrm{C}(44)=\mathrm{O}(7)$ bond with regards to the ring. One could suspect the formation of cyclic dimers in the crystals to alter these angles but the similar behaviour of $\mathbf{7 3}$ suggests that this could be the consequence of an inappropriate transfer of the bending parameters of the $\mathrm{C}(3)-\mathrm{N}(9)-\mathrm{H}(28)$ moiety to the $\mathrm{C}(44)-\mathrm{N}(40)-\mathrm{H}(23)$. The usually poor localisation of the H atoms by X-rays prevented us from trying to improve these parameters.

## Conclusion

The definition, in a previous paper, of a new type of carbonyl C atom (type 44) in the MM2 force field, i.e. when it is crossconjugated has led us, after reparameterisation of the $\mathrm{C}=\mathrm{O}$ bond itself, to the parameterisation of adjacent heterocycle bonds. By means of a statistical study based on data from the C.S.D.S., we propose here some new stretching parameters and $\sigma$ dipole moments for the $\mathrm{C}(44)-\mathrm{O}(41)$ and $\mathrm{C}(44)-\mathrm{N}(40)$ bonds. These parameters are $\pi$-bond-order dependent and are globally satisfactory within limited $\pi$ bond order ranges: 0.25 to 0.32 for the C-O bond, 0.37 to 0.53 for the C-N bond.
They were set up assuming that the other adjacent bond type was 44-2. It was also assumed that the $C(3)-C(2)$ parameters were transferable to it. This has two consequences.

First, the proposed parameters are satisfactory for conjugated «lactones» and «lactams» but would not be suited to, for instance, organic carbonates, ureas, etc.

Second, as the present study has shown large deviations concerning the $\mathrm{C}(44)-\mathrm{C}(2)$ bond length, an effective parameterisation of that bond has proved to be necessary and is currently being undertaken. This could be responsible for part of the deviations observed on bond lengths (maximum $0.03 \AA$ ). Another part could be due to, as mentioned earlier, the sensitivity of the length of polar bonds to the variation of the effective dielectric constant D from one crystal to another.

The remark concerning the difference between $\mathrm{r}_{\mathrm{g}}$ and $\mathrm{r}_{\alpha}$ made in the previous paper [1] is, of course, still valid. Earlier works published on lactams and lactones presenting some conjugation are listed in the previous paper (ref 15 to 18 of [1]). In the MM2 calculations of conjugated amides Berg and Bladh [9] have a philosophy which differs from ours. The type of the carbonyl C atom remains 3 . The N atom however is included in the $\pi$ calculation (type $9^{*}$ ).

Aknowledgments The authors would like to thank Professor N.L. Allinger and his co-workers for allowing the Q.C.P.E. to communicate the source codes of MM2 and MM3, to the scientific community. These authors are, of course, not responsible for any «bugs» or errors due to the modifications introduced in their programs.

Help of Mrs Anne Altibelli and Mr Jacques Aussoleil in software handling is also gratefuly acknowledged.

In the present paper, the section concerning the $\mathrm{C}(44)$ $\mathrm{O}(41)$ bond is part of Dr J-Ph Rameau's thesis [10].
