#### Abstract

The conformational behavior of 1-halovinyl azides $\mathrm{CH}_{2}=\mathrm{CX}-\mathrm{NNN}(\mathrm{X}=\mathrm{F}, \mathrm{Cl}$ and Br ) were investigated by DFT-B3LYP and ab initio MP2 calculations with the $6-311++\mathrm{G}^{* *}$ basis set. The molecules were predicted to exist predominantly in the trans (the vinyl $\mathrm{CH}_{2}=\mathrm{CH}-$ and the azide -NNN groups are trans to each other) conformation. The relative energy between cis and trans were calculated to decrease in order: bromide>chloride>fluoride. Full optimization was performed at the ground and transition states in the molecule at both MP2 and B3LYP levels. The barrier to internal rotation around the $\mathrm{C}-\mathrm{N}$ single bond in the three molecules was calculated to be about $4-5 \mathrm{kcal} \mathrm{mol}^{-1}$. The vibrational frequencies were computed at the DFT-B3LYP level and the calculated infrared and Raman spectra of the cis-trans mixture of the three molecules were plotted. Complete vibrational assignments were made on the basis of normal coordinate calculations for both stable conformers of the three molecules.

Keywords Ab initio calculations • Structural stability . Vibrational spectra and assignments • Rotational barrier . 1-Fluorovinyl azide $\cdot$ 1-Chlorovinyl azide $\cdot$ 1-Bromovinyl azide

## Introduction

Recently the structural and conformational stability of some vinyl compounds of the general formula $\mathrm{CH}_{2}=\mathrm{CH}-$ $\mathrm{M}=\mathrm{X}=\mathrm{Y}(-\mathrm{MXY}$ is $-\mathrm{NCO},-\mathrm{NNN},-\mathrm{CHCO}$ or -NHCN$)$ were investigated by DFT-B3LYP calculations [1, 2, 3, 4]. When -MXY was isocyanate -NCO and ketene -CHCO, [1] azide -NNN [2] and cyanamide -NHCN, [3] all the molecules were predicted to exist in the planar

[^0]cis $\Leftrightarrow$ trans conformational equilibrium with the nonplanar gauche conformations being transition states.

The stability of the molecules only in the planar structure was explained as a result of pronounced conjugation effects. Furthermore, the size of the rotational barrier in these molecules was found to be significantly dependent on the type of the substituent. In vinyl ketene $\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{CHCO}$ [1] and vinyl cyanamide $\mathrm{CH}_{2}=\mathrm{CH}-$ NHCN [3] the rotational barrier was calculated to be about $7 \mathrm{kcal} \mathrm{mol}^{-1}$, while that in the corresponding isocyanate $\mathrm{CH}_{2}=\mathrm{CH}-\mathrm{NCO}$ is about $2 \mathrm{kcal} \mathrm{mol}{ }^{-1}$. For vinyl azide, [2] the cis and the trans conformers were predicted to have comparable relative stabilities with a rotational barrier of the order of $5 \mathrm{kcal} \mathrm{mol}^{-1}$. [2] However, an earlier microwave study of vinyl azide showed that the cis conformation is slightly more stable than the trans. [4]

In the present study, we investigated the effect of halogen substitution ( $\mathrm{F}, \mathrm{Cl}$ and Br ) on the conformational stability of vinyl azide. The energies of the three halogenated vinyl azide molecules in their possible structures were optimized at the DFT-B3LYP/6$311++\mathrm{G}^{* *}$ level and the structural parameters optimized at both MP2 and B3LYP levels. The vibrational frequencies were computed and the zero-point corrections were included in the calculation of the energies of ground and transition states. Also, normal coordinate analyses were carried out and the potential energy distributions (PED) among symmetry coordinates for the stable conformers of the molecule were calculated. The vibrational assignments of the normal modes were made based on the calculated PED values and the results are presented here.

## Ab initio calculations

The Gaussian 98 program, [5] running on an IBM RS/ 6000 43P model 260 workstation, was used to carry out the DFT-B3LYP calculations. The $6-311++\mathrm{G}^{* *}$ basis set was employed to optimize the structures and predict the energies and dipole moments of halovinyl azides 1-$\mathrm{CH}_{2}=\mathrm{CX}-\mathrm{NNN}$ (where $\mathrm{X}=\mathrm{F}, \mathrm{Cl}$ and Br ) in their stable

Fig. 1 Atom numbering for 1-halovinyl azides ( $\mathrm{X}=\mathrm{F}, \mathrm{Cl}$ and Br ) in the trans conformations
conformations (Fig. 1). The optimized energies and structural parameters of the three molecules in the two conformations are shown in Tables 1, 2 and 3.

Asymmetric torsional potential function

${ }^{\mathrm{a}} E_{0}$ is $-341.518307,-701.869865,-2815.789673$ hartrees for the fluoride, chloride and bromide, respectively
allowing the CCNN dihedral angle $(\varphi)$ in the three molecules to vary from $0^{\circ}$ (cis position) to $180^{\circ}$ (trans position). Full geometry optimizations at each of the fixed dihedral angles $(\varphi)$ of $15^{\circ}, 30^{\circ}, 45^{\circ}, 60^{\circ}, 75^{\circ}, 90^{\circ}, 105^{\circ}$, $120^{\circ}, 135^{\circ}, 150^{\circ}$, and $165^{\circ}$ were carried out for the three molecules. The computed relative energies and barriers to interconversion at the MP2/6-311++G** and the DFT-B3LYP/6-311++G** levels of calculations are listed in Tables 3 and 4. Also, the zero-point corrections, the corrected relative energies and the corrected energy barriers in this series of molecules were computed at the DFT-B3LYP/6-311++G** level and are shown in

Table 3. The torsional potential was represented as a Fourier cosine series in the dihedral angle ( $\varphi$ ):
$E(\varphi)=E_{0}+V_{0}+\sum_{n=1}^{n=6}\left(V_{n} / 2\right)[1-\cos (n \varphi)]$
where the potential coefficients from $V_{1}$ to $V_{6}$ are considered adequate to describe the potential function. The results of the energy optimizations at the B3LYP level were used to calculate the six coefficients by leastsquares fitting for the three systems (Table 4). The potential functions of 1 -halovinyl azides are shown in Fig. 2.

Fig. 2 Potential surface scan for the asymmetric torsion in 1fluorovinyl azide (solid line), 1-chlorovinyl azide (dashed line) and 1-bromovinyl azide (dotted line)

Vibrational frequencies and normal coordinate analyses
The optimized structural parameters of the three molecules were used to compute the vibrational frequencies at the DFT-B3LYP/6-311++G** level of calculation. 1Halovinyl azides in their planar cis and trans conformations have $\mathrm{C}_{\mathrm{s}}$ symmetry. In 1-halovinylazides, the 18 vibrational modes span the irreducible representations: 13 A' and 5 A'. The A' modes should be polarized whereas the A" modes should be depolarized in the Raman spectra of the liquid.

Normal coordinate analyses were carried out for the stable cis and trans conformers of the molecules to provide a complete assignment of the fundamental vibrational frequencies. A computer program was written for this purpose by following Wilson's method. [6] The Cartesian coordinates for the stable conformers together with the normal modes (in Cartesian coordinates) and the frequencies from Gaussian 98 output were used as an input in the program. A complete set of internal coordinates (Table 5) was used to form symmetry coordinates (Table 6) in the molecular systems. The potential energy distribution (PED) for each normal mode among the symmetry coordinates was calculated and is given in Tables $7,8,9,10,11,12$.

A complete vibrational assignment of the fundamentals was proposed. The assignments were made based on calculated PED, infrared band intensities, Raman line

activities, depolarization ratios and comparison with experimental values for similar molecules. The data of the vibrational assignments are listed in Tables 7, 8, 9, 10, $11,12$.

The vibrational infrared and Raman spectra were calculated using the computational method described previously. [7, 8] To calculate the Raman spectra, the frequencies $v_{j}$, the scattering activities $S_{j}$, and the depolarization ratios $\rho_{j}$ were obtained from the DFTB3LYP/ 6-311++G** calculations. The calculated vibrational infrared and Raman spectra of the 1-fluorovinyl

## Discussion

The high reactivity and importance of organoazides in synthetic chemistry and their applications in many important industries $[9,10,11,12,13,14,15,16,17$,
$18,19,20,21,22,23,24]$ attracted our attention to investigate the structure and conformational behavior of vinyl azide in an earlier study [2] and 1-halovinyl azides $\mathrm{CH}_{2}=\mathrm{CX}-\mathrm{NNN}$ (where X is fluoro, chloro and bromo) by DFT-B3LYP and ab initio MP2 calculations in the present work.

From full energy optimization, the trans conformer was predicted to be the predominant form of the three molecules. Additionally, the relative energy between cis and trans were calculated at the DFT-B3LYP level to decrease in the order: bromide $>$ chloride $>$ fluoride ( $2.17 \mathrm{kcal} \mathrm{mol}^{-1}, 1.82 \mathrm{kcal} \mathrm{mol}^{-1}$ and $1.03 \mathrm{kcal} \mathrm{mol}^{-1}$ ), respectively. The increase in the steric hindrance with the increase in the size of the halogen atom significantly destabilized the trans conformation on going from the fluoride, the chloride to the bromide (Fig. 2). This conclusion is supported by the significant change in several structural parameters and the total dipole moment with the change in conformation as going from cis to trans forms of the molecules (Tables 1 and 2).

The vibrational wavenumbers of 1-fluoro-, 1-chloroand 1-bromovinyl azides in the cis and the trans conformations were calculated and the vibrational infrared and Raman spectra were plotted in Figs. 3, 4, 5, 6, 7 and 8. The vibrational assignments of most of the fundamental vibrations of the three molecules were straightforward based on the calculated PED, as given in Tables $7,8,9,10,11,12$. Since the trans is predominantly the low energy conformer of the three molecules, the following discussion will concentrate on the analysis of the vibrational spectra of this conformation (Tables 8, 10 and 12).

The two $\mathrm{CH}_{2}$ stretching modes $\left(\mathrm{S}_{1}\right.$ and $\left.\mathrm{S}_{2}\right)$ of the vinyl group with the highest wavenumbers in the spectra of the three 1-halovinylazides were predicted to have little mixing with other vibrations (Tables $7,8,9,10,11,12$ ). The $\mathrm{C}=\mathrm{C}$ stretching mode was calculated at about $1,715 \mathrm{~cm}^{-1}\left(74 \% \mathrm{~S}_{5}\right), 1,667 \mathrm{~cm}^{-1}\left(75 \% \mathrm{~S}_{5}\right)$ and $1,658 \mathrm{~cm}^{-1}\left(77 \% \mathrm{~S}_{5}\right)$ for the fluoride, the chloride and the bromide as shown in Tables 8,10 and 12 , respectively. This mode was observed at $1,630 \mathrm{~cm}^{-1}$ in the Raman spectrum of the trans conformation of propenoyl fluoride. [25]

The $\mathrm{C}-\mathrm{N}, \mathrm{C}-\mathrm{X}$ and the symmetric NNN stretching modes in the spectra of the molecules were predicted to have a high degree of mixing with other vibrations. However, the antisymmetric NNN stretch was assigned with confidence to the calculated wavenumbers with the highest infrared intensity and negligible mixing at $2,270 \mathrm{~cm}^{-1}$ in the spectrum of the fluoride (Table 8) and at $2,262 \mathrm{~cm}^{-1}$ in the spectra of the chloride (Table 10) and the bromide (Table 12).

In the case of the bending modes, many were predicted to mix highly with other modes and therefore we could not make conclusive assignments for them based on PED values only. The lowest vibrational torsional mode in the spectra of 1-fluoro-, 1-chloro- and 1-bromovinyl azides were calculated at $72 \mathrm{~cm}^{-1}$ ( $100 \%$ PED), $65 \mathrm{~cm}^{-1}$ ( $100 \%$

PED) and $62 \mathrm{~cm}^{-1}$ ( $98 \%$ PED), respectively, as shown in Tables 8, 10 and 12.

Acknowledgment The authors gratefully acknowledge the support of this work by King Fahd University of Petroleum and Minerals. This work is taken in part from the thesis of K.S. Al-Ghamdi that was submitted in February 2003 to Chemistry Department at KFUPM, in partial fulfillment of the M.S. Degree.
