#### Abstract

The stereochemistry of A-type dimeric proanthocyanidins was studied, focusing on the factors that determine it, and the changes that occur with $\mathrm{R}=\mathrm{OCH}_{3}$, $\mathrm{R}^{\prime}=\mathrm{H}$, and $\mathrm{R}=\mathrm{OH}, \mathrm{R}^{\prime}=\mathrm{H}$ as substituents, starting with the study of the conformational space of each species. Using molecular dynamics at a semiempirical level, and complementing with functional density calculations, two conformers of lowest energy were characterized for $\mathrm{R}=\mathrm{H}$, eight conformers for $\mathrm{R}=\mathrm{OH}$, and three conformers for $\mathrm{R}=$ $\mathrm{OCH}_{3}$. Electronic distributions were analyzed at a higher calculation level, thus improving the basis set. Intramolecular interactions were examined and characterized by the theory of atoms in molecules (AIM). Detailed natural bond orbitals (NBO) analysis allowed the description of subtle stereoelectronic aspects of fundamental importance for understanding the stabilization and antioxidant function of these

## Introduction

Procyanidins are organic compounds found in some vascular plants, and have been synthesized as simple and dimeric molecules with a variety of substituents in the aromatic rings [1]. Their antioxidant activity is well documented, but there are no crystallographic data [2-6].

The interest in these compounds arises from the fact that one of their most important applications is in the stabilization of suspensions, which is useful in the food industry, mainly in the processing of citrus juices [1, 7]. Depending on the position of the ether bridge, dimeric procyanidins may have A- or B-type structures.

We previously reported [8] a conformational and electronic study of the A-type dimeric proanthocyanidin with $\mathrm{R}, \mathrm{R}^{\prime}=\mathrm{H}$ (Fig. 1), which has an intramolecular plane of symmetry. The occurrence of both C and E rings, and the $\mathrm{C}-3-\mathrm{H} 2$ bridge, markedly decreases the flexibility of the molecule. The main substructure of this molecule is a bicyclic structure consisting of two six-membered rings (C and E ), where each involves a benzo- $\gamma$-pyran group, fused by the $\mathrm{C}-3-\mathrm{H} 2$ bridge, with both $\mathrm{C}-2$ and $\mathrm{C}-4$ as

Fig. 1 Structure of Z- isomers of A-type dimeric proanthocyanidin substituted with $\mathrm{R}=\mathrm{H}$, $\mathrm{OH}, \mathrm{OCH}_{3}$. Atom numbering is indicated
bridgeheads. Consequently, this bridge is a stereo-center resulting in an $\mathrm{E} / \mathrm{Z}$ isomerism, depending on the configuration of $\mathrm{Ph}-2$ and $\mathrm{H}-4$, and any other substituent at those positions.

Scanning of the conformational space for $\mathrm{R}, \mathrm{R}^{\prime}=\mathrm{H}$ revealed two lowest energy conformers for the Z-isomer, and only one conformer for the E-isomer. The steric hindrance and high tension of the C and D rings characterize the E-isomer, thus giving rise to a higher energy for this isomer than that for Z [8].

Given its higher stability, the present study examines the effects of substitution on the Z-isomer, including $\mathrm{R}=$ $\mathrm{OCH}_{3}, \mathrm{R}^{\prime}=\mathrm{H}$, and $\mathrm{R}=\mathrm{OH}, \mathrm{R}^{\prime}=\mathrm{H}$ (Fig. 1).

The conformational space of the substituted stereoisomers of A-type procyanidin was scanned using molecular dynamics (MD) calculations, and further density calculations at the B3LYP level and $6-31 \mathrm{G}^{* *}$ basis were performed to optimize the geometry of the lowest-energy conformers of each species obtained in these simulations.

Maps of molecular electrostatic potential (MEP) were also obtained. The electronic distribution of the conformers was analyzed at the B3LYP/6-311++G** level, with intramolecular interactions being studied and characterized by the theory of atoms in molecules (AIM). The study was complemented by natural bond orbital (NBO) analysis.

The scant knowledge of the structural features of these compounds called for this analysis to be applied to their stereochemistry, advancing description of the factors that determine it, and the changes that occur upon substitutions with $\mathrm{R}=\mathrm{OCH}_{3}, \mathrm{R}^{\prime}=\mathrm{H}$, and $\mathrm{R}=\mathrm{OH}, \mathrm{R}^{\prime}=\mathrm{H}$. This analysis was designed to describe the stabilization and possible interactions with other organic molecules in a food matrix. Owing to the complexity of these molecules (presence of two prochiral carbons, and a rigid [3.1.3]-bicyclic substructure) a step-by-step analysis through an order of increasing complexity has been proposed, this work being the second
in a series of studies (see [8] for first in series) with the ultimate aim of studying polymeric species.

## Methods

The study of conformational space was performed by MD calculations using a module of the HyperChem software package [9]. Several simulations were carried out with the aid of the $\mathrm{MM}+$ force field. The input geometries were heated from 0 to 800 K in steps of 0.1 ps . Then, the temperature was kept constant by coupling the system to a simulated thermal bath with a relaxation time of 0.5 ps . The simulation time step was 0.5 fs . After an equilibration period of 1 ps , a simulation of 500 ps was performed, retaining atomic coordinates every 1 ps . These geometries were then optimized to an energy gradient less than $0.01 \mathrm{kcal} \mathrm{mol}^{-1} \mathrm{~A}^{-1}$ by the AM1 method.

The lowest energy conformers were studied using density functional theory (DFT) as implemented in the Gaussian 03 software package [10]. Total geometry optimization was performed with the three-parameter hybrid functional of Becke with the correlation functional of Lee-Yang-Parr. This combination gave rise to the well-known B3LYP method. The $6-31 \mathrm{G}^{* *}$ basis set was used for all atoms.

MEP maps were obtained in the van der Waals molecule surfaces using the Gaussian 03 software, and were further visualized using MOLEKEL 4.0 [11].

The topological analysis was performed with modules of the AIMPAC package [12], using wave functions obtained at the B3LYP level and $6-311++\mathrm{G}^{* *}$ basis set. NBO analysis was performed at the same level [13].

## Results and discussion

The study of the conformational space led to two conformers of lowest energy for $\mathrm{R}=\mathrm{H}$ [8] (Fig. 2), eight

Fig. 2 Optimized geometry of both conformers of the Z-isomer of Atype dimeric proanthocyanidin at B3LYP/6-31G** level. Geometries were confirmed as local minima by vibrational analysis

Fig. 3 Optimized geometry of conformers of the Z -isomer of A-type dimeric proanthocyanidin substituted with $\mathrm{R}^{\prime}=\mathrm{H}, \mathrm{R}=\mathrm{OH}$ at $\mathrm{B} 3 \mathrm{LYP} / 6$ $31 \mathrm{G}^{* *}$ level of theory. Dashed lines: Intramolecular hydrogen bond interactions. Only Z1 conformers are shown
conformers for $\mathrm{R}=\mathrm{OH}$ (Fig. 3), and three conformers for $\mathrm{R}=\mathrm{OCH}_{3}$ (Fig. 4). These structures have been confirmed as minima by the absence of negative frequencies.

The energy values and internal coordinates of the conformers under study are shown in Table 1. The conformers of the $\mathrm{R}=\mathrm{H}$ species show a high symmetry, the geometric parameters of ring A being similar to those of ring D. As expected, this symmetry is lost when substituted with $\mathrm{R}=\mathrm{OH}$, and $\mathrm{R}=\mathrm{OCH}_{3}$ (Table 1).

The C-3-C-2-C-1'-C-6' dihedral angle in relation to the position of ring $B$ has a mean value of $88^{\circ}$ for a set of structures called the Z 1 group, and close to $0^{\circ}$ for the other, Z 2 , group. Therefore, the conformers are defined as Z 1 and Z2 conformers, respectively (Fig. 2).

Analysis of the $\mathrm{H}-\mathrm{O}-3^{\prime \prime}-\mathrm{C}-3^{\prime \prime}-\mathrm{C}-4^{\prime \prime}$ and $\mathrm{H}-\mathrm{O}-5^{\prime \prime}-$ $\mathrm{C}-5^{\prime \prime}-\mathrm{C}-4^{\prime \prime}$ dihedral angles is suitable for distinguishing conformers whose mean values are either close to $180^{\circ}$ (anti position) or close to $0^{\circ}$ (syn position). The "T" and "C" subscripts for the conformers refer to trans (anti) or cis (syn) configuration in relation to the $\mathrm{C}-3^{\prime \prime}-\mathrm{C}-4^{\prime \prime}$ and $\mathrm{C}-5$ " $-\mathrm{C}-4^{\prime \prime}$ bonds, respectively (Figs. 3, 4).

Regardless of the substitution, the energy values show that Z 1 conformers are on average $1.88 \mathrm{kcal} \mathrm{mol}^{-1}$ more stable than Z2. For all conformers, the angles between the bonds that define rings C and E , and their respective
lengths, are very similar for both Z 1 and Z 2 conformers. However, there is a remarkable difference in the C-3-C-$2-\mathrm{C}-1^{\prime}$ angle, which averages $112.7^{\circ}$ for Z 1 , and $116.6^{\circ}$ for Z 2 . Although this angle differs by about $4^{\circ}, \mathrm{Z} 2$ can be considered a rotamer of Z 1 with respect to an axis through the $\mathrm{C}-1$ ' $-\mathrm{C}-2$ bond in all species under study.

For $\mathrm{R}=\mathrm{OH}$, the energy value found for the most stable conformer, called Z1 ${ }_{\mathrm{CT}}$ (Fig. 3), was-697,033.86 $\mathrm{kcal} \mathrm{mol}^{-1}$. The energy differences for the other conformers with respect to the most stable were $0.63 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z1}_{\mathrm{CC}}$, and $2.51 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z1}_{\mathrm{TC}}$ and $\mathrm{Z} 1_{\mathrm{TT}}$. The energy differences for Z 2 conformers were $1.88 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z2}_{\mathrm{CT}}$, $2.51 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z2}_{\mathrm{CC}}$, and $4.39 \mathrm{kcal} \mathrm{mol}^{-1}$ for both $\mathrm{Z}_{\mathrm{TC}}$ and $\mathrm{Z}_{\mathrm{TT}}$.

The energy value found for the most stable conformer with $\mathrm{R}=\mathrm{OCH}_{3}\left(\mathrm{Z1} \mathrm{CT}_{\mathrm{CT}}\right.$; Fig. 4) was $-746,362.16 \mathrm{kcal} \mathrm{mol}^{-1}$, and the energy differences for the other conformers were $1.25 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z1}_{\mathrm{CC}}$, and $3.07 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z}_{\mathrm{CC}}$.

The "CT" conformers were $0.63 \mathrm{kcal} \mathrm{mol}{ }^{-1}$ ( $1.25 \mathrm{kcal} \mathrm{mol}^{-1}$ ) more stable than " CC " for $\mathrm{R}=\mathrm{OH}(\mathrm{R}=$ $\mathrm{OCH}_{3}$ ). These trends are rationalized below in the section on NBO analysis.
"TC" and "TT" conformers were not described for $\mathrm{R}=$ $\mathrm{OCH}_{3}$ (steric hindrance), but these conformers did exist for $\mathrm{R}=\mathrm{OH}$, and showed the same energy.

Fig. 4 Optimized geometry of conformers of the Z-isomer of A-type dimeric proanthocyanidin substituted with $\mathrm{R}^{\prime}=\mathrm{H}$, $\mathrm{R}=\mathrm{OCH}_{3}$ at $\mathrm{B} 3 \mathrm{LYP} / 6-31 \mathrm{G}^{* *}$ level of theory. Dashed lines: Intramolecular hydrogen bond interactions

Topology of the electronic charge density

The AIM theory [14] is based on the analysis of critical points (CP) of molecular charge density, $\rho$ [15, 16]. At these points, the gradient of the electronic density, $\nabla^{2} \rho$, is null and is characterized by the three eigenvalues, $\lambda_{i}(i=1-$ $3)$ of the $\rho$ Hessian matrix. The CPs were named and classified as ( $\mathrm{r}, \mathrm{s}$ ) according to their rank, r (number of nonzero eigenvalues), and signature, $s$ (the algebraic sum of the three eigenvalues). Several properties evaluated at the bond $\mathrm{CP}[\mathrm{BCP}$, a $(3,-1) \mathrm{CP}]$ constitute powerful tools to classify a given chemical structure. The negative eigenvalues of the Hessian matrix ( $\lambda_{1}$ and $\lambda_{2}$, respectively) measure the degree of contraction of $\rho$ at a normal direction to the bond towards the CP , while a positive eigenvalue (i.e., $\lambda_{3}$ ) gives a quantitative indication of the contraction degree parallel to the bond and from the CP towards each of the neighboring nuclei. When the positive eigenvalues are dominant, the electronic density is concentrated locally at each atomic basin. The interaction is classified as closed shell and is typical of highly ionic bonds, hydrogen bonds, and van der Waals interactions. This particular interaction is described by relatively low $\nabla^{2} \rho_{\mathrm{b}}$ values, $\nabla^{2} \rho_{\mathrm{b}}>0$ and $\left|\lambda_{1}\right| / \lambda_{3}<1$ and $\mathrm{G}_{\mathrm{b}}>1$. Another interesting parameter is the ellipticity, $\varepsilon$, defined as $\lambda_{1} / \lambda_{2}-1$. Ellipticity is indicative of the similarity between perpendicular curvatures ( $\lambda_{1}$ and $\lambda_{2}$ ) at BCP, and measures the extent to which density is preferentially accumulated in a given plane containing the bond path. If $\lambda_{1}=\lambda_{2}$, then $\varepsilon=0$, and the bond is cylindrically symmetric, e.g., a $\mathrm{C}-\mathrm{C}$ single bond in ethane, and a triple bond in acetylene.

As supplementary material, the values of electron charge density $\left(\rho_{\mathrm{b}}\right)$, Laplacian of charge density ( $\nabla^{2} \rho_{\mathrm{b}}$ ), Hessian matrix eigenvalues $\left(\lambda_{1}, \lambda_{2}\right.$ and $\left.\lambda_{3}\right)$, ellipticity $(\varepsilon)$, kinetic energy density $\left(\mathrm{G}_{\mathrm{b}}\right)$, and the $\left|\lambda_{1}\right| / \lambda_{3}$ and $\mathrm{G}_{\mathrm{b}} / \rho_{\mathrm{b}}$ relationships, in BCPs for all expected chemical bonds of the lowest energy conformers obtained by substituting $\mathrm{R}=\mathrm{OH}$ and $\mathrm{R}=\mathrm{OCH}_{3}$ are shown (Tables S 1 and S2, respectively).

According to the AIM theory, when negative eigenvalues dominate, the electronic charge is locally concentrated in the CP region, which leads to polar covalent interactions. These are characterized by high $\rho_{\mathrm{b}}$ values, $\left|\lambda_{1}\right| / \lambda_{3}>1$ and $G_{b} / \rho_{b}<1$, and large, less than zero, Laplacian values, indicating charge accumulation between the bound nuclei [14].

For all studied conformers this behavior occurs in $\mathrm{C}-\mathrm{H}$ bonds, and all $\mathrm{C}-\mathrm{C}$ bonds of rings $\mathrm{A}, \mathrm{B}$, and D . The $\mathrm{C}-$ $2-\mathrm{O} 1$ bond of ring C also shows the same behavior typical of a covalent bond, which is due, as previously demonstrated [8], to the change of C-2 hybridization (from $\mathrm{sp}^{2}$ to $\mathrm{sp}^{3}$ ), when the $\gamma$-pyran is formed.

The $\mathrm{C}-8 \mathrm{a}-\mathrm{O} 1$ bond of ring C , and the equivalent for ring $\mathrm{E}, \mathrm{C}-1$ "- O 1 and $\mathrm{C}-\mathrm{O}$ bonds accounting for $\mathrm{R}=$
$\mathrm{OCH}_{3}$ and $\mathrm{R}=\mathrm{OH}$, do not behave like $\mathrm{C}-2-\mathrm{O} 1$, since they show values corresponding to an intermediate or shared polar covalent bond (high $\rho b$, large and less than zero $\nabla^{2} \rho_{\mathrm{b}}$, $\left|\lambda_{1}\right| \lambda_{3}<1$, and $\mathrm{G}_{\mathrm{b}} / \rho_{\mathrm{b}}>1$ ).

We found that this behavior is typical of $\mathrm{C}-\mathrm{O}$ bonds in the pyranose ring, where the C atom also has $\mathrm{sp}^{2}$ hybridization. The $\mathrm{C}-8 \mathrm{a}-\mathrm{O} 1 \mathrm{BCP}$ topological features are a consequence of the charge density redistribution due to the conjugation of O1 lone pairs with the $\pi$-orbitals [8].

Hydrogen-bond intramolecular interactions have been also characterized in the substituted species. The occurrence of a hydrogen bond is associated with the BCP formation between the H atom and the acceptor atom (A) involved $[17,18]$. This CP has properties that are typical of a closed shell interaction. In particular, the following hydrogen bond interactions have been characterized: (1) $\mathrm{H} \cdots \mathrm{O}$ type (in $\mathrm{Z} 1_{\mathrm{CT}}, \mathrm{Z} 1_{\mathrm{CC}}, \mathrm{Z} 2_{\mathrm{CT}}$ and $\mathrm{Z} 2_{\mathrm{CC}}$ conformers for $\mathrm{R}=\mathrm{OH}$, and in all conformers for $\mathrm{R}=\mathrm{OCH}_{3}$ ), and (2) dihydrogen-type: C -$5-\mathrm{H}-5 \cdots \mathrm{H}-5^{\prime \prime}-\mathrm{O} 5^{\prime \prime}$ and $\mathrm{C}-4-\mathrm{H}-4 \cdots \mathrm{H}-5^{\prime \prime}-\mathrm{O} 5^{\prime \prime}$ (in Z1 ${ }_{\mathrm{TC}}$ and $\mathrm{Z} 1_{\mathrm{TT}}, \mathrm{R}=\mathrm{OH}$ ), and $\mathrm{C}-5-\mathrm{H}-5 \cdots \mathrm{H}-5^{\prime \prime}$ (in $\mathrm{Z}_{\mathrm{TC}}$ and $\left.\mathrm{Z}_{\mathrm{TT}}, \mathrm{R}=\mathrm{OH}\right)$. These interactions are shown with dotted lines in Figs. 3 and 4. Some relevant geometric parameters of these interactions, such as the distances $\mathrm{H}^{\cdots} \mathrm{O}, \mathrm{H}^{\cdots} \mathrm{H}$, $\mathrm{C} \cdots \mathrm{O}$, and the $\mathrm{C}-\mathrm{H} \cdots \mathrm{Y}, \mathrm{Y}=\mathrm{O}, \mathrm{H}$ bond angle are shown in Table 2. The formation of the H-bonds H-5 $\cdots \mathrm{O}-5^{\prime \prime}, \mathrm{H}-5^{\prime \prime}$ $\cdots \mathrm{H}-5$ and $\mathrm{H}-5{ }^{\prime \prime} \cdots \mathrm{H}-4$ closes seven-membered, eightmembered, and six-membered rings, respectively, and is accompanied by the appearance of ring critical points (RCPs), as required for the satisfaction of the Poincaré-Hopf relationship [14]. Local topological properties calculated in the respective BCP and RCP are listed in Table 3.

The $\mathrm{H}^{\cdots} \mathrm{O}$ type hydrogen bonds with distances around $2.80-2.93 \AA$ (in the expected range of $2-3 \AA$ for $\mathrm{C}-\mathrm{H}^{\cdots} \mathrm{O}$ bonds) were found in all conformers of the substituted structures, except for "TC" and "TT" with $\mathrm{R}=\mathrm{OH}$. According to other authors [19], the shorter the interatomic $\mathrm{H} \cdots \mathrm{A}$ distance, and closer to $180^{\circ}$ the $\mathrm{D}-\mathrm{H} \cdots \mathrm{A}$ angle, the higher the strength of the hydrogen bond interaction. Another parameter that characterizes this type of bond as a weak hydrogen bond is the distance between the C atom attached to the hydrogen of the bridge, and the O oxygen atom (in the range of $3.41-3.54 \AA$ ) [19]. The bond angle between donor and acceptor atoms $(\mathrm{C}-\mathrm{H} \cdots \mathrm{O})$ varies in the range $114.7-115.3^{\circ}$-also in agreement with this classification. The electron density values are lower than those expected for typical intramolecular hydrogen bonds (expected densities about $0.02-0.03$ a.u.) [17, 20] (see Table 3). Taking into account the correlation between the BCP density and the interaction strength [18], from the analysis of topological parameters it can also be concluded that this interaction is typically weak, contributing very little to structure stabilization. $\nabla^{2} \rho_{\mathrm{b}}$ varies in the range of $0.015-0.016$ a.u. (0.016-0.017 a.u. for $\mathrm{R}=\mathrm{OCH}_{3}$ ),

comparable with previous results ( 0.016 to 0.139 a.u.). Ellipticity varies around $0.256-0.273$ ( $0.239-0.261$ for $\mathrm{R}=\mathrm{OCH}_{3}$ ), the smallest values being for Z 2 .

The non-conventional dihydrogen-type bonds as well as the conventional hydrogen bonds such as those described above, may occur either as intermolecular or intramolecular bonds.

A dihydrogen bond always comprises an electronegative atom ( X ) on one side, and an electropositive atom ( Y ) on
the other side, $\mathrm{X}-\mathrm{H}^{+\delta} \ldots{ }^{-\delta} \mathrm{H}-\mathrm{Y}$. Spectroscopic studies indicate that the $\mathrm{H}^{\cdots} \mathrm{H}$ distance in such systems is typically 1.7-2.2 $\AA$ [21]. Dihydrogen bonds appear in "TC" and "TT" conformers for $\mathrm{R}=\mathrm{OH}$, for both Z 1 and Z 2 , and occur among H-5, H-4 and H-5". Multiple dihydrogen bonds [22] were characterized in $\mathrm{Z} 1_{\mathrm{TC}}$ and $\mathrm{Z} 1_{\mathrm{TT}}$. For these two conformers, the $\mathrm{H}-5-\mathrm{H}-5^{\prime \prime}$ distance is $2.33 \AA$, and that of $\mathrm{H}-4-\mathrm{H}-5$ " is $1.97 \AA$. The angle between the donor atom and the hydric hydrogen ${ }^{-\delta} \mathrm{H}\left(\mathrm{O}-\mathrm{H}^{+\delta} \ldots{ }^{-\delta} \mathrm{H}\right)$ is higher

${ }^{\mathrm{a}} \rho_{\mathrm{b}}, \nabla^{2} \rho_{\mathrm{b}}, G \mathrm{G} / \rho_{\mathrm{b}}, \lambda_{\mathrm{l}}, \lambda_{2}, \lambda_{3}$ are expressed in a.u. and bond lengths in $\AA$
(more linear, it varies around $150-170^{\circ}$ ) than the angle associated with the protic hydrogen $\mathrm{H}^{+\delta} \ldots{ }^{-\delta} \mathrm{H}-\mathrm{C}$ (more bent, it varies around $95-115^{\circ}$ ) as expected for such interactions [23]. The BCP topological parameter values and the difference found in the value of natural charges for the hydrogen atoms involved ( $\Delta \mathrm{q} \approx 0.3$ a.u.) led to closed shell weak electrostatic interactions [24, 25].

By subtracting structures the stabilizing effect (1.88 $\mathrm{kcal} \mathrm{mol}^{-1}$ ) associated with the position of ring B $\left(\Delta=4.39 \mathrm{kcal} \mathrm{mol}^{-1}-1.88 \mathrm{kcal} \mathrm{mol}^{-1}=2.51 \mathrm{kcal} \mathrm{mol}^{-1}\right)$ in Z2, it was shown that the stabilizing effect of dihydrogen interactions is similar in all cases.

## NBO analysis

NBO analysis transforms the canonical delocalized HartreeFock (HF) molecular orbitals (MOs), or corresponding natural orbitals of a correlated description, into localized orbitals that are closely linked to chemical bonding concepts.

Filled NBOs describe the hypothetical, strictly localized Lewis structure. The interactions between filled and vacant orbitals account for the deviation of the molecule from the Lewis structure and can be used as a measure of delocalization. This method provides energies of hyperconjugative interactions from the second-order perturbation approach
$E^{(2)}=-n_{i} \frac{F_{i j}^{2}}{\varepsilon_{j}-\varepsilon_{i}}$
where $F_{\mathrm{ij}}$ is the Fock matrix element between the $i$ and $j$ NBO orbitals, $\varepsilon_{i}$ and $\varepsilon_{j}$ are the energies of $i$ and $j$ NBOs, and $n_{i}$ is the population of the donor $i$ orbital.

The structures under study showed nearly the same secondorder stabilization energies for $1 \mathrm{n}_{\mathrm{O} 1 \rightarrow \sigma^{*}}{ }_{\mathrm{C}-8 \mathrm{a}-\mathrm{C}-8}$ transfers ( $0.55 \mathrm{kcal} \mathrm{mol}^{-1}$ on average). Energies associated with $1 n_{\mathrm{O} 1 \rightarrow} \sigma^{*}{ }_{\mathrm{C}-8 \mathrm{a}-\mathrm{C}-4 \mathrm{a}}$ and $2 \mathrm{n}_{\mathrm{O} 1 \rightarrow} \pi^{*}{ }_{\mathrm{C}-8 \mathrm{a}-\mathrm{C}-4 \mathrm{a}}$ transfers are $7.12 \mathrm{kcal} \mathrm{mol}^{-1}$ and $26.12 \mathrm{kcal} \mathrm{mol}^{-1}$, respectively, on average. The $\mathrm{R}=\mathrm{H}$ conformers have symmetric contributions
to these energies accounting for the resonance of the O oxygen with ring D. However, in the case of substituted species, this symmetry is broken, and hyperconjugative interactions related to O are now $1 \mathrm{n}_{\mathrm{O} \rightarrow} \sigma^{*}{ }_{\mathrm{C}-1^{\prime \prime}}-\mathrm{C}-2^{\prime \prime}$ ( $0.56 \mathrm{kcal} \mathrm{mol}^{-1}$ on average), $1 \mathrm{n}_{\mathrm{O} \rightarrow} \sigma^{*}{ }_{\mathrm{C}-1^{\prime \prime}-\mathrm{C}-6^{\prime \prime}}$ $\left(6.87 \mathrm{kcal} \mathrm{mol}^{-1}\right.$ on average), and $2 \mathrm{n}_{\mathrm{O} \rightarrow \pi^{*}}{ }_{\mathrm{C}-1^{\prime \prime}-\mathrm{C}-2^{\prime}}$ ( $26.88 \mathrm{kcal} \mathrm{mol}^{-1}$ on average). This information describes the resonance of oxygen lone pairs with rings A and D .

Bond polarization or ionicity is described by NBO calculations of the electron density percentage on each atom of the bond (Table 4). The results indicate that in substituted compounds (for $\mathrm{R}=\mathrm{H}$ there is almost no change) the C -$2-\mathrm{C}-3$ polarization is higher than that of the $\mathrm{C}-3-\mathrm{C}-4$ bond. On the other hand, upon comparison of $\mathrm{Z1}_{\mathrm{CT}}$ for $\mathrm{R}=\mathrm{OH}$ and $\mathrm{Z1}_{\mathrm{CT}}$ for $\mathrm{R}=\mathrm{OCH}_{3}$, it is evident that the C -2-C-3 polarization increases according to $\mathrm{R}=\mathrm{H}<\mathrm{R}=$ $\mathrm{OCH}_{3}<\mathrm{R}=\mathrm{OH}$.

It is remarkable that this behavior associated with conformational effects was correlated with relative structure stability ( Z 1 conformers are more stable than Z 2 , "CT" are more stable than "CC", which are in turn more stable than both "TC" and "TT"). In other words, at higher C-2-C-3 polarization, higher structural stability is expected.

For $\mathrm{R}=\mathrm{OCH}_{3}$, the second-order stabilization energy of the $\sigma_{\mathrm{C}-3^{\prime \prime} \mathrm{a}-\mathrm{O}-3^{\prime \prime}} \rightarrow \sigma^{*}{ }_{\mathrm{C}-3^{\prime \prime}-\mathrm{C}-4^{\prime \prime}}$ transfer is higher in the "CT" conformer than in "CC" (3.11 kcal mol ${ }^{-1}$ and $2.93 \mathrm{kcal} \mathrm{mol}^{-1}$, respectively; Table 5). This indicates a higher electron delocalization in "CT", and explains its relative stabilization ( $\Delta \mathrm{E}_{\text {Z1CT-Z1CC }}: 1.25 \mathrm{kcal} \mathrm{mol}^{-1}$; Table 1).
 ( $5.15 \mathrm{kcal} \mathrm{mol}^{-1}$ and $4.98 \mathrm{kcal} \mathrm{mol}^{-1}$; Table $6 ; \Delta \mathrm{E}_{\text {Z1CT-Z1CC }}$ : $0.63 \mathrm{kcal} \mathrm{mol}^{-1}$; Table 1); H is designated the hydrogen atom of the substituent.

The highest stabilization for $\mathrm{R}=\mathrm{OCH}_{3}$ is explained by the major efficiency of the $\sigma_{\mathrm{C}-3^{\prime \prime} \mathrm{C}-4^{\prime \prime}} \rightarrow \sigma^{*} \mathrm{C}-5^{\prime \prime}-\mathrm{O}-5^{\prime \prime}$ transfer, to which second-order stabilization energies of $5.06 \mathrm{kcal} \mathrm{mol}^{-1}$ in "CT", and $4.68 \mathrm{kcal} \mathrm{mol}^{-1}$ in "CC" are associated, while for $\mathrm{R}=\mathrm{OH}$ the respective energies are $4.67 \mathrm{kcal} \mathrm{mol}^{-1}$ in "CT" and $4.56 \mathrm{kcal} \mathrm{mol}^{-1}$ in "CC" (Tables 5, 6). This describes stabilization mechanisms operating in the substitution positions, which are more effective for $\mathrm{R}=\mathrm{OCH}_{3}$. The values corresponding to Z 2 conformers for $\mathrm{R}=\mathrm{OH}$ are shown in Table S 3 (electronic supplementary material).

## Analysis of MEP through the NBO-AIM study

MEP maps have been used extensively for predicting the behavior and reactivity of a wide variety of chemical systems [26-33].

The $V(\mathrm{r})$ potentials, created in the space around a molecule by its nuclei and electrons, are a useful tool for

the study of molecular reactivity. Unlike other parameters currently used as reactivity indices, $V(\mathrm{r})$ is an actual physical property that can be determined both experimentally and by computational methods. The calculation of physicochemical properties on molecular surface, and its visualization through a color code allows a different view of molecular behavior. This paper uses the procedure proposed by Politzer et al. [26] for predicting sites targeted for electrophilic attack in the regions of negative $V(\mathrm{r})$ values, and NBO and AIM results are reviewed in the light of the complementarity of the different theoretical tools used; thus, a thorough analysis of the role of substituents in the stabilization and reactivity of the structures studied was performed.

In non-substituted species, we found [8] two attack sites that are very close to each other, associated with the O atoms of rings C and E , where the higher values of negative $V(\mathrm{r})$ show that Z 1 conformers are more reactive to electrophilic attack, since the negative potential on a group or substructure indicates its tendency to participate in electrostatic interactions, formation of ion pairs or hydrogen bonds. Similar features were observed in substituted species. Upon comparison of negative $V(r)$ values, the following order for reactivity towards electrophilic attack: $\mathrm{R}=\mathrm{OH}<\mathrm{R}=\mathrm{H}<\mathrm{R}=\mathrm{OCH}_{3}$ was observed. The values of maximum [ $V_{\max }$, positive $V(\mathrm{r})$ ], and minimum [ $V_{\min }$, negative $V(\mathrm{r})$ ] potentials in $\mathrm{kcal} \mathrm{mol}^{-1}$ are shown in Table 7, (see also Fig. S1a-d in the electronic supplementary material).

Values of $V_{\min }$ are higher in Z 1 rotamers than in Z 2 (Table 7; Fig. S1c, d), which is indicative of the higher

Table 5 (continued)

${ }^{\mathrm{a}}$ All values are expressed in $\mathrm{kcal} \mathrm{mol}^{-1}$
inductive effect exerted by the O and O 1 oxygen atoms in the most stable rotamers (Z1) [8].

The percentage values of electron density on each atom of $\mathrm{C}-1^{\prime}-\mathrm{C}-6^{\prime}$ and $\mathrm{C}-1^{\prime}-\mathrm{C}-2^{\prime}$ bonds by NBO calculations are shown in Table 8. As already stated, the difference between the values found on each atom of a bond quantifies the polarization or ionicity thereof. Therefore, $\mathrm{C}-1^{\prime}-\mathrm{C}-6^{\prime}$ and $\mathrm{C}-1^{\prime}-\mathrm{C}-2^{\prime}$ bonds are more polarized in Z 1 rotamers than in Z2, which indicates a higher inductive effect in Z1 than in Z2 for all substituents. Interestingly, the highest polarization found in $\mathrm{C}-1^{\prime}-\mathrm{C}-6^{\prime}$ and $\mathrm{C}-1^{\prime}-\mathrm{C}-2^{\prime}$ bonds correlates with a greater electron delocalization in $\mathrm{Z1}$ conformers than in Z 2 , which is related to hyperconjugative interactions between $\mathrm{O}-1-\mathrm{C}-2$ and $\mathrm{O} 1-\mathrm{C}-8 \mathrm{a}$ bonds (and those of the symmetrically equivalent bonds: $\mathrm{O}-\mathrm{C}-2$ and $\mathrm{O}-\mathrm{C} 1^{\prime \prime}$ ) with adjacent bonds that connect the $\gamma$-pyran substructure with ring $\mathrm{B}: \mathrm{C}-2-\mathrm{C}-1^{\prime}, \mathrm{C}-1^{\prime}-\mathrm{C}-2^{\prime}$ and $\mathrm{C}-1^{\prime}-\mathrm{C}-6^{\prime}$. These interactions in Z 1 are up to $24 \%$ more intense than in Z 2 conformers, thus determining its higher stabilization.

When we related the major intensity of the hyperconjugative effects mentioned above with the highest polarization of $\mathrm{C}-1^{\prime}-\mathrm{C}-6^{\prime}$ and $\mathrm{C}-1^{\prime}-\mathrm{C}-2^{\prime}$ bonds, we found in all structures an inductive effect exerted by O and O 1 atoms assisted by resonance, which reaches a maximum intensity when each structure has the highest stabilization.

The plane of the molecule (ring A, and part of ring C) divides the space into two regions: one above this plane, and another below it. In Z 1 rotamers, ring B has one side towards the upper part of the molecule ("upper side of B"), and the other towards the lower part of the molecule ("lower side of B"). Regardless of the substitution, a remarkable difference in $V(\mathrm{r})$ distribution is observed in these two sides, a higher negative potential expansion being found on the second side due to the proximity of the O -1-C-O active site (Fig. 5a,b).

For $\mathrm{R}=\mathrm{OH}$, the negative $V(\mathrm{r})$ on the O attached to $\mathrm{C}-3^{\prime \prime}$ ("the outside one") is higher than that of the O attached to $\mathrm{C}-5^{\prime \prime}\left[\Delta_{\mathrm{O}-3^{\prime \prime}-\mathrm{O}-5^{\prime \prime}}:(-58.82)-(-43.35)=-15.47 \mathrm{kcal} \mathrm{mol}^{-1}\right.$ for $\mathrm{Z} 1_{\mathrm{TC}}$, ] (Figs. 5a,b). Consequently, the respective NCP charge density follows this trend, leading to an electron density on O-3" of 295.210 a.u. for Z 1 and 295.211 for Z2, and on O-5" 295.203 a.u. for Z1 and 295.197 a.u. for Z2.

It is also possible to relate $V(\mathrm{r})$ to the increase in CP electron density of the $\mathrm{C}-\mathrm{Z}^{\prime \prime}-\mathrm{O}$ bond, which is 0.284 a.u. (on average, considering Z 1 and Z 2 conformers) while the mean value for $\mathrm{C}-5^{\prime \prime}-\mathrm{O}$ is 0.281 a.u.

The O attached to $\mathrm{C}-5$ " has a lower negative $V(\mathrm{r})$ in "C" $\left(-43.3 \mathrm{kcal} \mathrm{mol}{ }^{-1}\right)$ than that in " T " disposition ( $-58.98 \mathrm{kcal} \mathrm{mol}^{-1}$; Fig. 5c,d), its electron density in NCP is also lower (295.195 a.u. and 295.204 a.u., respectively), and consequently the electron density in CP of the C-5"-O bond (Table S1).
$V(\mathrm{r})$ values for $\mathrm{R}=\mathrm{OCH}_{3}$ are also more negative on the O attached to $\mathrm{C}-3$ " ("the outside one") than that attached to $\mathrm{C}-5^{\prime \prime}\left[\Delta_{\mathrm{O}-3^{\prime \prime}-\mathrm{O}-5^{\prime \prime}}:(-64.89)-(-52.93)=\right.$ $\left.-11.96 \mathrm{kcal} \mathrm{mol}^{-1}\right]$. For any of these positions, more negative potentials (mean difference of $6.13 \mathrm{kcal} \mathrm{mol}^{-1}$ ) are always found than on the oxygen atoms of the $\mathrm{R}=\mathrm{OH}$ substituent (see Fig. 6a,b). For all conformers with $\mathrm{R}=$ $\mathrm{OCH}_{3}$, the mean electron density in BCP is also higher on $\mathrm{C}-3^{\prime \prime}-\mathrm{O}\left(0.28302\right.$ a.u.) than on $\mathrm{C}-5^{\prime \prime}-\mathrm{O}(0.27993$ a.u. $)$, in agreement with the findings for $\mathrm{R}=\mathrm{OH}$. Similarly, NCP electron density is 295.188 a.u. on C-3", and 295.172 a.u. on $\mathrm{C}-5^{\prime \prime}$, as mean values for Z 1 and Z .

Electron donation (transfers that remove charge from the bond) and electron back-donation (reverse charge transfers towards the bond) related to $\mathrm{C}-3^{\prime \prime}-\mathrm{O}$ and $\mathrm{C}-5$ " -O bonds show that the difference between both contributions is negative and large in the former case, thus explaining the higher intensity of negative $V(\mathrm{r})$ on $\mathrm{O}-3^{\prime \prime}$ than on $\mathrm{O}-5^{\prime \prime}$ (Tables 5, 6). Using the same arguments, it is also possible

Table 6 Second-order stabilization energies, $\mathrm{E}^{(2)}$, calculated at B3LYP/6-311++G** level of theory, for donation and back donation transferences related to $\mathrm{R}=\mathrm{OH}$ moiety in Z 1 conformers ${ }^{\mathrm{a}}$

${ }^{\mathrm{a}}$ All values are expressed in $\mathrm{kcal} \mathrm{mol}^{-1}$
to justify the higher intensity of negative $V(\mathrm{r})$ of the oxygen atoms of $\mathrm{OCH}_{3}$ groups with respect to the potential on oxygen atoms of OH groups, as has been observed in the MEPs mentioned above.

All this suggests a higher reactivity of the substituent at $\mathrm{C}-3^{\prime \prime}$, and explains the mechanisms underlying this condi-
tion. The substituent at $\mathrm{C}-5^{\prime \prime}$ operates in hydrogen bondtype interactions in all structures, as described above.

Hyperconjugative interactions related to $\mathrm{R}=\mathrm{OCH}_{3}$ and $\mathrm{R}=\mathrm{OH}$ substituents are shown in Tables 5 and 6, respectively. From these tables it is possible to delve deeper into the study of the role of substituents in the structures of

A-type proanthocyanidins. Thus, it is shown that all bonds are better acceptors than donors, i.e., transfers that take charge to antibonding orbitals are more important than those that remove charge from bonding orbitals. The exception is the OH bond, which is a much better donor than acceptor (cf. transfer energies that take charge to it with those from it; Table 6, S3). Therefore, since only part of the OH electron delivery comes from hyperconjugative delocalizations $(\mathrm{OH}$ donates more than it receives by hyperconjugation) it is postulated that, by charge conservation, the remaining charge delivered comes from the charge concentration in the area associated with the higher EW (electron withdrawing) effect of $\mathrm{O}-5^{\prime \prime}-\mathrm{H}$ and $\mathrm{O}-3^{\prime \prime}-\mathrm{H}$, e.g., from the $\sigma$ cloud via inductive effects. From NBO analysis, this mechanism then describes the major EW effect of OH against the $\mathrm{OCH}_{3}$ group. Although the electron donor ability of a $\mathrm{CH}_{3}$ towards a closed $\pi$-system is known, the occurrence of the methoxyl oxygen atom prevents donations from $\mathrm{CH}_{3}$ reaching the aromatic ring, thus showing the EW effect of the oxygen of the adjacent $\mathrm{C} — \mathrm{O}$ bond (Table 5).

The occurrence of an inductive effect assisted by resonance has been reported for O-O1 atoms [8]. Concerning the oxygen atoms of substituents, as mentioned above, the associated resonance mechanisms are higher for $\mathrm{R}=\mathrm{OH}$, and a higher inductive effect can also be postulated in agreement with that mentioned above, due to the high O-H donor capacity.

This high donor capacity is also evidenced by MEP analysis. The difference in electrostatic potential values on the various hydrogens is remarkable. Those of the OH group

have always a higher positive value ( $72.79 \mathrm{kcal} \mathrm{mol}^{-1}$ ) regardless of the conformer, thus indicating the high donor role of this group (Fig. 6b). The increase in positive $V(\mathrm{r})$ on the hydrogen atoms of the $\mathrm{C}-3-\mathrm{H} 2$ group (Fig. 7c, oblique lines) can be similarly explained. The donor role of these $\mathrm{C}-\mathrm{H}$ bonds in hyperconjugative interactions has been related to their weakening and elongation [8].

Upon analysis of the hydrogen atoms of the $\mathrm{OCH}_{3}$ group, we found that those attached to $\mathrm{C}-5$ " in the "C"-type position showed an extended area of higher positive $V(\mathrm{r})$ value ( $34.05 \mathrm{kcal} \mathrm{mol}^{-1}$ ), covering the three hydrogen atoms. Similar results were observed for the hydrogen atoms attached to $\mathrm{C}-3$ " in "C". However, when this substituent adopted the " T " configuration, the area of positive potential was reduced, being concentrated only on each individual hydrogen atom (Fig. 7). Again, these results have a counterpart in the donor role of the related $\mathrm{C}-$ $H$ bonds. In fact, by NBO analysis (Table 5), the increase in positive potential in "C" dispositions was explained by taking into account the increase in $\mathrm{C}-\mathrm{H}$ donor capacity (and/or increase in the acceptor ability of the $\mathrm{C}-3^{\prime \prime}-\mathrm{O}-3^{\prime \prime}$ bond) in this configuration with respect to the donor ability in the "T" configuration (the energy associated with $\sigma_{\mathrm{C}-3 \mathrm{a} "-\mathrm{H} \rightarrow \sigma^{*}}{ }_{\mathrm{C}-2-\mathrm{O}-3 \text { " }}$ transfer is $3.64 \mathrm{kcal} \mathrm{mol}^{-1}$ for " T ", and $3.61 \mathrm{kcal} \mathrm{mol}^{-1}$ for " C "). Therefore, a higher loss of charge on hydrogen atoms is expected in " C " than in " T ".

The $V(\mathrm{r})$ values on oxygen atoms that comprise a hydrogen bond (atom of the acceptor moiety) become less negative (higher) than $V(\mathrm{r})$ of those that do not comprise it ( $\Delta_{\mathrm{O}-3^{\prime \prime}-\mathrm{O}-5^{\prime \prime}}=15.46 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{Z1}_{\mathrm{CC}}$ conformers with $\mathrm{R}=\mathrm{OH})$.

Fig. 5 Maps of molecular electrostatic potential (MEP) for $\mathrm{Z} 1_{\mathrm{TC}}$ conformers of A-type dimeric proanthocyanidin substituted with $\mathrm{R}=\mathrm{OH}$ (in a.u.). The upper (a) and lower (b) sides of ring $B$ are shown (see text for definitions). (c) Rotamer ( $\mathrm{Z}_{\mathrm{CT}}$ ). Horizontal lines indicate the spreading of negative potential at the lower side of ring $B$. Vertical lines indicate the differences in $V(\mathrm{r})$ over oxygen atoms of substituents. Oblique lines indicate the differences of $V(\mathrm{r})$ at O-5" in Z1 (b) and in Z2 (c). Dashed lines indicate changes in $V(\mathrm{r})$ at $\mathrm{O}-5$ " for type " C "(c) and "T" (d) arrangements

The positive $V(\mathrm{r})$ values on hydrogens of the $\mathrm{O} \cdots \mathrm{H}$ hydrogen bridge (belonging to the donor $\mathrm{C}-\mathrm{H}$ moiety) become more negative (lower) than the other H of the benzene ring (Figs. 5c, $6 \mathrm{a}-\mathrm{c}, 7 \mathrm{c}$ ), i.e., in $\mathrm{Z1} 1_{\mathrm{CC}}$ for $\mathrm{R}=\mathrm{OCH}_{3}$
$\Delta_{\mathrm{H} \neq 5-\mathrm{H} 5}=18.52-3.05 \mathrm{kcal} \mathrm{mol}^{-1}=15.47 \mathrm{kcal} \mathrm{mol}^{-1}$. Thus, MEP analysis suggests the formation of intramolecular $\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds. The $V(\mathrm{r})$ value on the atom that belongs to the acceptor moiety increases, while the $V(\mathrm{r})$

Fig. 6 Maps of MEP for $\mathrm{Z1}_{\mathrm{CT}}$ conformers of A-type dimeric proanthocyanidins substituted with $\mathrm{R}=\mathrm{OCH}_{3}$ (a) and $\mathrm{R}=\mathrm{OH}$ (b) (in a.u.). Circles in (a) and (b) indicate differences between $V(\mathrm{r})$ at
oxygen atoms of $\mathrm{OCH}_{3}$ and OH moieties. $\mathrm{Z2}_{\mathrm{CT}}$ rotamer with $\mathrm{R}=\mathrm{OH}$ is also shown (c). Vertical lines indicate different behavior of $V(\mathrm{r})$ at hydrogen atoms

Fig. 7 Maps of MEP for $\mathrm{Z1}_{\mathrm{CT}}(\mathbf{a}, \mathbf{b})$ and $\mathrm{Z} 2_{\mathrm{CC}}(\mathbf{c})$ conformers of A-type dimeric proanthocyanidin substituted with $\mathrm{R}=\mathrm{OCH}_{3}$ (in a.u.). Oblique lines indicate the increase of $V(\mathrm{r})$ at hydrogen atoms of the

C-3H2 moiety. Vertical lines indicate different behavior of $V(\mathrm{r})$ at hydrogen atoms of the $\mathrm{R}=\mathrm{OCH}_{3}$ substituent
conventional interactions. These interactions have been the focus of much recent research, and their discovery in organic compounds is of high interest.

Specifically, at the B3LYP/6-311++G** level of calculation, the following intermolecular hydrogen bond interactions were characterized: (1) $\mathrm{H}^{\cdots} \mathrm{O}$ type (in $\mathrm{Z1}_{\mathrm{CT}}, \mathrm{Z1}_{\mathrm{CC}}$, $\mathrm{Z} 2_{\mathrm{CT}}$ and $\mathrm{Z} 2_{\mathrm{CC}}$ conformers for $\mathrm{R}=\mathrm{OH}$, and in all conformers for $\mathrm{R}=\mathrm{OCH}_{3}$ ), and (2) dihydrogen-type, such as $\mathrm{C}-5-\mathrm{H}-5 \cdots \mathrm{H}-5^{\prime \prime}-\mathrm{O} 5^{\prime \prime}$ and $\mathrm{C}-4-\mathrm{H}-4 \cdots \mathrm{H}-5^{\prime \prime}-\mathrm{O} 5^{\prime \prime}$ (in $\mathrm{Z1}_{\mathrm{TC}}$ and $\mathrm{Z} 1_{\mathrm{TT}}, \mathrm{R}=\mathrm{OH}$ ), and $\mathrm{C}-5-\mathrm{H}-5 \cdots \mathrm{H}-5^{\prime \prime}$ (in $\mathrm{Z}_{\mathrm{TC}}$ and $\mathrm{Z}_{\mathrm{TT}}, \mathrm{R}=\mathrm{OH}$ ).

Through a detailed NBO analysis, subtle stereoelectronic aspects of fundamental importance to the understanding the stabilization and antioxidant function of these structures were described. We described the resonance of the lone pairs of both O and O 1 oxygens and concluded that substitution gives rise to a $\mathrm{C}-2-\mathrm{C}-3$ bond that is more polarized than $\mathrm{C}-3-\mathrm{C}-4$, and that polarization increases in the order $\mathrm{R}=\mathrm{H}<\mathrm{R}=\mathrm{OCH}_{3}<\mathrm{R}=\mathrm{OH}$. Furthermore, we showed that conformational changes are correlated with the relative structure stability through the hyperconjugative mechanisms described above. Stabilization mechanisms were also described in the substitution positions, being more effective when $\mathrm{R}=\mathrm{OCH}_{3}$.

This study was enriched by a deep analysis of MEP maps, which are used for predicting sites targeted for electrophilic attack in the negative $V(\mathrm{r})$ regions, and also for rationalizing other aspects of their distribution in the light of the complementarity of the different theoretical tools used herein.

All species had two, closely spaced attack sites associated with the oxygen atoms of rings C and E , where higher negative $V(\mathrm{r})$ values show that Z 1 conformers are more reactive for electrophilic attack. Accordingly, it was concluded that $\mathrm{C}-1^{\prime}-\mathrm{C}-2^{\prime}$ and $\mathrm{C}-1^{\prime}-\mathrm{C}-6^{\prime}$ bonds are more polarized in Z 1 than in Z 2 , thus correlating with the higher intensity of hyperconjugative interactions between them and those oxygen atoms. This in turn leads to the conclusion that an inductive effect, assisted by resonance, is exerted by both O and O 1 atoms, which reaches maximal intensity when each structure has the highest stabilization.

As for the substituted ring, the major reactivity of the substituent group was found at $\mathrm{C}-3^{\prime \prime}$, and thus mechanisms supporting this condition can be explained. It was also established that the substituent at C-5" exhibits hydrogen bond-type intramolecular interactions in all structures.

The possibility of distinguishing hydrogen atoms from each other according to the donor role of the bond to which they belong is also noteworthy. Similarly for oxygens, showing that the more important their donor role according to NBO analysis, the more their negative potential will decrease in absolute values.

In addition, we have shown that, in proanthocyanidins, MEP analysis allows the formation of $\mathrm{H}^{\cdots} \mathrm{O}$ intramolecular hydrogen bonds to be suggested. Another aspect that must be highlighted is the possibility of characterizing both $\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{H} \cdots \mathrm{H}$ intramolecular interactions found as weak electrostatic interactions, and to appreciate their remarkable directionality. This is of great interest, primarily in the study of non-conventional-type interactions like dihydrogen bonds, whose nature is still under discussion. The study of the effect of solvent and level of calculation on such interactions is in progress in our laboratory.

This work deepens the analysis of the stereochemistry of dimeric proanthocyanidins, describing hyperconjugative and conjugative effects associated with substituents, and the effect thereof on structure. This analysis aimed to describe a posteriori the stabilization and possible interactions with other organic molecules in a food matrix, thus enabling and validating useful analysis tools to be implemented in subsequent studies of more complex structures. Owing to the unique structural features of proanthocyanidins (presence of two prochiral carbons, and a [3.1.3]bicyclic rigid substructure), this work represents a major step in the process towards the final study of polymeric species.
