#### Abstract

Ab initio calculations have been carried out to study the substitution effect on the $\pi$ pnicogen bond in $\mathrm{ZH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{HM}\left(\mathrm{Z}=\mathrm{H}, \mathrm{H}_{3} \mathrm{C}, \mathrm{NC}, \mathrm{F} ; \mathrm{M}=\mathrm{H}, \mathrm{CH}_{3}, \mathrm{Li}\right)$ dimer, cooperative effect of the $\pi$ pnicogen bond and hydrogen bond in $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{X}=\mathrm{HO}, \mathrm{NC}, \mathrm{F} ; \mathrm{Y}=\mathrm{P}$ and As) trimer, and solvent effect on the $\pi$ pnicogen bond in $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{FH}_{2} \mathrm{P}$ $\mathrm{C}_{2} \mathrm{H}_{4}, \mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{2}$, and $\mathrm{FH}_{2}$ As- $\mathrm{C}_{2} \mathrm{H}_{4}$ dimers. The interaction energy of $\pi$ pnicogen bond increases in magnitude from $1.51 \mathrm{kcal} \mathrm{mol}^{-1}$ in $\mathrm{H}_{3} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ dimer to $-7.53 \mathrm{kcal} \mathrm{mol}^{-1}$ in $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{HLi}$ dimer at the MP2/aug-cc-pVTZ level. The $\pi$ pnicogen bond is enhanced by $12-30 \%$ due to the presence of hydrogen bond in the trimer. The $\pi$ pnicogen bond is also enhanced in solvents. The natural bond orbital analysis and symmetry adapted perturbation theory (SAPT) were used to unveil the source of substitution, cooperative, and solvent effects.

## Introduction

Intermolecular interaction plays a great role in molecular recognition, crystal engineering, and chemical reactions [1-3]. These roles are dependent to a great extent on its strength. The latter is related not only to the nature of atoms or groups participating directly in the intermolecular interactions but also with other factors such as substitution, cooperativity, and solvent effects. Due to the greater acidity, the proton of OH group in phenol forms a stronger hydrogen bond than that in water [4]. Because of the lower electronegativity of $\mathrm{N}, \mathrm{NH}_{3}$ is a stronger Lewis base than $\mathrm{H}_{2} \mathrm{O}$ in hydrogen, lithium, and halogen bonds [5-7]. Ethylene is easier to provide electrons than acetylene [8] because the electrons in the $\mathrm{sp}^{2} \mathrm{C}$ atom are more far from the atomic nucleus and the constraint on them is smaller.

The substituted groups adjoined with the atoms or groups participating directly in the intermolecular interactions have a regulating effect on the strength of intermolecular interactions [ $9-11$ ]. The electron-withdrawing groups in the Lewis acids play an enhancing role, while those in the Lewis bases have a weakening effect. The effect of electron-donating groups is reverse to that of electron-withdrawing ones. The methyl group is an interesting group and DNA methylation is an important phenomenon in biological systems [12]. Its roles in different types of intermolecular interactions have been studied systematically [13-15]. For example, in hydrogenbonded complex of dimethylsulfoxide-methanol, the methyl group in dimethylsulfoxide is electron-donating and that in methanol is electron-withdrawing, both making a positive contribution to the formation of $\mathrm{OH} \cdots \mathrm{O}$ hydrogen bond [13].

The cooperativity is one of the most important properties of molecular interactions in biological systems [16] and molecular self-assembly [17]. Often binding of one molecule can enhance or reduce its affinity to bind subsequent
molecules. Such effects are in general referred to as "cooperativity". Because of its biological and chemical importance, cooperative effect has for a long time been attracting attention. A review for the cooperativity of intermolecular interactions has been presented by Alkorta et al. [18]. Many studies have been performed for cooperative effects in systems where two or more non-covalent interactions coexist [19-23]. The cooperativity in hydrogen bonding or $\sigma$-hole interactions is mainly induced by the polarization effect of the positive region by the negative site with which it is interacting [24, 25].

Solvent also has a prominent effect on the strength of intermolecular interactions. Its effect is different for different systems. The interactions in systems including ions and some stronger interactions may be weakened with the increase of solvent polarity [26-28]. An enhancing effect could occur for some weaker interactions [29]. The solvent effect can be studied by employing continuum models as well as molecular dynamics and Monte Carlo techniques.

It has been demonstrated that some group V molecules $\mathrm{R}_{3} \mathrm{X}$ can interact with nucleophiles through the regions of positive electrostatic potentials found on their outer surfaces along the extensions of the R-X bonds [30]. Such interactions fall under the umbrella of $\sigma$-hole interactions, which are formed between the regions of positive electrostatic potentials found on covalently-bonded group IV-VII atoms and negative sites [31]. The tunability has been studied for $\sigma$-holes found on covalently-bonded group IV-VII atoms [32]. This is particularly notable for atoms which have more than one $\sigma$-hole [33]; how positive a $\sigma$-hole is can be altered by changing the substituent whose formation causes the $\sigma$-hole [34].

Recently, pnicogen bonding has been recognized as a new type of intermolecular interaction, which occurs between the pnicogen atom and the Lewis base site in another molecule. This interaction was proposed in a series of $\mathrm{P} \cdots \mathrm{P}$ complexes by Hey-Hawkins et al. [35]. They also studied a $\mathrm{P} \cdots \mathrm{N}$ interaction in an aminoalkyl- ferrocenyldichlorophosphane [36]. Other authors also focused their attention on this interaction [37-43]. This interaction has some similar properties with hydrogen and halogen bonds, but it shows some peculiar characteristics. Unlike halogen bonds, there is no requirement of a $\sigma$-hole of positive electrostatic potential on the P atom, nor is it necessary for the two interacting atoms to be of differing potential [38]. It should be noted that the electrostatic effects play an important role for the pnicogen bonding donor $\mathrm{FH}_{2} \mathrm{P}$ studied in the present paper. In contrast to hydrogen bonds, the pertinent hydrogen is oriented away from, instead of toward, the N in $\mathrm{H}_{3} \mathrm{P}-\mathrm{NH}_{3}$ dimer, and the N lone pair overlaps with the lobe of the $\mathrm{P}-\mathrm{H}$ anti-bonding orbital [38]. In these studies of pnicogen bonds, the lone pair electrons in the Lewis bases bind with the pnicogen atoms. Given the ability of $\pi$ electrons to form a hydrogen bond, they also form a $\pi$ pnicogen bond with ethylene, acetylene, and benzene [41].

In this paper, we will study a series of $\pi$ pnicogen bonded complexes involving ethylene and acetylene. $\mathrm{FH}_{2} \mathrm{P}$ was selected as the pnicogen bonding donor because of its stronger binding with lone pair electrons [39]. For comparison with $\mathrm{FH}_{2} \mathrm{P}$, the $\mathrm{FH}_{2} \mathrm{As}$ counterpart was also studied considering that $\mathrm{FH}_{2} \mathrm{As}$ shows a positive region of electrostatic potential on the extension of the F-As bond [44]. Our aims are (1) to determine the structures, binding energies, and bonding characteristics of these complexes, (2) to examine the effect of substituents on the $\pi$ pnicogen bonds, (3) to character the cooperative effect between the $\pi$ pnicogen and hydrogen bonds, and (4) to study the solvent effect on $\pi$ pnicogen bonds. We also performed an analysis for these complexes with natural bond orbital (NBO) and symmetryadapted perturbation theory (SAPT) methods.

## Theoretical methods

All complexes and the respective monomers have been optimized at the MP2/aug-cc-pVTZ level. Frequency calculations at the same level were carried out to confirm that the optimized structures are local minima on their potential surfaces. The frozen core (FC) approximation was applied in all calculations. All calculations were performed using Gaussian 09 program [45]. The interaction energy was calculated as a difference by subtracting the energy sum of the monomers from the total energy of the complex. The basis set superposition error (BSSE) was calculated with the counterpoise method of Boys and Bernardi [46] to correct the interaction energy. A singlepoint calculation was also performed at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-ccpVTZ level on the MP2/aug-cc-pVTZ geometry.

The $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$, and $\mathrm{FH}_{2} \mathrm{As}$ $\mathrm{C}_{2} \mathrm{H}_{4}$ complexes were optimized with a polarized continuum model (PCM) [47] at the MP2/aug-cc-pVTZ level. Natural bond orbital (NBO) analysis [48] was performed via the procedures within Gaussian 09. The interaction energy was decomposed with the symmetry adapted perturbation theory (SAPT) method using the SAPT2002 program [49]. The electrostatic potentials at the 0.001 electrons $\mathrm{Bohr}^{-3}$ isodensity surfaces were calculated at the MP2/aug-cc-pVTZ level with WFA surface analysis suite [50].

## Results and discussion

Substitution effect

It has been evidenced that the $\pi$ systems of the various unsaturated hydrocarbon molecules $\left(\mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{C}_{2} \mathrm{H}_{4}\right.$, and $\mathrm{C}_{6} \mathrm{H}_{6}$ ) can serve as electron donors in $\pi$ pnicogen bonds [41] and the strength of $\mathrm{P} \cdots \mathrm{N}$ pnicogen bond is affected greatly by substituents [39]. Thus we want to know if a
similar substitution effect is also present for $\pi$ pnicogen bonds. Figure 1 shows the optimized structures of $\mathrm{ZH}_{2} \mathrm{P}$ $\mathrm{C}_{2} \mathrm{HM}\left(\mathrm{Z}=\mathrm{H}, \mathrm{H}_{3} \mathrm{C}, \mathrm{NC}, \mathrm{F} ; \mathrm{M}=\mathrm{H}, \mathrm{CH}_{3}, \mathrm{Li}\right)$ dimers. The structures are all rather similar, with the $\mathrm{P}-\mathrm{Z}$ bond swung around away from the source of electrons. Their formation can be understood with electrostatic potentials of $\mathrm{FH}_{2} \mathrm{P}$ and $\mathrm{FH}_{2}$ As shown in Fig. 2. It is found that the positive $\sigma$-holes on the extensions of the F-P and F-As bonds are more positive than those on the extensions of the H-P and H-As bonds. Some of the most important properties of these complexes are summarized in Table 1. The P atom is almost perpendicular to the C atom of the triple bonded $\mathrm{HC} \equiv \mathrm{CH}$ in $\mathrm{NCH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ complex. It is turned to the C-H bond in $\mathrm{H}_{3} \mathrm{P}-$ $\mathrm{C}_{2} \mathrm{H}_{2}$ and $\left(\mathrm{H}_{3} \mathrm{C}\right) \mathrm{H}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ complexes and deflects to the $\mathrm{C} \equiv \mathrm{C}$ bond in other complexes. The two free H atoms in $\mathrm{ZH}_{2} \mathrm{P}$ are located at the same side with the triple bond. The $\mathrm{P}-\mathrm{Z}$ covalent bond is in a line with the C atom in $\mathrm{FH}_{2} \mathrm{P}-$ $\mathrm{C}_{2} \mathrm{HLi}$ complex and is turned away from the $\mathrm{P} \cdots \mathrm{C}$ axis by 166.8-177.6 ${ }^{\circ}$.

The counterpoise-corrected interaction energies span the range of $-1.51 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{H}_{3} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ complex up to

Fig. 2 Electrostatic potentials on the molecular surfaces of $\mathrm{FH}_{2} \mathrm{P}$ and $\mathrm{FH}_{2} \mathrm{As}$ molecules color ranges, in eV , are: red, greater than 004; yellow, between 004 and 002 ; green, between 002 and -001 ; blue, less than -001

$-7.53 \mathrm{kcal} \mathrm{mol}^{-1}$ for $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{HLi}$ complex. They are arranged from up to down in order of increasingly negative in Table 1. It shows that the methyl group in the P subunit slightly strengthens the interaction with respect to an H atom, while the F substituent in the P subunit greatly enhances it. It is also expected that the enhancing effect of the nitro group is greater than that from the F atom in the $\pi$ pnicogen bond like in the $\mathrm{P} \cdots \mathrm{N}$ pnicogen bonds [39]. The methyl group in the electron donor also strengthens the $\pi$ pnicogen bond and its enhancing effect is better than that in the P subunit. The methyl effect here is similar to that in $\mathrm{OH} \cdots$ O hydrogen bond between dimethyl ether and methanol [51]. Surprisingly, the interaction energy amounts to $-7.53 \mathrm{kcal} \mathrm{mol}^{-1}$ due to the Li substitution in the electron donor. It is about double as much as that in $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ complex. The prominent effect of alkali metal was also observed in halogen bonds [52]. The $\pi$ pnicogen bond is stronger in the As complex than in the P analog due to the larger positive electrostatic potential on the As surface shown in Table 2. Ethylene forms a stronger $\pi$ pnicogen bond than acetylene as expected.

Zero-point vibrational energies (ZPE) are added to the MP2/aug-cc-pVTZ values in the parentheses of Table 1. They result in a general reduction in the interaction energy by an amount of $0.91-1.92 \mathrm{kcal} \mathrm{mol}^{-1}$. It is shown that ZPE has a prominent effect on the stability of the complexes. The $\mathrm{H}_{3} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ complex has a positive energy. Even so, the stability of the complexes has an unchanged trend from one substituent to the next.

To ensure that the MP2 interaction energies are reliable, computations were also performed with the $\operatorname{CCSD}(\mathrm{T})$ method.

Table 1 Interaction energies $\left(\Delta E^{\mathrm{CP}}, \mathrm{kcal} \mathrm{mol}^{-1}\right)$ corrected for BSSE, binding distance $(R, \AA)$, change of $\mathrm{P}-\mathrm{Z}$ and As-F bond lengths $(\Delta r, \AA)$, bond angles ( $\alpha$ and $\beta$, degree), and shift of P-Z and As-F stretch

| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{HH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ | $-151(022)$ | -113 | 3424 | 0002 | 1668 | 989 | -18 |
| $\left(\mathrm{H}_{3} \mathrm{C}\right) \mathrm{H}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ | $-157(-010)$ | -120 | 3394 | -0000 | 1704 | 1049 | 2 |
| $\left({\mathrm{NC}) \mathrm{H}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}}^{\mathrm{HH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}}\right.$ | $-267(-105)$ | -209 | 3264 | 0005 | 1709 | 880 | -9 |
| $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{HCH}_{3}$ | $-362(-170)$ | -286 | 3017 | 0007 | 1776 | 859 | -19 |
| $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2} \mathrm{Li}$ | $-453(-362)$ | -359 | 2962 | 0010 | 1750 | 849 | -30 |
| $\mathrm{FH}_{2}{\mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{2}}^{\mathrm{HH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}}$ | $-753(-636)$ | -643 | 2835 | 0028 | 1798 | 831 | -75 |
| $\mathrm{FH}_{2}{\mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}}$ | $-403(-213)$ | -313 | 3013 | 0011 | 1764 | 837 | -22 |

Note: The interaction energies in parentheses are also corrected with zero-point vibrational energy (ZPE). The $\Delta E_{\operatorname{CCSD}(\mathrm{T})}$ was obtained with a single-point calculation at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level on the MP2/aug-cc-pVTZ geometry

The $\Delta E_{\mathrm{CCSD}(\mathrm{T})}$ value was obtained with a single-point calculation at the $\operatorname{CCSD}(\mathrm{T}) /$ aug-cc-pVTZ level on the MP2/aug-ccpVTZ geometry. As expected, the MP2 method overestimates the interaction energy relative to the $\operatorname{CCSD}(\mathrm{T})$ one. The reduced percentage in the interaction energy is in a range of $15-25 \%$ and becomes smaller for the stronger interaction.

The binding distance $R$ in Table 1 is the distance between the P atom in $\mathrm{ZH}_{2} \mathrm{P}$ and the C atom in $\mathrm{C}_{2} \mathrm{HM}$ as shown in Fig. 1. It is decreased from $3.424 \AA$ in $\mathrm{H}_{3} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ complex to $2.835 \AA$ in $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{HLi}$ complex. This is consistent with the interaction energy. Upon complexation, the P-Z bond is elongated and the respective stretch exhibits a red shift in most complexes. NBO analysis shows that there is an orbital interaction between the $\mathrm{C} \equiv \mathrm{C}$ bonding orbital and the anti-bonding P-Z orbital. The charge is transferred from the former to the latter. This accumulation of density in the antibonding orbital is responsible for the weakening of the $\mathrm{P}-\mathrm{Z}$ bond.

As seen from Table 3, the NPA charge on Z is negative, while that on M is positive. The complexation leads to an increase for both the former and the latter. This means that Z is electron-withdrawing but M is electron-donating. The $\Delta q_{\mathrm{CH} 3}$ in the pnicogen donor is larger in magnitude than the $\Delta q_{\mathrm{CH} 3}$ in the pnicogen acceptor. This is not consistent

Table 2 The most positive electrostatic potentials $\left(\mathrm{V}_{\text {max }}, \mathrm{kcal} \mathrm{mol}^{-1}\right)$ on the Y atom in $\mathrm{FH}_{2} \mathrm{Y}$ ( $\mathrm{Y}=\mathrm{P}$ and As ) monomer and its dimer $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{Y}$ ( $\mathrm{X}=\mathrm{HO}, \mathrm{NC}$, and F ) calculated at the MP2/ aug-cc-pVTZ level

|  | $\mathrm{V}_{\mathrm{s}, \max }$ |
| :--- | :---: |

vibrations $\left(\Delta v, \mathrm{~cm}^{-1}\right)$ in the $\mathrm{ZH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{HM}\left(\mathrm{Z}=\mathrm{H}, \mathrm{H}_{3} \mathrm{C}, \mathrm{NC}, \mathrm{F} ; \mathrm{M}=\mathrm{H}\right.$, $\left.\mathrm{CH}_{3}, \mathrm{Li}\right), \mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$, and $\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimers
with the size of their contribution in the formation of pnicogen bond.

For understanding the source of stability, we performed energy decomposition for these complexes. The SAPT components are presented in Table 4. The various terms follow the same trend as the total interaction energy except in $\left(\mathrm{H}_{3} \mathrm{C}\right) \mathrm{H}_{2} \mathrm{P}-$ $\mathrm{C}_{2} \mathrm{H}_{2}$ complex. In this complex, the electrostatic contribution is a little smaller than the dispersion one, while in other complexes, the former is larger than the latter. The induction contribution is very small for $\mathrm{Z}=\mathrm{H}, \mathrm{H}_{3} \mathrm{C}$, and NC and becomes larger for $\mathrm{Z}=\mathrm{F}$. In all complexes, it is smaller than the electrostatic and dispersion terms. The methyl substituent in the electron donor leads to an increase in magnitude for all terms, while the reverse result is observed for the methyl substitution in the electron acceptor. The former brings out a more prominent effect on each term than the latter. The Li substituent in the electron donor causes a big increase for each term and its increased percentage climbs in magnitude from

the dispersion term to the electrostatic term, and then to the induction term. A similar sequence is also found for the F substituent in the electron acceptor.

## Cooperative effect

We also optimized the $\pi$ pnicogen bond dimer of $\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{4}$ ( $\mathrm{Y}=\mathrm{P}$ and As) shown in Fig. 1 and then combined it with XH ( $\mathrm{X}=\mathrm{HO}, \mathrm{NC}, \mathrm{F}$ ) through a $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond. Figure 3 shows the optimized structure of $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{4}$ trimer. Its energetic parameters are collected in Table 5. The total interaction energy varies from $-7.42 \mathrm{kcal} \mathrm{mol}{ }^{-1}$ in $\mathrm{HOH}-\mathrm{FH}_{2} \mathrm{P}-$ $\mathrm{C}_{2} \mathrm{H}_{4}$ trimer to $-11.51 \mathrm{kcal} \mathrm{mol}^{-1}$ in $\mathrm{FH}-\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}$ trimer. The $\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimer is more stable than the $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimer. This is similar to that in $\mathrm{H}_{3} \mathrm{P}-\mathrm{NH}_{3}$ and $\mathrm{H}_{3} \mathrm{As}-\mathrm{NH}_{3}$ dimers [53]. The hydrogen bond is stronger in $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{As}$ dimer than in $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{P}$ one due to the smaller electronegativity of As element.

One sees from Table 5 that the addition of the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond to the $\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimer leads to a stronger $\pi$ pnicogen bond. Similarly, the presence of the $\pi$ pnicogen bond strengthens the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond inXH- $\mathrm{FH}_{2} \mathrm{Y}$ dimer. The enhancement of the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond is larger than that of the $\pi$ pnicogen bond. The stronger $\pi$ pnicogen bond has a greater enhancing effect on itself and the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond, while the stronger $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond also has a similar effect. This shows that the $\pi$ pnicogen bond can interplay with the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond. The cooperative effect can be estimated with the cooperative energy. This term is calculated to be the difference between the total interaction energy in the trimer and the sum of the interaction energies for the $\pi$ pnicogen bond and $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond in the respective dimers. It is negative, indicating that both interactions have a positive cooperative effect. This value becomes larger for the stronger $\pi$ pnicogen bond and $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond. This effect is smaller than that between the halogen bond and hydrogen bond in $\mathrm{H}_{3} \mathrm{~N}-\mathrm{XY}-$

HF ( $\mathrm{X}, \mathrm{Y}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$ ) trimer [19]. A similar cooperative effect is also found in $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{X}=\mathrm{HO}$ and $\mathrm{F} ; \mathrm{Y}=$ P and As) and $\mathrm{NCH}-\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{2}$ trimers shown in Table 5. However, the NCH- $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}$ trimer shows a cyclic structure (Fig. S1), which is different from the NCH-FH2 $\mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$ trimer. In this complex, the interaction energies of pnicogen and hydrogen bonds are decreased and a positive cooperative energy is thus found.

The cooperativity between the $\pi$ pnicogen bond and $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond can also be reflected in the geometrical and spectroscopic changes. Table 6 presents the binding distances of the $\pi$ pnicogen bond and $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond in the complexes as well as their changes in the trimers relative to the dimers. Due to the stronger interaction, the binding distance of the $\pi$ pnicogen bond is shorter in $\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimer than in $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimer although the

As atom has a bigger atomic radius. The binding distance of the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond is also consistent with the interaction strength in the dimer. It can be seen that both types of the binding distances are shorter in the trimers, indicating that both interactions enhanced each other.

The change ( $\Delta r$ ) of Y-F and X-H bond lengths are given in Table 7. The associated Y-F bond is lengthened in XH$\mathrm{FH}_{2} \mathrm{Y}$ dimer, while the free one is also elongated in $\mathrm{FH}_{2} \mathrm{Y}-$ $\mathrm{C}_{2} \mathrm{H}_{4}$ dimer. The elongation of Y-F bond is larger in the former than in the latter. The $\Delta r_{Y-\mathrm{F}}$ is $0.009 \AA$ in $\mathrm{FH}_{2} \mathrm{P}$ $\mathrm{C}_{2} \mathrm{H}_{4}$ dimer and $0.015 \AA$ in $\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimer. One can see that the $\Delta r_{\mathrm{Y}-\mathrm{F}}$ in the trimer is larger than the sum of $\Delta r_{\mathrm{Y}-\mathrm{F}}$ in the respective dimers. For example, it is $0.028 \AA$ in $\mathrm{HOH}-$ $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$ trimer and the sum is $0.024 \AA$ for $\mathrm{HOH}-\mathrm{FH}_{2} \mathrm{P}$ and $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimers. This is because the Y-F bond elongation is a combinative result of the $\pi$ pnicogen bond and $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond in the trimers. The X-H bond is also elongated in the trimer and dimer, and its elongation is also larger in the trimer. The red shift of the respective bond stretch frequency also shows a similar change.

The interaction energies of the $\pi$ pnicogen bond and $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond in the trimers were decomposed into four terms: electrostatic energy, exchanged energy, induction

Table 6 Binding distance of pnicogen bond $\left(R_{1}\right)$ and hydrogen bond $\left(R_{2}\right)$ as well as their change $(\Delta R)$ in the $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{X}=\mathrm{HO}, \mathrm{NC}$, $\mathrm{F} ; \mathrm{Y}=\mathrm{P}$ and As) trimers All are in $\AA$

[^1]energy, and dispersion energy. It can be seen from Table 8 that all terms are increased in the trimers relative to the respective dimers. They have a larger increase in magnitude in the $\pi$ pnicogen bond than in the $\mathrm{H} \cdots \mathrm{F}$ hydrogen bond. However, their increased percentage has some difference in different trimers. For the $\pi$ pnicogen bond, it increases in order of dispersion energy<electrostatic energy<induction energy. A similar order is also found for the hydrogen bond in the $\mathrm{H}_{2} \mathrm{O}$ trimer. For the hydrogen bond in other trimers, however, the electrostatic energy has the largest increased percentage, followed by the induction energy, and the dispersion energy shows the smallest increased percentage. The interaction of XH and $\mathrm{F}_{2} \mathrm{HY}$ results in an increase of the most positive electrostatic potential on the Y atom surface given in Table 2, indicating that the electrostatic interaction is important in the enhancement of $\pi$ pnicogen bond in the trimer.

effect on the $\pi$ pnicogen bond. Calculations in solution were performed via the standard polarizable continuum model (PCM) [47] at the MP2/aug-cc-pVTZ level in two media with dielectric constants, 1.9 (heptane) and 4.9 (chloroform). The energetic, geometrical, and spectroscopic data are collected in Table 9. With the increase of dielectric constants, the binding distance is shorter, the elongation of F-P and F-As bonds is larger, and the red shift of F-P and F-As stretch vibrations is increased. These results show that the $\pi$ pnicogen bond becomes stronger in solvent. However, the interaction energy in solution calculated with a similar method like in gas phase is decreased with the increase of dielectric constants. This is not consistent with the geometrical and

Table 9 The interaction energy ( $\Delta E^{\mathrm{CP}}$, kcal mol ${ }^{-1}$ ) corrected for BSSE, binding distance ( $R, \AA$ ), change of P-F and As-F bond lengths ( $\Delta r, \AA$ ), and frequency shift of P-F and As-F stretch vibrations $(\Delta v$, $\mathrm{cm}^{-1}$ ) for $\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{2}, \mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}, \mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{2}$, and $\mathrm{FH}_{2} \mathrm{As}-\mathrm{C}_{2} \mathrm{H}_{4}$ dimers in different media

spectroscopic data in solution. Such inconsistency in solution has been reported before [54]. Thus we calculated the interaction energy in solution by subtracting the energy sum of the monomers from the energy of dimer with all of them frozen in the geometry in solution. One sees from Table 9 that it becomes more negative in solution although the change is small, supporting the stronger $\pi$ pnicogen bond in solvents. Additionally, this can also be evidenced by the strength of the $\pi$ pnicogen bond in the $\mathrm{HOH}-\mathrm{FH}_{2} \mathrm{P}-\mathrm{C}_{2} \mathrm{H}_{4}$ and $\mathrm{HOH}-\mathrm{FH}_{2} \mathrm{As}$ $\mathrm{C}_{2} \mathrm{H}_{4}$ trimers.

## Conclusions

Quantum chemical calculations have been performed to study the substitution, cooperative, and solvent effects on the $\pi$ pnicogen bond at the MP2/aug-cc-pVTZ level. The methyl group in the electron donor exhibits a bigger contribution to the $\pi$ pnicogen bond than that in the electron acceptor. The electron-withdrawing group F in the electron acceptor leads to a larger increase in the strength of $\pi$ pnicogen bond. A similar big enhancing effect is from the Li group in the electron donor. The $\pi$ pnicogen bond can interplay with the hydrogen bond in the $\mathrm{XH}-\mathrm{FH}_{2} \mathrm{Y}-\mathrm{C}_{2} \mathrm{H}_{4}$ ( $\mathrm{X}=\mathrm{HO}, \mathrm{NC}, \mathrm{F} ; \mathrm{Y}=\mathrm{P}$ and As) trimer and both types of interactions enhanced each other. In solvent, the $\pi$ pnicogen bond is also strengthened. Although it has been shown that trivalent phosphines are a common structural and enzymatic element in inorganic systems [55-57], their interaction with unsaturated hydrocarbon molecules might be important in organic systems because they are often used to synthesize some organophosphorous and organoarsenic compounds.
