SPECTROSCOPIC STUDIES OF BRUSATOL<br>Yoshihiro Harigaya,* Yaeko Konda, Mieko Iguchi, Masayuki Onda,<br>School of Pharmaceutical Sciences, Kitasato University, Minato-ku, Tokyo 108, Japan<br>Xian Li,* Lijun Wu, Shaoshun Li, and Xuelong Sun<br>Shenyang College of Pharmary, Wenhua-lu, Shenyang, China

#### Abstract

The absolute stereochemistry of brusatol has been confirmed to be $5 S, 7 R$, $8 R, 9 R, 10 S, 11 R, 12 S, 13 S, 14 S, 15 R$ by a combination of $2 \mathrm{D} \mathrm{nmr}\left[{ }^{1} \mathrm{H}-{ }^{-1} \mathrm{H}\right.$ and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ (onebond and long-range) COSY , nOe, and cd spectroscopic analyses.

In our studies on biologically active natural products, an antitumor quassinoid, brusatol [1], was recently isolated from the traditional Chinese medicine "Yandanzi," Brucea javanica (L.) Merr (Simaroubaceae) (1). Sim et al. (2) had previously reported that 1 was a bitter principle of Brucea sumatrana and that $2^{\prime}, 3^{\prime}$-dihydrobrusatol, which was obtained by the hydrogenation of $\mathbf{1}$, was identical with bruceine $A[2]$. It is known that bruceines A [2], B [3], and C [4], bruceantarin [5], bruceantin [6], and bruceantiol [7] are the $\mathrm{C}_{20}$ quassinoids with the same basic skeleton as that of $\mathbf{1}$ and only differ in the nature of 15 -ester grouping (3-7). The absolute stereochemistry of bruceine C [4] was elucidated on the basis of X-ray analysis of its tetraacetate by Polonsky et al. (7). Thus, the absolute stereochemistry of the basic skeleton of these quassinoids was assumed to be the same as that of 4 . This paper is concerned with an approach to the absolute stereochemistry of $\mathbf{1}$ by a combination of high-resolution ( ${ }^{1} \mathrm{H}, 400 \mathrm{MHz} ;{ }^{13} \mathrm{C}$, 100.6 MHz ) nmr and cd spectroscopic analyses.

## RESULTS AND DISCUSSION

Nmr spectroscopy.-The nmr spectra were taken in pyridine- $d_{5}$ unless otherwise cited. Because the resonances of $\mathrm{H}-15$ and $\mathrm{C}-14$ were obscured at ambient temperature and those of $\mathrm{H}-5, \mathrm{H}-14, \mathrm{C}-5$, and $\mathrm{C}-15$ were slightly broad, the spectra were measured at $50^{\circ}$.

The 1 Dnmr spectra showed the number of hydrogens (except three hydroxyls) and carbons corresponding to the molecular formula $\mathrm{C}_{26} \mathrm{H}_{32} \mathrm{O}_{11}$ of $\mathbf{1}$. The number of hydrogens attached to each individual carbon was determined by DEPT experiments: five methyls, three methylenes, eight methines, and ten quaternary carbons. Hydroxyls (exchangeable with $\mathrm{D}_{2} \mathrm{O}$ ) were examined in DMSO- $d_{6}$. Several protons ( $\mathrm{H}-1 \alpha$ and H 9, $\mathrm{H}-7$ and $\mathrm{H}_{\mathrm{B}}-20, \mathrm{H}-14$ and $\mathrm{H}_{\mathrm{A}}-20$ ) that displayed close or overlapping resonances in pyridine- $d_{5}$ showed more separated resonances for each pair in DMSO- $d_{6}$.

The ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$, one-bond ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$, and long-range ${ }^{1} \mathrm{H}^{-13} \mathrm{C}$ COSY spectra are shown in Figures $1-3$, respectively, and the spectral parameters including ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ coupling constants are given in Table 1. The 2D nmr spectra of 1 are published by us for the first time. The assignments of ring protons (in part) for $\mathbf{1}$ (2), 2 (5), $\mathbf{3}(5,6)$, and $\mathbf{6}$ (7) were made on the basis of the comparison with those for related quassinoids and the application of the empirical rules. The assignments of carbons for 3 (8), $\mathbf{4}$ (8), and 6 (9) have been previously reported, but it was found that there are large discrepancies in the carbon resonances at $\mathrm{C}-8(-3.1 \mathrm{ppm}), \mathrm{C}-9(2.5 \mathrm{ppm}), \mathrm{C}-10(5.8 \mathrm{ppm})$, and $\mathrm{C}-15$ (2.8 ppm ) between ours and those cited above.

Each proton and carbon belonging to protonated carbons was readily associated with each orher by the ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ (one-bond) COSY spectrum. Therefore, the assignments of these carbons were straightforward from the proton assignments which were achieved as follows.

Figure 1. ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum of brusatol [1].

Three methyls (vinylic) were easily distinguished. A coupling was observed between $\mathrm{H}_{3}-19$ and $\mathrm{H}-5$ by decoupling experiments. The correlation of $\mathrm{H}_{3}-4^{\prime}$ and $\mathrm{H}_{3}-5^{\prime}$ with $\mathrm{H}-2^{\prime}$ (vinylic), which was assigned on the basis of its proton and carbon chemical shifts, was shown by the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ (long-range) COSY spectra. These two methyls were differentiated by nOe experiments: $\mathrm{H}-2^{\prime} \longleftrightarrow \mathrm{Me}-4^{\prime}$. The distinction between two methyls, $\mathrm{H}_{3}-18$ (angular) and $\mathrm{H}_{3}-23$ (OMe), was straightforward on the basis of their proton and carbon chemical shifts. Decoupling experiments showed that one methylene, $\mathrm{H}_{2}-6$, constitutes the spin system, $\mathrm{H}-5-\mathrm{H}_{2}-6-\mathrm{H}-7$, including $\mathrm{H}-5$ coupled to $\mathrm{H}_{3}-19$. Two methylenes, $\mathrm{H}_{2}-1$ and $\mathrm{H}_{2}-20$, were readily identified by the observation of correlation of $\mathrm{H}-1 \alpha$ and $\mathrm{H}_{\mathrm{A}}-20$ with $\mathrm{H}_{3}-18$ and $\mathrm{H}-9$, respectively ( ${ }^{1} \mathrm{H}-$ ${ }^{1} \mathrm{H}$ and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ ). Decoupling experiments indicated that $\mathrm{H}-11$ containing a geminal hydroxyl is vicinally coupled to $\mathrm{H}-9$ (decoupling) which is correlated to $\mathrm{H}_{\mathrm{A}}-20\left({ }^{1} \mathrm{H}\right.$ ${ }^{1} \mathrm{H}$ ) and $\mathrm{H}_{2}-1, \mathrm{H}-7, \mathrm{H}_{3}-18$, and $\mathrm{H}_{\mathrm{B}}-20\left({ }^{1} \mathrm{H}_{-}{ }^{13} \mathrm{C}\right)$. Two methines with oxygen groupings, $\mathrm{H}-12$ and $\mathrm{H}-15$, were unambiguously assigned: $\mathrm{H}-12$ was related to $\mathrm{H}-11\left({ }^{1} \mathrm{H}-\right.$ ${ }^{1} \mathrm{H}$ and ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ ) and $\mathrm{H}-14\left({ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}\right)$; $\mathrm{H}-15$ was vicinally coupled to $\mathrm{H}-14$ (decoupling). The assignments of three hydroxyls were readily made by the ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY spectrum

Figure 2. ${ }^{1} \mathrm{H}_{-}{ }^{13} \mathrm{C}$ (one-bond) COSY spectrum of brusatol [1].
taken in DMSO- $d_{6}$. Quaternary carbons were completely assigned by the ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ (longrange) COSY spectrum as well as their chemical shifts.

The relarive stereochemistry and ring conformation were established by nOe (Table 2 ) and decoupling experiments. 13,20-Epoxy grouping sterically required $8 \beta$ (ax)-C20 and $13 \beta$ (ax)-O-21 [13 (eq)-COOMe $]^{1}$ with respect to $C$ ring regardless of its conformation. Irradiation of $\mathrm{H}-9$ (DMSO- $d_{6}$ ) gave nOe's at $12-\mathrm{OH}$ and $\mathrm{H}-15$, leading to $\mathrm{H}-9 \alpha(\mathrm{ax}), 12 \alpha(\mathrm{ax})-\mathrm{OH}[\mathrm{H}-12 \beta$ (eq)] and $14 \alpha(\mathrm{ax})-\mathrm{C}-15[\mathrm{H}-14 \beta$ (eq)] with respect to $C$ ring with a chair form. As a result, the $B / C$ trans and $C / D$ cis ring junctures were established as shown in structural fragment $\mathbf{A}$. An nOe observed between $\mathrm{H}-9 \boldsymbol{\alpha}$ and $\mathrm{H}-$ 11 and a coupling constant, $J_{9,11}=4.5 \mathrm{~Hz}$, suggested $\mathrm{H}-11 \alpha(\mathrm{eq})$ and $11 \beta$ (ax) OH . The lack of a coupling constant between $\mathrm{H}-11 \alpha$ and $\mathrm{H}-12 \beta$ (dihedral angle ca. $90^{\circ}$ ) suggested the slight deformation of $C$ ring to relieve the strain caused by two $\alpha$ (axial) and three $\beta$ (axial) substituents.

NOe's observed between $\mathrm{H}-6$ ( $\delta$ 1.652) and $\mathrm{H}_{3}-18$ and between $\mathrm{H}_{3}-18$ and $\mathrm{H}_{\mathrm{B}}-20$ ( $\delta 4.955$ ) led to $\mathrm{H}-6 \beta(\mathrm{ax})(\delta 1.652), 8 \beta$ (ax)-C-20, and $10 \beta$ ( ax )-Me- 18 with respect to B ring with a chair form. An nOe observed between H-7 and $\mathrm{H}_{\mathrm{A}}-20$ (DMSO- $d_{6}$ ) and
${ }^{1} \alpha$ and $\beta$ notations are tentatively used until the absolute stereochemistry is made clear.

Figure 3. ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ (long-range) COSY spectrum of brusatol [1].
coupling constants $J_{6 \alpha, 7}=J_{6 \beta, 7}=2.5 \mathrm{~Hz}$ suggested $\mathrm{H}-7 \beta$ (eq) with respect to B ring and the B/D cis ring juncture. Saturation of H-5 afforded nOe's at H-1 ( $\delta 2.395$ ) and $\mathrm{H}-9 \alpha$, leading to $\mathrm{H}-1 \alpha(\mathrm{ax})(\delta 2.395), \mathrm{H}-5 \alpha(\mathrm{ax})$, and $\mathrm{H}-9 \alpha(\mathrm{ax})$ with respect to A ring and/or $B$ ring and the $A / B$ trans juncture. A coupling constant, $J_{5,6 \beta}=13.0 \mathrm{~Hz}$, was in accord with $\mathrm{H}-5 \alpha(\mathrm{ax})$. At this stage, the A ring conformation cannot be distinguished among an envelope, a half-boat, and a half-chair form.

It is known that $\delta$ lactones adopt a half-chair or a half-boat form with a planar C -$\mathrm{C}(=\mathrm{O})$-O-C grouping (10). A Dreiding model showed that a half-boat form of the D ring remarkably lengthens the distance between $\mathrm{C}-20$ and $\mathrm{O}-21$, and as a result, the formation of an ether bridge between C-13 and C-20 sterically becomes impossible. Thus, it was considered that the D ring adopts a strain-free half-chair form. NOe's observed among $\mathrm{H}-9 \alpha, 12 \alpha-\mathrm{OH}$, and $\mathrm{H}-15$ and a coupling constant, $J_{14,15}=13.0 \mathrm{~Hz}$, led to $\mathrm{H}-15 \alpha$ (ax) and $15 \beta$ (eq)-O-seneciate with respect to the D ring. Further evidence supporting the $\mathrm{B} / \mathrm{D}$ and $\mathrm{C} / \mathrm{D}$ cis ring junctures was obtained by the observation of nOe's at $\mathrm{H}-14 \beta$ and $\mathrm{H}_{\mathrm{A}}-20$ on saturation of $\mathrm{H}-7 \beta$ (DMSO- $d_{6}$ ).

The Dreiding model $1 \mathbf{1 a}^{2}$ based on the data above clearly accounts for the additional data presented in Tables 1 and 2.

${ }^{\text {a }}$ The spectra were taken on a Varian XL- $400\left({ }^{1} \mathrm{H}, 400 \mathrm{MHz} ;{ }^{13} \mathrm{C}, 100.6 \mathrm{MHz}\right)$ in pyridine- $d_{5} ;$ ppm.
${ }^{b}$ These data were obtained by ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ COSY experiments.
${ }^{c}$ These data were obtained by ${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY experiments; the data in parentheses were additionally obtained in DMSO- $d_{6}$.
${ }^{\mathrm{d}}$ The data in parentheses were obtained in DMSO- $d_{6}$. Coupling constants $(\mathrm{Hz})$ were as follows: $J_{1 \alpha, \beta}=$ $16.0, J_{5,6 \alpha}=2.5, J_{5,6 \beta}=13.0, J_{5,19}=1.3, J_{6 \alpha, \beta}=14.5, J_{6 \alpha, 7}=J_{6 \beta, 7}=2.5, J_{9,11}=4.0, J_{14,15}=$ $13.0, J_{20 \mathrm{~A}, \mathrm{~B}}=7.3,\left(J_{11,11-\mathrm{OH}}=J_{12,12-\mathrm{OH}}=4.7\right)$.

CD SPECTROSCOPY.-The absolute stereochemistry was examined by means of cd spectroscopy. It is well known that the cd spectra of $\alpha, \beta$-unsaturated ketones show the characteristic $n \rightarrow \pi^{*}$ Cotton effects, the sign of which is due to the ring conformations containing a $\mathrm{C}=\mathrm{C}-\mathrm{C}=\mathrm{O}$ grouping (11). A number of $\Delta^{1}$-3-oxo- $5 \alpha$-steroids with the A/B trans ring juncture, in which the A ring adopted an envelope or a half-boat form, indicated negative $n \mapsto \pi^{*}$ Cotton effect (11-13). Snatzke (11,14) pictorially correlated the sign of the $n \mapsto \pi^{*}$ Cotton effect with the A-ring conformations as shown in Figure 4 . The $\mathrm{C}-4-\mathrm{C}-5$ bond in the right lower back octant of an envelope form and the $\mathrm{C}-1-$ $\mathrm{C}-2$ bond in the left upper one of a half-boat form afford a negative contribution to the $n \mapsto \pi^{*}$ Cotton effect. The ed spectrum of $\mathbf{1}$ indicated a Cotton effect $[\theta]_{312.5}-15340$

A

12
Scheme 1
(Figure 5). The inspection of the molecular drawing based on X -ray analysis by Polonsky et al. (7) suggested that the A ring in bruceine C [4] tetraacetate adopts an envelope form with a planar diosphenol grouping. If it is assumed that the A ring in $\mathbf{1}$ adopts an envelope form in solution, the observed negative $n \mapsto \pi^{*}$ Cotton effect is explainable by Figure 4a. Thus, the $5 S, 10 S$ configuration was assigned to 1 . It seems probable that this assignment is supported by the cd spectrum of 3,4-dihydrobruceine $B$, which shows a positive $n \mapsto \pi^{*}$ Cotton effect (4). The absolute configurations at the remaining asymmetric centers were assigned as $7 R, 8 R, 9 R, 11 R, 12 S, 13 S, 14 S, 15 R$ on the basis of the relative stereochemistry. The absolute stereochemistry of $\mathbf{1}$ obtained above was in accord with that of 4.

## EXPERIMENTAL

General.-Melting points were determined on a micro hot-stage apparatus and are uncorrected. Specific rotations were taken on a JASCO DPI- 181 polarimeter. Spectra were recorded on the following spectrometers: uv, Hitachi EPS-2U; cd, JASCO J-20; ir, Hitachi $260-30$; ${ }^{1} \mathrm{H} \mathrm{nmr}$, XL- 400 at 400 MHz ;

Figure 4. Negative $n \rightarrow \pi^{*}$ Cotton effect and A-ring conformation in $\Delta^{\prime}$-3-oxo-5 $\alpha$-steroids (A/B trans) and brusatol [1]: a, Envelope form; $b$, Half-boat form. Figures in parentheses are the numbering for 1 .

Figure 5. Cd spectrum of brusatol [1].
${ }^{13} \mathrm{C} \mathrm{nmr}$, Varian XL-400 at 100.6 MHz ; hrms, JEOL JMS DX-300; elemental analysis, Perkin-Elmer 240B.

All nmr spectra were taken at a probe temperature of $50^{\circ}$ using a $5-\mathrm{mm}$ tube.
${ }^{1} \mathrm{H}-{ }^{1} \mathrm{H}$ COSY: ${ }^{1} \mathrm{H}$ single probe; relaxation delay $1 \mathrm{sec} ; 90^{\circ}\left({ }^{1} \mathrm{H}\right)=15 \mu \mathrm{sec} ; 90^{\circ}$ mixing pulse; $\mathrm{F}_{1}=\mathrm{F}_{2}=3238\left(2891\right.$ in DMSO- $d_{6}$ ) Hz ; data matrix $1024 \times 128 ; 16$ scans during 128 time increments (zero filling in $\mathrm{F}_{1}$ ); 2 dummy scans; spectra were symmetrized about diagonal axis using FOLDT command after 20 transformations.
${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ COSY: ${ }^{13} \mathrm{C}, 30-105 \mathrm{MHz}$ probe; relaxation delay $1 \mathrm{sec} ; 1$ dummy scan; $90^{\circ}{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ pulses were calibrated at 31.0 and $9.7 \mu \mathrm{sec}$, respectively. One-bond correlation: $F_{1}=3243 \mathrm{~Hz}$, $F_{2}=14389 \mathrm{~Hz}$; data matrix $2048 \times 512 ; 96$ scans during 64 time increments; aquisition time 0.071 sec ; ${ }^{1} J_{\mathrm{CH}}$ (average) 140 Hz ; size of final data points 2 K . Long-range correlation: $\mathrm{F}_{1}=3257 \mathrm{~Hz}, \mathrm{~F}_{2}=18904$ Hz ; data matrix $2048 \times 512 ; 1408$ scans during 96 time increments (zero filling in $\mathrm{F}_{1}$ ); acquisition time, $0.054 \mathrm{sec} ;{ }^{\mathrm{LR}} J_{\mathrm{CH}}$ (average) 7.0 Hz ; size of final data points 2 K .

The nOe spectra were recorded by means of nOe difference spectroscopy. The pre-irradiation time of each resonance was 2 sec . The interpulse delay was 0 sec . The irradiation data sets were interleaved to cancel drift and changing magnet homogeneity. These spectra were transformed by the difference between two free induction decays.

Brusatol [1].-Extraction and isolation of 1 from B. javanica have been described by Li et al. (1). Colorless prisms, mp 274-276 ${ }^{\circ}\left(\mathrm{Me}_{2} \mathrm{CO}\right)$ [lit. (2) mp 276-278 ${ }^{\circ}\left(\mathrm{Me}_{2} \mathrm{CO}\right)$ ]; $R_{f} 0.39$ [Si gel, $\mathrm{CHCl}_{3}$ $\mathrm{MeOH},(10: 1)] ;[\alpha]^{20} \mathrm{D}+39.1^{\circ}\left(c=1.50, \mathrm{Me}_{2} \mathrm{CO}\right)\left[\right.$ lit. (2) $\left.[\alpha]^{26} \mathrm{D}+43.6^{\circ}\left(c=1.50, \mathrm{Me}_{2} \mathrm{CO}\right)\right] ;$ uv $\lambda$ max $(\mathrm{MeOH})(\log \epsilon) 331(2.89), 275(4.11), 217$ (4.39); cd ( $\left.c=4.0 \times 10^{-5}, \mathrm{MeOH}\right)[\theta]^{25}(\mathrm{~nm}) 0(360)$, -15340 ( 312.5 ) (negative maximum), -2600 ( 287.0 ) (positive maximum), -7540 (267.0) (negative maximum), $0(244.0),+28600(223.0)$ (positive maximum); ir $v \max \left(\mathrm{CHCl}_{3}\right) \mathrm{cm}^{-1} 1751,1731,1672$, 1646; hrms m/z [M] 520.1930 ( 520.1944 for $\mathrm{C}_{26} \mathrm{H}_{32} \mathrm{O}_{11}$ ). Anal. calcd for $\mathrm{C}_{26} \mathrm{H}_{32} \mathrm{O}_{11} \cdot 1 / 4 \mathrm{H}_{2} \mathrm{O}$, C 59.48, H 6.24; found C 59.54, H 6.29.

## ACKNOWLEDGMENTS

The authors thank Dr. H. Komura, Suntory Institute for Bioorganic Research, for the measurements of cd spectrum.
