ABSTRACT.—It is reported that the demosponge *Echinochalina mollis* contains in relatively large amounts (+)-(12*R**,5*Z*,8*Z*,10*E*,14*Z*,17*Z*)-12-hydroxy-5,8,10,14,17-icosapentaenoic acid, (+)-(12*S*,5*Z*,8*Z*,10*E*,14*Z*)-12-hydroxy-5,8,10,14-icosatetraenoic acid, (+)-(12*R**,4*Z*,7*Z*,10*Z*,12*E*,16*Z*,19*Z*)-14-hydroxy-4,7,10,12,16,19-docosahexaenoic acid, and (+)-(12*R**,4*Z*,7*Z*,10*Z*,12*E*,16*Z*)-14-hydroxy-4,7,10,12,16-docosapentaenoic acid. The latter three acids are detected for the first time in a marine invertebrate. The acids are isolated as the methyl esters (+)-**1**, (+)-**2**, (+)-**3**, and (+)-**4**.

12-Hydroxyicosapentaenoic (1,2) and 12-hydroxyicosatetraenoic acids (1, 3–10) and 14-hydroxydocosapentaenoic (11) and 14-hydroxydocosahexaenoic acids (12,13) have been identified in terrestrial mammals (11, 12) and as products of either enzymatic (1,4,6,11,12) or oxidative nonenzymatic (2,13) transformation of unsaturated fatty acids. 12-Hydroxyicosapentaenoic acid has also been detected in subtrace amounts in marine invertebrates and algae (3,6). Finally, prostaglandin E₂, contained in the edible red seaweeds *Gracilaria chorda* and *Gracilaria verrucosa*, was the cause of deadly intoxication.

tions in Japan in 1980 and 1982 (14), and the same icosanoid was found in *Gracilaria lichenoides* from West Australian waters (15).

We report here on 12-hydroxyicosapentaenoic acids and on 14-hydroxydocosapentaenoic and 14-hydroxydocosahexaenoic acids identified for the first time in a marine invertebrate along with 12-hydroxyicosatetraenoic acid. Notably, these acids are present in the marine organisms in relatively large amounts.

Cc of the CH₂Cl₂ extract of the marine sponge *Echinochalina mollis* Levi, first on Polyamid and then on an ion-exchange support, followed by reversed-phase flash chromatography, led to a mixture of unsaturated fatty acids. To improve the separation, the mixture was esterified and separated by Si gel hplc into four esters that were eluted in the order (+)-**4**, (+)-**2**, (+)-**3**, and (+)-**1**.

The ¹³C-nmr data for (+)-**1** in Table 1 reveal 10 olefinic CH groups, 7 CH₂ groups, one O-bearing CH group, an aliphatic Me, and a COOMe group, which amounts to the composition C₂₁H₃₂O₃. The mass spectrum shows an ion corresponding to [M - H₂O]⁺ as the highest mass ion. Because there is only one methyl group and all olefinic bonds are 1,2-disubstituted, the ester must be linear. The fragments C-2-C-5, C-6-C-14 and C-15-C-20 were established by double-quantum filtered COSY experiments (16). The C-14-C-15 connection is based on delayed COSY experiments (17) while the C-5-C-6 connection is demanded by disubstitution at all double bonds. The mass spectrum shows the fragment *m/z* 223 which indicates cleavage at C-12-C-13 and thus the C-12 position for the OH group.

TABLE 1. ¹³C-nmr Data (in CDCl₃).

Carbon assignments in Table 1 are based on ¹H-¹³C chemical-shift correlation experiments (18) and fully support the assigned structure (+)-**1**.

The stereochemistry of the C-8-C-12 fragment rests on the characteristic uv absorption at λ max 236 nm (19). This and the *Z* configuration at both C-14 and C-17

find confirmation in the pattern of ^1H - ^1H coupling constants of Table 2. The *Z* configuration at C-5 is supported both by the typically shielded ^{13}C resonances for C-4 and C-7 (19) (Table 1) and by chemical-shift calculations (20).

The (12*R*)-hydroxyacid analogue of (+)-**1** has been reported, without either chiroptical or nmr data, as deriving from the action of the lipxygenase of the sea urchin *Strongylocentrotus purpuratus* on (5*Z*,8*Z*,11*Z*,14*Z*,17*Z*)-icosapentaenoic acid (1). Racemic **1** has been described as a product of autoxidation of methyl icosapentaenoate followed by NaBH_4 reduction, though no direct structural proof has been given (2).

^aPartially superimposed.^bSuperimposed.

Structure (+)-**2** is assigned on the basis of similarity of nmr data (Tables 1 and 2) with those for ester (+)-**1**. The free acid of (+)-**2** has been reported by radioimmunoassay, obviously without either spectra or chiroptical data, to be present in subtrace amounts in *Euglena gracilis* (Euglenophyta) (6), in the sponge *Terpios zeteki* (3), in the mollusks *Aplysia californica* (3) and *Helix aspersa* (3), and in the sea urchin *Arbacia* sp. (3). In contrast with these marine organisms (3,6), the hydroxycarboxylic acid precursor of (+)-**2** is accumulated in our sponge. The (12*R*)-hydroxyacid analogue of (+)-**2** has been reported from the above sea-urchin lipoxygenase (1) or from rat-liver microsomal cytochrome P-450 (4) on arachidonic acid. Finally, ¹H-nmr data have been reported for synthetic (±)-**2** (10), (12*R*)-**2** (7), and (12*S*)-**2** (8,9).

The C-9–C-20 portion of the ¹³C-nmr spectrum of (+)-**3** is superimposable to the C-7–C-20 portion of the ¹³C-nmr spectrum of (+)-**1** (Table 1). The remaining spectral portions show that (+)-**3** has two olefinic CH signals more than (+)-**1** to form a third (*Z*) CH₂-CH=CH-CH₂ group. The position of the extra double bond with (+)-**3** can be unambiguously assigned on the basis that the 22.84 τ is typical of a CH₂ in the β position of a COO group. Double quantum COSY experiments (16) confirm the assignments. The *Z* configuration at both C-4 and C-7 rests on high-field shift of C-3, C-6, and C-9 (19,20).

The carboxylic acid analogue of (+)-**3** has been reported, without chiroptical data, from human-platelet lipoxygenase (12) on (4*Z*,7*Z*,10*Z*,13*Z*,16*Z*,19*Z*)-docosahexaenoic acid. Compound (±)-**3** has been described from the autoxidation of (4*Z*,7*Z*,10*Z*,12*E*,16*Z*,19*Z*)-docosahexaenoic acid (13) without giving any direct structural proof, however.

The C-1–C-15 portion of the ¹³C-nmr spectrum of (+)-**4** is superimposable to the C-1–C-15 portion of (+)-**3**. Moreover, the C-9–C-22 portion of the ¹³C-nmr spectrum of (+)-**4** is superimposable to the C-7–C-20 portion of (+)-**2**. This points to structure (+)-**4**, which is confirmed by both COSY and delayed COSY experiments (17).

The parent acid of (+)-**4** has already been reported as a product of in vitro transformation of (4*Z*,7*Z*,10*Z*,13*Z*,16*Z*)-docosapentaenoic acid by human blood platelets (11). Neither chiroptical data nor any direct structural proof have been offered, however.

EXPERIMENTAL

GENERAL EXPERIMENTAL PROCEDURES.—Nmr spectra [δ values in ppm relative to internal TMS (= 0 ppm) and *J* values in Hz]: Varian XL-300 spectrometer (¹H at 300 MHz, ¹³C at 75.4 MHz), *J* in Hz; multiplicities from DEPT experiments (21). HETCOR (18) experiments have been carried out for all compounds except (+)-**2**. Uv spectra (λ max in nm, ϵ in mol⁻¹ cm⁻¹): Perkin-Elmer Lambda-3 spectrophotometer. Polarimetric data: JASCO-DIP-181 polarimeter. Flash chromatography: Merck-LiChroprep RP-18 (40–63 μ m). Cc: Riedel-De Haën Polyamid 6S or Aldrich Amberlyst A-21. Hplc: 25 × 1 cm column filled with Merck-LiChrosorb Si-60 (7 μ m), uv monitoring at λ 254 nm, solvent flux 5 ml/min, tlc: Merck-Si_{F254} plates. Mass spectra were taken with a home-made spectrometer, based on the ELF-4-162-8 Extranuclear quadrupole (22).

COLLECTION AND WORKUP.—The sponge was collected in June 1986, around Noumea and was identified by Professor C. Levi, from the Muséum National d'Histoire Naturelle, Paris. The genus *Echinochalina* comprises a few rare species from Australian waters. The sponge can probably be classified in the family Clathriidae, order Poecilosclerida, in spite of the aberrant structure of its skeleton.¹ The fresh sponge (approximately 3 liters in volume) was lyophilized and then extracted with 80% EtOH. The extract was partly evaporated and then partitioned between H₂O and CH₂Cl₂. The organic layer was evaporated to dryness to leave a dark sticky residue (3.0 g) that was subjected to gradient-elution chromatography on 100 g Polyamid 6S [MeOH-H₂O (4:1) to pure MeOH] collecting 10 fractions of 100 ml each. Fractions 1–4, obtained with MeOH/H₂O mixtures of composition ranging from 4:1 to 9:1 were evaporated to give a sticky residue (0.3 g) which was chromatographed on the weakly basic ion-exchange resin Amberlyst A-

¹Personal communication from Professor C. Levi.

21, eluting first with Et₂O and then with MeOH to remove nonacidic substances. Further elution with MeOH-HOAc (95:5) (designed to recover acidic substances) led to an eluate which was partly evaporated and then subjected to RP-18 flash chromatography, eluting first with H₂O to remove HOAc and then with MeOH/H₂O mixtures, first of composition 85:15 and then 9:1. The eluates from the 85:15 and 9:1 mixtures were evaporated, and the residue was dissolved in ethereal CH₂N₂. The mixture was evaporated, and the residue was subjected to hplc with hexane-EtOAc (92:8) to give (+)-**4** (1.5 mg, Rt = 23 min), (+)-**2** (3.5 mg, Rt = 36 min), (+)-**3** (3.5 mg, Rt = 38.5 min), and (+)-**1** (2.1 mg, Rt = 41 min).
