#### Abstract

The combined $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and MeOH crude extract of a new species of the marine sponge Dysidea, collected in Northern Australia was found to inhibit the binding of [I125] interleukin-8 [IL-8] to the human recombinant IL-8 receptor type A at $500 \mu \mathrm{~g} / \mathrm{mL}$. Bioassay-guided fractionation led to the isolation of three new polyoxygenated sterols 3, 4, and 5. Their structures were assigned on the basis of 1D and 2D NMR experiments, and relative stereochemistries were established by ROESY correlations and analysis of coupling constants. The IC $\mathrm{C}_{50}$ values for inhibition of IL-8Ra for sterols 3, 4, and $\mathbf{5}$ were 20, 5.5, and 4.5 $\mu \mathrm{M}$, respectively.

Marine sponges are well-known as a rich source of bioactive steroid compounds ranging in size and type of carbon skeleton and oxygenation patterns. ${ }^{1}$ The genus Dysidea (Dictyoceratida) has provided a wide array of polyoxygenated sterols, including the first example of a 9,11-epoxide present in $\mathbf{1}^{2}$ and the rare $\Delta^{8}$, 11-keto functionality as in the cytotoxic sterol $2 .^{3}$ In this report, the isolation of three new polyoxygenated sterols (3-5) from a new species of Dysidea using bioassay-guided fractionation for inhibition of the binding of [I125] interleukin (I L8) to the human recombinant IL-8 receptor type A is described.

Flash chromatography of the combined $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and MeOH extracts of the Dysidea sp. on Si gel yielded six fractions, three of which were active. Sterol $\mathbf{3}$ was present in the most polar fraction. The other two active fractions were pool ed and further chromatographed on a silica HPLC column using isocratic elution of hexane/EtOAc, 70:30, yielding 4 and 5 .

The molecular formula of sterol 3 was established as $\mathrm{C}_{31} \mathrm{H}_{50} \mathrm{O}_{7}$ based on high-resolution measurements (positive ESI ) m/z 557.3460 (calcd for $\left[\mathrm{C}_{31} \mathrm{H}_{50} \mathrm{O}_{7}+\mathrm{Na}\right]^{+} 557.3448$ ). The ${ }^{1}$ H NMR spectrum of 3 (Table 1) showed two acetate methyl singlets ( $\delta 2.10$ and 2.06), two aliphatic methyl singlets ( $\delta 1.26$ and 0.58 ), and three aliphatic methyl doublets ( $\delta 0.93,0.88$, and 0.87 ). Four oxygenated oneproton signals were present at $\delta 5.61,5.35,4.46$, and 4.10. The ${ }^{13} \mathrm{C}$ NMR spectrum of $\mathbf{3}$ (Table 1) showed the presence of 31 carbons: five oxygenated carbons (four methines and one quaternary), one tetrasubstituted double bond (142.8 and 132.2 ppm$)$, seven methyl groups, two aliphatic quaternary carbons, 13 aliphatic methylene and methine carbons, and two acetate carbons. One-bond correlations between protons and carbons were obtained by HMQC experiments, and the connectivity of the carbon framework was based on HMBC and COSY correlations (Table 1). Correlations from the oxygenated methines at $\delta 5.35(\mathrm{H}-$ 6 ) and $5.61(\mathrm{H}-7)$ to each of the carbonyls $7-\mathrm{OCOCH}_{3}(170.1$ ppm) and $6-\mathrm{OCOCH}_{3}$ (170.4 ppm) established a 6,7 oxygenation pattern. HMBC correlations from H-2a ( $\delta 1.55$ ), $\mathrm{H}-4 \mathrm{a}(\delta 1.40)$, and $\mathrm{H}-4 \mathrm{~b}(\delta 2.07)$ to the oxygenated carbon

at 66.7 ppm and corresponding COSY correlations to its attached methine proton ( $\delta 4.10$ ) indicated that an alcohol group was attached to C-3. Correlations from the oxygenated methine H-11 ( $\delta 4.46$ ) to C-8, C-9, and C-13 indicated
Table 1. ${ }^{1 \mathrm{H}}(600 \mathrm{MHz})$ and ${ }^{13} \mathrm{C}(150 \mathrm{MHz}) \mathrm{NMR}$ Data and HMBC and COSY Correlations for Sterols 3, 4, and $\mathbf{5}$ in $\mathrm{CDCl}_{3}$

that another alcohol group was attached to C-11. The quaternary carbon at 75.6 ppm was established as $\mathrm{C}-5$ from HMBC correlations from $\mathrm{H}-4 \mathrm{~b}, \mathrm{H}-7$, and $\mathrm{H}-19$. COSY correlations established the remaining steroid nucleus. ROESY correlations from the methine doublet at $\delta 5.35$ (H-6) to the methine at $\delta 5.61(\mathrm{H}-7)\left(\mathrm{J}_{6,7}=6 \mathrm{~Hz}\right)$, to the methyl at $\delta 1.26(\mathrm{H}-19)$, and to methylene at $\delta 1.40(\mathrm{H}-4 \mathrm{a})$ established those groups on the $\beta$ face of the molecule. The methyl group at $\delta 0.58(\mathrm{H}-18)$ showed strong ROESY correlations to the methylene at $\delta 1.34(\mathrm{H}-16 \mathrm{a})$, to the methyl at $\delta 0.93(\mathrm{H}-21)$ and to the methylene at $\delta 2.40(\mathrm{H}-$ 12b). The latter showed strong correlation to the methine at $\delta 4.46$ (H-11), which, in turn, showed correlation back to the methyl at $\delta 1.26$ (H-19), thus establishing those groups on the same $\beta$ face. The methylene at $\delta 1.67(\mathrm{H}-$ 12a) showed correlations to the bridgehead methine at $\delta$ $2.53(\mathrm{H}-14)$ and the methine at $\delta 1.36(\mathrm{H}-17)$ correlated to the methylene at $\delta 1.92(\mathrm{H}-16 \mathrm{~b})$. These were thus placed on the $\alpha$ face of the molecule, establishing the side chain at $\mathrm{C}-17$ on the $\beta$ face. Also on the $\alpha$ face was the oxygenated methine at $\delta 4.10$, with correlations to the methylene protons at $\delta 2.07(\mathrm{H}-4 \mathrm{~b}), 1.96(\mathrm{H}-2 \mathrm{~b})$, and $2.33(\mathrm{H}-1 \mathrm{~b})$.

The structures of sterols 4 and 5 were also determined by 1D and 2D NMR experiments and were supported by MS analysis. Their molecular formulas were established as $\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}$ and $\mathrm{C}_{29} \mathrm{H}_{46} \mathrm{O}_{5}$ by high-resolution measurements $\mathrm{m} / \mathrm{z} 599.3569\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}+\mathrm{Na}\right]^{+}$(calcd for $\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}\right.$ $\left.+\mathrm{Na}]^{+} 599.3554\right)$ and $\mathrm{m} / \mathrm{z} 497.3244\left[\mathrm{C}_{29} \mathrm{H}_{46} \mathrm{O}_{5}+\mathrm{Na}\right]^{+}$ (cal cd for $\left[\mathrm{C}_{29} \mathrm{H}_{46} \mathrm{O}_{5}+\mathrm{Na}\right]^{+} 497.3237$ ). The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C} \mathrm{NMR}$ spectra of 4 were very similar to those of $\mathbf{3}$, with the coincidence of many chemical shifts (see Table 1). The major difference was the presence of an extra acetate group at C-3, which resulted in changes in chemical shifts for the proton from $\delta 4.10$ (al cohol) to $\delta 5.15$ (acetate) and for the carbon from 66.7 ppm (al cohol) to 69.7 ppm (acetate). Other carbons around C-3 were also affected, such as C-2 and C-4 (see Table 1). The ROE SY spectrum of 4 was consistent with that of $\mathbf{3}$ and confirmed their relativestereochemistry. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of 5 were again fairly similar tothose of $\mathbf{3}$ and $\mathbf{4}$. The major differences were the presence of only one acetate group and one ol efinic proton triplet at $\delta 5.33$, which establ ished a trisubstituted $\Delta^{7}$. The presence of an epoxide ring was indicated by the oxygenated proton doublet at $\delta 3.16$ (C-11 at 53.8 ppm ), which showed HMBC correlations to the oxygenated quaternary C-9 ( 62.6 ppm ), the bridgehead C-13 (40.0 ppm), and methylene C-12 (40.0 ppm). ROESY correlations observed in the spectrum of 5 were consistent with those observed for $\mathbf{3}$ and 4. The assignment of the epoxide ring on the $\alpha$ face of the mol ecule was based on correlations observed between the oxygenated methine at $\delta 3.16(\mathrm{H}-11)$ to the methyl group at $\delta 1.23(\mathrm{H}-$ 19) and to the methylene protons at $\delta 0.98(\mathrm{H}-1 \mathrm{a})$ and $\delta$ 2.15 (H-12b).

Sterol 5 may be the precursor of the other two sterols, via acetate addition at C-7, double-bond migration, and epoxide-ring opening. Sterols 3, 4, and 5 inhibited the binding of [I125] IL-8 to the human recombinant IL-8 receptor type A in a competitive fashion. The $\mathrm{IC}_{50}$ values for inhibition of IL-8Ra for sterols 3, 4, and 5 were 20, 5.5, and $4.5 \mu \mathrm{M}$, respectively.

## Experimental Section

General Experimental Procedures. NMR spectra were recorded on a Varian Unity INOVA at 599.926 MHz for ${ }^{1} \mathrm{H}$ and 149.98 MHz for ${ }^{13} \mathrm{C} .{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ were referenced to the peak solvent $\left(\mathrm{CDCl}_{3}\right) \delta 7.26$ and 77.3 ppm or $\left(\mathrm{DMSO}_{-} \mathrm{d}_{6}\right) \delta 2.49$ and 39.5 ppm , respectively. Standard parameters were used for 1D and 2D NMR spectra, which included ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}, ~ D E P T$,
gradient COSY, HMQC, HMBC, and ROESY. UV spectra were recorded on a GBC 916 UV-vis spectrometer, and IR spectra were recorded on a Perkin-Elmer 1725X FT-IR spectrometer. Optical rotation was measured on a J ASCO P-1020 polarimeter. Davisil silica powder ( $30-40 \mu \mathrm{~m}$ ) was used for packing the semi preparative AP-1 Waters glass column ( $10 \times 100 \mathrm{~mm}$ ). Rainin $3 \mu \mathrm{~m}$ silica analytical HPLC column ( $4.6 \times 100 \mathrm{~mm}$ ) was used for analytical and semi preparative chromatography. A Waters 600 pump with a 717 Autosampler connected to an Alltech 500 evaporative light-scattering detector and a Waters 410 differential refractometer detector were used for analytical and semi preparative HPLC separations. Low-resolution mass spectra were measured on a Fisons VG Platform II, using positive electrospray ionization mode.

Animal Material. The Dysidea sample, which appears to represent a new species, was collected off Lizard Island, North Queensland, Australia. A voucher sample (QMG304134) has been lodged at the Queensland Museum, South Brisbane, Australia. Taxonomy: Porifera; Demospongiae; Dictyoceratida; Dysideidae; Dysidea new species (QM species number \#1519). Description: shape, ranging from thinly encrusting to erect, arborescent, shrub-like, producing distinct lobate, flat lamellate, ridgelike or erect fingers superficially resembling an alga. Color: live coloration dull gray-green, yellowish-green, or greenish with yellow tips. Oscules: small, less than 3 mm in diameter, scattered on apexes of digits. Texture: very soft, compressible, mucus; produces copious amounts of a dark brown to purple-brown pigment after collection. Surface: microconulose, with small conules interconnected by ridges, producing a furry surface, and with soft ridges and shallow grooves running longitudinally along branches, producing a macroscopi cally angular surface. Ectosomal skeleton: membranous, with minimal surface detritus, but with ascending primary spongin fibers cored by sand grains and spicule fragments protruding through the surface and forming surface microconules; areas between conules free of detritus. Choanosomal skeleton: distinct primary and secondary spongin fibers. Primary fibers mainly ascending, up to $120 \mu \mathrm{~m}$ in diameter, depending on the detritus contained within, and secondary fibers mainly transverse, up to $60 \mu \mathrm{~m}$ in diameter, together forming an irregular but more-or-less relatively evenly spaced reticulation throughout, with fibers only occasionally branching and rejoining, forming very large meshes ( $>1 \mathrm{~mm}$ diameter). Primary fibers fully cored with small and large detritus (sand grains, foreign spicule fragments, diatoms, and molluscan shell fragments), secondary fibers often with only a thin axial core of detritus. Spongin fibers heavy, with relatively dense but mostly unpigmented collagen, distinct from collagenous mesohyl. Mesohyl composed of very dense collagen, lightly or heavily pigmented yellowish-brown, with few scattered detritus particles; choanocyte chambers are oval, eurypylous $90-140 \mu \mathrm{~m}$ long and $40-60 \mu \mathrm{~m}$ wide. From the literature of Australasian and New Caledonian Dysidea, this taxon is probably new to science.

Extraction and Isolation. The freeze-dried and ground sponge ( 4.468 g ) was exhaustively extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ followed by MeOH and the extracts combined ( 304.5 mg ). The crude extract was filtered through a plug of charcoal ( 300 mg ) using $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ followed by MeOH as eluent. The filtered crude extract ( 177.8 mg ) was fractioned on a Waters AP-1 silica col umn using stepped gradient elution: $100 \% \mathrm{CH}_{2} \mathrm{Cl}_{2}, 50 \%$ $\mathrm{CH}_{2} \mathrm{Cl}_{2} / \mathrm{EtOAc}, 100 \%$ EtOAc, $20 \% \mathrm{MeOH} / \mathrm{EtOAc}, 50 \% \mathrm{MeOH} /$ EtOAc, and $100 \% \mathrm{MeOH}$ for 60 min at $4 \mathrm{~mL} / \mathrm{min}$. Six fractions were collected, of which fractions 3 to 5 were active. Fraction 5 consisted of pure sterol $\mathbf{3}$ ( 18.4 mg ). Fractions 3 and 4 were combined and further fractionated on analytical silica HPLC column using isocratic elution of hexane/EtOAc, 70:30, in 25 min. The separation was optimized using an ELSD for detection, and the collection of fractions was performed using a differential refractometer detector. Sterol $\mathbf{4}(1.3 \mathrm{mg})$ eluted at 8 min , and sterol $5(2.3 \mathrm{mg})$ eluted at 17 min .

Cholest-8-ene-3 $\beta, 5 \alpha, 6 \alpha, 7 \alpha, 10 \alpha$-pentol 6,7-diacetate (3): white powder ( $18.4 \mathrm{mg}, 0.41 \%$ ): $[\alpha]^{24}{ }_{\mathrm{D}} 589^{\circ}(0.680 \mathrm{~g} / 100 \mathrm{~mL}$, $\left.\mathrm{CHCl}_{3}\right)=+74^{\circ}$; UV $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) \lambda_{\text {max }}(\log \epsilon) 231 \mathrm{~nm}(1.13), 250$
nm (0.30); IR $v_{\max }(\mathrm{NaCl}$ cell) 3416, 2951, 1730, 1653, 1457, 1374, 1243, 1048, $741 \mathrm{~cm}^{-1}{ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR, see Table 1; (+)LRESMS m/z $557\left[\mathrm{C}_{31} \mathrm{H}_{50} \mathrm{O}_{7}+\mathrm{Na}\right]^{+} ;(+) \mathrm{HRESMS} \mathrm{m} / \mathrm{z}$ $557.3460\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}+\mathrm{Na}\right]^{+}$(calcd for $\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}+\mathrm{Na}\right]^{+}$ 557.3448).

Cholest-8-ene-3 $\beta, 5 \alpha, 6 \alpha, 7 \alpha, 10 \alpha$-pentol 3,6,7-triacetate (4): white powder ( $1.3 \mathrm{mg}, 0.03 \%$ ); $[\alpha]^{24} \mathrm{D} 589^{\circ}(0.031 \mathrm{~g} / 100 \mathrm{~mL}$, $\left.\mathrm{CHCl}_{3}\right)=+21^{\circ}$; UV $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) \lambda_{\text {max }}(\log \epsilon) 231 \mathrm{~nm}(2.265), 244$ nm (1.273); IR $v_{\max }(\mathrm{NaCl}$ cell) 3438, 2959, 2106, 1715, 1651 , 1456, 1373, 1243, 1028, $738 \mathrm{~cm}^{-1}$; ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR, see Table 1; (+)LRESMS m/z $599\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}+\mathrm{Na}\right]^{+} ;(+) \mathrm{HRESMS} \mathrm{m} / \mathrm{z}$ $599.3569\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}+\mathrm{Na}\right]^{+}$(calcd for $\left[\mathrm{C}_{33} \mathrm{H}_{52} \mathrm{O}_{8}+\mathrm{Na}\right]^{+}$ 599.3554).

9 $\alpha, 11 \alpha$-E poxycholest-7-ene-3 $\beta, 5 \alpha, 6 \alpha$-triol 6-acetate (5): white powder ( $2.3 \mathrm{mg}, 0.05 \%$ ); $[\alpha]^{4}{ }^{2} \mathrm{D} 589^{\circ}(0.131 \mathrm{~g} / 100 \mathrm{~mL}$, $\left.\mathrm{CHCl}_{3}\right)=+32^{\circ}$; UV $\left(\mathrm{CH}_{2} \mathrm{Cl}_{2}\right) \lambda_{\text {max }}(\log \epsilon) 231 \mathrm{~nm}(0.657), 244$ nm (0.474); IR $\nu_{\max }(\mathrm{NaCl}$ cell) 3362, 2928, 1740, 1666, 1467, 1371, 1236, 1039, $736 \mathrm{~cm}^{-1}$; ${ }^{1 \mathrm{H}}$ and ${ }^{13} \mathrm{C}$ NMR, see Table 1;
$(+)$ LRESMS m/z $497\left[\mathrm{C}_{29} \mathrm{H}_{46} \mathrm{O}_{5}+\mathrm{Na}\right]^{+} ;(+) \mathrm{HRESMS} \mathrm{m} / \mathrm{z}$ $497.3244\left[\mathrm{C}_{29} \mathrm{H}_{46} \mathrm{O}_{5}+\mathrm{Na}\right]^{+}$(calcd for $\left[\mathrm{C}_{29} \mathrm{H}_{46} \mathrm{O}_{5}+\mathrm{Na}\right]^{+}$ 497.3237).

Acknowledgment. We are indebted to Mr. Ross Stevens, Griffith University, Brisbane, Australia, for the assistance with UV and IR spectra and to Mr. Rick Willis, AIMS, Australian Institute of Marine Science, Townsville, Australia, for the HRMS analyses.
