#### Abstract

An asymmetrical synthesis of bicyclo[2.2.1]hept-2-enes is described performed by [4+2]-cycloaddition of (-)-menthyl acrylate and (-)-menthyl methacrylate to cyclopentadiene in the presence of $\mathrm{BBr}_{3}$. The effect of different factors on isomer composition, yield, and enantiomeric purity of the compounds obtained was investigated. Kovatch indices were determined and boiling points were estimated with the use of gas-liquid chromatography.

A norbornene moiety is inherent to a large number of natural and synthetic biologically active compounds. Introduction of a norbornene moiety into pharmaceuticals improves their therapeutic effect [1]. In the synthesis of bicyclo[2.2.1]heptene derivatives is used as diene the cyclopentadiene that is a known by-product of ethylene and coal-tar chemical industry [2].

Since often only a single optically active isomer possesses physiological activity the synthesis of bicyclic compounds with a bridged structure in the enantiomerically pure state is especially valuable. The asymmetrical diene synthesis is among the promising procedures leading to the above compounds in an optically active form.

In these reactions Lewis acids $\left(\mathrm{AlCl}_{3}, \mathrm{TiCl}_{4}\right.$, $\mathrm{SnCl}_{4}, \mathrm{BF}_{3}-\mathrm{OEt}_{2}$ ) are known to be used as catalysts
[3, 4]. The application of $\mathrm{BH}_{2} \mathrm{Br}$ in combination with chiral polymers as catalyst in asymmetrical DielsAlder reaction of cyclopentadiene with methacrolein afforded adducts in a good yield and with a fair enantiomeric purity $[5,6]$.

In extension of our studies on asymmetrical diene synthesis [7-11] we report here of the asymmetrical [4+2]-cycloaddition of (-)-menthyl acrylate (II) and (-)-menthyl methacrylate (III) to cyclopentadiene (I) in the presence of $\mathrm{BBr}_{3}$ (Scheme 1).

The residual chiral alcohol, L-(-)-menthol ( $\mathrm{R}^{\prime}$ ) in compounds IV, $\mathbf{V}$ was removed by alkaline hydrolysis. The separation of isomeric endo-(VI, VII) and exo-(VIII, IX) acids was performed by conversion of the endo-isomers into lactones (Scheme 2).

On removing exo-acids VIII, IX from optically active iodolactones XIV, XV the reduction with the

Scheme 1.

$\mathrm{R}=\mathrm{H}(\mathbf{I I}, \mathbf{I V}, \mathbf{V I}, \mathbf{V I I I}, \mathbf{X}, \mathbf{X I I}), \mathrm{R}=\mathrm{CH}_{3}(\mathbf{I I I}, \mathbf{V}, \mathbf{V I I}, \mathbf{I X}, \mathbf{X I}, \mathbf{X I I I}) ; \mathrm{R}^{\prime}=\mathrm{L}-(-)$-menthyl.

## Scheme 2.

system $\mathrm{Zn}+\mathrm{CH}_{3} \mathrm{COOH}$ afforded the corresponding optically endo-acids VI, VII. To avoid the concomitant racemization of adducts IV, $\mathbf{V}$ during alkaline hydrolysis their reduction was carried out with the use of $\mathrm{LiAlH}_{4}$ (Scheme 1). The catalytic effect of $\mathrm{BBr}_{3}$ may be attributed to formation of its complex with dienophiles II, III.

The electron deficiency arising therefrom on the multiple bond of the dienophiles II, III facilitates their interaction with diene I. This assumption is corroborated by the displacement of the $v(\mathrm{C}=\mathrm{O})$ from 1730 to $1630 \mathrm{~cm}^{-1}$ on going from dienophiles

II, III to their complexes with $\mathrm{BBr}_{3}$. These results are consistent with the data reported in [12] on the shift of the $\mathrm{C}=\mathrm{O}$ absorption band in methyl acrylate from 1720 to $1640 \mathrm{~cm}^{-1}$ effected by $\mathrm{AlCl}_{3}, \mathrm{TiCl}_{4}$, $\mathrm{SnCl}_{4}$ due to complexing between the catalysts and dienophile.

The study was carried out in a wide temperature range (from -78 to $20^{\circ} \mathrm{C}$ ) in different solvents at varying ratio between catalyst and dienophiles II, III. The effect of these parameters on the yield, isomer composition, and enantiomeric purity is presented in Table 1.

As seen from Table 1 in contrast to noncatalyzed reaction of asymmetrical diene synthesis where the changing temperature weakly affects the enantiomeric purity of compounds obtained [13], in the presence of $\mathrm{BBr}_{3}$ this reactions at low temperature furnishes

Table 1. Effect of cycloaddition reaction parameters on the yield, isomer composition, and enantiomeric purity of compounds IV-XIII

compounds VI-XIII of significantly higher purity: It attains $84 \%$ for adduct IV and $70 \%$ for adduct $\mathbf{V}$ at $-78^{\circ} \mathrm{C}$. With decreasing temperature the stereoselectivity of reactions grows, and the overall yield of products decreases.

The increase in catalyst $\mathrm{BBr}_{3}$ amount virtually does not affect the enantiomeric purity of compounds VI-XIII, but their overall yield grows. The data of Table 1 also indicate that the character of solvent hardly affects the enantiomeric purity and the overall yield of the final products.

Under conditions of this study the reaction of dienophile II afforded predominantly endo-isomer, and that with dienophile III mostly exo-isomer.

Isomers of alcohols X, XII and XI, XIII were separated by preparative gas-liquid chromatography. The GLC data show that the isomer composition of alcohols X, XI and XI, XIII is the same as that of the adducts IV and $\mathbf{V}$ respectively.

The composition and structure of compounds synthesized were confirmed by elemental analysis, IR and ${ }^{1} \mathrm{H}$ NMR spectra (Tables 2, 3).

Mass spectra of compounds X, XII and XI, XIII support the structure of these compounds but are insensitive to the isomer composition.

We also developed in this study the preparative GLC methods for separation of compounds obtained. We determined the retention volumes, relative retention volumes, Kovatch indices, and estimated the boiling points of the compounds under study. The Kovatch indices were calculated by Kovatch formula [14], and boiling points by Sakharov equation [15]. In both calculations was used the retention time of the normal paraffins om Dynochrom P with Apieson at the temperature and analysis modes the same as used with compounds under study (Table 4).

Optical purity and enantiomeric excess (\%) of compounds VI-XIII were calculated from comparison of their specific rotation values with the corresponding figures for the enantiomerically pure samples of these compounds described in [16]. The relative configuration of products VI-XIII was estimated from the rule of correlation of the sign of optical rotation with that of structurally similar compounds of established configuration [14]: 5R for compounds (+)-(VII), (+)-(X), and (+)-(XI); $5 S$ for compounds $\quad(+)-(\mathbf{V I I I}), \quad(+)-(\mathbf{I X}), \quad(+)-(\mathbf{X I I})$, (+)-(XIII).

or KBr pellets. ${ }^{1} \mathrm{H}$ NMR spectra were registered on spectrometer Tesla BS-487 (operating frequency 80 MHz ) from solutions in $\mathrm{CCl}_{4}$, internal references HMDS or TMS. Mass spectra were run on mass spectrometer MKh-1303 with the input from a gas bulb (ionizing voltage 30 and 12 eV ). The optical rotation was measured on polarimeters Perkin-Elmer-141, Polamat A ( 546 nm ), and spectropolarimeter Spectrol-1. Preparative separation was carried out on a column $900 \times 0.8 \mathrm{~cm}$ packed with porovin with 5\% PEGA [poly(ethylene glycole) adipate], evaporizer temperature $250^{\circ} \mathrm{C}$, oven temperature $170^{\circ} \mathrm{C}$, carrier gas nitrogen, gas flow rate $200 \mathrm{~cm}^{3} \mathrm{~min}^{-1}$, sample introduced $100 \mu \mathrm{l}$, flameionization detector, chromatograph Varian-Aerograph. The chromatographic analysis and purity check of the compounds synthesized was performed with the use of columns $300 \times 0.3 \mathrm{~cm}$ packed with Dynochrom P with 5\% of Apiezon and PEGS [poly(ethylene glycol) succinate], carrier gas helium, gas flow rate $40 \mathrm{~cm}^{3} \mathrm{~min}^{-1}$, oven temperature $140-150^{\circ} \mathrm{C}$, chromatograph LKhM-8MD, thermal conductivity detector.
(-)-Menthyl acrylate (II) was prepared by procedure $[12],[\alpha]_{546}^{20}-127^{\circ}$ (c 4.4, MeOH). Cf.: $[\alpha]_{D}^{20}-77^{\circ} \quad[12]$.
(-)-Menthyl methacrylate (III) was prepared by the same procedure, $[\alpha]_{546}^{20}-113^{\circ}\left(c 5.72^{\circ}, \mathrm{MeOH}\right)$. Cf.: $[\alpha]_{D}^{20}-91.75^{\circ} \quad[12]$.
(-)-Menthyl bicyclo[2.2.1]hept-2-ene-5-carboxylate (IV). To a solution of $10.52 \mathrm{~g}(0.05 \mathrm{~mol})$ of compound II in 30 ml of anhydrous dichloromethane at $-10^{\circ} \mathrm{C}$ was added dropwise $3.12 \mathrm{~g}(0.01 \mathrm{~mol})$ of $\mathrm{BBr}_{3}$ in 20 ml of dichloromethane. The mixture was cooled to $-78^{\circ} \mathrm{C}$, and then was added 3.96 g ( 0.06 mol ) of cyclopentadiene ( $\mathbf{I}$ ) in 10 ml of dichloromethane. Then the mixture was stirred for 30 min at $-78^{\circ} \mathrm{C}$. The mixture was treated first with diluted HCl , then with $5 \%$ solution of $\mathrm{NaHCO}_{3}$, washed with water, and dried on $\mathrm{MgSO}_{4}$. On removing the solvent the residue was distilled in vacuo. We obtained 8.31 g ( $60 \%$ ) of adduct $\mathbf{I V}, \mathrm{MD}_{D} 79.50$, calc. $80.39,[\alpha]_{D}^{20}-48.18$ (c 4.5, EtOH).

The other runs for preparation of compound IV were carried out similarly (the reaction conditions and results are listed in Table 1).
(-)Menthyl 5-methylbicyclo[2.2.1]hept-2-ene-5carboxylate (V). From 11.2 g ( 0.05 mol ) of compound III and $3.92 \mathrm{~g}(0.06 \mathrm{~mol})$ of cyclopentadiene (I) along the above procedure at $-78^{\circ} \mathrm{C}$ we obtained
7.4 g of adduct $\mathrm{V}(52 \%) . M R_{D}$ found 83.04, calc. 84.07, $[\alpha]_{589}^{20}-54.48$ (c 7.93 EtOH$)$.

The other runs for preparation of compound $\mathbf{V}$ were performed similarly (the reaction conditions and results are listed in Table 1).

Isomeric bicyclo[2.2.1]hept-2-ene-5-carboxylic acids (VI, VIII). Compound IV ( $13.8 \mathrm{~g}, 0.05 \mathrm{~mol}$ ) was boiled for 2 h in 30 ml of $5 \% \mathrm{KOH}$ solution in methanol. On removing methanol the residue was dissolved in 30 ml of water, the products were extracted into ether. The water layer was treated with diluted HCl and repeatedly extracted with ether. The extract was washed with water, and dried on $\mathrm{MgSO}_{4}$. On removing ether we obtained $5.6 \mathrm{~g}(89 \%)$ of isomers VI and VIII mixture. The separation of endo VI and exo VIII isomers was carried out as in [17]. 6.3 g of isomer mixture of VI and VIII was neutralized with $10 \%$ solution of KOH , treated with 76 ml of iodine solution ( 15 g of $\mathrm{I}_{2}, 30 \mathrm{~g}$ of KI were dissolved in 90 ml of water). The precipitated iodolactone XIV was extracted into ether, the water layer was acidified with diluted HCl , the extraction was repeated, the extract was washed with $5 \%$ sodium thiosulfate solution, then with water, and dried with $\mathrm{MgSO}_{4}$. On removing the solvent by distillation we obtained exo-acid VIII. Its constants are given in Table 2.

Iodolactone XIV, isolated from the first extract, is a colorless crystalline substance, mp $59-60^{\circ} \mathrm{C}$ (from aqueous ethanol); cf.: $\mathrm{mp} 55-58^{\circ} \mathrm{C}$ [18]. endoAcid VI was obtained from iodolactone XIV by procedure [17]. The constants of acid VI are given in Table 2.

Isomeric 5-methylbicyclo[2.2.1]hept-2-ene-5carboxylic acids (VII, IX). Compound V (14.5 g) was boiled for 2 h in 30 ml of $5 \% \mathrm{KOH}$ solution. Further hydrolysis was similar to that with adduct IV. We obtained $6.2 \mathrm{~g}(89.8 \%)$ of a mixture of endo VII and exo IX isomers. The separation thereof was carried out as above.

Iodolactone XV is a colorless crystalline compound, $\mathrm{mp} 86-87^{\circ} \mathrm{C}$ (from aqueous ethanol) (83$85^{\circ} \mathrm{C}$ [17]). IR spectrum, $v, \mathrm{~cm}^{-1} 1730(\mathrm{C}=\mathrm{O}) ; 1100$ (C-O). Found, \%: C 38.21; H 3.9; I 45.51. $\mathrm{C}_{9} \mathrm{H}_{10} \mathrm{IO}_{2}$. Calculated, \%: C 38.84; H 3.98; I 45.68. By reduction of 6.95 g of iodolactone $\mathbf{X V}$ along procedure [17] we obtained 3.2 g of endo-acid VII.

Physical constants of acids VII and IX are given in Table 2.

Isomeric 5-hydroxymethylbicyclo[2.2.1]hept-2enes (X, XII). To a dispersion of 4 g of $\mathrm{LiAlH}_{4}$ in 200 ml of anhydrous ethyl ether was added dropwise 6.6 g of adduct IV solution in 50 ml of anhydrous ether. The mixture was stirred for 2 h at $20^{\circ} \mathrm{C}$. The excess $\mathrm{LiAlH}_{4}$ was hydrolyzed with water, then to the mixture was slowly added cooled diluted HCl . The ether layer was separated, washed with $5 \%$ solution of $\mathrm{NaHCO}_{3}$ and with water till neutral, and then dried with $\mathrm{MgSO}_{4}$. On removing ether we obtained 6.1 g of a mixture containing menthol and compounds X, XII. The mixture was separated by preparative chromatography. Physical constants of compounds $\mathbf{X}$ and XII are presented in Table 2. Mass spectra of both isomers are identical and have the following characteristics (relative intensity at 30 and $12 \mathrm{eV}, \%$ ): $M^{+} 124(17 ; 67), 106(10 ; 40), 93(5 ; 09), 66(100 ;$ 100).

5-Methyl- 5-hydroxymethylbicyclo[2.2.1]hept-2enes (XI, XIII). From 7.3 g of adduct $\mathbf{V}$ by reduction with $\mathrm{LiAlH}_{4}$ along the above procedure was obtained 6.9 g of mixture containing menthol and alcohols XI, XIII that was separated by preparative chromatography. Physical constants of compounds XI and XIII are presented in Table 2.

Mass spectra of both isomers are identical and have the following characteristics (relative intensity at 30 and $12 \mathrm{eV}, \%): M^{+} 138$ (95:32), 107 (12:14), 95 (24:26), 81 (26:50), 66 (100:100), 55 (21:5).
