

"CONVERSION SERIES" FOR TRIETHYLTIN DERIVATIVES  
USING SILVER SALTS

HERBERT H. ANDERSON<sup>1</sup> AND JOSEPH A. VASTA

*Received February 3, 1954*

Before the present research there has been no systematic investigation of organotin esters, halides, halogenoids, oxides and sulfides to demonstrate the conversion of one compound into another.

This paper offers a complete "conversion series" for triethyltin derivatives using dry silver salts with or without an inert solvent such as benzene, carbon tetrachloride, toluene, or xylene. In the "conversion series",  $\text{Et}_3\text{SnSCH}_3$  and  $(\text{Et}_3\text{Sn})_2\text{S} \rightarrow \text{Et}_3\text{SnI} \rightarrow \text{Et}_3\text{SnBr} \rightarrow \text{Et}_3\text{Sn}(\text{CN}) \rightarrow \text{Et}_3\text{Sn}(\text{NCS}) \rightarrow \text{Et}_3\text{SnCl} \rightarrow (\text{Et}_3\text{Sn})_2\text{O} \rightarrow \text{Et}_3\text{Sn}(\text{NCO}) \rightarrow \text{Et}_3\text{SnOCOCH}_3 \rightarrow \text{Et}_3\text{SnF}$  heating with the appropriate silver salt converts a triethyltin compound into any other triethyltin compound to the right of it in the series. Reactions proceed only slightly to the left, if at all. Silver iodide converts  $(\text{Et}_3\text{Sn})_2\text{S}$  into  $\text{Et}_3\text{SnI}$ ; silver bromide converts anhydrous  $\text{Et}_3\text{SnSCH}_3$ ,  $(\text{Et}_3\text{Sn})_2\text{S}$  and  $\text{Et}_3\text{SnI}$  all into  $\text{Et}_3\text{SnBr}$ ; silver cyanide changes  $\text{Et}_3\text{SnSCH}_3$ ,  $(\text{Et}_3\text{Sn})_2\text{S}$ ,  $\text{Et}_3\text{SnI}$ , and  $\text{Et}_3\text{SnBr}$  all into  $\text{Et}_3\text{Sn}(\text{CN})$ . No other atom or radical in this "conversion series" can displace the fluorine atom in  $\text{Et}_3\text{SnF}$ . We may also write the "conversion series" as  $\text{SCH}_3$  and  $\text{S} \rightarrow \text{I} \rightarrow \text{Br} \rightarrow \text{CN} \rightarrow \text{NCS} \rightarrow \text{Cl} \rightarrow \text{O} \rightarrow \text{NCO} \rightarrow \text{OCOCH}_3 \rightarrow \text{F}$  in considering ester groups, halide, halogenoid, oxygen, sulfur (sulfide), and methylmercaptide group only.

Several publications nearly a century ago demonstrated the use of silver salts in changing  $\text{Et}_3\text{SnI}$  into  $\text{Et}_3\text{Sn}(\text{CN})$  (1),  $\text{Et}_3\text{SnI}$  into unanalyzed  $\text{Et}_3\text{Sn}(\text{NCS})$  (1), also  $\text{Et}_3\text{SnCl}$  into  $\text{Et}_3\text{Sn}(\text{NCO})$  (1, 2)—but omitted boiling points and melting points. We have reexamined  $\text{Et}_3\text{Sn}(\text{NCO})$ ,  $\text{Et}_3\text{Sn}(\text{NCS})$ , and  $\text{Et}_3\text{Sn}(\text{CN})$ , furnishing boiling points, melting points, and other information.

Our best center-fraction  $\text{Et}_3\text{Sn}(\text{NCO})$  melted at  $48^\circ$ , boiled at  $239^\circ$  at 760 mm.,  $162\text{--}163^\circ$  at 80 mm., or  $120\text{--}121^\circ$  at 11 mm.; made from  $\text{Et}_3\text{SnBr}$  and  $\text{AgNCO}$ , there was no bromine present in the  $\text{Et}_3\text{Sn}(\text{NCO})$ . Our center-fraction  $\text{Et}_3\text{Sn}(\text{NCS})$ , prepared from  $\text{Et}_3\text{SnI}$  and  $\text{AgNCS}$ , contained no iodine; the  $\text{Et}_3\text{Sn}(\text{NCS})$  boiled at  $130^\circ/1$  mm., or at  $282^\circ$  with much decomposition under 760 mm.;  $\text{Et}_3\text{Sn}(\text{NCS})$  melts at  $33^\circ$ , but easily supercools to  $20^\circ$  without crystallization, furnishing (on supercooled liquid)  $d_4^{20}$ , 1.458 and  $n^{20}$ , 1.5825. Our best  $\text{Et}_3\text{Sn}(\text{CN})$  melted at  $153^\circ$  and boiled at  $249^\circ$  under 760 mm., with formation of an infusible white solid.  $\text{Et}_3\text{Sn}(\text{CN})$  must be sublimed at 8 mm. to avoid excessive decomposition; it hydrolyzes easily in moist air. Our center-fraction  $\text{Et}_3\text{SnSCH}_3$ , a new compound, prepared from  $(\text{Et}_3\text{Sn})_2\text{O}$  and  $\text{CH}_3\text{SH}$ , boiled at  $224^\circ$ , had  $d_4^{20}$  1.319 and  $n^{20}$  1.5290.

As expected,  $(\text{Et}_3\text{Sn})_2\text{O}$  reacts with either anhydrous liquid hydrogen cyanide or a solution of isothiocyanic acid in diethyl ether to yield  $\text{Et}_3\text{Sn}(\text{CN})$  and

<sup>1</sup> Kindly address communications to this author. Experiments by both authors.

$\text{Et}_3\text{Sn}(\text{NCS})$  respectively, but  $(\text{Et}_3\text{Sn})_2\text{O}$  does not react with anhydrous isocyanic acid to give  $\text{Et}_3\text{Sn}(\text{NCO})$ . Perhaps  $\text{HNCO}$  polymerizes too rapidly into cyanuric acid, a trimer, for reaction with the organotin oxide.

Other researches undertaken in this department by one of us have centered around "conversion series" for organosilicon and organogermanium esters, halides, halogenoids, oxides, and sulfides (3). Eaborn (4) presents excellent evidence of a "conversion series" for organosilicon compounds not including esters.

It is beyond the present publication to explain the mechanism of the reactions with silver salts, or to compare numerous differences in the four individual series for silicon, germanium, tin, or phosphorus.

The "conversion series" does not follow the solubility products of silver salts (using data for pure aqueous solutions); oxide and sulfide are usually not in the relative positions which solubility products could predict, assuming formation of the least soluble silver salt.

Specific examination of the reported "conversion series" for organotin derivatives shows that sulfide may be changed into any other atom or group in the series. This is the only instance yet of sulfide as the most replaceable in a series. Reactions using silver oxide are surprisingly difficultly performed, since the organotin derivatives often reduce silver oxide to the metal in the absence of a solvent.

In a number of combinations the forward reaction such as  $\text{Et}_3\text{SnBr} + \text{AgF} \rightarrow \text{Et}_3\text{SnF} + \text{AgBr}$  was quantitative while the reverse reaction  $\text{Et}_3\text{SnF} + \text{AgBr} \rightarrow \text{Et}_3\text{SnBr} + \text{AgF}$  went 2% to completion in the absence of a solvent. Perhaps the small bromine content of the  $\text{Et}_3\text{SnF}$  sublimate was actually due to hydrogen bromide. We consider this small percentage without effect on the "conversion series". Reactions of  $\text{Et}_3\text{Sn}(\text{NCO})$  with the appropriate silver salt yielded 10% of the chloride, 8% of the thiocyanate, or 5% of the cyanide which a pure chloride, thiocyanate or cyanide would contain—while silver cyanate converted the organotin chloride, thiocyanate, and cyanide quantitatively into (iso) cyanate. We consider this slight contradiction to be due to the known decomposition of silver cyanate.

## EXPERIMENTAL

### I. "CONVERSION SERIES"

*Reactions of  $\text{Et}_3\text{SnSCH}_3$ .* In each reaction 0.2 g. of  $\text{Et}_3\text{SnSCH}_3$  and 0.4 g. of the silver salt were subjected to an hour of reflux, except for the reaction with silver fluoride which was instantaneous and violent, yielding  $\text{Et}_3\text{SnF}$ , and the reaction with  $\text{Ag}_2\text{O}$ , which was quite violent. Silver cyanate yielded  $\text{Et}_3\text{Sn}(\text{NCO})$  in 5 ml. of toluene;  $\text{AgNCS}$  in toluene yielded  $\text{Et}_3\text{Sn}(\text{NCS})$ . In the absence of a solvent  $\text{AgCl}$ ,  $\text{AgCN}$ ,  $\text{AgBr}$  and  $\text{AgI}$  yielded  $\text{Et}_3\text{SnCl}$ ,  $\text{Et}_3\text{Sn}(\text{CN})$ ,  $\text{Et}_3\text{SnBr}$ , and  $\text{Et}_3\text{SnI}$  respectively, whereas reactions in toluene were quite slow in rate. Silver acetate and 1 g. of  $\text{Et}_3\text{SnS-iC}_3\text{H}_7$  (5) yielded  $\text{Et}_3\text{SnOCOCH}_3$ , m.p.  $121^\circ$ , b.p.  $217^\circ$ , after ten minutes of reflux under 60 mm.

*Reactions of  $(\text{Et}_3\text{Sn})_2\text{S}$ .* When not specified, 0.3 g. of  $(\text{Et}_3\text{Sn})_2\text{S}$  and 0.8 g. of the silver salt were used in an hour of reflux. Gentle warming with  $\text{AgF}$  produced cotton-like  $\text{Et}_3\text{SnF}$  easily. A 60-minute reflux of 0.20 g. of  $\text{Ag}_2\text{O}$  and 0.30 g. of  $(\text{Et}_3\text{Sn})_2\text{S}$  in 3 ml. of toluene gave a product about 96%  $(\text{Et}_3\text{Sn})_2\text{O}$  and 4%  $(\text{Et}_3\text{Sn})_2\text{S}$ . One gram of  $(\text{Et}_3\text{Sn})_2\text{S}$  and 1.50 g. of  $\text{AgOCOCH}_3$  after 15 minutes reflux at 50 mm. yielded 1.15 g. of  $\text{Et}_3\text{SnOCOCH}_3$  (5), m.p.

120°, b.p. about 220°. Using AgNCO in 3 ml. of benzene, AgCl in 2 ml of CCl<sub>4</sub>, AgNCS in 3 ml. of benzene, AgBr in 3 ml. of xylene, AgCN without a solvent, and AgI in 3 ml. of xylene we obtained the corresponding organotin derivatives free of sulfide content, after a 30-minute reflux.

*Reactions of Et<sub>3</sub>SnI.* Et<sub>3</sub>SnI and AgF (0.5 g. each) yielded Et<sub>3</sub>SnF in 30-minutes reflux in 3 ml. of xylene. One g. of Ag<sub>2</sub>O and 0.7 g. of Et<sub>3</sub>SnI in 5 ml. of CCl<sub>4</sub> yielded pure (Et<sub>3</sub>Sn)<sub>2</sub>O, free from iodine, in ten-minutes reflux. One g. of AgOCOCH<sub>3</sub> and 0.8 g. of Et<sub>3</sub>SnI in 5 ml. of CCl<sub>4</sub> yielded pure Et<sub>3</sub>SnOCOCH<sub>3</sub> after ten-minutes reflux. One g. of AgNCO and 0.7 g. of Et<sub>3</sub>SnI in 5 ml. of CCl<sub>4</sub> yielded iodine-free Et<sub>3</sub>Sn(NCO) after ten-minutes reflux. Two g. of AgCl and 1.1 g. of Et<sub>3</sub>SnI without a solvent yielded iodine-free Et<sub>3</sub>SnCl, b.p. 209°, *n*<sup>20</sup> 1.504. Et<sub>3</sub>SnI (20 g.) and 17 g. of AgNCS after two-hours reflux in 35 ml. of CCl<sub>4</sub> yielded a liquid of apparently low miscibility with CCl<sub>4</sub>; the silver salt was washed with benzene and later with 100% ethanol. The ethanol fraction was kept apart from other material for study of properties of Et<sub>3</sub>Sn(NCS). Rather pure Et<sub>3</sub>Sn(NCS) resulted when the compound was distilled at 1 mm. and the center fraction was taken. One g. of AgCN and 0.8 g. of Et<sub>3</sub>SnI in a reaction without solvent during 30-minutes reflux gave an iodine-free solid of m.p. roughly 100°, perhaps partially hydrolyzed. Two g. of AgBr and 1 g. of Et<sub>3</sub>SnI in a 30-minutes reflux without a solvent yielded iodide-free Et<sub>3</sub>SnBr of *n*<sup>23</sup> 1.521. Ten g. each of Ag<sub>2</sub>S and Et<sub>3</sub>SnI in two-hours reflux without a solvent yielded a liquid containing much iodine and boiling at about 225°—unchanged Et<sub>3</sub>SnI.

*Reactions of Et<sub>3</sub>SnBr.* When 0.6 g. of Et<sub>3</sub>SnBr and 0.8 g. of AgF in 4 ml. of xylene were refluxed 30 min., bromine-free Et<sub>3</sub>SnF was obtained. One g. of Ag<sub>2</sub>O and 0.7 g. of Et<sub>3</sub>SnBr in 5 ml. of xylene after an hour of reflux yielded (Et<sub>3</sub>Sn)<sub>2</sub>O containing only a trace of bromide. Et<sub>3</sub>SnBr and AgOCOCH<sub>3</sub> (0.5 g. each) without a solvent yielded solid (long white needles) Et<sub>3</sub>SnOCOCH<sub>3</sub> after 15-minutes reflux. Forty-minutes reflux of 14 g. of Et<sub>3</sub>SnBr and 11 g. of AgNCO in 30 ml. of benzene and 30 ml. of CCl<sub>4</sub> finally yielded bromine-free Et<sub>3</sub>Sn(NCO), b.p. 239°/760 mm. and m.p. 48°; actual purification utilized distillation at 120–121°/11 mm. pressure. A four-hour reflux, without solvent, of 1.34 g. of Et<sub>3</sub>SnBr and 2.20 g. of AgCl yielded organotin material of *d*<sub>4</sub><sup>20</sup> 1.462, containing some bromine—approximately 10% Et<sub>3</sub>SnBr at most; the main product was Et<sub>3</sub>SnCl. Ninety-minutes reflux of 2 g. of AgNCS and 2.80 g. of Et<sub>3</sub>SnBr in 5 ml. of benzene finally yielded 1.63 g. of Et<sub>3</sub>Sn(NCS), m.p. 32°C, *n*<sup>20</sup> 1.572, b.p. 135°/1 mm. A reaction in a test tube between 0.5 g. each of Et<sub>3</sub>SnBr and AgCN yielded a sublimate of white needles, Et<sub>3</sub>Sn(CN). When 3 g. of Et<sub>3</sub>SnBr was given an hour of reflux, without solvent, with either Ag<sub>2</sub>S or AgI, no test for sulfide and only a slight test for iodide resulted; the density of Et<sub>3</sub>SnBr rose only 0.1% in the iodide treatment.

*Reactions of Et<sub>3</sub>Sn(CN).* Gentle warming of 0.3 g. of Et<sub>3</sub>Sn(CN) and 0.4 g. of AgF produced cotton-like, cyanide-free Et<sub>3</sub>SnF. One-hour reflux of 0.3 g. each of Ag<sub>2</sub>O and Et<sub>3</sub>Sn(CN) in 3 ml. of toluene gave a cyanide-free product evidently (Et<sub>3</sub>Sn)<sub>2</sub>O. One hour of reflux of 0.3 g. of Et<sub>3</sub>Sn(CN) and 0.6 g. of AgOCOCH<sub>3</sub> in 3 ml. of toluene gave a cyanide-free product, Et<sub>3</sub>SnOCOCH<sub>3</sub>. An hour reflux of 0.2 g. of Et<sub>3</sub>Sn(CN) and 0.50 g. of AgNCO in 3 ml. of toluene yielded a product shown to be all cyanate and no cyanide—Et<sub>3</sub>Sn(NCO). Ten-minutes free reflux of 0.50 g. of Et<sub>3</sub>Sn(CN) and 1.10 g. of AgCl, without a solvent, gave liquid Et<sub>3</sub>SnCl, b.p. 207°, *n*<sup>23</sup> 1.502. Ten-minutes reflux of 1 g. of Et<sub>3</sub>Sn(CN) and 2.2 g. of AgNCS, without a solvent, under 80 mm. pressure, yielded Et<sub>3</sub>Sn(NCS) distilled at 130–135°/1 mm.; found *n*<sup>27</sup> 1.541, also much thiocyanate present, although some decomposition occurred. Triethyltin cyanide did not react with Ag<sub>2</sub>S, AgBr, or AgI under comparable conditions.

*Reactions of Et<sub>3</sub>Sn(NCS).* Gentle warming of 0.4 g. each of Et<sub>3</sub>Sn(NCS) and AgF yielded cotton-like Et<sub>3</sub>SnF. Using CCl<sub>4</sub> as solvent, an hour reflux of 0.3 g. each of Ag<sub>2</sub>O and Et<sub>3</sub>Sn(NCS) yielded (Et<sub>3</sub>Sn)<sub>2</sub>O containing very little thiocyanate. Similarly, AgOCOCH<sub>3</sub> furnished Et<sub>3</sub>SnOCOCH<sub>3</sub>, free of thiocyanate content; AgNCO furnished Et<sub>3</sub>Sn(NCO), free of thiocyanate content. A gram of Et<sub>3</sub>Sn(NCS) and 2.20 g. of AgCl in 5 ml. of xylene after one hour of reflux gave material 98% Et<sub>3</sub>SnCl and 2% Et<sub>3</sub>Sn(NCS). However, Et<sub>3</sub>Sn(NCS)

failed to react with AgCN, with AgBr (3 hours reflux of 2 g. of each in 5 ml. of benzene), AgI, or Ag<sub>2</sub>S.

*Reactions of Et<sub>3</sub>SnCl.* Gentle warming of Et<sub>3</sub>SnCl and AgF furnished cotton-like Et<sub>3</sub>SnF. One-hour reflux of 2 g. of Ag<sub>2</sub>O and 0.9 g. of Et<sub>3</sub>SnCl in 4 ml. of xylene furnished a solution of (Et<sub>3</sub>Sn)<sub>2</sub>O containing no chloride. One g. of Et<sub>3</sub>SnCl and 1.2 g. of AgOCOCH<sub>3</sub> without a solvent yielded white solid Et<sub>3</sub>SnOCOCH<sub>3</sub>, chloride-free, after 15-minutes reflux. Similarly, Et<sub>3</sub>SnCl and AgNCO yielded chloride-free Et<sub>3</sub>Sn(NCO). Triethyltin chloride, usually 1.5 g., and an equal weight of AgNCS, AgCN, AgBr, AgI, and Ag<sub>2</sub>S did not react under similar conditions.

*Reactions of (Et<sub>3</sub>Sn)<sub>2</sub>O.* Gentle warming of (Et<sub>3</sub>Sn)<sub>2</sub>O and AgF in a small test tube produced cotton-like Et<sub>3</sub>SnF. Exactly 1 g. of (Et<sub>3</sub>Sn)<sub>2</sub>O and 2 g. of AgOCOCH<sub>3</sub>, upon an hour of gentle reflux in CCl<sub>4</sub>, ultimately furnished white solid Et<sub>3</sub>SnOCOCH<sub>3</sub>, m.p. 108° and b.p. 220°. Reflux of 0.6 g. of (Et<sub>3</sub>Sn)<sub>2</sub>O and 1.1 g. of AgNCO in 4 ml. of xylene for 15 minutes, gave a black silver salt and a solution containing Et<sub>3</sub>Sn(NCO); treated with 80% ethanolic AgNO<sub>3</sub>, white AgNCO precipitated, but was soluble in dilute nitric acid. Reflux of (Et<sub>3</sub>Sn)<sub>2</sub>O and AgCl without a solvent gave a liquid boiling at 230°, predominately Et<sub>3</sub>SnCl, formed when Ag<sub>2</sub>O decomposed. However, (Et<sub>3</sub>Sn)<sub>2</sub>O and AgCl did not react during an hour of reflux in xylene, nor did (Et<sub>3</sub>Sn)<sub>2</sub>O and AgCN react. Two g. of (Et<sub>3</sub>Sn)<sub>2</sub>O and 4 g. of AgNCS in one hour of free reflux without a solvent yielded a product containing very little Et<sub>3</sub>Sn(NCS). Likewise, (Et<sub>3</sub>Sn)<sub>2</sub>O reacted not at all with AgI or Ag<sub>2</sub>S and only 4% with AgBr.

*Reactions of Et<sub>3</sub>Sn(NCO).* Gentle warming of 0.4 g. each of Et<sub>3</sub>Sn(NCO) and AgF produced cotton-like Et<sub>3</sub>SnF. Fifty-minutes reflux in 4 ml. of CCl<sub>4</sub> gave mainly no reaction with 0.22 g. of Ag<sub>2</sub>O and 0.35 g. of Et<sub>3</sub>Sn(NCO), since the precipitate obtained with 80% ethanolic AgNO<sub>3</sub> solution was pure white. However, about 10% of the precipitated silver salt was insoluble in concentrated nitric acid—evidently, cyanide formed by overheating the Et<sub>3</sub>Sn(NCO). Similarly, Et<sub>3</sub>Sn(NCO) and AgOCOCH<sub>3</sub> furnished nearly pure Et<sub>3</sub>SnOCOCH<sub>3</sub>, which contained very little isocyanate according to a test with concentrated sulfuric acid, then sodium hydroxide and Nessler's reagent. A one-hour reflux of 1 g. of Et<sub>3</sub>Sn(NCO) and 2 g. of AgCl gave a product with about 10% of the chloride content which pure Et<sub>3</sub>SnCl has; perhaps the known decomposition of AgNCO accounts for this. Heating 0.6 g. of Et<sub>3</sub>Sn(NCO) and a three-fold weight of AgNCS in 5 ml. of xylene for 90 minutes yielded a product with 4% of the thiocyanate which pure Et<sub>3</sub>Sn(NCS) has. Heating equal weights of Et<sub>3</sub>Sn(NCO) and AgCN gave a product with 5% of the cyanide which Et<sub>3</sub>Sn(CN) has; the decomposition of AgNCO seems responsible. However, Et<sub>3</sub>Sn(NCO) did not react with AgBr, AgI, or Ag<sub>2</sub>S.

*Reactions of Et<sub>3</sub>SnOCOCH<sub>3</sub>.* Gentle warming of 0.2 g. each of Et<sub>3</sub>SnOCOCH<sub>3</sub> and AgF without a solvent easily produced cotton-like Et<sub>3</sub>SnF in a small test tube; no acetate was present in the Et<sub>3</sub>SnF. Silver oxide and Et<sub>3</sub>SnOCOCH<sub>3</sub> without a solvent gave a rapid evolution of gases; in CCl<sub>4</sub> there was no reaction in a 30-minute reflux. According to a Nessler test for nitrogen, Et<sub>3</sub>SnOCOCH<sub>3</sub> and AgNCO did not react. Likewise, Et<sub>3</sub>SnOCOCH<sub>3</sub> reacted either not at all or 1% with AgCl, AgNCS, AgCN, AgBr, AgI, and Ag<sub>2</sub>S.

*Reactions of Et<sub>3</sub>SnF.* Neglecting a 2% reaction with AgBr, Et<sub>3</sub>SnF did not react with anything except AgOCOCH<sub>3</sub>; Et<sub>3</sub>SnF reacted with AgOCOCH<sub>3</sub> in the absence of a solvent, but not in benzene solution. Probably the decomposition of AgOCOCH<sub>3</sub> was responsible.

## II. PREPARATION OF STARTING MATERIALS

*Bis(triethyltin) oxide, (Et<sub>3</sub>Sn)<sub>2</sub>O,* was prepared either by reaction of SnCl<sub>4</sub> and a deficiency of EtMgBr (5)—or from Et<sub>3</sub>Sn and iodine, followed by treatment with aqueous sodium hydroxide. This key material boils at 272/760 mm., or at approximately 100°/1 mm. Reaction of (Et<sub>3</sub>Sn)<sub>2</sub>O with hydrofluoric acid gave Et<sub>3</sub>SnF; with acetic acid gave Et<sub>3</sub>SnOCOCH<sub>3</sub> (1, 5); with hydrochloric, hydrobromic, and hydriodic acid gave Et<sub>3</sub>SnCl, Et<sub>3</sub>SnBr.

and  $\text{Et}_3\text{SnI}$  respectively. Reaction of  $(\text{Et}_3\text{Sn})_2\text{O}$  and hydrogen sulfide gave  $(\text{Et}_3\text{Sn})_2\text{S}$  (5), and with  $\text{CH}_3\text{SH}$  gave  $\text{Et}_3\text{SnSCH}_3$ , a new compound.

An excess of gaseous  $\text{CH}_3\text{SH}$  bubbling through 10 g. of  $(\text{Et}_3\text{Sn})_2\text{O}$ , followed by drying with  $\text{Na}_2\text{SO}_4$ , separation of the liquid by pipetting, and then distillation yielded pure  $\text{Et}_3\text{SnSMe}$ , of  $d_4^{20}$  1.319,  $n_D^{20}$  1.529, b.p. 224°.

*Anal.* for  $\text{SCH}_3$ ; Found, 18.8, 18.9, 18.8. Calc'd, 18.6.

Described among the reactions of  $\text{Et}_3\text{SnBr}$ , the reaction with  $\text{AgNCO}$  yielded  $\text{Et}_3\text{Sn}(\text{NCO})$ , m.p. 48°, but often supercooling, and b.p. 239°/760 mm.; 162–163°/80 mm.; or 120–121°/11 mm. There was no bromine present in the small crystals of  $\text{Et}_3\text{Sn}(\text{NCO})$ .

Described among the reactions of  $\text{Et}_3\text{SnI}$ , the reaction with  $\text{AgNCS}$  yielded pure  $\text{Et}_3\text{Sn}(\text{NCS})$ , m.p. 33°, but supercooling to 20° easily; b.p. 130°/1 mm. or 282°/760 mm. with severe decomposition. On the supercooled liquid  $\text{Et}_3\text{Sn}(\text{NCS})$  had  $d_4^{20}$  1.458,  $n_D^{20}$  1.5825.

*Anal.* Calc'd: M. W., 264.0; Neut. equiv., 264.

Found: M. W. (in camphor), 267; Neut. equiv. (to  $\text{AgNO}_3$  with ferric ion), 272, 269.

Condensing excess liquid anhydrous hydrogen cyanide in a solution of 10 g. of  $(\text{Et}_3\text{Sn})_2\text{O}$  in 30 ml. of  $\text{CCl}_4$  at 0°, after drying with  $\text{Na}_2\text{SO}_4$  and distillation of solvent, yielded  $\text{Et}_3\text{Sn}(\text{CN})$ . This  $\text{Et}_3\text{Sn}(\text{CN})$  had m.p. 153°, b.p. 249° with severe decomposition; the sample was sublimed at 8 mm.

### III. REACTIONS OF $(\text{Et}_3\text{Sn})_2\text{O}$ WITH ACIDS

*Thiocyanic acid.* Exactly 1 g. of  $(\text{Et}_3\text{Sn})_2\text{O}$  and 2.5 ml. of 2.23 *M*  $\text{HNCS}$  in diethyl ether stood four hours over  $\text{Na}_2\text{SO}_4$ . Distillation of the solvent, after pipetting, was followed by distillation of  $\text{Et}_3\text{Sn}(\text{NCS})$  at 180° under 9 mm. The m.p. was above 20°,  $n_D^{20}$  was 1.580, with a yield of 0.85 g. or 70%.

*Isocyanic acid and sulfur dioxide.* Both of these were passed separately into  $(\text{Et}_3\text{Sn})_2\text{O}$  in the absence of a solvent. No reactions occurred.

*Hydrogen cyanide.* This successful reaction is described in the previous section.

### IV. RELATED INVESTIGATIONS IN PROGRESS

A "conversion series" for organosilicon compounds including esters is complete (6), while another "conversion series" for organogermanium compounds including esters is nearly complete.

Information assembled at this institute shows that Cahours' boiling point of  $\text{Et}_3\text{Sn}(\text{NCO})$ , 230° (1) is approximately 6° too high, while the melting point is very nearly 121°.

### SUMMARY

1. Using dry silver salts with or without an inert solvent such as benzene, carbon tetrachloride, toluene, or xylene, the "conversion series" for triethyltin esters, halides, halogenoids, oxide, and sulfide is  $\text{Et}_3\text{SnSCH}_3$  and  $(\text{Et}_3\text{Sn})_2\text{S} \rightarrow \text{Et}_3\text{SnI} \rightarrow \text{Et}_3\text{SnBr} \rightarrow \text{Et}_3\text{Sn}(\text{CN}) \rightarrow \text{Et}_3\text{Sn}(\text{NCS}) \rightarrow \text{Et}_3\text{SnCl} \rightarrow (\text{Et}_3\text{Sn})_2\text{O} \rightarrow \text{Et}_3\text{Sn}(\text{NCO}) \rightarrow \text{Et}_3\text{SnOCOCH}_3 \rightarrow \text{Et}_3\text{SnF}$  respectively. Heating with the appropriate silver salt converts a triethyltin compound into any triethyltin compound to the right of it in this series. Reactions proceed only very slightly, if at all, to the left. Organotin derivatives like these often react quite vigorously with silver oxide to yield silver metal.

2. Bis(triethyltin) oxide reacts easily with anhydrous liquid hydrogen cyanide or with ethereal thiocyanic acid furnishing  $\text{Et}_3\text{Sn}(\text{CN})$  and  $\text{Et}_3\text{Sn}(\text{NCS})$  respectively, but does not react with isocyanic acid. New physical data are presented for some compounds:  $\text{Et}_3\text{Sn}(\text{CN})$  has m.p. 153° and b.p. 249°;  $\text{Et}_3\text{Sn}(\text{NCO})$  has m.p. 48° and b.p. 239°;  $\text{Et}_3\text{Sn}(\text{NCS})$  has m.p. 33° and b.p. 282°; and the new

compound  $\text{Et}_3\text{SnSMe}$  has b.p.  $224^\circ$ . These halogenoid formulas carry no structural implication.

PHILADELPHIA 4, PENNA.
