## Dimethylhydrazones of Aliphatic, Aromatic, and Heterocyclic Aldehydes and Their Infrared Absorption Characteristics

RICHARD H. WILEY, STEPHEN C. SLAYMAKER, AND HAROLD KRAUS

Received July 16, 1956

A series of 37 aldehyde dimethylhydrazones have been prepared as isosteres of the tumor-growth retardant 3,3-dimethyl-2-phenyltriazeno. Infrared absorption data clearly establish a band at 1640–1590  $\text{cm}^{-1}$  characteristic of the C=N linkage and, as the strongest absorption in the spectra, a band at 1070–960  $\text{cm}^{-1}$  which can be correlated with the electron releasing or electron attracting character of the substituents in the benzene ring of the aromatic aldehyde dimethylhydrazones.

The observation that 3,3-dimethyl-1-phenyltriazeno,  $\text{C}_6\text{H}_5\text{N}=\text{N}-\text{N}(\text{CH}_3)_2$ , is an effective material for the retardation of tumor growth<sup>1</sup> suggested that the isosteric grouping,  $>\text{C}=\text{N}-\text{N}(\text{CH}_3)_2$ , might confer a similar activity on the aldehyde dimethylhydrazones in which the group is found. This class of compounds is practically completely unknown. The only previously recorded examples are the dimethylhydrazones of benzaldehyde,<sup>2</sup> *p*-isopropylbenzaldehyde,<sup>2</sup> furfural,<sup>3</sup> cyclohexanal,<sup>2</sup> formaldehyde,<sup>3</sup> and acetaldehyde.<sup>3</sup> Thirty-seven additional derivatives have now been prepared and their properties are described in the tables along with infrared absorption characteristics.

The availability of infrared data for these compounds makes it possible to establish new structural correlations for the atomic groups present. The series of aliphatic aldehyde dimethylhydrazones all show an absorption in the 1610  $\text{cm}^{-1}$  region which is attributable to the C=N stretching vibrations. This is apparently the first location of the frequency (C=N) in compounds containing the  $>\text{C}=\text{N}-\text{N}<$  group. In the series of dimethylhydrazones of formaldehyde-acetaldehyde-acetone the band shifts from 1585  $\text{cm}^{-1}$  to 1610  $\text{cm}^{-1}$  to 1639  $\text{cm}^{-1}$ . A similar shift occurs with increasing methyl substitution on the C=C band and can be attributed to either a weighting effect or the electron release characteristics of the methyl group. For the glyoxal derivative, the band is split into bands at 1678  $\text{cm}^{-1}$  and 1550  $\text{cm}^{-1}$ , presumably as a result of mechanical interaction or resonance between the two identical C=N bonds in which one band is raised, the other lowered with the average at 1614  $\text{cm}^{-1}$ .<sup>4</sup> Conjugation with the benzene ring would probably place this absorption band in the 1590  $\text{cm}^{-1}$  region which is intermediate between the 1600  $\text{cm}^{-1}$  and 1580  $\text{cm}^{-1}$

benzene C=C absorption bands. As a result the C=N band is obscured in the aromatic aldehyde derivatives, and a similar situation exists in the heterocyclic series. These types show two characteristic absorption bands at 1613–1587  $\text{cm}^{-1}$  and 1580–1555  $\text{cm}^{-1}$  and, in about a fourth of the examples, a third band at 1681–1616  $\text{cm}^{-1}$ .

The presence of two absorption bands centered at about 1471  $\text{cm}^{-1}$  and 1450  $\text{cm}^{-1}$  in nearly all of the dimethylhydrazones are characteristic carbon-hydrogen deformation modes associated with methyl (and methylene where present) groupings. These along with strong, characteristic C—H absorption bands in the 2941–2778  $\text{cm}^{-1}$  range are of confirmatory interest. Additional characteristic bands occurring in spectra of all types of dimethylhydrazones are found near 1282  $\text{cm}^{-1}$ , 1136  $\text{cm}^{-1}$ , and 870–905  $\text{cm}^{-1}$ . The last probably results from contributions from the C—H out of plane deformation also characteristic of the aldehyde CHO group<sup>5</sup> and the N—N stretching band,<sup>6</sup> both of which are known to occur in this region. It is present in 36 out of 38 compounds. The two exceptions are the acetaldehyde derivative and the acetone derivative.

Perhaps the strongest, and therefore most characteristic, band observed with every one of the 38 derivatives prepared is the 1066–963  $\text{cm}^{-1}$  region. Shifts in this band can be correlated with the electron releasing and attracting nature of the substituents in the aryl groups. Such correlations have been recorded relating shifts in the carbonyl absorption band to Hammett *sigma* values for substituted benzoic acid,<sup>7</sup> dibenzoyl peroxides,<sup>8</sup> and acetophenones.<sup>9</sup> Fig. 1 shows a plot of the wave length at which this absorption band occurs vs. Hammett *sigma* values for fifteen *m*- and *p*-substituted aryl and the pyridine aldehydes. <sup>a</sup> In the 1660-850 cm.<sup>-1</sup> range. All measured in carbon tetrachloride solution. <sup>b</sup> F. Klages *et al.*, *Ann.*, 547, 1-38 (1941). <sup>c</sup> Also 1410w, 1170m, 1036m. <sup>d</sup> The low nitrogen values are attributed to the presence of traces of water which could not be removed by techniques successfully used with others in this series which are also hygroscopic and form constant boiling mixtures. The acetylacetone product rapidly turns colored on exposure to air, apparently undergoing oxidation. <sup>e</sup> Also 1404w, 935m. <sup>f</sup> Also 1412w. <sup>g</sup> Also 1404w, 1010m, 893m. <sup>h</sup> Also 1010 m. <sup>i</sup> Also 1610m, 1439s, 1220w, 1198m, 1081m, 964s. <sup>j</sup> Also 1570m, 1437m, 1190m, 1087w, 1058m, 986w, 977w, 919w.

FIG. 1. INFRARED ABSORPTION vs. HAMMETT sigma VALUE FOR SUBSTITUTED ARYL DIMETHYLHYDRAZONES.

presence of this strong band at 965 cm.<sup>-1</sup>, the highest value of the entire series, in acetone dimethylhydrazone, can be attributed to the electron release characteristics of the two methyl groups indicating the importance of hyperconjugation structures. This is not, however, consistent with the observation that this band occurs at 1008 cm.<sup>-1</sup> in formaldehyde dimethylhydrazone and 1028 cm.<sup>-1</sup> in acetaldehyde dimethylhydrazone. One would expect a value for the formaldehyde derivative below that for the acetaldehyde derivative.

Preliminary incomplete data on the evaluation of these materials in tumor growth retardation studies have shown that pyridine-3-carboxaldehyde dimethylhydrazone has a ±, - rating at a dose level of 30 mg./kg. in tests on experimental mouse sarcoma 180.<sup>10</sup> Tests with pyridine-2,6-dicarboxaldehyde dimethylhydrazone and with pyridine-4-carboxaldehyde methylhydrazone have shown ± (250 mg./kg.), - (125 mg./kg.) and ±, ? (125 mg./kg.) ratings, respectively. Many of the others are toxic. These results do not establish either strong or consistent activity and additional testing to determine the meaning of these results is necessary.

EXPERIMENTAL<sup>11</sup>

Details of typical preparations of materials listed in the tables are given. The aldehydes, dimethylhydrazine, and methylhydrazine were obtained from commercial sources.<sup>12</sup> Most of the heterocyclic hydrazones were unstable and turned dark on standing.

*Isobutyraldehyde dimethylhydrazone.* A solution of 7.0 g. (0.1 mole) of isobutyraldehyde and 7.0 g. (0.116 mole) of dimethylhydrazine was heated to reflux and cooled. Solid sodium hydroxide was added to induce the separation of two layers. The nonaqueous layer was separated and the treatment with solid sodium hydroxide was repeated until no aqueous layer separated. Distillation from sodium hydroxide gave 7.0 g., 64%, of isobutyraldehyde dimethylhydrazone, b.p. 125-127°.

(10) The authors are indebted to Dr. C. C. Stock and Dr. D. A. Clarke, Sloan-Kettering Institute, for conducting these evaluations. The testing procedure and rating scale have been described by Stock *et al.*, *Cancer Research, Suppl. No. 1*, p. 91 (1953) and *Suppl. No. 2*, p. 179 (1955).

(11) Analyses by Micro Tech Laboratories, Skokie, Ill.

(12) The authors acknowledge with thanks the gift of samples of acetylacetone and glutaraldehyde from Carbide and Carbon Chemicals Corp. and of 2,5-diethoxyterephthalaldehyde from Tennessee Eastman Co.

Todd, *J. Am. Chem. Soc.*, **71**, 1353 (1949).

*o*-Ethoxybenzaldehyde dimethylhydrazone. A solution of 15 g. (0.1 mole) of *o*-ethoxybenzaldehyde and 7.0 g. (0.116 mole) of dimethylhydrazine was refluxed 3 hr. Distillation of the reaction mixture, after evaporation of the excess hydrazine, gave 12.6 g., 66%, of the product, b.p. 136–138°/4 mm.

2,5-Diethoxyterephthalaldehyde bis(dimethylhydrazone). A solution of 6.6 g. (0.03 mole) of 2,5-diethoxyterephthalaldehyde and 5.0 g. (0.083 mole) of dimethylhydrazine in 25 ml. of alcohol was refluxed for 3 hr. The solid which precipitated on cooling was recrystallized from methanol-water to give 2.0 g., 22%, of the product, m.p. 147–148°.

*p*-Dimethylaminobenzaldehyde dimethylhydrazone. A solution of 15 g. (0.1 mole) of *p*-dimethylaminobenzaldehyde and 7.0 g. (0.116 mole) of dimethylhydrazine in 30 ml. of concentrated hydrochloric acid and 25 ml. of ethanol was refluxed for 3 hr. The solution was made basic with concentrated ammonium hydroxide, filtered hot, and cooled to precipitate the crude product. Recrystallization from ethanol-water gave 5.0 g., 26%, of the product, m.p. 74–75°.

Pyridine-2-carboxaldehyde dimethylhydrazone. A mixture of 5.35 g. (0.05 mole) of pyridine-2-carboxaldehyde and 4.0 g. (0.067 mole) of dimethylhydrazine was fractionated after standing 1 hr. to give 5.7 g., 77%, of the crude product, b.p. 128–132°/13 mm. Refractionation gave the pure product, b.p. 128–130°/13 mm.,  $n_D^{25}$  1.6038. The picrate prepared from this product melts at 185–186°.

Pyridine-4-carboxaldehyde dimethylhydrazone. This product was prepared by the procedure given for the isomeric 2-carboxaldehyde. The fraction b.p. 136–149°/21 mm. solidified in the receiver. Recrystallization from petroleum ether gave 73% of the product, m.p. 60–64°. Additional recrystallization from petroleum ether and from water gave the pure product, m.p. 65–66°.

Infrared spectra were determined using a Baird double beam recording spectrophotometer with sodium chloride optics. All measurements were calibrated against the 3.419 $\mu$  band for polystyrene. The medium used is given in the tables of data. Solutions were run at approximately 5% concentrations. The abbreviations used signify w (weak), m (medium), s (strong), S or vs (very strong), sh (shoulder)

## Infrared Spectra of Allenic Compounds

JOHN H. WOTIZ AND DALE E. MANCUSO<sup>1</sup>

Received July 31, 1956

From the inspection of the infrared spectra of 58 allenic compounds, 48 of them from the literature, 2 resynthesized, and 8 synthesized for this study, it was concluded that the bands at 1950 and 850  $\text{cm}^{-1}$  are characteristic of the allene bond system with certain variations due to substitution. The antisymmetrical stretching frequency at 1950  $\text{cm}^{-1}$  appears as a doublet when the allene group is terminal and is substituted by an electron-attracting group ( $\text{CO}_2\text{H}$ ,  $\text{CO}_2\text{R}$ ,  $\text{CONH}_2$ ,  $\text{COCl}$ ,  $\text{COR}$ ,  $\text{CF}_3$ ,  $\text{CN}$ ). Its intensity decreases with increasing substitution of electronically similar groups. The band at 850  $\text{cm}^{-1}$  is characteristic of the terminal  $=\text{CH}_2$  group and its absence is good evidence for the absence of terminal allenes. It has an overtone at 1700  $\text{cm}^{-1}$  of low intensity. The synthesis of the new allenes is described.

Because of the increasing interest in allenic compounds it became important to develop fast and safe methods for their identification. The present paper deals with the application of infrared spectroscopy to this problem. Certain empirical rules became apparent which were successfully tested and applied to all available allenic compounds. Some allenic compounds were especially synthesized for this study; other data were collected from the literature or obtained by personal communications with other investigators. In some cases infrared spectra of the allenic compounds prepared by other workers was determined in our laboratories.<sup>2</sup>

For the identification of allenes two bands are of special interest. In the 1950  $\text{cm}^{-1}$  region,  $\nu_1$  (due to the antisymmetrical  $\text{C}=\text{C}=\text{C}$  stretching vibration) sometimes appears as a doublet,<sup>3</sup> and  $\nu_2$

(due to torsional motion of an allenic terminal methylene) in the 850  $\text{cm}^{-1}$  region. The latter band has an overtone,  $2\nu_2$  at 1700  $\text{cm}^{-1}$ . The presence of  $\nu_1$  and  $\nu_2$  and their relative intensities clearly differentiates between allenes containing various substituents. Tables I to V list the allenic compounds available for this study and the position and intensities of the  $\nu_1$ ,  $\nu_2$  and  $2\nu_2$  bands.

*Explanation of Tables I to V.* Tables I to V contain pertinent infrared data collected during this study for allenic compounds. These data were obtained from many different sources, under diversified conditions and using many different instruments. Therefore, the actual frequencies of the absorption bands listed in these tables are quite uncertain.

Frequencies are in reciprocal centimeters ( $\text{cm}^{-1}$ ). The frequency of a band is followed by an intensity description. The usual terms ( $\nu$  = very, s = strong, m = medium, w = weak) are used.

The meanings of other terms are: — = no appreciable absorption band; na = information for this frequency range is not available; [] = "ac-
