## The Photolysis of Diazomethane and Ethyl Diazoacetate in the Presence of 4-Octyne<sup>1</sup>

HANNS LIND AND ARCHIE J. DEUTSCHMAN, JR.

Department of Agricultural Biochemistry, University of Arizona, Tucson, Arizona 85721

Received July 12, 1966

The addition of methylene and carboethoxycarbene, generated photochemically from diazomethane and ethyl diazoacetate, to 4-octyne yielded 1,2-di-n-propylcyclopropene and ethyl 1,2-di-n-propylcyclopropene-3-carboxylate, respectively. It is shown that a close to statistical reaction of methylene and a more discriminate reaction of carboethoxycarbene with the carbon-hydrogen bonds occur together with addition to the acetylenic bond. Diels-Alder reaction of 1,2-di-n-propylcyclopropene and 1,2-di-n-propylcyclopropene 3-carboxylate with cyclopentadiene afforded the *endo* adducts in both cases.

One of the many outgrowths of the chemistry of divalent carbon<sup>2</sup> has been the synthesis of cyclopropenes, especially the reactions of metal-catalyzed decomposition of diazoacetic esters<sup>3</sup> with acetylenes. Photolytic decomposition of diazomethane and methyl diazoacetate in the presence of 2-butyne has been reported<sup>4</sup> to yield 1,2-dimethylcyclopropene and methyl 1,2-dimethylcyclopropene-3-carboxylate, respectively. Because there was an interest in a one-step synthesis of <sup>14</sup>C-3 labeled cyclopropenes in this laboratory, the photoinduced reaction of diazomethane and ethyl diazoacetate with 4-octyne was investigated.

The photodecomposition of diazomethane was carried out at  $-78^{\circ}$  with a high-pressure mercury lamp giving light only above 300 m $\mu$  by use of a filter. No solvent was used in order to keep the number of reaction products as low as possible. 1,2-Di-n-propylcyclopropene (1) was isolated in yields up to 25% based on N-nitrosomethylurea. Its half-life at room temperature is about 4 weeks, and it can be stored in the refrigerator without polymerization.<sup>5</sup>

Structural proof of 1 is based on elemental analysis, and infrared and nmr spectra. The empirical formula  $C_9H_{16}$  could imply three structural isomers, 1-1b. The nmr spectrum shows two equivalent *n*-propyl groups and two allylic protons but no vinyl proton,

thus supporting structure 1. The infrared spectrum contains absorption at  $1865^6$  and 1007 cm<sup>-17</sup> with no absorption around 910 cm<sup>-18</sup> eliminating vinyleyclopropanes of the type 1a. There is no ultraviolet absorption above 200 m $\mu$ . In accordance with structure 1, a positive Halphen test<sup>9</sup> is observed.

The adduction of 1 with excess cyclopentadiene<sup>10</sup> was carried out directly in the photolysis mixture to give the adduct 5a in 75% yield. Elemental analysis and infrared and nmr spectra are in accord with the tricyclic structure. A choice between the *endo* or *exo* configuration for the tricycloctene 5a was accomplished by nmr spectroscopy. The cyclopropyl proton of *endo* form 5a should be shielded by the double bond and therefore shifted to a higher field compared to that

- (6) Faure and Smith<sup>7</sup> found a weak absorption in sterculic acid at 1865 cm<sup>-1</sup> and anticipate that the carbon-carbon double-bond stretching frequency in cyclopropenes should lie between those of simple olefins and acetylenes; for further references, see ref 3c.

for the same proton of the saturated adduct 6a. Shielding of 0.67 ppm for the cyclopropyl proton of 5a11 establishes the endo configuration.

The three possible side products of the photoinduced decomposition of diazomethane in the presence of 4-octyne, 6-methyl-4-octyne (2), 7-methyl-4-octyne (3), and 4-nonyne (4), which can result from methylene insertion into the carbon-hydrogen bonds of the 4octyne molecule, 12 were isolated. 4-Octyne contains

primary, secondary, and "allylic" hydrogens, and insertion of methylene can occur principally at each of these bonds to give 4, 3, and 2, respectively, in the statistical ratio of 6:4:4. Addition to the acetylenic bond can also take place to yield 1,2-di-n-propyleyclopropene (1). Actually these four products are formed in the ratio of 23:19:19:38,13 respectively. This suggests that the relative reactivity of methylene with the acetylenic bond of 4-octyne is about eight times that with a carbon-hydrogen bond in the same molecule and the distribution of methylene insertion products is close to statistical.

The structures of 6-methyl-4-octyne (2) and 7methyl-4-octyne (3) were confirmed by synthesis. They were prepared by alkylation of lithium-1-pentyne with sec-butyl bromide and isobutyl p-toluenesulfonate, respectively, according to the general procedure of Elsner and Paul.14 The low yields (17% for 3 and 4% for 2) are probably caused by either the limited solubility of lithium-1-pentyne in dioxane<sup>15</sup> or a basecatalyzed olefin formation. Carbon-hydrogen analyses and spectroscopic data are in agreement with the structures assigned.

Similar to the copper-catalyzed reaction, 16 the photodecomposition of ethyl diazoacetate in 4-octyne solu-

(11) M. A. Battiste 10 reports shielding constants of comparable magnitude for the adduct of triphenylcyclopropene-cyclopentadiene.

tion affords ethyl 1,2-di-n-propylcyclopropene-3-carboxylate (7) in high yield. Analysis of the reaction mixture indicated additional formation of ethyl 3ethyl-4-octynoate (8), ethyl 3-methyl-5-nonynoate (9), and ethyl 6-decynoate (10) according to insertion reactions of carboethoxycarbene into the various carbon-hydrogen bonds of 4-octyne. The actual ratio of formation of 8, 9, and 10 is 14:15:10, compared with the statistical, nondiscriminatory ratio of 4:4:6. This indicates a certain selectivity 17 of carbethoxycarbene in its reactivity toward the different carbonhydrogen bonds in 4-octyne. Although these experiments show the right trend, it is surprising that there seems to be no preference for the methylene group "allylic" to the acetylenic bond. The over-all ratio of products 7:8:9:10 is 61:14:15:10. This shows that the reaction of carbethoxycarbene with the acetylenic bond to yield the cyclopropene ester 7 is about 21 times that with a single carbon-hydrogen bond.

When the irradiations of ethyl diazoacetate in 4octyne were run in air rather than under nitrogen, extensive formation of an alkyne ketone and an alkyne carbinol occurred in addition to the reaction products 7, 8, 9, and 10. Thus, 4-octyn-3-one (11) and 4octyn-3-ol (12) in 15 and 9% yield, respectively, were isolated from the photolysis solutions. Since similar results were not obtained in the photolysis of diazo-

methane with 4-octyne, the formation of these oxidation products appears to be due to the reaction of molecular oxygen with some intermediate in the photodecomposition of ethyl diazoacetate. 18

The reaction products from photolysis of ethyl diazoacetate with 4-octyne were identified by comparison with authentic samples. Thus, reaction of 4-octyn-3-ol (12) with phosphorus tribromide-pyridine 19 yielded 3-bromo-4-octyne as the only product. Malonic ester synthesis and esterification of the resulting 3-ethyl-4octynoic acid gave 8 in reasonable yields. Infrared and nmr spectra are consistent with the proposed structure. Carbon-hydrogen analysis confirmed the empirical formula. The structures of 9 and 10 were elucidated by catalytic hydrogenation to give ethyl 3-methylpelargonate (13) and ethyl caprate. An authentic sample of 13 was prepared by malonic ester synthesis.20 Allylic oxidation of 4-octyn-3-ol (12) with active manganese dioxide21 gave 4-octyn-3-one (11) which showed strong infrared absorption at 2220 and 1680 cm<sup>-1</sup>. The spectral data and elemental analysis confirm the structure assigned.

Similar to 1, cyclopropene ester 7 yielded adduct 5b when refluxed with excess cyclopentadiene. Infrared and nmr spectra and carbon-hydrogen analysis sup-

<sup>(12)</sup> For the indiscriminate reaction of methylene with carbon-hydrogen bonds, see W. von E. Doering, R. G. Buttery, R. G. Laughlin, and N. Chaudhuri, J. Am. Chem. Soc., 78, 3225 (1956); D. B. Richardson, M. C. Simmons, and I. Dvoretzky, ibid., 82, 5001 (1960); 83, 1934 (1961).

<sup>(13)</sup> Differences between these statistical and actual ratios are not considered to be quantitative, because an estimated 10% experimental error exists in the determination of the actual ratios.

<sup>(14)</sup> B. B. Elsner and P. F. Paul, J. Chem. Soc., 893 (1957).
(15) The solubility of lithium alkynes in dioxane is directly related to the chain length of the alkyne: lithium-1-hexyne is completely soluble; lithium acetylide is completely insoluble [H. H. Schlubach and K. Repenning, Ann. Chem., 614, 37 (1958)].

<sup>(16)</sup> I. A. D'yakonov, M. I. Komendantov, I. G. Gokhamonova, and R. Kostikov, Zh. Obshch. Khim., 29, 3848 (1959).

<sup>(17)</sup> Carbethoxycarbene has been shown to increase in reactivity toward carbon-hydrogen bonds in the order primary, secondary, tertiary: E. Doering and L. H. Knox, J. Am. Chem. Soc., 78, 4947 (1956); 83, 1989 (1961).

<sup>(18)</sup> This observation is supported by results of Hamilton and Giacin who observed oxidation of saturated hydrocarbons with molecular oxygen and triplet carbenes: G. A. Hamilton and J. R. Giacin, *ibid.*, **88**, 1584 (1966). (19) W. J. Gensler and J. J. Bruno, J. Org. Chem., **28**, 1254 (1963). (20) F. S. Prout, D. E. Dickson, and R. J. Klimkowski, *ibid.*, **24**, 826

ported the tricyclooctene ester structure. Catalytic hydrogenation gave the saturated product (6b). Comparison of nmr spectra for 5b and 6b revealed the same relationship for the cyclopropyl proton resonance that was observed for 5a with similar shielding of 0.62 ppm. The configuration of the adduct 5b is therefore considered to be *endo*.

The mechanism of the photolytic reaction of diazomethane and ethyl diazoacetate with 4-octyne is not understood at this time. It is uncertain whether direct addition of free carbenes to the acetylenic bond or photolytic decomposition of intermediate pyrazolen-

$$RC \equiv CR + N_2C \leftarrow \begin{bmatrix} R & R & R \\ R & N^2N \end{bmatrix} \rightarrow \begin{bmatrix} R & R \\ R & R \end{bmatrix} + N_2$$

$$R = n \cdot C_2H_2$$

ines 14 occurs, or if both species are involved in formation of cyclopropenes and products of insertion reactions into the carbon-hydrogen bond.<sup>22</sup>

## **Experimental Section**

All boiling points are uncorrected. Infrared spectra were taken on Perkin-Elmer, Model 337 or Beckman IR-4 spectrophotometers. Nuclear magnetic resonance spectra were taken on a Varian A-60 spectrometer, using tetramethylsilane as an internal standard. Chemical shifts are measured to the estimated center of moment of a multiplet or singlet. Elemental analysis was carried out by Schwarzkopf Microanalytical Laboratory, Woodside, N. Y.

The Photolytic Reaction of Diazomethane with 4-Octyne.—A solution of diazomethane in decalin was prepared by adding 30 g of N-nitrosomethylurea to a well-stirred, ice-cold mixture of 600 ml of decalin and 120 ml of 40% aqueous potassium hydroxide over a 30-min period. After separation of the two-layer system and drying of the decalin phase over potassium hydroxide pellets, the diazomethane was transferred into 300 ml of chilled (-78°) 4-octyne by passing a stream of dry nitrogen through the diazomethane solution and allowing it to come to room temperature. The irradiation of the diazomethane-4-octyne system was accomplished by means of a water-cooled (25°), high-pressure mercury immersion lamp (75 w, designed and built in this laboratory) surrounded by a transparent Pyrex glass dewar vessel, which served as both a heat shield and light filter. This complete unit was immersed in the reaction solution which was maintained at -78°. A total of four doses of diazomethane was introduced at intervals sufficiently long to permit the decomposition of the preceding dose. The diazomethane content of each run was determined by titration against benzoic acid, and varied from 65 to 70% with the average concentration of 0.4 M in the 4-octyne.

Gas chromatography [15% tricyanoethylpropane on Chromosorb P (TCEP), 45°] of the photolyzed reaction mixture indicated 38% of 1,2-di-n-propylcyclopropene (1), 19% of 7-methyl-4-octyne (3), and 23% of 4-nonyne (4)<sup>23</sup> corresponding to 25, 12, and 15% of theory based on N-nitrosomethylurea (acetone as internal standard). Chromatography (15% TCEP, 45°) did not resolve 6-methyl-4-octyne (2) from 4-octyne but easily separated this mixture from the other compounds in a concentrate after distilling off most of the 4-octyne; in this case analysis was made by chromatography with known mixtures of the authentic acetylenes. Thus in a normal run 19% of 6-methyl-4-octyne (2) (12% based on N-nitrosomethylurea) was detected.

1,2-Di-n-propylcyclopropene (1).—Samples of 1 were collected on a preparative gas chromatography column (5 ft  $\times$  0.5 in. i.d.,

15% TCEP, 55°) from a fraction²⁴ boiling from 140 to 145° (760 mm) of the above photolysis solution and were stable when stored at 0° under nitrogen. At room temperature 1 polymerized slowly, and could not be detected²⁵ by means of the Halphen reaction after a period of 8 weeks. Pure 1 (n²⁰0 1.4310) showed no absorption in the ultraviolet (10⁻³8M, in ethanol). Infrared (CCl₄) showed 1865 (cyclopropenyl C=C stretch)² and 1007 cm⁻¹.⁵ Nmr (CCl₄) showed 2.48 (triplet, J=7.0 cps, 4 H, allylic), 1.66 (sextet, J=7.0 cps, 4 H, CH₂), 1.0 (triplet, J=6.5 cps, 6 H, CH₃), and 0.78 ppm (singlet, 2 H, cyclopropenyl), consistent with the structure assigned.

Anal. Calcd for  $C_9H_{16}$ : C, 87.02; H, 12.97. Found: C, 87.17; H, 13.02.

6-Methyl-4-octyne (2).—Lithium-1-pentyne<sup>26</sup> (0.15 mole in 140 ml of dry dioxane) was heated with sec-butyl bromide (41.1 g, 0.30 mole) in an autoclave for 17 hr at 150°. After cooling to room temperature the reaction mixture was poured into 1000 ml of water and the resulting mixture was extracted with ether. The extracts were neutralized with 10% sulfuric acid and dried over anhydrous calcium chloride. Evaporation of the ether and distillation of the residue afforded 1.5 g (4%) of product, bp 136–138° (760 mm). Purification by gas chromatography (15% TCEP, 90°) showed little contamination by 2-bromobutane. Collection of the major product afforded pure 2,  $n^{20}$ D 1.4237. Nmr (CCl<sub>4</sub>) showed 2.21 (multiplet, 3 H, allylic), 1.41 (broad multiplet, 4 H, CH<sub>2</sub>), and 0.81 ppm (multiplet, 9 H, CH<sub>3</sub>).

Anal. Calcd for  $C_9H_{16}$ : C, 87.02; H, 12.97. Found: C, 86.96; H, 13.17.

Both authentic and original 2 had the same analytical data.

7-Methyl-4-octyne (3).—To a slightly brown solution of lithium-1-pentyne<sup>26</sup> (0.15 mole in 140 ml of dry dioxane) was added dropwise at 90° isobutyl p-toluenesulfonate (32 g, 0.14 mole). After 1 hr at this temperature the reaction mixture solidified. On working up as shown for 6-methyl-4-octyne (2) the residue was distilled to yield 3.0 g (17%) of acetylene 3, bp 55° (27 mm);  $n^{24}$ D 1.4250. Nmr (CCl<sub>4</sub>) showed 2.20 (multiplet, 4 H, allylic), 1.60 (multiplet, 3 H, CH<sub>2</sub>), 1.01 (multiplet, 9 H, CH<sub>3</sub>) with superimposed peaks at 0.99 (triplet, J = 7.0 cps), and 0.98 ppm (doublet, J = 6.0 cps) consistent with 7-methyl-4-octyne (3).

Anal. Calcd for  $C_9H_{16}$ : C, 87.02; H, 12.97. Found: C, 87.05; H, 12.74.

Authentic and original 3 were identical in infrared and nmr spectroscopy.

The Reaction of 1,2-Di-n-propylcyclopropene (1) with Cyclopentadiene. Adduct 5a.—Freshly distilled cyclopentadiene (15 g, 0.227 mole) was added to 148 g of a reaction mixture from the photolysis of diazomethane with 4-octyne which contained 20 g of 1. After 24 hr at 50° the fraction boiling from 96 to 100° (5 mm) was collected; redistillation of this fraction yielded the pure adduct 5a (23 g, 75%), bp 98.5-100° (5 mm), n<sup>20</sup>D 1.4759. Infrared (neat) showed 3065, 1102, 1044, 995, 903, and 741 cm<sup>-1</sup>. Nmr<sup>27,28</sup> (CCl<sub>4</sub>) showed 5.76 (triplet), 2.57 (multiplet), 1.68 (multiplet), 1.43 (multiplet), 0.62 (doublet, cyclopropyl), and 0.91 ppm (triplet).

Anal. Calcd for  $C_{14}H_{22}$ : C, 88.35; H, 11.65. Found: C, 88.44; H, 11.76.

Hydrogenation of Adduct 5a.—A mixture of 5% palladium on charcoal (2 g) and 5a (9.0 g, 0.0474 mole) in 100 ml of ethyl acetate was hydrogenated under a hydrogen pressure of 200 psi at room temperature. After hydrogen uptake the solvent was removed. On distillation with a short-path still the pure, saturated adduct 6a was obtained (8.8 g, 97%), bp 93–94° (2.3 mm),  $n^{20}$ D 1.4725. Infrared (neat) showed 3065 (cyclopropyl CH), 1102, 1036, 986, and 903 cm<sup>-1</sup>. Nmr<sup>27</sup> (CCl<sub>4</sub>) showed 2.06 (broad singlet), 1.29 (doublet, cyclopropyl), and 1.17 ppm (broad singlet).

<sup>(22)</sup> The formation of cyclopropenes by photodecomposition of pyrazolenines is well established: G. L. Closs and W. A. Böll, Angew. Chem., 75, 640 (1963); J. Am. Chem. Soc., 85, 3904 (1963); R. Anet and F. A. L. Anet, ibid., 86, 525 (1964).

<sup>(23)</sup> Identified by comparison with commercially obtained 4-nonyne from K & K Laboratories, Inc.

<sup>(24)</sup> This fraction contained approximately 38% of 1, determined by nmr spectroscopic comparison of the cyclopropenyl-H singlet at 0.78 ppm in a pure sample of 1 and the above, distilled fraction.

<sup>(25)</sup> Cf. A. J. Deutschman, Jr., and I. S. Klaus, Anal. Chem., 32, 1809 (1960).

<sup>(26)</sup> Lithium-1-pentyne was prepared by adapting the procedure of Schlubach and Repenning<sup>18</sup> for lithium-1-hexyne.

<sup>(27)</sup> The spectrum had a rather complex pattern and only clearly distinguishable absorptions are listed. The relative peak areas agreed with the structure assigned. In all cases the CH<sub>2</sub> protons were masked and thus not identified.

<sup>(28)</sup> These values should be compared with the reported frequencies for the adduct cyclopropene-cyclopentadiene. 10a

Anal. Calcd for C14H24: C, 87.40; H, 12.58. Found: C, 87.42: H, 12.58.

The Photolytic Reaction of Ethyl Diazoacetate with 4-Octyne. -Ethyl diazoacetate (10 g, 0.87 mole) in 90 ml of degassed 4octyne was irradiated under oxygen-free nitrogen with a watercooled, high-pressure mercury immersion lamp (quartz ultraviolet) at room temperature until the diazoester could no longer be detected in the infrared (2130 cm<sup>-1</sup>, diazo stretching). After removal of excess 4-octyne by vacuum distillation [bp up to 55° (20 mm)] the residue was fractionated using gas chromatography (15% TCEP, 120°, nitrobenzene as internal standard). The major fraction (61%) had the following spectra: infrared (neat) showed 1900 (cyclopropenyl C=C stretching), 1725 (ester C=O), and 1025 cm<sup>-1</sup>; nmr (CCl<sub>4</sub>) showed 4.32 (quartet, J =7.0 cps, 2 H, OCH<sub>2</sub>), 2.51 (triplet, J = 7.5 cps, 4 H, allylic), 2.13 (singlet, 1 H, cyclopropenyl), 1.41 (broad multiplet, 13 H, aliphatical), with superimposed peaks at 1.26 (triplet, J=7.4 cps) and 0.98 ppm (triplet, J=7.0 cps), consistent with ethyl 1,2-di-n-propylcyclopropene-3-carboxylate (7)<sup>16</sup> (58%).

The first minor product (14%) was identical with authentic 8

in infrared and nmr spectra (15% yield).

The second minor product (15%) exhibited these spectra: infrared (neat) showed 1740 cm<sup>-1</sup> (ester C=O); nmr (CCl<sub>4</sub>) showed 4.39 (quartet, J = 7.0 cps, 2 H, OCH<sub>2</sub>), 2.30 (multiplet, 6 H, allylic), and 1.39 ppm (broad multiplet, 13 H, aliphatic), consistent with ethyl 3-methyl-5-nonynoate (9, 16%)

Anal. Calcd for C<sub>12</sub>H<sub>20</sub>O<sub>2</sub>: C, 73.30; H, 10.25. Found: C, 73.20; H, 10.15.

The third minor product (10%) showed a band at 1740 cm<sup>-1</sup> (ester C=O) in the infrared (neat). The nmr spectrum (CDCl<sub>3</sub>) contained absorptions at 4.39 (quartet, J = 7.0 cps, 2 H, OCH<sub>2</sub>), 2.50 (multiplet, 6 H, allylic), and 0.85 ppm (broad multiplet, 12 H, aliphatic), consistent with ethyl 6-decynoate (10, 11%)

Anal. Calcd for  $C_{12}H_{20}O_2$ : C, 73.30; H, 10.25. Found: C, 73.01; H, 10.05.

When radiation of the above mixture was carried out in the presence of atmospheric air, the above products were obtained in yields of 38% for 7, 14% for 8, 14% for 9, and 10% for 10, and two additional fractions were collected. The infrared and nmr spectra of the lowest boiling fraction (17%) were identical with those of authentic 4-octyn-3-one (11, 9%) while the spectra of the next higher boiling fraction (21%) were identical with those of authentic 4-octyn-3-ol (12, 15%, based on ethyl diazoacetate).

4-Octyn-3-ol (12).—The Grignard reagent prepared from ethylmagnesium iodide (0.60 mole) and 1-pentyne (34 g, 0.50 mole) was treated with propionaldehyde (29 g, 0.50 mole) for 3 hr in refluxing ether. On working up with saturated ammonium chloride solution, 7.8 g (13%) of 12 was obtained, bp 92-92.5° (24 mm,  $n^{20}$ D 1.4505. Infrared (neat) showed 3400 (asymmetric OH) and 2260 cm<sup>-1</sup> (C=C). Nmr (CCl<sub>4</sub>) showed 4.27 (triplet, J = 6.0 cps, 1 H, =CCHO), 3.90 (singlet, 1 H, OH), 2.20 (multiplet, 2 H, CH<sub>2</sub>C=C), 1.55 (multiplet, 4 H, CH<sub>2</sub>), 0.98 (triplet, J = 6.5 cps), and 0.98 ppm (triplet, J = 6.0 cps), both together integrating for six protons (CH3).

Anal. Calcd for C8H14O: C, 76.13; H, 11.18. Found: C, 76.37; H, 11.22.

4-Octyn-3-one (11).—To a suspension of active manganese dioxide<sup>21</sup> (1.32 g) in 15 ml of light petroleum ether (bp 30-60°) was added 12 (0.150 g, 0.0012 mole) and the reaction mixture was stirred for 30 min at room temperature. Filtration and evaporation of the solvent yielded 11 (0.140 g, 95%). Gas chromatography (15% TCEP, 115°) indicated 95% purity. Infrared (neat) showed 2220 (conjugated C≡C) and 1680 cm<sup>-1</sup> (ketone C=0). Nmr (CCl<sub>4</sub>) showed 2.30 (multiplet, 4 H, allylic), 1.10 (multiplet, 2 H, CH<sub>2</sub>), 0.90 (triplet, J = 7.0 cps) and 0.86 ppm (triplet, J = 7.0 cps) both together integrating for six protons

Calcd for C<sub>8</sub>H<sub>12</sub>O: C, 77.37; H, 9.74. Found: C, Anal. 77.45; H, 9.71.

Ethyl 3-Ethyl-4-octynoate (8).—To a solution of 12 (6.0 g, 0.048 mole) and pyridine (0.1 ml) in 20 ml of anhydrous ether was added dropwise phosphorus tribromide (4.66 g, 0.017 mole) then refluxed for 3 hr. On work-up, the ether layer yielded 3bromo-4-octyne (4.72 g, 52%), bp 89-93° (19 mm),  $n^{30}$ D 1.4860. Infrared (neat) showed 2262 cm<sup>-1</sup> (C=C). Nmr (CCl<sub>4</sub>) showed 4.51 (triplet, J = 6.5 cps, 1 H,  $\equiv$ CCHBr), and 1.60 ppm (broad multiplet, 12 H, allylic and aliphatic).

In a malonic ester synthesis, 29 3-bromo-4-octyne (4.1 g, 0.022 mole) and ethyl malonate (5.15 g, 0.32 mole) yielded 3-ethyl-4octynoic acid (2.75 g, 77%), bp 132-135° (5 mm),  $n^{20}$ D 1.4542. Infrared (neat) showed broad absorption in the 3340-cm<sup>-1</sup> region (asymmetric OH). Nmr (CCl4) showed 12.17 (singlet, 1 H, COOH) and 2.45 ppm (broad multiplet, 5 H, allylic).

Anal. Calcd for C<sub>10</sub>H<sub>16</sub>O<sub>2</sub>: C, 71.39; H, 9.58. Found: C, 71.41; H, 9.44.

Upon esterification of 3-ethyl-4-octynoic acid with excess ethanol containing small amounts of p-toluenesulfonic acid, 8 was obtained in 95% yield, bp 100-101° (55 mm), n<sup>20</sup>D 1.4426. Infrared (neat) showed 1740 cm<sup>-1</sup> (ester C=O). Nmr (CCl<sub>4</sub>) showed 4.12 (quartet, J = 7.5 cps, 2 H, OCH<sub>2</sub>), 2.65 (multiplet, 1 H, C=CCH), 2.15 (multiplet, 4 H, allylic), and 1.32 (multiplet, 13 H, aliphatic) with these superimposed peaks: 1.23 (triplet, J = 7.0 cps) and 0.96 ppm (triplet, J = 7.0 cps).

Anal. Calcd for  $C_{12}H_{20}O_2$ : C, 73.30; H, 10.25. Found: C,

73.43; H, 10.24.

Hydrogenation of Ethyl 3-Methyl-5-nonynoate (9) and Ethyl 6-Decynoate (10).—Samples of 9 and 10 in ethyl acetate were hydrogenated over 5% palladium on charcoal at room temperature and under atmospheric pressure. After purification by gas chromatography (SE 52, 155°) the hydrogenation product of 9 was identical with authentic ethyl 3-methylpelargonate (13) 30 and 10 with ethyl caprate.

The Reaction of 1,2-Di-n-propylcyclopropene-3-carboxylate (7) with Cyclopentadiene. Adduct 5b.-Freshly distilled cyclopentadiene (5 g, 0.076 mole) and 7 (5.05 g, 0.026 mole) were refluxed for 12 hr. After evaporation of excess cyclopentadiene the residue was distilled with a short-path still to yield the tricyclooctene ester **5b** (5.75 g, 85%), bp 95-96.5° (0.1 mm),  $n^{20}$ D 1.4812. Infrared (neat) showed 3065 and 1730  $cm^{-1}$  (ester Nmr (CCl<sub>4</sub>)<sup>27</sup> showed 5.86 (triplet), 3.93 (quartet), 2.70 (multiplet), 2.04 (multiplet), 1.40 (singlet, cyclopropyl31), 1.15 (triplet), and 0.92 ppm (triplet).

Hydrogenation of Adduct 5b.—On hydrogenation of 5b (0.66 g)

in 5 ml of ethyl acetate containing 5% palladium on charcoal (200 mg) at room temperature and atmospheric pressure the saturated adduct 6b (0.64 g, 96%) was obtained, bp 118° (0.65 mm),  $n^{20}$ D 1.4752. Infrared (neat) showed 3066 (cyclopropyl CH) and 1730 cm<sup>-1</sup> (ester C=O). Nmr (CCl<sub>4</sub>)<sup>27</sup> showed 4.0 (quartet), 2.18 (broad singlet), 1.82 (singlet, cyclopropyl), 1.25 (multiplet), 1.19 (triplet), and 0.89 ppm (triplet).

Anal. Calcd for  $C_{17}H_{28}O_2$ : C, 77.22; H, 10.67. Found: C, 77.22; H, 10.72.

<sup>(29)</sup> The general procedure of M. S. Newman and J. H. Wotiz, J. Am. Chem. Soc., 71, 1292 (1949).

<sup>(30)</sup> Authentic 13 was prepared according to the procedure in ref 20 and had the required analytical data.

<sup>(31)</sup> This assignment is supported by the work of Sauers and Sonnet who report the signal for the cyclopropyl proton in the endo adduct obtained from ethyl diazoacetate and norbornadiene at 1.34 ppm (r 8.66): R. R. Sauers and P. E. Sonnet, Chem. Ind. (London), 786 (1963).
