chloride on the spectra of III and VII were similar in chloroform to those observed in benzene, but the magnitude of the changes was much smaller. These small changes may have been due to the presence of the aromatic rings in the oximes themselves.⁷

In agreement with previous reports,^{2,5,6} the data in Table I demonstrate that for benzene solutions of ketoximes a given set of α protons resonates at lower field when syn to the oximino hydroxyl group than when anti. This fact has been explained⁸ in terms of complex formation between the oxime and the aromatic solvent. Such complexes (a preferential orientation of aromatic molecules with respect to the electric dipole in a polar solute) have been proposed in numerous cases to account for solvent-induced changes in chemical shifts.⁹⁻¹⁵ The complex proposed⁸ for oximes (1) satis-

factorily accounts for a large amount of experimental $data^{2,5-7,16,17}$ and, based on the currently accepted theory of complex formation, implies that the negative end of the dipole moment in oximes lies in the area of the oxygen atom.

We suggest that the effect of hydrogen chloride is due to the change in dipole moment produced by protonation of the oxime. Concommitant with this change in dipole moment, a reorientation of the solvent molecule¹⁸ with respect to the oxime hydrochloride would be anticipated.

On the basis of spectral evidence, oxime hydrochlorides are believed to be protonated on nitrogen.^{19,20} It has been suggested²⁰ that the dipole moment in these salts lies along the N⁺-H bond. If this is the case in benzene solution, one would anticipate a complex (2)

(20) H. Saito, I. Terasawa, M. Ohno, and K. Nukada, J. Amer. Chem. Soc., 91, 6696 (1969). having R_2 closer to the diamagnetic region of the solvent molecule than was the case in 1. Likewise, R_1 should be deshielded in 2 relative to 1. While such a model adequately explains the observed changes in chemical shifts, so would the oxygen protonated complex, 3. Since the addition of hydrogen chloride catalyzed chemical exchange of the hydroxyl proton as indicated by signal widths in the nmr spectra, we feel there is ample reason to consider both of the suggested species in explaining our data.

Experimental Section

Ketoximes.—All of the ketoximes used in this study were prepared in our laboratories using standard techniques²¹ and were of known configuration (see references in Table I).

Nmr Spectra.—Spectral data reported in this paper were recorded on a Varian HR60-IL (60 MHz) spectrometer. Similar results were also obtained from a Varian A-60-D spectrometer. The studies were carried out using approximately 10% (w/w) solutions in benzene or using saturated solutions where solubility was a problem (compound III).

General Procedure.—The nmr spectrum of the ketoxime was recorded, and the chemical shifts (V_0) for the α protons were measured. Hydrochloric acid vapor was withdrawn from the atmosphere in a concentrated hydrochloric acid reagent bottle using an eyedropper of sufficient length to reach to the bottom of an nmr sample tube. This gas was then slowly bubbled through the sample. The spectrum was recorded and chemical shifts were $(V_{\rm HCl})$ measured after each addition of hydrochloric acid vapor, made successively in 2-, 4-, and 4-ml portions. The foregoing volumes were based on the volume of the dropper bulb and must be regarded as approximate. Occasionally a precipitate began to form during the final addition but never became so voluminous that an acceptable spectrum could not be obtained.

Aliphatic Polynitro Compounds. II. Reactions of Substituted Polynitroalkanes¹

F. G. Borgardt, P. Noble, Jr.,* W. L. Reed, and A. K. Seeler

Lockheed Palo Alto Research Laboratory, Lockheed Missiles and Space Company, Palo Alto, California 94304

Received April 27, 1970

Following the discovery of the rearrangement of 2,2,2trinitrochloroethane (1) to dipotassium tetranitroethane (2) in the presence of nitrite ion,² a program was

initiated to investigate the generality of this reaction with other substituted polynitro compounds and to obtain evidence pertinent to the mechanistic path of this rearrangement. The compounds investigated were X-C(NO₂)CH₂-Y, where $X = -NO_2$, -Cl, -CH₂-

^a Reactions were run in aqueous methanol (60%) except those using NaOMe in anhydrous MeOH. ^b Reference 2. ^c Crude product yield, not further purified. ^d In all cases where no precipitate formed, reaction did take place as evidenced by color changes. Products in these cases could be similar to the others reported by Ungnade and Kissinger (ref 3) and others [see P. Noble, Jr., F. G. Borgardt, and W. L. Reed, *Chem. Rev.*, **64**, 19 (1964), for discussions and other references].

Cl, $-CH_2OAc$, and -CN, and Y = -Cl, -F, -OAc, -OTs, and $-OCOCF_3$.

Previously reported studies on the reaction of 2,2,2trinitrochloroethane (1) with bases indicated that the conversion of 1 to dipotassium tetranitroethane (2) is best effected in aqueous alcohol solution with excess nitrite ion.² The reaction is apparently base catalyzed since reactions run in the presence of potassium hydroxide were complete in less than 1 hr. The reaction with nitrite alone takes about 18 hr before the maximum yield is realized. Other additives such as iodide or cyanide ion also appear to accelerate the reaction but they, as well as hydroxide ion, result in lower yields of 2.

Results

Table I summarizes the results of the reactions of various substituted dinitroethyl compounds with bases. In this study no attempt was made to identify products other than the nitronate salts which could be readily precipitated out of the reaction mixture. Many of these reactions could have resulted in the formation of other aliphatic nitro derivatives similar to the production of 2,2-dinitroethyl methyl ether from 1,2-dichloro-1,1-dinitroethane (4)³ or the dinitroethylation reaction of Frankel.⁴ The identity of the nitronate salt products was established through previously characterized halogen derivatives, decomposition points, and infrared and nmr spectra.

Discussion

Table I shows that a variety of nitronate products can be formed from the reaction of structurally related polynitro compounds with potassium nitrite. The nitronate product formed depends on the substituents on the polynitro compound as well as the nature and concentrations of potassium nitrite and other reactants. Several reaction paths can be written which explain the production of these different products.

In the case of polynitro compounds with easily hydrolyzed substituents, such as 2,2,2-trinitroethyl acetate (6), the dominant point of attack by aqueous base is at the carbonyl leading to loss of acetate followed by loss of formaldehyde from the intermediate nitro alcohol in a reverse Henry reaction.^{5,6}

The product trinitromethyl anion is isolated by precipitation from solution as the potassium salt 7 in nearly quantitative yield. Other esters of 2,2,2-trinitroethanol that were observed to behave similarly were the trifluoroacetate 9, the *p*-toluenesulfonate 11, and the sulfite 10. These compounds produce potassium

nitroform in reactions with potassium nitrite and potassium hydroxide or potassium iodide. The acetate 6and 2-chloro-2,2-dinitroethyl acetate (12), however, produce the rearranged product 2 with potassium nitrite in the presence of iodide.

Esters of 2-chloro-2,2-dinitroethanol are expected to behave similarly. However, the presence of the labile positive halogen leads to competitive reactions possibly of the dinitroethylation type,⁴ which will be discussed below. In no case was a salt that corresponded to potassium chlorodinitromethane isolated.

However, difficultly hydrolyzed substituents, such as 2,2,2-trinitrochloroethane (1), with nitrogen bases or methoxide lead to the isolation of potassium dinitromethane (3). Most probably the initial attack of base is at the trinitromethyl group. This can be followed by acidic proton abstraction of hydrolysis of chloride resulting in the loss of one carbon as a derivative of formaldehyde. Sodium methoxide or nitrogen bases in reaction with 1, 2,2-dinitro-1,2-dichloroethane (4), and 2,2,2-trinitroethyl fluoride (5) produce this dinitromethane product. The fact that in no case was potassium trinitromethane formed and that in one case the rearranged product 2 was formed gives support to the speculation that the first point of attack occurs at the trinitromethyl group.

Discussion of the rearrangement of 2,2,2-trinitrochloroethane (1) to 2 was presented in ref 2. Since the 2,2,2-trinitroethyl acetate (6) and 2-chloro-2,2-dinitroethyl acetate (12) produce 2 only when reacted with potassium nitrite in the presence of iodide ion, it would seem more probable that a reaction path similar to that proposed in the dinitroethylation type reactions⁴ takes place with dinitroethylene as a common intermediate. Halogenation of intermediate nitronates by sources of positive halogen finds support in work reported by McEwen.⁴

Rearrangement to dipotassium 1,1,3,3-tetranitropropane (8) occurs in the absence of nitrite ion for compounds such as the chlorodinitroethyl acetate (12), the trinitroethyl acetate (6), and the sulfite 10 by reaction with iodide. Formation of the reactive intermediate dinitroethylene followed by Michael addition of 2,2dinitroethyl acetate leads to the formation of 8.

From the reactions discussed above, it is obvious that many factors are responsible for directing the courses of the many processes involved and that much further study is needed to define the actual processes and steps involved. It is hoped that the speculation presented, along with the interesting chemical evidence, will spur additional fundamental work in the area of aliphatic nitro chemistry.

Experimental Section⁷

Preparation of Nitronate Salt Derivatives (Table I).—A solution of potassium nitrite (plus other reactants, if used) in 25 ml of 60% aqueous methanol was prepared (mole amounts given in Table I). To this solution was added 0.01 mol of nitro aliphatic compound, and the resulting solution was allowed to stand at room temperature for 24 hr. The precipitate was collected and washed with cold aqueous methanol and then air dried. The nitronate salt products were identified by their ir spectrum, melting (decomposition) points, and halogenated derivatives.

(7) Melting points and boiling points are uncorrected. *Caution:* many of the compounds described are explosives and are sensitive to impact, friction, etc.; *handle with care*. Microanalysis by Berkeley Analytical Laboratories; nmr by Varian Associates.

2,2,2-Trinitrochloroethane (1), 1,2-dichloro-2,2-dinitroethane (4), 2,2,2-trinitroethyl sulfite (10), 2,2-dinitrochloropropane (15), 1,3-dichloro-2,2-dinitropropane (13), dipotassium tetranitroethane (2), and potassium dinitromethane (3) were prepared as previously reported.²

2,2,2-Trinitroethyl acetate (6) was prepared as described by Morans and Zelinsky.⁵

2-Chloro-2,2-dinitroethyl acetate (12) was prepared by the method of Ungnade and Kissinger.³

2,2,2-Trinitroethyl Trifluoroacetate (9).—A solution of 36 g (0.2 mol) of 2,2,2-trinitroethanol in 50 g (0.24 mol) of trifluoracetic anhydride was refluxed for 24 hr. The reaction mixture was fractionated under reduced pressure giving 47 g (85.5%) of product, bp 61-62° (4 mm), n^{25} D 1.4051.

Anal. Calcd for C₄H₂N₃O₈F₃: C, 17.34; H, 0.73; N, 15.17. Found: C, 17.28, 17.37; H, 1.08, 1.01; N, 15.12, 15.14. 2,2,2-Trinitroethyl Tosylate (11).--2,2,2-Trinitroethanol (15

2,2,2-Trinitroethyl Tosylate (11).—2,2,2-Trinitroethanol (15 g, 0.082 mol) and p-toluenesulfonyl chloride (15 g, 0.078 mol) were heated at 85° for 7 days. After the first 2 hr of heating, 4 drops of pyridine were added. The crude product was recrystallized twice for benzene giving 10.5 g (24.7%) of product, mp 136.5-137°.

Anal. Calcd for C₉H₉N₃O₉S: C, 32.22; H, 2.68; N, 12.59; S, 9.56. Found: C, 32.23; H, 2.73; N, 12.62; S, 9.54.

2,2.2. Trinitrofluoroethane (5).—Trinitroethanol was fluorinated with sulfur tetrafluoride by the method of Baum.⁸ A 50% yield of 5 was obtained, bp 52-53° (13 mm). Proton nmr shows a doublet at 310 and 355 ppm from TMS. Principal infrared absorption was consistant with ref 8.

1,2-Difluorotetranitroethane.—Dipotassium tetranitroethane (2) was fluorinated by the aqueous fluorination method of Grakanskas.⁹ A 45% yield of 1,2-difluorotetranitroethane was obtained: bp 60° (35 mm); n^{25} D J.4152; F¹⁹ nmr shows a pentet at 97.3 ppm (relative intensity 1:2:3:2:1 split by 9 cps); principal infrared absorption at 1630 (s), 1340 (m), 1300 (m), 1275 (m), 820 (m), and 770 cm⁻¹ (m).

Anal. Calcd for C₂F₂N₄O₈: C, 9.75; H, 22.76. Found: C, 9.77; N, 22.71.

1,3-Diffuoro-1,1,3,3-tetranitropropane.—This compound was prepared by the aqueous fluorination procedure⁹ and produced a 58% yield of product: bp 75-77° (5 mm); n^{25} D 1.4425; proton nmr shows a triplet with peaks at 291, 277, and 263 (relative intensity 1:2:1) from TMS; principal infrared absorption at 1620 (s) 1375 (w), 1310 (m), 1110 (w), 850 (w), and 820 cm⁻¹ (w).

Anal. Calcd for $C_8H_2F_2N_4O_8$: C, 13.86; H, 0.78; N, 21.54. Found: C, 14.54; H, 0.90; N, 21.18.
