to a stirred solution of $\mathrm{KO}-t-\mathrm{Bu}(200 \mathrm{mg})$ in THF $(10 \mathrm{~mL})$ at 25 ${ }^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$. After 15 min water ( 25 mL ) was added and the reaction mixture worked up as described above to furnish 14b ( $31 \mathrm{mg}, 89 \%$ ).

Reaction of 1-Phenyl-4-oxahepta-1,6-diyne (21) with Potassium tert-Butoxide in THF. A solution of $21(500 \mathrm{mg}$, 2.94 mmol ) in dry THF ( 15 mL ) was added dropwise to a stirred solution of KO- $t-\mathrm{Bu}(500 \mathrm{mg}, 4.5 \mathrm{mmol})$ in dry THF $(20 \mathrm{~mL})$ at room temperature under $\mathrm{N}_{2}$. The mixture was stirred for 4 h . Workup provided an oil which was chromatographed on silica eluting with $\mathrm{CH}_{2} \mathrm{Cl}_{3} /$ pentane (1:4) to give 22 ( $100 \mathrm{mg}, 20 \%$ ): mp $79-80^{\circ} \mathrm{C}$; MS $m / e 170.0741\left(\mathrm{C}_{12} \mathrm{H}_{10} \mathrm{O}\right.$ requires $\mathrm{m} / e$ 170.0732), $170\left(\mathrm{M}^{+}, 20 \%\right), 142,141,139,115(100 \%), 89 ;{ }^{1} \mathrm{H}$ NMR, see Discussion; ${ }^{13} \mathrm{C}$ NMR, see Table II; IR (KBr) 1490, 1450, 1420, $1380 \mathrm{~cm}^{-1}$; electronic spectrum, see Discussion. Anal. Calcd for $\mathrm{C}_{12} \mathrm{H}_{10} \mathrm{O}$ : ${ }^{\mathrm{C}}, 84.68 ; \mathrm{H}, 5.92$. Found: C, 84.57 ; $\mathrm{H}, 5.85$.
When the reaction was carried out at $60-62{ }^{\circ} \mathrm{C}$ for $15 \mathrm{~h}, 23$ ( $28 \%$ ), mp $158-159^{\circ} \mathrm{C}$ (lit. $.^{11} \mathrm{mp} 153-155^{\circ} \mathrm{C}$ ), identical in all observed respects to an authentic sample, was isolated.

Reaction of 22 with Potassium tert-Butoxide in THF. A solution of $22(20 \mathrm{mg}, 0.12 \mathrm{mmol})$ in THF ( 15 mL ) was added to a stirred solution of $\mathrm{KO}-t-\mathrm{Bu}(150 \mathrm{mg})$ in THF $(10 \mathrm{~mL})$ at $50^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$. After workup, preparative TLC on silica afforded, in addition to 4 mg of $22,23(10 \mathrm{mg}, 63 \%)$.

Reaction of 1,7-Diphenyl-4-methyl-4-azahepta-1,6-diyne (11c) with Potassium tert-Butoxide in THF. A solution of $11 \mathrm{c}(1.20 \mathrm{~g}, 4.6 \mathrm{mmol})$ in THF ( 15 mL ) was added dropwise over 2 min to a stirred solution of $\mathrm{KO}-t-\mathrm{Bu}(1.0 \mathrm{~g})$ in THF ( 10 mL ) at $20^{\circ} \mathrm{C}$ under $\mathrm{N}_{2}$. After addition was complete, the mixture was stirred for a further 1 min and water ( 30 mL ) was then added. Workup provided an oily semisolid which was recrystallized from ether as the dimer $24(230 \mathrm{mg}, 19.5 \%)$ : mp $248-252^{\circ} \mathrm{C}$; MS $m / e$ $518.2740\left(\mathrm{C}_{38} \mathrm{H}_{34} \mathrm{~N}\right.$ requires $\left.m / e 518.2722\right), 518\left(\mathrm{M}^{+}, 100 \%\right), 422$, $355,257,256$; ${ }^{1} \mathrm{H} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 7.20(\mathrm{~m}, 20 \mathrm{H}), 5.90(\mathrm{~s}, 4 \mathrm{H})$, 5.30 ( $\mathrm{s}, 4 \mathrm{H}$ ), 3.35 ( $\mathrm{s}, 6 \mathrm{H}$ ); ${ }^{13} \mathrm{C}$ NMR, see Table III; IR ( KBr ) 3500, $3050,2950,1600,1540,1500,1460,1400 \mathrm{~cm}^{-1}$. Anal. Calcd for $\mathrm{C}_{38} \mathrm{H}_{34} \mathrm{~N}_{2}: \mathrm{C}, 87.99 ; \mathrm{H}, 6.66 ; \mathrm{N}, 5.40$. Found: C, 87.62; H, 6.50; N, 5.23.

The ethereal mother liquor was treated with methanol when a yellow precipitate formed which was recrystallized from
methanol to afford pale yellow crystals of $25(190 \mathrm{mg}, 16 \%): \mathrm{mp}$ $209-210^{\circ} \mathrm{C}$; MS $m / e 518$ ( $\mathrm{M}^{+}, 92 \%$ ), 422, 355, 257, 256 ( $100 \%$ ); ${ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ) $\delta 7.18(\mathrm{bs}, 20 \mathrm{H}), 6.08(\mathrm{~s}, 4 \mathrm{H}), 4.80(\mathrm{~s}, 4 \mathrm{H})$, 3.40 (s, 6 H); ${ }^{13} \mathrm{C}$ NMR, see Table III; IR (KBr) 3500, 3050, 2950, $1600,1540,1500,1460,1400 \mathrm{~cm}^{-1}$. # Nucleophilic Character of Alkyl Radicals. 18. ${ }^{1}$ Absolute Rate Constants for the Addition of Primary Alkyl Radicals to Conjugated Olefins and 1,4-Benzoquinone 

A. Citterio,* A. Arnoldi, and F. Minisci<br>Istituto di Chimica del Politecnico, 20133 Milano, Italy

Received February 1, 1979

#### Abstract

The rate constants for the addition of the 5 -hexenyl radical to styrene, $\alpha$-methylstyrene, butadiene, acrylic monomers, methyl vinyl ketone, and 1,4-benzoquinone were measured from 16 to $69^{\circ} \mathrm{C}$. The importance of polar effects, due to the nucleophilic character of the alkyl radical in olefin addition, is emphasized. The inhibition of chain processes by quinone is discussed in terms of the high rate constant ( $2.0 \times 10^{7} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at $69{ }^{\circ} \mathrm{C}$ ) of the alkyl radical addition to 1,4-benzoquinone.

The concept of polar effects in free-radical reactions shows ambiguous points being derived from the ionic reactions. Ionic electrophilic and nucleophilic species are formally well defined, but the electrophilic or nucleophilic character of free radicals cannot always be deduced from their formal structures, not even for radical ions (i.e., the

[^0]radical anion $\mathrm{SO}_{4}^{-} \cdot$ has a clear-cut electrophilic character) or for borderline cases such as carbon-centered free radicals. The phenomenon is kinetic in nature and the terms of electrophilicity and nucleophilicity cannot be mechanically transferred from ionic to radical reactions. For a given reaction the rate constant sequence cannot measure the relative electrophilicity and nucleophilicity of free radicals, as it occurs for ionic reactions. Moreover, fixing an electrophilic or nucleophilic character for a given
radical, without taking into account the particular reaction involved, is not strictly correct. Both the extent and the nature of the polar effect in free-radical reactions depend on the features of the radical, the substrate, and the reaction medium.

Thus it is not surprising that the simplest alkyl radical, methyl, has been considered from time to time to be slightly electrophilic, ${ }^{2}$ nonpolar, ${ }^{3}$ and slightly ${ }^{4}$ or cleanly ${ }^{5,6}$ nucleophilic in atom transfer, ${ }^{2,6}$ in addition reactions with olefins ${ }^{4,5}$ and in homolytic aromatic substitution. ${ }^{3,5}$

There is much more agreement about the nucleophilic character of primary alkyl radicals in their main reactions. Thus, positive $\rho$ values were reported ${ }^{7}$ for hydrogen abstraction from substituted toluenes, and a clear-cut nucleophilic character has been drawn from positional and substrate selectivity in the homolytic alkylation of protonated heteroaromatic bases ${ }^{8}$ and in addition reactions with olefins. ${ }^{1,5 \mathrm{~b}, 9}$

The knowledge of the absolute rate constants in the addition of alkyl radicals to industrial monomers such as styrene, butadiene, acrylic monomers, methyl vinyl ketone, and 1,4 -benzoquinone involves polar effects, the struc-ture-reactivity relationship, synthetic possibilities from cheap materials, and the inhibition of chain processes. The largest body of data on rate constants concerning car-bon-centered free-radical addition to olefins has been supplied by gas-phase studies ${ }^{10}$ or by free-radical polymerization; ${ }^{11}$ only a few data are available for addition rates in solution, ${ }^{10}$ which does not involves polymerization.

Previous attempts ${ }^{1,9}$ to determine the absolute rate constants for the addition of alkyl radicals to styrene and acrylic monomers were based on competitive methods in which the known reference constants ( $k_{1}, k_{2}, k_{3}$ ) were the oxidation rates of alkyl radicals either by ligand-transfer ${ }^{9}$ (reactions 1 and 2) or by electron-transfer ${ }^{1}$ (reaction 3) processes.

$$
\begin{array}{r}
\mathrm{RCH}_{2} \mathrm{CH}_{2^{*}}+\mathrm{CuCl}_{2} \xrightarrow{k_{1}} \mathrm{RCH}_{2} \mathrm{CH}_{2} \mathrm{Cl}+\mathrm{CuCl} \\
\mathrm{RCH}_{2} \mathrm{CH}_{2} \cdot+\mathrm{Cu}(\mathrm{SCN})_{2} \xrightarrow{k_{2}} \mathrm{RCH}_{2} \mathrm{CH}_{2} \mathrm{SCN}+\mathrm{CuSCN} \tag{2}
\end{array}
$$

$\mathrm{RCH}_{2} \mathrm{CH}_{2} \cdot+\mathrm{Cu}\left(\mathrm{OCOCH}_{3}\right)_{2} \xrightarrow{k_{3}}$
$\mathrm{RCH}=\mathrm{CH}_{2}+\mathrm{CH}_{3} \mathrm{COOH}+\mathrm{CuOCOCH}_{3}$
These methods, however, have some limitations since reactions 1-3 are influenced by the reaction medium. Cupric halides are generally a composite of individual species ${ }^{12}\left(\mathrm{CuCl}^{+}, \mathrm{CuCl}_{2}, \mathrm{CuCl}_{3}{ }^{-}, \mathrm{CuCl}_{4}{ }^{2-}\right)$, which can all

[^1]Scheme I

transfer a chlorine atom, according to reaction 1 , very probably with different rates; the ratios among these individual species are considerably affected by the salt concentration, the nature of the solvent, and the reagents. Due to the very high values of $k_{1}$ and $k_{2}$, reactions 1 and 2 are suitable for kinetic studies only with very reactive substrates. Also the rate of reaction 3 is influenced by the medium, as it strictly depends on the monomer-dimer equilibrium ${ }^{13}$ (eq 4).

$$
\begin{equation*}
\mathrm{Cu}_{2}\left(\mathrm{OCOCH}_{3}\right)_{4} \rightleftharpoons 2 \mathrm{Cu}\left(\mathrm{OCOCH}_{3}\right)_{2} \tag{4}
\end{equation*}
$$

To avoid these complications, we have chosen a kinetic model based on the irreversible isomerization of the 5hexenyl radical to the cyclopentylmethyl radical, a process which is quite independent of the solvent. This model is suitable for determining absolute rate constants in the range $10^{4}-10^{7} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ for reactions involving primary alkyl radicals, by product analysis. ${ }^{8}$

## Results

The main problem in determining rate constants in the addition of alkyl radicals to butadiene, styrene, and acrylic monomers consists in cleanly avoiding polymerization or telomerization of the monomers. Such a problem does not exist with 1,4 -benzoquinone which has no tendency to polymerize and, on the contrary, is a polymerization inhibitor. In order to reach this result, we found it necessary to use two different kinetic models, both based on the copper(I)-catalyzed decomposition of di-6-heptenoyl peroxide as the free-radical source.
Kinetic Model I. The alkyl radical addition to an olefin involves the steps of Scheme I (eq 5-12, exemplified for styrene), with $k_{6}=10^{10.7} e^{-7.8 / \theta} \mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ taken from literature. ${ }^{14}$ Since allylic and benzylic radicals are efficiently oxidized by cupric acetate also in the presence of

a Deduced assuming $k_{6}$ from ref $14 ; k_{6}=9.6 \times 10^{4} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$ and $k_{6}=5.1 \times 10^{5} \mathrm{M}^{-1} \mathrm{~s}^{-1}$ at $69^{\circ} \mathrm{C}$. ${ }^{b}$ Standard deviation from experimental data.

Figure 1. Dependence of the ratio ( $R$ ) of the addition products on styrene concentration at different temperatures.
the monomer excess, this scheme was used for styrene, $\alpha$-methylstyrene, and butadiene. A similar one was used with 1,4 -benzoquinone, for which the oxidation reaction gives only substitution products. No traces of dimerization, telomerization, or polymerization coming from the benzylic radicals 3 and 4 occur under the reaction conditions. Small amounts ( $5 \%$ ) of the olefins 7 and 8 and the alcohols 9 and 10 are directly formed from oxidation of the radicals 3 and

## $\mathrm{PhCH}=\mathrm{CHR}$

$\mathrm{PhCH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{R}$
7, $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}=\mathrm{CH}_{2}$
$8, \mathrm{R}=\mathrm{CH}_{2}-\square$

9, $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}=\mathrm{CH}_{2}$

4 by cupric acetate or during the isolation and the analysis of the esters 5 and 6; their presence, however, does not affect the validity of kinetic scheme. The steady-state assumption for radicals 1 and 2 allows derivation of kinetic eq 13 (Appendix A) from eq 5-12 of Scheme I; if we assume

$$
\begin{equation*}
[5] /[6]=k_{9}\left[\mathrm{PhCH}=\mathrm{CH}_{2}\right] / k_{6}+k_{8}\left[\mathrm{Cu}^{2+}\right] / k_{6} \tag{13}
\end{equation*}
$$

that $k_{9} \simeq k_{10}$, the addition is irreversible, and the $\left[\mathrm{Cu}^{2+}\right] /\left[\mathrm{Cu}^{+}\right]$ratio is constant on the basis of previous works. ${ }^{15}$

At low conversions, the products ratio [5]/[6] is linearly correlated with the initial styrene concentration (Figure 1) in the temperature range $25-69^{\circ} \mathrm{C}$, at constant cupric salt concentration ( 0.025 M ). A least-squares treatment allows evaluation of $k_{9} / k_{6}$ from the slope and $k_{8} / k_{6}$ from the intercept. The rate constant $k_{9}$ at 25 and $69^{\circ} \mathrm{C}$ and the Arrhenius parameters for the addition reaction are reported in Table I. The value of $k_{8}=(6.5 \pm 0.7) \times 10^{5}$

[^3]

Figure 2. Dependence of the ratio $(R)$ of the addition products a and $\mathbf{c}$ for methyl vinyl ketone ( $\square$ ), methacrylic acid ( $O$ ), butadiene ( $\dot{\sim}$ ), $\alpha$-methylstyrene ( $\bullet$ ), and quinone on olefin concentration (all reactions at $69^{\circ} \mathrm{C}$, except butadiene reaction at $25^{\circ} \mathrm{C}$ ).
$\mathrm{L} \mathrm{mol}^{-1} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$, estimated for all the cupric salt without considering the monomer-dimer equilibrium (eq $4)$, is slightly lower than the reported one ${ }^{13}\left(1.2 \times 10^{6} \mathrm{~L}\right.$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$ ).

The behavior of $\alpha$-methylstyrene is strictly analogous. The dependence of the pyrolysis products 13 and 14 (arising from the acetates 11 and 12) on the $\alpha$-methyl-

13, $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{5} \mathrm{CH}=\mathrm{CH}_{2}$

styrene concentration is shown in Figure 2. An equation analogous to eq 13 allows evaluation of the addition rate constant $k=(8.9 \pm 1.1) \times 10^{4} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at $69^{\circ} \mathrm{C}$. With butadiene both 1,2 and 1,4 isomer esters $15,16,17$, and 18 are formed. Examination of the data in Figure 2 for
$\mathrm{CH}_{2}=\mathrm{CHCH}\left(\mathrm{OCOCH}_{3}\right) \mathrm{CH}_{2} \mathrm{R} \quad \mathrm{RCH}_{2} \mathrm{CH}=\mathrm{CHCH}_{2} \mathrm{OCOCH}_{3}$
$15, \mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}=\mathrm{CH}_{2}$
$16, \mathrm{R}=\mathrm{CH}_{2}-\square$
17, $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}=\mathrm{CH}_{2}$

the ratio $([15]+[17]) /([16]+[18])$ against butadiene concentration gives a rate constant of $(9.2 \pm 0.2) \times 10^{4} \mathrm{~L}$ $\mathrm{mol}^{-1} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$.
Somewhat different is the behavior of 1,4 -benzoquinone because the oxidation of the intermediate radicals $19 a$ and 19b by cupric salts leads to the alkylquinones 20 a and 20 b
(eq 14). Whether the cupric ion oxidizes the radicals 19 a

19a, $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}=\mathrm{CH}_{2}$ 19b, $\mathrm{R}=\mathrm{CH}_{2}-\square$

20a, $\mathrm{R}=\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}=\mathrm{CH}_{2}$

and $19 b$ or the corresponding enols depends on the relative rates of oxidation or enolization. However, this is irrelevant for kinetic purposes, because a very effective redox chain also takes place in this case. From the data of the ratio [20a]/[20b] (Figure 2) against quinone concentration, a rate constant of $(2.0 \pm 1) \times 10^{7} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at $69^{\circ} \mathrm{C}$ can be obtained. The high reactivity of benzoquinone determines a high yield of 20 a , so the ratio [20a]/[20b] is not very sensitive to quinone concentration and the accuracy of the analytical results is somewhat affected.

Kinetic Model II. The previous model is not suitable for acrylic monomers and methyl vinyl ketone, because cupric acetate does not prevent these olefins from polymerizing. ${ }^{16}$ We have used a somewhat more complex kinetic model, related to Scheme I and based on the alternating addition of primary alkyl radicals to a couple of olefins. ${ }^{1}$ One of these is always styrene, whereas the other is the acrylic monomer or methyl vinyl ketone. In addition to reactions 5-12 of Scheme I, radicals 1 and 2 undergo the addition reactions (15) and (16) of Scheme II.

The basis of the scheme is the fact that $k_{17}$ and $k_{18}$ are higher than the propagation rates of homopolymerization $\left(10-10^{3} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\right)^{11}$ of these monomers, due to the electrophilic character of the radicals involved. For this reason the addition to styrene is the only reaction of radicals 21 and 22 in proper range of monomer concentrations. This is the key step of the alternating effect in free-radical copolymerization. No oxidation of the radicals 21 and 22 occurs, always due to their electrophilic character. ${ }^{17}$

The oxidation products 25 and 26 are the lactones 25 a and 26a for acrylic acid, 25b and 26b for methacrylic acid, the cyano esters 25 c and 26 c for acrylonitrile, a mixture of $25 a$ and $26 a$ and the acetic esters $25 d$ and $26 d$ for methyl acrylate, and the $\gamma$-hydroxy ketones 25 e and 26 e for methyl vinyl ketone. In all cases compounds 5 and 6 were side reaction products.

The steady-state assumption for the radicals involved in Schemes I and II leads to kinetic eq 20-22 (Appendix B ), assuming $k_{9} \simeq k_{10}, k_{15} \simeq k_{16}$, and $k_{7} \simeq k_{8}$.

$$
\begin{equation*}
\frac{[25]}{[5]}=\frac{[26]}{[6]}=\frac{k_{16}}{k_{10}} \frac{\left[\mathrm{CH}_{2}=\mathrm{CHX}\right]}{\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]} \tag{21}
\end{equation*}
$$

Analysis of the ratio of the oxidation products 25 and 26 (or 5 and 6) against the acrylic monomer concentration in all cases shows the linearity foreseen from eq 20 and 21 (Figures 3-5). The intercepts have very similar values (the median value was 0.22 ) for all substrates, at a constant concentration of cupric acetate ( 0.025 M ) and styrene ( 0.25 $\mathrm{M})$; the value of $k_{8}=(9 \pm 1) \times 10^{5} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ at $25^{\circ} \mathrm{C}$ estimated at constant cupric salt concentration agrees with the reported value ${ }^{13}\left(1.2 \times 10^{6} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\right.$ at $\left.25^{\circ} \mathrm{C}\right)$. The slopes differ and allow evaluation of the addition constants

Figure 3. Dependence of the ratio ( $R$ ) of the addition products 25 a and 26a on methyl acrylate concentration at different temperatures.

Figure 4. Dependence of the ratio $(R)$ of the addition products $25 a$ and 26 a on acrylic acid concentration at different temperatures.
$k_{15}$ of the 5 -hexenyl radical to acrylic and methacrylic acids, acrylonitrile, and methyl vinyl ketone. Internal consistency of the data was checked by eq 22 . The results are summarized in Table I at 25 and $69^{\circ} \mathrm{C}$ with the Arrhenius parameters deduced for acrylic acid, methyl acrylate, and acrylonitrile (Figure 6). These values differ somewhat in some cases from the ones previously reported ${ }^{1}$ and, in our opinion, are more exact because the kinetic model has less experimental error.

Compounds $25 e$ and $26 e$, arising from methyl vinyl ketone, do not originate from the hydrolysis of the corresponding acetates because it has been verified that no substantial hydrolysis takes place under the reaction conditions. The mechanism of Scheme III could explain such a result.

The intramolecular addition of an alkyl radical to a keto group appears to be a very fast reaction as it competes with the fast hydrogen abstraction from the trialkyltin hydride radical $\left(k=1 \times 10^{6} \mathrm{~L} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}\right.$ at $25^{\circ} \mathrm{C}$ ). ${ }^{18}$ This result seems to disagree with other ones of similar radicals, for which no intramolecular addition to the carbonyl group was taken in account; ${ }^{19}$ however, in this case a detailed study of the mechanism excluding an intramolecular addition to the carbonyl group was not carried out. An analogous mechanism could explain the formation of lactones 25a and 26a with methyl acrylate (in addition to the acetates 25 d and 26 d ): a competition between the oxidation of the benzyl radical with formation of the acetates and intramolecular addition to the ester group

[^5]

Figure 5. Dependence of the ratio $(R)$ of the addition products $25 c$ and 26 c on acrylonitrile concentration at different temperatures.

Figure 6. Arrhenius plot of $k_{\mathrm{a}} / k_{6}$ for the substrates acrylonitrile $(\times)$, acrylic acid ( $\odot$ ), methyl acrylate ( $\odot$ ), and styrene ( $\square$ ) in the addition of the 6 -hexenyl radical.

## Scheme III

with formation of lactones (eq 23) could cause this behavior.

With acrylic and methacrylic acids a similar radical mechanism or an ionic one, involving the benzylic radical oxidation, could well explain the lactone formation. Intramolecular addition of alkyl radicals to carbonyl groups of esters ${ }^{20}$ and acids ${ }^{21}$ has been reported.

[^6]
## Discussion

Long ago ${ }^{22}$ Walling suggested that polar structures such as 27 and 28 could contribute to the transition state of radical addition reactions (respectively with electrophilic and nucleophilic species).

28
In terms of frontier orbital theory this picture could reflect a favorable SOMO/LUMO interaction in addition of alkyl radical to electron-deficient olefins, keeping in mind that the theory applies to the early stages of the interaction between orbitals, but it is not really about the transition state itself. Recent ab initio molecular orbital studies ${ }^{23}$ further suggest that the radical additions are dominated mainly by the charge-transfer (CT) interaction. Moreover, the importance of charge-transfer structures in free-radical addition to olefins has also recently been emphasized in the addition of carbon-centered radicals to olefins. ${ }^{24}$

As a satisfactory quantitative theoretical approach is at present lacking, this qualitative picture is still valid in explaining our results obtained with primary alkyl radicals.

A transition state similar to a charge-transfer complex (structures 29 and 30 ) determines a large contribution of

29

30
the polar effect to the activation energy, whereas in a transition state similar to the intermediate radical $\mathrm{CH}_{2} \mathrm{CHCN}$, the rate is mainly determined by the reaction enthalpy. The partition of activation energy between enthalpy, related to the starting olefin and intermediate radical stability, and polar contribution is quite a hard problem. ${ }^{25}$ However, it is reasonable to assume that in the absence of steric hindrance (as indicated by the similarity of preexponential factors in Table I) polar effects determine a smaller activation energy in acrylic monomers with respect to styrene, as the resonance energy is certainly higher for benzyl radicals than for the corresponding radicals arising from acrylic monomers.

The results of Table I clearly indicate that the nucleophilic character of the 5 -hexenyl radical plays a significant role in determining the sequence of the addition rates. The linear correlation of the rates at $69^{\circ} \mathrm{C}$ against $\sigma_{\mathrm{p}}{ }^{-}$and $\sigma_{\mathrm{p}}$ of the olefin substituent ( $\rho=1.19$ and $\rho=1.15$, respectively, Figure 7) indicates that structures like 29 and 30 would contribute to the observed sequence. The $\sigma_{\mathrm{p}}{ }^{-}$

[^7]

Figure 7. Hammett plot against $\sigma_{\mathfrak{p}}{ }^{-}$for the rate constants of the addition of the 6 -hexenyl radical to some conjugated olefins.
constants give better correlation ( $r=0.997$ ) than $\sigma_{\mathrm{p}}(r=$ $0.994)$, but the difference is not very significant, even if $\sigma_{\mathrm{p}}{ }^{-}$gives the correct sequence for $\mathrm{COCH}_{3}$ and $\mathrm{COOCH}_{3}$.
Two facts concerning the polar effects need consideration. The relatively high free-radical reactivity of styrene and butadiene (compared to that of ethylene) has always been ascribed to the stability of the intermediate benzyl and allyl radicals. However, the deviation of styrene from linearity in the correlation of Figure 7 is relatively small (as indicated by correlation coefficient); this could be the fortuitous result of a balance between the higher stability of the benzyl radical and the lower polar effect of phenyl which is an activating conjugative group for both electrophilic and nucleophilic species (as is shown by $\sigma_{\mathrm{p}}{ }^{+}$and $\sigma_{\mathrm{p}}{ }^{-}$values ${ }^{26}$ ) and a slightly electron-withdrawing inductive group. However, the polar effect could dominate the reactivity sequence also with styrene, especially if we consider a transition-state structure different from the intermediate radical adduct. The results obtained with $\alpha$-methylstyrene and methacrylic acid are particularly significant as concerns the role of the polar effects: both are somewhat less reactive than styrene and acrylic acid, respectively. Thus the deactivating polar effect of a poor electron-releasing group, such as methyl, overcomes the expected activating effect determined by the formation of a tertiary alkyl radical. A similar deactivating effect, deduced by relative rates, of the methyl group was already reported ${ }^{27,5 \mathrm{~b}}$ and recently confirmed. ${ }^{28}$ In contrast, the methyl radical has been reported to be more reactive ${ }^{29}$ with acrylic acid and styrene than with methacrylic acid and $\alpha$-methylstyrene. With 1,4-benzoquinone the intermediate radical stabilization and polar effects act in the same direction. However, it is surprising how rate constants for the addition of free radicals to quinones are presently lacking, if we consider the well-known importance of quinones as free-radical scavengers and as chain-process inhibitors. The high rate constant now determined with primary alkyl radicals enables us to better understand the quinones effectiveness in trapping free radicals. The importance of polar effects in determining this high rate is also shown by the low reactivity of electrophilic radicals such as amino radicals protonated or coordinated with metal salts, which do not react at all with $p$-benzo-

[^8]

## Scheme IV

quinone, ${ }^{30}$ or oxygen-centered radicals, which react faster with olefins, ${ }^{31}$ with aromatics, ${ }^{31}$ and in hydrogen abstraction. ${ }^{32}$ On the other hand, the effectiveness as a polymerization inhibitor is much higher for styrene and vinyl acetate, ${ }^{33}$ which originate nucleophilic carboncentered radicals, than for acrylates, in which the elec-tron-withdrawing group increases the electron affinity of the corresponding radical. This behavior has been recently confirmed ${ }^{31 \mathrm{a}}$ in the styrene oxidation by silver-catalyzed decomposition of peroxydisulfate in the presence of $p$ benzoquinone. No polymerization and telomerization of styrene was observed, but the benzyl radical was completely scavenged by benzoquinone, and 2-(2-hydroxy-1-phenylethyl)-1,4-benzoquinone was obtained (Scheme IV).

The high rate of quinone reaction toward nucleophilic radicals also suggests the possibility of the quinone-hydroquinone system synergism in inhibiting chain reactions such as autoxidation involving alkyl and peroxy radicals: quinone reacts faster with nucleophilic alkyl radicals and hydroquinone reacts faster with electrophilic peroxy radicals, both yielding similar stabilized radicals, which are too unreactive to carry on the chain.

Contribution to the transition state of polar form 31 can

31
explain these results. The degree of charge separation depends on donor character of the radical and the acceptance character of the quinone, a complete electron transfer being the limit case. This latter could explain the variable preference of free-radical attack at a carbon or oxygen atom of the quinone. Thus quinones with high potentials, such as chloranil, 2,3 -dichloro- 5,6 -dicyano-1,4-benzoquinone (DDQ), and quinizarinquinone react with nucleophilic radicals such as acy ${ }^{34}$ and allyl ${ }^{31 \mathrm{~b}}$ radicals at the oxygen atom, whereas 1,4 -benzoquinone and alkylquinones are attacked by the same radicals at the carbon atom ${ }^{31 a, 35}$ and 2,3,5,6-tetramethyl-1,4-benzoquinone does

[^9]not react with acyl radicals. ${ }^{35}$ An electron-transfer process should explain the attack at the oxygen atom (eq 24).

Depending on the reaction medium, the relatively stable and persistent radical anion 32 can either react with acyl cations or scavenge an acyl radical giving in the case of quinizarinquinone the corresponding monoacetate.

## Summary

The positive $\rho$ value observed for the addition of the 5 -hexenyl radical to substituted olefins clearly indicates the nucleophilic character of a primary alkyl radical in an olefin addition. The stabilization of the transition state by polar structures $\mathrm{R}^{+} \cdot \mathrm{CH}_{2}{ }^{-} \mathrm{CHX}$ explains the activation energies order reversed from that predicted by the resonance stabilization effect in substituted olefins, and it is the main factor in determining the high trapping effectiveness of 1,4 -benzoquinone. Complete electron transfer from radical to substrate is a limit case, which could explain the different reaction course observed with quinones of high electron affinity and radicals with low ionization potential.
The knowledge of the rate constants of alkyl radical additions to olefins, together with their oxidation rates, has also interesting synthetic potential for allowing selection of the best conditions for the synthesis of a variety of polyfunctional products starting from cheap industrial monomers

## Experimental Section

Melting and boiling points are uncorrected. NMR spectra were run in $\mathrm{CDCl}_{3}$ ( $\mathrm{Me}_{4} \mathrm{Si}$ as internal standard), using a Varian A 90 (or A 100) spectrometer. Mass spectra were obtained on a Hitachi Perkin-Elmer RMU-6D mass spectrometer at 70 eV , using an all-glass inlet system operating at $200^{\circ} \mathrm{C}$. IR spectra were obtained on a Perkin-Elmer E-177 grating infrared spectrometer.

Gas chromatographic (GC) analyses were performed on a Hewlett-Packard 5850 or a DANI 3600 chromatograph, using an $8 \mathrm{ft} \times 1 / 8 \mathrm{in} .10 \%$ UCC on Chromosorb W AW-DMCS column and an $8 \mathrm{ft} \times 1 / 8 \mathrm{in} .3 \% \mathrm{OV}_{17}$ on Chromosorb P 60-80 mesh column. Preparative-scale GC analyses were performed on a Varian Aerograph Model 90-P with a thermal conductivity detector. The columns used were as follows: $10 \mathrm{ft} \times 1 / 4 \mathrm{in}$. $\mathrm{OV}_{17}$ $20 \%$ on Chromosorb W and $10 \mathrm{ft} \times 1 / 4 \mathrm{in} 20 \$.$% UCC on$ Chromosorb W ( $60-80 \mathrm{mesh}$ ).

All reactions were run in a constant-temperature bath controlled with $\pm 0.1^{\circ} \mathrm{C}$.

Materials. Acetic acid and acetonitrile were refluxed and distilled over $\mathrm{P}_{2} \mathrm{O}_{5}$ under $\mathrm{N}_{2}$. Styrene, $\alpha$-methylstyrene, acrylonitrile, acrylic and methacrylic acids, and methyl vinyl ketone were redistilled under $\mathrm{N}_{2}$ at 100 mmHg immediately before use. 1,4-Benzoquinone was purified by sublimation (mp $115-116^{\circ} \mathrm{C}$ ). Butadiene was distilled by the trap-to-trap method. Hexadiene and methylenecyclopentane were commercial products. Di-6heptenoyl peroxide was prepared as described previously ${ }^{36}$ from 6 -heptenoyl chloride ( $\mathrm{bp} 35^{\circ} \mathrm{C}\left(1 \mathrm{mmHg}\right.$ ) ), $\mathrm{H}_{2} \mathrm{O}_{2}$, and pyridine; ${ }^{37}$ the residual solvents were removed at $0^{\circ} \mathrm{C}$ under vacuum for 6 h , and the peroxide was stored at $-30^{\circ} \mathrm{C}$ (its purity by iodometric

${ }^{a}$ All of the data summarized in this table are available for the interested reader.
analysis was $98 \%$ ). The same procedure was used with 2 cyclopentaneacetic acid (bp $125^{\circ} \mathrm{C}(25 \mathrm{mmHg})$ ) to obtain dicyclopentyl acetyl peroxide. The stock solution of copper(I) acetate was prepared as an acetonitrile complex by stirring 1.45 $\mathrm{g}\left(8 \times 10^{-3} \mathrm{~mol}\right)$ of $\mathrm{Cu}\left(\mathrm{OCOCH}_{3}\right)_{2}$ with an excess of copper powder in 100 mL of a degased $\mathrm{CH}_{3} \mathrm{CN}-\mathrm{CH}_{3} \mathrm{COOH}$ (4:6) mixture under $\mathrm{N}_{2}$. The solution was standardized against $0.1 \mathrm{~N} \mathrm{Ce}\left(\mathrm{SO}_{4}\right)_{2}$.
The standard solutions for the study of the addition reactions were prepared by dissolving under $\mathrm{N}_{2}$ weighed amounts of $\mathrm{Cu}\left(\mathrm{OCOCH}_{3}\right)_{2}(0.025 \mathrm{M})$, vinylic monomer ( $0.03-0.7 \mathrm{M}$ ), and 1 mL of a stock solution of copper(I) acetate in a degassed mixture of $\mathrm{CH}_{3} \mathrm{CN}-\mathrm{CH}_{3} \mathrm{COOH}$ (6:4) into 100 mL .
Kinetic Procedure and Analysis. Stock reagent solutions $(25 \mathrm{~mL}$ ) were poured into a degased $50-\mathrm{mL}$ flask and thermostated for 30 min under $\mathrm{N}_{2}$ at the selected temperature. To the magnetically stirred solution di-6-heptenoyl peroxide $\left(6.0 \times 10^{-3}\right.$ g) was added and the reaction run for 2 h under $\mathrm{N}_{2}$. All reactions were carried out in duplicate and in a few cases were repeated four or five times

The solution was poured into ethyl ether ( 40 mL ), water (30 mL ) was added, and the organic layer was separated. The water solution was extracted twice with ether (two $30-\mathrm{mL}$ portions), and the combined organic extracts were washed with water (four $30-\mathrm{mL}$ portions) and dried on $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The product distribution resulting from the various reactions was analyzed by GC. Calibration curves for concentration vs. peak area were prepared for the reaction products by using standard solutions of mixtures of authentic samples in toluene. The material balance was always good; $90-100 \%$ of the theoretical products from the heptenoyl peroxide are accounted for and include hexadiene, methylenecyclopentane, and the addition products. The results are summarized in Table II and, graphically, in Figures 1-5. Heptenoic acid was quantitatively determined by using an 8 ft $\times 1 / 8 \mathrm{in} .10 \%$ FFAP on Chromosorb P 60-80 mesh column; its yield was $90-95 \%$ on peroxide. The values of $k_{\mathrm{a}} / k_{6}$ and $k_{8} / k_{6}$ were calculated for each insaturated compound by using linear regression analysis. The errors quoted represent $95 \%$ confidence limits on each slope and intercept.

Product Identification. All cyclized addition products were prepared as pure samples by the following procedure: dicyclopentyl acetyl peroxide ( $1.5 \mathrm{~g}, 5.1 \times 10^{-3} \mathrm{~mol}$ ) was added under $\mathrm{N}_{2}$ in 1 h to 50 mL of a solution of styrene ( 0.4 M ) [or $\alpha$ methylstyrene ( 0.5 M ), butadiene ( 0.3 M ), or styrene ( 0.25 M ) and vinyl monomer ( 0.3 M )] in $\mathrm{CH}_{3} \mathrm{CN}-\mathrm{CH}_{3} \mathrm{COOH}$ (6:4) containing $\mathrm{CuOCOCH}_{3}(0.005 \mathrm{M})$ and $\mathrm{Cu}\left(\mathrm{OCOCH}_{3}\right)_{2}(0.025 \mathrm{M})$ at
$40^{\circ} \mathrm{C}$. The reaction mixture was concentrated to 20 mL on a rotary evaporator, ethyl ether ( 100 mL ) and water ( 100 mL ) were added, the layers were separated, and the aqueous portion was extracted twice with pentane (two $50-\mathrm{mL}$ portions). The combined extracts were washed with water (three $50-\mathrm{mL}$ portions), dried on $\mathrm{Na}_{2} \mathrm{SO}_{4}$, and evaporated. The residue was chromatographed on silica gel eluting with hexane-ethyl acetate (9:1) to give the addition products in yields ranging from $55 \%$ (for $\alpha$-methylstyrene) to $80 \%$ (for acrylic acid and methyl vinyl ketone). The isolated products were found to be identical with those isolated by preparative GC from the kinetic runs

The addition products to 1,4 -benzoquinone 20 b ( 2 -cyclo-pentylmethyl-1,4-benzoquinone) were synthesized following the reported procedure ${ }^{32}$ based on the $\mathrm{Ag}^{+}$-catalyzed oxidation of cyclopentaneacetic acid by peroxydisulfate in the presence of quinone ( $82 \%$ yield). Analytical data for 20 a and $\mathbf{2 0 b}$ are reported elsewhere. ${ }^{31 \mathrm{a}}$

Compounds 11 and 12 were identified as a mixture by NMR spectra because TLC separation was impossible. The quantitative response of the signals at $\delta 7.3$ ( s , aromatics), $4.9-5.8$ ( m , termina vinyl), and 2.2 ( $\mathrm{s}, \mathrm{OCOCH}_{3}$ ) was checked for analysis, but the intrinsic error of the method precluded its use. The analyses of these compounds were carried out on the pyrolysis products 13 and 14, obtained by introducing the kinetic runs in the gas chromatograph at $280^{\circ} \mathrm{C}$ injection temperature.

All the other reaction products were isolated from kinetic runs by preparative vapor-phase chromatography, and elemental analyses agree well in all cases.

5-Cyclopentyl-2-penten-1-yl Acetate (18): IR $\nu_{\text {max }}$ 1745, 975 $\mathrm{cm}^{-1}$; NMR $\left(\mathrm{CDCl}_{3}\right) \delta 5.0-6.0(\mathrm{~m}$, vinyl, 2 H$), 3.5(\mathrm{t}, \mathrm{CHO}, 2 \mathrm{H})$, $2.4\left(\mathrm{~s}, \mathrm{COCH}_{3}, 3 \mathrm{H}\right), 1.4-2.6(\mathrm{~m}, 13 \mathrm{H})$; MS $m / e 196\left(\mathrm{M}^{+}\right), 154$, 113, $70,43$.
4-Phenyl-2-(6-heptenyl)butanolide (25a): $\operatorname{IR} \nu_{\max } 1780,1645$, $1160,910 \mathrm{~cm}^{-1} ; \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 7.4$ (s, 5 H ), 4.9-5.1 (m, vinyl,

3 H), 5.45 (dd, CHAr, 1 H), 2.8 (dd, CHCO, 1 H), 1.9-2.2 (m, 4 H), 1.3-1.9 (m, 8H); MS m/e 258 ( $\mathrm{M}^{+}$.), 240, 229, 143, 129, 117, 104, 91, 67.

4-Phenyl-2-(6-heptenyl)-2-methylbutanolide (25b): IR $\nu_{\text {max }}$ $1785,910 \mathrm{~cm}^{-1}$; NMR ( $\mathrm{CDCl}_{3}$ ) o 7.3 ( $\mathrm{s}, 5 \mathrm{H}$ ), 4.9-5.9 (m, vinyl, $3 \mathrm{H}), 5.2$ (dd, CHO, 1 H ), 2.1 ( $\mathrm{s}, \mathrm{CH}_{3}, 3 \mathrm{H}$ ), 1.1-2.4 (m, 12 H ); MS $m / e 272\left(\mathrm{M}^{+} \cdot\right), 254,243,159,117,104,91$.

1-Phenyl-3-cyano-9-decen-1-yl Acetate (25c): IR $\nu_{\text {max }} 2250$, $1745,910 \mathrm{~cm}^{-1} ; \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right) \delta 7.3(\mathrm{~s}, 5 \mathrm{H}), 5.83(\mathrm{t}, \mathrm{CHAr}, 1 \mathrm{H})$, $4.8-5.8$ (m, vinyl, 3 H ), 2.6 (quintet, $\mathrm{CHCN}, 1 \mathrm{H}$ ), 2.4 (td, $\mathrm{CHC}=\mathrm{C}$, $2 \mathrm{H}), 2.5\left(\mathrm{~s}, \mathrm{COCH}_{3}, 3 \mathrm{H}\right), 1.0-2.0(\mathrm{~m}, 10 \mathrm{H}) ; \mathrm{MS} \mathrm{m} / \mathrm{e} 299\left(\mathrm{M}^{+}\right.$., small) 257, 149, 117, 107, 104, 77, 43.

Methyl 2-(6-Heptenyl)-4-(acetoxy)-4-phenylbutanoate (25d): IR $\nu_{\text {max }} 1750,1740,910 \mathrm{~cm}^{-1}$; NMR ( $\left.\mathrm{CDCl}_{3}\right) \delta 7.4(\mathrm{~s}, 5 \mathrm{H})$, $4.9-5.9\left(\mathrm{~m}\right.$, vinyl, 3 H ), $4.2(\mathrm{t}, \mathrm{CHO}, 1 \mathrm{H}), 3.2\left(\mathrm{~s}, \mathrm{OCH}_{3}, 3 \mathrm{H}\right), 2.5$ ( $\mathrm{s}, \mathrm{COCH}_{3}, 3 \mathrm{H}$ ), 1.4-2.5 (m, 12 H ); MS m/e 332, 300, 290, 149 , 117, 104, 77.

1-Phenyl-3-acetyl-9-decen-1-ol (25e): IR $\nu_{\text {max }} 3450,1720 \mathrm{~cm}^{-1}$; NMR ( $\mathrm{CDCl}_{3}$ ) $\delta 7.3(\mathrm{~s}, 5 \mathrm{H}), 4.8-6.0(\mathrm{~m}$, vinyl, 3 H ), 5.4 (dd, CHAr, 1 H ), 3.1 (broad, $\mathrm{OH}, 1 \mathrm{H}$ ), $3.0(\mathrm{~m}, 1 \mathrm{H}), 2.1\left(\mathrm{~s}, \mathrm{CH}_{3}, 3 \mathrm{H}\right), 1.3-2.6$ (m, 12 H ); MS m/e 274 ( $\mathrm{M}^{+}$., small), 213, 173, 91, 43.

4-Phenyl-2-(2-cyclopentylethyl)butanolide (26a): IR $\nu_{\text {max }}$ $1780,1160,940 \mathrm{~cm}^{-1}$; NMR ( $\mathrm{CDCl}_{3}$ ) $\delta 7.3(\mathrm{~s}, 5 \mathrm{H}), 5.54(\mathrm{t}, \mathrm{CHAr}$, $1 \mathrm{H}), 2.6-2.9(\mathrm{~m}, 2 \mathrm{H}), 1.1-2.1(\mathrm{~m}, 13 \mathrm{H})$; MS $m / e 258\left(\mathrm{M}^{+}.\right), 257$, $240,162,154,136,117,104,91,82,67,59$.

4-Phenyl-2-(2-cyclopentylethyl)-2-methylbutanolide (26b): IR $\nu_{\text {max }} 1785 \mathrm{~cm}^{-1} ;$ NMR ( $\mathrm{CDCl}_{3}$ ) $\delta 7.3(\mathrm{~s}, 5 \mathrm{H}), 5.4$ (dd, CHAr, 1 H ), 2.3 (dd, CHCO, 1 H ), 1.1-2.2 (m, 12 H ); MS m/e $272\left(\mathrm{M}^{+}\right.$. ), 254, 159, 117, 77.

1-Phenyl-3-cyano-5-cyclopentylpentan-1-yl Acetate (26c): IR $v_{\text {max }} 1785 \mathrm{~cm}^{-1} ;$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 7.3(\mathrm{~s}, 5 \mathrm{H}), 5.8(\mathrm{t}, \mathrm{CHO}, 1$ H ), 2.6 (quintet, $\mathrm{CHCN}, 1 \mathrm{H}$ ), $2.4-2.6(\mathrm{~m}, 2 \mathrm{H}), 2.0\left(\mathrm{~s}, \mathrm{COCH}_{3}\right.$, $3 \mathrm{H}), 1.0-2.0(\mathrm{~m}, 14 \mathrm{H})$; MS $m / e 299\left(\mathrm{M}^{+}.\right), 216,148,117,107$, 104, 77, 43.

Methyl 2-Cyclopentylmethyl-4-(acetyloxy)-4-phenylbutanoate (26d): IR $\nu_{\max } 1750,1740 \mathrm{~cm}^{-1}$; NMR ( $\left.\mathrm{CDCl}_{3}\right) \delta 7.4$ ( $\mathrm{s}, 5 \mathrm{H}$ ), $5.7(\mathrm{t}, \mathrm{CHAr}, 1 \mathrm{H}), 3.3\left(\mathrm{~s}, \mathrm{OCH}_{3}, 3 \mathrm{H}\right), 1.1-2.5(\mathrm{~m}, 16 \mathrm{H})$; MS m/e 332, 300, 149, 117, 104, 77.

1-Phenyl-3-acetyl-5-cyclopentylpentan-1-01 (26e): IR $\nu_{\text {max }}$ $3450,1720 \mathrm{~cm}^{-1}$; NMR $\left(\mathrm{CDCl}_{3}\right) \delta 7.3(\mathrm{~s}, 5 \mathrm{H}), 4.9-6.0$ (m, vinyl, 3 H ), $5.8(\mathrm{t}, \mathrm{CHO}, 1 \mathrm{H}), 2.1(\mathrm{~s}, 3 \mathrm{H}), 1.1-2.4(\mathrm{~m}, 16 \mathrm{H})$; MS m/e 274 ( $\mathrm{M}^{+} \cdot$ ), 213, 173, 129, $91,43$.

## Appendix A

Derivation of Eq 13. Application of the steady-state assumption for radical 2 according to Scheme I

$$
\mathrm{d}[2] / \mathrm{d} t=k_{6}[1]-\left(k_{9}[\mathrm{CH}=\mathrm{CHPh}]+k_{8}\left[\mathrm{Cu}^{2+}\right]\right)[2]=0
$$

allows derivation of the ratio of radical 1 and 2 stationary concentrations:

$$
[1] /[2]=k_{9}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right] / k_{6}+k_{8}\left[\mathrm{Cu}^{2+}\right] / k_{6}
$$

Because the addition products 5 and 6 are formed respectively at the rates

$$
\begin{aligned}
& \frac{\mathrm{d}[\mathbf{5}]}{\mathrm{d} t}=k_{9}[\mathbf{1}]\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]+ \\
& \frac{k_{10} k_{9}}{k_{6}}[\mathbf{2}]\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]\left[\mathrm{Cu}^{2+}\right]+ \\
& \quad \frac{k_{10} k_{9}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]^{2}[\mathbf{2}] \\
& \mathrm{d}[\mathbf{6}] / \mathrm{d} t=k_{10}[\mathbf{2}]\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]
\end{aligned}
$$

the ratio of the formation rates for products 5 and 6 is

$$
\frac{\mathrm{d}[5]}{\mathrm{d}[6]}=\frac{k_{9}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]+\frac{k_{9} k_{8}}{k_{6} k_{10}}\left[\mathrm{Cu}^{2+}\right]
$$

and under the hypothesis that $k_{9}=k_{10}$, the relative yields
of 5 and 6 are given by eq 13 ( $\mathrm{f}=$ final, $\mathrm{i}=$ initial):

$$
\begin{equation*}
\frac{[5]_{\mathrm{f}}}{[6]_{\mathrm{f}}}=k_{9}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]_{\mathrm{i}} / k_{6}+k_{8}\left[\mathrm{Cu}^{2+}\right]_{\mathrm{i}} / k_{6} \tag{13}
\end{equation*}
$$

## Appendix B

Derivation of Kinetic Eq 20-22. Application of the steady-state assumption for the radical 2 according to Schemes I and II gives rise to

$$
\begin{aligned}
& \mathrm{d}[2] / \mathrm{d} t=k_{6}[1]-k_{8}\left[\mathrm{Cu}^{2+}\right][2]- k_{10}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right][2]- \\
& k_{16}\left[\mathrm{CH}_{2}=\mathrm{CHX}\right][2]=0
\end{aligned}
$$

The addition products $25,26,5$, and 6 are formed respectively at the rates

$$
\begin{gathered}
\frac{\mathrm{d}[\mathbf{2 5}]}{\mathrm{d} t}=k_{15}[1]\left[\mathrm{CH}_{2}=\mathrm{CHX}\right]= \\
\frac{k_{8} k_{15}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHX}\right]\left[\mathrm{Cu}^{2+}\right][\mathbf{2}]+\frac{k_{10} k_{15}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right] \times \\
{\left[\mathrm{CH}_{2}=\mathrm{CHX}\right][\mathbf{2}]+\frac{k_{15} k_{16}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHX}\right]^{2}[\mathbf{2}]} \\
\frac{\mathrm{d}[\mathbf{2 6}]}{\mathrm{d} t}=k_{16}\left[\mathrm{CH}_{2}=\mathrm{CHX}\right][\mathbf{2}] \\
\frac{\mathrm{d}[6]}{\mathrm{d} t}=k_{10}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right][\mathbf{2}] \\
\frac{\mathrm{d}[\mathbf{5}]}{\mathrm{d} t}=k_{9}\left[\mathrm{CH}_{2}=\mathrm{CHPh}^{2}[1]=\right. \\
\frac{k_{8} k_{9}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]\left[\mathrm{Cu}^{2+}\right][\mathbf{2}]+ \\
\frac{k_{9} k_{10}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]^{2}[\mathbf{2}]+ \\
\frac{k_{9} k_{16}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHX}\right]\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right][\mathbf{2}]
\end{gathered}
$$

and the relative yield of 25 and 26,5 and 6 , or 25 and 5 can be obtained by eq $20-22$ under the hypotheses that $k_{9}=k_{10}, k_{15}=k_{16}$, and $k_{7}=k_{8}$

$$
\begin{array}{r}
\frac{[\mathbf{2 5}]_{\mathrm{f}}}{[\mathbf{2 6}]_{f}}=\frac{k_{15}}{k_{6}}\left[\mathrm{CH}_{2} \mathrm{CHX}\right]_{\mathrm{i}}+\frac{k_{10}}{k_{6}}\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]_{\mathrm{i}}+ \\
\frac{k_{8}}{k_{6}}\left[\mathrm{Cu}^{2+}\right]_{\mathrm{i}} \tag{20}
\end{array}
$$

$$
\begin{equation*}
\frac{[\mathbf{2 5}]_{\mathrm{f}}}{[5]_{\mathrm{f}}}=\frac{[\mathbf{2 6}]_{\mathrm{f}}}{[6]_{\mathrm{f}}}=\frac{k_{16}}{k_{10}} \frac{\left[\mathrm{CH}_{2}=\mathrm{CHX}\right]_{\mathrm{i}}}{\left[\mathrm{CH}_{2}=\mathrm{CHPh}\right]_{\mathrm{i}}} \tag{21}
\end{equation*}
$$
