

The product 11 has been reported earlier<sup>1a</sup> to undergo intramolecular Diels-Alder reaction leading to a mixture of 12 and 13. If 10b is heated at 180 °C for 20 h, cyclization occurs. The product (mainly one isomer) is assigned structure 14 (equatorial Me<sub>3</sub>Si) based on the assumption that the bulky Me<sub>3</sub>Si group must occupy an equatorial position in the Diels-Alder transition state 15.<sup>12</sup> When 14 was treated with KH/HMPA, a stereospecific<sup>13</sup> Brook rearrangement<sup>8</sup> led to exclusive axial alcohol 13.

In conclusion, we point out that the efficient desilylation of silyl carbinols makes their acyl silane precursors equivalent to aldehydes that are sterically hindered. Two additional advantages are the following: (1) acyl silanes are less prone to self-condensation than aldehydes and thus give higher overall yields and (2) the bulky Me<sub>3</sub>Si substituent can be used to control the stereochemistry of subsequent reactions.

(11) Reich, H. J.; Olson, R. E.; Clark, M. C. *J. Am. Chem. Soc.* 1980, 102, 1423-1424.

(12) Additional support for the equatorial disposition of the Me<sub>3</sub>Si group comes from the addition of Me<sub>3</sub>SiLi<sup>7</sup> to known<sup>1a</sup> ketone 16 which gives 14.

(13) The stereospecificity (retention) of the Brook rearrangement<sup>8</sup> can be rationalized by kinetic equatorial protonation of the anionic intermediate. A related aliphatic Brook rearrangement has also been reported (Hudlick, P., Howard University, personal communication) to occur with retention.

## Bifunctional Cyclopropyl Reagents: Stereocontrolled Approach to Vinyl Sulfides and Chemodifferentiated 1,4-Dicarbonyl Systems

**Summary:** The use of (*E*)-2-(hydroxymethyl)cyclopropyl phenyl sulfide as a useful conjunctive reagent, particularly in a stereocontrolled synthesis of vinyl sulfides, is reported.

**Sir:** The immense importance of the carbonyl group in structural elaboration stems from the ability to add nucleophiles to the carbonyl carbon atom and, most importantly, the ability to functionalize at the  $\alpha$  carbon atom through the intermediacy of enols or enolates. Stereocontrolled methods for enol or enolate formation, which are generally lacking, would greatly enhance the utility of such synthetic intermediates. Vinyl sulfides not only have the possibility of serving as enol substitutes but, due to a myriad of other reactions involving direct replacement of sulfur or isomerizations to allylic systems, also may provide a much diverse reactivity profile. Thus, stereocontrolled syntheses of vinyl sulfides are particularly important but virtually nonexistent. We report herein that the bifunctional conjunctive reagent, 2-(hydroxymethyl)-cyclopropyl phenyl sulfide (1),<sup>1</sup> provides a novel stereocontrolled approach to such systems which can greatly enhance the utility of this functionality. Furthermore, it additionally allows transformation into several important building blocks—particularly chemodifferentiated 1,4-dicarbonyl systems.

The reagent 1 (bp 110–111 °C (0.07 torr)),<sup>2,3</sup> which has been made on multimole scale, is available in 45% overall yield from thiophenol and  $\gamma$ -butyrolactone as outlined in Scheme I. The pyrrophoric dilithium reagent 2, which forms readily in contrast to the metalation of 2-methylcyclopropyl phenyl sulfide, forms as a suspension in hexane.<sup>4-6</sup> For synthetic purposes, two volumes of THF are

added to the hexane suspension to give a solution of the dianion. Quenching 2 with DMF generates lactol 3<sup>2,3</sup> (mp 98–99.5 °C, recrystallized from 40% ethyl acetate in hexane and carbon tetrachloride), a second valuable conjugative reagent.

Lactol 3 serves as an intriguing precursor to functionalized 1,4-dienes as shown by eq 1 and summarized in Table I. The vinyl sulfide is generated with 100% *E* stereoselectivity! Transition states arising from conformation I, which correspond to placing a *trans* double bond in a seven-membered ring, are geometrically precluded. Rearrangement proceeds exclusively via the sterically much more favorable conformation II which produces the *E* vinyl sulfide.<sup>9c</sup> The stereochemistry of the enol silyl ether depends upon reaction via rotamer IIa or IIb. the vinyl sulfide to a ketone is obvious and allows these compounds to serve as 1,4-dicarbonyl synthons. The nickel-catalyzed reactions are particularly noteworthy since the ability to completely control the stereochemistry of the vinyl sulfide translates into stereocontrolled tri- and disubstituted olefin syntheses. The stereochemical homogeneity is established by chromatography and 270-MHz <sup>1</sup>H and 15-MHz <sup>13</sup>C NMR spectroscopy.

A simple stereocontrolled approach to the side chain of trisporic acid **6**<sup>15,16</sup> emerges as the retrosynthetic analysis summarized in eq 2 illustrates. Furthermore, the fact that

the aldehyde is specifically enolized can also facilitate introduction of the X group for the final elimination. The dicarbonyl unit **7** is available in 38% overall unoptimized yield from **3** as summarized in Scheme III.

While the vinyl sulfide represents a carbonyl equivalent, it allows chemoselective structural elaboration of the other

Scheme V. Synthetic Transformations Derived from 2-(Hydroxymethyl)cyclopropyl Phenyl Sulfide (**1**)

carbonyl equivalent present, the enol silyl ether. Scheme IV summarizes a few of the selective transformations performed.<sup>17–19</sup> The ability to manipulate independently the two functionalities gives special merit to this type of building block.

Small ring bifunctional conjunctive reagents such as **1** and **3** appear to be potentially important new building blocks. From these systems, new syntheses of *Z* vinyl sulfides, 1,4-dienes, chemodifferentiated 1,4-dicarbonyl systems, and 2-methylenecyclobutanones<sup>20</sup> have emerged as shown in Scheme V. Particularly noteworthy is the rare stereocontrolled synthesis of the vinyl sulfide. Such an entry into this relatively little utilized class of compounds provides a new direction for their utility—stereocontrolled olefin synthesis.<sup>21</sup>

### Organic Sonochemistry. Ultrasound-Promoted Reaction of Zinc with $\alpha,\alpha'$ -Dibromo-*o*-xylene. Evidence for Facile Generation of *o*-Xylylene

**Summary:**  $\alpha,\alpha'$ -Dibromo-*o*-xylene and zinc powder react smoothly in the presence of dienophiles and sonic waves to give high yields of cycloaddition products. The reaction is believed to proceed via the reactive intermediate, *o*-xylylene.

**Sir:** The effects of ultrasounds on the rates of chemical reactions have been of general interest.<sup>1</sup> In most cases, modest rate enhancements<sup>2</sup> have been the major benefit from using sonic waves although the number of examples of synthetically useful applications is increasing. Recent

communications describing an improved modification of the Barbier reaction,<sup>3</sup> a facile reduction of  $\alpha,\alpha'$ -dibromo ketones,<sup>4</sup> coupling of organic<sup>5</sup> and organometallic<sup>6</sup> halides, and a new procedure for making thioamides<sup>7</sup> indicate considerable potential for ultrasound in synthesis. We have extended our investigations to organic dihalides and in this communication we report preliminary results of our studies of ultrasonically induced reactions of zinc powder with  $\alpha,\alpha'$ -dibromo-*o*-xylene (1).

We have found that ultrasound accelerates the reaction between zinc and 1 in dioxane, forming high yields of cycloaddition products when dienophiles are present in the reaction mixture. These results are summarized in Table I. No reaction occurs in the absence of ultrasound.

When a dioxane solution of 1 is treated with zinc and ultrasound in the absence of a reactive species, all of 1 is consumed, giving mostly polymer and small quantities (<5% by NMR) of bibenzo[*a,e*]-6,7,11,12-tetrahydrocyclooctadiene (3). These observations are consistent with

the formation of *o*-xylylene (2) as an important intermediate in these reactions. Attempts to trap an ionic intermediate like 4 with trimethylchlorosilane were unsuccessful. However, some 3 was detected by NMR.

In a typical experiment, 10 mmol of 1, 11 mmol of dienophile, and 23 mmol of activated zinc<sup>8</sup> were added to 10 mL of peroxide-free dioxane freshly distilled from KOH. The reaction mixture, contained in a 25-mL, round-bottom, single-neck flask under an atmosphere of nitrogen, was partly submerged in a common ultrasound laboratory cleaner (117 V, 150 W, 50/60 Hz). Bath temperatures were maintained at 20–25 °C by using a cooling coil.

Product isolation was straightforward: filtration of the crude product mixture to remove zinc bromide and excess
