Enolboration. 6. Dicyclohexyliodoborane, a Versatile Reagent for the Stereoselective Synthesis of Either Z or E Enolates from **Representative Esters**

Kumaraperumal Ganesan and Herbert C. Brown*

H. C. Brown and R. B. Wetherill Laboratories of Chemistry, Purdue University, West Lafayette, Indiana 47907-3699

Received December 16, 1993®

A smooth, rapid, quantitative, and highly stereoselective synthesis of either Z or E enclates from representative esters has been achieved with dicyclohexyliodoborane, Chx₂BI, in the presence of a suitable tertiary amine, such as triethylamine or N.N-diisopropylethylamine. A systematic investigation of the enolboration of ethyl propionate and ethyl phenylacetate, as model esters, by the various $Chx_{2}BX$ and BX-9-BBN reagents (X = OMs, I, and Br) established $Chx_{2}BI$ as the preferred reagent in terms of yield and selectivity. Further study of representative esters (RCH₂-COOR') with Chx₂BI established that the steric requirements of both the alkyl group (R) at the α -position and the alkoxy group (OR') play a significant role in controlling the enolate geometry. The steric requirements of the amine $(R''_{3}N)$ also contribute considerably to the stereoselectivity of the reaction. The present study provides a simple procedure for the synthesis of Z or E end borinates from representative esters (RCH₂COOR') using the combined stereodirecting effects of the alkyl (R) and the alkoxy (OR') groups. These enol borinates are highly reactive with aldehydes at temperatures as low as -78 °C and are exceptionally stereoselective even at 0 °C. In this exploratory study, the synthesis of stereoselective enclates from representative esters (RCH₂COOR') using Chx₂- $BI/R''_{3}N$ is discussed, with special emphasis on the effects of the steric requirements of R and OR' in controlling the enolate geometry.

Enol borinates are valuable intermediates in organic synthesis.¹ Evans has established that Z enol borinates give syn aldols and E enol borinates give anti aldols stereoselectively³ (Scheme 1). Similar studies of stereoselection have also been described by other groups.^{2,4-8}

Mukaiyama developed a simple methodology² for the generation of enol borinates, involving the reaction of ketones with R₂BX reagents containing a powerful leaving group (X = OTf) in the presence of suitable tertiary amines (eq 1).

The nomenclature of the enol borinate (Z or E) is based on the simplified rule^{1a} proposed by Evans. For the C-1 enolate substituents R' and OM, the highest priority designation is always assigned to the OM group, independent of the metal. The normal priority designations of substituents at C-2 are maintained. Thus, irrespective of the nature of the R' group (H, alkyl, aryl, N,N-dialkyl, N,N-diaryl, O-alkyl, O-aryl, S-alkyl, and S-aryl), the enol borinate is designated Z when CH_3 and OBR_2 are cis and E when CH₃ and OBR₂ are trans (eq 1). This simplified rule has been widely adopted in this field.²⁻⁸ The major advantage of this designation is the simple relationship between the stereochemistry of the enolate intermediate and the aldol product. In all cases, Z enol borinates give syn aldols and E enol borinates give anti aldols.

Many R_2BX reagents (X = OTf, OMs, I, Br, and Cl) have now been examined for the enolboration of ketones.²⁻⁸ However, very little is known of reagents which can enolize esters, a very important class of carbonyl compounds. The widely used R₂BOTf and R₂BCl reagents are ineffective for the enolization of esters.^{3,6a} However, thioesters are readily enolized by these reagents.^{3,4b,d,6a}

© 1994 American Chemical Society

The lack of simple and effective organoboron reagents for the enolization of esters encouraged us to explore new reagents. Only one reagent, $R*_2BBr$, had been reported in the literature⁹ until we communicated that Chx_2BI was a simple, successful reagent for the enolization of esters and tertiary amides.¹⁰ The utility of the $R*_2BBr$ was also demonstrated only for the *tert*-butyl esters, a special class of sterically hindered esters, to obtain the corresponding E enol borinates.⁹ A systematic study of the enolboration of esters with a range of representative structures was, therefore, considered highly desirable to achieve an understanding of the factors influencing the enolboration of a wide range of substrates.

Results and Discussion

Since both dialkylboron triflate and chloride reagents could not enolize esters, Chx_2BX and BX-9-BBN reagents with other leaving groups, such as mesylate, iodide, and bromide, were examined using ethyl propionate, as a representative aliphatic ester, and ethyl phenylacetate, as a representative aromatic ester. From this study, Chx_2 -BI was selected as the most favorable reagent in terms of yield and selectivity. Representative esters (RCH₂COOR') of variable steric and/or electronic requirements of R (Me, Et, *i*-Pr, *t*-Bu, and Ph) and OR' (OMe, OEt, O-*i*-Pr, O-*t*-Bu, and OPh) were selected to achieve an understanding of their effects on the enolate geometry. Et₃N, a smaller amine, and *i*-Pr₂EtN, a bulkier amine, were employed to establish the effect of the amine on the enolate geometry.

Enolboration. Enolization was carried out in CCl₄ since this solvent permitted the direct recording of the ¹H NMR spectrum for the reaction mixture. ¹H NMR was employed to determine the yield and the Z/E ratio of the enol borinate using both the well-established internal standard method and the aldolization technique, respectively.^{5–8,11} Enolization could also be carried out in other organic solvents, such as CH₂Cl₂, CHCl₃, toluene, pentane, and hexane. Wherever the subsequent aldolization was to be performed at -78 °C, the corresponding enolization was carried out in hexane.

Selection of the Best Reagent. A preliminary study with representative Chx_2BX and BX-9-BBN reagents (X = OMs, I, and Br) for the enolboration of ethyl propionate and ethyl phenylacetate revealed that both Chx_2BI and Chx_2BBr achieve the quantitative enolboration of esters. However, Chx_2BI proved to be more stereoselective than Chx_2BBr (eq 2).

^a Enolizations were carried out in CCl₄ and in hexane when the corresponding aldolizations were carried out at 0 °C (or at 25 °C) and at -78 °C, respectively. ^b In cases where the spectrum shows only one major isomer, we have indicated the minor isomer to be <3% since such small peaks may be lost in the background. ^c Determined by ¹H NMR. ^d The yields were also confirmed by collecting and weighing the precipitated R"₃N-HI. ^eZ/E ratio was determined on the basis of the syn/anti ratio of their corresponding benzaldehyde aldol products.

The highly reactive Chx_2BI reagent generates Z enol borinate essentially exclusively from ethyl propionate and E enol borinate essentially exclusively from ethyl phenylacetate, while the corresponding bromide reagent yields a significantly larger amount of the other isomer. It is surprising to note that the BI-9-BBN reagent also failed to enolize esters. The stronger complexation between this smaller reagent and the amine used for the enolization may be responsible. Consequently, Chx_2BI was selected as the most favorable reagent for the stereoselective enolboration of esters.

Steric Requirements of R in RCH₂COOEt on the Enolate Geometry. The formation of Z enolate from ethyl propionate and E enolate from ethyl phenylacetate (eq 2) suggests a significant effect of the phenyl substituent at the α -position for the opposite E selectivity. To determine if this strong influence of the phenyl group is due to its steric or electronic effect and to examine also the effect of the steric requirements of the alkyl group (R) at the α -position, a series of representative ethyl esters, RCH₂COOEt, with variable steric requirements of R (Me, Et, *i*-Pr, and *t*-Bu) was selected for our further study (eq 3). The results are given in Table 1.

$$R = Me, Et, +Pr, t-Bu$$

$$O = Chx_2BI, Et_3N = OBChx_2 OBChx_2$$

The results in Table 1 reveal a strong influence of the steric requirements of the R group on the enolate geometry. For example, when R = Me or Et, the smaller substituents, Z enolate is formed essentially exclusively. But when R = i-Pr or t-Bu, the more bulky substituents, the E enolate is obtained essentially exclusively. It is now possible to get either Z or E enolate merely by controlling the steric requirements of the α -substituent. This study, however, does not establish the precise nature of the influence of

the phenyl substituent (steric or electronic) in favoring the formation of the E enolate geometry. Possibly, the extra stability of the trans enol borinate is due in part to the effect of the extended conjugation.

The results provide a simple procedure to obtain the syn or the anti aldol from representative ethyl esters by varying the steric and/or electronic requirements of the α -substituent (Scheme 2).

Steric Requirements of OR' in EtCOOR' on the Enolate Geometry. The effect of the steric requirements of the carbonyl substituent (R' in EtCOR', EtCOOR', EtCOSR') in controlling the enolate geometry has been well established.³⁻⁹ E enolates are provided essentially exclusively when R' = t-Bu. In the recent study of the enolization of esters with $R*_2BBr$, various *tert*-butyl esters were selected to obtain the corresponding E enol borinates.⁹ The sterically hindered aryloxy groups have also been used in the enolization of esters with LDA to achieve the synthesis of anti aldols.¹²

Even though there are a few reports indicating the effect of sterically hindered carbonyl substituents favoring the E enolate geometry, no systematic study has been reported to understand this important stereodirecting effect. Such an effect is especially valuable in the case of esters, since the synthesis of an ester with a suitable alkoxy group is usually quite easy by transesterification. Accordingly, we undertook a detailed study of this valuable stereodirecting effect of the OR' group. Representative propionate esters with different OR' groups (OMe, OEt, O-*i*-Pr, O-*t*-Bu, and OPh) of variable steric and/or electronic requirements were selected (eq 4), and the results are summarized in Table 2.

The results in Table 2 reveal the influence of the steric requirements of the OR' group in controlling the enolate geometry. As the steric requirements of the OR' group increase from OMe to O-t-Bu, the amount of E enolate formed also increases. The propionate ester, with the smaller methoxy or ethoxy group, gives essentially exclusive Z enolate, while that with the more bulky isopropoxy or *tert*-butoxy group gives a mixture of Z and E enolates. The effect of steric and/or electronic requirements of the phenyloxy group also contributes to the enolate geometry, providing E enolate predominantly in the enolboration of phenyl propionate.

Table 2. Effect of Steric Requirements of OR' on the Enolate Geometry in the Stereoselective Enolboration of Representative Propionate Esters, EtCOOR', with Chx₂BI/R"₃N⁴

Steric Requirements of Amine on the Enolate Geometry. It has been established in the enolboration of ketones with $R_2BOTf^{2,3,5}$ and $R_2BCl^{5,8}$ reagents that smaller amines favor the formation of E enolates and bulkier amines favor the formation of Z enolates. However, such data on the effect of the amine are not now known for the enolboration of esters.

In the present study, it was observed that those amines which are smaller than Et_3N , such as pyridine, 2,6-lutidine, Me₂EtN, and Et_2MeN , coordinate strongly with Chx_2BI and cause the reagent to be totally ineffective for enolization, while those amines which are bulkier than *i*-Pr₂-EtN, such as *i*-Pr₃N, give a very poor yield. Therefore, only Et_3N and *i*-Pr₂EtN with the suitable steric requirements have been examined in the present study. Incidentally, these are the two amines established for the quantitative and stereoselective enolboration of ketones with Chx_2BCl^8 and are also widely used with triflate reagents.^{2-4,9}

A comparison of the results obtained with Et_3N and i-Pr₂EtN in Tables 1 and 2 reveals the role of the steric requirements of the amine on the enolate geometry. Unlike the previous trend observed for ketones, an opposite trend was realized, with the smaller Et_3N favoring the formation of Z enolates and the bulkier i-Pr₂EtN favoring the formation of E enolates. These studies reveal the possibility of proceeding from the synthesis of the syn to the anti aldol from alkyl propionate esters using the combined stereodirecting effects of the alkoxy group and the amine (Scheme 3).

A similar effect of Et_3N and *i*-Pr₂EtN favoring the opposite enolate geometry, resulting in the selective synthesis of either syn or antialdols, has also been reported for the aldolization of enol borinates derived from oxazolidinone with *n*-Bu₂BOTf and aromatic aldehydes.¹³

Effect of Temperature on the Enolate Geometry. The results in Tables 1 and 2 suggest that good stereocontrol can be achieved when the enolization is carried

out at 0 °C. A small amount of the other isomer is also obtained at 25 °C. To get a good kinetic aldol stereoselection, aldolization is usually carried out at -78 °C.^{2–9} In the present study, however, the results obtained with the aldolizations at -78 °C and at 0 °C are essentially the same, except for ethyl propionate with Chx₂BI/*i*-Pr₂EtN. This clearly shows that the enol borinates derived from these esters using Chx₂BI are highly reactive and exceptionally stereospecific. The required ¹H NMR data for the benzaldehyde aldol products are contained in Table 3.

The yields are essentially quantitative with $Chx_2BI/$ Et₃N at 0 °C with all esters examined, except for the sterically hindered *tert*-butyl propionate. With *i*-Pr₂EtN, the yields are somewhat lower, as compared with Et₃N. However, better yields were obtained by carrying the reaction out at 25 °C. Under all the experimental conditions tried, very low yields were obtained from phenyl propionate. It may be due to the +I effect of OPh group making the α -proton less acidic for enolization. While the effect of steric and electronic requirements of the alkoxy group (OR') may affect the yield considerably, that of the alkyl group (R) does not.

Under the experimental conditions, no cleavage of esters was observed. Ether solvents were avoided in the present study since the R₂BI reagents are known to cleave such solvents. A ¹¹B NMR study of Chx₂BI (δ 83 ppm) in ether suggested a slow but definite cleavage of ether, even at 0 °C. About 25% borinate (Chx₂BOEt, δ 51.04 ppm), a cleaved product, was observed after 0.5 h and 89% was observed after 4 h at 0 °C. However, a model enolboration of CH₃CH₂COOMe in diethyl ether using the reverse addition, Chx₂BI to Et₃N in ether followed by the ester, achieved quantitative and stereoselective (>97%) syn aldol. A white solid, due to the complexation of Chx₂BI and Et₃N, was observed when Chx₂BI was added to Et₃N in ether at 0 °C which may be either unreactive or less reactive toward ether. However, when the ester was added, the enolization occured with the concurrent formation and precipitation of Et₃N·HI. The solid Et₃N·HI was collected by centrifugation, washed with ether, dried, and weighed. An essentially quantitative yield was obtained. Two more experiments were also carried out by adding 1 equiv of PhCH₂OCH₃ and CH₃CH₂OCH₂CH₃, respectively, to the reaction mixture in the enolboration of CH₃CH₂COOMe with Chx₂BI/Et₃N using the standard procedure. Stereoselective syn aldol (\geq 97%) was obtained quantitatively. These studies suggest that ether can be used as a solvent, if desired, using reverse addition and that substrates with protecting ether groups may be enolized successfully without cleaving the protecting groups.

Conclusions

This is the first systematic, detailed study of the enolboration of esters. A preliminary investigation of the various Chx_2BX and BX-9-BBN reagents (X = OMs, I, and Br) using ethyl propionate and ethyl phenylacetate established Chx₂BI as the best reagent in terms of yield and selectivity. A further study in the enolboration of representative esters, RCH₂COOR', with Chx₂BI reveals that the steric requirements of both R and OR' play a vital role in controlling the enolate geometry. A significant contribution from the steric requirements of amine was also observed. Unlike the trend observed for ketones, the esters showed the opposite trend, with the smaller Et₃N favoring the formation of Z enolates and the bulkier i-Pr₂-EtN favoring the formation of E enclates. The present study leads to a simple procedure for the synthesis of essentially pure (>97%) Z or E enol borinates from representative esters, RCH₂COOR', using the combined stereodirecting effects of the alkyl (R) and the alkoxy (OR') groups of the ester with a suitable amine. The remarkable reactivity, impressive stereoselectivity, ease of preparation and handling, and the greater stability combined to make Chx₂BI a highly versatile reagent for the stereoselective enolboration of esters.

Experimental Section

Materials. All glassware was throughly dried in an air oven, cooled, and assembled under nitrogen for the experiments. Degassed, anhyd solvents, CH_2Cl_2 , $CHCl_3$, CCl_4 , toluene, pentane, and hexane, were used in the present study. Et₃N and *i*-Pr₂EtN were distilled over CaH₂. Cyclohexene and all esters, except for isopropyl and *tert*-butyl propionate, were commercial products of the highest purity available. Borane-methyl sulfide (BMS), monobromoborane-methyl sulfide (MBBS), and 9-BBN were purchased from Aldrich and used as such for the reaction. The special experimental techniques used in handling air- and moisture-sensitive compounds have been described elsewhere.¹⁴ All of the following experiments were conducted under a nitrogen atmosphere.

Synthesis of Various R_2BX (X = OMs, I, and Br) Reagents. The syntheses of various Chx_2BX and BX-9-BBNreagents are described in our earlier paper.^{7b} Only the synthesis of Chx_2BI , the preferred reagent for esters, is described below.

Synthesis of Chx₂BI Reagent. A 250-mL two-necked, roundbottom flask capped with rubber septums, a magnetic stirring bar, and a connecting tube attached to a mercury bubbler was kept at 0 °C and charged with Chx₂BH^{6a} (26.7 g, 150.0 mmol) and CH₂Cl₂ (100 mL). Powdered iodine (19.1 g, 75.2 mmol), kept under a nitrogen atmosphere in a solid transfer tube attached to the side neck, was added in small installments with constant stirring. Hydrogen is evolved and should be safely vented.

⁽¹⁴⁾ Brown, H. C.; Kramer, G. W.; Levy, A. B.; Midland, M. M. Organic Synthesis via Boranes; Wiley-Interscience: New York, 1975.

Addition of I₂ was repeated immediately after the previous addition had been consumed (disappearance of pink color). After all the I₂ was added, the stirring was continued at 0 °C for 2 h and at 25 °C for 1 h. A pale pink color (due to the small excess of I₂) persists, which establishes completion of the reaction. Then the solvent was removed using a water aspirator (15-20 mm). Distillation of the concentrated mixture under vacuum yields pure, colorless Chx₂BI: bp 198-200 °C (1.25 mm); yield 80%; ¹H NMR (CDCl₃) 1.64-1.84 (10 H, m), 1.48-1.60 (2 H, m), 1.18-1.42 (10 H, m); ¹¹B NMR (CDCl₃) 84.52; ¹³C NMR 42.29, 28.73, 26.65, 26.48.

Synthesis of Esters. Isopropyl and *tert*-butyl propionate esters were prepared from the commercially available propionyl chloride and the corresponding alcohol using the standard procedure. Distillation provided >99% GC pure isopropyl propionate (bp 108-109 °C) and *tert*-butyl propionate (bp 121 °C), and ¹H NMR spectra confirmed the structures.

Spectra. ¹H, ¹³C, and ¹¹B NMR spectra were recorded on a 300-MHz instrument, and the chemical shift values are in δ (ppm) relative to TMS and BF₃·OEt₂, respectively.

General Procedure for the Enolization of Esters with Chx₂BX Reagents (X = I and Br). To a stirred solution of Chx₂BX (5.15 mmol), and R^{"3}N (5.15 mmol) in CCl₄ (17.0 mL), kept at the required temperature (0 °C or 25 °C), was added the ester (5.00 mmol) dropwise. The enol borinate was generated rapidly with concurrent formation and precipitation of $R''_{3}N$ ·HX. An internal standard, benzene (0.50 mL, 1.00 M in CCl₄, 0.50 mmol), was added for quantification of the enolate by ¹H NMR analysis, except in the cases of ethyl phenylacetate and phenyl propionate, where the aromatic ring was used as the standard. The reaction mixture was stirred at the enolization temperature for 2 h and then transferred into a centrifuge vial using a doubleended needle (18 gauge). Centrifugation resulted in the separation of the enol borinate solution from the precipitated R"₃N·HX. In representative cases, the solid R"₃N·HX has been collected, washed, dried, and weighed. Essentially quantitative yields were obtained. The enol borinate solution was then transferred into an NMR tube using a double-ended needle. The ¹H NMR analysis gave the extent of enolization, and the ¹¹B NMR (borinate region, usually broad, around 50-56 ppm) also confirmed the formation of enol borinates. The ¹H NMR data of the olefinic protons of the various ester enolates were reported in our earlier paper.10

General Procedure for the Aldolization (at 0 °C) of the Enolates, Generated with Chx_2BBr/Et_3N , with PhCHO. To a solution of enolate in CCl₄ generated from 5.00 mmol of the ester using Chx_2BBr/Et_3N as described above was added PhCHO (5.00 mmol) dropwise at 0 °C, and the reaction mixture was stirred for 2-3 h. Then 10 mL of methanol was added to dissolve the precipitated Et_3N ·HBr. To this homogeneous mixture at 0 °C was added 1.70 mL of H_2O_2 (30%) dropwise. The resulting mixture was stirred at 25 °C for 3-4 h. The solvent and methanol were then removed by a water aspirator (15-20 mm), and the reaction mixture was extracted with ether, washed with water, and then dried over anhyd Na₂SO₄. The solvent was removed, and the products were analyzed as such by ${}^1\!H\,NMR$ to determine the syn/anti ratio.

General Procedure for the Aldolization (at 0 °C) of the Enolates, Generated with Chx2BI/R"3N, with PhCHO. To a solution of enolate in CCl₄ generated from 5.00 mmol of the ester using Chx₂BI/R"₃N as described above was added PhCHO (5.00 mmol) dropwise at 0 °C, and the reaction mixture was stirred for 2-3 h. Then 10 mL of methanol was added to dissolve the precipitated R"₃N·HI. To this homogeneous mixture at 0 °C was added 2.50 mL of H_2O_2 (30%) dropwise. A pink color was observed due to the formation of iodine. [Oxidation of the reaction mixture containing the aldol borinates produced from the Chx₂BI requires excess H₂O₂ (2.50 mL in place of 1.70 mL used for Chx₂BBr). The excess hydrogen peroxide is necessary because the iodide, present as R"₃N·HI, also gets oxidized to iodine]. The resulting mixture was stirred at 25 °C for 3-4 h. The solvent and methanol were then removed by a water aspirator (15-20 mm), and the reaction mixture was extracted with ether. The dark-colored ether solution containing iodine was washed with dilute sodium thiosulfate solution and then with water. The colorless ether solution was dried over anhyd Na₂SO₄, the solvent was evaporated, and the products were analyzed as such by ¹H NMR to determine the syn/anti ratio.

General Procedure for the Aldolization (at -78 °C) of the Enolates, Generated with Chx2BI/R"2N, with PhCHO. To a solution of enolate in hexane generated from 5.00 mmol of the ester using Chx₂BI/R"₃N as described above was added PhCHO (5.00 mmol) dropwise at -78 °C. The reaction mixture was stirred at this temperature for 2-3 h and was allowed to warm slowly to room temperature overnight. Then 10 mL of methanol was added at 0 °C to dissolve the precipitated R"₃N·HI. To this homogeneous mixture at 0 °C was added 2.50 mL of H₂O₂ (30%) dropwise. The resulting mixture was stirred at 25 °C for 3-4 h. The solvent and methanol were then removed by a water aspirator (15-20 mm), and the reaction mixture was extracted with ether. The dark-colored ether solution was washed with dilute sodium thiosulfate solution and then with water. The colorless ether solution was dried over anhyd Na₂SO₄, the solvent was evaporated. and the products were analyzed as such by ¹H NMR to determine the syn/anti ratio.
