#### Abstract

The 1,3-dipolar cycloaddition reactions of benzonitrile oxide with 5 -substituted adamantane-2thiones (2-X) and 2-methyleneadamantanes (3-X) produced two geometrically isomeric $\Delta^{2}-1,4,2-$ oxathiazolines (5-Xs) and two $\Delta^{2}$-isoxazolines (6-Xs), respectively. The substituent was varied from fluoro, chloro, bromo, to phenyl. X-ray single-crystal analysis confirmed the configuration of (Z)-5-F. The product formation bias resulting from the favored attack of nitrile oxide on the zu-face is discussed in terms of transition-state hyperconjugation and frontier molecular orbital theory.

1,3-Dipolar cycloadditions offer a convenient one-step route for the construction of a variety of complex fivemembered heterocycles that are synthetically useful compounds. ${ }^{1}$ Nitrile oxide cycloadditions to terminal alkenes proceeded regioselectively to give 5-substituted $\Delta^{2}$-isoxazolines as single products. ${ }^{1 b}$ The cycloaddition of nitrones and nitrile oxides to thiones leading to $\Delta^{2}-$ 1,4,2-oxathiazolidines and $\Delta^{2}$-1,4,2-oxathiazolines, respectively, have also drawn much attention recently. ${ }^{2}$ Because of their extremely high reactivity toward 1,3dipoles, thiones have been called superdipol arophiles by Huisgen. ${ }^{2 a, b}$

5-Substituted adamantan-2-ones 1-X and their derivatives have proven to be useful probes in research aimed at understanding the electronic factors in face selection. ${ }^{3}$ Studies by le Noble et al. ${ }^{3 a}$ of a variety of reactions indicate that the reagent prefers to attack the face that is antiperiplanar to the more electron-rich vicinal bonds (zu and en face preference in $\mathbf{1}$ when $\mathbf{X}$ equals an electronwithdrawing and electron-donating group, respectively). Their results have been reconciled with Cieplak's transi-tion-state hyperconjugation model. ${ }^{4}$

1-X, $\mathrm{Y}=\mathrm{O}, \mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$ and Ph $\mathbf{2}-\mathrm{X}, \mathrm{Y}=\mathrm{S}, \mathrm{X}=\mathrm{F}, \mathrm{Cl}$ and Br 3-X, $\mathrm{Y}=\mathrm{CH}_{2}, \mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$ and Ph

TheDiels-Alder reaction of 2,3-dimethylbuta-1,3-diene with 5-fluoroadamantane-2-thione (2-F) has been re-

[^0]ported to follow Cieplak's prediction. ${ }^{5}$ When frontier molecular orbital (FMO) theory is applied to this DielsAlder reaction, the diene functions as the donor, and the reaction is controlled by the HOMO (diene)-LUMO (dienophile) interaction. In other words, this is a normal Diels-Alder-type reaction. ${ }^{1 \mathrm{a}, 2 \mathrm{~d}, 6}$ On the other hand, 1,3dipolar cycloadditions of benzonitrile oxide with thiones 2, or terminal alkenes 3, are controlled mainly by the LUMO (dipole)-HOMO (dipolarophile) interaction (an inverse electron-demand type of reaction). Thus, 1,3dipolar cycloaddition reactions to $\mathbf{2}$ and $\mathbf{3}$ provide an important test of the transition-state hyperconjugation model because Cieplak's model stresses that, regardless of the type of reaction (nucleophilic, electrophilic, radical addition, etc.), the newly developing $\sigma^{*}$ orbital should attract electron density with the same directional preference provided the transition states are electron deficient. ${ }^{3 a, 4 c}$ We report here our study of the 1,3-dipolar cycloaddition reactions of benzonitrile oxide with 5-substituted adamantane-2-thiones ( $\mathbf{2}-\mathbf{X}$ ) and 2-methyleneadamantanes (3-X). We find that the favored approach is indeed syn as predicted, in all instances.

## Results and Discussion

The reaction of thione 2-F with benzonitrile oxide generated in situ from benzohydroximoyl chloride (4) and

${ }^{\text {a }}$ Calculated values are in parentheses. ${ }^{\text {b }}$ M easured with a Varian Unity 300 NMR spectrometer operated at 75.4 MHz and reported in $\delta$ units, $\mathrm{CDCl}_{3}(\delta 77.00)$. J is in Hz . In the parent compound $\mathbf{5 - H}$, the sulfur is understood to be syn to $\mathrm{C}_{8}$ and $\mathrm{C}_{10}$.

Scheme 1

triethylamine in methylene chloride occurs smoothly at room temperature to give a 69:31 (GC ratio) mixture of E - and Z - adducts 5-F in 82\% yield after chromatography (Scheme 1). Both adducts are stable to the reaction conditions, and they are characterized as 5-fluoro-3'-phenyladamantane-2-spiro-5'-( $\Delta^{2}-1^{\prime}, 4^{\prime}, 2^{\prime}$-oxathiazolines) on the basis of their mass and NMR spectroscopy. ${ }^{7}$ In all instances examined ( $\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$ ), the major isomer was (E)-5-X, which results from syn attack of the nitrile oxide on 2-X (see Scheme 1). The configurational assignment of the epimers 5-X was based on the relative shielding power of oxygen vs sulfur directly "above" the flanking methylene groups. The shielding effect of an oxygen atom on these CH bonds in a series of spirocyanooxetanes ${ }^{8}$ was found to be $1.59 \pm 0.17$ ppm when the 1-X substituent was fluoro, chloro, bromo, or phenyl. On

[^2]the other hand, a sulfur atom was found to have a deshielding effect of 0.6 ppm in 5-fluorospiro[adaman-tane-2,2'-thiocyclohex-4'-ene]. Thus, C-4 and C-9 (identified by their ${ }^{19} \mathrm{~F}$ coupling), which are syn to the oxygen in the parent compound $\mathbf{5 - H}$, are determined to be shielded vs C-8 and C-10 by a margin of $\geq 2.2 \mathrm{ppm}$. Moreover, application of the ${ }^{13} \mathrm{C}$ NMR additivity scheme ${ }^{9}$ to the oxathiazolines furthermore led to carbon resonances correctly predicted to be within $\pm 0.4 \mathrm{ppm}$ if the major product is assumed to have the E-configuration, whereas deviations of several ppm are found when the opposite assumption is used (Table 1). Finally, the configuration of (Z)-5-F was established independently by means of an X-ray structural determination (see Figure 1). ${ }^{7}$

The reaction of benzonitrile oxide with 5 -substituted methyleneadamantanes 3-X was sluggish at room temperature but was accelerated by refluxing in THF for 24 h to give two isoxazolines 6-Xs in 72-88\% i solated yield (see Scheme 2). Again, these products were proven to bestableunder the reaction conditions; i.e, both products are formed in kinetically controlled processes. In all instances examined (where $\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}$, and Ph ), the major isomer ( $\sim 60: 40$ ratio as determined by both GC and ${ }^{1} \mathrm{H}$ NMR integration) has the Z configuration. It should be noted that the major product (Z)-6-X is still derived from syn attack of the nitrile oxide on 3-X. Strong NOE of the 4'-methylene hydrogens and the flanking pair at C-8 and C-10, but not at C-4 and C-9, confirmed the configuration of the major isomer to be (Z)-6-X. No traces of the regioisomers 7-X or $\mathbf{8 - X}$ were detected in the reactions of $\mathbf{2 - X}$ or $\mathbf{3 - X}$ with benzonitrile oxide, which is consistent with a previous observation of thione 2-H. ${ }^{2 d}$ Thus, the 1,3-dipolar cycloaddition reactions of adamantanethiones 2-X and methyleneadaman-

Figure 1. ORTEP drawing of oxathiazoline Z-5-F.

## Scheme 2

tanes 3-X with benzonitrile oxide are regiospecific. This is probably due to the steric interaction between the phenyl group and the bulky adamantyl group of $\mathbf{2}$ or $\mathbf{3}$ in the transition state.

7-X

An attempt to react nitrile oxide with adamantanone 1-H was unsuccessful even at high temperature and with a long reaction time. Kinetic studies ${ }^{2 a, b}$ of 1,3 -dipolar additions of nitrones to thiones revealed that the weakness of the $\mathrm{C}=\mathrm{S} \pi$ bond was not responsible for the high reaction rates; instead, the low HOMO-LUMO energy gap of the $\mathrm{C}=\mathrm{S} \pi$ bond was suggested to be the decisive factor. AM 1 calculations ${ }^{10}$ of the HOMO -LUMO energy of 1-3 reveal that all of the 1,3-dipolar reactions described here are LUMO (dipole)-HOMO (dipolarophile) controlled reactions, and the rates diminish in the order

[^4]$\mathrm{k}(\mathrm{C}=\mathrm{S})>\mathrm{k}\left(\mathrm{C}=\mathrm{CH}_{2}\right) \gg \mathrm{k}(\mathrm{C}=\mathrm{O})$. The 1,3-dipolar cycloaddition reaction of thione 2-F with benzonitrile oxide was also carried out in solvents with increasing polarity; they were varied from n-hexane ( $\mathrm{E}_{\mathrm{T}}=30.9$ ) to methanol ( $E_{T}=55.5$ ) to water ( $E_{T}=63$ ). In all (14) solvents studied ( $E_{T}=30.9-63$ ), the face selectivity was hardly affected; i.e, they all fall in the range of $64 \pm 4 \%$ in favor of (E)-5-F. The results argue against the involvement of zwitterionic intermediates in the reaction pathways and favor a concerted mechanism for the 1,3-dipolar cycloaddition reaction.

The present study provides strong support for the Cieplak transition-state hyperconjugation model: while the dipolarophiles 1-3 behave as electron donors in an inverse electron-demand-type 1,3-dipolar addition, the dienophiles 2 and 3 behave as electron acceptors in a normal Diels-Alder reaction. Nevertheless, both the diene (in a Diels-Alder reaction) and the dipole (in a 1,3dipolar cycloaddition) approach the trigonal carbon from the same direction antiparallel to the most electron-rich bonds. Although the involvement of electrostatic effects in face-selectivity is not excluded, claims to that effect have relied mainly on calculations. ${ }^{3 b, c}$ Ab initio and semiempirical calculations of the transition states for 1,3dipolar cycloaddition reactions of 5 -substituted adaman-tane-2-thiones and 2-methyleneadamantanes are now in progress and will be reported in due course. ${ }^{10}$ We are presently studying the electronic effect of para-substituted phenylnitrile oxides in 1,3-dipolar cycloaddition reactions.

## Experimental Section

General Procedure for the Synthesis of 5-Substituted 3'-Phenyladamantane-2-spiro-5'-( $\mathbf{1}^{\prime}, 4^{\prime}, 2^{\prime}$-oxathiazolines) 5-X. All 5-substituted $3^{\prime}$-phenyladamantane-2-spiro-$5^{\prime}$-( $1^{\prime}, 4^{\prime}, 2^{\prime}$-oxathiazolines) were prepared from the corresponding adamantane-2-thiones $\mathbf{2 - X}$ with a standard procedure ${ }^{2 d}$ described below for the fluoro derivative $(\mathbf{X}=\mathrm{F})$. Triethylamine $0.124 \mathrm{~g}(1.22 \mathrm{mmol})$ was added gradually at $0^{\circ} \mathrm{C}$ to a stirred solution of $\mathbf{2 - F}(0.15 \mathrm{~g}, 0.82 \mathrm{mmol})$ and benzohydroximoyl chloride ( $0.19 \mathrm{~g}, 1.22 \mathrm{mmol}$ ) in 10 mL of dry dichloromethane. After being stirred for 3 h at rt , the mixture was poured into 15 mL of water. Following removal of the organic solvent, the solid residue was purified on a silica gel column by elution with n-hexane/dichloromethane gradient to give two isomeric adducts (E)- and (Z)-5-F. The isolated yields based on converted starting materials are as fol lows: 5-F 82\%, 5-CI $78 \%$, and $5-\mathrm{Br} 75 \%$. For all ${ }^{13} \mathrm{C}$ NMR spectra data, see Table 1 ; all ${ }^{1} \mathrm{H}$ NMR spectra were measured at 300 MHz in $\mathrm{CDCl}_{3}$.

${ }^{\text {a }}$ Calculated values are in parentheses. ${ }^{\mathrm{b}}$ Measured by means of a Bruker DRX-300 NMR spectrometer operating at 75.4 MHz and reported in $\delta$ units, $\mathrm{CDCl}_{3}(\delta 77.00)$. J is in Hz . In the parent compound $\mathbf{6 - H}$, the oxygen is understood to be syn to $\mathrm{C}_{4}$ and $\mathrm{C}_{9}$.
(E) $\mathbf{~ - 5 - B r}$ : colorless solid; $\mathrm{mp} 181-182{ }^{\circ} \mathrm{C}$; $\delta_{\mathrm{H}} 1.8-2.0(\mathrm{~m}, 4$ H), 2.12 (bs, 1 H), 2.15-2.30 (m, 2 H), 2.38 (bs, 2 H), 2.58 (bs, $2 \mathrm{H}), 2.85-3.00(\mathrm{~m}, 2 \mathrm{H}), 7.3-7.5(\mathrm{~m}, 3 \mathrm{H}), 7.60-7.75(\mathrm{~m}, 2$ H); MS (EI, m/z) 365 ( $\mathrm{M}^{+}+2,53$ ), 363 ( ${ }^{+}$, 51 ), 246 ( $\mathrm{M}^{+}+2$ - PhCNO, 22), 244 (M ${ }^{+}$- PhCNO, 21), 165 (40), 135 (100), 91 (28), 79 (36); HRMS calcd for $\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{ONS}^{79} \mathrm{Br} 363.0293$, found 363.0291. Anal. Calcd for $\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{ONSBr}: \mathrm{C}, 56.05 ; \mathrm{H}$, 4.98; N, 3.85. Found: C, $56.02 ; \mathrm{H}, 4.85 ; \mathrm{N}, 3.87$.
(Z)-5-Br: colorless solid; mp 158-158.5 ${ }^{\circ} \mathrm{C}$; $\delta_{H} 1.65-1.75$ $(\mathrm{m}, 2 \mathrm{H}), 2.10(\mathrm{bs}, 1 \mathrm{H}), 2.3-2.6(\mathrm{~m}, 10 \mathrm{H}), 7.35-7.50(\mathrm{~m}, 3$ H), 7.65-7.70 (m, 2 H); MS (EI, m/z) 365 ( ${ }^{+}+2,27$ ), 363 $\left(M^{+}, 26\right), 246\left(M^{+}+2-\operatorname{PhCNO}, 9\right), 244\left(M^{+}-\right.$PhCNO, 9), 165 (17), 135 (100), 91 (13), 79 (18); HRMS calcd for $\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{ONS}^{79} \mathrm{Br} 363.0293$, found 363.0297.

General Procedure for the Synthesis of 5-Substituted 3'-Phenyl-4'-hydrospiro[adamantane-2:5'- $\Delta^{\mathbf{2}}$-i soxazolines] 6-X. (E)- and (Z)-6-X were synthesized by the use of a procedure similar to that of Zwanenburg et al. ${ }^{12}$ An excess of triethylamine ( 1.5 mol equiv) was added to a well-stirred solution of the methyleneadamantanes 3-X ( 100 mg ) and benzohydroximoyl chloride ( 1.5 mol equiv) in anhydrous THF $(10 \mathrm{~mL}$ ). The mixture was stirred at reflux for 24 h , diluted with dichloromethane, washed with water, and dried with $\mathrm{MgSO}_{4}$. After filtration and sol vent evaporation, the residue was purified on a silica gel column with $n$-hexane/dichloromethane to give two isomeric adducts ( E )- and (Z)-6-X. The isolated yields based on converted starting materials are as follows: 6-F 72\%, 6-CI 81\%, 6-Br 76\%, and 6-Ph 88\%. For all ${ }^{13} \mathrm{C}$ NMR spectra data see Table 2.
(Z)-6-F: colorless solid; mp 91-93 ${ }^{\circ} \mathrm{C}$; $\delta_{H} 1.62-1.85$ ( $\mathrm{m}, 6$ H), 1.94 (bs, 2 H), 2.17 (bs, 3 H), 2.45-2.60 (m, 2 H ), 3.17 (s, $2 \mathrm{H}), 7.35-7.55(\mathrm{~m}, 3 \mathrm{H}), 7.55-7.72$ (m, 2 H ); MS (EI, m/z) 285 ( $\mathrm{M}^{+}, 100$ ), 268 (65), 117 ( $\mathrm{M}^{+}-\mathrm{C}_{10} \mathrm{H}_{13} \mathrm{OF}, 31$ ), 91 (20), 77 (40); HRMS calcd for $\mathrm{C}_{18} \mathrm{H}_{20}$ ONF 285.1530, found 285.1529.

X-ray Structure Analysis of (Z)-5-F. A col orless prism crystal of $\mathrm{C}_{17} \mathrm{H}_{18} \mathrm{ONSF}$ was crystallized from $30 \%$ methylene chloride in hexanes. Its structure was determined by means of single-crystal X-ray analysis on a Rigaku AFC6S diffractometer with graphite-monochromated MoK $\alpha(\lambda=0.71069 \AA$ ) radiation at $296 \pm 1 \mathrm{~K}$, with an $\omega$ - $2 \theta$ type scan at $16^{\circ} / \mathrm{min}$ (in
$\omega)$. The crystals are C-centered monoclinic, with space group $C 2 / c$ (15) and unit cell dimensions $a=19.454$ (4) $\AA \AA, b=6.635(5)$ $\AA, \mathrm{C}=24.956(4) \AA, \beta=111.30(2)^{\circ}, \mathrm{V}=3001(1) \AA^{3}, \mathrm{Z}=8, \rho_{\text {calcd }}$ $=1.343 \mathrm{~g} \mathrm{~cm}^{-3}$, crystal size $(\mathrm{mm}) 0.33 \times 0.41 \times 0.46, \mu(\mathrm{MoK} \alpha)$ $=2.24 \mathrm{~cm}^{-1}, \mathrm{~F}(000)=1280.00,2554$ reflections, 2467 unique reflections, 1403 with I > $3.00 \sigma(\mathrm{I})$ and with 190 variable parameters. The non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included but not refined. The model was finally refined by the full-matrix least-squares methods with weight $\omega=1 /\left[\sigma^{2}\left(\mathrm{~F}_{0}\right)\right]$ to final R values of 0.048 and Rw $=0.037$ (for details, see the Supporting Information). ${ }^{13}$

Acknowledgment. We thank Professor T.-J . Lu for valuable suggestions. This work was supported at NCTU by the National Science Council of the Republic of China (Grant NSC-86-2113-M-002-004).

[^2]:    (7) All compounds mentioned in this paper have been completely characterized; see the Experimental Section. The final structural assignment of oxathiazolines was not straightforward. We were initially misled by the X-ray crystal structure of (Z)-5-Br, which crystallized from a 95:5 mixture of (E)-:(Z)-5-Br (due to poor separation). F ortunately, (Z)-5-F can be separated in pure form by means of column chromatography, and this finally revealed the fact that only the Z-form of oxathiazol ine produced single crystals.
