Grignard reagents were added to 2,2-disubstituted 1,3-oxazolidines and enolizable ketimines prepared from hydroxyacetone and phenylglycinol derivatives, with high to excellent diastereoselectivity, to yield 2,2-disubstituted 1,2-amino alcohol derivatives. Lewis acids had considerable influence on the yield and diastereoselectivity of the addition. This method was applied to the first asymmetric synthesis of the 5-HT reuptake inhibitor Cericlamine.

Although the asymmetric synthesis of amines by addition of organometallic reagents to aldimines and 2-monosubstituted 1,3 -oxazolidines has gained much interest in recent years, ${ }^{1}$ the corresponding reactions with ketimines and 2,2-disubstituted 1,3-oxazol idines remain largely unexplored. This is due to their poorer reactivity toward nucleophilic addition and their propensity to enolize on addition of Grignard reagents. ${ }^{2}$ Hua et al. observed that addition of allylmagnesium bromide to N -sulfinylketimines, which have one potential site for enolization, occurred in 47-98\% yields, but more basic Grignard reagents gave only enolization. ${ }^{3}$ We recently showed ${ }^{4}$ that a broad variety of Grignard reagents could be added in a highly diastereoselective manner to (2heteroaryl)alkylimines with phenylglycinol derivatives as chiral auxiliaries, ${ }^{5}$ the key feature being chelate formation of $\mathrm{MgBr}_{2}$ with the imine nitrogen and the heteroatom of the arene. The chelate activated the imine toward nucleophilic attack and "locked" it into the (E) configuration. After demonstrating the first example of an asymmetric addition of a Grignard reagent to a phenyl-glydinol-derived ketimine, we set out to broaden the scope of the methodology. We report here the unprecedented

addition of Grignard reagents to imines and oxazolidines prepared from hydroxyacetone and phenylglycinol derivatives. In this work, we demonstrate that the chelating substituent on the imine can be extended to include not only aromatic heterocycles but also an aliphatic $\mathrm{CH}_{2} \mathrm{OR}$ group. These substrates have two potential sites for enol ization; therefore, the addition of Grignard reagents to them represents a significant synthetic challenge.

In this study, we have focused on two types of substrates, the oxazolidine $\mathbf{3}$ and the O-TBDMS-protected imine 4. The oxazolidine $\mathbf{3}$ was prepared from (S)phenylglycinol (1) and methoxyacetone (2) by stirring with $\mathrm{MgSO}_{4}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. ${ }^{6}$ The imine 4 was prepared from (S)-O-TBDMS-phenylglycinol (TBDMS-1) and 2 with $\mathrm{MgSO}_{4}$ in benzene (Scheme 1). The configuration of the double bond in $\mathbf{4}$ and the configuration at $\mathrm{C}-2$ of $\mathbf{3}$ were determined by NOESY experiments in $\mathrm{CD}_{2} \mathrm{Cl}_{2}$.
With the starting materials in hand, we investigated the feasibility of the addition of Grignard reagents. The reactions were carried out in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ instead of the more commonly used THF to increase the coordination of Lewis acids to the substrates. ${ }^{4}$ We were gratified to find that Grignard reagents could indeed be added with high selectivity. We optimized the addition of Grignard reagents to $\mathbf{3}$ and $\mathbf{4}$ using benzylmagnesium halides by
(6) It is interesting to note that oxazolidine $\mathbf{3}$ does not exist as a mixture of the open-chain hydroxyimine and the cyclized oxazol idines, as was observed in our earlier work with the corresponding pyridylsubstituted compounds.

varying the Lewis acids and the halide (Table 1, entries $1-8^{7,8}$ ). Selectivity was highest with $\mathrm{MgBr}_{2}$ and BnMgBr (entries 4 and 8 ). Addition of BnMgBr to the oxazolidine 3 afforded the amine 5 a in $38 \%$ yield with a $99.5 \%$ de. The yield could be improved by the addition of BnM gBr to the O-TBDMS-protected imine 4. In this case, an $87 \%$ yield of amine product was realized with a $98.8 \%$ de.

This method can be extended to a variety of Grignard reagents. For example, under the optimized conditions, allylmagnesium bromide was added to $\mathbf{3}$ and $\mathbf{4}$ in $80 \%$ and $73 \%$ yield, respectively (entries 9 and 10). Even phenylmagnesium bromide could be added to 4 (entry 11, $50 \%$ yield), despite the considerably higher basicity of this Grignard reagent and the fact that the substrate has two sites for enolization. ${ }^{9}$ In all of the above cases, the de was $\geq 95 \%$. The addition of allenylmagnesium bromide (entry 12) to 3 deserves special comment. It proceeded with $98 \%$ de and a ratio of homopropargylamine 5 e:allenylamine 8 of $\geq 99: 1$ (Scheme 3). To the best of our knowledge, this
(7) Other Lewis acids such as $\mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}, \mathrm{Cul}_{1} \mathrm{BF}_{3} \cdot \mathrm{OEt}_{2}, \mathrm{CeCl}_{3}$, $\mathrm{Yb}(\mathrm{OTf})_{3}, \mathrm{ZnI}_{2}$, and TMSOTf gave inferior results.
(8) We observed that the yields for the addition of BnMgCl in the presence of $\mathrm{MgBr}_{2}$ to imine 4 increased from $53 \%$ and $66 \%$ to $71 \%$ with 3, 4, and 5 equiv of this Grignard reagent, respectively. The selectivity dropped slightly ( $98.7 \%, 98.5 \%, 98.4 \%$ ee, respectively). With oxazolidine 3 and BnMgCl , the yields did not change; however, the selectivity increased ( $83 \%$ and $92 \%$ ee with 3 and 5 equiv, respectively).
(9) We also tried to add ethylmagnesium bromide (as an example for very basic alkyl Grignard reagents) but obtained only poor yields of the desired addition product.

## Scheme 3

is the first highly diastereo- and chemoselective addition of this Grignard reagent to a 1,3-oxazol idine.
The auxiliary was efficiently removed from 5 by $\mathrm{Pb}(\mathrm{OAc})_{4}$ oxidation ${ }^{10}$ to give the 2,2 -disubstituted $1,2-$ amino alcohol derivatives 6. ${ }^{11}$ This reaction requires an unprotected 1,2-amino alcohol moiety, so the compounds TBDMS-5 had to be desilylated. Both acidic and TBAF/ THF deprotection worked in good yield. We found that the desilylation of TBDMS-5 and also the hydrolysis of the intermediate benzaldimine generated from 5 by Pb ( OAC$)_{4}$ could be performed very conveniently by using disposable syringe barrel columns containing a bonded silica support functionalized with ethylbenzenesulfonic acid (SCX), designed for solid-phase extraction. ${ }^{12}$ To our knowledge, these are the first examples of performing synthetic reactions on these columns. Additionally, from both TBDMS-5a and 5a, the auxiliary could be removed by transfer hydrogenation $\left(\mathrm{NH}_{4} \mathrm{HCO}_{2}, 10 \% \mathrm{Pd} / \mathrm{C}, \mathrm{MeOH}\right.$, reflux). ${ }^{13}$ The methyl ether of $\mathbf{6 a}$ and $\mathbf{6} \mathbf{c}$ was cleaved with $\mathrm{BBr}_{3}$ in good yield to give the 1,2-amino alcohols 7a and 7c (Scheme 2).

Both the oxazol idine $\mathbf{3}$ and the imine $\mathbf{4}$ gave predominantly the same diastereomer of the addition product. On the basis of the sign of optical rotation of the known amino alcohols 7a, ${ }^{14} \mathbf{7 c},{ }^{15}$ and $\mathbf{1 0 , 1 4}$ the (S) configuration of the auxiliary leads to the (S) configuration at the newly formed stereocenter. A possible transition structure is

[^1]

Figure 1. Possible transition structure.

## Scheme 4. Synthesis of (S)-Cericlamine [(S)-10]

shown in Figure 1. We postulate that the stereochemistry can be explained by $\mathrm{A}^{1,3}$ strain, which favors the conformation shown. The phenyl group blocks the reface, and the delivery of the nucleophile occurs from the less hindered si face. ${ }^{16}$ The $\mathrm{MgBr}_{2}$ seems to activate the imine through complexation. ${ }^{17}$ In addition, the methoxyl oxygen could also participate in coordination with magnesium. ${ }^{18}$ This transition structure is analogous to the one we previously reported. ${ }^{4}$

To demonstrate the utility of this methodology, we have synthesized the serotonin reuptake inhibitor Cericlamine (10) ${ }^{19}$ which is in clinical trials as an antidepressant. ${ }^{20}$ The patented synthesis of enantiopure $\mathbf{1 0}$ starts from the corresponding amino acid that has been resolved by crystallization with tyrosine hydrazide. ${ }^{21}$ An enzymatic resolution of the amino acid amide has also been published. ${ }^{14}$

The key step is the addition of 3,4-dichlorobenzylmagnesium halides to imine 4 (see Table 1, entries 13 and 14). Both 3,4-dichlorobenzylmagnesium halides gave high selectivities ( $89 \%$ and $95 \%$ de). The bromide was more selective than the chloride and also gave a higher yield

[^2]( $67 \%$ vs $59 \%$ ), as was observed with the simple BnMgCl and BnMgBr . ${ }^{22}$
Scheme 4 shows our final synthesis. After addition of 3,4-dichlorobenzylmagnesium bromide to ketimine 4, the phenylglycinol auxiliary was desilylated and removed by oxidative cleavage with $\mathrm{Pb}(\mathrm{OAc})_{4}(73 \%$ for desilylation and removal of auxiliary). Dimethylation of $\mathbf{6 d}$ with formic acid/formaldehyde gave the amine 9 in high yield (89\%). Cleavage of the methyl ether with $\mathrm{BBr}_{3}$ (67\%) yielded (S)-Cericlamine (10).

In summary, we have developed an unprecedented, asymmetric synthesis of 2,2-disubstituted 1,2-amino alcohols ${ }^{23}$ via a highly diastereoselective addition of Grignard reagents to ketimines and 2,2-disubstituted 1,2oxazolidines. We applied this to the first asymmetric synthesis of the 5-HT reuptake inhibitor Cericlamine. In the course of that work, we used solid-phase extraction SCX columns for cleaving TBDMS ethers and hydrolysis of benzaldimines.

General Procedures. Proton NMR spectra were recorded at 270 or 400 MHz in $\mathrm{CDCl}_{3}$ using TMS ( $\delta 0.00$ ) or $\mathrm{CHCl}_{3}(\delta$ 7.26) as the internal standard. ${ }^{13} \mathrm{C}$ NMR spectra were recorded at 100.6 MHz in $\mathrm{CDCl}_{3}$ using $\mathrm{CDCl}_{3}(\delta 77.00)$ as the internal standard. Multiplicities were determined by the DEPT sequence and are given as follows: $(+) \mathrm{CH}$ or $\mathrm{CH}_{3},(-) \mathrm{CH}_{2}$, ( $\mathrm{C}_{\text {quat }}$ ) C. Commercially available chemicals were used as received. Column chromatography was carried out on silica gel 60 (E. Merck, 230-400 or 60-230 mesh). Solid-phase extraction SCX columns were obtained from Varian Sample Preparation Products.

    (17) In a related case, Corey et al. recently observed the superiority of $\mathrm{Mgl}_{2}$ over $\mathrm{MgBr}_{2}$ in the addition of a silyl enol ether to an $\alpha$-aminoaldehyde in terms of yield and reactivity. This was explained by the more facile dissociation of the iodide: Corey, E. J.; Weidong, L.; Reichard, G. A. J. Am. Chem. Soc. 1998, 120, 2330-2336.

[^3]:    (22) The addition of 3,4-dichlorobenzylmagnesium bromide to N -Me-3 gave an excellent yield ( $82 \%$ ) but poor selectivity ( $38 \% \mathrm{de}$ ).
    (23) We al so prepared the compounds corresponding to 3 and $\mathbf{4}$ with a methylthio or dimethylamino substituent in place of the methoxy group, aiming at 1,2-aminothiols and 1,2-diamines, respectively. However, only poor yields were obtained. This may be explained in the methylthio case by the enhanced acidity of the adjacent methylene protons, leading to deprotonation instead of addition.
