Received March 12, 1999

A cyclohexane ring usually prefers the chair (**1**) over the twist-boat (TB, **2**) conformation when present in unconstrained saturated hydrocarbons.<sup>1,2</sup> Bulky substituents (e.g., *tert*-butyl groups) can modify the chair/TB energy gap, and in some substitution patterns they may even render the TB the preferred conformation by preferentially destabilizing the chair form.<sup>1–4</sup> A computational study predicted that four isopropyls or just two isopropyls and two methyls attached to a cyclohexyl ring in a *cis,trans,trans*-1,2,3,4 or *cis,syn,cis*-1,2,4,5 pattern are sufficient for rendering the TB the preferred conformation.<sup>4</sup> This change in the normal conformational preferences is due to the selective destabilization of the chair conformation. A system with the first substitution pattern (*cis,trans,trans*-1,2,3,4-tetracyclohexylcyclohexane) was shown by X-ray crystallography to adopt a TB conformation.<sup>5</sup> In this note we demonstrate experimentally that a system with the *cis,syn,cis*-1,2,4,5 pattern prefers the TB conformation.

1,2,4,5-Tetracyclohexylcyclohexane (**3**) exists in seven stereoisomeric forms (three *meso* forms and two enantiomeric pairs, Scheme 1).<sup>6</sup> Calculations of the TB/chair gaps of 1,2,4,5-tetracyclohexylcyclohexanes were per-

(6) For simplicity, the configurational isomers of **3** will be described by the method commonly used for fused-ring cyclohexanes. The mutual disposition of two vicinal groups will be denoted as "cis" or "trans". If the two substituents at the 1 and 5 positions of the central ring are in a mutual *cis* or *trans* relationship, this will be denoted by the "syn" and "anti" descriptors, respectively.

**Scheme 1**

formed with the MM3(92) program<sup>7</sup> together with the HUNTER conformational search procedure (Table 1).<sup>8</sup> As indicated by the calculations, the *cis,syn,cis* form is predicted to adopt a TB conformation. The unusually large stability of the TB form relative to the chair form (7.1 kcal mol<sup>-1</sup>) is most likely the result of unavoidable 1,3-diaxial interactions in the chair form. These interactions cannot be alleviated by ring inversion, because the process relocates the pair of equatorial substituents into axial positions (Scheme 2). The TB/chair energy gaps are similar to those previously calculated for the corresponding 1,2,4,5-tetraisopropylcyclohexanes.<sup>4</sup> This is reasonable because isopropyl and cyclohexyl groups are nearly isosteric near their attachment point.<sup>9</sup> In all of the configurational isomers of **3** calculated, in the lowest energy conformation the peripheral cyclohexyl rings were found to adopt a chair conformation and to be connected to the central rings through their equatorial positions.

Catalytic hydrogenation of 1,2,4,5-tetraphenylbenzene<sup>10</sup> (**4**) at 250 °C (Pd/C, 660 psi H<sub>2</sub>) afforded the *trans,syn,trans* and *trans,anti,trans* isomers of **3** (mp 221 and 240 °C), which were separated by fractional crystallization. According to the calculations (Table 1), these products correspond to the lowest energy isomers. X-ray crystallography indicated that in both compounds all rings adopt the chair conformation (Figures 1 and 2).<sup>11</sup> In the *trans,syn,trans* form the peripheral rings are all located at equatorial positions of the central ring, whereas in the *trans,anti,trans* form a pair of vicinal cyclohexyl substituents are located at axial and a pair at equatorial positions.

*trans,anti,trans*-**3** displays eight NMR signals in the <sup>13</sup>C NMR spectrum (CDCl<sub>3</sub>, rt). Upon lowering of the temperature of a CD<sub>2</sub>Cl<sub>2</sub> solution, the signals broadened and decoalesced. The barrier measured ( $\Delta G_c^\ddagger = 9.7$  kcal mol<sup>-1</sup> at 194 K) is ascribed to a ring inversion process of the central ring that exchanges the axial with the equatorial substituents (Scheme 3). This barrier is comparable to the barrier of cyclohexane ( $\Delta G^\ddagger = 10.2$ – $10.5$

<sup>a</sup> Lowest energy conformation with all (or most) of the alkyl groups in equatorial positions. <sup>b</sup> Lowest energy conformation with all (or most) of the alkyl groups in axial positions. <sup>c</sup> Lowest calculated twist-boat conformation. Ic, Ψa, and Ψe denote that the substituents are located at isoclinal, pseudoaxial, or pseudo-equatorial positions of the central ring, respectively. <sup>d</sup> Heat of formation of the lowest energy conformation. <sup>e</sup> No chair(ax) conformation was found.

**Figure 1.** Crystal structure of *trans,syn,trans*-3.

kcal mol<sup>-1</sup>),<sup>1,12</sup> indicating that the four cyclohexyl substituents in *trans,anti,trans*-3 do not markedly affect the rigidity of the central ring.

According to heat of formation calculations, the *cis,syn,cis* isomer corresponds to a high energy form. To avoid epimerization of the product, the hydrogenation of 4 was carried out at a relatively low temperature of 85 °C (640 psi H<sub>2</sub>). Fractional crystallization of the product afforded *cis,syn,cis*-3 together with 1,2,4,5-tetracyclohexylbenzene (5). X-ray analysis of a single crystal of *cis,syn,cis*-3<sup>11</sup> corroborates the predictions of the calculations and indicates that the central ring adopts a twist boat conformation of approximately C<sub>2</sub> symmetry (Figure 3) with the peripheral "chair" cyclohexyls located at isoclinal and pseudo-equatorial positions of the central ring. The <sup>3</sup>J coupling constants between the methylene and methine protons of the central ring of the chair and TB forms of *cis,syn,cis*-3 were estimated using the MM3 geometry (for the chair form) and the crystal coordinates

(for the TB form). The <sup>3</sup>J values were calculated by the Karplus equation (using Altona's parameters)<sup>13</sup> assuming that the chair form undergoes fast chair inversion while the TB form undergoes fast enantiomerization on the NMR time scale (Scheme 4). The calculated <sup>3</sup>J values were 9.6 and 1.4 Hz for the chair form and 12.4 and 4.7 Hz for the TB. Analysis of the NMR spectrum of *cis,syn,cis*-3 (CDCl<sub>3</sub>, rt, 600.132 MHz) indicated that these

coupling constants are  $13.0 \pm 0.4$  and  $4.3 \pm 0.4$  Hz, in agreement with the presence of a TB conformation in solution.

In conclusion, we have shown experimentally that four cyclohexyl groups in a *cis,syn,cis*-1,2,4,5 pattern render the TB the lowest energy conformation of the central ring.

### Experimental Section

Pd/C (5% Pd) was purchased from Aldrich. Different batches of the catalyst showed different reactivity. Coupling constants were determined from the active couplings in the cross-peaks of the COSY DQF spectrum.<sup>14</sup>

***trans,syn,trans*- and *trans,anti,trans*-3.** Compound **4**<sup>10</sup> (0.2 g) dissolved in cyclohexane (40 mL) and acetic acid (0.5 mL) was hydrogenated using a Parr pressure reactor (0.21 g Pd/C, 650 psi H<sub>2</sub>, 250 °C, 145 h). After work up, an additional hydrogenation was performed (0.20 g Pd/C, 640 psi H<sub>2</sub>, 230 °C, 40 h), affording a mixture of *trans,syn,trans*-**3** and *trans,anti,trans*-**3** which were separated by fractional crystallization (CHCl<sub>3</sub>/EtOH). The first fraction was *trans,syn,trans*-**3** (35%), and the second fraction afforded the *trans-anti-trans* isomer in 25% yield. *trans,syn,trans*-**3**: mp 240 °C; <sup>13</sup>C NMR (CDCl<sub>3</sub>) δ 44.05 (C1), 37.72 (C1'), 32.03 (C6'), 27.50 (C5'), 27.12 (C3'), 27.06 (C4'), 26.87 (C2), 26.25 (C2') ppm; MS *m/z* 412.4.
