### Introduction

The need for reliable thermochemical data often outstrips the rate at which they can be generated from experiments. This is true even for some simple, fundamental molecules. For example, the thermochemical data for even the simplest of cumulenes, allenes, are scarce.<sup>1</sup> Since the enthalpies of formation have important applications in the studies of chemical reactivity and equilibrium, such values are very useful. We have recently used the combination of high level ab initio methods and isodesmic reaction schemes in order to obtain standard enthalpies of formation for haloethenes.<sup>2</sup> In this work we extend our investigations to haloallene derivatives. To obtain accurate enthalpies one needs to employ a computational method that provides sufficiently accurate total electronic energies. The newly introduced G3 method<sup>3</sup> was shown to provide such energies.<sup>4</sup> Also, accurate standard enthalpies for species participating in isodesmic reactions need to be known. As reference enthalpies, we have utilized the established enthalpies for ethene<sup>5</sup> and tetrafluoro-<sup>6,7</sup> and tetrachloroethene.<sup>5</sup> The standard experimental enthalpy for C<sub>2</sub>F<sub>4</sub> is  $-658.56 \pm 2.9$  kJ/mol.<sup>5</sup> However, two recent theoretical studies<sup>6,7</sup> have suggested values of  $-671.5$  and  $-668.6$  kJ/mol, respectively. This implies that the experimental value is most probably incorrect. We have used the mean of the two theoretical results ( $-670.0$  kJ/mol) as C<sub>2</sub>F<sub>4</sub> enthalpy in this work.

### Method of Calculation

The ab initio calculations were performed with Gaussian 98 program<sup>8</sup> which incorporates the G3 method as standard. The choice of "anchor" compounds in isodesmic reactions is important, so we have selected the compounds for which available experimental data are the most accurate and the most recent.<sup>2,5</sup> The reliability of the G3 method has been shown previously to be typically  $\pm 8.2$  kJ/mol. The reason for not considering alternative methods of predicting enthalpies, based on atomization or formation reactions, is that such methods have been shown to be less accurate than suitable isodesmic reactions.<sup>9</sup> The molec-

ular structures of haloallenes had been compared with experiment (where such data are available) and are shown in Table 1.

Table 1 indicates that the structural parameters are well reproduced by our calculations. The molecular structures parameters of the remaining haloallenes do not exhibit any significant trends. They vary within 10 pm/1° ranges and hence are not included in Table 1. It is also interesting that even small deviation of <CCC angle from 180° (allenes are slightly bent along CCC axis) is well reproduced by our calculations.

### Results and Discussion

The results of the calculations are presented in Table 2. Table 2 displays  $\Delta H_f^0$  values for all the compounds studied together with the previous results for fluoroallenes<sup>10</sup> and the isodesmic reaction equations which were used in deducing enthalpies. The accurate enthalpy of propyne was taken from NIST-JANAF tables.<sup>5</sup> The enthalpy of parent allene was then derived from the isomerization reaction between propyne and allene. The enthalpies presented in Table 2 are useful because they enlarge the very small database of accurate thermochemical data on substituted cumulenes.<sup>1</sup> The discrepancies between previous<sup>10</sup> and present  $\Delta H_f^0$  values for fluoroallenes (Table 2) can be attributed to two factors: (1) an improved value for C<sub>2</sub>F<sub>4</sub> enthalpy;<sup>6,7</sup> (2) the different levels of treating correlation energies in previous work<sup>10</sup> (MP2-valence) and current work (G3 method which includes QCISD).

The enthalpies of haloallenes in general become more negative and exothermic (i.e., the compounds become more stable thermodynamically) upon increasing the number of halogen substituents. However, this trend is more evident in fluoroallenes than in chloroallenes (Table 2). Besides enthalpy data themselves, it is interesting to deduce the influence of substituents on allene stability. In Table 3 we have presented a series of isodesmic reactions which permit us to determine relative stabilities of haloallenes vs haloethenes. The allene itself was found to be destabilized by 10.7 kJ mol<sup>-1</sup> vs parent ethene.<sup>1</sup> The data in Table 3 indicate that chlorine and fluorine substitution leads to the destabilization of allene system ( $\Delta H_f > 0$ ). The destabilization increases monotonically with increased halogenation. Fluoroallenes are destabilized more than their chloroallene counterparts by 13–24 kJ mol<sup>-1</sup>. 1,1- and 1,3-Dihalo substitution patterns

<sup>a</sup> Appropriate haloethene isomers were used in isodesmic reactions; the superscripts indicate references.

(isomers) show little difference in stability; the difference falls within uncertainty range of G3 method (N.B. the average uncertainty for the G3 method is  $\pm 8.2$  kJ mol<sup>-1</sup>). This can be expected in view of the nonconjugated nature of allenic  $\pi$ -bonds and is at variance with haloethenes where distinct differences in stability between 1,1- and 1,2-substituted haloethenes were observed.<sup>2</sup>

To gain better insight into these variations of thermodynamic stability we have performed population analysis. The results are presented in Table 4. In fluoroallenes, the increased halogenation leads to the increased negative charge on central carbon while no effect of comparable magnitude appears in chloroallenes. One can tentatively suggest that increasing CC bond polarization plays a part in destabilizing fluoroallenes, but that in

chloroallenes it has little significance. Table 5 describes relative stabilities of 1,1- vs 1,3-haloallene isomers. The results displayed can be compared with relative isomer stabilities of corresponding haloethenes. For the range of compounds studied, 1,1-isomers appear to be more stable than 1,3- with two exceptions. The exceptions are however within the uncertainty limits of the G3 method. The similar effect, i.e., enhanced stability of 1,1- over 1,2-isomers, was observed in haloethenes<sup>2</sup> although there the effect was more pronounced. The enhanced stability of 1,1- over 1,3- isomers can be attributed to the preponderance of LP (lone pair) interactions between halogen lone pair and  $\sigma$  antibonding orbitals along the lines of the same argument as presented earlier.<sup>2</sup> Among two other types of possible interactions, geminal interactions are known to be small,<sup>2</sup> while vicinal interactions in allenes are quenched due to molecular symmetry.
