A new and practical synthetic strategy is developed for the synthesis of six-membered lactambridged dipeptides, 4 -substituted-3-aminopiperidin-2-ones, featuring two key steps: (a) a diastereoselective addition of cuprate to $(E)$ - $\alpha, \beta$-unsaturated ester (3) and (b) racemization-free reductive amination. On the basis of this methodology, conformationally constrained tetrapeptide $N$-acetyl-Ser-Asp-Lys-Pro (AcSDKP) (2) has been successfully synthesized from 3-amino-4-vinylpiperidin-2-one (22).

## Introduction

The design and synthesis of conformationally constrained peptidomimetics is an important approach in searching for the bioactive compounds with improved biological potency, selectivity, and metabolic stability relative to endogenous linear peptides. ${ }^{1-3}$ Among the numerous strategies developed for reducing the conformational mobility, tethering the backbone side chain with the neighboring amide nitrogen into a so-called "Freidinger" lactam ${ }^{4}$ has proven useful for the design of a variety of medicinally relevant enzyme inhibitors, ${ }^{5}$ especially in the case of the peptidase/protease inhibitors. ${ }^{6 a}$

[^0]Therefore, synthesis of novel Freidinger lactams is currently an area of intensive research in the field of peptide and medicinal chemistry, and several types of Freidinger lactams have been synthesized. ${ }^{4-7}$ Although 3 -aminopi-

peridin-2-one is known, to the best of our knowledge a few syntheses have been reported for 1,4-disubstituted3 -aminopiperidin-2-one (1) (Figure 1). ${ }^{61-0,7}$ We have been interested in developing a short asymmetric synthesis of this type of lactam based on the following reasoning. The incorporation of a substituent at the C-4 position would not only introduce an additional point of diversity but also influence the conformation of the molecule by modulating the bulkiness of the substituent as well as the relative stereochemistry between C-3 and C-4. Because the side chains of amino acids often play important roles in bioactivities of the peptide, we deemed it important to develop a convergent synthesis that could allow us to vary systematically the substituents $\left(R, R_{1}, R_{2}\right)$ at the periphery of the piperidin-2-one surrogate.

In this paper, we report a straightforward synthesis of enantiomerically pure ( $3 S, 4 R$ )-3-amino-4-alkyl(aryl)-piperidin-2-ones in detail based on a strategy depicted retrosynthetically in Scheme 1. In a forward sense, lactam 1 was to be produced by a cycloamidation of amino acid $\mathbf{A}$ that in turn could be obtained by a reductive amination of amino aldehyde $\mathbf{B}$ and $\alpha$-amino ester or $\alpha$-amino amide $\mathbf{C}$. Compound $\mathbf{B}$ can be traced back to Garner's aldehyde, whereas $\mathbf{C}$ is commercially available. The design and synthesis of a conformationally constrained analogue of $N$-acetyl-Ser-Asp-Lys-Pro (AcSDKP) (2) based on this chemistry is also to be documented (Figure 1).

## Results and Discussion

Synthesis of 4-Substituted-3-aminopiperidin-2one. Reductive amination of a suitably functionalized amino aldehyde and an amino ester is the key step in our planned synthesis of piperidin-2-one. The prerequisite amino aldehydes $\mathbf{6 a - 6 c}$ were synthesized following literature procedure (Scheme 2). 1,4-Addition of lithium dimethyl or divinyl cuprates to the enoate $\mathbf{3}$ derived from serine in the presence of trimethylsilyl chloride furnished

syn $4 \mathbf{a}$ and $4 \mathbf{c}$, respectively, ${ }^{8}$ in good yields and with excellent diastereofacial selectivities. Curiously, diphenyllithium cuprate failed to react with $\mathbf{3}$ under identical conditions. After much experimentation, it was found that the 1,4 -Michael addition of phenylmagnesium bromide in the presence of $\mathrm{Cu}(\mathrm{I})$, according to Hruby, ${ }^{9}$ occurred smoothly. Under these conditions, the desired syn 4b was obtained as a single diastereomer in 64\% isolated yield. Lithium aluminum hydride reduction of esters $\mathbf{4 a}-\mathbf{4} \mathbf{c}^{10}$ and subsequent Swern oxidation of alcohols $5 \mathbf{5}-\mathbf{5 c}$ gave the corresponding aldehydes $\mathbf{6 a}-\mathbf{6 c}$, respectively.

Reductive amination of aldehyde $\mathbf{6 a}$ with L-phenylalanine methyl ester 7a (sodium triacetoxyborohydride, THF) proceeded smoothly to provide secondary amine 8a in $90 \%$ yield (Scheme 3). After N-protection of $8 \mathbf{a}$ with CbzCl , the resulting carbamate 9 a was subjected to Jones oxidation to afford directly carboxylic acid 10a. Activation of the carboxylic acid as pentafluorophenyl ester 11a followed by tandem N -deprotection/lactamization under catalytic hydrogenolysis conditions provided the desired piperidin-2-one ( $\mathbf{1 2 a})^{7}$ in $79 \%$ yield. Compound $\mathbf{1 2 b}$ was prepared following the same synthetic scheme as described above for 12a, starting from aldehyde $6 \mathbf{b}$ and L-leucine methyl ester 7b (Scheme 3). The stereochemistry of 12a has been confirmed by X-ray analysis.

Having developed the methodology for the synthesis of lactam $12 \mathbf{a}$ and $\mathbf{1 2 b}$, we turned our attention to the synthesis of the 3 -amino-4-vinylpiperidin-2-one system. The presence of the vinyl function at the C-4 position of the piperidin-2-one ring would allow us to introduce a carboxylic acid required for the synthesis of the $N$ AcSDKP analogue (Scheme 6) and other functionalities. To further illustrate the generality of the present meth-

Thus, reductive amination of aldehyde $\mathbf{6 c}$ with L-Lys $(\mathrm{Cbz}) \mathrm{OBn}$ (7c) afforded amine 13a in $85 \%$ yield. was designed wherein the $\beta$-carbon of the aspartic acid and the adjacent amide nitrogen of the lysine were connected via ethylene linkage producing a piperidin-2one unit. It was expected that such a cyclic lactam motif should render the molecule more resistant to in vivo enzymatic degradation because the cyclic scaffold can shelter the cleavable amide bond from degradative peptidases.

From the viewpoint of synthesis, dipeptide $\mathbf{1 6 b}$ is appropriately functionalized for the synthesis of a diverse set of conformationally constrained peptides by elongation at both the N - and the C-terminals. However, for the synthesis of the specifically targeted $N$-AcSDKP analogue (2), a more convergent synthesis is developed featuring a key reductive amination of the aldehyde $\mathbf{6 c}$ with a tert-butyl ester of $\omega$ - $N$-Cbz-Lys-Pro (17) that is synthesized from $\omega$ - $N$-Cbz- $N$-Fmoc-Lys ${ }^{19}$ and proline tertbutyl ester. Reductive amination between aldehyde $\mathbf{6 c}$ and dipeptide amine $\mathbf{1 7}$ took place without event to produce compound 18 in $74 \%$ yield. Protection of the

[^5]secondary amine ( FmocCl , THF- $\mathrm{H}_{2} \mathrm{O}, \mathrm{Na}_{2} \mathrm{CO}_{3}$ ) followed by Jones oxidation of the $N$-Boc oxazolidine afforded acid 20. Removal of the $N$-Fmoc function ( $\mathrm{Et}_{2} \mathrm{NH}$, THF) followed by lactamization (TBTU, HOBt, ${ }^{i} \mathrm{Pr}_{2} \mathrm{NEt}$ ) furnished piperidin-2-one (21) in $71 \%$ yield. Selective removal of the $N$-Boc function without affecting the tertbutyl ester was realized under mild acidic conditions (3 $\mathrm{M} \mathrm{HCl}-\mathrm{EtOAc}$ at $-50^{\circ} \mathrm{C}$ for 2 h then at $0^{\circ} \mathrm{C}$ for 1 h ). Coupling of the resulting amine 22 with Boc-L-Ser(OBn)OH afforded tetrapeptide 23 that was then converted to the $N$-Ac derivative by a sequence of selective N-deprotection and acetylation under classic conditions (51\%). Oxidative cleavage of the vinyl group under Sharpless conditions ${ }^{20}$ afforded the desired compound 26a together with the benzoate 26 b ( $1: 1$ ratio) resulting from the concomitant oxidation of the benzyl ether group. The $O$-benzyl protected serine was selected with the hope to achieve, at the final stage of the synthesis, the simultaneous deprotection of the $O-\mathrm{Bn}$ and N -Cbz functions. Unforturnately, this seemingly trivial transformation was found to be more difficult than one may expect. Indeed, our attempts to cleave the $O$-benzyl ether and the $N$-Cbz protective group under various hydrogenolysis conditions varying the catalysts $\left[\mathrm{Pd} / \mathrm{C}, \mathrm{Pd}(\mathrm{OH})_{2}\right]$ and the solvents ( MeOH , EtOAC, room temperature, 1 atm ) gave a mixture of $O$-benzyl ether product and hydroxyamine. Unfortunately, when we forced the hydrogenolysis condition under pressure ( 60 psi ) and forced transfer hydrogenolysis (cyclohexene/EtOH, $\mathrm{PdCl}_{2}$, reflux and $\mathrm{Zn} / \mathrm{HCO}_{2^{-}}$ $\mathrm{NH}_{4}, \mathrm{MeOH}$, rt), it resulted in complete decomposition of the starting material and failed to produce the desired tetrapeptide 2.

To surmount this problem, the synthesis was started again using $O$-tert-butyl protected serine as the coupling partner (Scheme 6). Thus, coupling of tripeptide amine 22, obtained by deprotection of the terminal primary amine of 21, with $N$-Fmoc-L-Ser (OtBu) (27) under standard conditions (EDC, HOBt) afforded tetrapeptide 28 in $85 \%$ yield. Removal of the Fmoc protective group with diethylamine and subsequent acetylation gave acetyl tetrapeptide 30. Oxidation of double bonds according to Sharpless proceeded smoothly in this case to provide the corresponding carboxylic acid 31 in $75 \%$ yield. Simultaneous removal of the tert-butyl ester and the $O$-tert-butyl ether from 31 under acidic conditions (TFA) followed by hydrogenolysis of the crude diacid afforded tetrapeptide 2 in $54 \%$ yield. Tetrapeptide 2 was thus prepared starting from $\alpha, \beta$-unsaturated ester 3 in 13 steps with $4 \%$ overall yield. The biological studies for tetrapeptide 2 are under investigation and the results will be reported in due course.

## Conclusion

In summary, we developed a concise synthesis of 4 -substituted-3-aminopiperidin-2-one that can be considered as a conformationally constrained dipeptide. The synthesis is highly convergent and features a key reductive amination of the $\alpha$-amino ester and the functionalized aldehyde, derived from serine. A variety of substituents can be installed adjacent to the ring nitrogen by

[^6]varying both the aldehyde and the $\alpha$-amino ester or the $\alpha$-amino amide inputs in the reductive amination step. On the basis of this synthetic strategy, synthesis of an $N$-AcSDKP analogue is documented.

General Procedure 1. Preparation of Aldehydes 6ac. To a solution of oxalyl chloride ( 9.34 mmol ) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( 15 mL ) at $-78^{\circ} \mathrm{C}$ was added dropwise a solution of DMSO (20.33 $\mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(15 \mathrm{~mL})$. The resulting reaction mixture was further stirred at the same temperature for another 15 min before a solution of alcohols $5 \mathbf{a}-\mathbf{c}(5.49 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(15$ mL ) was added dropwise over 15 min while the temperature was kept at $-78^{\circ} \mathrm{C}$. Stirring was continued for an additional 15 min followed by addition of $\mathrm{Et}_{3} \mathrm{~N}(38.4 \mathrm{mmol})$, and the reaction mixture was allowed to warm to room temperature. Water ( 50 mL ) was then added, and the aqueous layer was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The organic layers were washed with $1 \mathrm{M} \mathrm{HCl}, \mathrm{H}_{2} \mathrm{O}$, saturated $\mathrm{NaHCO}_{3}$, and brine, successively, and then dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$. The filtered solution was concentrated under reduced pressure to give aldehydes $\mathbf{6 a - c}$, which were used directly for the next reaction without further purification.
