Rare-earth silylamides, $\operatorname{Ln}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]_{3}(\mathrm{Ln}=\mathrm{Y}, \mathrm{La}, \mathrm{Sm})$, catalyzed regio- and stereoselective dimerization of terminal alkynes in the presence of amine additives to give conjugated enynes in high yields. The additives played a crucial role to depress the oligomerization and to control the regio- and stereochemistry of the dimerization. Thus, the selectivity for ( $Z$ )-head-to-head enynes was increased in the order of tertiary < secondary < primary amine additives. On the other hand, the reversed order was observed for the formation of head-to-tail dimers. When $\alpha, \omega$-diynes were subjected to the dimerization, very novel cyclic bisenyne compounds were given through doubledimerization in satisfactory yields. In addition, an application of the system allowed subsequent hydrophosphination of the enynes generated in situ with diphenylphosphine, giving rise to 1-phosphinyl-1,3-dienes as the sole products in excellent yields after oxidative workup.

## Introduction

Enyne compounds have been known as important building blocks in organic synthesis ${ }^{1}$ and as key units found in a variety of biologically active compounds. ${ }^{2}$ Of their synthetic methods, the dimerization of terminal alkynes could be a very practical and straightforward approach in an atom-economical manner. For this reason, the reaction has been frequently investigated with use of many metal catalysts, which include group 4 and 8-10 metals, ${ }^{3}$ lanthanides, ${ }^{4}$ actinides, ${ }^{5}$ and others. ${ }^{6}$ However, exclusive formation of one enyne out of three possible isomers: $(Z),(E)$-head-to-head and head-to-tail dimers, could be achieved with only a few catalysts. ${ }^{3 c, f, h, 4 b}$ Moreover, effective catalysts for the dimerization of both aromatic and aliphatic alkynes have been rarely reported. ${ }^{6}$ With respect to lanthanide catalysts, only metallocene and half-metallocene complexes have been used

[^0]for the alkyne dimerization. ${ }^{4}$ Preparation of these complexes needs multisteps despite their good catalyst activities. ${ }^{7}$ In contrast, readily available rare-earth silylamides, $\mathrm{Ln}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]_{3}$, would be potentially attractive catalysts,

because they are found to be effective for hydroamination, ${ }^{8}$ hydrosilylation, ${ }^{9}$ and hydrophosphination ${ }^{10}$ of unsaturated bonds as well as the lanthanocenes. In fact, we recently reported that regio- and stereoselective dimerization of various functional terminal alkynes was induced by the amide complexes. ${ }^{11}$ In this paper, we describe more detailed features of the reaction, particularly, the scope and limitation, and double-dimerization of $\alpha, \omega$-diynes leading to cyclic bisenynes. As an application of the present method, one-pot synthesis of 1-phos-phinyl-1,3-butadiene derivatives through the dimerization and subsequent hydrophosphination using the single catalyst is also documented herein.

## Results and Discussion

When phenylacetylene (1a) was treated with $\mathrm{Y}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]_{3}(5 \mathrm{~mol} \%)$ in toluene at $100{ }^{\circ} \mathrm{C}$ for 17 h , $97 \%$ of $\mathbf{1 a}$ was consumed, but head-to-tail dimer, 2,4-diphenylbut-1-en-3-yne (2a), and head-to-head dimer, ( $Z$ )and ( $E$ )-1,4-diphenylbut-1-en-3-yne ( $\mathbf{3 a}$ ) and ( $\mathbf{4 a}$ ) were obtained only in $5 \%, 11 \%$, and $2 \%$ yields, respectively. The low mass balance was attributed to the formation of oligomers, which were not fully characterized. The selectivities of $\mathbf{2 a - 4 a}$ hardly changed even by decrease of the conversion 1a at lower temperature ( $60{ }^{\circ} \mathrm{C}$ ). The reaction became sluggish in THF, wherein $\mathbf{2 a}$ was given in $17 \%$ yield as a single product with $50 \%$ conversion after 46 h at refluxing temperature. Then, we investigated the effect of various additives in order to improve the product yield and selectivity. An addition of $\mathrm{Ph}_{3} \mathrm{P}$, $\mathrm{Ph}_{2} \mathrm{PH}$, and $\mathrm{Ph}_{2} \mathrm{O}$ showed no significant effect and PhOH ceased the reaction. Fortunately, amine additives exhibited a different effect to produce the dimer $\mathbf{3 a}$ with much improved selectivity. These results are summarized in Table 1. Tertiary aliphatic amines such as $\mathrm{Et}_{3} \mathrm{~N}$ showed no effect for inhibition of the oligomerization (entry 2), but $\mathrm{Ph}_{3} \mathrm{~N}$ slightly increased the yield of $\mathbf{3 a}$ to $37 \%$ (entry 3 ). With secondary amine, $\mathrm{Ph}_{2} \mathrm{NH}$, the enyne $\mathbf{3 a}$ was obtained in similar yield, but head-to-tail enyne 2a was also provided in $22 \%$ yield (entry 4). Surprisingly, good regio- and stereospecific dimerization was caused by $\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{NH}_{2}$ in high yield (entry 5). Moreover, better yield was attained by the addition of $\mathrm{PhNH}_{2}$ (entry 6). These results indicate that the selectivity of $\mathbf{3 a}$ is increased in the order of tertiary < secondary < primary-amine, and higher reactivity is observed by aromatic amines rather than aliphatic ones. We next tested the effect of substituted aromatic primary amines. Bulky amines such as $2,6-{ }^{i} \mathrm{Pr}_{2} \mathrm{C}_{6} \mathrm{H}_{3} \mathrm{NH}_{2}$ predominantly caused the alkyne to oligomerize (entry 7), whereas both electron-donating and -withdrawing groups substituted at the para position

${ }^{a}$ The additive was pretreated with the catalyst for 1 h at room temperature. ${ }^{b}$ Determined by GC.
gave exclusively the enyne $\mathbf{3 a}$ in more than $90 \%$ yield, except for $4-\mathrm{MeC}_{6} \mathrm{H}_{4} \mathrm{NH}_{2}$ (entries 8-11). Comparing the metal size of the lanthanide catalysts, smaller Y is superior to larger Sm and La (entries 11-13).

In the reaction of oct-1-yne ( $\mathbf{1 h}$ ) without an additive, the dimerization proceeded mainly to afford the 2 -hexyl-dec-1-en-3-yne ( $\mathbf{2 h}$ ) and ( $Z$ )-hexadec-7-en-9-yne (3h) in $62 \%$ and $5 \%$ yield, respectively. When the screening of various amine additives was performed in a similar manner, their effect was found to be very different from that observed in the dimerization of the aromatic alkyne 1a (Table 1, entries 14-23). Addition of $\mathrm{Et}_{3} \mathrm{~N}$ gave a better yield of $\mathbf{2 h}(73 \%)$ than $\mathrm{Ph}_{3} \mathrm{~N}$ (entries 15 and 16). The yield and selectivity decreased with the secondary amines, wherein $\mathrm{Et}_{2} \mathrm{NH}$ gave the lowest product selectivity in the screening (entries 17 and 18). Although the addition of $\mathrm{C}_{5} \mathrm{H}_{11} \mathrm{NH}_{2}$ and $\mathrm{PhNH}_{2}$ resulted in the exclusive formation of $\mathbf{3 h}$ (entries 19 and 20), they seemed to depress the catalyst activity. Thus, it can be concluded that selectivity for the synthesis of the head-to-tail dimer from the aliphatic alkyne $\mathbf{1 h}$ increased in the order of primary < secondary < tertiary-amine additive, and that aliphatic amines were superior to aromatic additives, in sharp contrast to the results in the dimerization of 1a. Other strong organic bases such as DBU (1,8-diazabicyclo-[5.4.0]undec-7-ene) and quinuclidine (1-azabicyclo[2.2.2]octane) exhibited an undesirable effect, resulting in the predominant oligomerization with the former base and

${ }^{a}$ Isolated yield. The value in parentheses indicates GC yield. ${ }^{b} 10 \mathrm{~mol} \%$ of the catalyst and additive were used.
lower yields with the latter (entries 21 and 22). Finally, a bulky tris(trimethylsily)amine, $\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{3}$, gave $\mathbf{2 h}$ and $\mathbf{3 h}$ in $92 \%$ and $5 \%$ yields, respectively (entry 23 ). The smaller metal, i.e., Y, gave better results as in the case of $1 \mathbf{a}$ (entries 23-25).

We next investigated the scope of terminal alkynes under the optimized conditions (Table 2). The reaction of aromatic alkynes $\mathbf{1 b}-\mathbf{e}$ with electron-donating and -withdrawing groups at the para position of the aromatic ring gave the corresponding enynes $\mathbf{3 b}-\mathbf{e}$ in high yields (entries 2-5). However, the presence of an ortho substituent such as 1-ethynyl-2-methylbezene (1f) resulted in lower yield of the product $\mathbf{3 f}(27 \%)$ with retention of the substrate (entry 6). The problem could be overcome by increasing the catalyst loading to give $\mathbf{3 f}$ in $77 \%$ yield (entry 7). The dimerization could not be applied to aromatic alkynes containing acetyl, ester, and dioxolanyl groups at the para position. ${ }^{12}$ In the reaction of aliphatic alkynes using $\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{3}, \mathbf{2 g}$ and $\mathbf{2 h}$ were provided in $92 \%$ and $99 \%$ yield, respectively (entries 8 and 9 ). Substitution of the tertiary amine by a primary amine like amylamine enabled exclusive formation of $(\boldsymbol{Z})$-head-to-head dimer $\mathbf{3 g}$, though in low yield (entry 10).

When the silylamide complex was substituted by lithium hexamethyldisilazane, $\mathrm{LiN}\left(\mathrm{SiMe}_{3}\right)_{2}$, no reactions of the terminal alkynes took place under the identical conditions. The result indicated that the present dimerization is owing to the useful characteristics of the rareearth silylamide. By referring to the work of Teuben ${ }^{4 a}$ and Hou, ${ }^{4 b}$ it is almost certain that the dimerization proceeded through alkyne insertion to the rare-earth alkynide, followed by protonation with another molecule of the alkyne to give the enyne and the alkynide. The present reaction sharply depended on the nature of the amine additives. Although their exact role has not been clear, they would act as proton sources to inhibit the alkyne oligomerization and as ligands to prevent an aggregation of the reaction intermediates. In the latter case, it is likely that a more active species such as
(12) Molander, G. A.; Romero, J. A, C. Chem. Rev. 2002, 102, 21612185

## SCHEME 1

SCHEME 2

monomer and dimer could be generated in situ through coordination or ligand exchange with the silylamide. ${ }^{13}$ Of course, no reaction took place with these additives alone and their excess loading lowered the catalyst activity. ${ }^{14}$ As regards the regioselectivity of the reaction, the alkyne would insert preferentially to the alkynide coordinated by bulky amine through the transition state $\mathbf{A}$ as depicted in Scheme 1. On the other hand, the dimerization with primary amine would proceed via $\mathbf{B}$ to avoid the steric hindrance between substituents of the alkynes. The formation of the ( $Z$ )-isomer of the two head-to-head dimers may be accounted for by the participation of dimeric alkynide species. ${ }^{4 \mathrm{~b}}$

Performing the head-to-tail dimerization of $\alpha, \omega$-diynes potentially enables two distinctive processes, i.e., monoand double-dimerization to afford $(n+3)$ and $(2 n+6)$ membered rings, respectively, as shown in Scheme 2. With respect to the former reaction, Trost has employed the palladium-catalyzed reaction to obtain mono cyclic head-to-tail enynes. ${ }^{15}$ In addition, Hidai has reported the synthesis of cyclic ( $Z$ )-head-to-head enynes from $\alpha, \omega$ diynes catalyzed by ruthenium complexes. ${ }^{16}$ To the best of our knowledge, there is no precedent of a direct synthesis of cyclic bisenynes from $\alpha, \omega$-diynes by the double-dimerization. However, we expected that $\alpha, \omega$ diynes containing a short carbon chain would dimerize intermolecularly at first due to the steric reason, which would be followed by intramolecular dimerization instead of oligomerization, because the resulting two terminal alkyne units would come close together by coordination to the electron-deficient rare-earth metal center.

When 1,7-octadiyne (5a) was treated with the yttrium catalyst and $\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{3}$ in toluene $(0.7 \mathrm{M})$ at $100{ }^{\circ} \mathrm{C}$ for
(13) Evans reported that $\left(\mathrm{C}_{5} \mathrm{Me}_{5}\right)_{2} \mathrm{LnN}\left(\mathrm{SiMe}_{3}\right)_{2}$ did not react with phenylacetylene in toluene even at $100^{\circ} \mathrm{C}$, but the metathesis occurred in THF. Evans, W. J.; Keyer, R. A.; Ziller, J. W. Organometallics 1993, 12, 2618-2633.
(14) When 1a was treated with $\mathrm{PhNH}_{2}(15 \mathrm{~mol} \%)$ and $\mathrm{Y}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]_{3}$ ( $5 \mathrm{~mol} \%$ ), no reaction commenced (see entry 4 in Table 1). The reaction of $\mathbf{1 h}$ using $\mathrm{Et}_{3} \mathrm{~N}(15 \mathrm{~mol} \%)$ and the Y-silylamide ( $5 \mathrm{~mol} \%$ ) decreased the yield of $\mathbf{2} \mathbf{g}$ and $\mathbf{3 g}$ to 21 and $7 \%$ yields, respectively, with $49 \%$ conversion (see entry 15).

TABLE 3. Examples for Double-Dimerization of $\alpha, \omega$-Diynes Leading to Bisenynes

${ }^{a}$ Isolated yield. The ratio was determined by NMR. ${ }^{b} 10 \mathrm{~mol} \%$ of the catalyst and additive were used.

20 h , a mixture of two dimeric products (76:24) was obtained in $71 \%$ total yield, which was inseparable even by HPLC. The mixture showed no signals assignable to carbons and protons of terminal alkynes in the ${ }^{13} \mathrm{C}$ and ${ }^{1} \mathrm{H}$ NMR spectra, but two pairs of four olefinic protons were observed in the region of 5.13-5.18 ppm, instead. Therefore, the two compounds should be double-dimerization products 7a and 8a (Figure 1). Considering their structural symmetry, it is reasonable to assume that four methylene protons A-D situated in linear relation for 7a, and four methylene protons a-d separated in two parts for 8a, would appear independently. Thus, we measured the $\mathrm{H}-\mathrm{H}$ COSY spectra of the mixture to determine their structures (see Supporting Information, Figure S1). The major product exhibited four methylene signals at ca. 1.5 (B), 1.8 (C), 2.2 (D), and 2.4 (A) ppm as expected, wherein three COSY signals of $A-B, B-C$, and $\mathrm{C}-\mathrm{D}$ were clearly found, in addition to those of D-olefinic protons. The minor product also showed three separate signals at ca. 1.6 (c), 1.7 (b), and 2.3 (a) and one obscured signal at 2.2 (d). However, only two COSY signals of $a-b$ and $c-d$ were observed, other than those of d-olefinic protons. On the basis of these results, the structure of the major isomer was determined as $7 \mathbf{a}$ and the minor as 8a.

The present reaction was found to be very sensitive to the reaction conditions, particularly to the concentration of the $\alpha, \omega$-diynes and the length of their methylene chains, because the initial products $\mathbf{6}$ were able to react further both intra- and intermolecularly to yield cyclic bisenynes and oligomers, respectively (Table 3). The reaction of $5 \mathbf{a}$ in 2.0 M solution gave a mixture of the bisenynes 7a and 8a and mono-dimerization product 6a in $30 \%$ and $53 \%$ yields, respectively (entry 2). Mass

${ }^{a}$ Isolated yield based on the phosphine. ${ }^{b}$ Carried out at 100 ${ }^{\circ} \mathrm{C} .{ }^{c}$ The value in parentheses indicates an NMR yield. ${ }^{d} 10 \mathrm{~mol}$ \% of the catalyst and additive were used.
balance of the reaction decreased with increasing concentration to 4.9 M due to the formation of oligomers (entry 1). In contrast, 7a and 8a were isolated in $90 \%$ combined yield at lower concentration ( 0.3 M ) (entry 4). Similarly, 1,8 -nonadiyne ( $\mathbf{5 b}$ ) was converted to the 16 membered cyclic bisenynes $\mathbf{7 b}$ and $\mathbf{8 b}$ in $78 \%$ yield in the dilute solution (entry 5). Interestingly, the ratio of 7 and 8 was always ca. 73:26 irrespective of the concentration and carbon-chain length. The reaction mode was changed in the dimerization of 1,13-tetradecadiyne (5c), which gave 13 -membered monoenyne 9 in $61 \%$ yield exclusively (entry 6).

Last, we investigated one-pot synthesis of 1-phosphi-nyl-1,3-butadienes from two moles of terminal alkyne and one mole of phosphine in order to explore the synthetic utility of the present dimerization. This idea evolved from the fact that the rare-earth amide catalysts did not decompose after completion of the alkyne dimerization in the first step, and that they could catalyze hydrophosphination of the alkyne moiety of the thus-generated enyne in the second step. ${ }^{10 \mathrm{~b}}$ It turned out that the reaction worked successfully (Table 4). Thus, after generation of ( $Z$ )-1,4-diphenylbut-1-en-3-yne (3a) from phenylacetylene (1a) with the yttrium catalyst and 4-chloroaniline under the standard conditions, the mixture was subsequently treated with half-molar amounts of diphenylphosphine in the presence of the HMPA ligand ( $15 \mathrm{~mol} \%$ ) at room temperature and then, oxidized with hydrogen peroxide to give 1-diphenylphosphinyl-1,3-butadiene 10a in $94 \%$ yield (entry 1). Similarly, various phosphinylbutadienes 10 were prepared in high yields via the head-to-head dimers 3, starting from aromatic terminal alkynes. In the reaction of $\mathbf{1 b}$, the hydrophosphination in the second step took place only at elevated temperature probably because the chelate effect of the methoxy substituent would retard the reaction.

All products 10 were obtained as single isomers whose structures were determined unambiguously by X-ray crystallographic analysis of 10c (see the Supporting Information, Figure S 2 ). The $\mathrm{Ph}_{2}(\mathrm{O}) \mathrm{P}$ group was attached to $\mathrm{C}(1)$ to form an $(E)$-double bond between $\mathrm{C}(1)-\mathrm{C}(2)$, in agreement with the previous results, ${ }^{10 \mathrm{~b}}$ whereas the original ( $Z$ )-stereochemistry of $\mathrm{C}(3)-\mathrm{C}(4)$ in $3 \mathbf{c}$ was reversed to $(E)$. The change of the stereochemistry of the $\mathrm{C}(3)-\mathrm{C}(4)$ double bond would be explained as shown in Scheme 3. Initially, some yttrium amide species remained

## SCHEME 3

after the dimerization reacted with $\mathrm{Ph}_{2} \mathrm{PH}$ to yield phosphide complex C. ${ }^{10 \mathrm{~b}}$ syn-Addition of C to the alkyne moiety of $\mathbf{3}$ affords dienyl yttrium ( $Z$ )-D. Because the ( $Z$ )stereochemistry causes severe steric repulsion, ( $Z$ )-D would isomerize to more stable $(E)$-D via an allenic intermediate E. Subsequent protonation with $\mathrm{Ph}_{2} \mathrm{PH}$ affords the product 10 and phosphide C.

## Summary

Regio- and stereoselective dimerization of terminal alkynes to produce conjugated enynes has been achieved using rare-earth silylamide catalysts and amine additives. The yttrium catalyst is superior to larger metals such as Sm and La. The amine additives play a crucial role to control efficiency of the reaction and regiochemistry of the products. Oligomerization of the alkynes predominates or competes with the dimerization in the absence of the additives. As a rule, primary amines tend to produce ( $Z$ )-head-to-head dimers preferentially and, in contrast, tertiary amines bring about the head-to-tail products. Thus, nearly complete formation of ( $Z$ )-head-to-head dimers from aromatic terminal alkynes with aniline derivatives and head-to-tail dimers from aliphatic alkynes with $\mathrm{N}\left(\mathrm{SiMe}_{2}\right)_{3}$ is realized. When this reaction is extended to $\alpha, \omega$-diynes, unprecedented double dimerization takes place to afford cyclic bisenyne compounds, depending on the length of the carbon chain and concentration of the reaction mixture. Moreover, dimerization of aromatic terminal alkynes, followed by hydrophosphination with diphenylphosphine enables highly efficient synthesis of 1-phosphiny-1,3-butadienes in one-pot using single rare-earth catalysts.

## Experimental Section

General Procedure for the Dimerization of Terminal Alkynes Catalyzed by $\mathrm{Y}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]_{3}$ with Amine Additives. According to entry 1 in Table 2, $\mathrm{Y}\left[\mathrm{N}\left(\mathrm{SiMe}_{3}\right)_{2}\right]_{3}(39 \mathrm{mg}$, $0.07 \mathrm{mmol})$ and $4-\mathrm{ClC}_{6} \mathrm{H}_{4} \mathrm{NH}_{2}(8.9 \mathrm{mg}, 0.07 \mathrm{mmol})$ were placed in a $20-\mathrm{mL}$ Schlenk tube and dissolved in toluene ( 1.4 mL ). After the mixture was stirred for 1 h at room temperature, phenylacetylene ( $\mathbf{1 a}$ ) ( $146 \mathrm{mg}, 1.4 \mathrm{mmol}$ ) was added. The Schlenk tube was sealed, and stirring was continued for 17 h at $100{ }^{\circ} \mathrm{C}$. The reaction mixture was cooled, quenched with $\mathrm{H}_{2} \mathrm{O}(2 \mathrm{~mL})$ and saturated $\mathrm{NH}_{4} \mathrm{Cl}$ solution ( 1 mL ), and diluted
with ether ( 2 mL ). GC yield was determined by using methyl benzoate as an internal standard. The aqueous layer was extracted with ether $(30 \mathrm{~mL})$. The combined organic layer was washed with brine ( 30 mL ), dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated in vacuo. The crude mixture gave 129 mg ( $90 \%$ ) of the dimer $\mathbf{3 a}$ by flash column chromatography on silica gel with hexane eluent.

2-Butyloct-1-en-3-yne ( $\mathbf{2}$ g) [CAS Registry No. 5663-865]: isolated in $85 \%$ yield as a yellow liquid; IR (neat) 3094, 2957, 2930, $2224 \mathrm{~cm}^{-1}$; MS m/z 164 (M+ $\mathrm{M}^{+}$), 149 (4), 122 (60), 107 (91), 93 (86), 79 (100); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta 0.91$ ( $3 \mathrm{H}, \mathrm{t}, J=$ $7.3 \mathrm{~Hz}), 0.92(3 \mathrm{H}, \mathrm{t}, J=7.3 \mathrm{~Hz}), 1.25-1.55(8 \mathrm{H}, \mathrm{m}), 2.12(2 \mathrm{H}$, $\mathrm{t}, J=7.4 \mathrm{~Hz}), 2.31(2 \mathrm{H}, \mathrm{t}, J=6.9 \mathrm{~Hz}), 5.12(1 \mathrm{H}, \mathrm{s}), 5.20(1 \mathrm{H}$, $\mathrm{s}) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta$ 10.8, 11.1, 16.2, 19.1, 19.2, 27.5, 28.1, 34.5, 78.2, 87.2, 116.5, 129.6.
