# De Novo Asymmetric Synthesis of Anamarine and Its Analogues 

Dong Gao and George A. O'Doherty*<br>Department of Chemistry, West Virginia University, Morgantown, West Virginia 26506<br>George.ODoherty@mail.wvu.edu

Received August 9, 2005

The enantioselective synthesis of anamarine has been achieved in 21 steps. The route relies on enantio- and regioselective Sharpless dihydroxylation of dienoate ester and zinc borohydride reduction to establish the C-8-C-11 stereochemistry. A diastereoselective Leighton allylation established the desired C-5 stereochemistry. The route has also been used to prepare two diastereoisomers of anamarine in 14 steps.

## Introduction

For the last five years, we have been interested in a class of natural products with a skipped, 1,3-polyol/5,6-dihydro- $2 H$-pyran-2-one structural motif which possess a wide range of biological properties. ${ }^{1,2}$ This interest has met with some degree of success in terms of total synthesis. ${ }^{3}$ As a result of these efforts, we became interested in the synthesis of natural products with a 1,2-polyol/5,6-dihydro- $2 H$-pyran-2-one structural motif. Thus, we targeted the antitumor pyranone natural product anamarine for synthesis (1a, Figure 1).

The 5,6-dihydro- 2 H -pyran-2-one containing natural product, anamarine ( $\mathbf{1 a}$ ), was isolated from the flowers and leaves of a Peruvian hyptis. Other members of this $\alpha, \beta$-unsaturated lactone class of natural products include spicigerolide (2), hyptolide (3), and synrotolide (4) (Figure 1 ), which possess an array of properties ranging from cytotoxicity against human tumor cells to antibacterial and/or antifungal activity. ${ }^{4}$

Numerous synthetic approaches to this class of molecules have been reported. ${ }^{5}$ In contrast to these previous syntheses, which derived their absolute and relative stereochemistry from carbohydrates, ${ }^{5}$ we were interested

[^0]
anamarine (1a)

hyptolide (3)

FIGURE 1. The anamarine-type $\alpha, \beta$-unsaturated lactones.
in preparing several stereoisomers of anamarine via asymmetric catalysis. ${ }^{6}$ Recently, we demonstrated the viability of this approach for the preparation of two epimers of anamarine. ${ }^{5 f}$ Key to this approach was the discovery of an expedient and practical synthesis of C-6substituted galacto-sugars from simple achiral precursors with complete stereocontrol (5-6, Scheme 1). ${ }^{7}$ Herein, we report the full account of this approach and detail the application for the synthesis of anamarine.

## SCHEME 1. Retrosynthetic Analysis of Anamarine and Its Analogues

## Results and Discussion

We envisioned that the lactone rings of anamarine $\mathbf{1 a}$ could be prepared by a ring-closing metathesis reaction ${ }^{8}$ of triene $5 \mathbf{5 a}$ (Scheme 1), which could be obtained from 6a by a reduction, a Leighton allylation, ${ }^{9,10}$ and acylation. Finally, it was envisioned that the C-8 through C-11 tetrol stereochemistry of $\mathbf{6 a}$ could be established by applying two Sharpless dihydroxylations followed by an inversion at C-10. ${ }^{11}$ By simply skipping the inversion at C-10 and performing a diastereo-divergent allylation reaction, two diastereomers of anamarine ( $\mathbf{1 b}$ and $\mathbf{1 c}$ ) should be produced.

In our initial approach to 10-epi-anamarine (1b), we targeted the bis-acetonide $6 \mathbf{b}$ as a key intermediate (Scheme 2). We envisioned preparing $\mathbf{6 b}$ from trienoate 8, which was easily prepared by a Wittig reaction of commercially available 2,4-hexadienal and ylide ( $\mathrm{EtO}_{2^{-}}$ $\mathrm{CCH}=\mathrm{PPh}_{3}$ ). Exposing trienoate 8 to the Sharpless dihydroxylation protocol yielded a diol, which was protected as the acetonide to give dienoate $\mathbf{9}$ in a good yield ( $72 \%$ for two steps) and enantiomeric excess ( $90 \%$ ee). A second Sharpless dihydroxylation on dienoate 9 was preformed using the stereochemically matched ligand system ((DHQD) ${ }_{2}$ PHAL). The desired diol 10b was formed with excellent diastereocontrol; however, to our surprise, it was also formed with a significant amount of the undesired regioisomer 10a. The two regioisomers 10a and 10b were obtained in a 1:1 ratio. To our delight,

## SCHEME 2. Initial Synthesis of Ester 6b

the desired regioisomer $\mathbf{1 0 b}$ was separated by chromatography and protected as bis-acetonide $\mathbf{6 b}$.

Unfortunately, removing the acetonide protecting group had no positive effect on the regioselectivity of the second dihydroxylation. ${ }^{12}$ This loss of regiocontrol is not solely due to the ligand. It also occurred when 9 was dihydroxylated under ligandless conditions (i.e., when 9 was exposed to $\mathrm{OsO}_{4} / \mathrm{NMO}$, four diastereomeric tetrol products were produced).

In a search for better regioselectivity in the synthesis of ester $\mathbf{6 b}$, we investigated the bis-dihydroxylation of the commercially available ethyl sorbate (7) (Scheme 3). Thus, ethyl sorbate (7) was enantioselectively dihydroxylated $\left(1 \mathrm{~mol} \% \mathrm{OsO}_{4}\right.$ and $\left.2 \mathrm{~mol} \%(\mathrm{DHQ})_{2} \mathrm{PHAL}\right)$ and

## SCHEME 3. Improved Synthesis of Ester 6b

(12) In contrast to our results for acetonide 14 and its corresponding diol, Smith observed excellent regiocontrol ( $>10: 1$ ) in the dihydroxylation of related substituted epoxytrienoates. Similarly, they observed no significant loss of stereocontrol in the mismatched (slower) case. See: Smith, A. B., III; Walsh, S. P.; Frohn, M.; Duffey, M. O. Org. Lett. 2005, 7, 139-142.
the corresponding diol was protected to give acetonide 11 in good yield ( $74 \%$ for two steps) and enantiomeric excess ( $80 \%$ ee). ${ }^{7 a}$ Once again, the $\alpha, \beta$-unsaturated ester 11 was dihydroxylated in a diastereomerically matched sense, ${ }^{5 f}$ with the pseudoenantiomeric reagent ( $2 \mathrm{~mol} \%$ $\mathrm{OsO}_{4}, 4 \mathrm{~mol} \%(\mathrm{DHQD})_{2} \mathrm{PHAL}, 3$ equiv of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}, 3$ equiv of $\mathrm{K}_{2} \mathrm{CO}_{3}$, and 1 equiv of $\mathrm{MeSO}_{2} \mathrm{NH}_{2}$ ). This diastereoselectively matched reaction gave a diol (diastereomeric ratio $=10: 1$ ), which was protected as the acetonide 12 ( $66 \%$ yield for two steps). It is worth noting that as a result of performing the second dihydroxylation (11-12) with a diastereomerically matched chiral reagent system, the bis-acetonide 12 was isolated with greater enantiomeric purity (>96\% ee) than the initial acetonide 11. ${ }^{13}$

Having established the relative and absolute stereochemistry of 10 -epi-anamarine $\mathbf{1 b}$ in 12, we looked to convert ester 12 into $\alpha, \beta$-unsaturated ester $\mathbf{6 b}$. This was accomplished by an exhaustive reduction of ester 12 with DIBALH (3.0 equiv, 93\%) followed by a Swern oxidation, providing aldehyde 13 ( $82 \%$ yield, two steps). Finally, a Wittig reaction of aldehyde 13 with $\mathrm{EtO}_{2} \mathrm{CCH}=\mathrm{PPh}_{3}$ provided the desired ester $\mathbf{6 b}$ in $81 \%$ yield.

To approach the correct diastereomer 6a, we returned to the asymmetric synthesis of the diastereomeric aldehyde 21 from the ethyl sorbate 7 (Scheme 4). As we previously described, ethyl sorbate was enantioselectively dihydroxylated and the corresponding diol was converted into cyclic carbonate 14 in good yield ( $74 \%$ for two steps) and enantiomeric excess ( $80 \%$ ee). ${ }^{7 \mathrm{~b}}$ Treatment of carbonate 14 with a catalytic amount of palladium ( 0 ) ( 0.5 mol $\% / 2 \mathrm{~mol} \% \mathrm{PPh}_{3}$ ) and $p$-methoxyphenol as the nucleophile provided the protected alcohol 15 in $91 \%$ yield. The other hydroxyl group was protected as silyl ether to give 16. Enoate 16 was then dihydroxylated in a diastereomerically matched sense, ${ }^{7 \mathrm{~b}}$ with the matched reagent ( 2 mol $\% \mathrm{OsO}_{4}, 4 \mathrm{~mol} \%(\mathrm{DHQD})_{2} \mathrm{PHAL}, 3$ equiv of $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}$, 3 equiv of $\mathrm{K}_{2} \mathrm{CO}_{3}$, and 1 equiv of $\mathrm{MeSO}_{2} \mathrm{NH}_{2}$ ) to diastereoselectively give a diol which was protected as the acetonide 17 ( $66 \%$ yield for two steps). As a result of performing the second dihydroxylation (16-17) with a diastereomerically matched chiral reagent system, the acetonide 17 was isolated with greater enantiomeric purity ( $>96 \%$ ee) than the initial diol.

We next looked into the inversion of the stereochemistry at C-10. Because our initial efforts to accomplish this with Mitsunobu chemistry met with little success, we turned to an oxidation/reduction strategy. Selective deprotection of the $p$-methoxyphenoxy ether (CAN) followed by Dess-Martin periodinane oxidation provided ketone 18. Cleavage of the silyl ether with benzoic acid and TBAF gave alcohol 19. Sodium borohydride reduction of the TBS-protected ketone 18 gave two diastereomers in a $4: 1$ ratio. Unfortunately, the major diastereomer was the undesired syn-diol. So, we turned to a chelationcontrolled reduction. Treating the deprotected ketone 19 with zinc borohydride gave the anti-diol as the major product in a 5:1 ratio. The anti-diol was then treated with 2,2-dimethoxypropane and CSA, providing bis-acetonide

[^2]
## SCHEME 4. Synthesis of Epimeric Ester 6a

20 in good yield. With the relative and absolute tetrol stereochemistry established in 20, we next looked to homologate ester 20 into enaote 6a. Exhaustive reduction of ester 20 with DIBALH ( 3.0 equiv, $93 \%$ ) followed by a Swern oxidation (88\%) provided aldehyde 21 in $82 \%$ yield for two steps. A Wittig reaction of aldehyde 21 with corresponding ylide $\left(\mathrm{EtO}_{2} \mathrm{CCH}=\mathrm{PPh}_{3}\right)$ provided a $1: 1$ ratio of $Z / E$ isomers of acetonide $\mathbf{6 a}, \mathbf{c}$ in $86 \%$ yield, which were inseparable. ${ }^{14}$

In an attempt to shorten the route to ester 6a, we tried oxidizing the C-10 alcohol before the asymmetric dihy-

## SCHEME 5. Alternative Approach to Ester 6a

[^3]
## SCHEME 6. Installation of the Pyranone Ring in 26a,b

droxylation (Scheme 5). The oxidation of the allylic alcohol in $\mathbf{2 2}$ with TEMPO was accomplished after initial TBS protection of the C-5 alcohol ( $67 \%$ for two steps). To our surprise, the dihydroxylation reaction only gave a $3: 1$ mixture of diastereomers 23a and 23b, respectively (75\% yield for the two isomers). Although this is a shorter sequence, because of the difficulty in separating the diastereomers 23a and 23b, we found it easier to prepare material by the previous route (Scheme 4).

The problem associated with inseparable double-bond isomers 6a and 6c was solved when the esters were converted into aldehydes 24a and 24c. This was accomplished by a reduction/oxidation sequence. Exposure of a THF solution of two isomers, 6a,c, with 3.0 equiv of DIBALH at $-78{ }^{\circ} \mathrm{C}$ provided allylic alcohol (Scheme 6), which without purification was oxidized with $\mathrm{MnO}_{2}$ to give aldehyde 24a,c in good yield ( $82 \%$ for two steps). At the aldehyde stage, the two isomers were separable. More importantly, the undesired isomer 24c was converted back to the desired isomer upon treatment with 10 mol $\%$ TFA in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ( $80 \%$ of a $10: 1$ ratio). By an identical sequence, the $\mathrm{C}-10$ diastereomer $\mathbf{6 b}$ was converted into aldehyde 24b (82\%).

With the two desired aldehydes 24a,b in hand, we turned to the installation of the pyranone portion of the natural product. We envisioned that a diastereoselective allylation of aldehydes $\mathbf{2 4 a , b}$ could be achieved by using either enantiomer of the easily prepared Leighton allyl silane reagents ( $S, S$ )-27 ${ }^{9}$ (Schemes 6 and 7). This was accomplished by simply adding a solution of either aldehyde 24a or 24b to the allylsilane reagent ( $S, S$ )-27 ( 0.2 M in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ ) at $-10^{\circ} \mathrm{C}$ to give allylic alcohols 25a,b in $91 \%$ and $92 \%$ yields with near complete stereocontrol

## SCHEME 7. Installation of the Pyranone Ring in 26c

( $>99 \%$ ee and dr). ${ }^{15,16}$ The allylic alcohols 24a,b were coupled with DCC (4 equiv) and acrylic acid (4 equiv) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, providing trienes 5a and 5b in $83 \%$ and $78 \%$ yields, respectively. We next turned to the use of a ringclosing metathesis reaction to form the lactone ring. This was easily implemented by exposure of a refluxing $\mathrm{CH}_{2}{ }^{-}$ $\mathrm{Cl}_{2}$ solution of the trienes $\mathbf{5 a}, \mathbf{b}$ to the Grubbs catalyst 28 ( $10 \mathrm{~mol} \%$ ), resulting in a clean cyclization to dihydropyrans 26a and 26b in $77 \%$ and $82 \%$ yields, respectively.

The other diastereomeric series can be made by simply switching to the enantiomeric Leighton reagent $((R, R)$ -ent-27, Scheme 7). Thus, exposing aldehyde 24b to the enantiomeric Leighton reagent, ( $R, R$ )-ent-27, yielded a diastereomerically pure allylic alcohol $\mathbf{2 5 c}$ (95\%), which, as before, could be converted into lactone $26 \mathbf{c}$ via an acylation and metathesis sequence ( $61 \%$ yield for the two steps).

To complete the synthesis of anamarine 1a and its two epimers, 1b,c (Scheme 8), all that remains is to deprotect the acetonides and acylate the resulting tetrols. We found that this was most easily accomplished by heating the

[^4]three diastereomeric lactones $\mathbf{2 6 a}-\mathbf{c}$ in $10 \%$ aqueous hydrochloric acid in THF for 10 min at $65^{\circ} \mathrm{C}$. Because of the high polarity, the crude tetrol products were directly acylated by removal of solvent and addition of pyridine, acetic anhydride, and DMAP. This two-step/one-pot protocol provided excellent yields of anamarine 1a (85\% for two steps) and its two diastereomers 1b,c (86\% and $82 \%$ yields).

## Conclusion

In summary, an enantioselective synthesis of anamarine has been developed. This highly enantio- and diastereocontrolled route illustrates the utility of an iterative Sharpless Asymmetric Dihydroxylation reaction and a Leighton allylation sequence. Although this approach to anamarine is rather long ( 21 steps), this route provides diastereomers of anamarine in significantly less steps (14 steps). This approach provided anamarine in $8 \%$ overall yield and provided its two diastereomers in $14 \%$ and $13 \%$ yields. It is also worth noting that these new routes start from achiral sources. Further application of this approach to other members of this class of natural products is ongoing.

## Experimental Section ${ }^{17}$

(E,4S,5S)-Ethyl-4-(4-methoxyphenoxy)-5-(tert-butyldi-methylsiloxy)-2-enoate (16). To a solution of alcohol 15 (13.2 $\mathrm{g}, 47.1 \mathrm{mmol}$ ) in 10 mL of dry DMF was added imidazole ( 9.6 $\mathrm{g}, 141.3 \mathrm{mmol})$ and $\mathrm{TBSCl}(10.2 \mathrm{~g}, 68.3 \mathrm{mmol})$ at room temperature. The reaction was stirred for 2 h , and then the reaction mixture was directly purified by flash chromatography on silica gel (7:3 ( $\mathrm{v} / \mathrm{v}$ ) hexane/EtOAc) to provide compound 16 ( $18.5 \mathrm{~g}, 100 \%$ yield) as a colorless oil: $R_{f}=0.60(7: 3(\mathrm{v} / \mathrm{v})$ hexane/EtOAc); IR (neat, $\mathrm{cm}^{-1}$ ) 2930, 1720; [ $\left.\alpha\right]^{25} \mathrm{D}-15^{\circ}$ (c 1, $\left.\mathrm{CHCl}_{3}\right) ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 270 \mathrm{MHz}\right) \delta 7.02(\mathrm{dd}, J=4.5,15.8$ $\mathrm{Hz}, 1 \mathrm{H}), 6.78$ (s, 2H), 6.77 (s, 2H), 6.06 (dd, $J=1.5,15.8 \mathrm{~Hz}$, 1 H ), 4.58 (ddd, $J=1.5,4.2,4.2 \mathrm{~Hz}, 1 \mathrm{H}), 4.14(\mathrm{dq}, J=1.0,7.2$ $\mathrm{Hz}, 1 \mathrm{H}), 4.07(\mathrm{q}, J=7.2 \mathrm{~Hz}, 1 \mathrm{H}), 4.05(\mathrm{q}, J=7.2 \mathrm{~Hz}, 1 \mathrm{H})$, $3.69(\mathrm{~s}, 3 \mathrm{H}), 1.23(\mathrm{t}, J=7.2 \mathrm{~Hz}, 3 \mathrm{H}), 1.16(\mathrm{~d}, J=6.2 \mathrm{~Hz}, 3 \mathrm{H})$, 0.87 (s, 9H), 0.07 ( $\mathrm{s}, 3 \mathrm{H}$ ), $0.04(\mathrm{~s}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $\mathrm{CDCl}_{3}, 62.5$ $\mathrm{MHz}) \delta 165.7,154.0,151.7,144.0,123.0,116.5,116.5,114.3$, $114.3,81.3,69.5,60.1,55.2,25.6,25.6,25.6,18.8,17.8,14.0$, $-4.91,-4.95$; HRMS (CI) calcd for $\left[\mathrm{C}_{21} \mathrm{H}_{34} \mathrm{O}_{5} \mathrm{Si}+\mathrm{Na}\right]^{+}$ 417.2068, found 417.2086.
(2S,3S,4S,5S)-Ethyl-4-(4-methoxyphenoxy)-5-(tert-bu-tyldimethylsiloxy)-2,3-dihydroxyhexanoate (A). ${ }^{18}$ Into a 250 mL round-bottom flask was added 50 mL of $t-\mathrm{BuOH}, 50$ mL of water, $\mathrm{K}_{3} \mathrm{Fe}(\mathrm{CN})_{6}(19.7 \mathrm{~g}, 60.0 \mathrm{mmol}), \mathrm{K}_{2} \mathrm{CO}_{3}(8.3 \mathrm{~g}, 60.0$ mmol ), $\mathrm{MeSO}_{2} \mathrm{NH}_{2}(1.9 \mathrm{~g}, 20.0 \mathrm{mmol})$, (DHQD) ${ }_{2}$ PHAL ( 321 mg , $0.4 \mathrm{mmol}, 2 \mathrm{~mol} \%)$, and $\mathrm{OsO}_{4}(51 \mathrm{mg}, 0.2 \mathrm{mmol}, 1 \mathrm{~mol} \%)$. The mixture was stirred at room temperature for about 15 min and then cooled to $0{ }^{\circ} \mathrm{C}$. To this solution was added a solution of $\mathbf{1 6}(7.8 \mathrm{~g}, 20.0 \mathrm{mmol})$ in 5 mL of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and the reaction was stirred vigorously at $0{ }^{\circ} \mathrm{C}$ for 20 h . The reaction was quenched with solid sodium sulfite at room temperature. Then the mixture was filtered through a pad of Celite/florisil and eluted with $(2 \times 80 \mathrm{~mL})$ ethyl acetate. The combined organic layers were washed with 2 N KOH and brine and dried over anhydrous sodium sulfate. The solvent was removed in vacuo. The crude product was purified by flash chromatography on silica gel (7:3 (v/v) hexane/EtOAc) yielding compound $\mathbf{A}$ (7.3 $\mathrm{g}, 85 \%$ yield) as a viscous oil: $R_{f}=0.39(7: 3(\mathrm{v} / \mathrm{v})$ hexane/

[^2]:    (13) Although the conversion of $\mathbf{1 0 - 1 1}$ is a diastereoselective matched reaction with the ( DHQD$)_{2} \mathrm{PHAL} / \mathrm{OsO}_{4}$ reagent system, the reaction occurs at a significantly slower rate and, as such, higher catalyst loading is required ( $2 \% \mathrm{OsO}_{4}$ and $4 \%$ (DHQD) $)_{2} \mathrm{PHAL}$, see Scheme 3).

[^3]:    (14) The lack of $E / Z$ selectivity (1:1) in the Wittig reaction with aldehyde 21 is quite surprising when compared to the nearly identical Wittig reaction with the C-5 diastereomeric aldehyde 13 , where the $E$ isomer $\mathbf{6 b}$ was formed with almost 10:1 selectivity. Although we cannot offer an explanation for this result, we did find this result to be reproducible.

[^4]:    (15) Previous approaches to this class of pyranone natural products used the Brown AllylBIpc $2_{2}$ reagent for this transformation; see ref 5ad. We have found that the Leighton reagent works equally well in terms of stereochemical outcome and allows for a significantly simpler product isolation procedure; see ref 9 .
    (16) All enantioexcesses were determined by examining the ${ }^{1} \mathrm{H}$ NMR of the corresponding Mosher esters. See: Sullivan, G. R.; Dale, J. A.; Mosher, H. S. J. Org. Chem. 1973, 38, 2143.

[^5]:    (17) Experimental procedures for the synthesis of anamarine are presented in the Experimental Section. Complete experimental procedures and spectral data for all compounds are presented in the Supporting Information.
    (18) These structures are not shown in the text.
