# Novel Diastereoselective Synthesis of Bicyclic $\boldsymbol{\beta}$-Lactams through <br> Radical Cyclization and Their Reduction toward 2-(1-Alkoxy-2-hydroxyethyl)piperidines and 2-(1-Alkoxy-2-hydroxyethyl)azepanes 

Erika Leemans, ${ }^{\dagger}$ Matthias D'hooghe, ${ }^{\dagger}$ Yves Dejaegher, ${ }^{\dagger}$ Karl W. Törnroos, ${ }^{\dagger}$ and Norbert De Kimpe*, ${ }^{\text {t }}$<br>Department of Organic Chemistry, Faculty of Bioscience Engineering, Ghent University, Coupure Links 653, B-9000 Ghent, Belgium, and Department of Chemistry, University of Bergen, Allégt. 41, 5007 Bergen, Norway<br>norbert.dekimpe@UGent.be

Received October 22, 2007

1-Allyl- and 1-(3-phenylallyl)-substituted 4-(2-bromo-1,1-dimethylethyl)azetidin-2-ones were transformed into 3-substituted 7-alkoxy-5,5-dimethyl-1-azabicyclo[4.2.0]octane-8-ones through radical cyclization by means of $n$-tributyltin hydride and AIBN in toluene with excellent diastereocontrol ( $\geq 99 \%$ ). The radical cyclization of 4-(2-bromo-1,1-dimethylethyl)-1-(2-methylallyl)azetidin-2-ones afforded 8-alkoxy-3,6,6-trimethyl-1-azabicyclo[5.2.0]nonan-9-ones in good diastereomeric excess (75-78\%). The reductive ring opening of 1 -azabicyclo[4.2.0]octane-8-ones and 1-azabicyclo[5.2.0]nonan-9-ones with lithium aluminum hydride resulted in novel 2-(1-alkoxy-2-hydroxyethyl)piperidines and -azepanes, which were isolated as single isomers.

## Introduction

The extensive use of ( $\beta$-lactam) antibiotics in the last decades has resulted in the rapid emergence of bacterial resistance and the development of multi-drug-resistant strains. ${ }^{1}$ Hence, the search for novel types of bioactive $\beta$-lactams has become one of the major challenges in medicinal and pharmaceutical chemistry. The majority of biologically active $\beta$-lactams comprises a bicyclic framework bearing the nitrogen atom at the bridgehead. In this way, the lactam functionality has less planarity and resonance stability, favoring nucleophilic attack

[^0]and consecutive ring opening. ${ }^{2}$ Besides their biological relevance, azetidin-2-ones have acquired a prominent place in organic synthesis as building blocks due to their inherent reactivity, which has led to the introduction of the term " $\beta$ lactam synthon method" in 1997. ${ }^{3}$

In recent years, more and more efforts have been devoted to the development of new radical cyclization processes, especially in the field of natural product synthesis. ${ }^{4}$ Several attractive features of radical chemistry can account for this interest, such

[^1]as the ability to form new $\mathrm{C}-\mathrm{C}$ bonds (even at congested sites), functional group tolerance, and high regioselectivity. An important strategy in this respect comprises the formation of $\mathrm{C}-\mathrm{C}$ bonds through intramolecular endo- or exo-cyclization of carbon radicals onto alkene moieties. ${ }^{5}$ In the literature, several interesting syntheses of bicyclic $\beta$-lactams have been reported based on this approach. 1-Azabicyclo[3.2.0]heptan-7-ones and 5-oxa-1-azabicyclo[4.2.0]octan-8-ones have been prepared in good yields by radical annulations of monocyclic $\beta$-lactams bearing appropriate appendages by means of tributyltin hydride and azoisobutyronitrile in benzene. ${ }^{6}$ An analogous approach with tributyltin hydride and azoisobutyronitrile has been reported for the synthesis of a 3-methylene-1-azabicyclo[5.2.0]non-4-en-9one. ${ }^{7}$ Furthermore, the 6 -endo-trig cyclization of an N -allyl-7-bromo-3a-methylhexahydroindolinone system has been described under high dilution conditions with tributyltin hydride and a catalytic amount of AIBN toward a tricyclic $\gamma$-lactam, whereas also 5-exo-trig cyclization was observed as a minor reaction pathway if the radical reaction was executed with only tributyltin hydride and no AIBN. ${ }^{8}$

In continuation of our interest in the synthesis of novel bicyclic $\beta$-lactams, ${ }^{9}$ an efficient and straightforward radical approach toward 1 -azabicyclo[4.2.0]octan-8-ones and 1-aza-bicyclo[5.2.0]nonan-9-ones with excellent diastereocontrol is described in the present paper. The bicyclic azetidin-2-ones obtained in this work were subsequently transformed into functionalized 2-(1-alkoxy-2-hydroxyethyl)piperidine and -azepane derivatives as single diastereomers via a reductive ring opening. Besides the frequent occurrence of azaheterocyclic systems in bioactive compounds, 2-(1-alkoxy-2-hydroxyethyl)piperidines and -azepanes are of general importance in medicinal chemistry due to the presence of a 1,2,3-triheteroatom-substituted submoiety, ${ }^{10}$ and analogous compounds have been described as cardiovascular agents. ${ }^{11}$ Furthermore, 2-(1,2-dihydroxyethyl)piperidine has been used as an intermediate in the synthesis of pipecolic acid (a component of several secondary metabolites in plants and fungi ${ }^{12}$ ), as a precursor of nonribosomal peptides with novel pharmacological activities, ${ }^{13}$ and as a key structural component in the synthesis of the NMDA receptor antagonists etoxadrol 1 and dexoxadrol 2 (Figure 1). ${ }^{14,15}$

## Results and Discussion

$N$-Allyl- $\beta$-bromoimine $\mathbf{4 a}$ was prepared in good yield via imination of 3-bromo-2,2-dimethylpropanal 3 in diethyl ether at room temperature utilizing 1 equiv of allylamine in the presence of $\mathrm{MgSO}_{4}$ (Scheme 1). ${ }^{16}$ Accordingly, $N$-(3-phenyla-llyl)- $\beta$-bromoimine 4b and $N$-(2-methyl-2-propenyl) $\beta$-bromoimine $\mathbf{4 c}$ were prepared in excellent yields via imination of 3-bromo-2,2-dimethylpropanal $\mathbf{3}$ in the presence of $\mathrm{MgSO}_{4}$ and $\mathrm{Et}_{3} \mathrm{~N}$ utilizing 1 equiv of the corresponding allylammonium bromide (Scheme 1), which were prepared from the corresponding allylic bromides using a 7 N solution of ammonia in methanol under high pressure. ${ }^{17}$ 3-Bromo-2,2-dimethylpropanal 3 was obtained via oxidation of 3-bromo-2,2-dimethyl-1propanol with pyridinium chlorochromate, mixed with silica, in dichloromethane in $75 \%$ yield. ${ }^{16}$

Subsequently, the obtained imines 4 were used as substrates for a Staudinger reaction with different ketenes toward the corresponding $\beta$-lactams. Thus, treatment of $N$-allylimine 4a and $N$-(3-phenylallyl)imine $\mathbf{4 b}$ with 1.3 equiv of methoxy-, phenoxy-, or benzyloxyacetyl chloride in the presence of triethylamine in dichloromethane afforded 1-allyl-4-(2-bromo-1,1-dimethylethyl)azetidin-2-ones 5a-c and 1-(3-phenylallyl)-4-(2-bromo-1,1-dimethylethyl)azetidin-2-ones 5d-f in 63-90\% yield (Scheme 2, Table 1). ${ }^{18}$

An important issue in the Staudinger synthesis of $\beta$-lactams involves the diastereocontrol. The stereochemical outcome of the Staudinger reaction toward azetidin-2-ones 5 was shown to be cis based on the coupling constants between the protons at C 3 and C 4 in ${ }^{1} \mathrm{H}$ NMR $(5.2-5.5 \mathrm{~Hz}) .{ }^{19}$ The cis/trans stereoselectivity is dependent on the competition between ring closure and isomerization of the imino moiety in the zwitterionic intermediate. Electron-donating ketene substituents and electronwithdrawing imine substituents lead to a preference for $c i s-\beta$ lactam formation, ${ }^{20}$ although different experimental factors such as the solvent, the base, the temperature, and the chloride anion could affect the stereochemical outcome. ${ }^{21}$

The synthesis of the targeted bicyclic azetidin-2-ones $\mathbf{6}$ was accomplished via the unprecedented intramolecular ring closure of 4-(2-bromo-1,1-dimethylethyl)azetidinones 5 through a radicalar reaction triggered by the organotin reagent tributyltin

hydride. ${ }^{22,23}$ Treatment of 1-allylazetidin-2-ones 5a-c and 1-(3-phenylallyl)azetidin-2-ones $\mathbf{5 d}-\mathbf{f}$ with 1.5 equiv of tributyltin hydride and 0.7 equiv of azoisobutyronitrile (AIBN) in refluxing toluene afforded bicyclic 7-alkoxy-5,5-dimethyl-1-azabicyclo-[4.2.0]octane-8-ones $\mathbf{6}$ for the first time as single diastereomers in $28-37 \%$ yield after purification by means of column chromatography or recrystallization from $\mathrm{Et}_{2} \mathrm{O}$ (Scheme 3, Table 2). ${ }^{24}$ Besides bicyclic compounds $\mathbf{6}$, the corresponding monocyclic 4 -(tert-butyl)- $\beta$-lactams 7 were also formed in substantial amounts (sometimes $>50 \%$ ), explaining the lower yields of the bicycles 6 . After purification by means of column chromatography, 4 -(tert-butyl)- $\beta$-lactams 7 were isolated in $6-11 \%$ yield (Scheme 3, Table 2). The low material balance of this radical reaction is mainly due to decomposition of the 4-(tert-butyl)-$\beta$-lactams 7 during the chromatographic purification on silica gel. The use of triethylborane as a radical initiator at -78 or $0{ }^{\circ} \mathrm{C}$ in tetrahydrofuran was unsuccessful and the starting materials were recovered. ${ }^{25}$

When the radical cyclization of a chloro derivative, cis-1-allyl-4-(2-chloro-1,1-dimethylethyl)-3-phenoxyazetidin-2-one 8 , was evaluated applying the same reaction conditions, the reaction could not be driven to completion, resulting in the formation of the contemplated bicyclic compound $\mathbf{6 b}$ besides the presence of monocyclic 4 -(tert-butyl)- $\beta$-lactam 7b and unreacted starting material 8 in a $36 / 58 / 6$ ratio (Scheme 4). Therefore, preference was given to the use of 4-(2-bromo-1,1-

[^3]dimethylethyl)azetidin-2-ones $\mathbf{5}$ as substrates for the radical cyclization toward bicyclic $\beta$-lactams 6, as in these cases no starting material was recovered afterward. $\beta$-Lactam 8 was synthesized using the same reaction conditions as described for the preparation of 4-(2-bromo-1,1-dimethylethyl)azetidin-2-ones 5 (Scheme 2). ${ }^{18}$

The above-described method led to the formation of carbacephams 6 as the sole bicyclic products via radical cyclization of the methyl radical $\mathbf{9}$, derived from the corresponding bromo compound 5 through the action of $\mathrm{Bu}_{3} \mathrm{SnH} / \mathrm{AIBN}$. Although both 6 -exo-trig and 7 -endo-trig are favored according to the Baldwin rules, ${ }^{26}$ only the 6 -exo-trig product was obtained after cyclization giving rise to intermediates 10 (Scheme 5). When $R^{2}$ is a phenyl group, the radical in intermediate $\mathbf{1 0 b}$ is located at a benzylic position, favoring the 6 -exo-trig step. Also for $\mathrm{R}^{2}$ $=\mathrm{H}$, the formation of a six-membered ring via a primary radical intermediate 10a is preferred over the formation of a sevenmembered ring via a more stable secondary radical intermediate 11. Since the yields with $R^{2}=H$ are similar to those with $R^{2}$ $=\mathrm{Ph}$, the transition state must be quite early and the cyclization is controlled by the best alignment of the orbitals involved, which appears to be better for a 6 -exo-trig than for a 7 -endotrig cyclization.

Besides the observed regioselectivity, the merit of this radical cyclization approach comprises the stereoselective synthesis of functionalized 1 -azabicyclo[4.2.0]octan-2-ones 6 as single diastereomers bearing three stereogenic centers. The relative stereochemistry at positions 6 and 7 is a direct result from the diastereoselective Staudinger reaction affording cis- $\beta$-lactams 5. During the subsequent radical cyclization step, the preformed geometry of the azetidin-2-one ring accounts for the observed stereoselectivity. Several attempts were performed in order to elucidate the relative configuration at C-3 with respect to the 7-alkoxy group. Nuclear Overhauser effect (NOE) experiments were unsuccessful due to proton overlap, making selective irradiation impossible. Fortunately, X-ray analysis of the bicyclic azetidin-2-one 6b revealed that the methyl substituent at C3 accommodates a pseudoequatorial position at the six-membered ring, which is folded in a chairlike conformation (see the Supporting Information). Thus, it could be derived that the C-3 substituents and the 7 -alkoxy group in compounds $\mathbf{6}$ are in a trans-disposition.

The observed relative stereochemistry can be explained considering the transition states involved in the radical cyclization process (Scheme 6). On the basis of a 3D-model, the transition states TTS 1 and TTS 2 are disfavored because of spacial interaction (electronic repulsion) between the methylene radical and one of the electron pairs of oxygen of the alkoxy substituent. In transition states TTS 3 and TTS 4, however,

[^4]
## SCHEME 3

$1)$. Treatment of this $\beta$-bromoimine $\mathbf{4 c}$ with an alkoxy- or phenoxyacetyl chloride in dichloromethane in the presence of $\mathrm{Et}_{3} \mathrm{~N}$ furnished cis-1-(2-methylallyl)azetidin-2-ones $\mathbf{1 2}$ in 71$90 \%$ yield (Scheme 7, Table 3).

When these novel brominated azetidinones $\mathbf{1 2}$ were reacted with 1.5 equiv of tributyltin hydride and 0.7 equiv of azoisobutyronitrile (AIBN) in refluxing toluene, novel bicyclic azetidinones $\mathbf{1 3}$ were obtained as a mixture of stereoisomers through intramolecular cyclization (Scheme 8, Table 4). After purification by means of column chromatography or recrystallization from $\mathrm{Et}_{2} \mathrm{O}$, the mixtures of 3,6,6-trimethyl-1-azabicyclo[5.2.0]-nonane-9-ones trans-13 (major) and cis-13 (minor) were isolated in $16-21 \%$ yield. All attempts to separate the diastereomers from each other failed. Also in this approach, the formation of monocyclic 4-tert-butyl- $\beta$-lactams $\mathbf{1 4}$ as side products in yields of $7-11 \%$ was observed.

In contrast with the synthesis of 1-azabicyclo[4.2.0]octan-8ones 6, a seven-membered ring is fused to the $\beta$-lactam ring in compounds $\mathbf{1 3}$ instead of a six-membered ring. These results indicate that the radical cyclization of 1-(2-methylallyl)substituted $\beta$-lactams 12 proceeds through a 7 -endo-trig cyclization protocol via a stable intermediate tertiary radical 17 (Scheme 9). Steric hindrance at the 6-exo-trig cyclization center is probably the main factor orienting the cyclization to a 7 -endotrig selectivity in the case of bicyclic $\beta$-lactams $\mathbf{1 3}$. On the basis of the rationalization discussed in Scheme 5, it can also be assumed that a similar favorable transition state is involved,
the radical center and the alkoxy group are oriented away from each other. In TTS 3, the double bond is pointed pseudoaxial, resulting in a considerable steric hindrance with the lactam moiety. On the other hand, the pseudoequatorial position of the double bond in TTS 4 minimizes the latter steric repulsion. On the basis of these arguments, the diastereoselective formation of azabicycles 6 can be explained via the most favorable transition state TTS 4, resulting in the observed stereochemistry.

Next, the influence of a substituent at the $2^{\prime}$-position of the $N$-allyl group was examined. For this purpose, 4-(2-bromo-1,1-dimethylethyl)-1-(2-methylallyl)azetidin-2-ones $\mathbf{1 2}$ were synthesized under Staudinger reaction conditions. The starting N -(3-bromo-2,2-dimethylpropylidene)-2-methylallylamine $4 \mathbf{c}$ was prepared via condensation of 3-bromo-2,2-dimethylpropanal 3 with the hydrobromide salt from 2-methylallylamine (Scheme

affording 3-methyl-1-azabicyclo[5.2.0]nonan-9-ones trans-13 as the major stereoisomers ( $87-89 \%$ ). Since this transition state comprises a puckered seven-membered ring, the stereoselectivity is less pronounced as compared to the synthesis of the corresponding 1 -azabicyclo[4.2.0]octan-8-ones 6, explaining the formation of compounds cis-13 as minor constituents (11$13 \%$ ).

The second objective of this research was the stereoselective synthesis of 2-(1-alkoxy-2-hydroxyethyl)piperidines and 2-(1-alkoxy-2-hydroxyethyl)azepanes via reductive ring opening of the corresponding bicyclic precursors. 7-Alkoxy-1-azabicyclo-

[4.2.0] octane-8-ones 6 were reduced by means of 2 equiv of lithium aluminum hydride in ether, affording 2-(1-alkoxy-2hydroxyethyl)piperidines $\mathbf{1 8}$ in good yields after 16 h at reflux (Scheme 10, Table 5). Only two similar compounds have been reported to date, i.e., 2-(2-hydroxy-1-phenoxyethyl)-7-methyl-6-oxa-3,7-diazabicyclo[3.2.1] octane and 2-(1-benzyloxy-2-hy-droxyethyl)-7-methyl-6-oxa-3,7-diazabicyclo[3.2.1]octane, in which the proton CHOPh of the former was described as a quadruplet at 4.35 ppm and the $\mathrm{CH}_{2} \mathrm{OH}$ protons as two times a $\mathrm{d} \times \mathrm{d}$ at 3.81 and $4.07 \mathrm{ppm}\left({ }^{1} \mathrm{H}\right.$ NMR, $\left.\mathrm{CDCl}_{3}\right) .{ }^{27,28}$ The chemical shifts obtained for piperidines $\mathbf{1 8}$ were comparable to those mentioned in the literature.

In an analogous reaction, the reduction of 8-alkoxy-3,6,6-trimethyl-1-azabicyclo[5.2.0]nonane-9-ones $\mathbf{1 3}$ (as mixtures of trans and cis isomers) with lithium aluminum hydride was evaluated. Treatment of the latter bicycles $\mathbf{1 3}$ with 2 equiv of $\mathrm{LiAlH}_{4}$ in diethyl ether afforded the corresponding 2-(1-alkoxy-2-hydroxyethyl)azepanes 19, again as mixtures of trans and cis isomers. After purification by column chromatography on silica gel, the major compounds trans-2-(1-alkoxy-2-hydroxyethyl)azepanes 19 were isolated as single stereoisomers (Scheme 11, Table 6). In literature, no precedents of the analogous azepanes 19 have been reported.

In summary, the radical cyclization of 1-allyl-4-(2-bromo-1,1-dimethylethyl)azetidin-2-ones and 1-(3-phenylallyl)-4-(2-bromo-1,1-dimethylethyl)azetidin-2-ones by means of $n$-tributyltin hydride and AIBN has been described for the first time as an elegant approach toward the synthesis of 3-substituted 7 -alkoxy-5,5-dimethyl-1-azabicyclo[4.2.0]octane-8-ones with excellent diastereocontrol. The relative configuration of the latter compounds was determined by using X-ray analysis. On the other hand, the radical cyclization of 4-(2-bromo-1,1-dimeth-ylethyl)-1-(2-methylallyl)azetidin-2-ones furnished 8 -alkoxy-3,6,6-trimethyl-1-azabicyclo[5.2.0]nonan-9-ones in good but lower diastereomeric excess (75-78\%). Finally, 1-azabicyclo-[4.2.0]octane-8-ones and 1-azabicyclo[5.2.0]nonan-9-ones were subjected to an efficient reductive ring opening with lithium

## Experimental Section

Synthesis of 4-(2-Bromo-1,1-dimethylethyl)azetidin-2-ones 5 and 12. As a representative example, the synthesis of cis-4-(2-bromo-1,1-dimethylethyl)-3-phenoxy-1-(2-methylallyl)azetidin-2one $\mathbf{1 2 b}$ is described here. To a stirred, ice-cooled solution of imine $4 \mathbf{c}(1.50 \mathrm{~g}, 6.88 \mathrm{mmol})$ and $\mathrm{Et}_{3} \mathrm{~N}(2.09 \mathrm{~g}, 21.65 \mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(20 \mathrm{~mL})$ was added phenoxyacetyl chloride. After being stirred for

15 h at room temperature, the reaction mixture was poured into water ( 50 mL ) under vigorous stirring and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(2 \times 20 \mathrm{~mL})$. The combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$, filtered, and concentrated to furnish cis-1-allyl-4-(2-broom-1,1-dimethylethyl)-3-phenoxyazetidin-2-one 12b, which was purified by column chromatography on silica gel (petroleum ether/EtOAc 3/1).

Synthesis of 5,5-Dimethyl-1-azabicyclo[4.2.0]octan-8-ones 6 and 3,6,6-Trimethyl-1-azabicyclo[5.2.0]nonan-9-ones 13. As a representative example, the synthesis of 3-benzyl-7-methoxy-5,5-dimethyl-1-azabicyclo[4.2.0]octan-8-one $\mathbf{6 d}$ is described here. $n-\mathrm{Bu}_{3} \mathrm{SnH}(1.37 \mathrm{~mL}, 5.11 \mathrm{mmol})$ and AIBN $(0.39 \mathrm{~g}, 2.38 \mathrm{mmol})$ were added to a refluxing solution of cis-4-(2-bromo-1,1-dimeth-ylethyl)-3-phenoxy-1-(3-phenylallyl)azetidine-2-one 5d (1.20 g, 3.41 mmol ) in toluene ( 10 mL ) in 3 portions, the interval between each addition being 1 h . Afterward, the reaction mixture was stirred for an additional 8 h at reflux temperature. After cooling to room temperature, an aqueous sodium hydroxide solution $(20 \mathrm{~mL}, 2 \mathrm{~N})$ was added to the resulting mixture, followed by a period of stirring of 1 h at room temperature. The suspension was then filtered over Celite, and the organic phase was separated and washed with a sodium hydroxide solution $(10 \mathrm{~mL}, 2 \mathrm{~N})$ and with brine. The organic layer was dried $\left(\mathrm{MgSO}_{4}\right)$, and the crude reaction product was obtained after filtration and evaporation of the solvent. The tin hydroxides were removed by column chromatography on silica gel (hexane/EtOAc 3/1), yielding pure 3-benzyl-7-methoxy-5,5-dim-ethyl-1-azabicyclo[4.2.0]octan-8-one $\mathbf{6 d}$.

## SCHEME 11

Synthesis of 2-(1-Alkoxy-2-hydroxyethyl)piperidines 18 and 2-(1-Alkoxy-2-hydroxyethyl)azepanes 19. As a representative example, the synthesis of 2-(1-phenoxy-2-hydroxyethyl)-3,3,5trimethylpiperidine 18b is described here. To a stirred, ice-cooled solution of 7-phenoxy-3,5,5-trimethyl-1-azabicyclo[4.2.0]octan-8one $\mathbf{6 b}(0.20 \mathrm{~g}, 0.77 \mathrm{mmol})$ in diethyl ether $(15 \mathrm{~mL})$ was added lithium aluminum hydride $(0.06 \mathrm{~g}, 1.54 \mathrm{mmol})$ in small portions, and the resulting mixture was stirred at room temperature for 16 h . Afterward, water was added dropwise at $0{ }^{\circ} \mathrm{C}$ until all residual lithium aluminum hydride was consumed completely. The resulting suspension was filtered over Celite, and the aqueous layer was extracted with diethyl ether $(2 \times 20 \mathrm{~mL})$. The combined organic layers were dried $\left(\mathrm{MgSO}_{4}\right)$ and filtered and crude 2-(1-phenoxy-

[^5]2-hydroxyethyl)-3,3,5-trimethylpiperidine 18b was obtained after removal of the solvent in vacuo, which was purified by recrystallization from $\mathrm{Et}_{2} \mathrm{O}$.
