Furo[3,2-b]pyrroles and furo[3,2-b]pyridines can be conveniently prepared in good yields from the cycloisomerization reactions of cis-4-hydroxy-5-alkynylpyrrolidinones and cis-5-hydroxy-6-alkynylpiperidinones, respectively, using $\mathrm{Ag}(\mathrm{I}), \mathrm{Pd}(\mathrm{II}) / \mathrm{Cu}(\mathrm{I})$, or $\mathrm{Au}(\mathrm{I})$ catalysis. In one case, the cycloisomerization product was unstable and produced a furan derivative by a ring-opening reaction.

## Introduction

The furo[3,2-b]pyrrole nucleus $1(X=O)$ is a key structural feature of the bioactive fungal metabolites lucilactaene, ${ }^{1}$ a cell-cycle inhibitor in p53-transfected cancer cells, $13 \alpha$-lucilactaene, ${ }^{2}$ the structurally related alkaloids fusarins A and $\mathrm{D},{ }^{3}$ and the telomerase inhibitors UCS1025A and B (Figure 1). ${ }^{4}$ A general and versatile synthesis of this heterocyclic ring system and its furo[3,2-b]pyridine homologue 2 would thus provide valuable scaffolds for new drug discovery programs (Scheme 1). Bicyclic heterocyclic systems $\mathbf{1}$ and 2 could in principle be prepared via a metal-catalyzed cycloisomerization of the heterocyclic cis- $\beta$-hydroxy alkynes $4(n=1,2)$ followed by reduction of the resulting unsaturated bicyclic heterocyclic system 3 (Scheme 1).

[^0]The synthesis of unsaturated five-membered ring heterocycles in general, via metal-catalyzed cycloisomerization reactions of homopropargylic alcohols, amines (and their N -derivatives), and thiols and related ortho-alkynyl phenols, anilines, and arylthiols, is well-established. ${ }^{5}$ In the case of homopropargylic alcohols, $\mathrm{Pd}(\mathrm{II}),{ }^{6}\left(\mathrm{Et}_{3} \mathrm{~N}\right) \mathrm{Mo}(\mathrm{CO})_{5},{ }^{7}$ $\mathrm{Au}(\mathrm{I}),{ }^{8}$ and $\mathrm{Pt}(\mathrm{II}){ }^{9}$ have been employed as catalysts in the

## SCHEME 1

key $\mathrm{C}-\mathrm{O}$ bond forming reaction. Reactions involving the latter two metal catalysts have been performed in alcohol solvent, resulting in conversion of the initially formed 1,2dihydrofuran to a 2-alkoxytetrahydrofuran. ${ }^{8,9}$ In the case of homopropargylic alcohol itself, cycloisomerization with $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ was not successful and only starting material was recovered. ${ }^{10}$ Bis-homopropargylic alcohols (4-alkyn-1-ols) undergo cycloisomerization reactions with $\mathrm{Pd}(\mathrm{II}),{ }^{6} \mathrm{Ag}(\mathrm{I}),{ }^{11}$ $\mathrm{Au}(\mathrm{I}),{ }^{8,12} \mathrm{Pt}(\mathrm{II}),{ }^{9} \mathrm{Ir}(\mathrm{I}),{ }^{13} \mathrm{Ru}(\mathrm{I}),{ }^{14}$ and $\left(\mathrm{Et}_{3} \mathrm{~N}\right) \mathrm{Mo}(\mathrm{CO})_{5},{ }^{15}$ to give 5 -exo ${ }^{7,9,11-13}$ and/or 6 -endo ${ }^{14,15}$ cyclic enol ether products. 5-Alkyn-1-ols often give 6 -exo products; ${ }^{9,12,13}$ however, under $\left(\mathrm{Et}_{3} \mathrm{~N}\right) \mathrm{Mo}(\mathrm{CO})_{5}$ catalysis, seven-membered ring glycals have been formed. ${ }^{15}$ While the cycloisomerization reactions of acyclic homopropargylic alcohols are welldocumented, we are not aware of such studies on saturated cyclic $c i s$ - $\beta$-hydroxy alkynes, either carbocyclic (2-alkynyl1 -cycloalkanols) or heterocyclic analogues related to 4 , to give bicyclic systems incorporating a dihydrofuran moiety. The lack of ready accessibility of these cyclic cis- $\beta$-hydroxy alkyne substrates may be a major reason for this.

We report here a direct method for the synthesis of the novel heterocyclic cis-hydroxy alkynes $7 \mathbf{a}-\mathbf{c}$, via cis-diastereoselective reactions of cyclic N -acyliminium ions ${ }^{16}$ with potassium 1-alkynyltrifluoroborates and the synthesis of novel furo[3,2-b]pyrrole and furo[3,2-b]pyridine derivatives from the metal-promoted cycloisomerization of these substrates under $\operatorname{Ag}(\mathrm{I}), \mathrm{Pd}(\mathrm{II}) / \mathrm{Cu}(\mathrm{I})$, or $\mathrm{Au}(\mathrm{I})$ catalysis.

[^2]
## SCHEME 2

## Results and Discussion

The cis-hydroxy alkyne substrates $7 \mathbf{a}-\mathbf{c}$ were prepared via the $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$-catalyzed reactions between the hemiaminals $\mathbf{5 a}-\mathbf{c}^{17,18}$ and the potassium alkynyltrifluoroborates $\mathbf{6 a}, \mathbf{b}$ (Scheme 2 and Table 1). $\mathrm{We}^{17}$ and Batey et al. ${ }^{18}$ have previously reported the successful reactions of $\mathbf{5 b}, \mathbf{c}$ with vinyl and arylboronic acids. Under similar reaction conditions that we have developed earlier, ${ }^{17}$ the reactions of 1-benzyl$4 S$-hydroxy-5-methoxypyrrolidin-2-one 5 a with the potassium 1-alkynyltrifluoroborates 6a,b gave the 4,5-cis-adducts 7a and 7b, respectively, with high cis-diastereoselectivity and in moderate to good yields, respectively (Table 1, entries 1 and 2). In contrast, the reaction of racemic $N$-Cbz-4,5-dihydroxypyrrolidine $\mathbf{5 b}$ with $\mathbf{6 b}$ gave the racemic hydroxy alkyne $7 \mathbf{c}$ in $89 \%$ yield as a 73:27 mixture of diastereomeric adducts that could be separated (Table 1, entry 3 ).

The six-membered ring hemiaminal (5S)-5c gave the corresponding 5,6 -cis-adducts $\mathbf{7 d}, 7 \mathbf{e}$, and $\mathbf{7 f}$ with high diastereoselectivity but in modest yields (Table 1, entries 4-6). These yields were low due to formation of the known Ritter reaction product $\mathbf{A}$, comprising $18-30 \%$ of the product yields, formed between the in situ generated cyclic N -acyliminium ion and acetonitrile. ${ }^{19}$ The use of alternative solvents such as nitromethane did not improve the yields of $\mathbf{7 d}-\mathbf{f}$. To assist in the stereochemical assignments of these adducts, these reactions were repeated on the $4-O$ - and $5-O$-protected analogues $\mathbf{8 a}-\mathbf{c}$ of the substrates $\mathbf{5 a}-\mathbf{c}$, respectively (Scheme 3). The reactions were highly trans-diastereoselective and proceeded in generally higher yields (Table 2). This was due in part to the better solubility properties of the substrates in the nonparticipating solvent dichloromethane.

The 4,5-cis-stereochemistry of products $7 \mathbf{a}$ and $7 \mathbf{b}$ was based on the magnitude of $J_{4,5}$ ( 5.0 and 5.1 Hz , respectively) for these compounds. Their related trans-isomers 9a $\left(\mathrm{R}^{3}=\mathrm{Ac}, \mathrm{Bn}\right.$, and TBPDS) and trans-7b that was prepared from $O$-TBS deprotection of 9 c (Supporting Information) had $J_{4,5}$ values of $0-2 \mathrm{~Hz}$. In related literature examples, $J_{4,5}$

${ }^{a}$ Ratio from ${ }^{1} \mathrm{H}$ NMR analysis of crude reaction mixture. ${ }^{b}$ Ratio of trans/cis $=96: 4$ after purification by column chromatography.
is typically $0-2.5 \mathrm{~Hz}$ for trans-isomers and $6.0-7.5 \mathrm{~Hz}$ for the corresponding cis-isomers. ${ }^{17}$ For compound 9d, $J_{4,5}$ was $<1 \mathrm{~Hz}$, consistent with its relative 4,5-trans-configuration; however, $J_{4,5}$ for its corresponding cis-isomer, $7 \mathbf{d}$, could not be determined due to peak broadening. The cis-stereochemistry of $\mathbf{7 e}$ was established by a single-crystal X-ray analysis (see Supporting Information).

The $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$-catalyzed reactions between N -benzyl-3,4,5-triacetoxy-2-pyrrolidinone and potassium 1-alkynyltrifluoroborates have previously been shown to be 4,5-cis-diastereoselective (4,5-cis/4,5-trans $=70-90: 30-10) .{ }^{20}$ The stereochemical outcomes of these reactions, however, were thought to be due to neighboring group participation of the 3-acetoxy group; this group is absent in our substrate 5a. The cis-diastereoselectivity observed in the products $7 \mathbf{a}-\mathbf{c}$, therefore, arises via a different reaction mechanism, presumably via a boronate intermediate involving the free hydroxyl group of substrates $\mathbf{5 a - c} .{ }^{17}$

Initial studies on the cycloisomerization reactions of the cis- $\beta$-hydroxy alkynes $7 \mathbf{a}-\mathbf{e}$ involved their reactions with $\mathrm{AgNO}_{3},{ }^{21} \mathrm{Au}\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cl},{ }^{8 \mathrm{a}, \mathrm{b}}$ or $\mathrm{PdCl}_{2}\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} / \mathrm{CuI},{ }^{22}$ using

[^4]modified literature procedures. Consequently, compounds 7b and 7f (both bearing a phenyl alkynyl moiety) were cycloisomerized into the corresponding dihydrofurans 10b and $\mathbf{1 0 e}$ in good to excellent yields using all three of the chosen catalyst systems in DMF as solvent (Table 3, entries $2-5$ and $14-16$ ). While substrates $7 \mathbf{b}$ and $7 \mathbf{f}$ required reaction temperatures of $60-70^{\circ} \mathrm{C}$, the substrate 7 c underwent reaction at rt with all three catalysts in DMF (not shown in Table 1) or MeOH (Table 1, entries 6-8). These reactions gave not the expected product 10c but the furan derivative $\mathbf{1 1}$ (Scheme 4). The structure of $\mathbf{1 1}$ was clear from NMR analysis that showed resonances for two vicinally coupled furan methines ( $\delta_{\mathrm{H}} 6.54(\mathrm{~d}, J=3.5 \mathrm{~Hz}), \delta_{\mathrm{c}} 105.7(\mathrm{H}-4 / \mathrm{C}-4)$, and $\left.\delta_{\mathrm{H}} 6.13(d, J=3.5 \mathrm{~Hz}), \delta_{\mathrm{c}} 108.7(\mathrm{H}-3 / \mathrm{C}-3)\right)$ and a carbamate $\mathrm{NH}\left(\delta_{\mathrm{H}} 4.99-4.87\right.$ (br s)). This compound clearly arises from a ring-opening reaction of the desired product $\mathbf{1 0 c}$, surprisingly at rt and in the absence of a strong base or acid catalyst. Notably, the $N$-Boc analogue of 10c, but lacking the 5 -phenyl substituent, is a known compound that was stable to distillation at low pressure. ${ }^{23}$

It was also observed that $30 \mathrm{~mol} \%$ of AgF (DMF, 65$\left.70{ }^{\circ} \mathrm{C}, 2.5 \mathrm{~h}\right)$ and $\mathrm{Ag}_{2} \mathrm{O}(\mathrm{MeOH}, \mathrm{rt}, 5 \mathrm{~h})$ could be used in the silver-catalyzed reactions of $\mathbf{7 b}(70 \%$ yield of $\mathbf{1 0 b})$ and $\mathbf{7 c}$ ( $77 \%$ yield of $\mathbf{1 1}$ ), respectively. Compounds $7 \mathbf{a}$ and $7 \mathbf{d}$, each bearing a terminal alkyne, were cycloisomerized using $\mathrm{AgNO}_{3}$ to their respective dihydrofurans 10a and 10d (Table 3, entries 1 and 9); however, all attempts to cycloisomerize compound $\mathbf{7 d}$ using either the $\mathrm{Au}(\mathrm{I})$ or $\mathrm{Pd}(\mathrm{II}) / \mathrm{Cu}(\mathrm{I})$ catalyst systems were unsuccessful, leading only to the recovery of the starting material. The $\mathrm{AgNO}_{3}$-mediated cyclization of compound $\mathbf{7 e}$, bearing the trimethylsilylethynyl moiety, led to the formation of $\mathbf{1 0 d}$, with the associated loss of the TMS group (Table 3, entry 10). The order of catalyst reactivity in these reactions proved to be $\mathrm{AgNO}_{3}>$ $\mathrm{PdCl}_{2}\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2} / \mathrm{CuI}>\mathrm{Au}\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cl}$. Catalyst loadings of $\mathrm{PdCl}_{2}-$ $\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{2}$ were low ( $4 \mathrm{~mol} \%$ ), while the higher loading used for $\mathrm{Au}\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cl}(10-30 \mathrm{~mol} \%)$ reflected the slower observed rates of reaction when using this catalyst. $\mathrm{AgNO}_{3}$ and $\mathrm{Au}\left(\mathrm{Ph}_{3} \mathrm{P}\right) \mathrm{Cl}$ could be used in amounts as low as $5-10$ $\mathrm{mol} \%$ (Table 3, entry 11 and footnotes a-c); however, this resulted in slower reaction times and slightly decreased yields. The corresponding trans- $\beta$-hydroxyl alkyne 9 ( $n=$ $1, \mathrm{R}^{2}=\mathrm{H}, \mathrm{X}=\mathrm{O}$ ) did not undergo a cycloisomerization reaction with any of the aforementioned catalysts.

In order to further explore the synthetic potential of metalcatalyzed cycloisomerizations of cis- $\beta$-hydroxy alkynes of the type 7 , the sequential palladium-catalyzed cycloisome-rization/cross-coupling reactions of $\mathbf{7 b}, \mathbf{c}$ were examined

## SCHEME 4

## SCHEME 5

using iodobenzene. ${ }^{24}$ These reactions gave moderate yields of the arylated products $\mathbf{1 2 a}(45 \%)$ and $\mathbf{1 2 b}(38 \%)$, respectively, along with significant amounts of the previously observed products $\mathbf{1 0 b}(23 \%)$ and 11 (19\%), respectively (Scheme 5). We assume that compound 10b arises via protonation of a $3-\mathrm{PhPd}(\mathrm{II})$-furo[3,2-b]pyrrole intermediate, while products $\mathbf{1 2 a}, \mathbf{b}$ are from reductive elimination

[^6]of this same or analogous $\mathrm{Pd}(\mathrm{II})$ complex, respectively. Interestingly, compound $\mathbf{1 2 b}$ was stable under the reaction conditions and did not produce the corresponding ringopened furan derivative.

In conclusion, furo[3,2-b]pyrroles and furo[3,2-b]pyridines can be conveniently prepared in good yields from the cycloisomerization reactions of cis-4-hydroxy-5-alkynylpyrrolidinones and cis-5-hydroxy-6-alkynylpiperidinones, respectively, using $\mathrm{Ag}(\mathrm{I}), \mathrm{Pd}(\mathrm{II}) / \mathrm{Cu}(\mathrm{I})$, or $\mathrm{Au}(\mathrm{I})$ catalysis. The $N$-Cbz substrate 7c gave an unexpected furan product (11). These $\beta$-hydroxy alkyne substrates are readily prepared from the $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$-catalyzed reactions between in situ formed $N$-acyliminium ions and potassium 1-alkynyltrifluoroborates. $\mathrm{AgNO}_{3}$ proved to be the most effective catalyst for these cycloisomerization reactions in terms of substrate versatility, rate of reaction, and catalyst loading (down to 5-10 mol \%).

## Experimental Section

(4S,5S)-1-Benzyl-5-ethynyl-4-hydroxypyrrolidin-2-one (7a). To a stirred solution of $\mathbf{5 a}(60 \mathrm{mg}, 0.27 \mathrm{mmol})$ and potassium trimethylsilylacetylenetrifluoroborate $\mathbf{6}{ }^{25}(166 \mathrm{mg}, 0.81 \mathrm{mmol})$ in $\mathrm{MeNO}_{2}(1.3 \mathrm{~mL})$ maintained at $0{ }^{\circ} \mathrm{C}$ under a nitrogen atmosphere was added $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}(0.154 \mathrm{~g}, 1.08 \mathrm{mmol})$. The resulting mixture was stirred for 1 h before warming to rt and stirring for a further 12 h . The reaction mixture was then diluted with EtOAc ( 8 mL ) and washed with $\mathrm{NaHCO}_{3}(8 \mathrm{~mL}$ of a $10 \%$ aqueous solution). The separated organic phase was dried then concentrated under reduced pressure. The resulting residue was dissolved in THF ( 5 mL ) then treated with LiOH ( 2 mL of a saturated aqueous solution), and the resulting mixture was stirred for 1 h before being diluted with EtOAc ( 8 mL ). The separated organic layer was dried and the solvent removed in vacuo. The resulting crude product (present only as the cis-diastereomer, as judged by ${ }^{1} \mathrm{H}$ NMR analysis) was purified by column chromatography (silica, $2: 1 \mathrm{v} / \mathrm{v} \mathrm{EtOAc} /$ petrol + $0.5 \% \mathrm{MeOH}$ ). Concentration of the relevant fractions ( $R_{f} 0.5$ in $2: 1 \mathrm{v} / \mathrm{v} \mathrm{EtOAc} /$ petrol $+0.5 \% \mathrm{MeOH}$ ) gave the title compound 7 a ( $24 \mathrm{mg}, 41 \%$ ) as a pale yellow solid: mp $74-76^{\circ} \mathrm{C}$; $[\alpha]_{\mathrm{D}}^{25}-17.1$ (c 2.1, $\mathrm{CHCl}_{3}$ ); $v_{\max } 3314,2929,2371,1673,1439,1414,1291$, 1072 , and $708 \mathrm{~cm}^{-1} ; \delta_{\mathrm{H}} 7.33-7.27(5 \mathrm{H}$, complex m$), 5.10$ $(1 \mathrm{H}, \mathrm{d}, J=14.7 \mathrm{~Hz}), 4.37(1 \mathrm{H}, \mathrm{m}), 4.23(1 \mathrm{H}, \mathrm{dd}, J=2.0$ and 5.0 Hz$), 4.02(1 \mathrm{H}, \mathrm{d}, J=14.9 \mathrm{~Hz}), 2.64(1 \mathrm{H}, \mathrm{dd}, J=17.1$ and 6.6 Hz$), 2.63(1 \mathrm{H}, \mathrm{d}, J=2.0 \mathrm{~Hz}), 2.51(1 \mathrm{H}, \mathrm{dd}, J=17.1$ and $3.5 \mathrm{~Hz}) ; \delta_{\mathrm{C}} 172.0,136.0,128.7,128.4,127.8,78.1,76.3$,

(4S,5R)-1-Benzyl-4-(acetyloxy)-5-(phenylethynyl)pyrrolidin-2-one (9a). To a stirred solution of $8 \mathbf{a}^{3}(100 \mathrm{mg}, 0.34 \mathrm{mmol})$ and potassium phenylacetylenetrifluoroborate $\mathbf{6 b}(92 \mathrm{mg}, 0.44$ $\mathrm{mmol})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1.5 \mathrm{~mL})$ maintained at $0^{\circ} \mathrm{C}$ under a nitrogen atmosphere was added dropwise $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}(0.20 \mathrm{~g}, 1.37 \mathrm{mmol})$. The resulting mixture was stirred for 1 h before being warmed to rt and stirred for a further 12 h . The reaction mixture was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and washed with $\mathrm{NaHCO}_{3}(8 \mathrm{~mL}$ of a saturated aqueous solution). The separated organic layer was dried and then concentrated under reduced pressure. The crude product ( $90: 10$ ratio of trans/cis) was purified by column chromatography (silica, $1: 3 \mathrm{v} / \mathrm{v}$ EtOAc/petrol), and concentration of the relevant fractions $\left(R_{f} 0.55\right.$ in 1:3 EtOAc/petrol) afforded the title compound 9 a ( $78 \mathrm{mg}, 68 \%, 96: 4$ trans/cis mixture) as a light brown gum: $[\alpha]_{\mathrm{D}}^{22}-65.3\left(c 3.0, \mathrm{CHCl}_{3}\right) ; v_{\text {max }}$ $1744,1700,1490,1408,1231,1036$, and $703 \mathrm{~cm}^{-1} ; \delta_{\mathrm{H}}$ (major trans-diastereomer) $7.40-7.26(10 \mathrm{H}$, complex m), $5.34(1 \mathrm{H}, \mathrm{d}$, $J=6.5 \mathrm{~Hz}), 5.14(1 \mathrm{H}, \mathrm{d}, J=15.2 \mathrm{~Hz}), 4.27(1 \mathrm{H}, \mathrm{s}), 4.11(1 \mathrm{H}, \mathrm{d}$, $J=15.2 \mathrm{~Hz}), 3.05(1 \mathrm{H}, \mathrm{dd}, J=17.9$ and 6.6 Hz$), 2.53(1 \mathrm{H}, \mathrm{d}$, $J=17.9 \mathrm{~Hz}$ ), $2.03(3 \mathrm{H}, \mathrm{s})$; minor cis-diastereomer $7.40-7.26$ ( 10 H , complex m), $5.90(1 \mathrm{H}, \mathrm{s}), 5.06(\mathrm{~d}, J=15.0 \mathrm{~Hz}), 4.17(1 \mathrm{H}, \mathrm{s})$, $4.15(1 \mathrm{H}, \mathrm{d}, J=15.0 \mathrm{~Hz}), 2.80(1 \mathrm{H}, \mathrm{dd}, J=17.0$ and 7.0 Hz$), 2.70$ $(1 \mathrm{H}, \mathrm{dd}, J=17.0$ and 2.5 Hz$) ; \delta_{\mathrm{C}}$ (major trans-diastereomer) $171.4,170.0,135.5,131.8,128.9,128.7,128.3,128.2,127.7$, 121.6, 87.2, 82.4, 72.0, 55.5, 44.5, 36.9, 20.8; MS (ESI ${ }^{+}$) $m / z 334\left[(\mathrm{MH})^{+}, 100 \%\right]$; HRMS (ESI ${ }^{+}$) found 334.1450, $\mathrm{C}_{21} \mathrm{H}_{20} \mathrm{NO}_{3}$ requires (MH) ${ }^{+}, 334.1443$.
(3aS,6aS)-4-Benzyl-2-phenyl-6,6a-dihydro-3a H -furo[3,2-blpyrrol$\mathbf{5 ( 4 H )}$-one (10b). Method A ( $\mathrm{AgNO}_{3}$ ): A magnetically stirred solution of $\mathbf{7 b}(30 \mathrm{mg}, 0.10 \mathrm{mmol})$ in DMF ( 1 mL ) maintained at rt under a nitrogen atmosphere was treated with $\mathrm{AgNO}_{3}$ $(2 \mathrm{mg}, 0.012 \mathrm{mmol})$. The reaction mixture was then heated at $65-70{ }^{\circ} \mathrm{C}$ for 1.5 h , before being cooled and diluted with water $(3 \mathrm{~mL})$. The resulting mixture was extracted with $\mathrm{EtOAc}(2 \times 10 \mathrm{~mL})$. The combined extracts were dried, and the solvent was removed in vacuo. The crude product was subjected to column chromatography (silica, 1:4 v/v EtOAc/petrol), and concentration of the relevant fractions $\left(R_{f} 0.5\right.$ in $1: 4 \mathrm{v} / \mathrm{v} \mathrm{EtOAc} /$ petrol) gave the title compound $\mathbf{1 0 b}$ ( $23 \mathrm{mg}, 77 \%$ ) as a colorless gum: $[\alpha]_{\mathrm{D}}^{24}-9.3\left(c 1.6, \mathrm{CHCl}_{3}\right) ; v_{\max } 1669,1438,1248,1020$, and $756 \mathrm{~cm}^{-1} ; \delta_{\mathrm{H}} 7.53-7.28(10 \mathrm{H}$, complex m$), 5.38(1 \mathrm{H}, \mathrm{d}, J=2.4$ $\mathrm{Hz}), 5.17(1 \mathrm{H}, \operatorname{app} \mathrm{t}, J=7 \mathrm{~Hz}), 4.92(1 \mathrm{H}, \mathrm{d}, J=14.8 \mathrm{~Hz})$, $4.71(1 \mathrm{H}, \mathrm{dd}, J=7.8,2.2 \mathrm{~Hz}), 4.07(1 \mathrm{H}, \mathrm{d}, J=14.8 \mathrm{~Hz}), 2.97$ $(1 \mathrm{H}, \mathrm{dd}, J=18.0$ and 7.1 Hz$), 2.88(1 \mathrm{H}, \mathrm{d}, J=18.0 \mathrm{~Hz}) ; \delta_{\mathrm{C}} 171.7$, $160.4,136.2,129.6,129.5,128.7,128.4,128.3,127.7,125.7,93.5$, 77.4, 65.5, 44.7, 38.3 MS (ESI $\left.{ }^{+}\right) m / z 292\left[(\mathrm{MH})^{+}, 100 \%\right] ;$ HRMS ( $\mathrm{ESI}^{+}$) found 292.1356, $\mathrm{C}_{19} \mathrm{H}_{18} \mathrm{NO}_{2}$ requires (MH) ${ }^{+}$, 292.1338.

Method B $\left(\mathbf{P d}\left(\mathbf{P P h}_{3}\right)_{2} \mathbf{C l}_{2} / \mathbf{C u I}\right)$ : To a stirred solution of $\mathbf{7 b}$ ( $30 \mathrm{mg}, 0.10 \mathrm{mmol}$ ) in DMF ( 1 mL ) maintained at rt under a nitrogen atmosphere were added $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}(3 \mathrm{mg}, 4.0 \mu \mathrm{~mol})$ and $\mathrm{CuI}(2 \mathrm{mg}, 0.01 \mathrm{mmol})$. The resulting mixture was heated at $65-70{ }^{\circ} \mathrm{C}$ for 1.5 h , before being cooled and diluted with water ( 3 mL ). The resulting mixture was extracted, and the crude
product was subjected to column chromatography as described above to give the title compound $\mathbf{1 0 b}(21 \mathrm{mg}, 70 \%)$ as a colorless gum. The spectral data of the purified product were in good agreement with those obtained from the sample of compound 10b prepared by Method A.

Method C $\left.\mathbf{( A u}\left(\mathbf{P P h}_{3}\right) \mathbf{C l}\right)$ : To a stirred solution of $\mathbf{7 b}(10 \mathrm{mg}$, $0.046 \mathrm{mmol})$ in $\mathrm{EtOH}(0.6 \mathrm{~mL})$ maintained at rt under a nitrogen atmosphere was added $\mathrm{Au}\left(\mathrm{PPh}_{3}\right) \mathrm{Cl}(5 \mathrm{mg}, 0.01 \mathrm{mmol})$. The resulting mixture was heated at $65-70^{\circ} \mathrm{C}$ for 24 h before being cooled and diluted with water ( 2 mL ). The resulting mixture was extracted, and the crude product was subjected to column chromatography as described above to give the title compound $\mathbf{1 0 b}$ ( $7 \mathrm{mg}, 72 \%$ ) as a colorless gum. The spectral data of the purified product were in good agreement with those obtained from the sample of compound 10b prepared by Method A.
(3aS,6aS)-4-Benzyl-2,3-diphenyl-6,6a-dihydro-3a $H$-furo[3,2-blpyrrol-5(4H)-one (12a). A solution of iodobenzene ( 49 mg , $0.24 \mathrm{mmol})$ and $\mathrm{K}_{2} \mathrm{CO}_{3}(66 \mathrm{mg}, 0.48 \mathrm{mmol})$ in acetonitrile $(1.5 \mathrm{~mL})$ maintained at $50^{\circ} \mathrm{C}$ under a nitrogen atmosphere was treated with $\mathrm{Pd}(\mathrm{dba})_{2}(7 \mathrm{mg}, 7.2 \mu \mathrm{~mol})$. The resulting mixture was stirred for 30 min before adding a solution of $\mathbf{7 b}$ ( $35 \mathrm{mg}, 0.12 \mathrm{mmol}$ ) in acetonitrile ( 1.5 mL ), and stirring was continued for a further 12 h . The reaction solvent was then removed in vacuo, and the resulting residue was filtered through a short plug of silica gel using EtOAc. The filtrate was concentrated under reduced pressure, and the resulting crude material was purified using flash column chromatography (1:3 v/v $\mathrm{EtOAc} /$ petrol) to furnish three fractions, $\mathrm{A}, \mathrm{B}$, and C. Concentration of the fraction $\mathrm{A}\left(R_{f} 0.5\right.$ in $1: 4 \mathrm{v} / \mathrm{v}$ EtOAc/petrol) gave compound $\mathbf{1 0 b}(8 \mathrm{mg}, 23 \%)$ as a colorless gum. The spectroscopic data of this material were in good agreement with those obtained from the sample of compound $\mathbf{1 0 b}$ prepared previously. Concentration of the fraction $\mathrm{B}\left(R_{f} 0.5\right.$ in $1: 3 \mathrm{v} / \mathrm{v}$ $\mathrm{EtOAc} /$ petrol) gave compound 12a ( $20 \mathrm{mg}, 45 \%$ ) as a white solid: $\mathrm{mp} 144-146{ }^{\circ} \mathrm{C} ;[\alpha]_{\mathrm{D}}^{23}+44.0\left(c 1.0, \mathrm{CHCl}_{3}\right) ; v_{\max }$ 1682, 1433, 1227, 911, and $765 \mathrm{~cm}^{-1} ; \delta_{\mathrm{H}} 7.36-6.73(15 \mathrm{H}$, complex m), $5.21-5.17(1 \mathrm{H}, \mathrm{m}), 5.13(1 \mathrm{H}, \mathrm{d}, J=7.8 \mathrm{~Hz}), 4.96$ $(1 \mathrm{H}, \mathrm{d}, J=15.2 \mathrm{~Hz}), 3.40(1 \mathrm{H}, \mathrm{d}, J=15.2 \mathrm{~Hz}), 3.04-2.96(2 \mathrm{H}, \mathrm{m})$; $\delta_{\mathrm{C}} 172.4,154.1,135.9,134.0,130.3,129.2,129.1,128.9,128.4$, 128.1, 127.95, 127.5, 127.4, 127.3, 111.0, 75.8, 68.5, 44.5, 38.2; $\mathrm{MS}\left(\mathrm{ESI}^{+}\right) m / z 368\left[(\mathrm{M}+\mathrm{H})^{+}, 100 \%\right]$; HRMS $\left(\mathrm{EI}^{+}\right)$found 367.1572, $\mathrm{C}_{25} \mathrm{H}_{21} \mathrm{NO}_{2}$ requires $\mathrm{M}^{+}, 367.1565$. Concentration of fraction $\mathrm{C}\left(R_{f} 0.5\right.$ in $2: 1 \mathrm{v} / \mathrm{v} \mathrm{EtOAc} /$ petrol $\left.+1 \% \mathrm{MeOH}\right)$ gave unreacted 7b $(10 \mathrm{mg})$ as a colorless solid.
