#### Abstract

FR901464 (1) and spliceostatin A (2) are potent inhibitors of spliceosomes. These compounds have shown remarkable anticancer activity against multiple human cancer cell lines. Herein, we describe efficient, enantioselective syntheses of FR901464, spliceostatin A, six corresponding diastereomers and an evaluation of their splicing activity. Syntheses of spliceostatin A and FR901464 were carried out in the longest linear sequence of 9 and 10 steps, respectively. To construct the highly functionalized 

FR901464, 1 ( $\mathrm{R}=\mathrm{H}$ ) Spliceostatin A, $2(R=M e)$ tetrahydropyran $A$-ring, we utilized CBS reduction, Achmatowicz rearrangement, Michael addition, and reductive amination as key steps. The remarkable diastereoselectivity of the Michael addition was specifically demonstrated with different substrates under various reaction conditions. The side chain $\boldsymbol{B}$ was prepared from an optically active alcohol, followed by acetylation and hydrogenation over Lindlar's catalyst. The other densely functionalized tetrahydropyran C-ring was derived from readily available ( $R$ )-isopropylidene glyceraldehyde through a route featuring 1,2addition, cyclic ketalization, and regioselective epoxidation. These fragments were coupled together at a late stage through amidation and cross-metathesis in a convergent manner. Six key diastereomers were then synthesized to probe the importance of specific stereochemical features of FR901464 and spliceostatin A, with respect to their in vitro splicing activity.

## INTRODUCTION

FR901464 (1) was isolated from a fermentation broth of the bacterium Pseudomonas sp. No. 2663 by Fujisawa Pharmaceutical Co. in 1996 (Figure 1). ${ }^{1}$ It exhibited potent anticancer activity. It showed enhancement of activity of a promoter of the SV40 DNA tumor virus at 10 nM concentration in M-8 cells. It also displayed dominant cytotoxicity against multiple human cancer cell lines with $\mathrm{IC}_{50}$ values ranging from 0.6 to 3.4 nM in vitro and exhibited a prominent effect at $0.056-1 \mathrm{mg} / \mathrm{kg}$

dosage against human solid tumors implanted in mice. ${ }^{1 b}$ Yoshida and co-workers also reported that spliceostatin A (2) displayed remarkable antitumor activity similar to FR901464. ${ }^{2}$ Spliceostatin A is a methoxy derivative of FR901464 at the C1 position and shows better chemical stability than FR901464. Most importantly, both FR901464 and spliceostatin A exhibited a novel mechanism of action by inhibiting in vitro splicing and promoting pre-mRNA accumulation by binding to SF3b, a protein in the spliceosome. ${ }^{2 \mathrm{~b}}$ To date, FR901464 and the structurally distinct pladienolide B (3), ${ }^{3,4}$ which has entered human clinical trials for cancer, ${ }^{5}$ are the only known molecular scaffolds capable of modulating splicing and generating an antitumor response.

Exceptional biological activity of FR901464 and spliceostatin A has attracted considerable interest from the synthetic community. ${ }^{6}$ In 2000, the first total synthesis of FR901464 was reported by Jacobsen and co-workers using an asymmetric hetero-Diels-Alder reaction as the key transformation. ${ }^{7}$ The synthesis was accomplished in the longest linear sequence of 19 steps (40 total steps). Subsequently, total syntheses of FR901464 and spliceostatin A were presented by Kitahara and co-workers in 2001. ${ }^{8}$ They took full advantage of the chiral pool to build each fragment and completed the syntheses with 22 linear steps ( 41 total steps). Recently, Koide and co-workers

reported their total synthesis of FR901464 and related analogues in the longest linear sequence of 13 steps ( 29 total steps), featuring a $\mathrm{Zr} / \mathrm{Ag}$-promoted alkynylation and [2,3]sigmatropic rearrangement as the key steps. ${ }^{9}$

Our interest in FR901464 and spliceostatin A arose from their unique biological profile and novel mechanism of action. Therefore, we sought to develop a more concise and versatile procedure toward the syntheses of FR901464 and spliceostatin A. ${ }^{10}$ Herein, we provide a full account of our work which culminated in the total syntheses of spliceostatin A and FR901464 with the longest linear sequence of 9 or 10 steps, respectively. Six additional diastereomers were then synthesized to probe the importance of specific stereochemical features of spliceostatin A and FR901464. These derivatives were evaluated for their in vitro splicing activity.

## - RESULTS AND DISCUSSION

(I). Syntheses of FR901464 (1) and Spliceostatin A (2). FR901464 and spliceostatin A both feature a relatively complex molecular architecture consisting of two highly functionalized tetrahydropyran $A$ - and $C$-rings connected through a diene system. They also possess an ester side chain $\boldsymbol{B}$ attached to the central tetrahydropyran $A$-ring via an $\alpha, \beta$-unsaturated amide bond. Furthermore, both agents contain nine stereogenic centers, two of which are quaternary centers. Our initial retrosynthetic analysis of FR901464 (1) and spliceostatin A (2) is depicted in Scheme 1. Disconnection of the diene (C6-C7) and the amide $\left(\mathrm{Cl}^{\prime}-\mathrm{N}\right)$ leads to three fragments $(4-6)$. We anticipated that amine 4 and acid 5 could be coupled under standard amidation conditions, followed by formation of the diene using cross-metathesis ${ }^{11}$ at a very late stage of the synthesis. Fragment 4 would be derived from ketone 7 by means of cross-metathesis and reductive amination. An

Achmatowicz rearrangement ${ }^{12}$ of chiral furan 8 might be utilized to build pyranone 7. Acid 5 could be conveniently obtained from the known optically active alcohol 9. ${ }^{13}$ Construction of pyran 6 could be carried out by a sequence of deprotection/cyclic ketalization and regioselective epoxidation of intermediate $\mathbf{1 0}$. Compound $\mathbf{1 0}$ would be synthesized from commercially available ( $R$ )-isopropylidene glyceraldehyde $11 .{ }^{14}$

Our initial attempt at constructing pyranone 7, according to the scheme described above, commenced with preparation of the known chiral alcohol 8, ${ }^{15}$ as shown in Scheme 2. Treatment of 5-methylfurfural 12 with allylmagnesium bromide, followed by lipase resolution of the resulting racemic, homoallylic alcohol 13, provided optically active 8 in $98 \%$ ee (determined by HPLC analysis using a chiral column) and $47 \%$ yield. Achmatowicz reaction of 8 with $t-\mathrm{BuO}_{2} \mathrm{H}$ in the presence of a catalytic amount of $\mathrm{VO}(\mathrm{acac})_{2}$ furnished a rearranged hemiketal, which was directly reduced to enone 15 as a single diastereomer, according to a procedure developed by Kishi and co-workers. ${ }^{16}$, 2 -Addition of enone 15 with methylmagnesium bromide afforded a tertiary alcohol as a mixture of diastereomers. Oxidation of the mixture of tertiary alcohols to enone 16 was achieved using 3 equiv of PCC in $75 \%$ yield. ${ }^{17}$

Our synthetic plan then required stereoselective 1,4reduction of enone 16 to give cis-pyranone 7 as a major product. However, treatment of 16 with Stryker's reagent $t^{18}$ in benzene resulted in a mixture of desired 7 and unexpected 17 in a ratio of $1: 10$, which could not be separated via flash chromatography. Subsequently, a series of reducing reagents including $\mathrm{LiAlH}(t-\mathrm{BuO})_{3},{ }^{19} \quad \mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{4},{ }^{20} \quad \mathrm{Ph}_{2} \mathrm{SiH}_{2} / \mathrm{ZnCl}_{2} /$ $\left(\mathrm{Ph}_{3} \mathrm{P}\right)_{4} \mathrm{Pd}^{21}$ In $/ \mathrm{NH}_{4} \mathrm{Cl}^{22}{ }^{22} \mathrm{LiAlH}_{4} / \mathrm{CuI} / \mathrm{HMPA}{ }^{23} \mathrm{MeLi} / \mathrm{CuI} /$ HMPA/Dibal-H, ${ }^{24} \mathrm{Al} / \mathrm{NiCl}_{2},{ }^{25} \mathrm{NaBH}_{4} / \mathrm{NiCl}_{2}$, ${ }^{26}$ and $\mathrm{Li} / \mathrm{NH}_{3}$ (liquid) ${ }^{27}$ were carefully examined. Unfortunately, these conditions provided ketone 17 as the major product. Presumably, nucleophilic addition to pyranone ring 16 proceeded from the $\beta$-face (path a, Scheme 3) over the $\alpha$ face (path b) due to developing nonbonding interactions. On the basis of this assumption, an alternative method for constructing pyran 7 was carried out. We speculated that nucleophilic addition of a methyl anion to structurally modified enone 18 should lead to the desired product (Scheme 3).

Accordingly, we turned our attention to the preparation of enone 18. As shown in Scheme 4, Corey-Bakshi-Shibata reduction ${ }^{28}$ of commercially available acetyl furan 19 with (S)-2-Me-CBS and $\mathrm{BH}_{3} \cdot \mathrm{Me}_{2} \mathrm{~S}$ provided chiral alcohol 20 in $94 \%$ yield and $93 \%$ ee (determined by HPLC analysis using a chiral column). Treatment of alcohol 20 with $t-\mathrm{BuO}_{2} \mathrm{H}$ and catalyst $\mathrm{VO}(\mathrm{acac})_{2}$ afforded an unstable hemiketal, which was directly reduced using $\mathrm{Et}_{3} \mathrm{SiH} / \mathrm{TFA}$ to afford enone 18 as a single diastereomer in $63 \%$ yield over two steps. Next, the aforementioned Michael addition of enone 18 was investigated. To our delight, reaction of 18 with lithium dimethylcopper generated in situ efficiently furnished the expected cis-pyranone 7 in $92 \%$ yield and excellent diastereoselectivity (25:1).

Pyranone 7 was subjected to cross-metathesis coupling with known alkene $21^{29}$ in the presence of Grubbs' secondgeneration catalyst ${ }^{30}$ in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ for 7 h to form a terminal tosylate (Scheme 5). Base-promoted elimination ${ }^{31}$ of the resulting tosylate afforded diene 22 in $41 \%$ yield over two steps. Our subsequent synthesis required stereoselective installation of an amine group at the C14 position, which we envisioned could be accomplished by a substrate-controlled reductive amination reaction. As expected, treatment of ketone

22 with $\mathrm{NH}_{4} \mathrm{Ac} / \mathrm{NaBH}_{3} \mathrm{CN}$ in methanol furnished cis-amine 4 as a major product along with diastereomer $23(\mathrm{dr}=6: 1)$. The mixture could not be separated by silica gel chromatography. We therefore planned to carry out our amide formation using the mixture with the corresponding side chain acid prior to separation of isomers.

Recently, Trost and Quintard reported an efficient enantioselective protocol for the synthesis of chiral propargylic alcohols, including alcohol $9 .{ }^{13}$ This alcohol could be utilized to construct the Z-allylic acetate side chain in FR901464 (1). As
depicted in Scheme 6, hydrolysis of ester 9 with LiOH in aqueous THF for 3 h afforded acid 24 in $97 \%$ yield. Acetylation of acid 24 followed by Lindlar hydrogenation ${ }^{32}$ conveniently provided the desired side chain acid 5 in $82 \%$ yield. Subsequently, coupling carboxylic acid 5 to the mixture of amines 4 and 23, under standard amidation conditions, gave the separable diastereomers 26 and 27 in the ratio of 6.5:1.

Our next objective was the enantioselective synthesis of the other highly funcitonalized tetrahydropyran 6 (Scheme 7). Treatment of the commercially available ketone 28 with ethylene glycol furnished dioxolane 29 in $87 \%$ yield. 1,2Addition of the vinyl lithium reagent derived in situ from 29 to (R)-isopropylidene glyceraldehyde (11) afforded anti-product 30 as a major diastereomer $(\mathrm{dr}=5: 1)$. The diastereoselectivity of 30 is due to the directing effect of the $\alpha$-stereogenic center of 11. ${ }^{33}$ Treatment of alcohol 30 with $\mathrm{NaH} / \mathrm{PMBCl}$ provided 31 in excellent yield. However, selective removal of the isopropylidene group in 31 without affecting the dioxolane moiety proved to be difficult after extensive examinations. A stable, bridged ketal 32 was obtained in most cases. Thus, we turned to explore substrate with a more tolerant protecting group, such as 1,3 -dithiane, instead of the dioxolane moiety in 31. Reaction of ketone 28 with 1,3-propanedithiol furnished dithiane 33 in $93 \%$ yield. However, subsequent 1,2-addition of the lithium reagent generated from 33 to aldehyde 11 gave diastereomers 34 and 35 in an approximate ratio of $1: 1$ with no stereoselectivity. This outcome was unexpected because of the high diastereoselectivity displayed in the preparation of 30 . Further investigation of this 1,2 -addition in the presence of Lewis acids such as $\mathrm{CeCl}_{3},{ }^{34} \mathrm{ZnCl}_{2},{ }^{35}$ and $\mathrm{MgBr}_{2}{ }^{36}$ in THF or $\mathrm{Et}_{2} \mathrm{O}$ showed similar results. To improve the overall yield for the formation of 34 , the undesired epimer 35 was subjected to Mitsunobu conditions ${ }^{37}$ to invert the C 4 stereocenter, followed by methanolysis of the resulting ester, to provide 34 in $89 \%$ yield.

The hydroxy group in 34 was then protected as its PMB ether, and the isopropylidene group was conveniently removed by treatment with TFA, in a one-pot manner, to afford diol 36 in $93 \%$ yield (Scheme 8). Regioselective tosylation of diol 36 was performed in the presence of dibutyltin oxide, ${ }^{38}$ furnishing monotosylate 37 in nearly quantitative yield. Tosylate 37 was initially treated with NaH in THF to form teminal epoxide 38. However, the instability of epoxide 38 prompted us to seek one-pot conditions for epoxide formation and subsequent opening to give the chiral allylic alcohol 10. In light of this idea, tosylate 37 was subjected to excess Corey-Chaykovsky dimethylsulfonium methylide ${ }^{39}$ (prepared by adding 5 equiv of $n$-BuLi dropwise to 6 equiv of trimethylsulfonium iodide) in THF for 3 h , providing allylic alcohol 10 in $88 \%$ yield. A similar functional group transformation was previously reported by Carreira and co-workers. ${ }^{40}$

## Scheme 7. Preparation of Alcohol 34

Removal of the dithiane unit in 10 and subsequent cyclic ketalization to form the pyran ring was carried out using 2 equiv of $\mathrm{Hg}\left(\mathrm{ClO}_{4}\right)_{2}$ and 10 equiv of 2,6-lutidine in methanol, thereby affording the corresponding methyl ketals as a mixture of 39 and its C 1 -anomer. ${ }^{41}$ Epimerization of 1 -epi- 39 by treating the crude mixture of anomers with a catalytic amount of PTSA in methanol at $0{ }^{\circ} \mathrm{C}$ provided the single thermodynamic product 39 in $73 \%$ yield. Oxidative cleavage of the PMB group with $\mathrm{DDQ}^{42}$ under basic conditions gave alcohol 40 in $79 \%$ yield. The last step to build the highly functionalized tetrahydropyran 6 was hydroxyl-induced stereoselective epoxidation. The initial attempt with $t-\mathrm{BuO}_{2} \mathrm{H}$ in the presence of a catalytic amount of $\mathrm{VO}(\mathrm{acac})_{2}$ only resulted in decomposition of starting material. However, reaction of 40 with $m$-CPBA and $\mathrm{NaHCO}_{3}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ stereoselectively furnished the desired segment 6 as a white solid in $76 \%$ yield.

With fully functionalized fragments 6 and 26 in hand, the stage was set to examine the cross diene-ene metatheis (Scheme 9). To our delight, treatment of 6 and 26 with Grubbs' second-generation catalyst in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ gave the metathesis adduct spliceostatin A (2) as a white solid in $57 \%$ yield based on one recycle of unreacted 6 and 26 to the same conditions. Subsequently, hydrolysis of the ketal moiety in 2 proceeded smoothly using PPTS in wet THF ${ }^{43}$ at $0^{\circ} \mathrm{C}$ to afford FR901464 (1) as a white powder in $79 \%$ yield. The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR of our synthetic FR901464 $\left\{[\alpha]_{\mathrm{D}}{ }^{23}-13.0\right.$ (c $\left.\left.0.45, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\right\}$ are in full agreement with the reported spectra of natural $\left\{[\alpha]_{\mathrm{D}}^{23}-12.0\left(c \quad 0.5, \mathrm{CH}_{2} \mathrm{Cl}_{2}\right)\right\}^{\text {1a }}$ and synthetic FR901464. ${ }^{7-9}$
(II). Syntheses of FR901464 (1), Spliceostatin A (2) and Their Diastereomers. During the total syntheses of FR901464 (1) and spliceostatin A (2), epimers 27 and 35 of two advanced intermediates 26 and 34 were obtained at C 4 and

C14 positions, respectively. We envisioned that these epimers could be utilized to synthesize the corresponding diastereomers of FR901464 and spliceostatin A to probe the importance of C4 and C14 stereochemical requirement for biological activity. As shown in Scheme 10, for the preparation of the corresponding ring C, a similar strategy as pyran 6 was employed. The synthesis of epimer 46 from alcohol 35 was completed in $28 \%$ overall yield ( 6 steps). One detail different from the previous synthesis was that cyclic ketalization of compound 43 using $\mathrm{Hg}\left(\mathrm{ClO}_{4}\right)_{2}$ and 2,6-lutidine directly gave ketal 44 as a single product.

After all segments 46, 26, 6, and 27 had been synthesized, six diastereomoers 47-52 of spliceostatin A and FR901464 were synthesized by following the sequence of cross-metathesis coupling and hydrolysis in good yields as solid powders (Scheme 11).
(III). Biological Activity Studies. The biological properties of FR901464 (1), spliceostatin A (2), along with their six

Scheme 10. Synthesis of Compound 46

diasteromers (47-52) were evaluated in an in vitro splicing system (Figure 2). ${ }^{44}$ We added the compounds to splicing reactions containing a synthetic pre-mRNA substrate, ATP, and nuclear extract from HeLa cells. Splicing chemistry was examined by denaturing PAGE to separate the substrate and product mRNA, while splicing efficiency was quantified as the percent of pre-mRNA converted to mRNA. In this system, DMSO alone has no effect on splicing efficiency, while spliceostatin A (2) and FR901464 (1) both inhibit splicing with an $\mathrm{IC}_{50}$ of 0.01 and $0.05 \mu \mathrm{M}$, respectively (Figure 2, A, C, and D). Surprisingly, compounds 47, 49, and 50 showed an approximately 100 -fold reduction in potency relative to spliceostatin A, with $\mathrm{IC}_{50}$ values between 1 and $1.5 \mu \mathrm{M}$ (Figure 2, A-D). Additionally, compounds 48, 51, and 52 were the least potent splicing inhibitors with $\mathrm{IC}_{50}$ between 10 and 35 $\mu \mathrm{M}$.

We also examined the effect of the compounds on spliceosome assembly. Spliceosome assembles on pre-mRNA substrates via an ordered series of intermediate complexes. A subset of these complexes (H/E, A, B, and C) can be visualized by native gel analysis of the same in vitro splicing reactions described above. $H / E$ and $A$ complexes form as early intermediates that convert to $B$ and subsequently to $C$ complexes, at which point the splicing reaction is catalyzed. As with splicing chemistry, DMSO alone has no effect, and spliceosomes assemble over time in the normal progression from $\mathrm{H} / \mathrm{E} \rightarrow \mathrm{A} \rightarrow \mathrm{B} \rightarrow \mathrm{C}$ complex (Figure 2, A and B). With increasing concentrations of spliceostatin A (2) and FR901464 (1) spliceosome assembly halts at a previously observed A-like complex. ${ }^{19}$ The six diastereomers have the same effect on spliceosome assembly, but with decreased potencies that coincide directly with inhibition of splicing chemistry (Figure 2, A and B ).

## - CONCLUSION

We have achieved the enantioselective total syntheses of spliceostatin A (2) and FR901464 (1) in 19 and 20 total steps with the longest linear sequence of 9 and 10 steps, respectively. While constructing the highly functionalized tetrahydropyran $A$-ring, a series of transformations including CBS reduction, Achmatowicz rearrangement, and Michael addition were successfully carried out. In particular, diastereoselectivity of the Michael addition was investigated under various reaction conditions. Side chain $\boldsymbol{B}$ was rapidly prepared from a known chiral propargylic alcohol. Subsequently, another densely

functionalized tetrahydropyran $C$-ring was built from (R)isopropylidene glyceraldehyde by a route featuring cyclic ketalization and regioselective epoxidation. Finally, these three segments were coupled to afford spliceostatin A and FR901464.

Furthermore, six diastereomers of FR901464 and spliceostatin A were synthesized in the same manner. They were utilized to probe the importance of certain stereochemical features of FR901464 and spliceostatin A in terms of biological activity studies. Strikingly, all diastereomers showed over 100fold reduction in potency relative to spliceostatin A, which indicates that each modification strongly impacts their activity at some level. In particular, the stereochemistry at C4 had the largest influence on splicing inhibitory activity, although there appears to be some synergistic effects with the modifications at C1 and C14.

## - EXPERIMENTAL SECTION

General Experimental Details. Those reactions which required anhydrous conditions were carried out under an argon atmosphere using oven-dried glassware ( $120^{\circ} \mathrm{C}$ ). All chemicals and reagents were purchased from commercial suppliers and used without further purification. Anhydrous solvents were obtained as follows: anhydrous tetrahydrofuran and diethyl ether were distilled from sodium metal under argon; anhydrous dichloromethane was dried via distillation from $\mathrm{CaH}_{2}$ immediately prior to use under argon; anhydrous methanol and ethanol were distilled from activated magnesium under argon. All other solvents were reagent grade. TLC analysis was conducted using glass-backed thin-layer silica gel chromatography plates ( $60 \AA, 250 \mu \mathrm{~m}$ thickness, F-254 indicator). Flash chromatography was performed using 230-400 mesh, $60 \AA$ A pore diameter silica gel. ${ }^{1} \mathrm{H}$ NMR spectra were recorded at 400,500 , or $800 \mathrm{MHz} .{ }^{13} \mathrm{C}$ NMR spectra were recorded at 100 or 150 MHz . Chemical shifts are reported in parts per million and are referenced to the deuterated residual solvent peak. NMR data are reported as $\delta$ value (chemical shift, $J$-value ( Hz ), integration, where $s=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{brs}=$ broad singlet, $\mathrm{m}=$ multiplet). IR spectra were recorded on a Varian 2000 infrared spectrophotometer and are reported as $\mathrm{cm}^{-1}$. LRMS and HRMS spectra were recorded at the Purdue University Department of Chemistry Mass Spectrometry Center using both ion trap and quadrapole analyzers. Melting points were measured on a melting point apparatus and were uncorrected.

Alcohol (8). To a solution of 5 -methylfurfural $12(550 \mathrm{mg}, 5.1$ $\mathrm{mmol})$ in THF ( 10 mL ) at $-15{ }^{\circ} \mathrm{C}$ was added allyl magnesium bromide ( 1.0 M in THF, $6.5 \mathrm{~mL}, 6.5 \mathrm{mmol}$ ) dropwise over 10 min . The reaction mixture was stirred for an additional 20 min and then quenched with water $(10 \mathrm{~mL})$. The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$. The combined organic extracts were dried over

To a solution of $8(791 \mathrm{mg}, 5.2 \mathrm{mmol})$ in dichloromethane $(12 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$ was added VO $(\mathrm{acac})_{2}(138 \mathrm{mg}$, 0.5 mmol ) and ${ }^{t} \mathrm{BuOOH}(5.5 \mathrm{M}, 1.23 \mathrm{~mL}, 6.8 \mathrm{mmol})$. After stirring for 2 h , the mixture was treated with water ( 10 mL ). The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$. The combined organic extracts were dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated to give the crude hemiketal as a yellow oil.

The crude hemiketal was dissolved in anhydrous dichloromethane $(10 \mathrm{~mL})$ at $-45^{\circ} \mathrm{C}$ under argon. $\mathrm{Et}_{3} \mathrm{SiH}(4.15 \mathrm{~mL}, 25.9 \mathrm{mmol})$ and TFA ( $5.79 \mathrm{~mL}, 77.9 \mathrm{mmol}$ ) were then added subsequently. After stirring at $-45^{\circ} \mathrm{C}$ for 1 h , the mixture was treated with $30 \% \mathrm{NaHCO}_{3}$ to adjust the pH to a range of $\sim 8-9$. The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$. The combined organic extracts were dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated. Enone (16). To a solution of enone $15(592 \mathrm{mg}, 3.9 \mathrm{mmol})$ in THF $(8 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$ was added methyl magnesium bromide $(3.0 \mathrm{M}$ in $\mathrm{Et}_{2} \mathrm{O}, 1.69 \mathrm{~mL}, 5.1 \mathrm{mmol}$ ) dropwise over 5 min . The reaction mixture was stirred for an additional 1 h and then quenched with water ( 10 $\mathrm{mL})$. The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 10 \mathrm{~mL})$.

Figure 2. Impact of analogues on in vitro splicing. A and B: (1) Top panels: Denaturing gel analysis of radiolabeled RNA isolated from splicing reactions. The first five lanes include a time course of splicing reactions in $1 \%$ DMSO followed by 30 min time points of splicing reactions incubated with indicated concentration. Identities of bands are schematized to the left as (from top to bottom) lariat intermediate, pre-mRNA, mRNA, $5^{\prime}$ exon intermediate. (2) Bottom panels: Native gel analysis of spliceosome assembly. Aliquots of the splicing reactions described above were separated under native conditions. The identity of splicing complexes is denoted with assembly occurring in the following order: $\mathrm{H} / \mathrm{E} \rightarrow \mathrm{A} \rightarrow \mathrm{B} \rightarrow \mathrm{C}$. C : Quantification of normalized splicing efficiency vs inhibitor concentration for the splicing reactions shown in (A) and (B), respectively. D: Summary of splicing inhibition data. $\mathrm{IC}_{50}$ refers to the concentration required to reduce in vitro splicing efficiency by half compared to DMSO control.

The combined organic extracts were dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated give the crude tertiary alcohol as a yellow oil.

The crude tertiary alcohol was dissolved in anhydrous dichloromethane ( 20 mL ) at $23{ }^{\circ} \mathrm{C}$. PCC ( $3.35 \mathrm{~g}, 15.6 \mathrm{mmol}$ ) and silica gel $(3.5 \mathrm{~g})$ were then added subsequently. After stirring at $23^{\circ} \mathrm{C}$ for 24 h , the mixture was filtered and concentrated. The residue was purified via silica gel chromatography ( $15: 1$ to $8: 1$ hexane/ethyl acetate) to afford enone 16 ( $440 \mathrm{mg}, 68 \%, 2$ steps) as a light yellow oil: $[\alpha]_{D}{ }^{20}-111.6$ (c 1.07, ethyl acetate); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 5.93(\mathrm{~s}, 1 \mathrm{H})$, $5.92-5.80(\mathrm{~m}, 1 \mathrm{H}), 5.17-5.06(\mathrm{~m}, 2 \mathrm{H}), 4.32($ brs, 1 H$), 4.03-3.95$ $(\mathrm{m}, 1 \mathrm{H}), 2.64-2.53(\mathrm{~m}, 1 \mathrm{H}), 2.48-2.37(\mathrm{~m}, 1 \mathrm{H}), 1.90(\mathrm{~s}, 3 \mathrm{H}), 1.35$ $(\mathrm{d}, J=6.4 \mathrm{~Hz}, 3 \mathrm{H}) ;{ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta$ 196.6, 161.5, 133.3, 125.1, 117.6, 76.4, 76.3, 36.7, 19.6, 15.2; IR (neat) 1765, 1683, 1378, 1128, $917 \mathrm{~cm}^{-1}$; LRMS (ESI), $m / z 189.1(\mathrm{M}+\mathrm{Na})^{+}$.

Ketone (17). To a solution of enone $16(149 \mathrm{mg}, 0.9 \mathrm{mmol})$ in benzene ( 5 mL ) at $23{ }^{\circ} \mathrm{C}$ under argon was added $\left[\mathrm{PPh}_{3} \mathrm{CuH}\right]_{6}(1.4 \mathrm{~g}$, 0.7 mmol ). The resulting mixture was stirred for 3 h at $23^{\circ} \mathrm{C}$, and then it was filtered and concentrated. The residue was purified via silica gel chromatography ( $20: 1$ to 10:1 hexane/ethyl acetate) to afford ketone $17(129 \mathrm{mg}, 85 \%)$ as a colorless oil: $[\alpha]_{\mathrm{D}}{ }^{20}+19.6(c 0.76$, ethyl acetate); ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 5.99-5.86(\mathrm{~m}, 1 \mathrm{H}), 5.15-$ $5.05(\mathrm{~m}, 2 \mathrm{H}), 3.85(\mathrm{dd}, J=13.2,6.4 \mathrm{~Hz}, 1 \mathrm{H}), 3.34(\mathrm{dt}, J=8.0,3.6 \mathrm{~Hz}$, $1 \mathrm{H}), 2.64-2.53(\mathrm{~m}, 1 \mathrm{H}), 5.50-2.43(\mathrm{~m}, 1 \mathrm{H}), 2.32-2.20(\mathrm{~m}, 1 \mathrm{H})$, $2.14-2.00(\mathrm{~m}, 2 \mathrm{H}), 1.27(\mathrm{~d}, J=6.8 \mathrm{~Hz}, 3 \mathrm{H}), 0.94(\mathrm{~d}, J=6.0 \mathrm{~Hz}, 3 \mathrm{H})$; ${ }^{13} \mathrm{C}$ NMR ( $100 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta 209.3,134.5,116.9,81.8,79.2,45.5$, 37.4, 36.9, 18.3, 15.1; IR (neat) 1738, 1643, 1381, 1239, $1079 \mathrm{~cm}^{-1}$; HRMS (ESI), $m / z(M+N a)^{+}$calcd for $\mathrm{C}_{10} \mathrm{H}_{10} \mathrm{O}_{2} \mathrm{Na}$ 191.1048, found 191.1051.

Alcohol (20). To a solution of (S)-2-Me-CBS catalyst $(4.357 \mathrm{~g}$, 15.7 mmol ) in anhydrous THF ( 80 mL ) at $0^{\circ} \mathrm{C}$ under argon was added $\mathrm{BH}_{3} \cdot \mathrm{Me}_{2} \mathrm{~S}(3.3 \mathrm{~mL}, 34.6 \mathrm{mmol})$. After stirring for 30 min , the mixture was cooled to $-10{ }^{\circ} \mathrm{C}$, and a solution of $19(4.716 \mathrm{~g}, 31.4$ mmol ) in THF ( 20 mL ) was added. The resulting mixture was stirred for 30 min and then quenched with $\mathrm{MeOH}(10 \mathrm{~mL})$ and water ( 20 $\mathrm{mL})$. After warming to room temperature, the reaction mixture was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(100 \mathrm{~mL})$. The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 30 \mathrm{~mL})$. The combined organic extracts were dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated. The residue was purified via silica gel chromatography ( $10: 1$ to $6: 1$ hexane/ethyl acetate) to afford 20 ( $4.49 \mathrm{~g}, 94 \%$ yield, $93 \% \mathrm{ee}$ ) as a colorless oil. Amides 26 and 27. To a solution of $22(65 \mathrm{mg}, 0.3 \mathrm{mmol})$ in anhydrous methanol ( 3 mL ) at $0{ }^{\circ} \mathrm{C}$ under argon was added ammonium acetate $(482 \mathrm{mg}, 6.3 \mathrm{mmol})$ and $\mathrm{NaBH}_{3} \mathrm{CN}(99 \mathrm{mg}, 1.6$ mmol ). The reaction mixture was then gradually warmed to room temperature. After stirring for 24 h , the reaction mixture was added to aqueous $\mathrm{NaOH}(4 \mathrm{M}, 1.2 \mathrm{~mL})$ to adjust the pH to a range of $\sim 8-9$ and then diluted with ethyl acetate $(10 \mathrm{~mL})$. The resulting mixture was directly dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated to give crude amines (4 and 23) as a light yellow oil.

To a stirred solution of acid $5(59 \mathrm{mg}, 0.4 \mathrm{mmol})$ in anhydrous acetonitrile $(2 \mathrm{~mL})$ at room temperature under argon was added HATU ( $143 \mathrm{mg}, 0.4 \mathrm{mmol}$ ) and DIPEA ( $273 \mu \mathrm{~L}, 1.6 \mathrm{mmol}$ ). The resulting mixture was then transferred via cannula to a stirred solution of crude amines ( 4 and 23) in acetonitrile ( 2 mL ) at room
temperature and rinsed with additional acetonitrile ( 1 mL ). After stirring for 24 h , the reaction was quenched by addition of saturated aqueous $\mathrm{NH}_{4} \mathrm{Cl}(3 \mathrm{~mL})$ and then diluted with ethyl acetate $(15 \mathrm{~mL})$. The aqueous phase was extracted with ethyl acetate $(3 \times 10 \mathrm{~mL})$. The combined organic extracts were dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated. The residue was purified via silica gel chromatography (5:1 to $3: 1$ hexane/ethyl acetate) to afford amide $26(57 \mathrm{mg}, 52 \%, 2$ steps) and amide 27 ( $9 \mathrm{mg}, 8 \%, 2$ steps) as colorless oil. Conversion of Alcohol 35 into Alcohol 34. To a solution of 35 ( $230 \mathrm{mg}, 0.8 \mathrm{mmol}$ ) in anhydrous THF ( 4 mL ) at room temperature under argon was added triphenylphosphine ( $397 \mathrm{mg}, 1.5 \mathrm{mmol}$ ) and $p$-nitrobenzoic acid ( $253 \mathrm{mg}, 1.5 \mathrm{mmol}$ ), which was stirred for a period of 10 min . DEAD $(239 \mu \mathrm{~L}, 1.5 \mathrm{mmol})$ was then added dropwise. After stirring at room temperature for an additional 12 h , the reaction
mixture was diluted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(10 \mathrm{~mL})$ and quenched with $10 \%$ $\mathrm{NaHCO}_{3}(10 \mathrm{~mL})$. The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (3 $\times 10 \mathrm{~mL})$. The combined organic extracts were dried over $\mathrm{MgSO}_{4}$, filtered, and concentrated to give crude product as a yellow oil.

The aforementioned crude product was dissolved in anhydrous $\mathrm{MeOH}(5 \mathrm{~mL})$ at room temperature under argon, and $\mathrm{NaOH}(91 \mathrm{mg}$, 2.3 mmol ) was then added. After stirring at room temperature for 2 h , the reaction mixture was concentrated to give a yellow oil which was then purified via silica gel chromatography ( $10: 1$ to $5: 1$ hexane/ethyl acetate) to afford $34(205 \mathrm{mg}, 89 \%)$ as a colorless oil.

Diol (36). To a solution of $34(1.206 \mathrm{~g}, 3.9 \mathrm{mmol})$ in anhydrous THF ( 12 mL ) and DMF ( 6 mL ) at $0^{\circ} \mathrm{C}$ under argon was added NaH $(60 \%, 476 \mathrm{mg}, 11.9 \mathrm{mmol})$. After stirring at $0^{\circ} \mathrm{C}$ for $1 \mathrm{~h}, \mathrm{PMBCl}(1.08$ $\mathrm{mL}, 7.9 \mathrm{mmol}$ ) was added dropwise. The resulting mixture was stirred for 11 h at this temperature and then concentrated. The residue was then dissolved in anhydrous $\mathrm{CH}_{2} \mathrm{Cl}_{2}(40 \mathrm{~mL})$ at $0^{\circ} \mathrm{C}$, to which TFA $(3 \mathrm{~mL})$ and $\mathrm{H}_{2} \mathrm{O}(3 \mathrm{~mL})$ were added. In Vitro Splicing Reactions. Pre-mRNA substrate was derived from the adenovirus major late transcript. A ${ }^{32} \mathrm{P}$-UTP body-labeled $\mathrm{G}\left(5^{\prime}\right) \operatorname{ppp}\left(5^{\prime}\right) \mathrm{G}$-capped substrate was generated by T 7 runoff transcription followed by gel purification. Nuclear extract was prepared from HeLa cells grown in DMEM/F12 1:1 and 5\% (v/v) newborn calf serum. For splicing reactions, 10 nM pre-mRNA substrate was incubated with 60 mM potassium glutamate, 2 mM magnesium acetate, 2 mM ATP, 5 mM creatine phosphate, $0.05 \mathrm{mg} \mathrm{mL}^{-1}$ tRNA, and $50 \%(\mathrm{v} / \mathrm{v}) \mathrm{HeLa}$ nuclear extract at $30^{\circ} \mathrm{C}$.

Denaturing Gel Analysis. RNA was extracted from in vitro splicing reaction and separated on a $15 \%$ (v/v) denaturing polyacrylamide gel. ${ }^{32} \mathrm{P}$-labeled RNA species were visualized by phosphorimaging and quantified with ImageQuant software (Molecular Dynamics). Splicing efficiency is the amount of mRNA relative to total RNA and normalized to a DMSO control reaction. $\mathrm{IC}_{50}$ values for inhibitors are the concentration of inhibitor that causes $50 \%$ decrease
of splicing efficiency, which were derived from averaged plots of splicing efficiency vs compound concentration.

Native Gel Analysis. Splicing reactions were set up as described above and incubated at $30^{\circ} \mathrm{C}$ for $4-30 \mathrm{~min}$. Time point samples were kept on ice until all samples were ready for analysis. Amounts of $10 \mu \mathrm{~L}$ of splicing reactions were mixed with $10 \mu \mathrm{~L}$ of native gel loading buffer ( 20 mM Trizma base, 20 mM glycine, $25 \%$ ( $\mathrm{v} / \mathrm{v}$ ) glycerol, $0.1 \%$ (w/v) cyan blue, $0.1 \%(\mathrm{w} / \mathrm{v})$ bromophenol blue, $1 \mathrm{mg} \mathrm{mL}^{-1}$ of heparin sulfate) and incubated at room temperature for 5 min before loading onto a $2.1 \%(\mathrm{w} / \mathrm{v})$ low-melting temperature agarose gel. Gels were run at 72 V for 3.5 h , dried onto Whatman paper, and exposed to phosphorimaging screens, which were digitized with a Typhoon Scanner (Molecular Dynamics).
