ABSTRACT: We report herein copper(II)-catalyzed cyclization reactions of silyl enol ethers derived from methyl ketones with α -diazo- β -ketoesters or α -diazoketones to afford 2-siloxy-2,3-dihydrofuran derivatives or 2,3,5-trisubstituted furans, respectively, under mild conditions. The former cyclization products serve as versatile 1,4-diketone surrogates, allowing facile preparation of 2,3,5-trisubstituted furans, pyrroles, and thiophenes.

INTRODUCTION

Transition-metal carbenoids generated through the decomposition of diazocarbonyl compounds have been extensively utilized as electrophilic reactive intermediates for a diverse set of catalytic transformations. Olefins represent the most frequently employed nucleophilic reaction partners to electrophilic carbenoids, which typically take part in cyclopropanation.² In this context, the reactivity of silyl enol ethers, typical electron-rich olefins utilized in numerous organic reactions, has been extensively studied. Their reactions with common α diazoesters under copper or rhodium catalysis lead to donor/ acceptor-substituted cyclopropane derivatives (Scheme 1a),

which have proved to serve as useful intermediates for natural product synthesis.⁴ On the other hand, Kitamura and coworkers recently reported a rhodium-catalyzed reaction of enol silyl ether and diazonaphthoquinone to afford a dihydronaphthofuran derivative (Scheme 1b).5 As Kitamura's study was specifically focused on the reaction of ketene silyl acetal and diazonaphthoquinone, this [3 + 2] mode of cycloaddition remains largely unexplored with respect to both enol silyl ethers and diazocarbonyl compounds regardless of its potential utility for the synthesis of furans and other five-membered heterocycles.6

Recently, we developed a copper-catalyzed condensation reaction of ketimines and α -diazo- β -ketoesters to afford multisubstituted pyrroles. The reaction is considered to involve a copper carbenoid stabilized by two adjacent carbonyl groups, which serves as an electrophile toward the nitrogen atom of ketimine to generate an azomethine ylide. 7,8 In this connection as well as in light of the aforementioned background on the reaction of enol silyl ethers, we became interested in the reactivity of the same or similar copper carbenoids toward silyl enol ethers. We report here that a simple copper(II) salt, $Cu(hfacac)_2$ (hfacac = hexafluoroacetylacetonate), is capable of promoting a coupling reaction of silyl enol ethers derived from methyl ketones with a variety of α diazo- β -ketoesters (R³ = ester) and α -diazoketones (R³ = aryl) (Scheme 1c). The former diazo compounds afford 2-siloxy-2,3dihydrofurans that serve as 1,4-diketone surrogates for facile preparation of multisubstituted furan, pyrrole, and thiophene derivatives, while the latter directly furnish trisubstituted furans.

■ RESULTS AND DISCUSSION

The present study commenced with screening of reaction conditions for the condensation of acetophenone-derived silvl enol ether 1a and ethyl acetoacetate-derived diazo compound 2a (1.2 equiv). Treatment of these starting materials with a catalytic amount of Cu(hfacac)₂ (10 mol %) in CH₂Cl₂ at 40 °C resulted in a smooth denitrogenative coupling reaction to afford a 2-siloxy-2,3-dihydrofuran derivative 3aa in 84% isolated yield (Table 1, entry 1). The same reaction could also be

followed by direct treatment of crude 3aa with p-TsOH, which furnished a trisubstituted furan 4aa in 86% overall yield. In sharp contrast, less Lewis acidic Cu(tfacac)₂ (tfacac = trifluoroacetylacetonate) completely failed to promote the reaction (entry 2), although it was the optimum catalyst for our previously developed pyrrole-forming reaction using ketimine as a nucleophilic reaction partner. In this case, the silyl enol ether 1a was mostly recovered, whereas the diazo compound 2a underwent complete decomposition to unidentified products. We speculate that the copper carbenoid derived from Cu(tfacac)₂ and 2a was not electrophilic enough toward 1a. Not unexpectedly, even less Lewis acidic Cu(II) salts such as Cu(acac)₂ and Cu(OAc)₂ were entirely ineffective as well (entries 3 and 4). The reaction using Rh₂(OAc)₄ as a catalyst resulted in a much lower yield (entry 5). An attempt to reduce the loading of Cu(hfacac)₂ to 5 mol % resulted in a decreased yield (entry 6). Note that α -(tert-butyldimethylsiloxy)styrene, instead of 1a, could also be converted to the furan product 4aa under the standard conditions albeit in a slightly lower yield (entry 7).

Having identified Cu(hfacac)₂ as an effective catalyst for the coupling of 1a and 2a, we explored the scope of the present furan synthesis. First, a series of α -diazo- β -ketoesters and related compounds 2a-n were subjected to the reaction with silyl enol ether 1a (Table 2). The reaction proved to tolerate a variety of R¹ groups such as primary and secondary alkyl groups (4aa-ae), aryl and heteroaryl groups with electron-donating or -withdrawing groups (4af-al), and a trifluoromethyl group

(4am), thus affording the corresponding trisubstituted furans in moderate to good yields. Besides the α -diazo- β -ketoesters, α diazo- β -ketosulfone also smoothly participated in the reaction with 1a to afford 3-sulfonylfuran 4an in a good yield. Unfortunately, the reaction of α -diazo- β -diketone such as the one derived from acetylacetone did not afford a desired furan product but gave an intractable mixture of products.

When α -diazoketones **20**-r were used as reaction partners for 1a, the Cu-catalyzed reaction directly afforded 2,3,5trisubstituted furan products 4ao-ar in good yields, without a need for the treatment with p-TsOH (Scheme 2a). We

consider that the lack of electron-withdrawing groups on the 4-position of the corresponding 2-siloxy-2,3-dihydrofuran intermediates makes them prone to loss of silanol, which is presumably assisted by the Lewis acidic copper catalyst. Note also that the reaction of 1a with α -diazoester 2s directly afforded a 1,4-ketoester derivative 5 in a good yield (Scheme 2b), without a trace of cyclopropane or other cyclic intermediates.

Silyl enol ethers derived from various methyl ketones were amenable to the Cu-catalyzed coupling with α -diazo- β -ketoester **2a**, thus furnishing the desired trisubstituted furans in moderate to good yields (Table 3). Tolerable R groups on

silyl enol ether include functionalized aryl (4ba-ga), heteroaryl (4ha and 4ia), alkyl (4ja-la), and alkenyl (4ma) groups. Silyl enol ether derived from 1,4-diacetylbenzene underwent 2-fold coupling with 2a to afford a teraryl product 4na in a modest yield. Unfortunately, reactions of trisubstituted silyl enol ethers, such as those derived from propiophenone, tetralone, and cyclohexanone, with 2a under the present conditions resulted in full recovery of the silyl enol ethers and complete decomposition of 2a. Note also that the reaction of ketene silyl acetal was rather sluggish. For example, the Cu-catalyzed coupling of phenyl acetate derived ketene silyl acetal with 2a afforded the corresponding 2-siloxy-2,3-dihydrofuran in only 16% yield (data not shown).

2-Siloxy-2,3-dihydrofuran serves as a 1,4-diketone surrogate for the preparation of five-membered heteroarenes other than furan (Table 4). Thus, fluoride-mediated desilylation of the crude coupling product 3aa was followed by treatment with ammonium acetate in acetic acid under heating conditions, affording a N–H pyrrole derivative 6a in 83% overall yield. This protocol was effective for a series of silyl enol ether/ α -

diazo- β -ketoester coupling products, thus enabling facile preparation of trisubstituted N–H pyrroles **6b**–**f** in moderate to good yields. Likewise, the use of Lawesson's reagent instead of ammonium acetate in the above procedure allowed preparation of trisubstituted thiophenes 7a–**f** in moderate to good yields.

compound with the copper catalyst generates an electrophilic copper carbenoid **A**. The silyl enol ether then undergoes nucleophilic attack on the carbenoid carbon to give an intermediate **B** bearing oxonium and enolate moieties. Intramolecular attack of the enolate oxygen to the oxonium carbon would directly afford 2-siloxy-2,3-dihydrofuran 3 while

liberating the copper catalyst. An alternative pathway involving a siloxycyclopropane intermediate C, its ring-opening, and recyclization may not be fully excluded, however. When the R³ substituent of 3 is not electron-withdrawing, loss of the siloxy group would be facilitated by the copper catalyst, thus leading to direct formation of the furan product 4.

CONCLUSION

In summary, we have demonstrated that 2-siloxy-1-alkenes serve as excellent nucleophiles toward copper carbenoids generated from α -diazo- β -ketoesters or α -diazoketones, affording 2-siloxy-2,3-dihydrofuran derivatives or 2,3,5-trisubstituted furans, respectively. By simple follow-up operations, the former products can be transformed into 2,3,5-trisubstituted furans, pyrroles, and thiophenes. While the same type of multisubstituted furans may be directly prepared by transition-metal-catalyzed coupling of α -diazo- β -ketoesters and terminal alkynes^{8c,d,9} or by other means, ^{10,11} the accessibility to analogous pyrroles ¹² and thiophenes would make the present approach useful alternative to existing synthetic methods for five-membered heteroarenes. ¹³

■ EXPERIMENTAL SECTION

General Information. All reactions dealing with air- and moisturesensitive compounds were carried out in oven-dried reaction vessels under a nitrogen atmosphere using standard Schlenk techniques. All commercial materials were used without further purification. Silyl enol ethers¹⁴ and diazocarbonyl compounds⁷ were prepared according to the literature procesures. Analytical thin-layer chromatography (TLC) was performed on Merck 60 F254 silica gel plates. Standard flash chromatography was performed on silica gel 60 (300-400 mesh). Melting points (°C) were determined using a capillary melting point apparatus and are uncorrected. ¹H and ¹³C NMR spectra were recorded on 400 MHz NMR spectrometers. Chemical shifts are reported in ppm relative to an internal standard, tetramethylsilane (0.00 ppm), or residual protiated solvent. Data are presented as follows: chemical shift (ppm), multiplicity (s = singlet, d = doublet, t = triplet, q = quartet, sept = septet, m = multiplet), coupling constant I (Hz), and integration. High-resolution mass spectra (HRMS) were obtained by ESI method using a Q-Tof Premier LC HR mass spectrometer.

General Procedure for Furan Synthesis from Silyl Enol Ethers and α-Diazo- β -ketoesters (Tables 2 and 3). A 10 mL Schlenk tube equipped with a stirrer bar was charged with silyl enol ether (0.20 mmol), Cu(hfacac)₂ (9.6 mg, 0.020 mmol, 10 mol %), and diazocarbonyl compound (0.24 mmol), followed by the addition of dichloromethane (1.0 mL). The resulting mixture was stirred at 40 °C for 6 h. Upon cooling to room temperature, p-toluenesulfonic acid monohydrate (11.4 mg, 0.030 mmol, 30 mol %) was added, followed by the addition of toluene (1.0 mL). The resulting mixture was stirred at 110 °C for 1.5 h and then cooled to room temperature. The reaction mixture was diluted with ethyl acetate (5 mL), passed through a pad of silica gel, and concentrated under reduced pressure. The residue was purified by flash chromatography on silica gel to afford the furan product.

A 10 mL Schlenk tube equipped with a stirrer bar was charged with silyl enol ether (0.20 mmol), Cu(hfacac)₂ (9.6 mg, 0.020 mmol, 10 mol %) followed by the addition of dichloromethane (0.5 mL). A dichloromethane solution (0.5 mL) of diazoketone (0.26 mmol) was added dropwise over 5 min at room temperature. The resulting mixture was then stirred at 40 °C for 6 h. Upon cooling to room temperature, the reaction mixture was diluted with ethyl acetate (5 mL), passed through a pad of silica gel, and concentrated under reduced pressure. The residue was purified by flash chromatography on silica gel to afford the furan product.
