**S** Supporting Information

[AB](#page-9-0)STRACT: [Direct unequ](#page-9-0)al C−H bond difunctionalization of phosphorylated diamantane was achieved in high yield from the corresponding phosphonates. Reduction of the functionalized phosphonates provides access to novel primary and secondary alkyl/aryl diamantane phosphines. The prepared primary diamantyl phosphines are quite air stable compared to their adamantyl and especially alkyl or aryl analogues. This finding is corroborated by comparing the singly occupied molecular orbital energy levels of the corresponding phosphine radical cations obtained by density functional theory computations.

## **ENTRODUCTION**

Naturally occurring diamondoids<sup>1</sup> are nanometer-sized hydrocarbons (i.e., nanodiamonds) with structures resembling the diamond crystal lattice.<sup>2</sup> Higher [d](#page-9-0)iamondoids bridge the gap between simple organic molecules and diamond, possessing some properties of bul[k d](#page-9-0)iamond. Further progress in material applications of diamondoids requires synthesis of functionalized derivatives by introducing strategically placed substituents into their skeleton.<sup>3</sup> For instance, self-assembled monolayers (SAMs) of [121]tetramantane-6-thiol deposited on Ag and Au surfaces dis[p](#page-9-0)lay unusually high negative electron affinities (NEAs).4 However, the metal−sulfur bond breaks at elevated temperatures,<sup>5</sup> and the thiol moiety is therefore not ideal as a surface [a](#page-9-0)ttachment group. One of the ways to solve this problem is [to](#page-9-0) create additional attachment points on the diamondoid (e.g., adamantane tripods bearing several anchoring thiol groups). $6-8$  Alternatively, the thiol group may be replaced with a phosphonate moiety providing thermally stable multival[e](#page-9-0)nt surface [bo](#page-9-0)nding.<sup>9</sup>

Phosphonic acid dichlorides are also ideal starting materials for the preparation of phosp[hi](#page-9-0)nes that are viable building blocks for new materials<sup>3,10</sup> and as ligands in catalysis.<sup>11,12</sup> Phosphines bearing bulky alkyl moieties such as adamantyl (Figure 1) have shown excellent [liga](#page-9-0)nd properties and have [pro](#page-9-0)vided many

advances in terms of scope and efficiency for C−C and C−N bond formation reactions.13−<sup>23</sup>

Preparation of diadamantyl phosphines (e.g., CataCXium (7), Mor-DalPhos (8), F[igure](#page-9-0) 1b) was achieved by reacting halophosphorus compounds with organometallic reagents.14,24−<sup>28</sup> Synthesi[s of hig](#page-1-0)her diamondoid phosphines was accomplished after reduction of di-4-diamantyl and di-9 triama[ntyl p](#page-9-0)[ho](#page-10-0)sphonic acid chlorides using HSiCl<sub>3</sub> with a Lewis acid. The corresponding secondary phosphines 4a and 4b as well as salt 5a were obtained in good yields.<sup>29</sup> Preliminary studies using phosphonium salt 5a as a ligand in C−C bond formation reactions showed promising resul[ts.](#page-10-0)<sup>29</sup> Recently, triadamantyl phosphine metal complexes were synthesized, and their application in cross coupling reactions i[nv](#page-10-0)olving aryl chlorides and boronic acids was reported.<sup>30</sup>

Although primary phosphines have been used as starting materials in asymmetric catalysis,  $31,32$  t[hei](#page-10-0)r applications are limited due to their air sensitivity. $^{33}$  Low molecular weight, lack of steric hindrance, and the abse[nce o](#page-10-0)f a heteroatom in the backbone can even result in [py](#page-10-0)rophoricity of such compounds.<sup>33</sup> The air stability of some primary phosphines (e.g.,

(d) 10 equiv of PCl<sub>3</sub>, 98% H<sub>2</sub>SO<sub>4</sub> at −15 °C for 1 h, 3.5 h at rt. Inset: X-ray crystal structure of 13 (color code: C, gray; H, white; P, orange; O, red; Cl, green). The X-ray crystal structure of 13 was also obtained, and we found bond lengths somewhat shorter than those typical for C−P and O−P bonds (C<sub>apical</sub>–P = 1.813(3) Å, and O−P = 1.463(2) Å).

binaphthyl MOP phosphines) that are neither hindered nor include a heteroatom in their structures<sup>34−36</sup> is due to a high degree of  $\pi$ -conjugation. Bulky substituents also inhibit the reaction with dioxygen, thereby makin[g](#page-10-0) [prim](#page-10-0)ary phosphines more "user friendly". <sup>33</sup> The primary adamantane phosphine 3 (Figure 1), prepared through the reduction of the corresponding phosphonic dichl[or](#page-10-0)ide  $16$ ,  $37$  is very air-sensitive, making its application as a ligand in catalysis challenging. We envisioned that larger diamondoid gr[oup](#page-10-0)s (e.g., diamantane) would substantially increase the air stability of the corresponding primary phosphines. Diamondoid cage substitution changes the electronic properties significantly.<sup>38</sup> We also studied the influence of additional functional groups on the stability of primary diamondoid phosphines. T[his](#page-10-0) requires the preparation of novel phosphorylated diamondoid derivatives via the C−H bond substitution, which is described in the present work.

## ■ RESULTS AND DISCUSSION

Diamondoid Phosphorylations. In contrast to  $1, ^{39,40}$  2 displays two types of tertiary carbons, apical and medial, thus making its selective functionalization by cationic act[ivatio](#page-10-0)n challenging.2,3,10 Therefore, use of protection/deprotection sequences<sup>41-43</sup> is necessary to obtain unequally difunctionalized diamantyl derivatives. Diamondoid phosphonic dichloride derivatives are typically obtained via Lewis acid catalysis,  $37,44$ but the direct monophosphorylation of diamantane in the  $AICI_3/PCI_3/CH_2Cl_2$  system<sup>45</sup> results in mixtures<sup>29</sup> and [low](#page-10-0) yields compared to that of adamantane. We found that employing a Brønsted acid<sup>[46](#page-10-0)−48</sup> gives rise to h[igh](#page-10-0)er yields and, most importantly, that it is applicable to cages larger than adamantane.<sup>49</sup> However, thi[s proc](#page-10-0)edure does not allow for the preparation of unequally disubstituted diamondoids, and in trifluoroacet[ic](#page-10-0) acid, the reaction of 10 resulted only in product 13 (Scheme 1). $49$  This can be understood readily because 10 and all monosubstituted intermediates are soluble in TFA, while 13 preci[pita](#page-10-0)tes from this media. As 10 is only poorly soluble in  $H_2SO_4$ , a variety of products can form. We first tested the phosphorylation of 10 with PCl<sub>3</sub> in concd  $H_2SO_4$ , which gave monophosphorylated derivative 14 in up to 60% yield (with method a, Scheme 1) depending on the reaction conditions.

It has been shown that PCl<sub>3</sub> decomposes rapidly in  $\mathrm{H_2SO_4}^{47}$ Because the reaction proceeds slowly in sulfuric acid due to the low solubility of the substrate, the carbocation can be attack[ed](#page-10-0) by either nucleophile, resulting in chlorination and phosphorylation products. Therefore, we chose a different approach based on C−H bond functionalization (Scheme 2).

#### Scheme 2. C−H Bond Functionalization of Diamondoid Phosphonic Acid Dichlorides

We showed previously that oxidation of diamondoids with 100% nitric acid affects only tertiary positions and can be performed in a kinetically controlled way.<sup>50</sup> While the question of regioselectivity does not arise for 16, diamantane derivative 19 displays three different tertiary C−H [p](#page-10-0)ositions. Moreover, the electron withdrawing group (EWG) deactivates the medial positions, and only the remaining apical position reacts. Consequently, with HNO3, C−H bond functionalization of 19 occurs regioselectively in position 9 (apical) of the diamantane cage. For the medially substituted diamantane phosphonic dichloride 20, C−H bond functionalization occurs at the position farthest from the  $\text{POC1}_2$  group, resulting in a mixture of 1,6- and 1,4- derivatives (24 and 23, respectively).

We also attempted the Brønsted acid catalyzed phosphorylation with two different substituents (alkyl and aryl) present on phosphorus.<sup>46</sup> We chose trifluoroacetic acid to avoid the formation of chlorinated products. The phosphorylation of 4 hydroxydiaman[tan](#page-10-0)e 18 with  $PhPCl<sub>2</sub>$  gave the corresponding phenyl-4-diamantylphosphonic acid chloride (25) in high yield (Scheme 3). Although medially substituted diamantane derivatives are sterically hindered,  $50$  the phosphorylation of 1hydroxydiamantane (26) also proceeded smoothly to give phenyl-1-diamantylphosphonic ac[id](#page-10-0) chloride (27). The phosphonic dichlorides and chlorides described above were used as precursors for primary and secondary diamondoid phosphines.

Primary Diamondoid Phosphines. Commonly used metal catalyzed hydrogenation methods or reducing agents cannot be applied to the reduction of diamondoid phosphonic dichlorides; conversely, use of LiAlH<sub>4</sub> has been reported.<sup>5</sup> Starting from diamantane phosphonic dichlorides 19 and 20, the corresponding primary phosphines 29 and 31 we[re](#page-10-0) obtained. They have different topologies, 29 being less hindered than 31, as the medial position is known to be

Scheme 3. Synthesis of Diamantyl Phosphonic Chlorides

much more crowded than the apical one. $10$  The two primary phosphines 29 and 31 were characterized only by NMR and show the following characteristic signal[s i](#page-9-0)n the  $31P$  NMR:  $\delta_{\rm P}(29) = -85.2$  ppm,  $^{1}J_{\rm PH}(29) = 145$  Hz,  $\delta_{\rm P}(31) = -97.4$  ppm, and  $1_{\rm JPH}(31)$  = 194 Hz, respectively. They were fully characterized via the corresponding Staudinger iminophosphorane derivatives 30 and 32 (Scheme 4). The  ${}^{1}H$  and  ${}^{31}P$  NMR spectra of primary phosphines 29 and 31 show broadening of the signals at room tempera[ture in chlo](#page-3-0)roform-d. To clarify this observation, we undertook further NMR investigation using 31 in various solvents with different additives and at various temperatures (Supporting Information, pages S101−S105). When THF- $d^8$  was used as the solvent, the broadening phenomenon [was not observed, but up](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)on addition of acid, broadening occurred again. Therefore, we concluded that the observed behavior was solely caused by proton exchange at the phosphine.

The primary diphosphine 33 prepared by reduction of diphosphorylated derivative 13 could be fully characterized because it appears to be stable for several minutes in air unlike monophosphine 29. In compound 29, the donor effect of the cage is proposed to influence only one phosphorus atom, thus making it more electron-rich, which is not the case for 33. Therefore, the monosubstituted phosphine should react with oxygen more readily. Primary diphosphine 33 also showed the same signal broadening in  ${}^{1}\text{H}$  and  ${}^{31}\text{P}$  NMR spectra like monophosphines 29 and 31 at room temperature, a consequence of phosphine proton exchange.

Reduction of unequally substituted diamondoids 12, 14, and 17 with LiAlH<sub>4</sub> readily led to primary phosphines 37, 36, and 34, respectively (Scheme 5), similar to the reduction of monophosphorylated and diphosphorylated compounds 19, 20, and 13. Compound 34 is air-sensitive and quantitatively converts to oxide 35[.](#page-3-0) [This](#page-3-0) [resu](#page-3-0)lt is consistent with the reported high air sensitivity of other 1-adamantyl phosphines substituted in position  $3^{52}$ 

An increase in the  $^1J_{\rm PH}$  coupling constant is noticeable when c[om](#page-10-0)paring compounds 29 and 36 ( $\Delta J = 45$  Hz). Despite the large spatial separation along the cage framework between the hydroxy group and the phosphorus, the electron-withdrawing effect is enhanced by hyperconjugation.53−<sup>56</sup> It is know that primary phosphines attached to a backbone containing a heteroatom are more likely to be air sta[ble co](#page-10-0)mpared to their homologues without heteroatoms.<sup>33</sup> This is also the case for compounds 36 and 37 because we found that in solution they were stable for at least 1 h in [air](#page-10-0). Such stability was not observed for the adamantane homologues despite the presence of an EWG. Two EWGs (OH or Cl) seem to provide additional air stability (e.g., compare compounds 3 and 29 with

#### <span id="page-3-0"></span>Scheme 4. Synthesis of Primary Diamantyl Phosphines

Scheme 5. Synthesis of Unequally Substituted Primary Diamondoid Phosphines

34 and 36, respectively). The mechanism of phosphine oxidation by  $O_2$  has not been fully elucidated, but the formation of the radical cation of primary phosphine is a postulated pathway.<sup>34–36</sup> Primary phosphines with extended  $\pi$ electron structural motifs (such as naphthyl, binaphthyl, and triptycenyl) do not [have](#page-10-0) a significant phosphorus contribution to their HOMO and are stable to air oxidation.<sup>35</sup> Even though in our case there is no such conjugated motif, we propose that an increase of bulkiness by the diamantane c[age](#page-10-0) surrounding the phosphorus atom can induce a significant resistance toward air oxidation (compare 34 with 36).

It was suggested that the SOMO level and geometry of the corresponding phosphine radical cation is key for understanding the air stability of the related primary phosphine. $35$  An empirically derived value of -10.0 eV was proposed to be a threshold, and phosphines with radical cation SOMO en[erg](#page-10-0)ies below this value are expected to be easily oxidized in air.<sup>35</sup> This agrees in part with our computed SOMO energies of the radical cations derived from phosphines 3, 29, 33, 34, 36, [an](#page-10-0)d 49

(Figure 2), where these values for relatively air stable 33•<sup>+</sup> (−9.9 eV) and 36•<sup>+</sup> (−10.3 eV) approach the above threshold. [Note that](#page-4-0) the SOMO of  $36^{\bullet+}$  is located predominantly on the oxygen atom of the hydroxy group, which is a complementary explanation for the stability of 36 toward oxidation. As experimentally observed, primary diphosphine 33 also is more stable than primary monophosphine 29. This finding is in agreement with the computed SOMO energies of the radical cations derived from 33 and 29 ( $-9.9$  and  $-11.0$  eV, respectively). We also performed an NBO analysis of spin densities for radical cations derived from primary diamondoid phosphines and found that the spin density on phosphorus is generally smaller for more air stable derivatives (Table S1). These findings are in agreement with the proposed radical mechanism of phosphine oxidation because radical [cations o](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)f stable diamondoid phosphines have spin densities distributed in other parts of the molecule, implying that the spin is not solely localized on the phosphorus atom, resulting in higher resistance to oxidation.

Secondary Diamondoid Phosphines. Secondary diamantane phosphines were also prepared using a  ${\rm LiAlH_4}/$ ethereal system (Scheme 6). In contrast to primary phosphines 29 and 31, only the apical secondary phosphine 38 forms a phosphazo deriv[ative. The](#page-4-0) medial phosphine 39 is unreactive, probably due to steric hindrance caused by the cage in the medial position.<sup>57</sup> The 31P NMR characterization of 38 at room temperature in  $CDCI<sub>3</sub>$  was surprising because no signal was observed. At ar[ou](#page-10-0)nd 240 K, the expected doublet appears at  $-9.5$  ppm  $(^1J_{PH}(38) = 178$  Hz) as well as the corresponding doublet at 3.82 ppm in the <sup>1</sup>H NMR. Fluxional behavior was also observed in the  $^{31}P$  and  $^{1}H$  NMR spectra of 1diamantylphenylphosphine (39), which is only slightly different from those of secondary phosphine 38 because at 273 K the spectrum of 39 indicates a broad singlet at −23.1 ppm. Upon cooling, decoalescence occurs at around 255 K, and at 240 K, the expected doublet is observed at  $-23.9$  ppm  $(^1J_{\rm PH}(39) = 178$ 

<span id="page-4-0"></span>

Figure 2. Shapes and energies (eV) of the SOMOs for the B3LYP/6-311+G(d,p) optimized structures of the radical cations derived from primary phosphines 3, 29, 33, 34, 36, and 49.

Hz). As was the case for primary diamantyl phosphines, proton exchange is responsible for the observed NMR behavior of secondary diamantyl phosphines. For further understanding of phosphines 38 and 39, we performed computational studies and identified their stationary structures for the rotation around the C−P bonds (Figures S1 and S2, pages S111−S112). The results indicate that a planar inversion around phosphorus is not an energetical[ly favorable pathwa](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)y and that the conformers interconvert through a rotation of the diamantane cage or the phenyl group.

Diamondoid Phosphine Postfunctionalization. Conversion of primary diamantane phosphines was explored as a direct synthetic pathway toward functionalized higher analogues. We aimed at exploring whether the direct functionalization of primary diamondoid phosphines would be a feasible method. By refluxing hydroxyphosphine 36 with benzyl bromide, the expected alkylation reaction occurred, but we mainly isolated the phosphonium salt 40 in modest yield (16%, Scheme 7). A characteristic <sup>31</sup>P NMR signal at 27.5 ppm was observed for 40, and its X-ray structure indicates a weak hydrogen bond between the hydroxy group and the bromide O−H…Br  $(d(O-Br) = 3.4239(15)$ ; angle O−H−Br = 162.6°). The observed bond length values for C4−P = 1.835(2) Å and C9−O = 1.429(2) Å were expected and correspond to typical C−P and C−O bonds.

As the direct approach for phosphine functionalization was low-yielding, an indirect strategy was envisioned that would Scheme 7. Benzylation of Unequally Substituted Primary Diamantane Phosphine 36 and the X-ray Single Crystal Diffraction Structure of Phosphonium Salt  $40<sup>a</sup>$ 

a Color code: C, gray; H, white; P, orange; O, red; Br, dark red.

lead to pentacoordinated phosphorus derivatives that could further be reduced.<sup>58,59</sup> We first arylated diamondoid phosphonic dichlorides to obtain the mixed phosphorylated oxides 41−44 (Sche[me 8\)](#page-10-0). In the X-ray crystal structures of 41−44, typical C−P and O−P bond lengths were observed (e.g., C<sub>apical</sub>–P [= 1.833\(2\)](#page-5-0) Å and O–P = 1.500(2) Å for 43). Their reduction was expected to give access to mixed aryl/alkyl diamondoid phosphines.

Unfortunately, adamantyl derivative 41 ( $\delta_{\rm P}$  = 34.3 ppm, in agreement with the literature $^{60}$ ) could not be reduced with  $LiAlH<sub>4</sub>$  in THF or dioxane<sup>51</sup> to the corresponding phosphine, and we did not pursue this lin[e o](#page-10-0)f investigation further with the diamantyl homologues. Ins[tea](#page-10-0)d, we prepared the parent sulfide 46 and selenide 47 that could be readily reduced to the target phosphine 48 in 60% yield (Scheme 9). In the X-ray crystal structure of sulfide 46, we found somewhat longer bond lengths:  $C_{\text{median}}-P = 1.859(2)$  [Å and P](#page-5-0)−S = 1.9717(7) Å.

The  $1_{P=Se}$  (47) = 712 Hz coupling constant is lower than the value for triphenylphosphine selenide ( ${}^{1}J_{P=Se}$  = 730 Hz), which is consistent with an electron-donating effect of the adamantyl group toward phosphorus. Thus, we expect a higher basicity of 48 compared to that of  $\text{PPh}_3$ , rendering this phosphine potentially useful in the catalytic steps of cross-coupling reactions.61−<sup>63</sup> The pathway to 48 using sulfide 46 is the most efficient synthetically (Scheme 9) with an overall yield

<span id="page-5-0"></span>Scheme 8. Arylation of Diamondoid Phosphonic Acid Dichlorides and the X-ray Single Crystal Diffraction Structures of 42, 43, and  $44<sup>a</sup>$ 

from bromide 45 of 27%. Compound 48 has previously been reported as a side-product formed in the photochemical reaction of 1,3-dichloroadamantane with the  $[Ph_2P^-]$  anion in liquid ammonia but had not been isolated (because oxide 41 forms instead). $59$ 

#### ■ CONCLU[SIO](#page-10-0)NS

Direct unequal difunctionalization of phosphorylated diamondoid derivatives avoiding protection/deprotection sequences has now been made possible by C−H bond functionalization without affecting the existing POCl<sub>2</sub> group. Using Brønsted acid catalysis, we prepared unequally substituted diamantyl phosphonic chlorides, which are excellent precursors for the corresponding phosphines. The reduction of phosphonic chlorides described herein provided access to novel primary and alkyl/aryl secondary diamantane phosphines. Primary diamantyl phosphines were found to be surprisingly air stable compared to their adamantyl homologues. We computed diamantyl and adamantyl phosphine radical cation energies and found that the corresponding SOMO levels were close to the air stability threshold of −10 eV. These functionalized diamondoid phosphines are currently being explored in material science and catalytic applications.

## **EXPERIMENTAL SECTION**

General Information. Synthesis of sensitive products was done using Schlenk techniques. Glassware was dried in an oven at 110 °C before use. THF and diethyl ether were prepared by distillation under argon using sodium and benzophenone; dichloromethane (DCM) was purified by distillation under argon using CaH<sub>2</sub>. 1,4-Dioxane was purified by stirring with LiAlH<sub>4</sub> under argon overnight and was then distilled under argon (bp = 101  $^{\circ}$ C). CDCl<sub>3</sub> was dried over activated 4 Å molecular sieves under argon. The other solvents were obtained directly from the manufacturer or distilled from technical grade. Commercially available reagents were used without further purification. TLC was done on 0.2 mm silica gel with fluorescent indicator (precoated polyester sheets  $UV_{254}$  or TLC silica gel 60  $F_{254}$  on aluminum sheets). Column chromatography was done on silica gel (70−230/100−160/230−400mesh ASTM). NMR spectra were recorded at 300, 400, 500, and 600 MHz spectrometers in chloroform (CDCl3) unless stated otherwise with/without TMS as an internal standard.  ${}^{1}H$  and  ${}^{13}C$  NMR assignments were confirmed by DEPT-135/JMOD and sometimes with two-dimensional  ${}^{1}H-{}^{13}C$  NMR experiments. High-resolution mass spectra (HRMS) were recorded using electron impact ionization on a focusing sector field-type mass spectrometer.

Phosphorylation of 4,9-Dihydroxydiamantane (10) in Sulfuric Acid to Prepare Compounds 11, 12, 13, and 14. Concentrated sulfuric acid (98%, 8.5 mL, freshly prepared from oleum 20% and H<sub>2</sub>SO<sub>4</sub> 94%) was cooled to 0 °C or −15 °C. At the respective temperature, 4,9-dihydroxydiamantane (10) (0.880 g, 4 mmol) was added followed by  $\text{PCl}_3$  (PCl<sub>3</sub> was varied according to Scheme 1). The reaction mixture was stirred for 1 h at the corresponding temperature and 3.5 or 6 h at rt. The reaction mixture was slowly poured onto crushed ice. The white precipitate that formed was fi[ltered](#page-1-0) [w](#page-1-0)ith a Bü chner funnel and rinsed with distilled water until reaching a neutral pH; the remaining solid was dried in air. Purification by column chromatography on silica gel with pentane:diethyl ether (3:1) afforded 4,9-dichlorodiamantane (11)  $(R_f = 0.88)$  and (9-chloro-diamant-4yl)phosphonic dichloride (12) ( $R_f = 0.28$ ). Changing the eluent to DCM:diethyl ether (3:1) gave (4,9-diamantyl)diphosphonic dichloride (13)  $(R_f = 0.76)$ . Changing the ratio of the same eluent to 1:1 afforded (9-hydroxydiamant-4-yl)phosphonic dichloride (14)  $(R_f = 0.22)$  as a white solid. Yields are specified in Scheme 1 as a function of the reaction conditions.

4,9-Dichlorodiamantane (11). Sp[ectral data](#page-1-0) were identical to those previously reported.<sup>64</sup>

(4-Diamantyl)phosphonic Dichloride (19). 19 was identical to the material previously obtained through the phosphorylation of 18 in sulfuric acid.<sup>49</sup> The X-ray structure is available in the Supporting Information, page S139.

Another [M](#page-10-0)ethod for Preparing (9-Hydroxydiamant-4-yl) phosphonic Dichloride (14) from 19. Concentrated s[ulfuric acid](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf) [\(96%, 2.5 m](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)L) was placed in a 5 mL round-bottom flask and cooled to −15 °C with an ice-salt bath. 4-Diamantylphosphonic acid dichloride (19) (0.332 g, 1.1 mmol) was added followed by  $HNO<sub>3</sub> 100%$  (0.4 mL, 9.8 mmol, 9 equiv). The reaction mixture was stirred for 1 h at −15 °C and for 7 h at 18 °C. The reaction mixture was poured slowly onto 40 g of crushed ice. DCM (40 mL) was added followed by solid  $NaHCO<sub>3</sub>$  in portions until a neutral pH was reached and the aqueous phase turned clear yellow. It was extracted with DCM  $(3 \times 30 \text{ mL})$ and dried over MgSO<sub>4</sub>. The solvent was evaporated to yield 0.325 g of crude product. It was purified by column chromatography on silica gel using DCM:diethyl ether (1:1) to afford (9-hydroxydiamant-4 yl)phosphonic dichloride (14) (0.242 g, 69% yield) as a white solid.

(3-Hydroxyadamant-1-yl)phosphonic Dichloride (17). In a 10 mL round-bottom flask, 3 mL of  $H_2SO_4$  94% was cooled with an ice-salt bath to −13 °C. 1-Adamantylphosphonic dichloride (16) (1.66 g, 6.6 mmol) was added and stirred until completely dissolved. Then,  $HNO<sub>3</sub>$ 100% (3 mL, 72 mmol, 11 equiv) was slowly added. The solution was stirred for 1 h at −13 °C and for 22 h at rt. The colorless solution was slowly poured onto 15 g of crushed ice. DCM (100 mL) was added, and the mixture was stirred at rt. Solid  $NAHCO<sub>3</sub>$  was added in small portions until no more gas evolution was observed. The aqueous phase was extracted with DCM  $(3 \times 30 \text{ mL})$  and diethyl ether  $(4 \times 40 \text{ mL})$ . The combined organic layers were dried over  $MgSO<sub>4</sub>$ , and the solvent was evaporated and gave a yellow sticky compound. Purification by column chromatography on silica gel in diethyl ether 100% ( $R_f = 0.3$ ) gave pure (3-hydroxyadamant-1-yl)phosphonic dichloride (17) (1.42 g, 80%). The X-ray structure is available in the Supporting Information, page S132. <sup>1</sup>H NMR (400 MHz, 300 K, CDCl<sub>3</sub>):  $\delta$ 2.50−2.36 (m, 2H), 2.04−1.94 (m, 6H), 1.78−1.69 (m, 5H), 1.69− 1.57 (m, 2H) ppm.  $^{13}$ C NMR (100 MHz, 300 K, CDCl<sub>3</sub>):  $\delta$  [68.1 \(d,](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)  $J(C,P) = 19.4 \text{ Hz}, C_a$  $J(C,P) = 19.4 \text{ Hz}, C_a$ , 51.0 (d,  $J(C,P) = 91.3 \text{ Hz}, C_a$ ), 43.9 (d,  $J(C,P)$ )  $= 2.5$  Hz, CH<sub>2</sub>), 42.6 (d, J(C,P) = 4.6 Hz, CH<sub>2</sub>), 34.5 (d, J(C,P) = 2.8 Hz, CH<sub>2</sub>), 34.0 (d,  $J(C,P) = 3.8$  Hz, CH<sub>2</sub>), 30.1 (d,  $J(C,P) = 17.6$  Hz, CH) ppm.  ${}^{31}P{^1H}$  NMR (162 MHz, 300 K, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub> external standard):  $\delta$  62.21 ppm. General Procedure for the Preparation of Diamondoid Phosphines in Benzene/Ether. A solution of the respective diamantylphosphonic acid chloride (1.64 mmol) in dry benzene (8 mL) was added to a mixture of  $LiAlH<sub>4</sub>$  (16.4 mmol, 10 equiv) in dry ether (3.5 mL). The reaction mixture was refluxed for 1−2 h, cooled to 0 °C, and 15 mL of 15% HCl was added dropwise. The aqueous phase was extracted with benzene  $(3 \times 15 \text{ mL})$ . Combined organic phases were washed with water (10 mL) and dried over  $Na<sub>2</sub>SO<sub>4</sub>$ . Evaporation of solvents in vacuo yielded respective phosphine in 70−96% yield.

4-Diamantylphosphine (29). 29 was isolated after 2 h of reflux in  $80\%$   $(0.288 \text{ g})$  yield as a colorless air-sensitive solid. <sup>1</sup>H NMR  $(600$ MHz, CDCl<sub>3</sub>):  $\delta$  2.83 (bs, 1H), 2.51 (bs, 1H), 1.79–1.73 (m, 10H), 1.72−1.70 (bs, 6H), 1.69−1.64 (bs, 3H) ppm. 13C NMR (150 MHz, CDCl<sub>3</sub>):  $\delta$  45.6 (d, CH<sub>2</sub>, J = 21 Hz), 38.2 (d, CH, J = 22 Hz), 37.8  $(CH<sub>2</sub>)$ , 36.3 (CH), 26.9 (d, C, J = 8 Hz), 25.6 (CH) ppm. <sup>31</sup>P NMR (243 MHz, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>):  $\delta$  = -85.2 (t, J = 145 Hz) ppm.

4-Diamantyldimethylphosphazo-p-nitrobenzene (30). To a solution of phosphine 29 (0.34 g, 1.54 mmol) in dry benzene (3 mL) was added 1 mL of methyl iodide, and the mixture was stirred for 3 h under reflux. After being cooled to rt and filtered, the precipitate (0.25 g) was dissolved in ethanol (6 mL), and NaOH (0.4 g, 10 mmol) was added. The mixture was stirred for 1 h at rt; the solvent was removed by distillation, and 3 mL of water was added. The residue was extracted with benzene  $(2 \times 10 \text{ mL})$ , and combined organic extracts

were washed with water and dried over  $Na<sub>2</sub>SO<sub>4</sub>$ . Solvent evaporation gave 0.242 g of a white solid which was dissolved in dry benzene (10 mL); 0.254 g (1.55 mmol) of p-nitrobenzene azide was added, and the solution was heated at 36 °C for 5 min. After completion of the gas evolution  $(N_2)$  and cooling, the yellow precipitate was filtered and washed with benzene to give 4-diamantyldimethylphenylphosphazo-pnitrobenzene (30) as yellow solid (0.320 g, 73%). Mp 285−287 °C (ethyl acetate). <sup>1</sup>H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  8.0-7.8 (m, 2H), 7.70−7.48 (m, 5H), 6.45 (bs, 2H), 2.00−1.80 (m, 9H), 1.83 (s, 3H), 1.75−1.70 (bs, 10H) ppm. <sup>13</sup>C NMR (100 MHz, CDCl<sub>3</sub>): δ 161.5  $(C)$ , 137.2  $(CH)$ , 132.2  $(d, CH, J = 9.0 Hz)$ , 128.9  $(d, CH, J = 10 Hz)$ , 125.7 (CH), 121.8 (bd, CH,  $J = 23$  Hz), 37.5 (CH<sub>2</sub>), 36.5 (d, CH,  $J =$ 14 Hz), 36.3 (CH), 35.2 (CH<sub>2</sub>), 31.3 (d, C, J = 90 Hz), 25.3 (CH), 5.30 (d, CH<sub>3</sub>, J = 55 Hz), ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CDCl<sub>3</sub>,  $H_3PO_4$ ):  $\delta$  21.2 ppm. 1-Diamantylphosphine (31). 31 was prepared after 1 h of reflux in 56% yield as a colorless air-sensitive solid. <sup>1</sup>H NMR (600 MHz, CDCl<sub>3</sub>, TMS): 2.80−2.24 (bs, 2H), 2.24 (AB, 2H,  $J_{AB}$  = 16 Hz), 1.86− 1.78 (m, 4H), 1.74–1.66 (m, 11H), δ 1.56 (AB, 2H,  $J_{AB} = 16$  Hz) ppm. <sup>13</sup>C NMR (150 MHz, CDCl<sub>3</sub>):  $\delta$  48.5 (d, CH<sub>2</sub>, J = 6 Hz), 42.2  $(d, CH, J = 7 Hz)$ , 38.7  $(d, CH<sub>2</sub>, J = 1 Hz)$ , 38.5  $(d, CH, J = 5 Hz)$ , 38.3 (CH<sub>2</sub>), 38.2 (CH<sub>2</sub>), 37.6 (CH), 37.0 (d, C, J = 8 Hz), 34.7 (d, CH, J = 6 Hz), 27.9 (d, CH, J = 6 Hz) ppm.  ${}^{31}P{^1H}$  NMR (243 MHz, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>):  $\delta$ = −97.4 (t, J = 194 Hz) ppm.

1-Diamantyldimethylphosphazo-p-nitrobenzene (32). 32 was prepared as described above (procedure for 30) from 31 in 96% yield (0.357 g) as yellow solid. Mp 162−164 °C (cyclohexane). <sup>1</sup> H NMR (400 MHz, CDCl<sub>3</sub>):  $\delta$  8.0 (d, 2H, J = 8 Hz), 6.52 (d, 2H, J = 8 Hz), 2.63 (AB, 2H,  $J_{AB}$  = 16 Hz), 2.15 (bs, 2H), 2.0 (bs, 1H), 1.9 (bs, 2H), 1.81−1.62 (m, 16H), 1.50 (AB, 2H, J<sub>AB</sub> = 16 Hz) ppm. <sup>13</sup>C NMR (100 MHz, CDCl3): δ 160.2 (C), 128.3 (CH), 125.9 (d, CH, J  $= 1$  Hz), 121.1 (d, CH, J = 18 Hz), 43.4 (d, C, J = 63 Hz), 39.0 (CH<sub>2</sub>), 38.6 (d, CH,  $J = 9$  Hz), 38.5 (CH<sub>2</sub>), 37.5 (d, CH,  $J = 11$  Hz), 37.3 (d, CH<sub>2</sub>, J = 13 Hz), 37.0 (d, CH, J = 2 Hz), 33.8 (CH<sub>2</sub>), 26.1 (d, CH, J = 10 Hz), 24.9 (CH), 12.1 (d, CH<sub>3</sub>,  $J = 61$  Hz) ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>):  $\delta$  26.0 ppm. HRMS (EI):  $m/z$  [M]<sup>+</sup> calcd for  $C_{22}H_{29}N_2O_2P: 384.1967$ ; found: 384.1957.

4,9-Diamantyldiphosphine (33). 4,9-Bis(dichlorophosphoryl) diamantane (13) (0.051 g, 0.12 mmol) was placed in a 5 mL flask under argon and dissolved in 0.5 mL dry THF. The obtained solution was cooled to  $-60$  °C, and 0.30 mL LiAlH<sub>4</sub> (1 M in THF, 2.5 equiv) was added dropwise for 15 min. The mixture was stirred at −20 °C for 1 h and at −10 °C for 4 h. The reaction was quenched with HCl 15% (0.1 mL) followed by extraction with cold dichloromethane (3  $\times$  3 mL) and drying over MgSO<sub>4</sub> under argon. The solvent was removed in vacuo, affording 4,9-diphosphinodiamantan (0.029 g, 85%) as a white powder. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta$  2.72 (d, 2H, J<sub>P−H</sub> = 195 Hz), 1.77 (s, 12H), 1.72 (s, 6H) ppm. 13C NMR (125 MHz, CDCl<sub>3</sub>):  $\delta$  45.2 (s, CH<sub>2</sub>), 37.0 (s, CH), 26.9 (s, C) ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (202 MHz, CDCl<sub>3</sub>):  $\delta$  = −85.4 ppm. HRMS (EI):  $m/z$  [M + H] + calcd for C<sub>14</sub>H<sub>23</sub>P<sub>2</sub> 253.1270; found: 253.1259.

3-Phosphinoadamantan-1-ol (34) and (3-Hydroxyadamant-1 yl)phosphine Oxide (35). (3-Hydroxyadamant-1-yl)phosphonic dichloride (17) (0.054 g, 0.2 mmol) was placed in a 5 mL flask under argon. Thereafter, dry THF (1 mL) was added. The solution was cooled to −78 °C, and LiAlH4 solution (1 mL, 1 M in THF, 1 mmol, 5 equiv) was slowly added at −78 °C. The colorless solution was stirred for 4 h at −78 °C and for 1 h at rt. Distilled water (1 mL) was added followed by extraction with DCM (total 10 mL) and drying over MgSO4. The solvent was evaporated to yield white air-sensitive solid compound 34 (0.034 g, 92%) that was stored under argon. When put in contact with air for 5 min, the product was quantitatively oxidized into (3-hydroxyadamant-1-yl)phosphine oxide 35.

3-Phosphinoadamantan-1-ol  $(34)$ .  $^{1}$ H NMR (600 MHz, 300 K,  $C_6D_6$ ): δ 2.70 (d, J(H,P) = 188 Hz, 2H), 1.91–1.83 (m, 2H), 1.59 (d, J = 4.2 Hz, 2H), 1.53−1.4 (m, 8H), 1.32−1.23 (m, 2H), 1.16 (s, 1H, OH) ppm. <sup>13</sup>C NMR (150 MHz, 300 K, C<sub>6</sub>D<sub>6</sub>):  $\delta$  67.8 (d, J(C,P) = 8.7 Hz, C<sub>q</sub>), 52.8 (d, J(C,P) = 7.8 Hz, CH<sub>2</sub>), 44.3 (s, CH<sub>2</sub>), 43.6 (d,  $J(C,P) = 8.8$  Hz, CH<sub>2</sub>), 35.0 (s, CH<sub>2</sub>), 31.6 (d,  $J(C,P) = 8.4$  Hz, CH), 31.5 (d,  $J(C, P) = 4.8$  Hz,  $C_q$ ) ppm. <sup>31</sup>P NMR (243 MHz, 300 K,  $(C_6D_6)$ : δ= -85.97 (t, <sup>1</sup>J(P,H)<sup>-</sup>= 188.5 Hz) ppm.

(3-Hydroxyadamant-1-yl)phosphine Oxide (35). <sup>1</sup>H NMR (600 MHz, 300 K, CDCl<sub>3</sub>):  $\delta$  7.15 (d, J(H,P) = 452.8 Hz, 2H), 2.40–2.34 (m, 2H), 1.95−1.67 (m, 13H) ppm. 13C NMR (150 MHz, 303 K, CDCl<sub>3</sub>):  $\delta$  67.7 (d, J(C,P) = 15.7 Hz, C<sub>q</sub>), 44.5 (s, CH<sub>2</sub>), 42.1 (s, CH<sub>2</sub>), 36.8 (d, J(C,P) = 72.7 Hz, C<sub>q</sub>), 35.1 (d, J(C,P) = 2.2 Hz, CH<sub>2</sub>), 33.6 (s, CH<sub>2</sub>), 30.0 (d,  $J(C,P) = 13.4$  Hz, CH) ppm. <sup>31</sup>P NMR (243) MHz, 303 K, CDCl<sub>3</sub>):  $\delta$  25.71 (t, <sup>1</sup>J(P,H) = 452.8 Hz) ppm.

9-Phosphinodiamantan-4-ol (36). 9-Hydroxydiamant-4-yl phosphonic dichloride (14) (0.050 g, 0.16 mmol) was placed in a 5 mL two-neck flask under argon and cooled to a temperature between −78 and −60 °C while 0.5 mL dry THF was added. The LiAlH<sub>4</sub> solution (0.19 mL, 1 M in THF, 0.2 mmol, 1.3 equiv) was added dropwise for 10 min. The mixture was stirred at −10 °C for 5 h. The reaction was quenched with HCl (5%, 0.5 mL) followed by extraction with cold dichloromethane  $(3 \times 3 \text{ mL})$  and drying over MgSO<sub>4</sub>. The solvent was removed in vacuo, affording 9-phosphinodiamantan-4-ol (36) (0.028 g, 76%) as a white powder. <sup>1</sup>H NMR (500 MHz, CDCl<sub>3</sub>):  $\delta$ 2.68 (d, 2H, J<sub>P−H</sub> = 192.85 Hz), 1.93–1.86 (m, 3H), 1.82–1.78 (m, 6H), 1.77−1.71 (m, 3H), 1.71−1.67 (m, 6H), 1.52 (br, 1H, OH) ppm. 13C NMR (125 MHz, CDCl3): <sup>δ</sup> 67.3 (s, C), 45.3 (s, CH2), 44.6 (d,  $CH<sub>2</sub>$  J = 8.75 Hz), 38.7 (s, CH), 37.1 (d, CH, J = 8.75 Hz), 26.9 (d, C,  $J = 2.5$  Hz) ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (202 MHz, CDCl<sub>3</sub>):  $\delta = -85.7$  ppm. HRMS (EI):  $m/z$  [M] <sup>+</sup> calcd for C<sub>14</sub>H<sub>21</sub>OP 236.1330; found: 236.1340.

(9-Chlorodiamant-4-yl)phosphine (37). (9-Chlorodiamant-4-yl) phosphonic dichloride (12) (0.051 g, 0.15 mmol) was placed in a 5 mL flask under argon and dissolved in 0.5 mL of dry THF. The obtained clear solution was cooled to  $-40$  °C, and 0.15 mL LiAlH<sub>4</sub> (1 M in THF, 1.2 equiv) was added dropwise for 10 min. The mixture was stirred at −10 °C for 4.5 h. The reaction was quenched with HCl (5%, 0.5 mL) followed by extraction with cold dichloromethane ( $3 \times 3$ ) mL) and drying over MgSO<sub>4</sub>. The solvent was removed in vacuo, affording (9-chlorodiamant-4-yl)phosphine (37) (0.030 g, 79%) as a white powder. <sup>1</sup>H NMR (600 MHz, CDCl<sub>3</sub>):  $\delta$  2.70 (d, 2H, J<sub>P−H</sub> = 192 Hz), 2.12−2.11 (m, 6H), 1.89 (br s, 3H), 1.82 (br s, 3H), 1.80− 1.78 (m, 6H) ppm. <sup>13</sup>C NMR (150 MHz, CDCl<sub>3</sub>):  $\delta$  67.3 (s, C), 47.7  $(s, CH<sub>2</sub>)$ , 44.4  $(d, CH<sub>2</sub>, J = 9 Hz)$ , 39.5  $(s, CH)$ , 36.6  $(d, CH, J = 7.5$ Hz), 26.6 (s, C) ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (243 MHz, CDCl<sub>3</sub>): −85.9 ppm. HRMS (EI):  $m/z$  [M + O + Na] <sup>+</sup> calcd for C<sub>14</sub>H<sub>20</sub>ClNaOP 293.0833; found: 293.0832.

4-Diamantylphenylphosphine (38). 38 was isolated in 85% yield as a white solid using the general procedure for the preparations of diamondoid phosphines in benzene/ether. Mp 96−98 °C. <sup>1</sup> H NMR  $(600 \text{ MHz}, 223 \text{ K}, \text{CDCl}_3): \delta 7.50 - 7.40 \text{ (m, 2H)}, 7.30 - 7.23 \text{ (bs, 3H)},$ 3.87 (d, 1H,  $J_{P-H}$  = 218 Hz), 1.80−1.71 (bs, 5H), 1.70−1.56 (m, 14H) ppm. <sup>13</sup>C NMR (150 MHz, 248 K, CDCl<sub>3</sub>):  $\delta$  135.5 (d, CH, J = 14 Hz), 132.2 (d, C, J = 12 Hz), 128.1 (CH), 127.8 (d, CH, J = 6 Hz), 42.2 (d, CH<sub>2</sub>,  $J = 9$  Hz), 38.2 (d, CH,  $J = 8$  Hz), 37.7 (CH<sub>2</sub>), 36.2 (CH), 25.4 (CH) ppm.  $^{31}P$  NMR (243 MHz, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>):  $\delta$ = −8.6 (bs, 293 K, d, J = 216.6 Hz, 243 K) ppm. HRMS (EI): m/z [M] <sup>+</sup> calcd for  $C_{20}H_{25}P$ : 296.1694; found: 296.1692.

1-Diamantylphenylphosphine (39). 39 was isolated in 75% yield as a colorless solid using the general procedure for the preparations of diamondoid phosphines in benzene/ether. Mp 147–148 °C. <sup>1</sup>H NMR  $(400 \text{ MHz}, 253 \text{ K}, \text{CDCl}_3): \delta 7.42 \text{ (m, 2H)}, 7.31 \text{ (m, 3H)}, 4.10 \text{ (d,$ 1H,  $J_{P-H}$  = 144 Hz), 2.62 (AB, 2H,  $J_{AB}$  = 12 Hz), 1.82–1.71 (m, 4H), 1.70−1.43 (m 17H), ppm. <sup>13</sup>C NMR (100 MHz, 253 K, CDCl<sub>3</sub>): δ 135.8 (d, CH, J = 10 Hz), 133.1 (d, C, J = 11.5 Hz), 128.1 (CH), 127.9 (d, CH, J = 4.8 Hz), 43.8 (d, CH<sub>2</sub>, J = 1.8 Hz), 39.7 (d, CH, J = 3 Hz), 39.3 (d, C, J = 9 Hz), 38.9 (d, CH<sub>2</sub>, J = 1.8 Hz), 38.8 (d, CH, J  $= 9$  Hz), 38.6 (d, CH,  $J = 2$  Hz), 38.3 (CH<sub>2</sub>), 38.2 (d, CH,  $J = 5$  Hz), 37.9 (CH<sub>2</sub>), 37.7 (CH<sub>2</sub>), 37.2 (d, CH, J = 4 Hz), 33.9 (d, CH<sub>2</sub>, J = 5.5 Hz), 33.6 (d, CH<sub>2</sub>,  $J = 5.5$  Hz), 27.3 (d, CH,  $J = 3$  Hz), 26.3 (CH) ppm.  ${}^{31}P$  NMR (162 MHz, 253 K, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub>, 235 K):  $\delta$ = -24.0 (d, J = 144 Hz) ppm. Tribenzyl(9-hydroxydiamantan-4-yl)phosphonium Bromide (40). 9-Phosphinodiamantan-4-ol (36) (0.050 g, 0.21 mmol) and dry toluene (2 mL) were placed under argon in a 5 mL flask equipped with a reflux system. Benzyl bromide (0.06 mL, 0.50 mmol, 2.4 equiv) was slowly added at rt. The resulting colorless solution was heated at 100 °C for 16 h; a white precipitate formed, which was filtered and rinsed with toluene and diethyl ether and dried in air. Purification by column chromatography on silica gel with eluent diethyl ether: methanol (3:1) gave tribenzyl(9-hydroxydiamantan-4-yl)phosphonium bromide (40). The crystals were grown in ethanol (0.020 g, 16%); the X-ray structure is available in the Supporting Information, page S165. <sup>1</sup>H NMR (600 MHz, 300 K, CD<sub>3</sub>OD)  $\delta$  7.43–7.37 (m, 9H), 7.22– 7.17 (m, 6H), 3.84 (d, J = 13.3 Hz, 6H), 1.99−1.94 (m, 6H), 1.94− 1.90 (m, 3H), 1.88–1.83 (m, 3H), 1.69 (d,  $J = 2.7$  $J = 2.7$  $J = 2.7$  $J = 2.7$  [Hz,](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf) [6H](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)) ppm. <sup>13</sup>C NMR (150 MHz, 300 K, CD<sub>3</sub>OD):  $\delta$  132.1 (d, J(C,P) = 4.8 Hz, CH), 130.7 (d,  $J(C,P) = 2.3$  Hz, CH), 129.8 (d,  $J(C,P) = 3.1$  Hz, CH), 129.7  $(d, J(C,P) = 8.2$  Hz, Cq), 66.9 (s, Cq), 45.3 (s, CH<sub>2</sub>), 39.4 (s, CH), 36.8 (d,  $J(C, P) = 10.3$  Hz, CH), 35.5 (s, CH<sub>2</sub>), 25.1 (d,  $J(C, P) = 41.3$ Hz, CH<sub>2</sub>) ppm.  ${}^{31}P{^1H}$  NMR (243 MHz, 300 K, CD<sub>3</sub>OD):  $\delta$  27.51 ppm.

1-Adamantyldiphenylphosphine Oxide (41). 1-Adamantylphophonic dichloride (16) (1.01 g, 4 mmol) and 15 mL of freshly distilled dry THF were placed under argon in a 50 mL flask equipped with a reflux system. The mixture was cooled to  $-78$  °C; phenyllithium (5.0 mL, 1.8 M in dibutyl ether, 9 mmol, 2.25 equiv) was slowly added with a syringe, and the solution was stirred for 30 min at the same temperature, for 40 min at rt, and for 24 h at 60 °C. Distilled water (10 mL) was added, and the water phase was extracted with diethyl ether  $(3 \times 20 \text{ mL})$  and DCM  $(3 \times 20 \text{ mL})$ . The combined organic phases were dried over  $MgSO_4$ , and the solvent was evaporated to yield the crude product. Purification by column chromatography on silica gel was performed first with pentane as the eluent and then with diethyl ether:ethanol (9:1). A second column chromatography on silica gel was done with diethyl ether:methanol (9:1) but failed to remove all of the impurities. The fractions containing the product were then recrystallized from warm methanol  $(60 °C)$  to give pure 1-adamantyldiphenylphosphine oxide  $(41)$ (0.772 g, 57%). The X-ray structure is available in the Supporting Information, page S170. <sup>1</sup>H NMR (400 MHz, 296 K, CDCl<sub>3</sub>):  $\delta$  8.06– 7.91 (m, 4H), 7.63−7.43 (m, 6H), 2.03−1.88 (m, 9H), 1.80−1.60 (m, 6H) ppm. <sup>13</sup>C NMR (100 MHz, 300 K, CDCl<sub>3</sub>):  $\delta$  132.4 (d, J[\(C,P\) =](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf) [7.9 Hz, CH\)](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf), 131.5 (d, J(C,P) = 2.6 Hz, CH), 130.8 (d, J(C,P) = 90.0 Hz, C<sub>q</sub>), 128.4 (d, J(C,P) = 10.9 Hz, CH), 37.2 (d, J(C,P) = 72.5 Hz, C<sub>a</sub>), 36.6 (d, J(C,P) = 1.3 Hz, CH<sub>2</sub>), 35.5 (d, J(C,P) = 1.8 Hz, CH<sub>2</sub>), 27.7 (d, J(C,P) = 10.3 Hz, CH) ppm.  ${}^{31}P{^1H}$  NMR (162 MHz, 296 K, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub> external standard):  $\delta$  34.30 ppm. HRMS (EI):  $m/z$ [M]  $^{+}$  calcd for C<sub>22</sub>H<sub>25</sub>PO: 336.1643; found: 336.1640. Anal. calcd for  $C_{22}H_{25}PO: C, 78.55; H, 7.49, found: C, 78.44; H, 7.58.$ 

(3-Hydroxyadamant-1-yl)diphenylphosphine Oxide (42). (3- Hydroxyadamant-1-yl) phosphonic dichloride (17) (0.269 g, 1 mmol) and fresh distilled dry THF (9 mL) were placed under argon in a two-neck 25 mL flask cooled to −78 °C. Phenyllithium (1.8 mL, 1.8 M in dibutylether, 3.3 mmol, 3.25 equiv) was slowly added with a syringe. The mixture was stirred for 1 h at −78 °C and further for 18 h at rt. Distilled water (4.5 mL) was added, and the water phase was extracted with diethyl ether (30 mL) and DCM (30 mL). The combined organic phases were dried over  $MgSO_4$ ; the solvent was evaporated, and the crude compound (0.302 g) was obtained. It was recrystallized from DCM/hexane to obtain crystals of 42 (0.269 g, 76%). The X-ray structure is available in the Supporting Information, page S174. <sup>1</sup>H NMR (600 MHz, 294 K, CDCl<sub>3</sub>): δ 7.98−7.93 (m, 4H), 7.56−7.51 (m, 2H), 7.51−7.45 (m, 4H), 2.28−2.21 (m, 2H), 1.96 (s, 1H, OH), 1.89 (d, J = 5.4 Hz, 2H), 1.87−[1.75](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf) [\(m,](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf) [4H\),](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf) [1.66](http://pubs.acs.org/doi/suppl/10.1021/acs.joc.6b01219/suppl_file/jo6b01219_si_001.pdf)  $(AB_{q} \Delta \delta_{AB} = 0.03, J_{AB} = 12$  Hz, 4H), 1.55 (s, 2H) ppm. <sup>13</sup>C NMR  $(150 \text{ MHz}, 294 \text{ K}, \text{CDCl}_3): \delta 132.4 \text{ (d, } J(C,P) = 8.4 \text{ Hz}, \text{ CH}), 131.7$  $(d, J(C,P) = 2.9$  Hz, CH), 130.3  $(d, J(C,P) = 91.1$  Hz, C<sub>q</sub>), 128.5  $(d,$  $J(C,P) = 11.1$  Hz, CH), 68.1 (d,  $J(C,P) = 12.5$  Hz,  $C_q$ ), 44.4 (s, CH<sub>2</sub>), 43.1 (s, CH<sub>2</sub>), 40.4 (d, J(C,P) = 72.0 Hz, C<sub>q</sub>), 35.1 (s, CH<sub>2</sub>), 34.3 (s, CH<sub>2</sub>), 30.3 (d,  $J(C,P) = 11.3$  Hz, CH) ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (243) MHz,294 K, CDCl<sub>3</sub>):  $\delta$  32.38 ppm.

4-Diamantyldiphenylphosphine Oxide (43). 4-Diamantylphophonic dichloride (19) (0.122 g, 0.4 mmol) and 1.5 mL of fresh distilled dry THF were placed under argon in a 5 mL flask. The mixture was cooled to −78 °C, and phenyllithium (0.5 mL, 1.8 M in dibutyl ether, 0.9 mmol, 2.25 equiv) was slowly added with a syringe. The mixture was stirred for 4 h at the same temperature and for 42 h at rt. Distilled water  $(1 \text{ mL})$  was added followed by saturated NH<sub>4</sub>Cl (3 mL) and diethyl ether (10 mL). The water phase was extracted with diethyl ether  $(2 \times 10 \text{ mL})$  and dichloromethane  $(3 \times 10 \text{ mL})$ . The combined organic phases were dried over  $MgSO<sub>4</sub>$ , and the solvent was evaporated. It was recrystallized from warm methanol (60 °C) to yield pure 4-diamantyldiphenylphosphine oxide (43) (0.042 g, 31%). The X-ray structure is available in the Supporting Information, page S180. <sup>1</sup>H NMR (400 MHz, 295 K, CDCl<sub>3</sub>):  $\delta$  8.03–7.91 (m, 4H), 7.58–7.42 (m, 6H), 2.00−1.85 (m, 6H), 1.80 (br s, 3H), 1.75 (m, 1H), 1.72− 1.55 (m, 9H) ppm. <sup>13</sup>C NMR (1[00](#page-9-0) [MHz,](#page-9-0) [296](#page-9-0) [K,](#page-9-0) CDCl<sub>3</sub>): δ 132.4 (d,  $J(C,P) = 8.1$  Hz, CH), 131.6 (d,  $J(C,P) = 2.6$  Hz, CH), 130.7 (d,  $J(C,P)$  = 73.1 Hz, C<sub>q</sub>), 128.4 (d,  $J(C,P)$  = 10.8 Hz, CH), 37.7 (d,  $J(C,P) = 1.5$  Hz, CH<sub>2</sub>), 36.8 (d,  $J(C,P) = 11.3$  Hz, CH), 36.4 (s, CH<sub>2</sub>), 35.2 (d,  $J(C,P) = 72.8$  Hz,  $C_q$ ), 25.48 (s, CH) ppm. <sup>31</sup>P{<sup>1</sup>H} NMR (162 MHz, 296 K, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub> external standard):  $\delta$  35.02 ppm. (9-Hydroxydiamant-4-yl)diphenylphosphine Oxide (44). (9-Hydroxydiamant-4-yl) phosphonic dichloride (14) (0.161 g, 0.5 mmol) and 4.5 mL of freshly distilled dry THF were placed under argon in a 50 mL two-neck flask. It was cooled to  $-78$  °C, and phenyllithium (0.9 mL, 1.8 M in dibutyl ether, 1.6 mmol, 3.25 equiv) was slowly added with a syringe. The mixture was stirred for 1 h at the same temperature and for 18.5 h at rt. Distilled water (4 mL) was added, and the water phase was extracted with diethyl ether (40 mL) and DCM (40 mL). The combined organic phases were dried over  $MgSO_4$ , and the solvent was evaporated. Recrystallization from warm MeOH at 60 °C yielded crystals that were rinsed with cold MeOH to obtain pure colorless crystals of 44 (0.019 g, 10%). The X-ray structure is available in the Supporting Information, page S186. <sup>1</sup>H NMR (400 MHz, 270 K, CDCl3): δ 8.20−7.86 (m, 4H), 7.71−7.42 (m, 6H), 2.05 (br s, OH), 2.01−1.92 (m, 6H), 1.88 (br s, 3H), 1.81 (br s, 3H), 1.77−1.59 (m, 6H) ppm. <sup>13</sup>C NMR (100 MHz, 270 K, CDCl<sub>3</sub>):  $\delta$  132.4 (d,  $J(C,P)$  = 8.1 Hz, CH), 131.9 (d,  $J(C,P) = 2.5$  Hz, CH), 128.5 (d,  $J(C,P) = 11.0$ Hz, CH), 67.1(s, C<sub>q</sub>), 45.1 (s, CH<sub>2</sub>), 38.8 (s, CH), 35.7(d, J(C,P) = 11.2 Hz, CH), 35.4 (s, CH<sub>2</sub>) ppm.  ${}^{31}P{^1H}$  NMR (162 MHz, 270 K, CDCl<sub>3</sub>):  $\delta$  35.96 ppm. HRMS (EI):  $m/z$  [M] <sup>+</sup> calcd for C<sub>26</sub>H<sub>29</sub>O<sub>2</sub>P: 404.1905; found: 404.1901.

1-Adamantyldiphenylphosphine Sulfide (46). First step: In a twoneck flask containing 20 mL of dry THF and lithium (0.240 g), distilled chlorodiphenylphosphine (0.9 mL, 5 mmol) was added under argon, and the mixture was stirred at rt for 19 h. The remaining Li was removed with forceps. Second step:1-Bromoadamantane (45) (1.08 g, 5 mmol, 1 equiv) in dry THF (10 mL) was added into the reaction mixture over 20 min at −78 °C and stirred for 2 h at the same temperature and for 5 days at rt. Third step: Sulfur powder (0.160 g, 5 mmol, 1 equiv) was added at rt, and the solution was stirred under argon for 3 h. The solvent was evaporated, and diethyl ether (60 mL) was added followed by distilled water. The mixture was extracted three times with DCM and dried over MgSO<sub>4</sub> and, after solvent evaporation, yielded white crystals (0.793 g, 45%). Note: using sodium (first step lasting 2.5 days) yielded 18% (0.317 g) of 46. The X-ray structure is available in the Supporting Information, page S191. <sup>1</sup>H NMR (300 MHz, 300 K, CDCl<sub>3</sub>): δ 8.12−7.99 (m, 4H), 7.55−7.39 (m, 6H), 2.08−1.95 (m, 9H), 1.76−1.59 (m, 6H) ppm. 13C NMR (75 MHz, 300 K, CDCl<sub>3</sub>):  $\delta$  133.5 (d, J[\(C,P\) = 8.9](#page-9-0) Hz, CH), 131.3 (d, J(C,P) = 2.9 Hz, CH), 130.4 (d,  $J(C,P) = 73.1$  Hz, C<sub>q</sub>), 128.2 (d,  $J(C,P) = 11.2$ Hz, CH), 39.2 (d,  $J(C,P) = 50.2$  Hz,  $C_q$ ), 36.4 (s, CH<sub>2</sub>), 28.2 (d,  $J(C,P) = 10.6$  Hz, CH) ppm. <sup>31</sup>P NMR (121 MHz, 300 K, CDCl<sub>3</sub>,  $H_3PO_4$  external standard):  $\delta$  56.33 (t, <sup>1</sup>J(P,C) = 35.7 Hz) ppm. HRMS (EI):  $m/z$  [M] <sup>+</sup> calcd for C<sub>22</sub>H<sub>25</sub>PS: 352.1415; found: 352.1410. Anal. calcd for C<sub>22</sub>H<sub>25</sub>PS: C, 74.97; H, 7.15. found: C, 74.89; H, 7.06.

1-Adamantyldiphenylphosphine Selenide (47). First step: In a two-neck flask containing dry THF (20 mL) and lithium (0.090 g), distilled chlorodiphenylphosphine (0.9 mL, 5 mmol) was added under argon, and the mixture was stirred at rt for 17 h. The remaining Li was <span id="page-9-0"></span>removed with forceps. Second step: 1-Bromoadamantane (45) (5 mmol, 1.08 g, 1 equiv) in 20 mL of dry THF was added into the reaction mixture over 20 min at −78 °C and stirred for 1 h at the same temperature and for 7 days at rt. Third step: Selenium powder (0.395 g, 5 mmol) was added at rt, and the mixture was stirred under argon for 3 h. The solvent was evaporated; distilled water was added, and it was then extracted with DCM, dried over  $MgSO_4$ , and filtered. The solvent was evaporated to afford 1.95 g of yellow oil. Diethyl ether (5 mL) was added, and the resulting white solid was separated, rinsed with pentane, and dried in air  $(0.679 \text{ g}, 34\%)$ . <sup>1</sup>H NMR  $(300 \text{ MHz},$ 297 K, CDCl<sub>3</sub>): δ 8.10−7.96 (m, 4H), 7.55−7.38 (m, 6H), 2.09−1.96 (m, 9H), 1.76−1.59 (m, 6H) ppm. 13C NMR (75 MHz, 297 K, CDCl<sub>3</sub>):  $\delta$  134.1 (d, J(C,P) = 8.9 Hz, CH), 131.3 (d, J(C,P) = 2.9 Hz, CH), 129.3 (d,  $J(C,P) = 65.7$  Hz,  $C_q$ ), 128.2 (d,  $J(C,P) = 11.3$  Hz, CH), 38.7 (d,  $J(C,P) = 40.6$  Hz,  $C_q$ ), 36.9 (s, CH<sub>2</sub>), 36.4 (s, CH<sub>2</sub>), 28.3 (d,  $J(C,P) = 10.4$  Hz, CH) ppm. <sup>31</sup>P NMR (121 MHz, 297 K, CDCl<sub>3</sub>, H<sub>3</sub>PO<sub>4</sub> external standard):  $\delta$  53.66 (t, <sup>1</sup>J(P,Se) = 712.3 Hz) ppm.

1-Adamantyldiphenylphosphine (48). Method A: 1-Adamantyldiphenylphosphine sulfide  $(46)$   $(0.053$  g, 0.15 mmol), LiAlH<sub>4</sub>  $(0.017$  g, 0.45 mmol, 3 equiv), and dry 1,4-dioxane (6 mL) were placed under argon in a Schlenk tube equipped with a reflux system, and the mixture was refluxed for 24 h. The reaction mixture was cooled and filtered under argon and rinsed with dry 1,4-dioxane (3 mL), and the solvent was evaporated. A very air-sensitive white solid was obtained (0.029 g, 60%). Any contact with air oxidizes 48 to 1-adamantyldiphenylphosphine oxide (41). Method B: 1-Adamantyldiphenylphosphine selenide  $(47)$  (0.060 g, 0.15 mmol), LiAlH<sub>4</sub> (0.017 g, 0.45 mmol, 3 equiv), and dry 1,4-dioxane (6 mL) were placed under argon in a Schlenk tube equipped with a reflux system, and the mixture was refluxed for 24 h. The reaction mixture was cooled, filtered under argon, rinsed with dry 1,4-dioxane (3 mL), and the solvent was evaporated. A very airsensitive white solid 48 was obtained (0.029 g, 60%). Any contact with air oxidizes 48 to 1-adamantyldiphenylphosphine oxide  ${\bf (41)}.$   $^1{\rm H}$  NMR  $(400 \text{ MHz}, 270 \text{ K}, \text{CDCl}_3): \delta 7.66 - 7.57 \text{ (m, 4H)}, 7.39 - 7.30 \text{ (m, 6H)},$ 1.99−1.91 (m, 3H), 1.88−1.79 (t, 6H), 1.75−1.61 (m, 6H) ppm. 13C NMR (100 MHz, 270 K, CDCl<sub>3</sub>):  $\delta$  135.7 (d, J(C,P) = 17.5 Hz, C<sub>a</sub>), 135.1 (d,  $J(C,P) = 20.0$  Hz, CH), 128.6 (s, CH), 128.1 (d,  $J(C,P) =$ 7.2 Hz, CH), 39.9 (d,  $J(C,P) = 11.3$  Hz, CH<sub>2</sub>), 36.9 (s, CH<sub>2</sub>), 34.6 (d,  $J(C,P) = 14.2$  Hz, C<sub>a</sub>), 28.8 (d,  $J(C,P) = 9.0$  Hz, CH) ppm. <sup>31</sup>P NMR  $(162 \text{ MHz}, 270 \text{ K}, \text{CDCl}_3): \delta$  16.25 ppm.

## ■ ACKNOWLEDGMENTS

This work was supported by the "Conseil Régional de Bourgogne" (Grant PARI-IME SMT08) and by the CNRS and Université de Bourgogne (Grant 3MIM-P4, Nanodiamonds Functionalization and Metallization project). The work in Giessen was supported in part by the United States Department of Energy, Office of Science, Basic Energy Sciences, Materials Sciences and Engineering Division, under Contract DE-AC02-76SF00515. The work in Kiev was supported by the Ukrainian Basic Research Foundation, Ministry of Science and Education of Ukraine. M.Š. would like to thank the Alexander-von-Humboldt Foundation for a Humboldt Research Fellowship for Postdoctoral Researchers. O.M. would also like to thank Natalie Fokina and Boryslav Tkachenko for fruitful discussions and help concerning diamondoid synthesis.
