Supporting Information

ABSTRACT: The reactions of a series of 1-halopolyynes with secondary amines led to novel amine end-capped polyynes exhibiting surprisingly high stability toward moisture. The new compounds were characterized by NMR spectroscopy, ESI-MS spectrometry, and X-ray single-crystal diffractometry. The use of amine end-capped polyynes as precursors to substituted pushpull thiophenes was next presented. The results show the first-to the best of our knowledge-transformation of ynamine to thiophene and the first regioselective transformation of a longer polyynes to butadiyne-substituted thiophene. Photophysical studies of the resulting compounds show that some of the substituted thiophenes have high quantum yield photoluminescence upon UV light irradiation.

INTRODUCTION

Polyynes and cumulenes have attracted an undiminished interest from the scientific community for more than half a century and a plethora of diverse compounds of this type have been synthesized to date.¹ These linear carbon rods are regarded as model compounds of hypothetical allotropic form of carbon-carbyne and they have significant application potential. Such molecules have been explored as molecular wires and switches in nanoelectronics,² as materials for optoelectronics (due to their nonlinear optical response),³ or as precursors for conducting polymers.⁴ Furthermore, polyynes exist in interstellar matter.⁵

Although ynamides are widely used as building blocks in organic synthesis,⁶ ynamines remain much less explored due to problems with their handling and purification^{6,7} owing to their high moisture sensitivity. In the literature, the hydrolytic instability of ynamines has even been described as follows: "it makes ynamine chemistry inaccessible".7c However, in situ generated, they are useful tools in organic synthesis and are used for instance in amide,⁸ thioamide,⁹ and substituted naphthalene¹⁰ syntheses.

Ynamines may be prepared via three general routes: elimination, substitution, or isomerization.^{7a} While the synthesis of ynamines via the reaction of 1-haloalkynes with secondary amines is known, the method has hardly been used and to date, the scope of the reaction has not been explored. A most probable reason for the low interest in this reaction was that it can give up to three types of unstable products: ynamines, 1,1-diaminoethenes, and 1,2-diaminoethenes (see Scheme 1) where the final structure of the main compound is strongly correlated with the electronic properties of an alkyne, steric bulkiness of an amine and, of course, reaction conditions.^{7a,11}

Ynamines or ynamides containing $(C \equiv C)_2$ or a longer polyyne fragment directly bound to nitrogen are very rare. Some older works reporting the synthesis of butadiyne,¹² hexatriyne,¹³ and octatetrayneamines¹⁴ with the use of perchlorobutenyne precursors and *n*-butyllithium are known, but usually harsh reaction conditions were needed and characterization of the final products was very poor. Nevertheless, some butadiyne-substituted amines were tested in 1,ntopochemical polymerization¹⁵ or were used for cyclization reactions.¹⁶ Moreover, interesting push-pull ynamide polyynes with up to four acetylenic units are known.¹

As reported above, the structures of products of a reaction between 1-halopolyynes and secondary amines were not obvious. Some of the older results suggested that 1bromobutadiynes react with secondary amines giving products of multiple amination.¹⁸ However, Guillemin and co-workers¹⁹ accidentally synthesized a butadiynyl-substituted amine via a similar reaction and proved that products of a simple substitution are possible. Nevertheless, there is no detailed investigation on the reactivity of 1-halopolyynes with secondary amines and the ultimate goal of this work was to fill this gap.

Our recent research interests have focused on the synthesis and reactivity of 1-halopolyynes.²⁰ To date, we have explored their reactivity in the synthesis of organometallic polyynes²¹ or in the mechanochemical synthesis of pyrrole end-capped polyynes.²² Herein, we present a simple and versatile procedure that leads from 1-halopolyynes to the isolable and surprisingly stable amine end-capped polyynes. Moreover, the use of the resulting rod-like amines as substrates for regioselective synthesis of push-pull thiophenes is presented.

RESULTS AND DISCUSSION

Synthesis of Amine End-Capped Polyynes. Starting 1halopolyynes were obtained according to the procedures previously developed in our group^{21b,22a} with only 1bromobutadiyne 1d being newly synthesized. Literature reports²³ and initial studies supported that the reaction of simple aryl 1-haloacetylenes with an excess of secondary amines gives diamination products. Therefore, we expected analogous products for 1-halopolyynes. Unexpectedly, test reactions of 1bromobutadiynes 1a-b and analogous iodides with pyrrolidine and piperidine gave only pure butadiynylamine instead of diaminoenynes. As such, we performed reactions using a series of 1-halopolyynes with a variety of secondary amines. First, we observed that the reaction times are shorter for bromides than iodides, therefore, for further reactions we used mostly bromides (if it was accessible). Second, we usually used THF as a solvent, but MeCN, CH2Cl2, and n-Bu2O also gave analogous results. Third, the reactions performed at elevated temperatures always gave the same ynamine product as those

carried out at room temperature. Fourth, an excess of amine did not affect the outcome of the reaction (we tested amounts from 2.0 to 8.0 equiv with identical result). In conclusion, we did not find any conditions that gave products of multiple amination instead of ynamine. With the above in mind, we performed reactions for a series of 1-halopolyynes to obtain the relevant amine end-capped polyynes.

In the first thrust, we performed the reactions for 1bromobutadiynes (Scheme 2). We noticed that the reactions with electron withdrawing end groups (1a-c) were faster than those for electron-rich anisole derivative (1d; see ExperimentalSection). Moreover, 1d did not react with the less nucleophilic amines (2c-e) so the products were obtained only for pyrrolidine and piperidine. We tested a series of secondary amines in this transformation and it was clear that the reaction time strongly depended on nucleophilicity of an amine. The most nucleophilic ones (pyrrolidine 2a and piperidine 2b) gave products within minutes. Reactions for *N*-methylbenzylamine (2e) and 1-(1,3-dioxolan-2-yl)-*N*-methylmethaneamine (2c)were slower and usually took several hours, while reactions with

Article

Scheme 5. Possible Products for the Reaction of Amine End-Capped Polyynes with Na₂S

diisopropylamine (2d) typically needed 24 h for completion. We also tested *N*-methylaniline and indoline, but no reaction was observed. For the working reactions the yields were from 28 to 98%, but in some cases the yields were further reduced by the purification process. Typically, products were dissolved in hexanes or a mixture of hexanes and CH_2Cl_2 and amine hydrobromide was filtered off, therefore, in case of low soluble products the yields might have been lowered.

Next, the reaction of 1-bromohexatriynes and 1-iodooctatetraynes with a series of secondary amines was performed (Scheme 3). Since 1-bromooctatetraynes appeared not enough stable, so for longer chains we used more stable 1iodooctatetraynes. Products were obtained with short reaction times (usually few hours), and only the reaction with less nucleophilic diisopropylamine was slightly slower. Yields obtained for hexatriynes (from 32 to 95%) and octatetraynes (from 48 to 94%) were acceptable.

In the literature ynamines are usually described as "highly unstable" due to their moisture sensitivity but, ynamines with $(C\equiv C)_2$ or longer carbon chains appeared to be quite stable. This was tentatively attributed to the C–N carbon atom which is less electrophilic than in analogues with single triple bond because of a resonance effect of a polyyne system. The NMR spectra of the ynamines were measured in wet CDCl₃ and no decomposition was observed even after few days in solution. Compounds stored for few days in open vials, however, showed new signals in the ¹H NMR spectra which originated from the corresponding amides. Only more electron rich **3da** and **3db** showed much faster decomposition in the presence of moisture and in these cases more careful handling was needed. In the literature ynamides are often mentioned as more convenient

and easier to handle modification of ynamines. As such, the chemistry of ynamides is far richer than ynamines. Our results show that amine end-capped polyynes are far more stable than short chained *N*-ethynylamines and may play an important role as convenient building blocks in organic chemistry.

Synthesis of Push–Pull Thiophenes. Next, we utilized the amine end-capped polyynes as substrates for the synthesis of functionalized thiophenes. Such a transformation for butadiynes is known,²⁴ but to the best our knowledge, the reaction for butadiynylamine has no literature precedence. Moreover, in the known examples, the presence of a strong base is usually needed.

We performed the reaction of nine amine end-capped polyynes with sodium sulfide in acetonitrile (no base added). Reactions at room temperature turned out to be very slow and were incomplete even after 24 h. The same reactions at 70 °C gave pure thiophenes already after few hours, proving that this simple procedure effectively produced push-pull 2-aminothiophenes (4aa, 4ac, 4ae, 4ba, 4ca) from the corresponding butadiynes under very mild conditions (see Scheme 4). Surprisingly, the reactions for hexatriynes (3ea, 3eb, and 3fb) were regioselective and the only observed products were 2amino-5-(phenylethynyl)thiophene (A in Scheme 5) with no traces of 2-(aminoethynyl)-5-phenylthiophene (B in Scheme 5). When octatetrayne 3ga was reacted with one equivalent of sodium sulfide the reaction was once again regioselective and the only product was 4ga (C in Scheme 5) and no traces of Eand D-type products were observed. The structures of 4ea, 4eb, 4fb, and 4ga derivatives were confirmed with the use of HMQC and HMBC experiments. Yields were usually from moderate to good (29-87%).

Interestingly, the reaction of **3ga** with excess sodium sulfide gave another product, which was probably the effect of its 2fold reaction with Na₂S (F in Scheme 5). Carefully increasing an excess of Na₂S we observed diminishing amount of **4ga** and increasing amount of product with four doublets from two thiophene rings in ¹H NMR. However, the product decomposes very quickly in solution and in solid state, so it was impossible to record its clear ¹H and ¹³C NMR spectrum. Moreover, decomposition of all the resulting thiophenes was observed during recording of the NMR spectra in CDCl₃, probably due to the presence of small amounts of HCl in a solvent. Thus, all the NMR spectra for the thiophenes were recorded in C₆D₆.

All the obtained thiophenes were stable in the solid state at room temperature for days but after longer exposure time we observed the decrease of doublets from thiophene moiety ($J_{\rm HH}$ = 4 Hz) in ¹H NMR spectra. Instead, new doublets with higher coupling constant ($J_{\rm HH}$ = 10 Hz) appeared. According to the literature, decomposition products are probably products of photo-oxidation.²⁵ So, all thiophenes were stored in refrigerator in the dark.

Substituted push-pull 2-aminothiophenes exhibit excellent properties for optoelectronic applications and play an important role in NLO (nonlinear optics) materials.²⁶ Compounds with 2-aminothiophene moiety exhibit also strong anti-AR (androgen receptor) potency,²⁷ are used as fluorescence biomarkers²⁸ or play an important role as fluorescent dyes.^{25,29} For instance, DTM-2 and BAP-2 (Figure 1) are used for *in vivo* fluorescence imaging of β -amyloid (A β) plaques that is expected to be a new method for detecting Alzheimer's disease.^{28b,c} Substituted 2-amino-5-phenylethynylthiophenes or 2-amino-5-phenylthiophenes (G and H in Figure 1) have also

Figure 1. Examples of biologically active 2-aminothiophenes and fluorescent biomarkers with 2-aminothiophene moiety.

an influence on A_1 adenosine receptor.³⁰ The approach presented so far to obtain these compounds was different from that shown in this work, so we believe, we have added a valuable contribution to the synthesis of such thiophenes with high application potential.

Recently, during the preparation of this article, Witulski and co-workers published the first synthesis of 2-(tosylamido) and 2,5-bis(tosylamido)thiophenes from butadiyneamides and butadiyne-1,4-diamides under similar conditions.³¹ Our work is the first synthesis of thiophenes from polyyneamines and may be considered as a complementary addition to Witulski's results and is the first synthesis of 2-amino-5-phenylthiophenes and 2-amino-5-phenylethynylthiophenes from butadiynes and hexa-triynes. Reactions of polyynes higher than butadiynes with sodium sulfide are rare and usually mixtures of different products are obtained.³²

Emission Spectroscopy. Some of the presented thiophenes exhibit strong photoluminescence upon the UV irradiation, thus we recorded absorption and emission/ excitation spectra for all the new thiophenes. Aryl-substituted thiophenes 4aa, 4ac, 4ae, and 4ba exhibited the strongest fluorescence in visible range, whereas for carbonyl 4ca, ethynyl 4ea, 4eb, 4fb and butadiynyl-substituted 4ga compounds no emission was observed. Absorption and emission spectra of all samples were recorded in a variety of solvents (see the Supporting Information). Stokes shifts and emission quantum yields of the best emitting samples are summarized in Table 1. Emission and excitation spectra in Et₂O are shown in Figure 2 (for spectra in other solvents see the Supporting Information). Compounds 4aa, 4ca, and 4ea exhibited very similar spectroscopic properties with nearly identical blue fluorescence.

Table 1. Emission Parameters	of Substit	tuted Thiophenes ^a
------------------------------	------------	-------------------------------

	Em _{max} [nm]	Ex_{max} [nm]	Stokes shift [cm ⁻¹]	reference sample	QY [%]
4aa	444	397	2670	quinine sulfate in 0.1 M H_2SO_4	74
4ac	443	393	2870	quinine sulfate in 0.1 M H_2SO_4	67

4ba	579	453	4800	rhodamine B in ethanol	6

^{*a*}All spectra recorded in Et₂O.

Figure 2. Emission and excitation spectra in Et₂O.

The highest value of QY was recorded for 4aa (74%), but compounds 4ac and 4ae exhibited comparable values (67 and 69%, respectively). The presence of a nitro substituent instead of a nitrile (compound 4ba) led to a lower QY (6%) and the maximum of the emission band shifted from 444 to 579 nm (orange emission). Moreover, 4ba did not exhibit significant emission in CH_2Cl_2 and DMF. Nitro-group-containing fluorophores are known to have generally low photo-luminescence quantum yield due to decrease in the radiative rate and the increase in the internal conversion rate of an exited state.³³

Compounds 4aa, 4ac, 4ae, and 4ba exhibited moderate solvatochromism and could be taken into consideration as solvent polarity probes. Stokes shifts for spectra recorded in solvents more polar than Et_2O were significantly higher (see the Table S1 in the Supporting Information). Correlation of absorption and emission maxima with solvents π^* values³⁴ for compound 4aa was examined (see Figures S5 and S6 in the Supporting Information). Correlation parameters were calculated using the equation:

 $\nu_{\rm max} = \nu_0 + s\pi^*$

where $u_{\rm max}$ is the absorption/emission maximum, u_0 shows the absorption/emission maximum of the compound in nonpolar solvent ($\pi^* = 0$), s describes quantitatively the sensitivity of the dye to solvent polarity change. In case of compound 4aa the value was -1200 cm^{-1} , which is rather low in comparison to the best known solvent polarity probes which are pyridinium betaines, which are about 8 times more sensitive to solvent polarity changes.³⁵ As the emission is much slower process than absorption, a larger solvatochromic shifts of emission bands are expected. Solvent sensitivity index s was much higher in case of emission spectra and its value was -2800 cm^{-1} for 4aa. The thorough spectroscopic experiments including quantum yields measurements in different solvents, the synthesis of larger series of substituted thiophenes and the theoretical calculations are now under study and will be the topic of our next publication. Herein, we present preliminary data to indicate possible application of this group of compounds.

X-ray Crystallography. According to the literature, a few crystal structures of butadiynamines are known,^{15,36} and the only crystal structure of nitrogen end-capped hexatriyne is the structure of hexatriynylamide.¹⁷ We obtained monocrystals of

five ynamines appropriate for single crystal X-ray analysis. Monocrystals were obtained from the mixture of CH_2Cl_2 and hexanes. Compounds **3ad**, **3ac**, and **3fd** crystallize in monoclinic system, $P2_1/c$ space group, whereas **3ec** and **3fe** crystallize in triclinic system, *P*-1 space group (for further details on the structures see the Supporting Information). Molecular views of the two butadiynes **3ad** and **3ca** and three hexatriynes **3ec**, **3fd**, and **3fe** are presented in the Figure 3. The

Figure 3. Molecular structures of amine end-capped polyynes. Thermal ellipsoids are drawn at 50% probability level.

bond lengths in polyyne chains and the contraction coefficients are presented in the Table 2. All hexatriynes (3ec, 3fd, 3fe) possess nearly linear polyyne chains whereas butadiynes were slightly more distorted due to packing forces. The N1 nitrogen atom in all cases exhibited a typical flat sp^2 geometry and the N1–C1 bond length was from 1.311 Å (for 3ca) to 1.322 Å (for 3ad).

Since aminobutadiynes and diaminobutadiynes are used in topochemical crystal-to-crystal polymerization, 15,36 we analyzed the packing motifs of the presented compounds in detail. The closest chain-chain separation was scrutinized for each structure, which was understood as the closest carbon-carbon distance from two neighboring polyyne carbon chains. We found two possible candidates for 1,*n*-topochemical polymerization: **3ca** and **3ec**. In the other cases, the carbon-carbon

The closest C–C contact in 3ca (3.513 Å) was slightly above the sum of the van der Waals radii for two carbon atoms (3.4 Å), making it a promising candidate for topochemical polymerization (see Figure 4). The closest carbon-carbon contact in 3ec was longer (3.965 Å) but still the polymerization could be possible.

Figure 4. Packing motifs for 3ca (top) and 3ec (bottom). Distances in Å. Symmetry operations for related atoms are 3ca (i) = x, y, z; (ii) = x, 1.5-y, 0.5+z; 3ec(i) = x, y, z; (ii) = -1 + x, y, z.

Moreover, an X-ray solid state structure of substituted thiophene 4aa was obtained. Its molecular view is presented in the Figure 5. The whole molecule adopts a nearly planar geometry, except slightly distorted pyrrolidine moiety. The C1-N1 bond was short (1.351 Å) and the N1 nitrogen atom adopted a nearly planar sp² geometry which was similar to the known structures of 2-amine-5-arylthiophenes.³

CONCLUSIONS

We showed that the reaction of 1-halopolyynes with secondary amines is a very convenient synthetic way to amine end-capped polyynes. The reaction gives products under very mild conditions and with good yields and selectivity. The resulting

N-capped polyynes are far more stable toward moisture than short N-ethynylamines and may be regarded, similarly to the ynamides, as a convenient substrate in synthetic organic chemistry. Moreover, single X-ray diffraction structures for five amine end-capped polyynes were obtained and the structural analysis was presented. The reaction of amine endcapped polyynes with sodium sulfide yielded a series of novel, substituted push-pull thiophenes and, according to our knowledge, it is the first known direct transformation of ynamines to thiophenes. Moreover, the reaction of hexatriynes and octatetraynes with sodium sulfide is the first regioselective example of such transformation. Some of the obtained thiophenes exhibit strong fluorescence with high quantum yields and may be regarded as solvent polarity probes.

EXPERIMENTAL SECTION

General. All reactions were conducted under N₂ by using standard Schlenk techniques. Glassware was predried at 120 °C. Solvents were treated as follows: hexane was distilled from Na, THF was distilled from Na/benzophenone, CH2Cl2 and CH3CN were distilled from P₂O₅, Et₂O (pure for analysis) was used as received. 1-Halopolyynes and ((4-methoxyphenyl)buta-1,3-diyn-1-yl)trimethylsilane were obtained according to the known procedures.^{21,38} Pyrrolidine (98%), piperidine (puriss p.a.), diisopropylamine (99.5%), N-methylbenzylamine (97%), 2-methylaminomethyl-1,3-dioxolane (98%), Pd-(PPh₃)₂Cl₂ (99%), N-bromosuccinimide (99%), sodium sulfide hydrate ($\geq 60\%$ of Na₂S), AgNO₃ (puriss p.a.), KF (puriss p.a.) were used as received.

¹H and ¹³C NMR spectra were recorded with a 500 MHz spectrometer with an inverse broadband probe. For all the ¹H NMR spectra, the chemical shifts are given in ppm relative to the solvent residual peaks (CDCl₃, ¹H: 7.26 ppm, ¹³C: 77.16 ppm; C_6D_{67} ¹H: 7.16

ppm, ¹³C: 128.06 ppm; CD₃C(O)CD₃, ¹H: 2.05 ppm, ¹³C: 29.84 ppm). Coupling constants are given in Hz. HMBC and HMQC techniques were used for peak assignment. HRMS spectra were recorded using a spectrometer with a TOF mass analyzer and an ESI ion source. Fluorescence emission and excitation spectra were recorded using an spectrophotometer equipped with a 450 W Xe lamp. Absorption spectra were recorded on a one-beam spectrometer. Quantum yields were recorded using comparative method of Williams et al.³⁹ in accordance with the Jobin Yvon Horiba guide.⁴⁰ Quinine sulfate in 0.1 M H₂SO₄ and rhodamine B in ethanol were used as standard samples with quantum yields of 0.54 and 0.49 QY, respectively.⁴¹

Details of X-ray Data Collection and Reduction. X-ray diffraction data were collected with the use of ω scan technique. The space groups were determined from systematic absences and subsequent least-squares refinement. Lorentz and polarization corrections were applied. The structures were solved by direct methods and refined by full-matrix, least-squares on F^2 by use of the SHELXTL Package.⁴² Non-hydrogen atoms were refined with anisotropic thermal parameters. Hydrogen atom positions were calculated and added to the structure factor calculations, but were not refined.

(1d) 1-(Bromobutadiynyl)-4-methoxybenzene. ((4-Methoxyphenyl)butadiynyl)trimethylsilane (391 mg, 2.22 mmol) was dissolved in acetonitrile and next NBS (474 mg, 2.66 mmol), AgNO₃ (377 mg, 2.22 mmol), KF (129 mg, 2.22 mmol), and H₂O (75 μL, 4.4 mmol) were added. The flask was wrapped with aluminum foil and the mixture was stirred for 24 h at room temperature under N₂ atmosphere. Next, the solvent was evaporated, the solid dissolved in eluent and filtrated through the silica gel plug (eluent: hexanes/chloroform; v/v; 1:1). Solvent was evaporated under reduced pressure yielding yellow solid, yield: 28% (0.150 g, 0.638 mmol). ¹H NMR (500 MHz, CDCl₃) δ 7.46–7.43 (m, 2H, H_{Ar}), 6.85–6.82 (m, 2H, H_{Ar}), 3.82 (s, 3H, CH₃). ¹³C NMR (126 MHz, CDCl₃) δ 160.9 (C_{Ar}O), 134.8 (C_{Ar}H), 114.5 (C_{Ar}C≡C), 113.3 (C_{Ar}H), 74.7 (C≡C), 73.5 (C≡C), 66.0 (C≡C) 55.7 (CH₃), 44.0 (C≡C). HRMS(ESI): *m*/*z* calcd for C₁₁H₈BrO: 234.9759 [M+H⁺]; found: 234.9753.

Synthesis of Amine End-Capped Polyynes. (3aa) 4-(Pyrrolidin-1-ylbutadiynyl)benzonitrile. 4-(Bromobutadiynyl)benzonitrile (1a, 12 mg, 0.052 mmol) was dissolved in a dry and oxygen-free THF (10 mL) under N₂ atmosphere. Next, pyrrolidine (26 μ L, 0.32 mmol) was added and the mixture was stirred for 1 h at room temperature. After this time the solvent was evaporated, product was dissolved in hexanes, filtrated with the use of the Schlenk technique and dried under reduced pressure. Product was obtained as a red solid, yield: 60% (6.9 mg, 0.031 mmol). ¹H NMR (500 MHz, CDCl₃) δ 7.56–7.53 (m, 2H, H_{Ar}), 7.46–7.42 (m, 2H, H_{Ar}), 3.38–3.34 (m, 4H, NCH₂), 1.90–1.87 (m, 4H, CH₂). ¹³C{¹H}NMR (126 MHz, CDCl₃) δ 132.0 (CH_{Ar}), 131.8 (CH_{Ar}), 129.2 (CC \equiv N), 118.9 (C \equiv N), 110.4 (C_{Ar}C \equiv C), 91.1 (C \equiv C), 81.3 (C \equiv C), 79.2 (C \equiv C), 52.1 (CH₂N), 51.7 (C \equiv C), 25.9 (CH₂). HRMS(ESI): m/z calcd for C₁₅H₁₃N₂: 221.1073 [M+H⁺]; found: 221.1072.

(3*ab*) 4-(*Piperidin-1-ylbutadiynyl*)*benzonitrile*. 4-(Bromobutadiynyl)benzonitrile (1a, 10 mg, 0.043 mmol), piperidine (26 μL, 0.26 mmol), and THF (10 mL) were reacted according to the procedure for 3aa. Reaction time: 1 h, orange solid, yield 44% (4.5 mg, 0.019 mmol). ¹H NMR (500 MHz, CDCl₃) δ 7.56–7.53 (m, 2H, H_{Ar}), 7.46–7.43 (m, 2H, H_{Ar}), 3.18–3.14 (m, 4H, NCH₂), 1.66–1.61 (m, 4H, CH₂), 1.57–1.53 (m, 2H, CH₂). ¹³C{¹H}NMR (126 MHz, CDCl₃) δ 132.1 (CH_{Ar}), 131.9 (CH_{Ar}), 129.0 (CC≡N), 118.9 (C≡ N), 110.6 (C_{Ar} C≡C), 92.4 (C≡C), 81.0 (C≡C), 78.8 (C≡C), 52.6 (CH₂N), 50.7 (C≡C), 25.1 (CH₂), 23.5 (CH₂). Synthesis of Push–Pull Thiophenes. (4aa) 4-(5-(Pyrrolidin-1yl)thiophen-2-yl)benzonitrile. 4-(Pyrrolidin-1-ylbutadiynyl)benzonitrile (3aa, 19 mg, 0.086 mmol) was dissolved in MeCN (10 mL) and the mixture was heated to 70 °C under N₂ atmosphere. Next, Na₂S·xH₂O (60% of Na₂S, 0.10 mmol) was added and the mixture was stirred for 2.5 h. After this time water (100 mL) was added and the product was extracted with Et_2O (3 × 30 mL). Combined organic layers were washed twice with H₂O (2 × 20 mL), dried over MgSO₄, filtered and the solvent was evaporated under reduced pressure yielding 19 mg (0.075 mmol) of yellow solid. Yield: 87%. ¹H NMR $\begin{array}{l} (500 \text{ MHz}, \ C_6 D_6) \ \delta \ 7.10-7.07 \ (m, \ 2H, \ H_{\text{benzonitrile}}), \ 7.05-7.02 \ (m, \ 2H, \ H_{\text{benzonitrile}}), \ 6.97 \ (d, \ J=4.0 \ \text{Hz}, \ 1H, \ H_{\text{thiophene}}), \ 5.58 \ (d, \ J=4.0 \ \text{Hz}, \ 1H, \ H_{\text{thiophene}}), \ 5.58 \ (d, \ J=4.0 \ \text{Hz}, \ 1H, \ H_{\text{thiophene}}), \ 5.28 \ (d, \ J=4.0 \ \text{Hz}, \ 1H, \ H_{\text{thiophene}}), \ 5.28 \ (d, \ J=4.0 \ \text{Hz}, \ 1H, \ H_{\text{thiophene}}), \ 2.86-2.81 \ (m, \ 4H, \ NCH_2), \ 1.38-1.33 \ (m, \ 4H, \ CH_2). \ 1^{3}C\{^{1}H\}NMR \ (126 \ \text{MHz}, \ C_6 D_6) \ \delta \ 157.2 \ (C_{\text{thiophene}}N), \ 139.8 \ (C_{\text{benzonitrile}}), \ 126.6 \ (CH_{\text{benzonitrile}}), \ 126.4 \ (CH_{\text{thiophene}}), \ 124.0 \ (C_{\text{thiophene}}), \ 124.0 \ (C_{\text{thiophene}}), \ 101.7 \ (CH_{\text{thiophene}}), \ 50.4 \ (NCH_2), \ 25.7 \ (CH_2). \ \text{HRMS(ESI): } m/z \ \text{calcd for} \ C_{15}H_{15}N_2S: \ 255.0950 \ [M+H^+]; \ found: \ 255.0949. \ \end{array}$

HRMS(ESI): m/z calcd for C₁₄H₁₅N₂O₂S: 275.0849 [M+H⁺]; found: 275.0850.

(4ca) Methyl 5-(Pyrrolidin-1-yl)thiophene-2-carboxylate. Methyl 5-(pyrrolidin-1-yl)penta-2,4-diynoate (3ca, 14.7 mg, 0.083 mmol), Na₂S·xH₂O (60% of Na₂S, 9.7 mg, 0.12 mmol) and MeCN (10 mL) were reacted according to the procedure for 4aa. Yellow solid (6.9 mg, 0.033 mmol), yield: 40% ¹H NMR (500 MHz, C₆D₆) δ 7.85 (d, *J* = 4.2 Hz, 1H, *H*_{thiophene}), 5.44 (d, *J* = 4.2 Hz, 1H, *H*_{thiophene}), 3.58 (s, 3H, CH₃), 2.65 (t, 4H, NCH₂), 1.21–1.19 (m, 4H, CH₂). ¹H NMR (500 MHz, Acetone) δ 7.48 (d, *J* = 4.2 Hz, 1H, 1H, *H*_{thiophene}), 5.79 (d, *J* = 4.3 Hz, 1H, 1H, *H*_{thiophene}), 3.72 (s, 3H, CH₃), 3.34–3.30 (m, 4H NCH₂), 2.09–2.07 (m, 4H CH₂). ¹³C{¹H}NMR (126 MHz, C₆D₆) δ 163.2 (C=O), 161.2 (C_{thiophene}N), 135.8 (CH_{thiophene}), 101.5 (CH_{thiophene}), 51.1 (CH₃), 50.1 (NCH₂), 25.5 (CH₂) (one signal under solvent). ¹³C{¹H}NMR (126 MHz, Acetone-d₆) δ 163.4 (C=O), 162.2 (C_{thiophene}N), 136.3 (CH_{thiophene}), 126.1 (CH_{thiophene}), 101.9 (CH_{thiophene}), 51.3 (CH₃), 51.2 (NCH₂), 26.4 (CH₂). HRMS-(ESI): *m*/z calcd for C₁₀H₁₄NO₂S: 212.0740 [M+H⁺]; found: 212.0751.

(4ea) 4-((5-(Pyrrolidin-1-yl)thiophen-2-yl)ethynyl)benzonitrile. 4-(Pyrrolidin-1-ylhexatriynyl)benzonitrile (3ea, 17 mg, 0.070 mmol), $Na_2S \cdot xH_2O$ (60% of Na_2S , 12 mg, 0.10 mmol), and MeCN (10 mL) were reacted according to the procedure for 4aa. Yellow solid (15 mg, 0.054 mmol), yield: 77% ¹H NMR (500 MHz, C_6D_6) δ 7.20 (d, J = 4.0 Hz, 1H, $H_{\text{thiophene}}$), 7.00–6.97 (m, 2H, $H_{\text{benzonitrile}}$), 6.80–6.77 (m, 2H, $H_{\text{benzonitrile}}$), 5.42 (d, J = 4.0 Hz, 1H, $H_{\text{thiophene}}$), 2.72–2.68 (m, 4H, NCH₂), 1.28–1.24 (m, 4H, CH₂). ¹³C{¹H}NMR (126 MHz, C_6D_6) δ 157.9 ($C_{\text{thiophene}}$ N), 135.2 (CH_{thiophene}), 132.0 (CH_{benzonitrile}), 130.8 (CH_{benzonitrile}), 128.8 (CC \equiv N), 118.8 (C \equiv N), 110.6 ($C_{\text{benzonitrile}}$ C), 104.3 ($C_{\text{thiophene}}$), 100.7 (CH_{thiophene}), 91.4 (C \equiv C), 90.7 (C \equiv C), 50.3 (NCH₂), 25.6 (CH₂). HRMS(ESI): m/z calcd for $C_{17}H_{15}N_2$ S: 279.0950 [M+H⁺]; found: 279.0953.

(4eb) 4-((5-(Piperidin-1-yl)thiophen-2-yl)ethynyl)benzonitrile. 4-(Piperidin-1-ylhexatriynyl)benzonitrile (3eb, 14 mg, 0.052 mmol), Na₂S·xH₂O (60% of Na₂S, 7.0 mg, 0.059 mmol), and MeCN were reacted according to the procedure for 4aa. Yellow solid (11 mg, 0.038 mmol), yield: 73% ¹H NMR (500 MHz, C₆D₆) δ 7.12 (d, J = 4.1 Hz, 1H, $H_{\text{thiophene}}$), 6.97–6.94 (m, 2H, $H_{\text{benzonitrile}}$), 6.79–6.76 (m, 2H, $H_{\text{benzonitrile}}$), 5.67 (d, J = 4.1 Hz, 1H, $H_{\text{thiophene}}$), 2.77–2.73 (m, 4H, NCH₂), 1.23–1.17 (m, 4H, CH₂), 1.10–1.04 (m, 2H, CH₂). ¹³C-{¹H}NMR (126 MHz, C₆D₆) δ 162.4 ($C_{\text{thiophene}}$ N), 134.5 (CH_{thiophene}), 131.9 (CH_{benzonitrile}), 131.0 (CH_{benzonitrile}), 128.4 (CC \equiv N), 118.7 (C \equiv N), 111.0 ($C_{\text{benzonitrile}}$ C \equiv C), 106.8 ($C_{\text{thiophene}}$), 104.1 (CH_{thiophene}), 91.4 (C \equiv C), 89.8 (C \equiv C), 51.5 (NCH₂), 25.1 (CH₂), 23.6 (CH₂). HRMS(ESI): m/z calcd for C₁₈H₁₆N₂NaS: 315.0926 [M +Na⁺]; found: 315.0925.

(4fb) 1-(5-((4-Nitrophenyl)ethynyl)thiophen-2-yl)piperidine. 1-((4-Nitrophenyl)hexatriynyl)piperidine (3fb 19 mg, 0.068 mmol), Na₂S·xH₂O (60% of Na₂S, 8.6 mg, 0.10 mmol), and MeCN (10 mL) were reacted according to the procedure for 4aa. Yellow solid (5.7 mg, 0.020 mmol), yield: 29% ¹H NMR (500 MHz, C₆D₆) δ 7.67–7.64 (m, 2H, H_{nitrobenzene}), 7.14 (d, *J* = 4.1 Hz, 1H, H_{thiophene}), 7.01–6.98 (m, 2H, H_{nitrobenzene}), 5.67 (d, *J* = 4.1 Hz, 1H, H_{thiophene}), 7.01–6.98 (m, 2H, H_{nitrobenzene}), 5.67 (d, *J* = 4.1 Hz, 1H, H_{thiophene}), 2.78–2.73 (m, 4H, NCH₂), 1.23–1.17 (m, 4H, CH₂), 1.10–1.05 (m, 2H, CH₂). ¹³C{¹H}NMR (126 MHz, C₆D₆) δ 162.6 (C_{thiophene}N), 146.6 (CNO₂), 134.9 (CH_{thiophene}), 131.0 (CH_{nitrobenzene}), 130.5 (C_{nitrobenzene}C≡C), 123.7 (CH_{nitrobenzene}), 106.6 (C_{thiophene}C≡C), 104.1 (CH_{thiophene}), 91.5 (C≡C), 91.0 (C≡C), 51.5 (NCH₂), 25.0 (CH₂), 23.6 (CH₂). HRMS(ESI): *m*/*z* calcd for C₁₇H₁₇N₂O₂S: 313.1005 [M+H⁺]; found: 313.1007.

(4ga) 4-((5-(Pyrrolidin-1-yl)thiophen-2-yl)butadiynyl)benzonitrile. 4-(Pyrrolidin-1-yloctatetraynyl)benzonitrile (3ga, 14 mg, 0.043 mmol), Na₂S-xH₂O (60% of Na₂S, 5.4 mg, 0.046 mmol), and MeCN (10 mL) were reacted according to the procedure for 4aa. Yellow solid (6.8 mg, 0.022 mmol), yield: 51% ¹H NMR (500 MHz, C₆D₆) δ 7.15 (d, *J* = 4.2 Hz, 1H, *H*_{thiophene}), 6.85–6.82 (m, 2H, *H*_{benzonitrile}), 6.69–6.67 (m, 2H, *H*_{benzonitrile}), 5.26 (d, *J* = 4.1 Hz, 1H, *H*_{thiophene}), 2.63–2.58 (m, 4H, NCH₂), 1.23–1.19 (m, 4H, CH₂). ¹³C{¹H}NMR (126 MHz, C₆D₆) δ 158.4 (*C*_{thiophene}N), 137.7 (CH_{thiophene}), 132.3 (CH_{benzonitrile}), 131.8 (CH_{benzonitrile}), 127.1 (CC≡ N), 118.4 (C≡N), 112.0 (*C*_{benzonitrile}C≡C), 103.2 (*C*_{thiophene}), 100.7 (CH_{thiophene}), 82.9 (*C*_{benzonitrile}C≡C), 81.3 (*C*_{thiophene}C≡C), 80.1 (C≡ C), 78.0 (C≡C), 50.2 (NCH₂), 25.5 (CH₂). HRMS(ESI): *m/z* calcd for C₁₉H₁₇N₂OS: 321.1056 [M+H₃O⁺]; found: 321.1057.
