# MOLECULAR STRUCTURE AND CHEMICAL PROPERTIES OF A BINUCLEAR CYCLOPENTADIENYLCOBALT NITROSYL CATION

FRANZ WOCHNER, EGBERT KELLER and HANS H. BRINTZINGER Fakultät für Chemie, Universität Konstanz, Postfach 5560, 7750 Konstanz (B.R.D.) (Received April 26th, 1982)

### Summary

The spectroscopic, structural and chemical properties of the binuclear cation  $(C_5H_5)_2Co_2(\mu-NO)_2^*$  are described.

### Introduction

Cationic cyclopentadienylcobalt nitrosyl derivatives have been shown by Clamp et al. [1] to be formed in reactions of  $(C_5H_5)Co(CO)_2$  with NOPF<sub>6</sub>. Correspondingly, we find that reaction of  $(C_5H_5)Co(CO)_2$  with nitrosyl salts in  $CH_2Cl_2$  solution affords the binuclear mono-cation  $(C_5H_5)_2Co_2(\mu-NO)_2^+$ , the existence of which had previously been inferred by Bernal et al. [2] from electrochemical studies on the neutral binuclear nitrosyl compound  $(C_5H_5)_2Co_2$ - $(\mu-NO)_2$  [3]. Since the IR spectral characteristics of this cation, a single NOabsorption at 1620 cm<sup>-1</sup>, are quite different, however, from those reported for this species in ref. 1, we have established its identity by additional chemical evidence and by a determination of its crystal and molecular structure.

#### Results

The cation  $(C_5H_5)_2Co_2(\mu-NO)_2^+(1)$  is formed in 40–50% yield either as its PF<sub>6</sub> or as its BF<sub>4</sub> salt when  $(C_5H_5)Co(CO)_2$  is treated with equimolar quantities or with a slight excess of NOPF<sub>6</sub> or NOBF<sub>4</sub> in CH<sub>2</sub>Cl<sub>2</sub> at room temperature. The product crystallizes in form of dark red platelets from CH<sub>2</sub>Cl<sub>2</sub>/pentane. Both the BF<sub>4</sub> and PF<sub>6</sub> salts of 1 are fairly soluble (ca.  $10^{-2} M$ ) in CH<sub>2</sub>Cl<sub>2</sub>, but much less so in CHCl<sub>3</sub>, CCl<sub>4</sub> and in less polar organic solvents. The crystalline product is quite stable in the air, but in solution, exposure to air causes decomposition within less than one hour.

The IR spectrum of the cation 1 in  $CH_2Cl_2$  solution is dominated by a very strong  $\nu(NO)$  absorption at 1620 cm<sup>-1</sup> (at 1610 cm<sup>-1</sup> in Nujol mull). Weaker

absorptions at 3093, 1398, 1017, 992 and 810–820 cm<sup>-1</sup>, assignable to the  $\eta$ -C<sub>5</sub>H<sub>5</sub>-rings, are partly hidden by the strong absorptions of the PF<sub>6</sub><sup>-</sup> or the BF<sub>4</sub><sup>-</sup> anion at about 845 and 1060 cm<sup>-1</sup>, respectively.

Crystals suitable for X-ray structural work were obtained from CH<sub>2</sub>Cl<sub>2</sub>/pentane solutions of  $(C_5H_5)_2Co_2(\mu-NO)_2BF_4$ . X-ray diffraction intensities were determined on a Syntex-P3 four-circle diffractometer at 293 K (Mo- $K_{\alpha}$ ,  $\lambda =$ 71.069 pm, graphite monochromator,  $\omega$ -scan with  $2.0 < \omega/t < 29.3^{\circ}$  min<sup>-1</sup>) and  $2 < 2\theta < 42^{\circ}$ . One standard reflection was measured for every 100 reflections during data collection as a check on crystal and instrumental stability.

The crystals are monoclinic, space group C2/c; a 1788(1), b 994.6(2), c 1947(1) pm,  $\beta$  123.73; V 2878  $\cdot$  10<sup>6</sup> pm<sup>3</sup>,  $d_{calc}$  1.82 g/cm<sup>-3</sup> for M = 394.9 and Z = 8;  $d_{exp}$  1.76 g/cm<sup>-3</sup>. The unit cell contains one BF<sub>4</sub><sup>-</sup> and two crystallographically independent half-units of (C<sub>5</sub>H<sub>5</sub>)<sub>2</sub>Co<sub>2</sub>( $\mu$ -NO)<sub>2</sub><sup>+</sup> per asymmetric unit; the two halves of each (C<sub>5</sub>H<sub>5</sub>)<sub>2</sub>Co<sub>2</sub>( $\mu$ -NO)<sub>2</sub><sup>+</sup> unit are related to each other by a crystallographic center of symmetry.

The structure was solved by direct methods and refined (SHELXTL program [4]) using 915 reflections with  $F_o > 4\sigma$  with anisotropic temperature parameters for Co, N, O and F and isotropic temperature parameters for C and B atoms. Hydrogen atoms were not determined. The refinement resulted in values of  $R_1 = 0.082$  and  $R_2 = 0.084$ . Residual electron density was  $\leq 1.0 \ e/10^6 \ pm^3$  throughout.

The results (see Table 1) indicate some disorder of the  $BF_4^-$  units: The tem-

Fig. 1. Molecular structure of (C<sub>5</sub>H<sub>5</sub>)<sub>2</sub>Co<sub>2</sub>(μ-NO)<sub>2</sub><sup>+</sup>.

1

perature parameters of the F atoms are large and a relatively high residual electron density  $(0.8-1 \ e/10^6 \ pm^3)$  is situated about 120–140 pm from the B atom. In one of the two independent  $(C_sH_s)_2Co_2(\mu-NO)_2^+$  units, the temperature parameters of N and O are twice as large as those of the other unit; the orientations of the thermal elipsoids indicate a fairly high degree of librational freedom of both NO ligands around the Co–Co axis.

In all other respects, the two independent  $(C_5H_5)_2Co_2(\mu-NO)_2^+$  units are identical within limits of standard deviations. The Co, N and O atoms of the Co( $\mu$ -NO)<sub>2</sub>Co core are all coplanar within standard deviations. The Co—Co, Co—N and N—O bond distances (Table 1) are quite similar to, albeit marginally (2—6 pm) shorter than those reported for the isoelectronic species  $(C_5R_5)_2Co_2(\mu-CO)-(\mu-NO)$  [2] and  $(C_5R_5)_2Co_2(\mu-CO)_2^-$  (R = H, CH<sub>3</sub>) [5,6]. Comparison with the neutral binuclear nitrosyl 2,  $(C_5H_5)_2Co_2(\mu-NO)_2$  [2] reveals that a very slight shortening of the Co—Co bond (235 vs. 237 pm) and a somewhat more pronounced shortening of the Co—N bonds (176 ± 1 vs. 183 pm) is associated with the one-electron oxidation  $2 \rightarrow 1$ . As with the other binuclear  $(C_5H_5)_2Co_2$  compounds mentioned above, both  $C_5H_5$  rings are parallel to each other and perpendicular to the Co—Co axis.

The close structural relationship between 1 and its neutral analogue 2 suggests a facile mutual interconversion of these two compounds by oxidationreduction reactions. Previous cyclic voltametry studies [1,2] have indicated reversible oxidation-reduction reactions in this series. We have observed some stoichiometric reactions of the binuclear cation 1 as follows. When a solution of 1 in CH<sub>2</sub>Cl<sub>2</sub> is stirred with Zn powder at room temperature, its IR spectrum changes completely to that of the neutral binuclear compound 2 ( $\nu$ (NO) at 1530 and 1590 cm<sup>-1</sup>) [3] during 4–5 h. Oxidation of 2 to 1 is brought about when a CH<sub>2</sub>Cl<sub>2</sub> solution of 2 is stirred with solid AgBF<sub>4</sub>. This reaction goes to completion, in about 5 h, using one equivalent of AgBF<sub>4</sub> per cyclopentadienylcobalt nitrosyl dimer, in accord with the mono-cationic charge of 1.

When a solution of 1 in  $CH_2Cl_2$  is stirred with an excess of solid KBr, its IR spectrum after about 8 h indicates conversion to a mixture of  $(C_5H_5)Co(NO)Br$ 

 $(\nu(NO) \text{ at } 1830 \text{ cm}^{-1})$  [7] and  $(C_5H_5)_2Co_2(\mu-NO)_2$ , i.e. a disproportionation of the mixed-valence oxidation state of Co in compound 1. If carried out with equimolar amounts of tetrabutylammonium bromide in CH<sub>2</sub>Cl<sub>2</sub> solution, this disproportionation reaction is instantaneous, even at temperatures around 0°C. Since the neutral nitrosyl dimer 2 is converted in the bromo derivative 3 by treatment with Br<sub>2</sub>, a practically quantitative conversion of the cation 1 in the nitrosyl bromo derivative 3 occurs when CH<sub>2</sub>Cl<sub>2</sub> solutions of 1 are treated at 0°C with a mixture of 1 equivalent of tetraethylammonium bromide and 1/2 equivalent of bromine. This synthesis of compound 3 demonstrates that a controlled oxidation of the air-stable cation 1 represents a convenient route to mononuclear (C<sub>5</sub>H<sub>5</sub>)Co(NO) derivatives.

## Experimental

Solvents were thoroughly dried and freed from dissolved oxygen. All manipulations were performed under an atmosphere of nitrogen in Schlenk type glassware.  $C_5H_5Co(CO)_2$  was prepared according to ref. 8. NOPF<sub>6</sub>, NOBF<sub>4</sub> and AgBF<sub>4</sub> were purchased from Fluka AG and used without further purification.

# Preparation of $(C_5H_5)_2Co_2(\mu-NO)_2PF_6$

To a slurry of 212 mg NOPF<sub>6</sub> (1.2 mmol) in 10 ml  $CH_2Cl_2$  is added at room temperature a solution of 218 mg  $C_5H_5Co(CO)_2$  (1.2 mmol) in 5 ml  $CH_2Cl_2$ . The mixture is then heated to 38°C until the IR bands at 2130 and 1900 cm<sup>-1</sup> have disappeared (1.5–2 h). After removal of solvent in vacuo, the residue is washed with three 5 ml portions of toluene and then dissolved in a small volume of  $CH_2Cl_2$ ; the solution is filtered, covered with a layer of pentane and kept at  $-50^{\circ}C$ .  $(C_5H_5)_2Co_2(\mu-NO)_2PF_6$  separates as dark red platelets.

Yield: 122 mg (45% of theory). The product was recrystallized from  $CH_2Cl_2$ /pentane.

Elemental analysis: Found: C, 26.76; H, 2.18; N, 6.06. C<sub>10</sub>H<sub>10</sub>O<sub>2</sub>N<sub>2</sub>Co<sub>2</sub>PF<sub>6</sub> calcd.: C, 26.49; H, 2.22; N, 6.18%.

An analogous procedure using NOBF<sub>4</sub> instead of NOPF<sub>6</sub> leads to  $(C_5H_5)_2Co_2$ - $(\mu$ -NO)<sub>2</sub>BF<sub>4</sub>.

## Synthesis of $(C_5H_5)Co(NO)Br$ (3) from $(C_5H_5)_2Co_2(\mu-NO)_2$ (2)

To a solution of 130 mg  $(C_5H_5)_2Co_2(\mu$ -NO)<sub>2</sub> (0.42 mmol) in 20 ml CH<sub>2</sub>Cl<sub>2</sub>, cooled to  $-78^{\circ}$ C, a CH<sub>2</sub>Cl<sub>2</sub> solution of 67.2 mg (0.42 mmol) of Br<sub>2</sub> is added during 1 h. The product, obtained from the dark green solution after removal of solvent at room temperature, is recrystallized twice from CH<sub>2</sub>Cl<sub>2</sub>/pentane. Its IR spectrum shows a strong  $\nu$ (NO) absorption at 1830 cm<sup>-1</sup>.

Elemental analysis: Found: C, 26.34; H, 2.10; N, 5.56. C<sub>5</sub>H<sub>5</sub>NOCoBr calcd.: C, 25.67; H, 2.15; N, 5.99%.

### Conversion of 1 to $(C_5H_5)Co(NO)Br(3)$

To a solution of 158 mg (0.4 mmol) of  $(C_5H_5)_2Co_2(\mu-NO)_2PF_6$  in 25 ml  $CH_2Cl_2$ , cooled to 0°C, is added during 2 h solution of 84 mg (0.4 mmol) of tetraethylammonium bromide and 32 mg (0.2 mmol) of  $Br_2$  in 10 ml  $CH_2Cl_2$ . The green product solution is warmed to room temperature and evaporated to

dryness. The residue is extracted with 40 ml of toluene, and the extract is covered with a layer of pentane and cooled to  $-40^{\circ}$  C, whereupon (C<sub>5</sub>H<sub>5</sub>)Co-(NO)Br separates as a dark powder.

Yield: 151 mg (81% of theory).

### Acknowledgements

This work was financially supported by Deutsche Forschungsgemeinschaft, by Fonds der Chemischen Industrie and by research funds of the University of Konstanz. We thank Professor Huttner for access to the diffractometer and Mr. Laszlo Zsolnai for helpful advice on the structural work.
