(Received October 1st, 1984)

## Summary

The $\left[\mathrm{CuPPh}_{3} \mathrm{C} \equiv \mathrm{CPh}\right]_{4}$ tetramer, obtained by treatment of $\left[\mathrm{Cu}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{BH}_{4}\right]$ with phenylacetylene and KOH (molar ratio $1 / 1 / 1$ ) in $1 / 1$ benzene/benzyl alcohol, consists of a tetrahedral skeleton of metal atoms bonded to four terminal phosphine molecules and to four $\mu_{3}$-bridging phenylacetylide ligands which behave essentially as $2 e$ donors.

Substituted acetylides are versatile ligands which have been shown to coordinate to metal polyhedra in a variety of bonding modes, i.e. $\mu_{1}-\eta^{1}$ (terminal), $\mu_{2}-\eta^{1}$ (double bridging), and a number of $\mu_{\mathrm{x}}-\eta^{2}$ patterns ( $x=2,3,4$ ) in which both the acetylenic carbons are at bond distance from one or more metal atoms [1-5]. However, no metal complex containing $\mu_{3}-\eta^{1}$ bridging acetylides has been isolated so far. We report here the synthesis and X-ray structure determination of the first example of such a compound, the copper tetramer $\left[\mathrm{CuPPh}_{3}-\mu_{3}-\mathrm{C} \equiv \mathrm{CPh}\right]_{4}$ (1).

Compound 1 can be obtained by treating tetrahydrogenoboratebis(triphenylphosphine)copper(I) with phenylacetylene and KOH (in the molar ratio $1 / 1 / 1$ ) in a benzene/benzyl alcohol $1 / 1$ solution. Yellow crystals of 1 suitable for X-ray analysis were obtained by slow diffusion of hexane into the solution. When the solution of 1 is stirred for several days an insoluble fluorescent
yellow-green compound 2 separates (melting point and analysis unchanged), which can be reconverted into 1 by refluxing in $\mathrm{CH}_{3} \mathrm{CN}$.

Crystal data. $\mathrm{C}_{104} \mathrm{H}_{80} \mathrm{Cu}_{4} \mathrm{P}_{4}, M=1707.85$, monoclinic, space group $C 2 / \mathrm{c}$, $a$ 14.866(4), $b$ 24.552(4), c 23.345(9) $\AA, \beta$ 95.89(2) ${ }^{\circ}, U 8476 \AA^{3}, Z=4$, $D_{\text {eale.d }} 1.338 \mathrm{~g} \mathrm{~cm}^{-3}, \mu\left(\mathrm{Mo}-K_{\alpha}\right) 11.54 \mathrm{~cm}^{-1} .6625$ intensity data were collected on a Nonius-CAD-4 automated diffractometer by the $\omega$-scan technique in the $2 \theta$ range $6-50^{\circ}$. The structure was solved by use of the MULTAN program and refined using 3769 independent absorption-corrected reflections having $I>3 \sigma(I)$. The final full-matrix least-squares refinement led to conventional $R$ and $R_{\mathrm{w}}$ values of 0.054 and 0.065 respectively.

The $\left[\mathrm{CuPPh}_{3}-\mu_{3}-\mathrm{C} \equiv \mathrm{CPh}\right]_{4}$ molecule, of crystallographic $C_{2}$ symmetry, consists of an essentially tetrahedral metal skeleton bearing four terminally

Fig. 1. ORTEP view of the [CuPPh $\left.{ }_{3}-\mu_{3}-\mathbf{C} \equiv \mathbf{C P h}\right]_{4}$ molecule. Only the first carbon atoms of the triphenylphosphine ligands are shown for clarity. Principal bond pararneters are: $\mathrm{Cu}(1)-\mathrm{Cu}\left(1^{\prime}\right)$ $2.600(1), \mathrm{Cu}(1)-\mathrm{Cu}(2) 2.523(1), \mathrm{Cu}(1)-\mathrm{Cu}\left(2^{\prime}\right) 2.676(1), \mathrm{Cu}(2)-\mathrm{Cu}\left(2^{\prime}\right) 2.620(1), \mathrm{Cu}(1)-\mathrm{P}(1)$ 2.234(1), $\mathrm{Cu}(2)-\mathrm{P}(2) 2.221(1), \mathrm{Cu}(1)-\mathrm{C}(1) 2.380(4), \mathrm{Cu}\left(1^{\prime}\right)-\mathrm{C}(1) 2.07$ 2(4), $\mathrm{Cu}\left(\mathbf{2}^{\prime}\right)-\mathrm{C}(1) 2.214(4)$, $\mathrm{Cu}(1)-\mathrm{C}(9) 2.096(5), \mathrm{Cu}(2)-\mathrm{C}(9) 2.232(4), \mathrm{Cu}\left(2^{\prime}\right)-\mathrm{C}(9) 2.115(4), \mathrm{C}(1)-\mathrm{C}(2) 1.154(6), \mathrm{C}(9)-\mathrm{C}(10)$ $1.193(6) \mathrm{A}, \mathrm{P}-\mathrm{Cu}-\mathrm{C}_{(\mathrm{av} .)} 113.7, \mathrm{C}-\mathrm{Cu}-\mathrm{C}_{(\mathrm{av} .)} \mathbf{1 0 4 . 6}^{\circ}$.
bonded triphenylphosphine molecules and four $\mu_{3}-\eta^{1}$ phenylacetylide ligands (see Fig. 1). Principal bond parameters are listed in the caption of Fig. 1. Important average distances are: $\mathrm{Cu}-\mathrm{Cu} 2.603, \mathrm{Cu}-\mathrm{P} 2.228, \mathrm{Cu}-\mathrm{C} 2.185$ and $\mathrm{C}=\mathrm{C}$ $1.174 \AA$. The copper-acetylide triple bridges are markedly asymmetric, with $\mathrm{Cu}-\mathrm{C}$ contacts in the range $2.072(4)-2.380(4) \AA$. The observed very short $\mathrm{C} \equiv \mathrm{C}$ distances are indicative of a typical triple bond (cf. for instance $1.20 \AA$ in the free acetylene [6] and $1.174 \AA$ in $\mathrm{Cu}_{6}\left(\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{NMe}_{2}-2\right)_{4}\left(\mathrm{C} \equiv \mathrm{CC}_{6} \mathrm{H}_{4} \mathrm{Me}-4\right)_{2}$ [1]) and of the absence of $\pi$ back-donation from the metals to the ligand $\pi^{\star}$ orbitals. The $C(1)-C(2)-C(3)$ and $C(9)-C(10)-C(11)$ fragments are strictly linear (average angle $178^{\circ}$ ), and the interactions of atoms $\mathrm{C}(2)$ and $\mathrm{C}(10)$ with metal triangles $\mathrm{Cu}(1)-\mathrm{Cu}\left(1^{\prime}\right)-\mathrm{Cu}\left(2^{\prime}\right)$ and $\mathrm{Cu}(1)-\mathrm{Cu}(2)-\mathrm{Cu}\left(2^{\prime}\right)$, respectively, are negligible (average C. . Cu distance $3.104 \AA$ ): both these features are in contrast with the substantial ligand-to-metal $\pi$-donation (which is known, for instance, in molecule 2 of $\left[(\mathrm{MeC} \equiv \mathrm{C})_{2} \mathrm{BeNMe}_{3}\right]_{2}$ [3], and in a number of metalacetylide complexes [2]) and indicate that in the present case the acetylide ligands behave as essentially 2 electron donors.

Although direct metal-metal bonds in organocopper clusters is considered to be unimportant [1], EHMO calculations performed by Hoffmann et al. on polynuclear copper(I) complexes of various geometries [7] have shown that $\mathrm{Cu}(\mathrm{I})-\mathrm{Cu}(\mathrm{I})$ distances in the range of those observed here are indicative of a soft metal-metal attraction. Consistently, the $\mathrm{Cu} . . \mathrm{Cu}$ distances in the topologically similar haloger-bridged cubane-like tetramers [CuLX] ${ }_{4}$ ( $\mathrm{L}=$ substituted phosphine, $\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I}$ ) are all longer [8] (shortest Cu. . . Cu distance $2.927(2) \AA$ for $\mathrm{L}=\mathrm{PEt}_{3}$ and $\mathrm{X}=\mathrm{I}$ [9]) and definitely non bonding, in keeping with the presence of bridging halide ligands which are generally believed to function as 4 electron donors. We conclude, therefore, that the description of the bonding in each $\mathrm{Cu}_{3} \mathrm{C}$ fragment of the electron-deficient [ $\mathrm{CuPPh}_{3}-\mu_{3}$ $\mathrm{C} \equiv \mathrm{CPh}]_{4}$ tetramer should refer to a four-centre two-electron $\sigma$-bond as providing the major contribution, with a minor supporting role played by metalmetal attraction.

IR spectra of 1 show a single $\mathrm{C} \equiv \mathrm{C}$ absorption at $2020 \mathrm{~m} \mathrm{~cm}^{-1}$ (Nujol phase or spread on NaCl discs), whereas compound 2 shows two absorption bands at 2060 m and $1935 \mathrm{w} \mathrm{cm}^{-1}$. It seems likely that the yellow-green isomer 2 may contain differently bonded phenylacetylide ligands, as previously found for instance in $\left[(\mathrm{MeC} \equiv \mathrm{C})_{2} \mathrm{BeNMe}_{3}\right]_{2}[3]$.

We thank the MPI and the CNR for financial support.
