#### Summary

1-Buten-3-yl-*n*-butyldichlorotin, generated *in situ* by redistribution of (*E/Z*)-2-butenyltri-*n*-butyltin and  $\text{BuSnCl}_3$ , reacts readily with neat  $\text{RCHO}$  ( $\text{R} = \text{CH}_3$ ,  $\text{C}_2\text{H}_5$ ,  $(\text{CH}_3)_2\text{CH}$ ) at  $25^\circ\text{C}$  to give linear alcohols  $\text{RCH}(\text{OH})\text{CH}_2\text{CH}=\text{CHCH}_3$  and/or 2,3,4,6-tetrasubstituted tetrahydropyrans,  $\text{CH}_2\text{CH}(\text{R})\text{OCH}(\text{R})\text{CH}(\text{CH}_3)\text{CH}(\text{Cl})$ , which are mainly in the *cis*-configuration with respect to the  $\text{CH}(\text{CH}_3)\text{-CH}(\text{Cl})$  bond. When  $\text{R} = (\text{CH}_3)_3\text{C}$  and  $\text{C}_6\text{H}_5$ , only the homoallylic alcohols are obtained.

These *cis*-stereoconvergent syntheses are explained in terms of kinetic control of the formation of adducts obtained by insertion of one or two aldehyde molecules into the organotin substrate.

#### Introduction

In recent years allyltins have assumed an important role among the family of allylic organometallics [1,2] used in stereocontrolled syntheses of open-chain compounds [3]. Crotlytributyltin adds stereospecifically to  $\text{PhCHO}$  at  $200^\circ\text{C}$  and to  $\text{CCl}_3\text{CHO}$  at  $20^\circ\text{C}$  [4] and stereoselectively to  $\text{PhCHO}$  in the presence of  $\text{BF}_3 \cdot \text{OEt}_2$  [5]. A total *cis*-convergence \*\* is noted with the use of the ternary system (*E/Z*)-

\* Ref. 9 is considered Part IV; for Part III see ref. 8.

\*\* Stereoconvergence denotes the predominant formation of one and the same product stereoisomer from both stereoisomeric precursors (see ref. 2).

$\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3/\text{RCHO}/\text{Bu}_2\text{SnCl}_2$ , where RCHO is a saturated [6] or an  $\alpha,\beta$ -unsaturated aldehyde [7].

More recently 2-butenylbutyldichlorotin has been shown to be a very versatile reagent: this substrate reacts with aldehydes to form homoallylic alcohols and/or a mixture of *cis/trans*-4-chlorotetrahydropyrans,  $\text{CH}_2\text{CH}(\text{R})\text{OCH}(\text{R})\text{CH}(\text{CH}_3)\text{CH}(\text{Cl})$ , in which the *trans*-isomer\* is the major product [8]. Tetrahydropyrans are also formed by treatment of  $\text{X}_3\text{SnCH}_2\text{CH}=\text{CH}_2$  compounds ( $\text{X} = \text{Cl}$  or  $\text{Br}$ ) with  $\text{C}_2\text{H}_5\text{CHO}$  [9].

These reactions have been explained by using pathways in which the insertion of two aldehyde molecules into  $\text{BuCl}_2\text{SnCH}_2\text{CH}=\text{CHCH}_3$  gives tin alkoxides of the type:  $\text{BuCl}_2\text{SnOCH}(\text{R})\text{OCH}(\text{R})\text{CHR}'\text{CH}=\text{CH}_2$  ( $\text{R}' = \text{H}$  or  $\text{CH}_3$ ), which collapse intramolecularly to the heterocyclic compounds.

In view of these findings, we have undertaken a study of the addition of  $\text{BuCl}_2\text{SnCH}(\text{CH}_3)\text{CH}=\text{CH}_2$ , generated *in situ* by redistribution of (*E/Z*)- $\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3$  and  $\text{BuSnCl}_3$ , to aldehydes, RCHO ( $\text{R} = \text{CH}_3$ ,  $\text{C}_2\text{H}_5$ ,  $(\text{CH}_3)_2\text{CH}$ ,  $(\text{CH}_3)_3\text{C}$  and  $\text{C}_6\text{H}_5$ ). Since  $\alpha$ -methylallyltin substrates are known to give *cis*-stereocontrolled syntheses [6,7,10], we expected to find a *cis*-convergent control in the formation of the products.

## Experimental

Details of the IR and NMR equipment and the preparation of the starting materials have been described previously [6,8].

GLC analyses were made with a Sigma-3P Perkin-Elmer apparatus operating with a flame-ionization detector.

### Addition reactions

The procedures were as follows: (a) Equimolecular amounts (25 mmol) of (*E/Z*)- $\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3$  (with various isomer ratios in the range 33/66 to 75/25) and RCHO were mixed. The mixture was added as quickly as possible to sufficient liquid  $\text{BuSnCl}_3$  at  $0^\circ\text{C}$  in order to give a mol ratio  $\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3/\text{RCHO}/\text{BuSnCl}_3$  of 1/1/1. Then the solvent-free mixture was allowed to reach a constant temperature at  $25^\circ\text{C}$ , under stirring. The progress of the reactions was monitored by infrared spectroscopy, as described previously [7,8]. Then, at the appropriate time, aqueous  $\text{Na}_2\text{CO}_3$  2 *M* (15–20 ml) was added and the products extracted with ethyl ether. Volatile components were separated from the solid residues by trap-to-trap distillation in a cold bath (liquid nitrogen). The solvent was taken off by subsequent distillation.

Runs performed by this procedure are listed in Table 1. Three main products were obtained: linear and branched alcohols and 4-chloro-2,6-dialkyl-3-methyltetrahydropyrans (alkyl =  $\text{C}_2\text{H}_5$ ,  $i\text{-C}_3\text{H}_7$ ). 1-Buten-3-ol was also recovered in small quantities (cf. runs 1–3 of Table 1).

(b) Following procedure (a), runs were also performed in  $\text{CH}_2\text{Cl}_2$  (30–40 ml). Results are given in Table 2.

(c) Another set of runs was performed using different molar ratios of the three

\* The isomerism occurs at the  $\text{CH}(\text{CH}_3)\text{-CH}(\text{Cl})$  bond.

components,  $\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3/\text{RCHO}/\text{BuSnCl}_3$ , ranging from 1/2.5/1 to 1/7/1 (Cf. Table 3).

Characterization of the compounds obtained and analysis of the recovered mixtures were made by  $^{13}\text{C}$  NMR and IR spectroscopy, mass spectra and GLC analysis as described previously [8]. For quantitative determinations the  $^{13}\text{C}$  NMR spectra were recorded using sufficiently long pulse intervals to avoid saturation of the nuclear spins (at least 25 s) and the nuclear Overhauser effect (NOE) was suppressed by the gated decoupling method [11].

## Results and discussion

For all of the systems studied here, allylstannation takes place under mild conditions: reaction is complete in less than 1 h when  $\text{R} = \text{CH}_3$ ,  $\text{C}_2\text{H}_5$  or  $i\text{-C}_3\text{H}_7$ , in 24 h when  $\text{R} = \text{C}_6\text{H}_5$  and in 2 days when  $\text{R} = (\text{CH}_3)_3\text{C}$ .

4-Chloro-2,6-dialkyl-3-methyltetrahydropyrans ( $\text{R} = \text{CH}_3$ ,  $\text{C}_2\text{H}_5$  and  $i\text{-C}_3\text{H}_7$ ), predominantly in the *cis*-isomeric form, were obtained, together with homoallylic alcohols, by mixing equimolar amounts of the three components,  $\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3/\text{RCHO}/\text{BuSnCl}_3$  (cf. Table 1). Under the same conditions only the carbinols were recovered when  $\text{R} = \text{C}_6\text{H}_5$  and  $(\text{CH}_3)_3\text{C}$ .

In  $\text{CH}_2\text{Cl}_2$  solution, still operating with equimolar amounts of the three reagents (cf. Table 2), only carbinols were obtained.

The formation of chlorotetrahydropyrans is predominant (cf. Table 3) when the reaction is carried out with an excess of aldehyde. Figure 1 describes, as an example, the behaviour of the system with  $\text{C}_2\text{H}_5\text{CHO}$ ; it gathers together the findings of runs 1–3 of Table 1 and runs 15–19 of Table 3. The yield of the chlorotetrahydropyran increases to reach a maximum value (82–85%) for a mol ratio  $\text{C}_2\text{H}_5\text{CHO}/\text{Bu}_3\text{SnCrotyl}$  in the range 2–3; then, for higher mol ratio values, it decreases because

Fig. 1. Dependence of the product composition on the  $\text{C}_2\text{H}_5\text{CHO}/\text{Bu}_3\text{SnCH}_2\text{CH}=\text{CHCH}_3$  mol ratio, in absence of solvent: runs 1–3 and 16–19 (cf. Tables 1 and 3). 4-Chloro-2,6-diethyl-3-methyltetrahydropyran (□), linear alcohols (○), branched alcohols (Δ), trimeric aldehyde  $(\text{C}_2\text{H}_5\text{CHO})_3$  (●).

SCHEME 2

$\alpha$ -methylallyl tin substrate in the presence of  $\text{BuSnCl}_3$ , leading crotyl tin isomers. These are known [8] to form *threo* and *erythro* adducts with aldehydes, which lead eventually to *trans* and *cis* products, respectively.
