## Summary

The reaction of $\mathrm{K}_{2} \mathrm{SN}_{2}$ with $\mathrm{ML}_{n}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right) \quad\left(\mathrm{ML}_{n}=\mathrm{Cr}(\mathrm{CO})_{5}, \quad \mathrm{Mo}(\mathrm{CO})_{5}\right.$, $\mathrm{MnCp}^{\prime}(\mathrm{CO})_{2} \quad\left(\mathrm{Cp}^{\prime}=\right.$ methylcyclopentadienyl)) yields complexes of the type $\mathrm{L}_{n} \mathrm{MP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PML}_{n}$ in which the bridging ligand adopts a cis, trans conformation and is coordinated through the phosphorus atoms to the two metal centres. In solution these complexes undergo a cis, trans $\rightarrow$ trans, cis interconversion, and a ${ }^{31} \mathrm{P}$ DNMR study has provided the activation energies for this process ( $E_{\mathrm{a}}=10.1$ $(\mathrm{M}=\mathrm{Cr}), 9.8(\mathrm{M}=\mathrm{Mo})$ and $\left.13.4(\mathrm{M}=\mathrm{Mn}) \pm 0.2 \mathrm{kcal} \mathrm{mol}^{-1}\right)$. The ${ }^{31} \mathrm{P}$ chemical shifts, infrared frequencies ( $\nu_{a s}$ and $\nu_{s}(\mathrm{NSN})$ ) and visible absorption maxima for this series of complexes are discussed in terms of the observed activation energies. The reaction of $\mathrm{K}_{2} \mathrm{SN}_{2}$ with cis- $\mathrm{ML}_{n}\left(\mathrm{Ph}_{2} \mathrm{PCl}_{2}\right)_{\left(\mathrm{ML}_{n}=\mathrm{Cr}(\mathrm{CO})_{4} \text { or } \mathrm{Mo}(\mathrm{CO})_{4}\right)}$ gives complexes of the type cis $-\mathrm{ML}_{n}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)$ in which the chelating cis, cis ligand is coordinated to the metal via both phosphorus atoms. The structure of cis- $\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right) \cdot 0.5 \mathrm{C}_{6} \mathrm{H}_{6}$ has been determined by X-ray crystallography. Crystal data: triclinic, space group $P \overline{1}, a \operatorname{9.878(1),~b~12.240(1),~c~}$ $12.610(2) \AA, \alpha 87.795(9), \beta 77.018(10), \gamma 81.027(9)^{\circ}, V 1467.6(6) \AA^{3}, Z=2$. The structure was solved by direct methods and refined by least-squares techniques to give a final $R=0.034$ and $R_{\mathrm{w}}=0.036$. The geometry around the chromium atom is approximately octahedral, but the planar, chelating PNSNP ligand is tilted at an angle of $126.7^{\circ}$ with respect to the plane containing the $\mathrm{C}_{2} \mathrm{CrP}_{2}$ unit. The $\mathrm{P}-\mathrm{N}$ bond distances are both $1.727(2) \AA$; the $\mathrm{S}-\mathrm{N}$ distances are $1.525(2)$ and 1.523(2) $\AA$; the angles at the nitrogen atoms are 129.4(1) and $128.8(1)^{\circ}$ and the angle at sulphur is $123.0(1)^{\circ}$.

[^0]
## Introduction

The free ligand $\mathrm{R}_{2} \mathrm{PNSNPR}_{2}$ is known only for $\mathrm{R}=\mathrm{t}-\mathrm{Bu}$ [1]. Other derivatives $(\mathrm{R}=\mathrm{Et}, \mathrm{Cy}, \mathrm{Ph})$ are unstable [2]. Recently we described the preparation of $(\mathrm{CO})_{5} \mathrm{MoP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PMo}(\mathrm{CO})_{5}$, the first stable homodinuclear complex of a ligand of this type [3]. An X-ray structural determination showed that the ligand $\mathrm{Ph}_{2} \mathrm{PNSNPPh}_{2}$ adopts a cis, trans conformation in this complex and ${ }^{31} \mathrm{P}$ DNMR studies provided evidence for a cis, trans $\rightarrow$ trans, cis conversion in solution (Fig. 1) [3]. Subsequently, Herberhold and co-workers [4,5] reported the preparation of the related complex $(\mathrm{CO})_{5} \mathrm{CrP}(\mathrm{Bu}-\mathrm{t})_{2} \mathrm{PNSN}(\mathrm{Bu}-\mathrm{t})_{2} \mathrm{PCr}(\mathrm{CO})_{5}$. As a result of these studies, three methods are now potentially available for the preparation of such complexes.(a) Treatment of complexes of the type $\mathrm{L}_{n} \mathrm{M}\left(\mathrm{Ph}_{2} \mathrm{PNSO}\right)$ with a base, e.g. potassium t-butoxide [3,6].
(b) The reaction of complexes of the type $\mathrm{L}_{n} \mathrm{M}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)$ with $\mathrm{K}_{2} \mathrm{SN}_{2}$ [3].
(c) Direct reaction of $\mathrm{t}-\mathrm{Bu}_{2} \mathrm{PNSNP}-\mathrm{t}-\mathrm{Bu}_{2}$ with metal carbonyl complexes containing easily displaced ligands, e.g. $\mathrm{M}(\mathrm{CO})_{5}(\mathrm{THF})(\mathrm{M}=\mathrm{Cr}, \mathrm{Mo}, \mathrm{W}), \mathrm{CpMn}(\mathrm{CO})_{2}(\mathrm{THF})$ or $\mathrm{Os}_{3}(\mathrm{CO})_{11}\left(\mathrm{CH}_{3} \mathrm{CN}\right)[4,5]$.

The main purpose of this investigation was to evaluate the effect of changing the metal fragments in complexes of the type $\mathrm{L}_{n} \mathrm{MP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PML}{ }_{n}$ on the activation energy for the cis, trans $\rightarrow$ trans, cis isomerization. To this end we have employed method (b) as a general route for the preparation of homodinuclear complexes of $\mathrm{Ph}_{2} \mathrm{PNSNPPh}_{2}$. We have also used this synthetic approach to prepare complexes of the type cis- $\mathrm{M}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)(\mathrm{M}=\mathrm{Cr}, \mathrm{Mo})$ and determined the X -ray crystal structure of the mononuclear chromium complex.

## Experimental

All experimental procedures were performed under dry nitrogen or argon. Solvents were dried by heating under reflux with the appropriate drying agent, distilled, and stored in bottles fitted with a teflon stopcock with two nitrogen inlets. Solvents were transferred under nitrogen through a rubber septum fitted to one of the outlets by use of a double-tipped stainless steel needle. The following chemicals were prepared by published methods: $\mathrm{K}_{2} \mathrm{SN}_{2}$ [7], $\mathrm{Cr}(\mathrm{CO})_{5}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)$ [8], $\mathrm{Mn}(\mathrm{CO})_{2} \mathrm{Cp}^{\prime}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)$ [9], cis $-\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)_{2}$ [10] and cis- $\mathrm{Mo}(\mathrm{CO})_{4}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)_{2}$ [10]. The preparation of $(\mathrm{CO})_{5} \mathrm{MoP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PMo}(\mathrm{CO})_{5}(\mathbf{1 b})$ was described in a communication [3]. Infrared spectra were recorded as Nujol mulls ( KBr windows)

Fig. 1. The interconversion of the cis, trans- and trans, cis-isomers of $\mathrm{L}_{n} \mathrm{MP}(\mathrm{R})_{2} \mathrm{NSN}(\mathrm{R})_{2} \mathrm{PML}_{n}$.
or hexane solutions on a Nicolet DX-5 FTIR spectrometer. Raman spectra were obtained on a Jarrell-Ash Model 25-100 double monochromator calibrated with carbon tetrachloride. A Coherent Radiation CR4 Argon ion laser fitted with an Innova plasma tube was used to obtain exciting radiation at 514 and 600 nm . Solid samples were made up as KBr discs (ca. 10 mm diameter) placed in a glass vial, which was rotated at 1000 rpm to prevent thermal decomposition. UV-VIS spectra were measured by use of a Cary 219 spectrophotometer. ${ }^{31} \mathrm{P}$ NMR spectra were recorded with use of a Varian XL-200 spectrometer. Chemical shifts are reported in ppm downfield from $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ in $\mathrm{D}_{2} \mathrm{O}$. Melting points were obtained on samples in open capillary tubes and are uncorrected. Chemical analyses were performed by the Analytical Services division of the Department of Chemistry, University of Calgary.

Preparation of $(\mathrm{CO})_{5} \mathrm{CrP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PCr}(\mathrm{CO})_{5}$ (la)
A solution of $\mathrm{Cr}(\mathrm{CO})_{5}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)_{2}(0.80 \mathrm{~g}, 1.94 \mathrm{mmol})$ in acetonitrile ( 15 ml ) was added dropwise over a period of 30 min to a stirred suspension of $\mathrm{K}_{2} \mathrm{SN}_{2}(0.12 \mathrm{~g}$, 0.90 mmol ) in acetonitrile ( 15 ml ) cooled to $-40^{\circ} \mathrm{C}$. The reaction mixture, which turned dark red during the addition, was allowed to warm to room temperature. Solvent was removed in vacuo and the residue was treated with methylene dichloride ( 5 ml ) and purified by chromatography on a silica-60 ( $230-430$ mesh) column ( $10 \times 2.5 \mathrm{~cm}$ ) using pentane/methylene dichloride (3/1) as eluant. The dark orange-red fraction was collected. After removal of the solvent, the residue was recrystallized from $n$-hexane to give black crystals of $(\mathrm{CO})_{5} \mathrm{CrP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PCr}-$ $(\mathrm{CO})_{5}\left(0.22 \mathrm{~g}, 0.27 \mathrm{mmol}, 30 \%\right.$ yield) m.p. $118-120^{\circ} \mathrm{C}$. Anal. Found: C, $49.66 ; \mathrm{H}$, $2.38 ; \mathrm{N}, 3.00 . \mathrm{C}_{34} \mathrm{H}_{20} \mathrm{Cr}_{2} \mathrm{~N}_{2} \mathrm{O}_{10} \mathrm{P}_{2} \mathrm{~S}$ calc: C, $50.13 ; \mathrm{H}, 2.48 ; \mathrm{N}, 3.44 \%$. Spectroscopic data are summarized in Table 1.

Preparation of $(\mathrm{CO})_{2} \mathrm{Cp}^{\prime} \mathrm{MnP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PMnCp}^{\prime}(\mathrm{CO})_{2}(\mathrm{Ic})\left(\mathrm{Cp}^{\prime}=\mathrm{CH}_{3} \mathrm{C}_{5} \mathrm{H}_{4}\right)$
A solution of $\mathrm{Mn}(\mathrm{CO})_{2} \mathrm{Cp}^{\prime}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)(1.02 \mathrm{~g}, 2.40 \mathrm{mmol})$ in acetonitrile $(20 \mathrm{ml})$ was added dropwise to a stirred suspension of $\mathrm{K}_{2} \mathrm{SN}_{2}(0.14 \mathrm{~g}, 1.01 \mathrm{mmol})$ in acetonitrile ( 20 ml ) cooled to $-40^{\circ} \mathrm{C}$. The mixture was allowed to warm to room temperature then stirred for 16 h . Solvent was removed in vacuo and the residue was purified by chromatography on a silica-60 (230-400 mesh) column ( $10 \times 2.5 \mathrm{~cm}$ )

Spectroscopic data are summarized in Table 1.

## Preparation of cis- $\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)$ (2a)

A solution of $\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{Ph}_{2} \mathrm{PCl}_{2}(0.59 \mathrm{~g}, 0.97 \mathrm{mmol})\right.$ in methylene dichloride ( 10 $\mathrm{ml})$ was added dropwise to a stirred suspension of $\mathrm{K}_{2} \mathrm{SN}_{2}(0.17 \mathrm{~g}, 1.23 \mathrm{mmol})$ in acetonitrile $(10 \mathrm{ml})$ cooled to $-40^{\circ} \mathrm{C}$. The mixture was allowed to warm to room temperature then stirred for 16 h . Solvent was removed in vacuo and the residue extracted with a hexane/methylene dichloride mixture ( $10 / 1$ ). Recrystallization from hexane/methylene dichloride $(2 / 1)$ yielded cis $-\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)$ $(0.13 \mathrm{~g}, 0.22 \mathrm{mmol}, 23 \%)$ as a dark purple solid, m.p. $160^{\circ} \mathrm{C}$ (dec.). Anal. Found: C, $56.40 ; \mathrm{H}, 3.37 ; \mathrm{N}, 4.71 . \mathrm{C}_{28} \mathrm{H}_{20} \mathrm{CrN}_{2} \mathrm{O}_{4} \mathrm{P}_{2} \mathrm{~S}$ calc: C, 56.57 ; $\mathrm{H}, 3.40 ; \mathrm{N}, 4.71 \%$. Spectroscopic data are summarized in Table 1.

## Preparation of cis-Mo(CO) ${ }_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)(2 b)$

A solution of cis $-\mathrm{Mo}(\mathrm{CO})_{4}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)(1.10 \mathrm{~g}, 1.69 \mathrm{mmol})$ in a mixture of acetonitrile ( 5 ml ) and methylene dichloride ( 5 ml ) was added dropwise to a stirred suspension of $\mathrm{K}_{2} \mathrm{SN}_{2}(0.23 \mathrm{~g}, 1.69 \mathrm{mmol})$ in acetonitrile ( 20 ml ) at $-40^{\circ} \mathrm{C}$. The mixture was allowed to warm to room temperature then stirred for 16 h . Solvent was removed in vacuo and the product was purified by chromatography on a silica- 60 ( $230-400$ mesh) column ( $10 \times 2.5 \mathrm{~cm}$ ) using pentane/methylene dichloride ( $2 / 1$ ) as eluant. An orange-brown fraction was collected. Removal of solvent yielded cis$\mathrm{Mo}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)(0.28 \mathrm{~g}, 0.44 \mathrm{mmol}, 26 \%)$. An analytically pure sample was obtained by recrystallization from hexane/methylene dichloride, m.p. $155^{\circ} \mathrm{C}$ (dec.). Anal. Found: C, 52.91; H, 3.10; N, 4.27. $\mathrm{C}_{28} \mathrm{H}_{20} \mathrm{MoN}_{2} \mathrm{O}_{4} \mathrm{P}_{2} \mathrm{~S}$ calc: C , 52.67 ; H, 3.16; N, 4.39\%. Spectroscopic data are summarized in Table 1.

## X-Ray analysis

Crystals of cis- $\mathrm{Cr}(\mathrm{CO})_{4} \mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P} \cdot 0.5 \mathrm{C}_{6} \mathrm{H}_{6}$ suitable for an X-ray structural determination were obtained by recrystallization from benzene/hexane. A purple crystal ( $0.5 \times 0.3 \times 0.2 \mathrm{~mm}$ ) was mounted in a glass capillary under an atmosphere of dry nitrogen. The complex crystallizes in the space group $P \overline{1}$ with cell dimensions of $a$ 9.878(1), $b 12.240(1), c 12.610(2) \AA, \alpha$ 87.795(9), $\beta$ 77.017(10), $\gamma$ $81.027(9)^{\circ}$, and $V 1467.6(6) \AA^{3}$ as determined by least-squares refinement of 25 accurately centered reflections with $8.9^{\circ}<\theta<16^{\circ}$. The final choice of space group was based on the centric distribution of $E$ values ( $K$ curve) [11] and the successful solution of the structure. For the formula $\mathrm{C}_{28} \mathrm{H}_{20} \mathrm{CrN}_{2} \mathrm{O}_{4} \mathrm{P}_{2} \mathrm{~S} \cdot 0.5 \mathrm{C}_{6} \mathrm{H}_{6}, Z=2, D$ $1.434 \mathrm{~g} \mathrm{~cm}^{-3}, \mu\left(\mathrm{Mo}-K_{\alpha}\right) 6.26 \mathrm{~cm}^{-1}$ and $F(000)=650$. The data were collected at $21(1)^{\circ} \mathrm{C}$ on an Enraf-Nonius CAD4F automated diffractometer using the $\omega-2 \theta$ scan technique (scan speed of 0.5 to $3.3^{\circ} \mathrm{min}^{-1}$, scan range $1.5(0.74+0.347 \tan \theta)$ and $\mathrm{Mo}-K_{\alpha}$ radiation (graphite monochromator)). The data were corrected for background, Lorentz, and polarization effects as well as crystal decay (average of $15 \%$ drop in intensity standards). 5150 unique reflections were collected to a maximum $\theta=25^{\circ}$, of which 3684 were considered observed ( $I>3 \sigma(I)$ where $\sigma(I)$ was derived from counting statistics). An absorption correction was applicd using
an empirical method (difabs) [12] in order to account for the capillary and grease used in the mounting of the crystal. The minimum and maximum absorption corrections were 0.87 and 1.06 , respectively.

Atomic scattering factors for non-H atoms were those of Cromer and Mann [13], the H scattering factors were taken from ref. 14 and real and anomalous dispersion corrections were applied to all non-H atoms [15]. The structure was solved by direct

methods (MULTAN 78) [16], which clearly revealed the positions of the atoms of the CrPNSNP ring, and difference Fourier syntheses. Refinement was carried out by full-matrix least-squares techniques based on $F$, minimizing the function $\Sigma w\left(\left|F_{0}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$, where $w=\left[\sigma^{2}(F)+0.0001 F^{2}\right]^{-1}$. H atoms were located on a difference Fourier map and included in idealized positions with an isotropic thermal parameter set to $1.1 \times B_{\text {eq }}$ of the bonded atom. In the final cycles all non- H atoms were refined anisotropically and a value of $0.87(11) \times 10^{-5}$ was determined for the isotropic extinction correction. The model converged for 3684 reflections and 371 variables with $R=\Sigma\left(\| F_{0}\left|-\left|F_{\mathrm{c}}\right|\right|\right) / \Sigma\left|F_{0}\right|=0.034, \quad R_{\mathrm{w}}=\left[\Sigma w\left(\left|F_{0}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}\right.$ $\left./ \Sigma W\left|F_{0}\right|^{2}\right]^{1 / 2}=0.036$ and $G O F=1.14$. The final atomic coordinates for the non-H atoms are given in Table 2. Lists of thermal parameters, hydrogen atom coordinates, complete bond lengths and angles, and structure factors are available from the authors.

## Results and discussion

Reactions of the complexes $M L_{n}\left(P h_{2} P C l\right)_{x}(x=1$ or 2$)$ with $K_{2} S_{2}$
The metathetical reaction of $\mathrm{K}_{2} \mathrm{SN}_{2}$ with complexes of the type $\mathrm{ML}_{n}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)_{x}$ ( $x=1,2$ ) in acetonitrile provides a convenient and general synthesis of complexes of the $\mathrm{Ph}_{2} \mathrm{PNSNPPh}_{2}$ ligand. Both homodinuclear and mononuclear complexes have been prepared in this way.
$2 \mathrm{ML}_{n}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)+\mathrm{K}_{2} \mathrm{SN}_{2} \rightarrow \mathrm{~L}_{n} \mathrm{MP}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{PML}_{n}+2 \mathrm{KCl}$

$$
\begin{aligned}
& \left(\mathbf{1 a}, \mathrm{ML}_{n}=\mathrm{Cr}(\mathrm{CO})_{s} ;\right. \\
& \text { 1b, } \mathrm{ML}_{n}=\mathrm{Mo}(\mathrm{CO})_{5} ; \\
& \left.\mathbf{1 c}, \mathrm{ML}_{n}=\mathrm{MnCp}^{\prime}(\mathrm{CO})_{2}\right)
\end{aligned}
$$

$c i s-\mathrm{M}(\mathrm{CO})_{4}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)_{2}+\mathrm{K}_{2} \mathrm{SN}_{2} \rightarrow c i s-\mathrm{M}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)+2 \mathrm{KCl}$

$$

& (\mathbf{2 a}, \mathrm{M}=\mathrm{Cr} ; \\
& \mathbf{2 b}, \mathrm{M}=\mathrm{Mo})
\end{aligned}
$$

The complexes $\mathbf{1 a} \mathbf{a} \mathbf{c}$ and $\mathbf{2 b}$ are dark orange or red and $\mathbf{2 a}$ is purple. In the solid state they are stable towards air or moisture, but hydrolysis occurs slowly in solution to give $\mathrm{M}(\mathrm{CO})_{5}\left(\mathrm{Ph}_{2} \mathrm{PNH}_{2}\right)$ identified by ${ }^{31} \mathrm{P}$ NMR spectroscopy [17]. The structure of $\mathbf{1 b}$ has been determined previously by X-ray crystallography [3] and spectroscopic data (Table 1) indicate that the other homodinuclear complexes, 1a and 1c, adopt a similar cis,trans conformation of the ligand. An X-ray structural analysis of 2a is described below.

Although ligands of the type RNSNR ( $\mathrm{R}=$ alkyl, aryl) form a variety of complexes with organometallic substrates, in which $\mathrm{M}-\mathrm{N}, \mathrm{M}-\mathrm{S}$ or $\mathrm{M}-\pi-\mathrm{N}=\mathrm{S}$ bonding may be involved [18], the major products of these metathetical reactions are complexes of $\mathrm{Ph}_{2} \mathrm{PNSNPPh}_{2}$ with only the phosphorus atoms coordinated to the metal. We have, however, detected by TLC very small amounts of an additional product in these reactions, but preparative scale chromatography gave insufficient material for spectroscopic identification. It is possible that these products involve a different mode of coordination of the $\mathrm{Ph}_{2} \mathrm{PNSNPPh}_{2}$ ligand to the metal centres.

Crystal and molecular structures of cis- $\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right) \cdot 0.5 \mathrm{C}_{6} \mathrm{H}_{6}$
The crystal structure of 2 a consists of discrete molecular units with no unusual intermolecular contacts. Half a molecule of benzene per molecule of $\mathbf{2 a}$ is present as solvent of crystallization. The benzene molecule sits on a crystallographically imposed centre of symmetry. Figure 2 shows an ORTEP drawing with the atomic numbering scheme for the molecule. Selected bond lengths and bond angles are given in Table 3. The complex 2a has approximately octahedral symmetry about the Cr atom and the $\mathrm{P}_{2} \mathrm{~N}_{2} \mathrm{~S}$ ligand, which is planar to within $0.02 \AA$, is tilted at an angle of $126.7^{\circ}$ with respect to the $\mathrm{C}_{2} \mathrm{CrP}_{2}$ unit, which is planar to within $0.04 \AA$. The conformation of the $\mathrm{Ph}_{2} \mathrm{PNSNPPh}_{2}$ ligand in this mononuclear, chelate complex is, of necessity, cis,cis in contrast to the cis,trans conformation of the homodinuclear complexes. The cis and trans designations refer to the geometry of substituents relative to individual $\mathrm{S}=\mathrm{N}$ bonds. The values of the angles at the nitrogen atoms in 2a (128.8(1) and 129.4(1) $\AA$ ) are close to that found for the nitrogen atom in the cis- $\mathrm{S}=\mathrm{N}$ unit of $\mathbf{1 b}\left(130.8(2)^{\circ}\right)$, but substantially larger than the angle at the nitrogen atom of the trans- $\mathrm{S}=\mathrm{N}$ bond of $\mathbf{1 b}\left(117.9(2)^{\circ}\right)$ [3]. The angle at the sulphur atom in 2 a of $123.0(1)^{\circ}$ is also significantly larger than the corresponding angles in 1b $\left(116.0(2)^{\circ}\right)$ or other cis, trans-sulphur diimides, ca. $117^{\circ}$ [19-21], but it is similar

Fig. 2. ORTEP plot ( $50 \%$ probability ellipsoids) and atomic numbering scheme for cis$\mathrm{Cr}(\mathrm{CO})_{4}\left(\mathrm{P}(\mathrm{Ph})_{2} \mathrm{NSN}(\mathrm{Ph})_{2} \mathrm{P}\right)(2 \mathrm{a})$. Half a molecule of $\mathrm{C}_{6} \mathrm{H}_{6}$ per molecule of 2 a is present in the crystal as solvent of crystallization.

to the values found for other cis, cis-sulphur diimides, $\mathrm{RNSNR}\left(\mathrm{R}=\mathrm{ClC}_{6} \mathrm{H}_{4} \mathrm{~S}\right.$ ( $124^{\circ}$ ) [22], $\mathrm{R}=\mathrm{Ph}_{2}$ As ( $125.7^{\circ}$ ) [23]). The $\mathrm{S}-\mathrm{N}$ bond lengths of 1.523(2) and $1.525(2) \AA$ in 2 a are not significantly different from either the cis- or trans- $\mathrm{S}=\mathrm{N}$ bonds in 1b ( $1.515(3)$ and $1.529(4) \AA$ ), respectively [3]). The $\mathrm{P}-\mathrm{N}$ bond lengths of $1.727(2) \AA$ are, however, slightly longer than the cis-P-N bond in $\mathbf{1 b}(1.706(3) \AA)$ and are comparable to the value of $1.732(3) \AA$ found for the trans-P-N bond in 1b [3]. All these $\mathbf{P}-\mathbf{N}$ bonds are significantly shorter than the value of $1.77 \AA$ usually quoted for a $\mathbf{P}_{-} \mathbf{N}$ single bond [24]. This may indicate some $\mathrm{N}(p \pi) \rightarrow \mathrm{P}(d \pi)$ contribution to these bonds (vide infra).

The tilting of the $\mathrm{P}_{2} \mathrm{~N}_{2} \mathrm{~S}$ ring towards $\mathrm{C}(2)$ appears to be reflected in a longer $\mathrm{Cr}-\mathrm{C}(2)$ bond length of $1.901(3)$, cf. $1.873(3) \AA$ for $\mathrm{Cr}-\mathrm{C}(1)$. Possibly as a consequence of the elongation of the $\mathrm{Cr}-\mathrm{C}(2)$ bond the shortest $\mathrm{C} \equiv \mathrm{O}$ bond, 1.142(4) $\AA$, also involves $C(2)$, cf. an average value of $1.153(4) \AA$ for the other three $C \equiv O$ bonds.

Fluxional behaviour of the homodinuclear complexes, la-c
In a preliminary study [3] we described the variable temperature ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of 1 b in acetone- $d_{6}$. At $-90^{\circ} \mathrm{C}$ two equally intense singlets were observed at +96.0 and +90.5 ppm consistent with the existence of the cis, trans isomer in solution at that temperature. When the temperature of the solution was gradually

TABLE 4

${ }^{a}$ In acetone- $d_{6}$ at $-90^{\circ} \mathrm{C}$; chemical shifts are in ppm relative to external $85 \% \mathrm{H}_{3} \mathrm{PO}_{4}$ in $\mathrm{D}_{2} \mathrm{O}$. The assignments for the non-equivalent phosphorus atoms are tentative (see text). ${ }^{b}$ In acetone- $d_{6}$ at $20^{\circ} \mathrm{C}$. ${ }^{c}$ Activation energies ( $\pm 0.2$ ) for the cis, trans $\leftrightarrow$ trans, cis interconversion [25].
raised, these two signals broadened and collapsed until at $+20^{\circ} \mathrm{C}$ a single, sharp singlet was observed at +93.7 ppm . The reverse of these changes was observed when the solution was cooled again to $-90^{\circ} \mathrm{C}$. These observations were interpreted in terms of a rapid cis, trans to trans, cis interconversion (Fig. 1). The coalescence temperature was $-60^{\circ} \mathrm{C}$ corresponding to an interconversion barrier of $9.4 \pm 0.2$ kcal $\mathrm{mol}^{-1}$ for this process [25]. The ${ }^{31} \mathrm{P}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra of 1a and 1 c in acetone- $d_{6}$ exhibit changes as a function of temperature similar to those described for $\mathbf{1 b}$. These similarities and the frequencies of the $\nu_{a s}$ and $\nu_{s}($ NSN $)$ bands in the vibrational spectra (Table 1) are good evidence for a cis,trans structure for 1a and 1c. The ${ }^{31} P$ NMR chemical shifts, coalescence temperatures, and activation energies for the cis, trans $\rightarrow$ trans, cis interconversion of 1a-c are given in Table 4.

It is not possible to make an unambiguous assignment of the two signals observed in the low temperature ${ }^{31} \mathbf{P}$ NMR spectra of $\mathbf{1 a} \mathbf{c}$ from the present data. A comparison of the $\delta\left({ }^{31} \mathrm{P}\right)$ values for $1 \mathbf{a}-1 \mathbf{c}, 2 \mathrm{a}$ and 2 b with those for the corresponding $\mathrm{Ph}_{2} \mathrm{PCl}$ complexes, e.g. $\mathrm{M}(\mathrm{CO})_{5}\left(\mathrm{Ph}_{2} \mathrm{PCl}\right)(\mathrm{M}=\mathrm{Cr}$ or Mo$)$, is, however, suggestive. To a first approximation, the subtraction of the latter values from the former eliminates the effect of the metal fragment on the $\delta\left({ }^{31} \mathrm{P}\right)$ values. Consequently, these differences can be taken as an indication of the influence of the sulphur diimide unit on ${ }^{31} \mathrm{P}$ chemical shifts. The ${ }^{31} \mathrm{P}$ NMR signals for $\mathbf{1 a}-\mathbf{c}, \mathbf{2 a}$ and $\mathbf{2 b}$ are all shifted to high field relative to those of the corresponding $\mathrm{Ph}_{2} \mathrm{PCl}$ complexes, but the upfield shifts for $\mathbf{2 a}$ and $\mathbf{2 b}$ are larger (Table 1). It is reasonable to assume that the cis, cis-conformation of the chelating ligand in $2 \mathbf{a}$ and $\mathbf{2 b}$ is rigid and will be retained in solution. Thus the higher upfield shifts of $\mathbf{2 a}$ and $\mathbf{2 b}$ are associated with phosphorus atoms that are in cis-conformations relative to the other substituent attached to the $\mathrm{N}=\mathrm{S}$ bond in these complexes. On this basis, we tentatively conclude that the upfield signal in the low temperature ${ }^{31} \mathrm{P}$ NMR spectra of la-c can be assigned to the phosphorus atom in a cis-conformation and the lower field signal belongs to the phosphorus atom in the trans-conformation. The shorter $\mathbf{P}-\mathbf{N}$ distance found for the cis compared to the trans phosphorus atom in $\mathbf{1 b}$ has been attributed to stronger $\mathrm{N}(p \pi) \rightarrow \mathrm{P}(d \pi)$ bonding to the cis-phosphorus atom consistent with the assignment of this phosphorus environment to the upfield signal.

Ab initio molecular orbital calculations for the model sulphur diimide MeNSNMe provide a value of $16.0 \mathrm{kcal} \mathrm{mol}^{-1}$ for the cis, trans $\rightarrow$ trans, cis interconversion barrier and predict lower values with increasing bulk of the substituents attached to nitrogen [26]. The $E_{\mathrm{a}}$ values of 10.1, 9.8 and $13.4 \pm 0.2 \mathrm{kcal} \mathrm{mol}^{-1}$ found for 1a, 1b, and 1c, respectively, are consistent with these theoretical predictions. A possible
explanation of the higher $E_{\mathrm{a}}$ value for 1c compared to the essentially identical values for $\mathbf{1 a}$ and $\mathbf{1 b}$ can be surmised from an inspection of the spectroscopic data in Table 1. The manganese complex, lc, shows a higher upfield ${ }^{31} \mathrm{P}$ NMR chemical shift relative to the corresponding $\mathrm{Ph}_{2} \mathrm{PCl}$ complex, lower NSN stretching frequencies, and lower transition energies for the visible absorption band when compared to the corresponding data for $\mathbf{1 a}$ and $\mathbf{1 b}$. As a result of the formal +1 charge on the metal, the $\mathrm{Cp}^{\prime} \mathrm{Mn}(\mathrm{CO})_{2}$ substituent is expected to be a weaker $\pi$-donor to phosphorus than $\mathrm{M}(\mathrm{CO})_{5}(\mathrm{M}=\mathrm{Cr}$ or W$)$. Consequently, $\mathrm{N}(p \pi) \rightarrow \mathrm{P}(d \pi)$ bonding will be stronger for 1 c than 1 la or $\mathbf{1 b}$ and this will be reflected in a higher upfield ${ }^{31} \mathrm{P}$ chemical shift for 1c. Concomitantly, the stronger involvement of nitrogen in $\pi$-bonding to phosphorus will result in weaker $\mathrm{S} \mathrm{N} \pi$-bonding in the sulphur diimide unit of 1c consistent with the observation of lower NSN stretching frequencies. The lower transition energy for the visible absorption band of $\mathbf{1 c}$ may also be a reflection of weaker $\pi$-bonding in the $\mathrm{N}=\mathrm{S}=\mathrm{N}$ unit if this band involves a transition from a $\pi$-type orbital. However, the assignment of the absorption spectra of sulphur diimides to the appropriate electronic transitions is not well established [27,28]. Nevertheless, the stronger $\mathrm{N}(p \pi) \rightarrow \mathrm{P}(d \pi)$ bonding in 1c is expected to make inversion at nitrogen more difficult and, hence, lead to a higher activation energy for the cis, trans $\rightarrow$ trans, cis interconversion.

## Acknowledgements

The authors are grateful to Professor M. Herberhold for helpful correspondence and preprints of refs. 4 and 5. We also thank Mr. K.J. Schmidt for providing the Raman spectra and Dr. K.A. Kerr for use of the X-ray diffractometer. This work received financial support from the NSERC (Canada) in the form of operating and infrastructure grants.
