# X-RAY CRYSTAL STRUCTURE OF TRIBENZYLALUMINUM • DIETHYL ETHERATE 

A.F.M. MAQSUDUR RAHMAN, KANIZ F. SIDDIQUI and JOHN P. OLIVER*<br>Department of Chemistry, Wayne State University, Detroit, Michigan 48202 (U.S.A.)<br>(Received July 3rd, 1986)

## Summary

The crystal structure of tribenzylaluminum • diethyl etherate has been determined by single crystal X-ray diffraction techniques. It crystallizes in the monoclinic system, space group $P 2_{1}$, with unit cell dimensions of $a$ 8.106(1), b 15.098(2), $c$ $10.037(1) \AA, \beta 111.02(1)^{\circ}, V 1146.6(3) \AA^{3}$, and $Z=2$. The final full matrix least-squares refinement on 1139 data gave $R_{F} 3.8$ and $R_{w F} 5.2 \%$. The compound is similar to other organoaluminum adducts yielding a four coordinate aluminum atom with average $\mathrm{Al}-\mathrm{C}$ distances of 1.986 and an $\mathrm{Al}-\mathrm{O}$ distance of $1.901(4) \AA$ which is significantly shorter than the $\mathrm{Al}-\mathrm{O}$ distance observed in other ether adducts. The average $\mathrm{C}-\mathrm{Al}-\mathrm{C}$ and $\mathrm{C}-\mathrm{Al}-\mathrm{O}$ angles are 113 and $106^{\circ}$, respectively.

## Introduction

Structural and spectroscopic studies on organoaluminum compounds and their adducts have been of great interest because of the unusual modes of bonding observed and the ability of suitable Lewis bases to disrupt these modes of bonding [1]. Many of the structural data have been reviewed [2] and several reviews have appeared which deal with the NMR spectral studies on these compounds [3-5]. In the earlier work two modes of bonding were reported for the dimeric aluminum species. The first of these, best represented by the studies of trimethylaluminum, can be described in terms of a three-centered molecular orbital arising from the interaction of a $\mathrm{C} s p^{3}$ orbital with two $s p^{3}$ hybrid orbitals, one from each of the Al atoms. This has been extended to include secondary interactions between $\pi$ electron systems or $p$ orbitals on the bridging group, as in the cyclopropyl derivatives or in the vinyl bridged derivatives, which provide additional stabilization to the bridge bond. The second type of interaction which has been described, is observed when an ethynyl moiety serves as the bridging group. In this dimer the bridging group is bonded to one Al atom by a $\sigma$ interaction and to the second by a $\pi$ interaction giving rise to an unsymmetrically bridged molecule both in the solid state [6,7] and in the gas phase [8]. An alternative mode of bonding is exhibited for the cyclopentadienyl derivative, $\mathrm{CpAlMe}_{2}$, which forms an infinite chain in the solid state
with unsymmetrical $\mathrm{C}_{5} \mathrm{H}_{5}$ bridging units with the bonding occurring through the $\pi$ system of the $\mathrm{C}_{5} \mathrm{H}_{5}$ unit in an alternating $\eta^{3}$ and $\eta^{2}$ fashion [9]. In the gas phase, this molecule has been shown to be monomeric with the Al atom bonded to the $\mathrm{C}_{5} \mathrm{H}_{5}$ ring in an $\eta^{2}$ fashion and appears to undergo rapid fluxional motion under these conditions [10].

We reported a second variation for the formation of an infinite chain in tribenzylaluminum with the interaction occurring between the vacant orbital on the aluminum atom with the $\mathrm{C}(2)$ carbon atom of a benzyl group in an adjacent molecule [11]. We now have shown that the extended bonding observed in the unsolvated tribenzylaluminum is disrupted by ether, giving a normal tribenzylaluminum • diethyl ether adduct.

## Experimental

## Preparation of compounds

Tribenzylaluminum was prepared by reaction of excess ( 10 -fold) aluminum granules with dibenzylmercury. The reaction was carried out in either toluene, as

Background measurements: the ratio of the background to scan time was 0.5 standard reflections: 3 standard reflections were measured every 97 reflections; no significant deviation from the mean was observed for either crystal
described by Eisch and Biedermann [13], or xylene solvent maintained at $140^{\circ} \mathrm{C}$ for 4 h in an oil bath. The resulting product contained yellow decomposition product which was removed by recrystallization from pentane or hexane and gave colorless crystals. These were dissolved in a mixed benzene-ether solvent system and crystals suitable for X-ray diffraction studies were obtained from this solution upon slow removal of a portion of the solvent on the vacuum system.

## $X$-Ray data collection

A crystal suitable for X-ray diffraction was mounted in a thin-walled capillary tube in the drybox, plugged with grease, removed from the drybox, flame sealed, and then mounted on a goniometer head. X-ray diffraction data were collected on a Syntex $\mathrm{P} 2_{1}$ diffractometer using $\mathrm{Mo}-K_{\bar{\alpha}}$ radiation diffracted from a highly oriented graphite crystal in the parallel mode. The data were collected with a $\theta-2 \theta$ scan. The specific conditions, unit cell, and unit cell dimensions are given in Table 1.

## Solution and refinement of structure

The tribenzylaluminum • diethyl ether adduct was found to be monoclinic and was assigned to the space group $P 2_{1}$ on the basis of systematic absences. The aluminum atom was located by the analysis of the three-dimensional Patterson

synthesis. The carbon and oxygen positions were determined from subsequent Fourier maps. The hydrogen atom positions were then calculated by using HFINDR [14]. Two additional cycles of refinement were carried out on all non-hydrogen atoms with the hydrogen atoms in fixed positions to give the final parameters listed. In the final least-squares, the number of variables was 243 , the number of observed data was 1139 , and the error in observation unit weight was 1.53 . The largest peak on the final difference map was 0.18 electrons $/ \AA^{3}, 1.244 \AA$ away from the Al atom. Neutral atom scattering factors, including anomalous dispersion, were used for all the atoms [14]. Final positional parameters are presented in Table 2. The errors were estimated by the variance-covariance method. Lattice errors were not included. Additional details for the structure is available [15].

## Results and discussion

A diagram showing the molecular unit with the atoms labeled is given in Fig. 1. Selected bond distances and angles are collected in Table 3. A comparison of the pertinent values with a variety of other organoaluminum compounds and adducts is given in Table 4. These data show that the gross features of the tribenzylaluminum adduct are similar in all respects to those of other aluminum addition compounds. A more detailed inspection of the data reveals that the $\mathrm{Al}-\mathrm{O}$ bond distance in this derivative is significantly shorter than in the other known structures, $0.027 \AA$ shorter than that in the $(o-\mathrm{Tol})_{3} \mathrm{Al} \cdot \mathrm{OEt}_{2}$ adduct and a full $0.1 \AA$ less than the reported distance in several of the $\mathrm{Me}_{3} \mathrm{Al}$ adducts given in Table 4. These observations are

Fig. 1. A perspective view of the tribenzylaluminum•diethyl etherate molecule with the atoms labeled.

consistent with the fact that the aromatic substituents on aluminum can better delocalize the negative charge on the organic group and, thus, increase the positive charge on the Al atom. This would tend to increase the Al-O bond energy and lead

to the bond shortening observed. To further substantiate this proposal additional cases need to be examined in which both the Lewis base and the substituent on the aluminum atom are varied.

Examination of the data in Table 3 reveals that the three sets of angles involving the aluminum atom, $\mathrm{C}-\mathrm{Al}-\mathrm{C}, \mathrm{C}-\mathrm{Al}-\mathrm{O}$, and $\mathrm{Al}-\mathrm{C}-\mathrm{C}$, show significant variations. Further, in each case where the angle deviates by a significant amount from the value that might be expected, the third benzyl group is involved. The molecular packing shows that the individual tribenzylaluminum $\cdot$ diethyl etherate molecules are separated in the lattice with no unusual interactions. This leaves the most probable explanation for the large variations observed in these angles, the interaction of the diethyl ether molecule with benzyl group 3 resulting in the angular deformation.

In contrast to the rather normal behavior of the addition compound, the structure of the parent molecule was shown to behave in an unusual manner with the aluminum atom in a pseudo-tetrahedral environment surrounded by the three methylene carbon atoms with the fourth position occupied by an ortho-carbon atom from a phenyl ring on an adjacent tribenzylaluminum molecule. The extended array is disrupted on addition of ether and the adduct formed behaves in a completely normal fashion for an aluminum addition compound.
