# COORDINATION CHEMISTRY OF SILOLES: VINYL-, ALLYL- AND ALKYNYL-SILOLES; SYNTHESIS AND STRUCTURE OF $\eta^{4}, \eta^{2}$-1-ALLYL AND 1-VINYL-2,5-DIPHENYLSILACYCLOPENTADIENE COMPLEXES * 

F. CARRÉ, R.J.P. CORRIU, C. GUERIN, B.J.L. HENNER, B. KOLANI and W.W.C. WONG CHI MAN<br>Laboratoire "Hétérochimie et Amino-Acides", U.A. C.N.R.S. 1097, Institut de Chimie Fine, Université des Sciences et Techniques du Languedoc, Place Eugène Bataillon, F-34060 Montpellier Cedex (France)

(Received December 12th, 1986)

## Summary

The reactions of 1-allyl-1-methyl- (8), 1-vinyl-1-methyl- (10), 1,1-diallyl- (14), 1,1-divinyl- (16), 1-ethynyl-1-methyl- (2a) and 1-propynyl-1-methyl-2,5-diphenylsilacyclopentadiene (2b) (or siloles) with transition metals are described. Competition between complexation of the diene and that of the triple bond of the propynylsilole is observed with $\mathrm{Co}_{2}(\mathrm{CO})_{8}$, but with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$, the $\eta^{4}$-complexes are obtained in all cases. $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ reacts with the vinyl- and allyl-siloles to give $\eta^{4}$-complexes, but $\mathrm{Mo}(\mathrm{CO})_{4}(\mathrm{COD})\left(\mathrm{COD}=1,5\right.$-cyclooctadiene) or $\mathrm{W}(\mathrm{CO})_{3}\left(\mathrm{CH}_{3}\right.$ $\mathrm{CN})_{3}$ gives $\eta^{4}, \eta^{2}$-complexes. The crystal structures of ( $\eta^{4}$ - $\eta^{2}$-endo- 1 -allyl)-exo-1-methyl)- (9a) and ( $\eta^{4}$-( $\eta^{2}$-endo-1-vinyl)-exo-1-methyl-2,5-diphenylsilacyclopentadiene)tricarbonyl molybdenum (12a) have been determined. They show that the dihedral angle between the diene and the $\mathrm{C}(1)-\mathrm{Si}-\mathrm{C}(2)$ plane is $28^{\circ}$ in the case of the allyl derivative 9a but only $8.9^{\circ}$ in the vinyl complex 12a.

## Introduction

We have shown previously that 2,5 -diphenylsilacyclopentadienes (or siloles) are good ligands for transitions metals [1]. We report here results obtained with 2,5-diphenylsilacyclopentadienes bearing an unsaturated group, vinyl, allyl or alkynyl, on silicon. These groups are interesting from two points of view: first they may coordinate to the transtion metal leading to other different geometries or polymetallic compounds, and secondly they are "pseudofunctional" groups which can be cleaved by electrophiles with possible formation of reactive functional groups

[^0](such as halides) at silicon. In the case of an alkynyl group bonded to silicon, the possibility arises of competition between complexation of the triple bond and that of the diene of the silole.

## Results and discussion

The ethynylsilole 2 a and propynylsilole $\mathbf{2 b}$ were prepared (eq. 1) from methylchlorosilole 1. These compounds have three possible modes of coordination, via the

(2a, R $=\mathrm{H}$;
2b, R = Me)
diene or the triple bond or both. All three modes are observed, depending on the transition metal (Schemes 1 and 2).

(3)

(4)

SCHEME 1

SCHEME 2

The reaction of $\mathbf{2 b}$ with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ gave the $\eta^{4}$-complex 3 with the methyl group in endo-position. The triple bond was not affected but complex 3 reacted further with $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ to give 4 , which contains one iron and two cobalt atoms.

The alkynyl derivatives 2 reacted with 2 moles of $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ to give 5 in which both the diene and the triple bond are complexed to the metal. But $\mathbf{2 b}$ reacted with 1 mole of $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ to give complex $\mathbf{5 b}$ together with a compound having only the triple bond complexed to the cobalt. Reaction of 2 b with 1.5 moles of $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ gave a low yield of the symmetric derivative 7 , which has six cobalt atoms in the molecule; two of these are complexed with the dienes and the remaining four with the two triple bonds (Scheme 2).

Reaction of 1-methyl-1-allyl-2,5-diphenylsilacyclopentadiene (8) with $\mathrm{Mo}(\mathrm{CO})_{4}-$ (COD) or $\mathrm{W}(\mathrm{CO})_{3}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}$ gave the complexes 9 (eq. 2).The structures of

complexes 9 were determined by IR, ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectroscopy (see Table 1 and Fig. 1 for ${ }^{1} \mathrm{H}$ NMR of 9 a ) and by X-ray analysis of 9 a (vide infra), which gave the dihedral angle between the diene plane and the ( $\mathrm{C}(1)-\mathrm{Si}-\mathrm{C}(2)$ ) plane. This angle

## SCHEME 3

Fig. 2. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{D}_{6}\right)$ spectrum of complex $\mathbf{1 2 b}$.
of $28^{\circ}$, is similar to that of $32^{\circ}$ observed by Muir [2] in the case of ( $\eta^{4}-1,1$-dimethyl2,5 -diphenylsilacyclopentadiene)tricarbonylruthenium, but it is larger than the $20^{\circ}$ observed for $\operatorname{bis}\left(\eta^{4}\right.$-1,1-dimethyl-2,5-diphenylsilacyclopentadiene)nickel [1].

In order to reduce the dihedral angle, vinyl derivatives were prepared (Scheme 3). Compound 10 reacted with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ to give the ( $\eta^{4}$-exo-1-methyl-endo-1-vinyl-2,5diphenylsilacyclopentadiene)tricarbonyliron complex 11. The exocyclic vinyl group is not coordinated to the iron atom, as observed in the case of allyl [1]. But, in the case of molybdenum and tungsten, the spectroscopic data for complexes 12 and crystal structure of $\mathbf{1 2 b}$ showed that the vinyl double bond is coordinated to the metal (Fig. 2 shows the ${ }^{1} \mathrm{H}$ NMR spectrum of 12b). In 12a (vide infra) the dihedral angle is only $8.9^{\circ}$ showing that it is possible to make the silacyclopentadiene ring flatter, and perhaps in that way permit aromaticity of the silacyclopentadiene ring.

The change in the dihedral angle results in the modification of the position of the $\mathbf{R}$ group, to exo with respect to the metal, and the reactivity of the R group should

(3)
$14 \xrightarrow{\mathrm{Fe}_{2}(\mathrm{CO})_{9}}$

(18)

SCHEME 4
thus be different. In order to check this, the disubstituted allyl- and vinyl-silicon derivatives were prepared (eq. 3, 4).

The diallyl derivative 14 reacted with $\mathrm{Fe}_{2}(\mathrm{CO})_{9}$ or $\mathrm{Co}_{2}(\mathrm{CO})_{8}$ to give the corresponding $\eta^{4}$-complexes 17 and 18 (Scheme 4), as observed in the case of the methyl(allyl)silole [1].

The ${ }^{1} \mathrm{H}$ NMR spectra showed that the endo-allyl group of complexes 17 and 18 were not coordinated to the metal; however, treatment of 14 and 16 with $\mathrm{Mo}(\mathrm{CO})_{4}(\mathrm{COD})$ or $\mathrm{W}(\mathrm{CO})_{3}\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}$ gave, as expected, the corresponding complexes 19 and 20 (eq. 5), with the exocyclic double bond complexed to the metal.

We tried to cleave the exo-silicon-carbon bond of complexes 19 and 20. $\mathrm{Me}_{3} \mathrm{SiOSO}_{2} \mathrm{Cl}$ normally brings about insertion of $\mathrm{SO}_{3}$ into silicon-carbon bonds

14 or $16 \xrightarrow[W]{\mathrm{Mo}(\mathrm{CO})_{4}(\mathrm{COD}) \text { or }\left(\mathrm{CH}_{3} \mathrm{CN}\right)_{3}}$

such as Si -aryl or Si -allyl [3], but 19a, gave a mixture of unidentified products. Reactions of 19a with HCl gas, $\mathrm{SbCl}_{5}$ intercalated in graphite, or $\mathrm{SnCl}_{4}$ (which is known to cleave the bond between the exo-methyl group and silicon in the tetraphenylsilole series [4]), gave intractable mixtures. With $\mathrm{SbF}_{5}$ intercalated in graphite [5], the exo-fluoro complex 21 was obtained in good yield (eq. 6). The corresponding reaction with the vinyl complex 20a was unsuccessful, as was that

(21)
of $\mathrm{CH}_{3} \mathrm{COCl} / \mathrm{AlCl}_{3}$ [6].
We are undertaking a study of the reactions of these new complexes.

## Crystal structures: results and comments

Structure of complex 9a. The labelling of the atoms is given in Fig. 3. The molecular configuration is best seen in Fig. 4. Bond lengths and bond angles are listed in Tables 2 and 3. The overall octahedral geometry is retained, with the three carbonyl groups trans to the three carbon-carbon double bonds. The mirror plane observed by Muir [2] in the free ligand, and even in the ruthenium tricarbonyl complex, is not retained here, owing to the configuration of the allyl group. Another feature is the fact that the $\mathrm{C}^{\prime}(3)-\mathrm{Mo}-\mathrm{C}^{\prime}(1)$ angle is $>14^{\circ}$ larger than the other $\mathrm{OC}-\mathrm{Mo}-\mathrm{CO}$ angles. This is due to steric hindrance of the allyl group trans to the carbonyl group $\mathrm{C}^{\prime}(2) \mathrm{O}(2)$, though the coordination distance of the vinyl ligand is much larger.

Within the silole ring, the $C(2)-C(3)$ distance, $1.457(8) \AA$, remains longer than the formal double bond distances (av. 1.42(1) $\AA$ ), thus suggesting a weaker coordi-

nation for molybdenum than for ruthenium (see ref. 2), the result is comparable to that we noted previously [1] for $\operatorname{bis}\left(\eta^{4}-1,1\right.$-dimethyl-2,5-diphenylsilacyclopentadiene)nickel.

| $\mathrm{C}(1)-\mathrm{Si}-\mathrm{Allyl}(1)$ | 111.2(3) | $\mathrm{C}(11)-\mathrm{C}(1)-\mathrm{C}(2)$ | 122.4(5) |
| C(4)-Si-Allyl(1) | 108.9(3) | $\mathrm{C}(41)-\mathrm{C}(4)-\mathrm{Si}$ | 130.0(5) |
| Me-Si-Allyl(1) | 113.4(3) | C(41)-C(4)-C(3) | 121.6(5) |

The phenyl rings are not coplanar with the butadiene unit; the phenyl rings $C(11-16)$ and $C(41-46)$ are rotated in the same sense (ca. 23.2 and $29.4^{\circ}$, respectively), with atoms $C(12)$ and $C(42)$, nearest to silicon, both lying away from the $\mathrm{Mo}(\mathrm{CO})_{3}$ moiety. The coordination of the allyl group decreases slightly the fold angle of the silole ring: the planar butadiene unit $C(1)-C(2)-C(3)-C(4)$ and the $\mathrm{C}(1)-\mathrm{Si}-\mathrm{C}(4)$ plane make a dihedral angle of $28.0^{\circ}$; this value is smaller than that observed for the molybdenum complex $\left(\mathrm{Me}_{4} \mathrm{Silole}\right)_{2} \mathrm{Mo}(\mathrm{CO})_{2}$ [7], in which the fold angle is $36.6^{\circ}$.

The mean $\mathrm{Si}-\mathrm{C}$ (silole) bond length, $1.88(1) \AA$, is identical with literature values [1,2] and longer than that observed for the disilole molybdenum complex [7] (1.86(1) $\AA$ ). The carbonyl group $\mathrm{C}^{\prime}(2) \mathrm{O}(2)$, trans to the vinyl group, looks slightly different from the two other CO groups: although the Mo---O(2) distance remains about $3.13(1) \AA$, the $C^{\prime}(2)$ atom is nearer to the Mo atom by $0.024(8) \AA$.

Fig. 5. Perspective view of complex 12a showing the labelling of the atoms, with the thermal ellipsoids at the $20 \%$ probability level.

Structure of complex 12a. Figure 5 gives a perspective view of the molecule with the atom numbering. A stereoscopic view is given in Fig. 4. Interatomic distances and main bond angles are listed in Tables 4 and 5. The overall geometry is the same as in complex 9a, but there is stronger coordination of the double bond of the vinyl group to the transition metal atom: Mo-C distances are 2.666 and $2.527(8) \AA$ in the "allyl"-complex discussed above; in 12a these distances are shorter at 2.498 and $2.527(7) \AA$, and fall in the range of Mo-to-butadiene distances (Mo-C(4): 2.500(7) $\AA$ ). As a consequence, the carbonyl ligand $\mathrm{C}^{\prime}(1) \mathrm{O}(1)$ trans to the vinyl group does not differ from the other carbonyl groups: the Mo- $\mathrm{C}^{\prime}(1)$ distance is equal to the average of the two other Mo-CO bond lengths, 1.976(8) A.

| Me-Si-Vinyl(1) | 120.1(3) | $\mathrm{C}(41)-\mathrm{C}(4)-\mathrm{C}(3)$ | 120.9(6) |

As would be expected, the absence of the $\mathrm{CH}_{2}$ link to silicon and a slight shortening of the vinyl carbon atoms to molybdenum distance lead to markedly smaller fold angle for the silole ring: the butadiene unit and the $\mathrm{C}(1)-\mathrm{Si}-\mathrm{C}(4)$ plane make a dihedral angle of $8.9^{\circ}$, leaving the Si atom only $0.21 \AA$ above the plane of the butadiene. Consequently, the Mo---Si Van der Waals contact shortens by about $0.24 \AA$ to fit the constrained geometry. This value for the fold angle is to our knowledge the smallest reported for a coordinated silole ring [1,2,7].

Another feature of the structure of complex 12a is the different conformations, at least in the solid state, of the phenyl rings; they are rotated in the same way, as for complex 9a, but not to the same extent: phenyl group $\mathrm{C}(11-16)$ makes an angle of ca. $14.1^{\circ}$ with the butadiene plane, whereas for phenyl group $\mathrm{C}(41-46)$ the angle is $52.2^{\circ}$. However, there are no significant differences in the $\mathrm{C}(1)-\mathrm{C}(2)$ and $\mathrm{C}(3)-\mathrm{C}(4)$ conjugated double bonds of the silole ring, i.e. the bond lengths are equal when the standard deviations are taken into account.

## Experimental

All reactions were carried out under nitrogen, a vacuum line and Schlenk tubes being used in the case of transition metal complexes. Solvents were dried and distilled before use. The preparations of the following starting materials have been described previously [1]: 1-chloro-1-methyl-, 1, 1-methyl-1-allyl-, 8, 1-methyl-1-vinyl-, 10, 1-hydro-1-allyl-, 13, 1-methoxy-1-vinyl-2,5-diphenylsilacyclopentadiene, 15. Melting points were determined with an oil-circulating apparatus. IR spectra were recorded with a Perkin-Elmer 298 spectrophotometer, ${ }^{1} \mathrm{H}$ NMR spectra with a Varian EM 360 or EM $390,{ }^{13}$ C NMR spectra with a Bruker WP 200 SY spectrometer (chemical shifts, $\delta(\mathrm{ppm})$, are relative to TMS). The mass spectra recorded with a JEOL JMS-D100 spectrometer, are electronic impact unless otherwise noted.

1-Methyl-1-ethynyl-2,5-diphenylsilacyclopentadiene (2a). A mixture of an excess of $\mathrm{HC} \equiv \mathrm{CMgBr}[8]$ and $\mathbf{1}$ in THF was stirred at room temperature for 20 h . After standard work up, the solvent was removed under vacuo and the residue chromatographed on florisil with $30 / 70$ toluene/hexane as eluant. Recrystallisation from hexane at $-20^{\circ} \mathrm{C}$ gave the product in $40 \%$ yield; m.p. $118-119^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CCl}_{4}\right): \delta 7.6-7.0(\mathrm{~m}, 12 \mathrm{H}$, aromatic and ethylenic), $2.5(\mathrm{~s}, 1 \mathrm{H}, \equiv \mathrm{C}-\mathrm{H}), 0.6(\mathrm{~s}, 3 \mathrm{H}$, $\mathrm{SiMe})$; IR $\left(\mathrm{CCl}_{4}\right): \nu(\mathrm{C} \equiv \mathrm{C}) 2030 \mathrm{~cm}^{-1}, \nu(\equiv \mathrm{C}-\mathrm{H}) 3280 \mathrm{~cm}^{-1}$; mass spectrum, $m / e$ (assignment) 272 (molecular peak). Found: C, $83.75 ; \mathrm{H}, 5.89, \mathrm{C}_{19} \mathrm{H}_{16} \mathrm{Si}$ calcd.: C , 83.82, H, 5.88\%.

1-Methyl-1-propynyl-2,5-diphenylsilacyclopentadiene (2b). A solution of 1 in ether was added dropwise to one of $\mathrm{CH}_{3} \mathrm{C} \equiv \mathrm{CLi}$ in the same solvent at $-30^{\circ} \mathrm{C}$. The mixture was allowed to warm up to room temperature with stirring during 0.5 h . After standard work up, the yellow residue was recrystallised from $1 / 9$ $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /hexane at $-78^{\circ} \mathrm{C}$. $15 \%$ yield; m.p. $101-102^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CCl}_{4}\right)$ : $\delta$ $7.6-7.1(\mathrm{~m}, 12 \mathrm{H}$, aromatic and ethylenic), $1.9(\mathrm{~s}, 3 \mathrm{H}, \mathrm{Me}), 0.5(\mathrm{~s}, 3 \mathrm{H}, \mathrm{SiMe})$; IR $\left(\mathrm{CCl}_{4}\right): \nu(\mathrm{C} \equiv \mathrm{C}) 2160 \mathrm{~cm}^{-1}$; mass spectrum, $m / e$ (assignment) 286 (molecular peak). Found: C, 83.62; H, 6.17. $\mathrm{C}_{20} \mathrm{H}_{18} \mathrm{Si}$ calcd.: C, $83.86 ; \mathrm{H}, 6.33 \%$.

1,1-Diallyl-2,5-diphenylsilacyclopentadiene (14). A ten-fold excess of allyl- MgBr ( $33 \mathrm{ml}, 1 \mathrm{M}$ ) in diethyl ether was added dropwise to a solution of $13(0.9 \mathrm{~g}, 3.25$ $\mathrm{mmol})$ with $\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{NiCl}_{2}(0.042 \mathrm{~g}, 2 \%)$. The mixture was stirred at room tempera-
ture ( 20 h ) (the disappearance of SiH was monitored by IR). After hydrolysis (cold $\mathrm{NH}_{4} \mathrm{Cl}$ solution) and standard work up, the solvent was pumped off and the remaining oil dissolved in hexane and kept at $-20^{\circ} \mathrm{C}$ to give yellow crystals of 14 . $40 \%$ yield; m.p. $45-46^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CCl}_{4}\right): \delta 7.5-7.0(\mathrm{~m}, 12 \mathrm{H}$, aromatic + ethylenic), $5.8-4.5\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{CH}=\mathrm{CH}_{2}\right), 2.2-1.95\left(\mathrm{~d}, 8 \mathrm{~Hz}, 4 \mathrm{H}, \mathrm{CH}_{2}\right)$. Found: C , 84.10; H, 7.19. $\mathrm{C}_{22} \mathrm{H}_{22} \mathrm{Si}$ calcd.: C, 84.07; H, $7.00 \%$.

1,1-Divinyl-2,5-silacyclopentadiene (16). To a solution of vinylmethoxysilole 15 in diethyl ether was added dropwise a ten-fold excess of vinyl- MgBr . The mixture was stirred for 20 h (disappearance of SiOMe monitored by TLC, toluene/hexane $10 / 90$ ). After standard work up, the remaining yellow oil was purified by preparative TLC with $30 / 70$ toluene/hexane as eluant. $61 \%$ yield; ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CCl}_{4}\right): \delta$ 7.5-7.0 (m, 12H, aromatic + ethylenic), $6.5-6.0\left(\mathrm{~m}, 6 \mathrm{H}, \mathrm{CH}=\mathrm{CH}_{2}\right)$. Found: 83.55; $\mathrm{H}, 6.70 . \mathrm{C}_{20} \mathrm{H}_{18} \mathrm{Si}$ calcd.: $\mathrm{C}, 83.88$; $\mathrm{H}, 6.33 \%$.
( $\eta^{4}$-exo-1-Propynyl-endo-1-methyl-2,5-diphenylsilacyclopentadiene)tricarbonyliron (3). A solution of $\mathbf{2 b}(0.2 \mathrm{~g}, 7 \mathrm{mmol})$ in 20 ml of toluene was added to a suspension of $\mathrm{Fe}_{2}(\mathrm{CO})_{9}(0.3 \mathrm{~g}, 7 \mathrm{mmol})$ in 30 ml of the same solvent, and the mixture was stirred at $40-50^{\circ} \mathrm{C}$ for 20 h . (IR monitoring). The solvent was pumped off and the residue extracted with hexane. The extract was filtered and kept at $-20^{\circ} \mathrm{C}$ to give red crystals of $3.35 \%$ yield. m.p. $150-152^{\circ} \mathrm{C}$ dec.; ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CCl}_{4}\right): \delta 7.7-6.8$ (m, 10 H , aromatic), 5.5 ( $\mathrm{s}, 2 \mathrm{H}$, ethylenic), 1.6 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{Me}$ ), 0.4 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{SiMe}$ ). IR (hexane) $\nu(\mathrm{C} \equiv \mathrm{C}): 2180 \nu(\mathrm{CO}) 2050,1990,1980 \mathrm{~cm}^{-1}$.
( $\eta^{4}$-exo-1-Methyl-endo-1-vinyl-2,5-diphenylsilacyclopentadiene)tricarbonyliron (11). The procedure as for 3 but with a reaction time 17 h . Yellow crystals. $41 \%$ yield; m.p. $152.5^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 7.40-7.0(\mathrm{~m}, 10 \mathrm{H}$, aromatic), $6.7-6.2(\mathrm{~m}, 3 \mathrm{H}$, vinyl), 6.0 (s, 2H, cyclic H), 0.15 (s, 3H, SiMe); IR (hexane): $\boldsymbol{\nu}$ (CO) 2050 (s), 1982(s, $\mathrm{br}) \mathrm{cm}^{-1}$; mass spectrum, $m / e$ (assignment, relative intensity) $414\left(M^{+}, 4\right), 386$ ( $M^{+}-\mathrm{CO}, 11$ ), $358\left(M^{+}-2 \mathrm{CO}, 14\right), 330\left(M^{+}-3 \mathrm{CO}, 100\right)$. Found: C, $64.03 ; \mathrm{H}$, 4.40. $\mathrm{C}_{22} \mathrm{H}_{18} \mathrm{FeO}_{3}$ Si calcd.: $\mathrm{C}, 63.78$; $\mathrm{H}, 4.38 \%$.
( $\eta^{4}$-exo-1-Allyl-endo-1-allyl-2,5-diphenylsilacyclopentadiene)tricarbonyliron (17). The procedure was as for 3 but with a reaction time of 24 h . Red crystals. $15 \%$ isolated yield, m.p. $110-111^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta 7.6-7.05(\mathrm{~m}, 10 \mathrm{H}$, phenyl), $6.8\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{H}^{\mathrm{C}}\right), 6.2\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{H}^{\mathrm{X}}\right), 6.0-5.3\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}^{\mathrm{B}}+\mathrm{H}^{\mathrm{E}}\right), 4.9-4.5\left(\mathrm{~m}, 2 \mathrm{H}, \mathrm{H}^{\mathrm{F}}\right)$, $2.1\left(\mathrm{~d}, 3 \mathrm{~Hz}, \mathrm{H}^{\mathrm{A}}\right), 1.6\left(\mathrm{~d}, 5-6 \mathrm{~Hz}, \mathrm{H}^{\mathrm{D}}\right)$. IR (hexane): $\boldsymbol{\nu}(\mathrm{CO}) 2050(\mathrm{~s}), 1980(\mathrm{~s}, \mathrm{br})$

$\mathrm{cm}^{-1}$. Found: $\mathrm{C}, 65.71$; $\mathrm{H}, 5.08 . \mathrm{C}_{25} \mathrm{H}_{22} \mathrm{FeO}_{3} \mathrm{Si}$ calcd.: $\mathrm{C}, 66.07$; $\mathrm{H}, 4.84 \%$.
( $\eta^{4}$-exo-1-(Propyne hexacarbonyldicobalt)-endo-1-methyl-2,5-diphenylsilacyclopentadiene)tricarbonyliron (4). A solution of complex $3(0.213 \mathrm{~g}, 0.5 \mathrm{mmol})$ and $\mathrm{Co}_{2}(\mathrm{CO})_{8}(0.17 \mathrm{~g}, 0.5 \mathrm{mmol})$ in 20 ml hexane was stirred at room temperature for 20 h , then filtered and cooled at $-20^{\circ} \mathrm{C}$ to give brown crystals of $4.45 \%$ yield; m.p.
$170-175^{\circ} \mathrm{C}$ dec. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right): \delta 7.1$ (s, broad, 10 H , aromatic), 5.2 (s, cyclic H ), 2.9 (s, 3H, CMe), 0.35 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{SiMe}$ ). ## Crystal structures of complexes 9a and 12a

Crystal preparation. Crystals of complexes 9a and 12a were grown at $-20^{\circ} \mathrm{C}$ from hexane solutions under nitrogen. Preliminary X-ray photography revealed a triclinic unit cell for complex 9a, and a monoclinic one for complex 12a, with space group $P 2_{1} / a$ (systematic absences: $0 k 0, k=2 n+1 ; h 0 l, h=2 n+1$ ). The hexagonal plates were mounted inside Lindeman glass capillaries with the [100] and [011] directions, respectively, parallel to the $\Phi$ axis of the diffractometer.
$X$-Ray data collection.' Data were collected on a CAD-4 automated diffractometer. For both compounds, the lattice constants given in Table 8 came from a least-squares refinement of 25 reflections. The intensities of three standard reflections were monitored after intervals of 60 min . In neither case was there an significant change in these intensities during data collection. The usual Lorentz and polarization corrections were applied. No absorption corrections were made because of the relatively small values of $\mu$.

Of the 2703 reflections collected for compounds $9 \mathrm{a}, 1991$ were found to have $I>2.5 \sigma(I)$ and were used in solving and refining the structure. A total of 4031 scans, including 739 redundant data, were measured for compound 12a. Equivalent reflections were averaged, to give 1973 unique observed intensities ( $I>1.5 \sigma(I)$ ).

| $\mathrm{C}(46)$ | $-1273(5)$ | $-1387(9)$ | $4618(5)$ |

Structure determination and refinement. The centric space group ( $P \overline{1}$ ) was initially chosen for the complex 9 a , and confirmed by the successful refinement of the structure. The molybdenum atom position was determined by the Patterson method. The remaining non-hydrogen atoms were located by Fourier syntheses. The scale factor and the positional and anisotropic thermal parameters were refined by minimizing the function $\Sigma w\left(\left|F_{0}\right|-\left|F_{\mathrm{c}}\right|\right)^{2}$, where $w=1 /\left(\sigma^{2}(F)+0.0019 F^{2}\right)$. The final values of the positional atomic parameters are listed in Table 9.

The structure of the complex 12a, was solved by direct methods. The position of the Mo so obtained was first checked by the heavy atom method and then used to phase a Fourier map calculation, which revealed all the 26 non-hydrogen atoms. After two cycles of refinement with isotropic thermal parameters, all atoms were given anisotropic thermal parameters. The weighting scheme was $w=0.011 /\left(\sigma^{2}(F)\right.$ $+1.728 F^{2}$ ). The residuals $R$ and $R_{\mathrm{w}}$ and the residual electron density are given in Table 8. The final atomic coordinates are listed in Table 10.

Lists of anisotropic thermal parameters and observed and calculated structure factors for compounds 9 a and 12 a are available from the authors.
