#### Abstract

$\eta^{6}$-Areneruthenium(II) complexes of the amino acids $l$-penicillamine ( $l$-penH), $l$-histidine ( $l$-hisH), $l$-histidine methyl ester ( $l$-hisMe) and the peptide triglycine (glyglyglyH) have been prepared by reaction of these amino acids with $\left[\left(\eta^{6}-\right.\right.$ $\left.\left.\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}$. Crystal structure analyses are reported for $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l \text {-pen })\right]_{2} \mathrm{Cl}_{2}$ (1), $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l-\mathrm{hisMe}) \mathrm{Cl}\right] \mathrm{Cl}$ (3) and $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\mathrm{glyglygly}) \mathrm{Cl}\right]$ (4). The amino acidate ligands are tridentate in $\mathbf{1}$, with the deprotonated sulphur atoms adopting a bridging position between two ruthenium atoms, leading to the formation of a four-membered RuSRuS-ring. Bidentate $N$ (ammine), $N$ (imidazole) and $N$ (ammine), $N$ (peptide) binding, respectively, are exhibited by the complexes $\mathbf{3}$ and 4 . The factors influencing the observed metal binding sites and chiralities are discussed.

## Introduction

Organoruthenium(II) complexes of $\alpha$-amino acids of the type [(diene) $\mathrm{Ru}(\mathrm{aa})_{2}$ ] ( $\mathrm{aa}=\mathrm{gly}, l$-ala) [1] and $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\mathrm{aa}) \mathrm{Cl}\right]$ ( $\mathrm{aa}=\mathrm{gly}, d, l$-ala) [2] have been prepared. Such complexes can exhibit chirality both in the ligand and at the metal. For instance, on the basis of ${ }^{1} \mathrm{H}$ NMR spectroscopic studies it was inferred that two diastereomerically related pairs of enantiomers are present for $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(d, l-\right.$ ala) Cl$]$ in $\mathrm{D}_{2} \mathrm{O}$ solution. In view of the the synthetic potential (e.g. asymmetric catalysis) of chiral organotransition metal templates [3] we are interested in the resolution of $\eta^{6}$-areneruthenium(II) complexes of $l$-amino acids. In general, a relative stabilization of one diastereomer may be achieved through preferential intramolecular hydrogen bonding or interaction with solvent molecules (or anions in

[^0]the case of cationic species). Furthermore, steric interactions may lead to a relative destabilization of the second diastereomer. We now describe the preparation and structural characterization of $\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}$-ruthenium(II) complexes of amino acids with coordinating side chains. We chose the potentially tridentate ligands $l$-penicillamine ( $l$-pen), $l$-histidine ( $l$-his) and the peptide triglycine (glyglygly). As suitable crystals of $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l-\mathrm{his}) \mathrm{Cl}\right] \mathrm{Cl}$ could not be grown, an X -ray structural analysis was performed on the analogous complex of $l$-histidine methyl ester ( $l$-hisMe).

## Results and discussion

The reaction of $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2} \quad[4,5]$ with $l$-penicillamine yields $\left[\left(\eta^{6}-\right.\right.$ $\left.\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l$-pen $\left.)\right]_{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}(1)$, the structure of the cation of which is depicted in Fig. 1. The carboxyl groups are protonated at O 112 and O 212 , and do not participate in metal binding. The $\mathrm{C}-\mathrm{O}$ bond distances are respectively $\mathrm{C} 11-\mathrm{O} 111$ $1.211(6), \mathrm{C} 11-\mathrm{O} 112$ 1.312(6), C21-O211 1.203(6) and C21-O212 1.322(6) £. Both penicillaminate ligands are tridentate, with the deprotonated sulphur atoms adopting a bridging position between the two ruthenium atoms and so giving rise to an essentially planar central four-membered RuSRuS-ring. Deviations from the best least-squares plane are: Ru1 0.008, Ru2 0.009, S13-0.009 and S23-0.008 A. The coordination spheres of the ruthenium atoms are completed by the amino nitrogens N 12 and N 22 , which are involved in five-membered chelate rings, both of which display an envelope conformation with C13 and C23 displaced from the best planes of the remaining four atoms. Distances from these least-squares planes are: Rul $-0.022, \mathrm{~N} 120.034, \mathrm{C} 12-0.027, \mathrm{~S} 130.015, \mathrm{C} 130.661 \AA$; Ru2 - 0.019 , N22 0.029 . $\mathrm{C} 22-0.023, \mathrm{~S} 230.013, \mathrm{C} 230.710 \AA$. The adoption of this conformation minimizes steric contacts to the penicillamine methyl groups.

Fig. 1. Structure of the cation $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l-\mathrm{pen})^{4}\right]_{2}(\mathbf{1})$. Hydrogen atoms have been omitted for clarity.

Fig. 2. Hydrogen bonding (open bonds) to the chloride ions in 1. $\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}$-ligands have been omitted for clarity.

As may be seen from Fig. 1 , the dimeric cation in 1 exhibits an approximately $C_{2}$ symmetry. The $\mathrm{Ru}-\mathrm{S}$ distances in the chelate rings $(2.346(1), 2.345(1) \AA)$ are markedly shorter than the bridging $\mathrm{Ru}-\mathrm{S}$ distances in the central four-membered ring ( $2.416(1), 2.398(1) \AA$ ). The chiralities of the individual Ru atoms may be established by assigning a higher priority to the sulphur which participates in the chelate ring, according to the rule of Prelog [6]. A diastereomeric pair with $R_{\mathrm{Ru}}, S_{\mathrm{S}}$, $S_{\mathrm{S}}, R_{\mathrm{Ru}}$ or $S_{\mathrm{Ru}}, R_{\mathrm{S}}, R_{\mathrm{S}}, S_{\mathrm{Ru}}$ configurations (both $R_{\mathrm{C}}, R_{\mathrm{C}}$ ) is feasible for the cis-arrangement of the $\eta^{6}$-benzene ligands displayed by 1 in the solid state. The former configuration observed for 1 is stabilised by $\mathrm{O}-\mathrm{H} \ldots \mathrm{Cl}(2.924,2.966 \AA)$ and $\mathrm{N}-\mathrm{H} \ldots \mathrm{Cl}(3.257,3.231 \AA)$ hydrogen bonds to the two chloride anions, as depicted in Fig. 2. Use of models indicates that the alternative $S_{\mathrm{Ru}}, K_{\mathrm{S}}, R_{\mathrm{S}}, S_{\mathrm{Ru}}$ configuration would lead to close steric contacts between the carboxyl groups, and would not be favourable for formation of four hydrogen bonds to the chloride anions. A trans-arrangement of the benzene ligands would also give rise to unfavourable steric contacts, in this case between these and amino acidate ligands, which would now be on the same side of the central four-membered ring. A diastereomeric pair with $R_{\mathrm{Ru}}, S_{\mathrm{S}}, R_{\mathrm{S}}, S_{\mathrm{Ru}}$ and $S_{\mathrm{Ru}}, R_{\mathrm{S}}, S_{\mathrm{S}}, R_{\mathrm{Ru}}$ configurations may be formulated for the trans-arrangement. The coordination mode in 1 is, to our knowledge, novel for penicillaminate ligands [7,8].

A single resonance at $\delta 5.92 \mathrm{ppm}$ is observed for the benzene protons in the ${ }^{1} \mathrm{H}$ NMR spectrum of 1 in $\mathrm{D}_{2} \mathrm{O}$. The methyne protons exhibit a doublet of doublets ( $J$ 5.7 Hz ), which can be attributed to spin-spin coupling with the nitrogen protons. In contrast a singlet is observed for this proton in the free ligand (present as a zwitterion), with a chemical shift ( 3.70 ppm ) at markedly lower field than in 1 ( 2.67 ppm ). The methyl resonance at 0.94 ppm may be assigned to C 25 (axial), that at 1.49 ppm to C 24 (equatorial) for the puckered five-membered chelate ring (Fig. 1). An ABX spin system is observed for the penicillaminate nitrogen and methyne protons in the $\mathrm{CD}_{3} \mathrm{OD}$ spectrum with chemical shifts at $6.30,6.19$, and 2.72 ppm , respectively. The following coupling constants may be assigned using the KarplusConroy curve: ${ }^{2} J 13 \mathrm{~Hz},{ }^{3} J_{\text {gauche }} 5 \mathrm{~Hz},{ }^{3} J_{\text {trans }} 11 \mathrm{~Hz}$.

Fig. 3. Structure of the cation $\left[\left(\eta^{4}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(/ \text { hisme }) \mathrm{Cl}\right]^{+}$(3).

Reaction of $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}$ with $l$-histidine and its methyl ester yields $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ku}(l\right.$-his $\left.) \mathrm{Cl}\right] \mathrm{Cl}$ (2) and the analogous complex $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l-\right.$ hisMe) Cl$] \mathrm{Cl}(3)$, the structure of the cation of which is displayed in Fig. 3. Bidentate coordination of the amino acid via the amino nitrogen N 2 and the imidazole nitrogen N5 is exhibited by 3 , which results in the formation of a six-membered chelate ring with a twisted-boat conformation. The following displacements are observed from the best least-squares plane through $\mathrm{N} 2, \mathrm{C} 2, \mathrm{C} 4$ and $\mathrm{N} 5: \mathrm{Ru} 1.014$, C3 $0.519, \mathrm{~N} 2-0.093, \mathrm{C} 20.100, \mathrm{C} 4-0.108$ and N 50.101 A . An $S_{\mathrm{c}}$, $S_{\mathrm{Ru}}$ configuration is adopted by the cation. The $S_{\mathrm{Ru}}$ configuration at the central metal allows the formation of both intramolecular $\mathrm{N} 2-\mathrm{H} 21 \ldots \mathrm{Cl} 1$ (3.012 $\AA$ ) and $\mathrm{N} 2-\mathrm{H} 22 \ldots \mathrm{O} 11(2.715 \AA)$ hydrogen bonds. For the alternative $R_{\mathrm{Ru}}$ configuration only the latter interaction is possible. As has been observed for $\left[\left(\mathrm{NH}_{3}\right)_{5} \mathrm{Ru}^{\mathrm{II}}(l\right.$ his) $\mathrm{Cl}_{3}$ ] [9] and other pentammine-ruthenium(III) complexes of nitrogen heterocycles, the $\mathrm{Ru}-\mathrm{N}$ (heterocycle) distance, $2.063(6)$, is significantly shorter than the $\mathrm{Ru}-\mathrm{N}($ ammine $)$ distance, $2.142(6) \AA$. The ruthenium(II) complex $\Delta, \Lambda-[\mathrm{Ru}($ bipy $)$, ( $l$ ala)] $\mathrm{ClO}_{4} \cdot \frac{1}{2} \mathrm{H}_{2} \mathrm{O}$ exhibits a similar average $\mathrm{Ru}-\mathrm{N}$ (heterocycle) bond length of 2.045 $\AA$ [10]; values of $2.07(1)$ and $2.13(1) \AA$ are found for the $\mathrm{Ru}-\mathrm{N}(l-\mathrm{ala})$ distances. No evidence is provided by the ${ }^{1} \mathrm{H}$ NMR spectrum of $3\left(S_{C}, S_{\mathrm{R}_{11}}\right)$ in $\mathrm{D}_{2} \mathrm{O}$ for the existence of a detectable quantity of the second diastereomer ( $S_{C}, R_{\mathrm{Ru}}$ ) in equilibrium in aqueous solution. Sharp singlets are observed for the benzenc, methyl. and histidine protons; The resonances for the amino acidate $\alpha-\mathrm{CH}$ and $\beta-\mathrm{CH}_{2}$ protons are shifted to higher field in the complexes 2 and 3. that for the histidine proton H6 to lower field in comparison to the free ligands. The similar positions for the proton resonances in $\mathbf{2}$ and $\mathbf{3}$ indicate that the coordination mode in the former histidine complex is identical (i. e. $N$ (ammine), $N($ imidazole)] to that in 3 . This means that the carboxyl group must be protonated in 2, a fact which is confirmed by the $\nu(\mathrm{C}=\mathrm{O})$ value of $1705 \mathrm{~cm}^{-1}$ in the IR spectrum of this compound.

The product of the reaction of $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}$ with the peptide triglycine. $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\right.$ glyglygly $\left.) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \frac{1}{2} \mathrm{CH}_{3} \mathrm{OH}(4)$, crystallises as a racemic mixture in the centrosymmetric space group $P \overline{1}$. Figure 4 depicts the enantiomer with $S_{\mathrm{Ru}}$-con-

Fig. 4. Structure of the $S_{\mathrm{Ru}}$-enantiomer of $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\mathrm{glyg} \mathrm{lyg} \mathrm{ly}) \mathrm{Cl}\right](4)$.
figuration. Both enantiomers display an intramolecular $\mathrm{N} 2-\mathrm{H} 2 \ldots \mathrm{Cl}$ hydrogen bond of length $3.234 \AA$. There are no further intramolecular hydrogen bonds or steric interactions which would lead to a relative stabilization of one of the enantiomers. As observed for the complexes of $l$-penicillamine and $l$-histidine discussed in this work, the carboxyl group does not participate in metal binding $\mathbf{4}$, emphasising once again the preference of ruthenium(II) for nitrogen (or sulphur) atoms as binding sites. Protonation occurs on O12, which is involved in an $\mathrm{O} 12-\mathrm{H} \ldots \mathrm{O} 5$ intermolecular hydrogen bond of length $2.566 \AA$ to a second molecule related by a translation of 1.0 in the $z$-direction. $\mathrm{C}-\mathrm{O}$ bond distances are $\mathrm{C} 1-\mathrm{O} 11$ $1.198(10)$ and $\mathrm{C} 1-\mathrm{O} 121.317(9) \AA$. The peptide binds ruthenium $(\mathrm{II})$ through the amino nitrogen N6 and the peptide nitrogen N4, so that a five-membered chelate ring is formed. Deviations from the best least-squares plane through all five atoms of the ring are relatively small: Ru1 -0.115 , N 40.099 , $\mathrm{C} 5-0.009$, $\mathrm{C} 6-0.137$, N6 $0.163 \AA$. Trigonal planar coordination is exhibited by both N4 and the second peptide nitrogen N2. As expected [11], the peptide bond C4-N4 to the coordinated nitrogen N4 is with a distance of $1.305(10) \AA$ shorter than $\mathrm{C} 3-\mathrm{N} 2$ to the uncoordinated peptide nitrogen $\mathrm{N} 2(1.330(10) \AA)$.

Tridentate coordination of the peptide may be ruled out for monomeric species, as this would require that the three donor groups, the central one of which is a peptide nitrogen, would have to be coplanar with the metal atom [11]. Three potential binding modes remain, namely $O$ (carboxyl), $N$ (peptide), $N$ (peptide), $N$ (peptide) or, as observed, $N$ (peptide), $N$ (ammine), which allows the retention of an $\mathrm{Ru}-\mathrm{Cl}$ bond. The C6-protons in the ${ }^{1} \mathrm{H}$ NMR spectrum are shifted markedly to higher field ( 3.19 ppm ), the C4-protons to lower field ( 4.58 ppm ) upon complexation of triglycine. Two resonances are observed, at 5.80 and 5.88 ppm , for the benzene protons. The former signal, which is larger (ratio ca. $86 / 14$ ) may be
assigned to 4 , and the latter to the cation $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\mathrm{glyg} \text { lygly })\left(\mathrm{D}_{2} \mathrm{O}\right)\right]^{+}$. The ready substitution of the coordinated chloride in $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(d, l\right.$-ala $\left.) \mathrm{Cl}\right]$ has previously been reported by Baird [2].

The results demonstrate that a selective crystallisation of one diastereomer of $\eta^{6}$-areneruthenium(II) complexes of the amino acids $l$-penicillamine and $t$-histidine can be achieved. The preference of ruthenium(II) for S and N coordination sites is confirmed.

## Experimental

IR spectra were recorded as $1 \% \mathrm{KBr}$ discs on a Perkin-Elmer 297 spectrometer. ${ }^{1}$ H NMR spectra were recorded on a Bruker AM 400 spectrometer for $\mathbf{1 , 2}$ and 4. on a Bruker WP200 spectrometer for 3 , in $\mathrm{D}_{2} \mathrm{O}$ with $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{SiCD}_{2} \mathrm{CD}_{2} \mathrm{COONa}$ as internal reference. Elemental analyses were performed with a Perkin-Elmer 240 apparatus. The $\alpha$-amino acids were purchased from Sigma Chemie GmbH and used as received; $\mathrm{RuCl}_{3} \cdot 3 \mathrm{H}_{2} \mathrm{O}$ was a gift from Degussa AG . $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}$ was prepared as described in the literature [5].

## Preparation of complexes $1-4$

$\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l \text {-pen })\right]_{2} \mathrm{Cl}_{2} \cdot \mathrm{H}_{2} \mathrm{O}(1) .\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}(100 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved with heating in 20 ml of water. The solution was filtered and $60 \mathrm{mg}(0.4$ mmol ) of $l$-penicillamine were added, and the volume of the solution was then reduced to 1 ml . Methanol ( 5 ml ) was added and the solution cooled to $6^{\circ} \mathrm{C}$ to give red crystals of 1 (yield 58\%). 1, Anal. Found: C. 34.8; H. 4.56; N. 3.8. $\mathrm{C}_{22} \mathrm{H}_{34} \mathrm{~N}_{2} \mathrm{O}_{5} \mathrm{~S}_{2} \mathrm{Cl}_{2} \mathrm{Ru}(M, 743.7)$ calcd.: C, $35.53 ; \mathrm{H}, 4.61 ; \mathrm{N}, 3.77 \%$. IR: 3600.3450 $\nu\left(\mathrm{NH}_{2}\right), 1733 \mathrm{~cm}^{-1} \nu(\mathrm{CO}) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{D}_{2} \mathrm{O}\right): 0.94\left(\mathrm{~s}, 6 \mathrm{H}\right.$, pen $\left.\mathrm{CH}_{3}\right) .1 .49(\mathrm{~s}, 6 \mathrm{H}$, pen $\mathrm{CH}_{3}$ ), $2.67(\mathrm{dd}, 2 \mathrm{H}$, pen $\alpha-\mathrm{CH}), 5.92\left(\mathrm{~s}, 12 \mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{6}\right)$.
$\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l-\right.$ his $\left.) \mathrm{Cl}\right] \mathrm{Cl}$ 2. $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}(100 \mathrm{mg}, 0.2 \mathrm{mmol})$ was dissolved with beating in 20 ml of water. The solution was filtered, and 62 mg ( 0.4 mmol ) of $l$-histidine were added, and the solvent was removed in vacuum. The residual solid was dissolved in 5 ml of ethanol and the solution cooled to $-5^{\circ} \mathrm{C}$ to yield yellow crystals of 2 (yield $74 \%$ ). 2, Anal. Found: C. 35.5 ; H, 3.75; N, 10.7. $\mathrm{C}_{12} \mathrm{H}_{15} \mathrm{~N}_{3} \mathrm{O}_{2} \mathrm{Cl}_{2} \mathrm{Ru}(M, 405.2$ ) calcd.: C, 35.57 ; H, 3.73; N. 10.37\%.. IR: 3275, 3215 $\nu\left(\mathrm{NH}_{2}\right), 1705 \mathrm{~cm}^{-1} \nu(\mathrm{CO}), 1630-1610 \delta\left(\mathrm{NH}_{2}\right) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{D}_{2} \mathrm{O}\right): 3.01(\mathrm{~d}, 2 \mathrm{H}$. his $\left.\beta-\mathrm{CH}_{2}\right), 3.82(\mathrm{~m}, 1 \mathrm{H}$, his $\alpha-\mathrm{CH}), 5.94\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{6}\right), 6.98(\mathrm{~s}, 1 \mathrm{H}$, his H8) $8.59(\mathrm{~s}$, 1 H , his H6).
$\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l\right.$-hisMe $\left.) \mathrm{Cl}\right] \mathrm{Cl} \cdot \mathrm{H}_{2} \mathrm{O}(3)$. A 1 M solution of NaOMe in methanol $(0.8 \mathrm{ml})$ and $100 \mathrm{mg}(0.2 \mathrm{mmol})\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}$ were added to a solution of 97 $\mathrm{mg}(0.4 \mathrm{mmol})$ of $l$-histidine methyl ester hydrochloride $l$-hisMe $\cdot 2 \mathrm{HCl}$. After $2-3 \mathrm{~h}$ stirring at room temperature the volume was reduced to yield an orange solid, which was recrystallised from methanol/water (3, yield $54 \%$ ). 3, Anal. Found: C, 35.9; H, 4.31; N, 9.6. $\mathrm{C}_{13} \mathrm{H}_{19} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{Cl}_{2} \mathrm{Ru}(M, 437.3)$ calcd.: $\mathrm{C}, 35.71 ; \mathrm{H}, 4.38 ; \mathrm{N}, 9.61 \%$. IR: 3590, $3440 \nu\left(\mathrm{NH}_{2}\right), 1725,1710$ sh $\nu(\mathrm{CO}), 1630 \mathrm{~cm}^{-1} \delta\left(\mathrm{NH}_{2}\right) .{ }^{1} \mathrm{H} \operatorname{NMR}\left(\mathrm{D}_{2} \mathrm{O}\right)$ : 3.01 br $\left(2 \mathrm{H}\right.$, his $\left.-\beta-\mathrm{CH}_{2}\right), 3.36\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.82 \mathrm{br}(1 \mathrm{H}$. his $-\alpha-\mathrm{CH}), 5.95(\mathrm{~s}, 6 \mathrm{H}$, $\mathrm{C}_{6} \mathrm{H}_{6}$ ), $6.99(\mathrm{~s}, 1 \mathrm{H}$, bis H 8$), 8.59$ ( $\mathrm{s}, 1 \mathrm{H}$, his H6).
$\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\right.$ glyglygly $\left.) \mathrm{Cl}\right]$ (4). $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{RuCl}_{2}\right]_{2}$ ( $100 \mathrm{mg}, 0.2 \mathrm{mmol}$ ) was dissolved with heating in 20 ml of water. The solution was filtered and $76 \mathrm{mg}(0.4$ mmol ) of triglycine were added. The volume was reduced, to 1 ml .2 ml of methanol
was added, and the solution cooled to $0^{\circ} \mathrm{C}$ to yield orange crystals of 4 (yield $76 \%$ ). 4, Anal. Found: $\mathrm{C}, 32.7 ; \mathrm{H}, 4.12 ; \mathrm{N}, 9.70 \% . \mathrm{C}_{12} \mathrm{H}_{16} \mathrm{~N}_{3} \mathrm{O}_{4} \mathrm{ClRu}(M, 402.8)$ calcd.: C , $32.81 ; \mathrm{H}, 3.90$; N, $9.57 \%$. IR: $3290,3220,3130 \nu\left(\mathrm{NH}_{2}\right)+\nu(\mathrm{NH}), 1705,1635,1610$ $\nu(\mathrm{CO}) \mathrm{cm}^{-1} .{ }^{1} \mathrm{H}$ NMR ( $\left.\mathrm{D}_{2} \mathrm{O}\right): 3.19\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{C}(6) \mathrm{H}_{2}\right), 3.89\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{C}(2) \mathrm{H}_{2}\right), 4.58(\mathrm{~s}$, $\left.2 \mathrm{H}, \mathrm{C}(4) \mathrm{H}_{2}\right), 5.80,5.88\left(\mathrm{~s}, 6 \mathrm{H}, \mathrm{C}_{6} \mathrm{H}_{6}\right)$.

X-ray structural analyses of 1,3 and 4
Suitable crystals of $\mathbf{1 , 3}$ and 4 were obtained by slow crystallisation of the complexes from methanol/water solution. 1 crystallises under these conditions as $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\text { pen })\right]_{2} \cdot \mathrm{H}_{2} \mathrm{O}$, (3) as $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(l\right.$-his Me$\left.) \mathrm{Cl}\right] \mathrm{Cl} \cdot \frac{1}{2} \mathrm{CH}_{3} \mathrm{OH}$ and 4 as $\left[\left(\eta^{6}-\mathrm{C}_{6} \mathrm{H}_{6}\right) \mathrm{Ru}(\right.$ glyglygly $\left.) \mathrm{Cl}\right] \cdot \mathrm{H}_{2} \mathrm{O} \cdot \frac{1}{2} \mathrm{CH}_{3} \mathrm{OH}$. Crystal and refinement data are summarized in Table 1. Unit cell constants were obtained from a least-squares fit to the settings of 25 reflections recorded on an Enraf-Nonius CAD4 diffractometer at varied scan rates using $\mathrm{Mo}-K_{\alpha}$ radiation for 1 and $\mathrm{Cu}-K_{\alpha}$ radiation for 3 and 4. Three reflections were monitored at regular intervals during data collection; no significant decreases in intensity were observed. The structures were solved by direct methods and difference syntheses and refined by full-matrix least-squares. The asymmetric unit of $\mathbf{3}$ contains a doubly disordered methanol molecule. tion factors of 0.5 were introduced for $\mathrm{C} 10,0.25$ for O 101 and O 102 . In addition to one molecule of crystal water, the asymmetric unit of 4 also contains a disordered methanol molecule. Site occupation factors of 0.5 were employed for O2 and C22. Anisotropic temperature factors were used for all non-hydrogen atoms in 1, 3 and 4, with the exception of the solvate atoms. A common isotropic temperature factor was employed for the methanol C and O atoms in 3. Hydrogen atoms were included, where possible, at calculated positions with $d(\mathrm{C}-\mathrm{H}) 1.08 \AA$. The carboxyl protons H11 and H21 in 1 were located in difference syntheses and refined freely. Terminal reliability indices are listed in Table 1 where $R_{\mathrm{w}}=\left[\sum w\left(F_{0}-F_{\mathrm{c}}\right)^{2} / \sum w F_{0}^{2}\right]^{1 / 2}$ with weights given by $w=\left(\sigma^{2}\left(F_{0}\right)+p^{2} F_{0}^{2}\right)^{-1}$. Final difference syntheses were effectively featureless. Analytical scattering factors, corrected for the real and imaginary parts of anomalous dispersion, were taken from ref. 12. Calculations were performed with SHELX-76 [13] and with local programs. Full details of the X-ray analyses are available from the authors.

Table 3
Lengths ( $\AA$ ) of bonds to the ruthenium atoms
