#### Abstract

The dihydride complex $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{PF}_{6}\right]$ reacts with $\left[\mathrm{PPh}_{4}\right][\mathrm{Co}$ $\left.(\mathrm{CO})_{4}\right]$ and $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$ to give the ionic complexes $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\right.$ $\left.\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ and $\left[\mathrm{Rh}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$ and neutral mixed $\mathrm{Rh} / \mathrm{Co}$ and $\mathrm{Rh} / \mathrm{Fe}$ complexes containing bridging $\mathrm{cHex}-\mathrm{DAB}$ ligands and metal-metal bonds. The complex $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ was studied by X-ray crystallography and shown to consist of cations [ $\mathrm{RhH}_{2}$ (cHex$\left.\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]^{+}$and anions $\left[\mathrm{Co}(\mathrm{CO})_{4}\right]^{--}$linked by coulombic forces, and possibly hydrogen bonds between the imine hydrogens and the oxygens of the carbonyl ligands.

## Introduction

1,4-Diazadienes have been widely used as bridging ligands between two different metals, and found to exhibit two possible modes of coordination, $\sigma-\mathrm{N}, \mu-\mathrm{N}^{\prime}, \eta^{2}$ $\mathrm{C}=\mathrm{N}^{\prime}$ and $\eta^{2}=-\mathrm{C}=\mathrm{N}, \eta^{2}-\mathrm{C}^{\prime}=\mathrm{N}^{\prime}[1]$. These ligands can also be converted by metallic hydrides into 3 -amino-1-aza-allyl coordinated fragments bonded to two metallic centres [2]. We are engaged in a systematic study of diazabutadienes and here investigated the synthesis and the reactions of cationic rhodium cis-dihydride complexes containing diazabutadiene and phosphine ligands [3]. Cyclooligomeriza-
tion of acetylenes was observed and some metallacyclopentadiene intermediates were also isolated [4] in these reactions. The cationic nature of rhodium complexes raises the possibility of interesting reactions with anionic carbonyl complexes, permitting exploration of new aspects of the behaviour of R-DAB as bridging ligands [5]. Such reactions should give heterodinuclear complexes on Rh-DAB species increasing the range of heterometallic compounds bridged by nitrogen ligands [6,7]. The rhodium complexes are very active catalysts, and so interesting possibilities can be expected when other metals are incorporated. An example of enhancement of catalysis by a second metal in a heterobinuclear complex containing a nitrogen centred bridging ligand has recently been reported [8]. We describe below the reactions of $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]^{+}\left(\mathrm{cHex}-\mathrm{DAB}=\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CHCH}=\right.$ $\mathrm{NC}_{6} \mathrm{H}_{11}$ ) with $\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ and $\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$ to give heterobimetallic complexes containing various types of DAB bridges.

## Results and discussion

The reactions of $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{PF}_{6}\right]\left(\mathrm{cHex}-\mathrm{DAB}=\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CH}-\right.$ $\mathrm{CH}=\mathrm{NC}_{6} \mathrm{H}_{11}$ ) with the carbonyl complexes $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ and $\left[\mathrm{PPh}_{4}\right]$ $\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$ at room temperature and in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solutions were found to give red-brown solutions containing new mixed $\mathrm{Rh}-\mathrm{Co}$ and $\mathrm{Rh}-\mathrm{Fe}$ complexes contaminated by carbonyl-chloro-triphenylphosphine complexes of rhodium. which were removed by precipitation of $\left[\mathrm{PP}_{4}\right]\left[\mathrm{PF}_{6}\right]$ with diethyl ether and concentration on a vacuum line. The first precipitate contained a mixture of $\left[\mathrm{RhCl}(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{2}\right]$ and $\left[\mathrm{Rh}_{2} \mathrm{Cl}_{2}(\mathrm{CO})\left(\mathrm{PPh}_{3}\right)_{3}\right]$ which were identified by comparison of their spectroscopic data with those in the literature [9]. Spectroscopic data for the products are given in Table 1.

## Reactions with $\left[\mathrm{Co}(\mathrm{CO})_{4}\right.$ ]

When stoichiometric amounts of $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{PF}_{6}\right](\mathrm{cHcx}-\mathrm{DAB}$ $=\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CHCH}=\mathrm{NC}_{6} \mathrm{H}_{11}$ ) and $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ was dissolved and mixed in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature the complex $\left[\mathrm{RhH}_{2}(\mathrm{CHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ (1) was isolated after precipitation of $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{PF}_{6}\right]$ in diethyl ether. The ${ }^{1} \mathrm{H}$ NMR spectrum of 1 was identical to that the starting cation, but the IR spectrum in KBr pellet in the $\nu(\mathrm{CO})$ region showed three bands, suggesting some distortion of the anion, and the presence of such distortion was confirmed by an X-ray diffraction study of complex 1 . When the same reaction was carried out in refluxing $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. the complex of $\left[\mathrm{RhCo}(\mathrm{CO})_{4}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)\right]$ (3) was formed. The ${ }^{1} \mathrm{H}$ NMR spectrum of 3 showed imine signals at 7.91 and 3.71 ppm characteristic of a $\sigma-\mathrm{N}, \mu-\mathrm{N}^{\prime}, \eta^{2}-\mathrm{C}=\mathrm{N}^{\prime}, \mathrm{cH}$ ex- DAB ligand. A broad signal at 7.5 ppm which integrated as 15 H indicated the presence of a single $\mathrm{PPh}_{3}$ ligand in the molecule. The IR spectrum of 3 shows four intense bands between 1945 and $1870 \mathrm{~cm}^{-1}$ corresponding to terminal carbonyl ligands. The complex 3 seems to be formed by a thermal rearrangement of 1 after elimination of $\mathrm{H}_{2}$ and $\mathrm{PPh}_{3}$. The presence of a metal metal bond in $\mathbf{3}$ is indicated by electron counting.

Molecular structure of $\left[\mathrm{RhH}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CHCH}=\mathrm{NC}_{6} \mathrm{H}_{11}\right)\left(\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right)_{2} /\left[\mathrm{Co}(\mathrm{CO})_{4}\right](\mathrm{I})\right.$
The molecular structure of $\mathbf{1}$ is shown in the Fig. 1. Atom coordinates are given in Table 2 and some relevant bond lengths and bond angles in Table 3.

The molecular structure of $\mathbf{1}$ ( Fig .1 ) involves cations $\left[\mathrm{RhII}_{2}\left(\mathrm{C}_{6} \mathrm{II}_{11} \mathrm{~N}=\mathrm{CIICII}=\right.\right.$ $\left.\mathrm{NC}_{6} \mathrm{H}_{11}\right)\left(\mathrm{P}_{\left.\left.\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right)_{2}\right]^{+} \text {and anions }\left[\mathrm{Co}(\mathrm{CO})_{4}\right]^{-} \text {complexes linked by coulombic }}\right.$ intermolecular forces. The cations are mononuclear rhodium complexes with a distorted octahedral geometry containing two triphenylphosphine ligands, a $\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CHCH}=\mathrm{NC}_{6} \mathrm{H}_{11}$ chelating ligand, and two hydrides. The phosphine ligands are pseudo-trans and tilted towards the hydride ligands, which were not located. The $\mathrm{P}(1)-\mathrm{Rh}-\mathrm{P}(2)$ angle is $152.5(3)^{\circ}$, the $\mathrm{Rh}(1)-\mathrm{P}(1)$ and $\mathrm{Rh}(1)-\mathrm{P}(2)$ distances are $2.094(67)$ and 2.063(6) $\AA$; these lengths are shorter than those in other rhodium(III) complexes $[10,11,12]$. The cHex-DAB ligand and the rhodium lie almost in a plane, with $\mathrm{Rh}(1)-\mathrm{N}(1)$ and $\mathrm{Rh}(1)-\mathrm{N}(2)$ distances of $2.363(20)$ and $2.167(22) \AA$, respectively. The bond lengths and angles in the coordinated ligand are different from those in similar R-DAB rhodium(III) dihydride complexes; thus relative to that in the latter, the $C(1)-C(2)$ distance of $1.742(43) \AA$ is very large $[11,12]$, as is the $\mathrm{N}(1)-\mathrm{Rh}(1)-\mathrm{N}(2)$ angle of $84.9(8)^{\circ}$. The anion $\left[\mathrm{Co}(\mathrm{CO})_{4}\right]^{-}$and the cations are packed in a way to minimize steric hindrance, but the carbonyl ligands are oriented towards the imine hydrogens in a way suggesting the possibility of hydrogen bonding. The shortest $\mathrm{C}-\mathrm{O}$ distance is in the carbonyl ligand close to the cation but the large distortion of the tetrahedral geometry in the anion prevents confirmation of the presence of hydrogen bonding.

## Reactions with $\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]^{-}$

The reaction of the complex $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{PF}_{6}\right]$ with $\left[\mathrm{PPh}_{4}\right][\mathrm{HFe}$ $(\mathrm{CO})_{4}$ ] is complex. At room temperature a mixture of compounds is always obtained, and depending on the reaction conditions various unambigously identified products can be isolated separatelly from the solution. Thus, when the reaction takes place in a CO atmosphere for about 2 h , an ionic complex 2 is obtained after precipitation of $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{PF}_{6}\right]$ in diethyl ether. The IR spectrum of 2 in the $\nu(\mathrm{CO})$ region shows three bands characteristics of the anion $\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]^{-}$. The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{2}$ is similar to the that of $\mathbf{1}$, and similar to that of the starting cation $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{DAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]^{+}$except for the absence of the hydride signal at -15.6 ppm. These spectroscopic properties suggest an ionic nature for 2 : [ $\mathrm{Rh}(\mathrm{cHex}-\mathrm{DAB})$ $\left.\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$. At room temperature under nitrogen, various products can be isolated by precipitation with diethyl ether depending on the reaction time. Thus, the products 4,5 and 6 are formed after $4 \mathrm{~h}, 24 \mathrm{~h}$, and 4 days of reaction,

respectively. All of them are brown, microcrystalline products, soluble in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$, and insoluble in petroleum ether and alcohols. The proposed structures for these complexes are shown in Scheme 1. It can be seen that two different modes of coordination of the $\mathrm{cHex}-\mathrm{DAB}$ are present in the products. Complexes 4 and 5 contain a six electron bridging $\mathrm{cHex}-\mathrm{DAB}$, as could be concluded from their ${ }^{1} \mathrm{H}$ NMR spectra. The signals from the imine protons appear at 8.27 and 3.71 ppm for 4 and at 7.8 and 3.60 ppm for 5 . A quartet at -15.63 ppm is present in the ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathbf{4}$, corresponding to a hydride ligand linked to rhodium. The IR spectrum of 4 in the $\nu(\mathrm{CO})$ region shows one band of medium intensity, at 1780 $\mathrm{cm}^{-1}$ in a KBr pellet and at $1789 \mathrm{~cm}^{-1}$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solution, that must be attributed to a bridging CO . Complex 5 shows only bands corresponding to terminal CO . Finally, the ${ }^{1} \mathrm{H}$ NMR spectrum, of complex 6 contains a signal at 7.92 ppm characteristic of a eight-electron bridging $\mathrm{cHex}-\mathrm{DAB}$ and one at -15.7 ppm corresponding to a hydride ligand linked to rhodium. The presence of only terminal CO , ligands is indicated by the IR spectrum of 6 .

Complex 2 seems to represent the first step in the formation of complexes $\mathbf{4}, 5$ and 6, but 2 can only be isolated under a CO atmosphere after a reductive elimination of $\mathrm{H}_{2}$ from the starting cation. Subsequently, the rhodium-iron bond is formed by coupling of the ions of 2 . The loss of different ligands generates the

Scheme 1. i, $+\mathrm{Co}(\mathrm{CO})_{4}$ : ii, $+\mathrm{HFe}(\mathrm{CO})_{4}^{-}$.
mixed complexes 4,5, and 6. No reasons can be offered for the formation of different complexes depending on the reduction time. No interconversions between the complexes have been detected. Determination of the molecular mass of the complexes by electronic impact mass spectrometry was not possible, and only the $\mathrm{PPh}_{3}$ and cHex-DAB peaks were detected, which made more difficult the elucidation of the exact nature of the new complexes.

## Experimental

All reactions were performed under $\mathrm{N}_{2}$. The ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a Bruker WM-360 Fourier spectrometer in $\mathrm{CDCl}_{3}$ solution. Infrared spectra were recorded on a Nicolet 60SX (FT IS) spectrometer with KBr discs or $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solutions ( $\nu(\mathrm{CO})$ region). Elemental analyses ( $\mathrm{C}, \mathrm{H}$ and N ) were performed at Departamento de Química Inorgánica of the Universidad de Alcalá de Henares (Madrid). The qualitative presence of rhodium, cobalt and iron was determined by the X-ray fluorescence technique with a Philips PW 1540 apparatus with a tungsten anticathode.

The starting complexes $\left[\mathrm{RhH}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CHCH}=\mathrm{NC}_{6} \mathrm{H}_{11}\right)\left(\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right)_{2}\right]$ [ $\mathrm{PF}_{6}$ ] [3], $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right][13]$ and $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$ [14] were prepared by published procedures.

General procedure for the synthesis of products:
A slight excess of $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{Co}(\mathrm{CO})_{4}\right]$ or $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{HFe}(\mathrm{CO})_{4}\right]$ was added to a solution of $\left[\mathrm{RhH}_{2}(\mathrm{cHex}-\mathrm{dAB})\left(\mathrm{PPh}_{3}\right)_{2}\right]\left[\mathrm{PF}_{6}\right](0.25 \mathrm{~g})$ in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and the mixture was either stirred at room temperature or refluxed. Diethyl ether was then added and a white precipitate of $\left[\mathrm{PPh}_{4}\right]\left[\mathrm{PF}_{6}\right]$ separated. The solid was filtered off and the solution concentrated, leading to separation of the carbonyl-chlorotriphenylphosphinerhodium complexes from the solution. Further concentration of the solution gave the mixed $\mathrm{Rh} / \mathrm{CO}$ and $\mathrm{Rh} / \mathrm{Fe}$ complexes, depending on the reaction condi-

tions. Table 4 lists the analytical data for products and shows the reaction conditions.
$X$-ray analysis of $\left.\left.\left[\mathrm{RhH}_{2}\left(\mathrm{C}_{6} \mathrm{H}_{11} \mathrm{~N}=\mathrm{CHCH}=\mathrm{NC}_{6} \mathrm{H}_{11}\right)\left(\mathrm{P}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{3}\right)_{2}\right] / \mathrm{Cot} \mathrm{CO}\right)_{4}\right]$ (1)
The crystals used for the X-ray study were protected with paraffin oil to prevent decomposition, and sealed in Lindeman glass capillary tubes. Details of crystal data, data collection, and structure refinement are given in Table 5.

The rhodium atom was located from Patterson synthesis and the remaining non-hydrogen atoms by difference Fourier synthesis. Isotropic refinement was by full matrix least squares. An absorption correction [15] was then made, and the structure refined by full matrix least squares with anisotropic thermal parameters. The $H$ atoms were located from successive difference maps and were kept fixed in
