#### Abstract

The reaction of $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mom}=\mathrm{CTol}\left(\mathrm{Cp}=\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}, \mathrm{Tol}=p-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}\right)$ and $\left(\mu-\mathrm{H}_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}\right.$ under mild conditions ( $5-20^{\circ} \mathrm{C}$ ) produces three molybdenum-triosmium mixed-metal cluster compounds, $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{11}\left[\mu_{3}-\eta^{2}-\mathrm{C}\left(\mathrm{O}^{2} \mathrm{CH}_{2} \mathrm{Tol}\right](4,65 \%)\right.$ as a major product together with two minor products $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\mathrm{CTol}\right)_{2}(\mu-\mathrm{H})(5,10 \%)$ and $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\eta^{2}-\mathrm{C}_{2} \mathrm{Tol}_{2} \mathrm{X} \mu-\mathrm{H}\right)(6,6 \%)$. Compounds 4,5 and 6 have been isolated as crystalline solids and characterized by spectroscopic methods. Fluxionality of compound 4 has been examined by variable temperature ${ }^{13} \mathrm{C}$ NMR spectroscopy. Compound 5 in solution undergoes a degenerate metal framework rearrangement. ${ }^{1} \mathrm{H}$ NMR analysis of the tolyl methyl resonances of 5 for the rearrangement process gives $\Delta G_{\mathrm{c}}^{*}=15.2 \pm 0.2 \mathrm{kcal} / \mathrm{mol}$ at the temperature of coalescence.

## Introduction

In the past years our research interest has been focused on the synthesis, characterization and reactivity of mixed-metal (group 6 and 8) cluster compounds [1]. Research in this area is stimulated by a belief that the presence of different metals in the cluster framework may result in drastically altered reactivity patterns compared to those of homometallic counterparts [2]. In previous work [1a-d], we have reported that the reaction of $(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$ and $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{~W}(\mathrm{CTol})(\mathrm{Cp}=$ $\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}$; $\mathrm{Tol}=p-\mathrm{C}_{6} \mathrm{H}_{4} \mathrm{Me}$ ) yields three tungsten-osmium mixed-metal clusters, $\mathrm{CpWOs}_{3}(\mathrm{CO})_{11}\left[\mu_{3}-\eta^{2}-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right](1)[1 \mathrm{a}, \mathrm{b}], \mathrm{CpWOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\mathrm{CTol}\right)_{2}(\mu-\mathrm{H})(2)$ [1c] and $\mathrm{Cp}_{2} \mathrm{~W}_{2} \mathrm{Os}(\mathrm{CO})_{7}\left(\mu_{3}-\eta^{2}-\mathrm{C}_{2} \mathrm{Tol}_{2}\right)(3)$ [1a,3], which exhibit a remarkable variety in structures and reactivities. We have extended our effort to the prepara-

[^0]tion of molybdenum-triosmium mixed-metal clusters by coupling $(\mu-H)_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$ with a molybdenum alkylidyne complex $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$. This approach has yielded three molybdenum-triosmium clusters: the major product $\mathrm{CpMoOs}_{3^{-}}$ $(\mathrm{CO})_{11}\left[\mu_{3}-\eta^{2}-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right]$ (4) and two minor products $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\right.$ $\mathrm{CTol})_{2}(\mu-\mathrm{H})(5)$ and $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\eta^{2}-\mathrm{C}_{2} \mathrm{Tol}_{2}\right)(\mu-\mathrm{H})(6)$. A preliminary account of reactivity of 4 has been published [4]. In this paper a fully detailed report of the synthesis and spectroscopic characterization of compounds 4,5 and 6 is given. The complex $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{11}(\mu-\mathrm{H})_{3}$ is, to our knowledge, the only previously reported molybdenum-triosmium cluster compound which was isolated in a low yield of $15 \%$ [5].

## Experimental

## General comments

All reactions were carried out under an atmosphere of nitrogen in oven-dried glassware. Solvents were rigorously dried before use. The progress of the reactions was monitored by analytical thin-layer chromatography (precoated TLC plates, Silica Gel 60 F-254, E. Merck). Preparative TLC was carried out using glass-backed silica gel plates ( $20 \times 20 \mathrm{~cm}$ ) prepared from silica gel $G$ (Type 60 , E. Merck). The method of Kaesz and co-workers [6] was used to prepare $(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$; $(\mu-\mathrm{D})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$ was prepared similarly, except that the compound was purified by crystallization instead of chromatography. Molybdenum alkylidyne complex $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$ was prepared as described in the literature [7].

Infrared spectra were obtained on a Nicolet 5-MX FT-IR spectrophotometer. Both ${ }^{1} \mathrm{H}$ NMR ( 300 MHz ) and ${ }^{13} \mathrm{C}$ NMR ( 75 MHz ) spectra were recorded on a Bruker AM-300 spectrometer. Mass spectra were recorded by the staff of the Analytical Laboratory at Lucky Ltd. using a JEOL DX-300 mass spectrometer. All $m / z$ values are referenced to ${ }^{98} \mathrm{Mo}$ and ${ }^{192} \mathrm{Os}$. Microanalytical data were provided by the Analytical Laboratory of the Korea Research Institute of Chemical Technology.

Reaction of $\left(\mu-\mathrm{H}_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}\right.$ with $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$
A cold $\left(-30^{\circ} \mathrm{C}\right)$ dichloromethane solution of $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$ ( $199 \mathrm{mg}, 0.623$ mmol ) was added to a dichloromethane solution of $\left(\mu-\mathrm{H}_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}(105 \mathrm{mg}\right.$, 0.124 mmol ) at $5^{\circ} \mathrm{C}$. The reaction mixture ( 60 mL ) was stirred at $5^{\circ} \mathrm{C}$ for 2 h and then slowly warmed to room temperature and stirred for 20 h . Evaporation of the solvent under vacuum and purification by preparative TLC (petroleum ether/ dichloromethane, 4:1) provided dark red $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{11}\left[\mu_{3}-\eta^{2}-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right](4$, $\left.91.5 \mathrm{mg}, 0.078 \mathrm{mmol}, 65 \%, R_{\mathrm{f}}=0.36\right)$, red $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\mathrm{CTol}\right)_{2}(\mu-\mathrm{H})(5$,
$\left.15.1 \mathrm{mg}, 0.0124 \mathrm{mmol}, 10 \%, R_{\mathrm{f}}=0.24\right)$, and brown $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\eta^{2}-\right.$ $\left.\mathrm{C}_{2} \mathrm{Tol}_{2}\right)(\mu-\mathrm{H})\left(6,8.6 \mathrm{mg}, 0.0071 \mathrm{mmol}, 6 \%, R_{\mathrm{f}}=0.19\right)$ isolated as crystalline solids.

## Preparation of ${ }^{13} \mathrm{C}$-enriched compound 4

Carbon-13-enriched $\left.(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}{ }^{( }{ }^{\circ} \mathrm{CO}\right)_{10}$ (approx. $50 \%$ enrichment) [8] was utilized to prepare ${ }^{13} \mathrm{C}$-enriched $\left.\mathrm{CpMoOs}_{3}{ }^{*}{ }^{*} \mathrm{CO}\right)_{11}\left[\mu_{3}-\eta^{2}-{ }^{*} \mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right]$ by a procedure similar to that described above.

## Results and discussion

Reaction of $(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$ with $\mathrm{Cp}\left(\mathrm{CO}_{2} \mathrm{Mo}(\mathrm{CTol})\right.$
The reaction of $(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$ with $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$ in dichloromethane under mild conditions affords three molybdenum-triosmium clusters: a triplybridging acyl complex 4 ( $65 \%$ ), a dialkylidyne complex 5 ( $10 \%$ ), and an alkyne complex 6 ( $6 \%$ ). Maximum yields have been obtained by using excess $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$ (approx. 6 equiv.). This is probably due to thermal decomposition of the unstable molybdenum alkylidyne complex before it can react with $(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$. The structures of compounds 4,5 and 6 have been determined by comparing spectroscopic data of the complexes with those of known tungsten analogues, $\mathrm{CpWOs}_{3}(\mathrm{CO})_{11}\left[\mu_{3}-\eta^{2}-\mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right]$ (1) [1b], $\mathrm{CpWOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\right.$ $\mathrm{CTol}_{2}(\mu-\mathrm{H})(2)[1 \mathrm{~b}]$ and $\mathrm{CpWOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\eta^{2}-\mathrm{C}_{2} \mathrm{Tol}_{2}\right)(\mu-\mathrm{H})[1 \mathrm{~g}]$. Infrared spectra are essentially identical for both the tungsten and molybdenum analogues as shown in Fig. 1. A low frequency band at $1718 \mathrm{~cm}^{-1}$ in the carbonyl stretching region is observed in the IR spectrum of 5 which can be assigned to the semi-triply bridging carbonyl observed at $1703 \mathrm{~cm}^{-1}$ in the case of 2 [1b]. The identity of compound 6 was further confirmed by preparing the complex from the reaction of $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{12} \mathrm{H}$ and di-p-tolylacetylene [9].

Monitoring the reaction by ${ }^{1} \mathrm{H}$ NMR reveals that three signals in the hydride region, at $\delta-5.50,-20.8$ and -21.5 , grow in as the reaction proceeds. Upon addition of carbon tetrachloride, the signal at $\delta-5.50$ disappears. This implies that the resonance is due to $\mathrm{CpMo}(\mathrm{CO})_{3} \mathrm{H}$, which undergoes reaction with $\mathrm{CCl}_{4}$ to give $\mathrm{CpMo}(\mathrm{CO})_{3} \mathrm{Cl}[10]$. The two hydride resonances at $\delta-20.8$ and -21.5 are

\end{gather*}
$$

Likely reaction mechanisms for the formation of 4,5 and 6 are shown in Scheme 1. The common intermediate involved may be species $\mathbf{A}$, a $1: 1$ adduct of the starting materials closely related to other adducts $\mathrm{H}(\mu-\mathrm{H}) \mathrm{Os}_{3}(\mathrm{CO})_{10} \mathrm{~L}(\mathrm{~L}=\mathrm{CO}$, $\mathrm{PPh}_{3}$ ) between $(\mu-\mathrm{H})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$ and the donor molecule L [11]. Hydrogen migration to the alkylidyne carbon would initiate the formation of 4 whereas CO migration to the molybdenum would lead to species $\mathbf{B}$. Complex 4 is formed by a $1: 1$ combination of the starting materials. The triply-bridging acyl carbon atom in 4 was observed to be enriched with carbon- 13 when the compound was prepared from the reaction of $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$ with carbon-13-enriched $\mathrm{H}_{2} \mathrm{Os}_{3}\left({ }^{( } \mathrm{CO}\right)_{10}$. The apparent sequence of steps for the formation of 4 would involve hydrogen

Scheme 1.
transfer from osmium to the alkylidyne carbon in the $1: 1$ adduct to form a benzyl group, migration of this group onto a carbonyl to form an acyl, and multiple coordination of the acyl. Reductive elimination of $\mathrm{CpMo}(\mathrm{CO})_{3} \mathrm{H}$ from B would form unsaturated species C. Shapley and co-workers in fact isolated and characterized the tungsten analogue of $\mathbf{B}$, whose reactivity clearly indicated the formation of the unsaturated intermediate $\mathbf{C}$ by the reductive elimination of $\mathrm{CpW}(\mathrm{CO})_{3} \mathrm{H}$ from $\mathbf{B}$ [12]. However, no evidence of formation of the species $\mathbf{B}$ has been obtained in the present reaction. This may imply that the reductive elimination of $\mathrm{CpMo}(\mathrm{CO})_{3} \mathrm{H}$ is more facile in the molybdenum species B than that of $\mathrm{CpW}(\mathrm{CO})_{3} \mathrm{H}$ in the tungsten analogue. The coupling of an alkylidyne group with an alkyne to form an allyl ligand is well known in several cases [13]. Formation of compounds 5 and 6 can be rationalized in similar terms, utilizing the isolobal analogy [14] between $\mathrm{C} \equiv \mathrm{C}$ and $\mathrm{M}=\mathrm{C}$ triple bonds. Coordination of the metalla-alkyne $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo} \equiv \mathrm{CTol}$ to $\mathbf{C}$ followed by coupling would lead to species D . Loss of carbon monoxide from $\mathbf{D}$ and subsequent metal framework rearrangement would give 5 , or subsequent coupling of the two alkylidyne moieties to an alkyne would afford 6. The coupling of two alkylidyne groups into an alkyne ligand has been observed previously in the formation of $3[1 \mathrm{a}, 3]$ and in other related reactions by Stone [15]. The dialkylidyne complex 5 is an isomer of the alkyne complex 6. The origin of both the benzylic hydrogens in 4 and the hydride ligand in 5 and 6 was confirmed by reaction of $\mathrm{Cp}(\mathrm{CO})_{2} \mathrm{Mo}(\mathrm{CTol})$ and $(\mu-\mathrm{D})_{2} \mathrm{Os}_{3}(\mathrm{CO})_{10}$. The hydride migration appears to be a predominant pathway since compound 4 is the major product from the present reaction.

Fig. 2. Variable-temperature ${ }^{13} \mathrm{C}$ NMR spectra of $\mathrm{CpMoOs}_{3}\left({ }^{*} \mathrm{CO}\right)_{11}\left[\mu_{3}-\eta^{2}-{ }^{*} \mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right][75 \mathrm{MHz}$, $\left.-10-30^{\circ} \mathrm{C}\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}\right), 40-50^{\circ} \mathrm{C}\left(\mathrm{CDCl}_{3}\right)\right]$.

The Wade-Mingos rule [16] predicts a tetrahedral cluster shape with 60 valence electrons (VE), and a triangular rhomboidal or "butterfly" arrangement with 62 VE. Both compounds 4 and 5 formally contain 62 VE and therefore the four metal atoms adopt a triangular rhomboidal and a "butterfly" structure, respectively. Compound 6 with 60 VE has the expected tetrahedral structure of metal atoms.

## Solution dynamics of 4

The limiting low-temperature spectrum $\left(-10^{\circ} \mathrm{C}, \mathrm{CD}_{2} \mathrm{Cl}_{2}\right)$ of ${ }^{13} \mathrm{C}$-enriched $\mathrm{CpMoOs}_{3}\left({ }^{\star} \mathrm{CO}\right)_{11}\left[\mu_{3}-\eta^{2}-{ }^{*} \mathrm{C}(\mathrm{O}) \mathrm{CH}_{2} \mathrm{Tol}\right]$ shows 12 carbonyl resonances at $\delta 231.4$, $189.4,189.0,186.1,184.3,184.2,180.8,180.1,177.9,177.2,175.2$ and 172.8 as shown in Fig. 2. The most downfield signal at $\delta 231.4$ is assigned to the carbonyl ligand $b$ on the molybdenum atom. This resonance lies in the reported region for terminal carbonyls on a molybdenum atom containing a cyclopentadienyl ligand $[6,17]$ and remains unchanged at higher temperatures. The remaining resonances
can be assigned in groups on the basis of their variable temperature behavior and by consideration of carbon-carbon coupling constants.

As the temperature is raised to $10^{\circ} \mathrm{C}$, the three resonances at $\delta 186.1,180.8$, 172.8 due to carbonyls $j, k$ and $l$ on the $\mathrm{Os}(1)$ atom become broad. Of these three signals, the resonance at $\delta 186.1$ shows ${ }^{13} \mathrm{C}$ satellites $\left({ }^{2} J(\mathrm{CC})=22.2 \mathrm{~Hz}\right)$ in the spectrum at $-10^{\circ} \mathrm{C}$; it therefore is assigned to the carbonyl ligand $j$ trans to the acyl carbon $a$. The acyl carbon resonates at $\delta 175.2$ with the same coupling $\left({ }^{2} J(C C)=22.2 \mathrm{~Hz}\right)$ and remains sharp at higher temperatures. Thus the line broadening is due to localized threefold exchange at the Os(1) atom. Both signals at $\delta 189.4$ and 189.0 exhibit an AB pattern of ${ }^{13} \mathrm{C}$ satellites $\left({ }^{2} J(\mathrm{CC})=35.0 \mathrm{~Hz}\right.$ ), characteristic of inequivalent trans axial carbonyl ligands, $c$ and $f$. Increasing the temperature to $40^{\circ} \mathrm{C}$, another set of three resonances at $\delta 189.0,180.1$ and 177.2 broaden to the same extent, while the resonance at $\delta 189.4$ remains sharp. This result is due to localized threefold exchange at the $(\mathrm{CO})_{4} \mathrm{Os}(3)$ center, as previously observed for the analogous center in $\mathrm{HOs}_{3}(\mathrm{CO})_{10}\left(\mathrm{COCH}_{3}\right)$ [18] and compound 1 [1b]. The resonances at $\delta 180.1$ and 177.2 are therefore assigned to the two equatorial carbonyl ligands $d$ and $e$ on the $\operatorname{Os}(3)$ atom. The remaining three signals which become broad at the slowest rate are assigned to the three carbonyl ligands $g, h$ and $i$ on the $\mathrm{Os}(2)$ atom. It is apparent that the activation barriers for localized threefold carbonyl exchange in 4 increase as $\operatorname{Os}(1)<\mathrm{Os}(3)<\mathrm{Os}(2)$, which is similar in trend to 1 [1b].

Fig. 3. Variable-temperature ${ }^{1} \mathrm{H}$ NMR spectra ( $300 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) of methyl resonances of $\mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\mathrm{CTol}\right)_{2}(\mu-\mathrm{H})$. The cyclopentadienyl and carbonyl ligands are omitted for clarity.

## Solution dynamics of 5

It has been proposed that compound $2, \mathrm{CpWOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\mathrm{CTol}\right)_{2}(\mu-\mathrm{H})$, undergoes a degenerate framework rearrangement which interchanges the two possible enantiomeric forms [1c] (see Fig. 3). This was viewed as breaking and making hydrogen-bridged metal-metal bonds. The variable-temperature ${ }^{1} \mathrm{H}$ NMR spectra of compound $5, \mathrm{CpMoOs}_{3}(\mathrm{CO})_{10}\left(\mu_{3}-\mathrm{CTol}\right)_{2}(\mu-\mathrm{H})$, also show two distinct methyl resonances at $-50^{\circ} \mathrm{C}$, arising from the tolyl moieties, which broaden at higher temperatures and coalesce at $23^{\circ} \mathrm{C}(300 \mathrm{MHz})$ as shown in Fig. 3. This indicates that the same framework rearrangement is also operative in compound 5. Free energy of activation ( $\Delta G_{c}{ }^{+}$) for the fluxional process was derived from the coalescence temperature ( $T_{\mathrm{c}}$ ) and peak separation ( $\delta \nu$ ) using the Eyring equation as given in eq. 4 [19].
$\Delta G_{\mathrm{c}}{ }^{\#}=4.575 \times 10^{-3} T_{\mathrm{c}}\left[9.972+\log \left(T_{\mathrm{c}} / \delta \nu\right)\right] \mathrm{kcal} / \mathrm{mol}$
The analysis gave $\Delta G_{c}{ }^{\neq}=15.2 \pm 0.2 \mathrm{kcal} / \mathrm{mol}$ for the enantiomer-interchange process of 5 , which is comparable with the value of $15.7 \pm 0.3 \mathrm{kcal} / \mathrm{mol}$ for 2 [1c].
